Medulloblastoma is a cerebellar tumor for which relapses are associated with poor survival rates of less than 5%. Molecular heterogeneity and dose-limiting toxicities that occur with standard of care approaches, which include surgical resection, craniospinal irradiation, and chemotherapy, complicate the treatment of both primary and recurrent medulloblastoma due to adverse long-term sequela. While the integration of molecular analyses into the histopathology of pediatric medulloblastomas has changed the way these diseases are diagnosed, classified, and treated, there remains an unmet need to further understand the underpinnings of the disease to improve clinical outcomes and minimize neuronal, cognitive, and hormonal toxicities that occur with standard-of-care therapies. We therefore aimed to investigate novel subgroups of pediatric medulloblastoma as a basis for further defining biological properties and targets for the disease through multi-omic characterization. We derived single-nucleotide variant, copy number variant, expression, alternative splicing, and methylation array data from pediatric medulloblastomas profiled as part of the Children's Brain Tumor Network (CBTN) and the Open Pediatric Cancer (OpenPedCan) projects. Using non-negative matrix factorization across the five datasets derived from genomic, transcriptomic, and epigenomic profiling, we identified 14 clusters found to be prognostically significant by Kaplan-Meier analysis of overall survival ($p < 0.0001$). Our model further subdivided sonic hedgehog (SHH) and Group 3/4 tumors, but not Wnt-driven tumors, suggesting that the latter forms a homogeneous molecular subgroup. Among our subgroups, we recapitulated the four classically defined medulloblastoma subtypes known to be associated with mutations in *KDM6A, KMT2C, CTNNB1, PTCH1, TP53, KBTBD4, MYC,* and *MYCN*. Cascading biological relationships across the copy number, methylation, and expression domains were observed among novel subgroups, potentially driving migratory, immuno-regulatory, GPCR-related, growth factor-related, and histone methylation biological programs. A comparison of subgroup expression profiles to transcriptional signatures from the Library of Integrated Network-Based Cellular Signatures (LINCS) program identified canonical oncogenic pathways unique to each subgroup as potentially targetable, including, but not limited to, MAPK, VEGFA, inflammatory, fatty acid metabolic, and PI3K/AKT signaling. Our work uncovers novel biological entities in pediatric medulloblastoma potentially driven by higher order mechanisms across the genome, transcriptome, and epigenome, with the possibility of informing novel precision medicine approaches for the disease.

#4890 *In silico* study of enzymes involved in heparan sulfate catabolic process in cancer resistant mammals.

F. Oliveri Payet, **C. Machicado Rivero**;
Universidad Peruana Cayetano Heredia, Lima, Peru

Some mammals such as elephants, bats, whales, and blind mole rats (*Spalax*) are resistant to cancer. One of the cancer protective mechanisms present in such species includes a reduced degradation of heparan sulfate (HS), an important component of the extracellular matrix (ECM), present in *Spalax*. Such effect occurs due to a splicing variant of heparanase, called variant 36, that lacks enzymatic activity. Consequently, both HS and ECM are very stable in Spalax's tissues. If HS is stabilized, in cancer resistant mammals, due to the decrease of heparanase or other enzymes involved in HS catabolic process is unknown. We studied total of 9 enzymes (HPSE2, GusB, IDUA, IDS, NAGLU, SGSH, GNS, Sulf-2, HGSNAT) that regulate HS catabolism and homologs in 9 mammals. Multiple sequence alignments were done by MEGA to identify substitutions present in cancer resistant species in comparison with cancer susceptible animals. Such amino acid variants were further analyzed and both their energy stability and their functional effects were predicted by using online *in silico* tools including MAESTROweb, Condel, PANTHER, REVEL, and CADD. Finally, homologs with deleterious predicted variants were modelled with SWISSMODEL and their 3D structures were analyzed with Pymol and ChimeraX to identify structural features likely related to its loss of function. We found two loss of function missense variants, K264Q and W626L, in Alpha-L-iduronidase (IDUA) of *Spalax*. In addition, most of Brandt's bat enzymes and the N-sulphoglucosamine sulphohydrolase (SGSH) of the bowhead whale were very energy destabilizing enzymes with positive and higher ΔΔG values compared to human homologs. In the other hand, although some catalytic residues in the study enzymes are conserved in cancer resistant animals, their spatial arrangement and conformation in the 3D structure are different compared to human homologs, including E182 of IDUA which is one of the catalytic residues. In general, the secondary structure is conserved across the 9 enzymes studied but some differences were observed in cancer resistant animals including one of the beta strands near the catalytic domain in human and mice IDUA that appears as a loop in *Spalax*. In summary, HS stabilization could raise in cancer resistant mammals through the existence of lack of enzymatic activity not only in heparanase but also in other enzymes that participate in HS catabolic process, via a set of loss of function variants and changes in secondary and tertiary structure as well as a reduction of energy stabilization. More interestingly, such mechanism could be present in other cancer resistant mammals such as bats and bowhead whales. This study demonstrates that computational approaches are useful to study biological mechanisms of cancer resistance present in some mammals. This knowledge could be translated to humans and HS catabolic process could offer a new source of therapeutic anticancer targets.

#4891 Discovery of novel biomolecular condensate drug targets in oncology using *in silico* predictive tools.

K. L. Saar[1], M. Rebmann[1], M. Kanchwala[2], S. Qamar[1], P. Radhakrishnan[2], J. Cornish[1], J. Doh[2], J. Cattin[1], A. Rotem[2], M. Ghandi[2], A. Seeber[2], R. C. Centore[2], S. A. Teichmann[3], T. Knowles[1], **S. Arora**[2];

[1]Transition Bio, Cambridge, United Kingdom, [2]Transition Bio, Watertown, MA, [3]Wellcome Sanger Institute,, Cambridge, United Kingdom

Biomolecular condensates play a crucial role in maintaining cellular homeostasis by regulating various cellular processes, such as signaling, gene expression, DNA repair, and stress response. Dysregulation of condensate function has been implicated in the onset and progression of several cancer types, highlighting the potential of targeting condensates as a therapeutic approach.

To establish a pipeline for discovering and prioritizing new oncology targets that function *via* biomolecular condensates, we developed *in silico* models that link protein condensate formation to its sequence. Leveraging publicly available data and neural network based protein language models, we built predictive models for protein phase separation and for their localization into heteromolecular condensates.

With these models, we mapped the condensation character of the full human proteome, including disease variants of genes/proteins. Our results suggested that approximately half of the proteome has the potential to localize into condensate systems. We identified a broad array of chromosomal rearrangements that lead to pathological condensation (e.g., EML4-ALK fusions in lung cancer) and several instances where disease specific isoforms suppressed condensation (e.g., BARD1 mutations in breast cancer and DAXX mutations in melanoma). To identify cases where commonly occurring missense mutations lead to abnormal condensation we analyzed omics data from patients and healthy volunteers, focusing on two mechanisms: (i) condensation due to protein overexpression and (ii) altered condensation characteristics of disease variants compared to wild type protein. We investigated 18 TCGA oncology indications and identified several targets where mutations were predicted to cause aberrant condensation. The identified targets presented a wide range of biological classes, with transcription factors, co-activators, and epigenetic modulators being the most prominent. We prioritized CTNNB1 (βcatenin) for experimental validation and successfully demonstrated both the phase separation ability of the reconstituted protein and the presence of CTNNB1 condensates in colon carcinoma cells with mutated WNT pathway.

Notably, many of our predicted targets contain extended intrinsically disordered regions (IDRs), which have remained challenging to target using conventional drug discovery approaches due to their lack of a well-defined 3D structure. To identify compounds that modulate IDR containing proteins we are utilizing our PhaseScan™ platform, which can screen tens of thousands of compounds against our predicted targets within condensates and measure their modulation potential. Subsequent cellular profiling of active compounds in the predicted disease models will allow us to validate the predictions made by our *in silico* models and ultimately unlock drugging novel targets within biomolecular condensate.

#4892 MicroRNA signature and telomere genes in kidney cancer survival.

S. Yerukala Sathipati, R. Sharma, S. Hebbring;
Marshfield Clinic Research Institute, Marshfield, WI

Introduction: Kidney cancer ranks among the top 10 most prevalent cancers in the United States, clear cell renal cell carcinoma (ccRCC) has the worst disease specific survival histology. MicroRNAs (miRNAs) have emerged as potential prognostic indicators in various cancers, including kidney cancers. Telomerase, a biomarker associated with uncontrolled cancer cell growth, plays a crucial role in the human kidney cortex's telomere shortening over time. However, the link between miRNAs and telomeres in kidney cancer survival remains underexplored. Our study aims to uncover a miRNA signature capable of predicting 5-year survival in ccRCC patients and to investigate the biological relevance of this signature, particularly its shared pathway enrichment mechanisms with telomere genes.

Methods: We extracted miRNA expression profiles from The Cancer Genome Atlas database, comprising 166 patients with ccRCC. To identify a robust miRNA signature predicting 5-year survival in ccRCC, we established an Evolutionary Kidney Survival Estimator (EKSE) using an optimal feature selection algorithm and support vector regression. Additionally, we conducted bioinformatics analyses to uncover common biological pathways between miRNAs and telomere genes using Kyoto Encyclopedia of Genes and Genomes (KEGG) and Gene Ontology (GO) categories, encompassing biological processes, molecular functions, and cellular components.

Results: EKSE identified a robust signature consisting of 37 miRNAs, achieving a mean correlation coefficient and mean absolute error of 0.82±0.01 and 0.65±0.18, respectively between actual and estimated survival times. The top 10 ranked miRNAs in the signature, including hsa-miR-26a-1-3p, hsa-miR-28-5p, hsa-miR-3913-5p, hsa-miR-3170, hsa-miR-148a-5p, hsa-miR-671-3p, hsa-miR-224-3p, hsa-miR-10a-5p, hsa-miR-29b-1-5p, and hsa-miR-106b-5p, also showed promise in diagnosing ccRCC with AUC values ranging from 0.56 to 0.91. Furthermore, bioinformatics analysis revealed that the miRNA signature targeted well known telomere-associated genes such as TERT, DKC1, CTC1, and RTEL1. Notably, miRNA signature and telomere genes shared several common pathways, including cellular senescence (hsa04218) and proteoglycans in cancer (hsa05205). They also had overlapping GO-Molecular functions, such as DNA-binding transcription factor activity (GO:0003700), histone deacetylase binding (GO:0042826), and promoter-specific chromatin binding (GO:1990841).

Conclusions: Our findings suggest an association between microRNAs and telomere genes, potentially playing significant roles in the survival of patients with ccRCC. The identified miRNA signature robustly predicts 5-year survival in ccRCC. The shared biological pathways between these miRNAs and telomere genes offer new insights into the mechanisms driving ccRCC, signaling potential for therapeutic targets and improved prognostic markers in kidney cancer.

#4893 Role of MGMT expression in the genomic landscape and immunogenicity in human colorectal carcinomas.

B. Rajendran[1], J. Zhang[1], S. Desai[1], J. Gibson[1], J. DiPalermo[1], P. LoRusso[1], Y. Kong[2], H. Zhao[2], M. Cecchini[1], K. A. Schalper[1];
[1]Yale University School of Medicine, New Haven, CT, [2]Yale School of Public Health, New Haven, CT

Introduction: Colorectal cancer (CRC) is second most common cause of cancer-related mortality in the USA and most patients with advanced tumors lack effective therapeutic options. Epigenetic silencing resulting in reduced expression of O^6-methylguanine-DNA methyltransferase (*MGMT*) has been described in diverse tumor types including CRC and it is linked with reduced DNA repair capability and increased sensitivity to alkylating agents such as temozolomide. However, the potential role and clinical significance of MGMT overexpression in cancer cells has not been studied.
Methods: We used spatially resolved multiplex quantitative immunofluorescence (mQIF) analysis to concurrently measure the levels of MGMT protein, γH2AX and CD8+ tumor infiltrating lymphocytes (TILs) in a cohort of 111 CRCs and paired non-tumor colorectal mucosa from the same patient represented in tissue microarray format. To assess the genomic and immunologic context of MGMT expression, we studied the methylome, mutation profiling and mRNA expression of 526 CRCs from TCGA. The immunologic landscape of tumors was studied using GSEA and multiple transcriptomic-based tumor immune infiltration scores such as TIMER, CIBERSORT, etc. Finally, the genomic alterations and immunogenicity of SW620 human CRC cells (with baseline *MGMT* hypermethylation) with or without MGMT transfection were studied using *in vitro* co-culture preparations coupled to ultra-deep DNAseq and flow cytometry analysis.
Results: On mQIF analysis, cancer-cell MGMT protein upregulation was identified in 73.9% of CRCs and was associated with reduced levels of γH2Ax in malignant cells and lower CD8+ TILs. 26.1% of cases showed MGMT protein downregulation. The genomic analysis of the TCGA cohort revealed that the mean nonsynonymous mutational load was significantly lower in MGMT-high than low tumors with marked differences in the type of variants and frequency of oncogenic mutations. The transcriptomic analysis revealed that MGMT overexpressing tumors showed lower immune infiltration than the MGMT-low group and reduced representation of immune associated signatures including interferon gamma response and TNF-alpha signaling. In contrast, DNA repair, *TP53* pathways, were enriched. The exogenous expression of MGMT in
SW620 cells reduced the number of nonsynonymous mutations by 15.6% (141 vs 119 mean mutations) and was also associated with low T-cell activation (CD69+/CD8+ T-cells) and cancer-cell elimination on allogenic co-cultures with human PBMCs.
Conclusion: MGMT protein upregulation is common in human CRCs and is associated with reduced DNA damage response, distinct genomic features, and adaptive immune evasion. To our knowledge, this study is the first to report the biological and clinical characteristics of CRCs with *MGMT* overexpression that could support diagnostic and therapeutic developments.

#4894 Multi-omic approach for drug repurposing in the poor prognosis CMS4 subtype of colon cancer.

T. M. Marvulli, D. Traversa, R. Di Fonte, L. Maurmo, A. Azzariti, L. Porcelli, C. A. Coppola, C. Saponaro, E. Mattioli, F. A. Zito, R. Fasano, S. Serrati, D. Quaresmini, O. Brunetti, S. Tommasi, R. Massafra, **S. De Summa**;
IRCCS Istituto Tumori Giovanni Paolo II, Bari, Italy

Introduction: Colon cancer (CC) is one of the deadliest malignancy in developing countries. Key drivers considered for the clinical management are RAS, BRAF alterations together with TNM staging and microsatellite status (MS). With the advancement of sequencing technologies and bioinformatic approaches, various molecular classifications of CC have been proposed. Guinney et al. proposed a transcriptomic-based molecular subtyping, the so-called four Consensus Molecular Subtypes (CMS). CMS4 patients have the worst prognosis. Biologically, CMS4, also known as mesenchymal, shows high expression of genes related to EMT, matrix remodelling, TGFb signaling, and inflammatory-related system and a peculiar enrichment in stromal cells. Thus, in the present study we are focusing on CMS4 subgroup in order to identify drugs to be repurposed in such a clinical setting through a multi-omic approach.
Methods: Using *TCGAbiolinks* R package, we retrieved STAR Counts transcriptome profiling data, for COAD and READ. CMSclassifier was used to determine the CMS of the samples. We separated the coding genes from the long noncoding RNAs (lncRNAs) using annotation databases generated from Ensembl. We estimated the fraction of cell populations throughout the CIBERSORTx. Features selection approaches was performed both for coding genes and lncRNA. Data normalization has been carried out through variance stabilizing transformation for read count data. To identify CMS and potential biomarkers, we adopted *mixOmics* N-integration method. Our independent validation cohort consists of 100 patients, locally enrolled, upon local Ethical Committee approval. Features contributing to CMS4 subtype have been extracted and use to construct drug-gene interaction network.
Results: To set-up the classification model the DIABLO approach was used, reaching a mean AUCROC of 0.9022. Contributing features related CMS4 subtypes included nine coding genes, six lncRNAs and, regarding CibersortX deconvolution, Macrophage M0 and M2.The drug-gene interaction network includes six subnetworks centered to ALOX5, KCNMA1, AQP9, TGFB3, THBS4 and DPYSL3. The role of TGFb pathway was confirmed, considering the contribution to classification. Interestingly, we found interactions with Non-Steroid Anti-Inflammatory Drugs (NSAIDs), such as Mesalazine. Moreover, THBSA gene, involved in cell-to-cell, cell-to-matrix and stromal response, could also be targeted.
Conclusions: The results of our drug repositioning approach have been biologically corroborated considering, as mentioned above, the peculiar enrichment of CMS4 subtype for TGFb pathway and stromal cells. The chance to modulate the macrophagic activity in the tumor microenvironment through NSAIDs could be evaluated. Experimental validation on patient-derived organoids (PDOs), related to samples included to local validation cohort, is ongoing.

#4895 Optical genome mapping analysis across multiple solid tumor types in Bionano VIATM software.

S. I. Al-Saffar, B. Clifford, A. Raksi, A. Hastie, N. Miller, A. Chaubey;
Bionano Genomics, San Diego, CA

Solid tumors can show highly complex somatic structural and copy number variants (CNVs) of multiple classes. These variants can reveal mechanisms behind carcinogenesis, including the amplification of oncogenes, deletion or inactivation of tumor suppressor genes, and fusions to create new oncogenes. High degrees of heterogeneity within solid tumors can complicate analysis.

Optical Genome Mapping (OGM) is a comprehensive technology which combines the resolution of molecular-level data with the scale of cytogenomic analysis. ≈5-15mg sections of freshly frozen tumor are homogenized in buffer to release ultra-high molecular weight DNA. Long fragments are then labeled at a regular 6mer, then linearized and imaged with native long-range structure (≥150kbp) preserved. In silico molecules are assembled into maps and aligned to a reference genome to detect structural variants with sensitivity to ≥5% allele fraction. Bionano VIATM software provides tools for visualization and interpretation of structural variants detected with OGM. VIA also provides CNV calling and detection of Absence of Heterozygosity (AOH) and allelic imbalance using SNP-FASST3, a segmentation algorithm for detecting mosaic events in OGM and other types of data. VIA calculates a B-Allele frequency (BAF) distribution from OGM data and adds a genome-wide BAF track to the applications suite, enabling calling of allelic imbalance events such as AOH. Visualized together, the overlay of structural variant information on copy number data provides context for chromosome fusions underlying copy number change. Additionally, balanced fusions are revealed consistently in cases where the impact is copy neutral. To demonstrate the utility of integrative analysis of structural, copy number, and allelic imbalance variants in solid tumor datasets, we processed a pilot set of six diverse solid tumors through Bionano software. Brain, breast, kidney, lung, ovarian, and prostate tumor data which had undergone previous analysis in Bionano Solve 3.7 were freshly analyzed in Solve 3.8 and VIA 7.0. In the lung tumor dataset there are clear allelic imbalance segments spanning most of chromosome 4 with no concomitant copy number change. In VIA, these segments can be merged on examination, converted to AOH calls, and further specified to reflect mosaic copy neutral loss of heterozygosity (CN-LOH). In the complex kidney tumor dataset, it is difficult to resolve ploidy state based on copy number data alone. This ambiguity is resolvable with VIA, by leveraging the copy number and BAF-based allelic imbalance distributions and recentering probes to a manually defined diploid region. The comprehensive OGM data approach facilitated by VIA can streamline analysis in challenging solid tumor datasets. Structural variant visualization, CNV detection and AOH detection are available in VIA 7.0.

#4896 A high throughput method of identifying cells with increased genomic content across diverse cancer tissues.

S. Priyadarsini Nair, K. J. Pienta, S. R. Amend;
Johns Hopkins University School of Medicine, Baltimore, MD

Cancer cells with increased genomic content have been associated with recurrence and poor patient outcomes. The current manual identification of these rare cells by pathologists is time-consuming and labor intensive, given their scarcity within tissue samples. This study introduces a robust methodology for the automated identification of cancer cells with increased genomic content within prostate cancer tissues. Leveraging Qupath software integrated with the Stardist extension, our approach combines precise nuclear segmentation with threshold setting using a Python script. This methodology enables the specific identification of noncancerous small cells, cancerous cells, and those exhibiting genomic content significantly surpassing the average cancer cell (3x to 5x), complemented by thresholds based on hematoxylin intensity for enhanced result accuracy. Thus, our methodology offers an efficient solution to streamline the identification processes for these challenging cells.

We have extensively validated our method across diverse models, including animal and human models, transgenic and subcutaneous models, and Human Tissue Microarrays (TMAs), to identify cancer cells with increased genomic content. The rarity of these cells within tissue samples underscores the practical significance of our research, providing a solution to the current difficulties faced by researchers and clinicians in their identification.

The integration of this methodology aims to improve efficiency in cancer tissue analysis. Ongoing efforts are directed towards the evaluation of this high-throughput methodology using animal models and TMAs with known outcomes, further substantiating its applicability and potential clinical relevance.

#4897 Personalized cell surface target identification from pan-cancer RNA-seq and proteomics profiling of tumors.

G. B. Marino[1], E. Z. Deng[1], D. J. Clarke[1], W. Ma[1], P. Wang[1], A. C. Resnick[2], A. Ma'ayan[1];
[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]The Children's Hospital of Philadelphia, Philadelphia, PA

In its third phase, the Clinical Proteomic Tumor Analysis Consortium (CPTAC) program collected pan-cancer data from 1,069 patients profiling the transcriptome, proteome, and phospho-proteome of tumors and adjacent tissues from ten cancer types. To identify potential immunotherapeutic candidates from this CPTAC cohort, we searched for cell-surface proteins that are highly expressed in tumor subtypes compared to their expression in normal tissues and cell types from ARCHS4 and the Genotype-Tissue Expression (GTEx) resources. For each cancer type, tumor samples were first clustered into subtypes based on RNA-seq data, and then cell surface targets were prioritized for each cluster. These targets were subsequently confirmed for high protein expression in the tumor subtypes. Tumor samples were also processed by their classification into immune subtypes to identify targets specific to hot (CD8+/IFNG+) and cold (CD8-/IFNG-) tumors of each cancer type. For each cancer type, the computational pipeline identified ~30 cell surface proteins that are highly expressed in the tumor and lowly expressed across tissues and cell types in both the ARCHS4 and GTEx backgrounds. Many of these targets are also robustly differentially expressed at the proteome level. Several targets were shared across tumor types, including VTCN1 and TMPRSS4. Altogether, this rational approach to identify potential targets demonstrates a pipeline that can be applied for personalized cancer diagnosis and therapeutic development.

#4898 Highly accurate profiling of leukocyte composition from bulk peripheral blood with targeted digital cytometry.

A. Nakao[1], A. M. Newman[2], A. A. Alizadeh[2], M. Diehn[2], M. Ghosh[3], M. Aliminati[3], J. Ghosh[3], K. Stephenson[3], **A. Ashutosh**[3];
[1]CiberMed Inc., Saratoga, CA, [2]Stanford University, Stanford, CA, [3]Agilent Technologies, Inc., Santa Clara, CA

Background: Cell profiling methods such as flow/mass cytometry and single-cell RNA-sequencing are powerful tools for quantifying immune composition from healthy and neoplastic tissues. However, only a modest number of markers can be interrogated by the former and the latter remains cost prohibitive for large-scale analysis. Here we demonstrate robust, accurate, and reproducible enumeration of immune cell subsets from 36 whole blood samples using SureSelect XT HS2 RNA sequencing combined with CiberMed's iSortTM digital cytometry solution. Enrichment of genes in the LM22 signature matrix, a well-established collection of reference profiles for deconvolving 22 human immune subsets, was achieved with two new targeted sequencing panels—Agilent SureSelect CD CiberMed Heme and Agilent SureSelect CD CiberMed Heme + HiRes. Both panels were assessed for their ability to profile leukocyte subsets with CiberMed's iSortTM Fractions software, an optimized and standardized version of CIBERSORTx with novel enhancements.
Methods: Whole blood samples were freshly collected from 36 healthy donors and split into two fractions—one was immediately processed for complete blood count (CBC) and flow cytometric enumeration of major leukocyte populations; the other was stored in PAXgene Blood RNA tubes for subsequent RNA sequencing. A Sysmex system was employed for CBC quantification and a Becton Dickinson 6-color TBNK MultiTest in vitro diagnostic (IVD) assay was employed for enumerating B cells, CD8 T cells, CD4 T cells, NK cells. These data were used as ground truth to assess iSortTM deconvolution performance from targeted and whole-transcriptome bulk RNA sequencing data. RNA-seq expression values were used as input to iSortTM Fractions to deconvolve 22 immune subsets in each sample.
Results: Across 7 major populations, cell type fractions determined by iSortTM Fractions were highly concordant with ground truth fractions determined by clinical grade standards (r□0.96) and exhibited strong reproducibility across technical replicates (r□0.98). Furthermore, targeted enrichment using the SureSelect CD CiberMed Heme panel reduced the sequencing requirement by nearly 50-fold compared to whole-transcriptome sequencing, while also improving accuracy.
Conclusion: These new panels for digital cytometry are being released through the Agilent Community Design program to enable focused, reliable, and high-throughput analysis of cell type composition from peripheral blood samples.

#4899 Interface-guided phenotyping of coding variants in the transcription factor RUNX1.

K. Ozturk[1], R. Panwala[1], J. Sheen[1], K. Ford[1], N. Jayne[1], D.-E. Zhang[1], S. Hutter[2], T. Haferlach[2], T. Ideker[1], P. Mali[1], H. Carter[1];
[1]UC San Diego, La Jolla, CA, [2]Munich Leukemia Laboratory GmbH, Munich, Germany

Understanding the consequences of single amino acid substitutions in cancer driver genes remains an unmet need. Perturb-seq provides a tool to investigate the effects of individual mutations on cellular programs. Here we deploy SEUSS, a Perturb-seq like approach, to generate and assay mutations at physical interfaces of the RUNX1 Runt domain. We measured the impact of 115 mutations on RNA profiles in single myelogenous leukemia cells and used the profiles to categorize mutations into three functionally distinct groups: wild-type (WT)-like, loss-of-function (LOF)-like and hypomorphic. Notably, the largest concentration of functional mutations (non-WT-like) clustered at the DNA binding site and contained many of the more frequently observed mutations in human cancers. Hypomorphic variants shared characteristics with loss of function variants but had gene expression profiles indicative of response to neural growth factor and cytokine recruitment of neutrophils. Additionally, DNA accessibility changes upon perturbations were enriched for RUNX1 binding motifs, particularly near differentially expressed genes. Overall, our work demonstrates the potential of targeting protein interaction interfaces to better define the landscape of prospective phenotypes reachable by amino acid substitutions.

#4900 Spatial Atlas of Human Anatomy (SAHA): A subcellular, multiscale spatial odyssey of immune and gastrointestinal tissues and tumors.

J. Park[1], R. Gregorio[1], E. Hissong[1], S. Patel[1], B. Robinson[1], F. Socciarelli[1], E. Metzger[2], Y. Liang[2], J. Reeves[2], J. Beechem[2], O. Elemento[1], A. Alonso[1], S. Houlihan[1], R. Schwartz[1], C. E. Mason[1];

[1]Weill Cornell Medicine, New York, NY, [2]NanoString Technologies, Seattle, WA

The Spatial Atlas of Human Anatomy (SAHA) is a foundational effort to map 250 million cells and transcriptomes and proteomes of 30 non-diseased organs from healthy adults at two spatial scales: whole transcriptome of histological features (50 µm to 2 mm), and 1,000-plex RNA and 64-plex protein panels at spatial subcellular resolution (50 nm across 1 cm2). The project aims to establish and validate best practices in experimental design, sample processing, data analysis, and data standards for high-content spatial analysis across multiple human organs at whole transcriptome and proteome levels. The profiled samples will capture variability across genders and ancestries. All results, including raw and processed data, will be made available to the scientific community through the SAHA data portal and AtoMxTM Spatial Informatics Platform.

Here we present the part of Phase I data collected specifically around immune (bone marrow and lymph node) and gastrointestinal tissues (ileum, appendix, colon, and liver), and compare these data to colon and liver cancer samples. On serial sections, we perform spatial whole transcriptome data (with GeoMx® Digital Spatial Profiler) and 1,000-plex RNA profiles and 64-plex protein profiles collected by the CosMx™ Spatial Molecular Imager (SMI) matched to the exact shape of functional histological organ features from H&E and immunofluorescence stainings. Our data, which spans ~1.5 million cells collected across ~1,100 fields of view, enables the highest-ever subcellular resolution maps of cell types, lineage states, metabolic capacity, cellular neighborhoods, subcellular movements of organelles, and spatially resolved (and novel) ligand-receptor interactions across normal and cancer tissues. Through comparing these data to several cancer samples collected across multiple spatial platforms, we show how spatial organ atlasing at multiple scales can uncover unique insights into organ development, health, and cancer. We also show how the SAHA data can serve as a benchmark reference for spatial precision medicine.

#4901 High-resolution spatial transcriptomics identifies candidate genes facilitating perineural invasion.

D. G. Olgun[1], P. L. Wang[2], R. Zhao[2], D. H. Gong[2], W. L. Hwang[2];

[1]University of Virginia, Charlottesville, VA, [2]Massachusetts General Hospital and Harvard Medical School, Boston, MA

Perineural invasion (PNI), or the invasion of cancer to the space surrounding nerves, is associated with poor prognosis, but the underlying molecular factors that drive its initiation and progression are poorly understood. To explore this systematically, we applied a 6000-plex spatial transcriptomic panel with subcellular resolution to curated microarrays from 5 pancreatic ductal adenocarcinoma (PDAC) patients spanning different stages of tumor-nerve involvement. With this preliminary cohort, we explored malignant cell signatures associated with invasion and adaptation to the intraneural environment. Strikingly, we observed enrichment of a classical-like malignant transcriptional program marked by genes involved in glucose and lipid metabolism in nerve-invading malignant cells. Despite the known association of chemoresistance with serine dependence, these cells also exhibited upregulation of genes involved in serine biosynthesis, suggesting that intraneural invasion may offer an orthogonal path of treatment evasion. Overall, our findings indicate that nerve-invasive cancer cells adopt a unique transcriptomic signature within the neuronal microenvironment. Further studies will aim to uncover the relevance of these signatures to survival within the nerve environment and treatment resistance.

#4905 Multimodal transformer model improves survival prediction in lung cancer compared to unimodal approaches.

A. Tripathi[1], A. Waqas[1], Y. Yilmaz[2], G. Rasool[1];
[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]University of South Florida, Tampa, FL

Integrating multimodal lung data including clinical notes, medical images, and molecular data is critical for predictive modeling tasks like survival prediction, yet effectively aligning these disparate data types remains challenging. We present a novel method to integrate heterogeneous lung modalities by first thoroughly analyzing various domain-specific models and selecting the optimal model for embedding feature extraction per data type based on performance on representative pretrained tasks. For clinical notes, the GatorTron models showed the lowest regression loss on an initial evaluation set, with the large GatorTron-medium model achieving 12.9 loss. After selecting the top performers, we extracted robust embeddings on the full lung dataset built using the Multimodal Integration of Oncology Data System (MINDS) framework. MINDS provides an end-to-end platform for aggregating and normalizing multimodal patient data. We aligned the multimodal embeddings to a central pre-trained language model using contrastive representation learning based on a cosine similarity loss function. To adapt the language model to the new modalities, we employed a parameter-efficient tuning method called adapter tuning, which introduces small trainable adapter layers that leave the base model weights frozen. This avoids catastrophic forgetting of the pretrained weights. We evaluated our multimodal model on prognostic prediction tasks including survival regression and subtype classification using both public and internal lung cancer datasets spanning multiple histologic subtypes and stages. Our aligned multimodal model demonstrated improved performance over models utilizing only single modalities, highlighting the benefits of integrating complementary information across diverse lung data types. This work illustrates the potential of flexible multimodal modeling for critical lung cancer prediction problems using heterogeneous real-world patient data. Our model provides a strong foundation for incorporating emerging data types, modalities, and predictive tasks in the future.

#4906 Biopsy free virtual histology to discriminate benign from malignant squamous neoplasms.

N. Kokikian[1], R. Wahhab[1], J. Li[1], S. Martin[2], D. P. Beynet[2], A. Ozcan[1], P. O. Scumpia[1];
[1]University of California, Los Angeles, Los Angeles, CA, [2]Veterans Affairs Greater Los Angeles Healthcare System, Los Angeles, CA

Reflectance confocal microscopy (RCM) is a noninvasive optical imaging modality that allows for cellular-level resolution, in vivo images of skin without performing a traditional skin biopsy. RCM image interpretation currently requires specialized training to interpret the grayscale output images that are difficult to correlate with tissue pathology. Here, we use a deep learning-based framework that uses a convolutional neural network to transform grayscale output images into virtually-stained hematoxylin and eosin (H&E)-like images allowing for the visualization of various skin layers, including the epidermis, dermal-epidermal junction, and superficial dermis layers. To train the deep-learning framework, a stack of a minimum of 7 time-lapsed, successive RCM images of excised tissue were obtained from epidermis to dermis 1.52 microns apart to a depth of 60.96 microns using the Vivascope 3000. The tissue was embedded in agarose tissue and a curette was used to create a tunnel through which drops of 50% acetic acid was used to stain cell nuclei. These acetic acid-stained images were used as “ground truth” to train a deep convolutional neural network using a conditional generative adversarial network (GAN)-based machine learning algorithm to digitally convert the images into GAN-based H&E-stained digital images. We used the already trained machine learning algorithm and retrained the algorithm with new samples to include squamous neoplasms. Through further training and refinement of the algorithm, high-resolution, histological quality images can be obtained to aid in earlier diagnosis and treatment of cutaneous neoplasms. The overall goal of obtaining biopsy-free virtual histology images with this technology can be used to provide real-time outputs of virtually-stained H&E skin lesions, thus decreasing the need for invasive diagnostic procedures and enabling greater uptake of the technology by the medical community.

#4907 RanBALL: Identifying B-cell acute lymphoblastic leukemia subtypes based on an ensemble random projection model.

L. Li, H. Xiao, J. D. Khoury, J. Wang, S. Wan;
University of Nebraska Medical Center, Omaha, NE

As the most common pediatric malignancy, B-cell acute lymphoblastic leukemia (B-ALL) has multiple distinct subtypes characterized by recurrent and sporadic somatic and germline genetic alterations like chromosomal alteration, transcription factor rearrangement or kinase inhibition. The treatment of B-ALL patients is personalized based on specific subtypes, as the treatment responses for different B-ALL subtypes may vary considerably. Identification of B-ALL subtypes can facilitate risk stratification and enable tailored therapeutic approaches. Existing methods for B-ALL subtyping primarily depend on immunophenotypic, cytogenetic and genomic analyses, which would be costly, complicated, and laborious in clinical practice applications. To overcome these challenges, we present RanBALL (an Ensemble Random Projection-Based Model for Identifying B-Cell Acute Lymphoblastic Leukemia Subtypes), an accurate and cost-effective model for B-ALL subtype identification based on transcriptomic profiling only. RanBALL leverages random projection (RP) to construct an ensemble of dimension-reduced multi-class classifiers for B-ALL subtyping. Specifically, the transcriptomic profiling features were projected onto low-dimensional spaces by random projection matrices whose elements conform to a distribution characterized by zero mean and unit variance. To ensure reliable and robust performance, we selected 20 subspace dimensions ranging from 600 to 2500, with intervals of 100. The transformed low dimensional data matrix was used for training an ensemble of multi-class support vector machine (SVM) classifiers, each corresponding to one of the RP matrices of various dimensions. The predicted probabilistic scores of each B-ALL subtype were integrated for determining the final decision. Results based on 10 times 10-fold cross validation tests for >1700 B-ALL patients demonstrated that the proposed model achieved an accuracy of 93.7%, indicating promising prediction capabilities of RanBALL for B-ALL subtyping. Furthermore, the 30% held-out tests suggested that the model was robust and consistent to maintain high confidence levels for accurate predictions. The high accuracies of RanBALL suggested that our model could effectively capture underlying patterns of transcriptomic profiling for accurate B-ALL subtype identification. To extend the impact of RanBALL, we have established a free and publicly available python package for RanBALL available at https://github.com/wan-mlab/RanBALL. We believe RanBALL will facilitate the discovery of B-ALL subtype-specific marker genes and therapeutic targets, and eventually have consequential positive impacts on downstream risk stratification and tailored treatment design.

#4908 Comprehensive tool for pan-cancer consensus data mining of drugs, targets and biomarkers.

S. Yoon;
Sookmyung Women's University, Seoul, Korea, Republic of

The rapid increase in collateral omics and phenotypic data has enabled data-driven studies for the discovery of drug targets and biomarkers. For this purpose, we have developed a convenient tool, Q-omics software, for general researchers and cancer scientists to carry out customized data mining without bioinformatics background. Q-omics provides a comprehensive interface and smart functions for facilitating pan cancer-wide association studies on mutations, RNA expression, protein abundance, shRNA/CRISPR efficacy, drugs, tumor-infiltrating cells, patient survival, clinical info. etc. Furthermore, consensus scores on associated data pairs from heterogeneous samples, help to predict the reproducibility of data mining results. Q-omics (download: http://qomics.io) improves the utility of cancer omics big data for non-computational scientists at all levels of cancer research.

#4909 An RNA-based model for tertiary lymphoid structure (TLS) prediction and classification in pancreatic adenocarcinoma (PDAC).

A. Livanova, A. Tyshevich, A. Kravets, S. Kurpe, N. Lukashevich, D. Ivchenkov, D. Dymov, A. Belozerova, K. Kryukov, A. Sarachakov, V. Svekolkin, V. Kushnarev;
BostonGene Corporation, Waltham, MA

Although TLS status possesses prognostic significance in PDAC and can potentially affect chemotherapy outcomes, there is currently a notable lack of RNA sequencing (RNA-seq) models that specialize in TLS identification and classification in PDAC. Here, we developed a model for predicting TLS status (high or low) based on RNA-seq data.

Design: Hematoxylin and eosin (H&E) whole slide images of PDAC samples from The Cancer Genome Atlas (TCGA, n = 118) and Clinical Proteomic Tumor Analysis Consortium (CPTAC, n = 129) were used to detect intratumoral and borderline TLSs followed by TLS density measurements (units/mm^2) by an experienced pathologist. The samples were then stratified into TLS-high and TLS-low groups based on median density values. Next, we used deconvolution by Kassandra algorithm to identify cell subtypes enriched in each TLS group based on gene expression (RNA-seq) data. Calculation of ssGSEA scores for gene signatures corresponding to cell subtypes and TLS structures was performed, along with survival analysis. Differential expression analysis between TLS-high and TLS-low samples, followed by functional enrichment ($|logFC| > 2$; $padj < 0.01$), was conducted. The LightGBM gradient boosting classifier was then trained on ranked expression data with sequential feature selection to predict TLS-high and TLS-low groups. We trained the model with H&E staining annotations and ranked RNA expression data from TCGA or CPTAC samples (total n = 167). The remaining 80 were designated as hold-out samples. The weighted F1 score was computed as a performance metric.

Findings: Median density of detected TLSs in the TCGA and CPTAC samples was 0.012 units/mm^2. Kassandra deconvolution revealed B-cell enrichment, but fibroblast and M2 macrophage depletion in the TLS-high group. Our calculated ssGSEA scores of previously described TLS gene signatures, along with those of different B-cell subtypes and follicular dendritic cells, showed significant association with the TLS-high group. Genes associated with B-cell proliferation, differentiation, and signaling (*CD19, CD22, CD79A, CD79B*, and *CR2*) were also upregulated in this group. Comparing the performance of our RNA-based model on the validation dataset with manual TLS
classification by a pathologist, we obtained an F1 weighted score of 0.72 and ROC-AUC score of 0.77. Thus, the TLS predictions by our model concurred with the TLS classification based on H&E annotations and pathological evaluation. Moreover, patients in the predicted TLS-low group had worse overall survival (OS) compared to the TLS-high group ($Log(HR) = 0.76$; 95% CI [0.04; 1.48]; $p<0.05$).

We present an RNA-based model that stratifies PDAC samples as TLS-high or TLS-low, with predictions that conform to pathological findings. We also found TLS-low samples to associate with worse OS, thus offering an objective means to predict prognoses of PDAC patients based on TLS status.

#4910 AI predicts drug response from the genomic features of cells and the kinase activity changes induced by compounds.

R. Janssens[1], K. Rizzolo[1], E. Artin[1], J. Wagner[1], M. Riester[1], J. Korn[1], **J. Park**[2],
[1]Novartis Biomedical Research, Cambridge, MA, [2]Novartis Biomedical Research, San Diego, CA

Human protein kinases are playing an important role in various biological activities including tumorigenesis and cancer progression, and for this reason, many kinase inhibitors have been developed as promising targeted therapies for cancer. To date, there are 72 FDA-approved treatments targeting about two dozen different protein kinases; 3 of them were approved in 2022. However, there are still critical challenges that can be addressed to improve the robustness and selectivity of the kinase inhibitors such as drug resistance, toxicity and compromised efficacy. To gain a deeper understanding of the biological mechanisms underlying the resistance to kinase inhibitors, we hereby design and train an artificial intelligence (AI) model that predicts in-vitro cell response to various kinase inhibition from the integration of the genomic features of cancer cell lines and the biochemical profiles of kinase activities. The inner-working of an optimized model provides important insights on the relevant kinase activities for the cell response. A major challenge for training such a model is that the training data for biochemical kinase activity is very sparse; the kinase panels are not consistent across different sources and each dataset contains many missing values. To address this, we train a secondary AI model to predict all the missing values for the kinase activity in our training data using the combination of the compound chemical structure and the kinase structure. The secondary model is independently validated to ensure the quality of the training data for the drug response prediction model. An investigation of the secondary model's inner mechanism sheds light on the kinase binding sites and which chemical substructures are important for its inhibition. The model accurately predicts the cell response to different CDK inhibition. A focused analysis of the model characterizes off-target effects of the CDK inhibitors which may be linked to the drug resistance mechanisms, suggesting ways to improve the inhibitors or potential targets for combination therapies.

#4911 PAIRWISE: Deep learning-powered personalized medicine approach identifies actionable drug combinations in B cell lymphoma.

C. Xu[1], J. Cohen-Setton[2], Z. Shen[3], M. Milo[2], I. US[1], B. Sidders[2], J. Fitzgibbon[2], H. Pan[4], O. Elemento[1], K. Bulusu[2];
[1]Weill Cornell Medicine, New York, NY, [2]AstraZeneca, Cambridge, United Kingdom, [3]Memorial Sloan Kettering Cancer Center, New York, NY, [4]Peking University Third Hospital, Beijing, China

Combination drug therapies offer promise for improving cancer treatment. However, identifying actionable drug combinations for specific cancer subtypes and individual patients remains challenging due to the vast number of possibilities. Existing approaches like high-throughput screening (HTS) and rule-based drug additions have limitations in their ability to predict clinically translatable synergistic combinations. Therefore, advanced machine learning focused on patient-centric modelling have the potential to optimize combination therapies.

PAIRWISE is a patient-centric deep learning-powered drug combination recommendation platform. Given gene expression along with chemical structures and targets from a set of two drugs being applied, the output is the binary combination outcome. PAIRWISE introduces a new approach of representing tumor genomics using the unsupervised pretraining design on 11K TCGA tumors. The power of PAIRWISE is derived from knowledge-guided transfer learning by learning from in vitro experiments with drug-drug-cell interactions and cellular heterogeneity. PAIRWISE can accurately predict combination synergy with area under the curve (AUC) > 0.85 across 10 tissue types in a large dataset of 200K in vitro drug combinations and significantly outperform all state-of-the-art methods.

Diffuse large B cell lymphoma (DLBCL) is the most common B cell non-Hodgkin lymphoma and remains incurable in around 40% of patients. Finding optimal combination therapy for each DLBCL patient is a critical unmet need. As independent validation, we applied PAIRWISE to an external HTS study of Bruton Tyrosine Kinase inhibitor (BTKi) combinations (Griner et al., 2014), confirming the reproducibility and accuracy of high-confidence predictions (AUC = 0.72).

PAIRWISE was also applied to transcriptomic data of 29 DLBCL cell lines (Bal et al., 2022) and predicted BTKi-containing combinations across ABC subtypes with higher synergy scores than GCB ($P = 0.02$). This is consistent with expected better overall efficacy of BTK inhibitors in ABC subtype (Younes et al., 2019; Davis et al., 2010; Wilson et al., 2015).

To predict opportunities in DLBCL, PAIRWISE was used to identify BTKi partners for an additional 211 anti-cancer drugs using 562 published ex vivo DLBCL samples (Schmitz et al., 2018). PAIRWISE effectively identified novel DLBCL sub-population with significantly higher response scores for predicted BTKi combinations and favorable survival. Notably, patients predicted as responsive had significantly better outcomes upon first-line chemotherapy treatments than non-responsive ones ($P < 0.0001$).

Collectively, we demonstrate that PAIRWISE is a highly efficient and generalizable framework that enables confident predictions of pairwise drug combinations at disease subtype level, with the potential of informing treatment options and clinical trial design.

#4912 Unsupervised detection of stromal phenotypes with distinct fibrogenic and inflamed properties in NSCLC.

N. Patel, N. Le, T. Nguyen, F. Najdawi, S. Srinivasan, A. Stanford-Moore, D. Kartik, J. Zhang, J. Brosnan-Cashman, R. Egger, J. Lee, M. Bronnimann; PathAI, Inc., Boston, MA

Background: Understanding the composition of cancer-associated stroma (CAS) is vital, as the number and location of immune cells and fibroblasts, as well as the degree of extracellular matrix deposition, have implications for cancer progression and response to treatment, including in non-small cell lung cancer (NSCLC). Manual analysis of CAS does not fully describe the stromal milieu, especially from a spatial perspective, and is highly subjective. To this end, we have developed an unsupervised machine learning (ML) model to characterize the CAS in NSCLC from hematoxylin and eosin (H&E) stained whole slide images (WSI) at scale.

Methods: PathExploreTM models were deployed to predict stromal tissue and cell types, while another ML model was used to detect collagen fibers from H&E stained WSIs from the TCGA LUAD (N=536) and LUSC (N=464) datasets. Stroma was divided into small regions (median = 0.02 mm2), and 88 features characterizing cell distribution, tissue composition and fiber density were extracted from each region. Graphs were generated connecting neighboring regions (nodes), and an unsupervised variational graph auto-encoder (VGAE) model was trained to learn 8 latent features through dimensionality reduction. Stromal phenotypes were then derived from the latent features using k-means clustering. The fraction of each phenotype in the stroma was correlated against immune- and stroma-related gene expression signatures (GES) and overall survival (OS).

Results: Deployment of VGAE on LUAD and LUSC WSIs revealed three distinct stromal phenotypes - P0, P1 and P2. Fibroblast density was elevated in P0 and P1 regions ($p<0.001$), immune cell density was elevated in P2 regions ($p<0.001$), and collagen fiber intensity was highest in P1 regions ($p<0.001$). P2 enrichment was correlated with elevated expression of the T cell-inflamed gene expression profile (TGEP; Spearman $\rho = 0.43$ in LUAD; $\rho = 0.27$ in LUSC) and with improved OS (HR = 0.696; 95% CIs: 0.571-0.847 in LUSC). Conversely, P1 enrichment was positively associated with a transforming growth factor-β-induced cancer associated fibroblast GES (TGFβ-CAF: $\rho = 0.19$ in LUAD and $\rho = 0.12$ in LUSC) and poor OS (HR = 1.358; 95% CIs: 1.149-1.603 in LUSC). These phenotypes are consistent with fibroblast-enriched, collagen-depleted stroma (P0), collagen-rich, fibroblast-enriched tumor-promoting stroma (P1), and immune cell-enriched, tumor-suppressive stroma (P2).

Conclusions: We describe an unsupervised, data-driven method of predicting stromal regions with discrete patterns of cell composition and collagen deposition in NSCLC. This approach identified three phenotypes of NSCLC stroma. These results highlight the ability of ML models to characterize and find meaningful patterns within the cell, tissue, and matrix components of a tumor. This work provides further evidence of the potential of ML to discover novel precision medicine biomarkers in NSCLC.

#4913 Morphological feature discrepancies in wild-type vs. BRCA1/BRCA2 mutated high-grade serous ovarian cancer.

J. Lee[1], **H. Kim**[1], Y. Lee[1], Y.-L. Choi[2], K. Jung[2], T.-Y. Kwak[1], S. Kim[1], H. Chang[1];

[1]Deep Bio Inc., Seoul, Korea, Republic of, [2]Samsung Medical Center, Seoul, Korea, Republic of

Introduction: The understanding of morphological heterogeneity at the cellular level in High-Grade Serous Ovarian Cancer (HGSOC), particularly in relation to BRCA1 and BRCA2 mutations, is still an ongoing area of research. This study aims to elucidate the morphological features that distinguish wild-type (WT) tumors from those with BRCA1/BRCA2 mutations using deep learning models.

Methods: A total of 300 H&E stained HGSOC slides were collected in a patient-wise manner and tumor areas were annotated by an expert pathologist. We used a convolutional neural network model with spatial attention pre-trained on pathological images to extract features from slides, and the features were clustered into 96 groups. Subsequently, a nuclei segmentation model was employed for precise cell segmentation, followed by measurement of cellular features including cell shape (area, eccentricity) and cell texture (dissimilarity, correlation). The assessment of cell texture evaluates the variation and uniformity in gray-level intensity across the cell. We performed independent t-tests on samples of 100 patches from each cluster, comparing cells of selected patches from the top-N clusters representing the highest proportion of each label.

Results: H&E slides (n=300) include 69 (23%) BRCA1 mutants and 50 (16.7%) BRCA2 mutants. In Table1, negative t-statistics suggest that WT carcinoma cancer cells exhibit lower values for the measured features compared to BRCA mutants, whereas positive values denote higher values in WT. BRCA1 and BRCA2 mutant carcinoma cancer cells showed significantly larger areas and higher eccentricity than WT carcinoma cancer cells in all top-N clusters settings (N=3, 5, 10, 30). Furthermore, WT carcinoma cancer cells showed higher dissimilarity and reduced correlation compared to BRCA1 mutant carcinoma cells in four settings.

Conclusions: Our observations in BRCA-mutated HGSOC cells enrich our understanding of tumor cell morphology with BRCA mutations.

Table1. Comparison of cell features between WT and BRCA mutants

cell feature	comparison	top-3 clusters (t-statistics, p-value)	top-5 clusters (t-statistics, p-value)	top-10 clusters (t-statistics, p-value)	top-30 clusters (t-statistics, p-value)
area	WT vs BRCA1	-37.41, <0.001	-50.2, <0.001	-37.53, <0.001	-85.95, <0.001
	WT vs BRCA2	-42.14, <0.001	-50.61, <0.001	-16.57, <0.001	-51.98, <0.001
eccentricity	WT vs BRCA1	-24.40, <0.001	-34.14, <0.001	-38.02, <0.001	-37.40, <0.001
	WT vs BRCA2	-26.77, <0.001	-30.46, <0.001	-29.47, <0.001	-47.64, <0.001
dissimilarity	WT vs BRCA1	55.17, <0.001	52.73, <0.001	103.57, <0.001	166.78, <0.001
	WT vs BRCA2	-38.15, <0.001	-24.75, <0.001	0.2, <0.001	107.73, <0.001
correlation	WT vs BRCA1	1.94, <0.001	-2.46, <0.001	-50.24, <0.001	-65.96, <0.001
	WT vs BRCA2	87.62, <0.001	90.83, <0.001	52.6, <0.001	-48.90, <0.001

#4914 Mapping the cancer immune landscape in colorectal adenocarcinoma using multiplexed imaging and AI based analysis.

Vasundhara Agrawal[1], Lisa Arvidson[2], Michael J. Smith[1], Katie O. White[1], Richard A. Heil-Chapdelaine[1], Samuel Jensen[2], **Arindam Bose**[1]

[1]Leica Microsystems, Waltham, MA,[2]Cell Signaling Technology, Danvers, MA

Colorectal cancer is a high burden cancer in the United States, leading to the second highest cause of cancer deaths. Despite chemotherapeutic intervention and surgical resection, recurrent disease may occur in some patients and typically, has a poorer prognosis. Thus, there is a demand for advanced therapies such as immunotherapies for improved clinical outcomes. An in-depth understanding of the colon cancer microenvironment is necessary to improve outcome in this subset of patients. Spatial biology approaches are well positioned to comprehensively uncover the molecular and biological mechanisms of cancer cell aggression in colorectal cancer. Here, we visualized nearly 30 biomarkers in colon adenocarcinoma (CAC) tissue using the Cell DIVE multiplexed imaging workflow and validated antibodies from Cell Signaling Technology (CST®). Using this approach, we were able to probe multiple pathways of interest in cancer progression, such as vascularization of tumor tissue, immune cell responses, and cell proliferation. Together, these data allow the creation of a spatial map of tumor cell aggression and offer predictive value for the progression of the disease. Deep molecular and architectural insights on this level are possible only with a spatial biology approach and offer multiple downstream hypotheses to further understand cancer progression and interrogate the heterogeneity within the tumor microenvironment.

#4915 Identification and validation of novel prognostic genetic markers in HER2-negative advanced gastric cancer (AGC) by artificial intelligence (AI) deep learning and machine learning algorithm.

S. Park[1], S.-J. Heo[2], C.-K. Lee[3], Y. Lee[2], W. Kwon[1], J. Che[4], M. Kim[2], H. Chung[3], S. Rha[3];

[1]Song-Dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]Pharos iBio Co., Ltd., Seoul, Korea, Republic of

Introduction: Despite advances in anticancer treatments, there has been urgent need to identify novel prognostic markers for HER2-negative AGC. We propose AI based deep learning and machine learning pipeline to explore genetic markers that predict patient response to chemotherapy in HER2-negative AGC.
Methods: We retrospectively assessed 179 stage IV HER2-negative AGC patients who have been treated with first-line chemotherapy in Yonsei Cancer Center, Korea between 2015 and 2021. In-house targeted sequencing panel data (CancerSCAN^{TM} and CancerMaster) were used to identify candidate prognostic markers. DeepSurv was mainly used to analyze the progression-free survival (PFS), which is a deep learning algorithm that can investigate prognostic roles. The SHapley Additive exPlanations (SHAP) method was applied to open the deep learning models' black-box and calculate the importance ranking of gene features. Machine learning models-random survival forest, elastic-net, and lasso-were also investigated to identify potentially meaningful gene variants. To rank the gene features, we calculated variable importance (VIMP) for random survival forest, and penalized regression coefficients for elastic-net and lasso. All deep learning and machine learning models were trained using 5-folds cross-validation in 1,000 iterations of re-sampling bootstrapping with hyperparameter tuning by grid search. To classify responder or non-responder related genetic markers to chemotherapy, we used the signs of averaged penalize coefficients obtained from elastic-net and lasso. Based on the median linear predictor with candidate gene features, patients were classified into high-risk and low-risk group.
Results: A total of 7,824 common variants were analyzed and 20 prognostic genetic markers were identified based on the top average values of SHAP, VIMP, and penalized regression coefficients. The top 10 non-responder genetic markers are included as follows: PARP4(p.S873N), CHUK(p.V268I), BARD1(359_365del), CREBBP(p.Y1125F), BARD1(p.P24S), PHLPP2(p.R1312Q), FAT3(p.Q3375R), CASP5(p.T106A), PHLPP2(p.I544V), and PTCH2(p.T988M). Otherwise, the top 10 responder genetic markers are defined as follows: IL7R(p.I66T), NOTCH4(L16delinsLL), FGFR3, BCL2A1(p.G82D), ZNF217(p.T548I), BRCA1(p.K1183R), FANCA(p.A412V), ADGRA2, CDKN2B, and FANCM(p.S175F). The high-risk group had worse PFS compared with low-risk group (median PFS 4.1 vs. 9.1 months; *P*-value <0.0001).
Conclusion: This study showed the potential of AI deep learning and machine learning pipeline that employs an innovate prognostic genetic markers for HER2-negative AGC. Current ongoing analyses of larger cohort with more comprehensive clinical data will be presented.

#4916 Enhancing multi-organ frozen section cancer discrimination model by sharing cancer discrimination and organ classification task.

J. Lee[1], **J. Cho**[1], J. Lee[1], Y.-L. Choi[2], K. Jung[2], T.-Y. Kwak[1], S. Kim[1], H. Chang[1];
[1]Deep Bio Inc., Seoul, Korea, Republic of, [2]Samsung Medical Center, Seoul, Korea, Republic of

Introduction: Frozen section(FS) testing is an important method that removes part or all of a patient's tissue of a suspected tumor during surgery and microscopic examination to determine a diagnosis and surgical method that requires a rapid and accurate diagnosis. In this study, we developed a deep learning model to determine the presence of cancer and the type of organ in H&E FS whole slide images(WSIs) of 5 organs such as Breast(BR), Lung(LU), Stomach(ST), Breast Sentinel Lymph Node(LN), and Prostate(PR).
Design: In this study, we utilized a dataset comprising 19,881 H&E FS WSIs and 11,985 H&E-stained formalin-fixed paraffin-embedded (FFPE) WSIs to enhance generalization. The dataset included FS and FFPE WSIs from 33 different organs sourced from The Cancer Genome Atlas (TCGA) and additional FS and FFPE WSIs from a domestic hospital and the Camelyon 16 dataset, respectively. For the FS dataset, 20% was set aside for performance evaluation, while the remaining was randomly split into a 3:1 ratio for train and validation. In our methodology, we utilized instance-based multi-instance learning (MIL) to identify patches (1024*1024 pixels, 20x mag) with a high likelihood of cancer presence in each WSI. Then, we implemented multi-task learning (MTL) to predict the presence of cancer and the organ simultaneously.
Result: The table shows the WSI level performance through the 5 organs. The top 5 rows show results of MIL that only discriminate cancer. In comparison, the bottom 5 rows show results of MIL with MTL that share features from the cancer discrimination and organ classification. MIL with MTL make higher roc/auc than MIL only.
Conclusion: This study explores the automated analysis of H&E-stained FS WSIs using a deep-learning to discriminate cancer and classify organs. We could figure out that training cancer discrimination and organ classification simultaneously can make general features, and it leads to increased diagnostic performance.

Performance Table Between MIL vs MIL + MTL

Method	Organ	F1-score	Sensitivity	Specificity	ROC/AUC	Organ Accuracy
MIL	**LN**	0.9358	0.9669	0.6170	0.7919	NaN
	ST	0.9458	0.9583	0.8302	0.8943	
	LU	0.9577	0.9457	0.9275	0.9366	
	BR	0.9902	0.9895	0.9757	0.9826	
	PR	0.9346	0.9328	0.8786	0.9057	
MIL + MTL	**LN**	0.9448	0.9448	0.7872	0.8660	0.8816
	ST	0.9771	0.9697	0.9623	0.9660	0.7595
	LU	0.9700	0.9721	0.9203	0.9462	0.9509
	BR	0.9932	0.9910	0.9877	0.9894	0.8979
	PR	0.9480	0.9515	0.8913	0.9214	0.9803

#4918 Cancer mutations converge on a constellation of molecular assemblies to predict resistance to replication stress agents.

X. Zhao, A. Singhal, S. Park, J. Kong, R. Bachelder, T. Ideker;
University of California, San Diego, La Jolla, CA

Rapid proliferation is a hallmark of tumor cells, associated with sensitivity to therapeutics that cause DNA replication stress (RS). Many tumors exhibit drug resistance, however, via molecular pathways that are incompletely understood. Here, we develop an ensemble of predictive models that elucidate how cancer mutations impact the response to common RS-inducing (RSi) agents. The models implement recent advances in deep learning to facilitate multi-drug prediction and mechanistic interpretation. Instead of associating individual genetic alterations with RSi drug responses directly, the strategy is to project these alterations on a map of protein complexes and larger molecular assemblies associated with cancer. Initial studies in tumor cells identify 41 molecular assemblies that integrate alterations in hundreds of genes for accurate drug response prediction. These cover roles in transcription, repair, cell-cycle checkpoints, and growth signaling, of which 30 are shown by loss-of-function genetic screens to regulate drug sensitivity or replication restart. The model translates to cisplatin-treated cervical cancer patients, highlighting an RTK-JAK-STAT assembly governing resistance. This study defines a compendium of mechanisms by which mutations affect therapeutic responses, with implications for drug selection and combination.

#4919 AI-enabled hit selection of drug screening on human pancreatic cancer organoids.

Z. Tong[1], A. Lim[1], M. Meyer[2], M. Claples[3], O. Sirenko[1], N. Brandenberg[3];
[1]Molecular Devices, LLC (Moldev), San Jose, CA, [2]DOPPL SA, Lausanne, Switzerland, [3]SUN bioscience SA, Lausanne, Switzerland

Cancer remains one of the leading causes of death in the 21st century. Despite the latest advances in oncology, most cancer patients lack tailored therapeutic approaches with lasting benefit. Measuring the impact of anticancer compounds and their combinations is only possible on *ex vivo* assays. To this end, patient-derived organoids (PDOs) have been proposed as viable and efficient models for ex vivo testing. PDOs show long-term expansion potential while retaining tumor histopathology as well as cancer gene mutations. However, the translation of organoids in screening applications has so far been hampered by the lack of homogeneity and difficulties in handling and automation. Moreover, organoids are typically randomly distributed across the culture which complicates imaging and images analyses. To overcome these challenges, we set up a compound screening workflow with PDOs using Gri3D platform, comprising plates with micro-cavities suitable for high-throughput and reproducible organoid culture. Based on a standard 96 microtiter plate, each well contains a microwell array patterned in a cell repellent hydrogel. On Gri3D®, organoids are robustly generated in the microwells and are located in the same imaging plane. This greatly facilitates quantitative analyses in high content image-based screens. Furthermore, the pipetting port enables automation of cell seeding, media exchange and compound incubation with liquid-handlers, thus increasing assay reproducibility. In the presented work, we exposed human pancreatic cancer PDOs to a panel of anti-cancer compounds at different doses and followed their response to the drugs using viability dyes Calcein AM (live stain) and Ethidium Homodimer-1 (dead stain) with high-content confocal imaging. Using an AI-based approach, we efficiently detected each single organoid and extracted phenotypic features from all three channels (TL, live stain and dead stain) which correlate with cytotoxicity. The extracted features (more than 100) were first dimensionally reduced to 3 components using either PCA or UMAP, the treatments were then visualized in 3D scatter plots, ranked and clustered using machine learning. The data suggests that the compound treatment Palbociclib 50uM has significant cytotoxicity effects similar to the positive control, which is consistent with the traditional live/dead analysis. The AI approach demonstrates feasibility to perform drug screening in a robust and un-biased data analysis approach.

#4920 A nanopore sequencing approach characterizes cell-free DNA methylation-fragmentomics profiles indicative of breast cancer in a large cohort.

X. Bai, B. T. Lau, A. Almada, S. Grimes, T. Chen, H. Lee, H. P. Ji;
Stanford University School of Medicine, Stanford, CA

The detection of breast cancer from cell-free DNA (cfDNA) offers a new approach with the potential to benefit individual screening and early detection. However, identifying breast cancer from cfDNA remains a major challenge when one uses conventional short-read sequencing. Methylation and DNA fragmentation characteristics provide highly informative biomarkers for detecting and monitoring cancer. To characterize these genomic features from cfDNA, we developed an approach using single molecule Nanopore sequencing. Single cfDNA molecules are sequenced intact with the methylation and fragment size directly extrapolated from Nanopore data. Moreover, our approach requires small amounts of cfDNA to discern specific genomic features from individual molecules. Thus, the use of Nanopore sequencing provides both methylation and fragment size as directly measured from native cfDNA without the use of any chemical processing or other molecular manipulation. We studied an extended breast cancer cohort with in total 1080 of samples, consisting of 440 untreated breast cancer patients and 640 healthy controls. Nanopore sequencing analysis of these cfDNA samples identified a range of 1 to 4 million CpG sites from 1 ml of plasma. Leveraging the cohort, we developed an ensemble classifier for breast cancer detection based on cfDNA methylation and fragmentation. The classifier leveraged a leave-one-out cross-validation (LOOCV) to generate predicted probability. We created nucleosome-specific methylation scores as the input features to the classifier, which scores quantified the similarity of each sample's methylation profile to a training set on a selected set of CpG sites associated with cancers. Furthermore, we also identified DNA fragmentation features, revealing distinct mono-nucleosome and di-nucleosome patterns that distinguish cancers from healthy controls. Aggregating the DNA nucleosome-specific scores and fragmentation features, we built an ensemble LOOCV random forest model. We applied the model to the breast cancer cohort and achieved a detection specificity of 74%, a sensitivity of 71%, and an overall accuracy of approximately 73%. The area under the receiver operating characteristic curve (AUROC) reached 80%. We validated the classifier with two external independent cohorts. Validation cohort 1 demonstrated as a specificity of 85%, a sensitivity of 80%, and overall accuracy of 83% with AUROC of 90%. Validation cohort 2 without controls demonstrated that the classifier achieved a sensitivity of 94%. Both validation sets confirm that our model can achieve excellent performance for early breast cancer detection. In summary, our findings demonstrate that nanopore sequencing provides cfDNA methylation and fragment profiling that enables breast cancer detection. This approach holds the potential to improve cancer diagnosis and treatment outcomes.

#4921 A user-friendly R Shiny web app for predicting cancer genetic dependencies using deep learning.

M. J. Kasper, L.-J. Wang, M. Ning, Y. Huang, Y.-C. Chiu;
UPMC Hillman Cancer Center, Pittsburgh, PA

Understanding the genetic vulnerabilities (*i.e.*, genetic dependencies) of cancer cells is crucial for developing novel anti-cancer treatments. The Cancer Dependency Map (DepMap) projects, conducted by the Broad Institute and Wellcome Sanger Institute, have performed comprehensive genome-wide CRISPR-Cas9 knockout screens across diverse cancer cell lines. These data resources have enabled computational biologists to glean insights into cancer genetic dependencies using sophisticated computational models. As different genomic mechanisms govern tumorigenesis and genetic vulnerability, the relationship between cancer genomics and genetic dependencies is nonlinear, making the prediction of genetic dependencies challenging. Addressing this challenge, we previously developed a deep learning model, namely DeepDEP, to predict cancer genetic dependencies using multi-omic profiles (Chiu *et al.* DOI:10.1126/sciadv.abh1275). DeepDEP has a transfer learning scheme that integrates genomic representations captured from unlabeled tumor samples of the Cancer Genome Atlas (TCGA) and genomic features that are predictive of genetic dependencies in cell lines. Such a design enables the application of DeepDEP to both cell lines and tumors. The model demonstrated superior performance compared to various conventional machine learning methods. Prediction results were validated using independent cell-line datasets and patient clinical data. Here, we developed an intuitive web application for DeepDEP which allows users to easily utilize the model on their in-house data. Users can simply indicate whether the query sample is derived from a cancer cell line or a tumor, upload any combination of mutation, gene expression, DNA methylation, and copy number alteration datasets, and view the predicted dependencies of 1,298 cancer-relevant genes. Along with the genetic dependency predictions, users are provided with model performance metrics, detailed gene annotations, and links to useful resources such as Ensembl and COSMIC. Our web application features a variety of interactive visualizations to guide users to interpret the results at the levels of individual genes and pathways. The tool has two supplemental modules to enhance its functionality. One allows users to search for similar cell lines to the query sample within the DepMap project or for similar tumors within the TCGA project. The other supplemental module provides data exploration tools for pre-calculated predictions across all TCGA tumors. In summary, this user-friendly web application provides researchers with access to deep learning predictions of cancer genetic dependencies with various interactive visualization and analysis tools. It is anticipated that this application will facilitate the study of cancer genetic dependencies and enhance the efficiency of anti-cancer drug discovery.

#4922 Unraveling sarcomatoid features in clear cell renal cell carcinoma with RNA-seq.

K. Kryukov, S. Davitavyan, D. Stupichev, A. Sharun, A. Love, M. Kleimenov, S. Kuznetsov, A. Tkachuk, V. Kushnarev;
BostonGene, Waltham, MA

Introduction: Sarcomatoid clear cell renal cell carcinoma (ccRCC) represents a challenging and aggressive subset of kidney cancers with poor prognosis and resistance to conventional treatments. Recent studies have shown the benefit of checkpoint inhibitors (CPIs) for patients with sarcomatoid components; therefore, precise and objective evaluation of sarcomatoid differentiation is essential for CPI selection. Here, we developed a predictive model to identify sarcomatoid features in ccRCC.

Methods: The machine learning-based transcriptomic sccRCC model was developed on 512 samples from publicly available datasets: TCGA-KIRC and CPTAC-ccRCC. Samples were excluded with the following criteria: inconsistent with ccRCC, less than 10% sarcomatoid component, or <20% tumor neoplastic cellularity. Sarcomatoid features for each case were assessed by 3 pathologists. The meta-cohort was divided into training (n = 348) and validation (n = 164) cohorts.The model was tested on a publicly available cohort of ccRCC patients from Sato et al. (n = 100). Clinical validation was performed using an additional prospective cohort that received BostonGene's Tumor PortraitTM test (n = 32) with RNA-seq and whole exome sequencing (WES). The JAVELIN Renal 101 cohort was used to uncover differences in progression-free survival (PFS) associated with a predicted sarcomatoid component in advanced or metastatic ccRCCs treated with a combination of CPIs and tyrosine kinase inhibitors (TKIs).

Results: H&E analysis of the TCGA, CPTAC, and BostonGene cohorts identified zones with sarcomatoid features in 129 out of 556 (23.2%) samples. The sarcomatoid predictive model demonstrated robust performance, with weighted F1-scores of 0.85 when applied to the test cohort (Sato et al.) and 0.70 for the prospective clinical cohort. The model accurately classified 9 out of 10 total sarcomatoid samples in the prospective clinical cohort, highlighting its potential for real-world clinical applications. When applied to TCGA validation samples, sarcomatoid patients identified by the transcriptomic model exhibited median overall survival (mOS) of 55 months, whereas sarcomatoid patients based on H&E assessment had a mOS of 67 months, indicative of the model's superior performance when detecting sarcomatoid features for OS prediction. Moreover, the sarcomatoid ccRCCs predicted by transcriptomic model that were treated with a combination of CPIs and TKIs had statistically (p=0.0001) improved PFS compared to the TKI-treated group.

Conclusion: The developed transcriptomic model effectively differentiated sarcomatoid from non-sarcomatoid ccRCC samples with robust performance metrics. With additional investigation, the predictive value of the sarcomatoid ccRCC transcriptomic model can be leveraged to guide CPI and TKI selection.

#4923 A systematic framework for predicting adverse drug reaction signals using medical data.

J. Jeon, E. Hong, H. Kim;
Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

Prescribing a combination of medications is a common strategy to enhance the effectiveness of disease treatment. While this approach aims to improve therapeutic outcomes, it may lead to unintended adverse drug reactions (ADRs) due to interactions between prescribed drugs and individual factors. Recognizing the importance of ADRs, various machine learning models have been developed. However, these models face limitations, particularly in predicting reactions induced by three or more drugs and in accounting for individual patient factors, such as age and medical history. To address these limitations, we propose a systematic framework that leverages medical data for predicting ADR signals. In the framework, the MIMIC-IV database was systematically preprocessed, and a series of machine learning models were developed that predict the ADR signals. The model predictions were validated using the eICU collaborative research database. The machine learning models process multiple inputs, including information on administered drugs, age, gender, ethnicity, and underlying medical conditions to predict ADR signals. The ADR signals are determined by classifying abnormalities in 20 specific laboratory test values, such as hematocrit, creatinine, and hemoglobin. The machine learning models developed in this study hold promise as a valuable tool for assessing potential risks, such as ADRs, associated with the concurrent use of multiple drugs.

#4924 Assessing microsatellite instability dominance in colorectal cancer phenotype: A multi-study initiative using multi-target transformers for genomic biomarker prediction.

M. Gustav[1], M. van Treeck[1], Z. I. Carrero[1], C. M. L. Loeffler[1], N. G. Reitsam[2], B. Markl[2], A. Rabasco Meneghetti[1], L. A. Boardman[3], A. J. French[3], E. L. Goode[3], A. Gsur[4], S. Brezina[4], M. J. Gunter[5], N. Murphy[5], P. Limburg[3], S. Thibodeau[3], S. Foersch[6], R. Steinfelder[7], T. Harrison[7], U. Peters[7], A. Phipps[7], J. N. Kather[1];

[1]Technische Universitat Dresden, Dresden, Germany, [2]University of Augsburg, Augsburg, Germany, [3]Mayo Clinic, Rochester, MN, [4]Medical University of Vienna, Vienna, Austria, [5]World Health Organization, Lyon, France, [6]University Medical Center Mainz, Mainz, Germany, [7]Fred Hutchinson Cancer Center, Seattle, WA

We used deep learning (DL) to predict multiple genetic biomarkers of colorectal cancer (CRC) from routine histopathology images, aiming to identify morphological changes associated with the mutational profile of tumors.

A new Transformer-based prediction model was developed which can simultaneously predict multiple biomarkers from a single histopathology image. We compared the performance of the multi-target approach to conventional single-target models. We analyzed five patient cohorts from the Genetics and Epidemiology of CRC Consortium (GECCO) with colorectal cancer (N=1,385 patients). Our model was trained on an internal data set (N=739) to predict the presence of >200 genetic alterations, focusing on genes with non-silent mutations and mutational signatures, which were assessed using targeted sequencing. We used a 7-fold cross validation and validated the model on an independent, external data set (N=646). Morphological features of microsatellite instability (MSI) are detectable by DL models in histopathology images, making MSI a potential confounding factor. Thus, we also assessed whether our model can predict genetic alterations regardless of MSI status, or whether the model identifies the MSI phenotype.

For the majority of biomarkers, the multi-target transformer reached a higher prediction performance as measured by the mean Area Under the Receiver Operating Characteristic (AUROC) Curve and lower standard deviation than single-target DL models. For the external validation set, the mean AUROC of the multi-target versus the single-target model was 0.78 (+/- 0.01) versus 0.72 (+/- 0.06) for BRAF mutations, 0.88 (+/- 0.01) versus 0.86 (+/- 0.03) for hypermutation status, 0.94 (+/- 0.01) versus 0.91 (+/- 0.02) for MSI, 0.86 (+/- 0.01) versus 0.80 (+/- 0.05) for RNF43 mutations and 0.72 (+/- 0.02) versus 0.69 (+/- 0.05) for TP53 mutations, respectively. However, our analysis of the individual prediction scores suggests that the model does not identify the phenotype of the alterations themselves. Instead, the model seems to determine the status of specific genetic alterations based on their correlation with MSI. Consequently, biomarkers which are associated with microsatellite stability have prediction scores negatively correlated with predicted MSI scores. Conversely, biomarkers which are associated with MSI have prediction scores positively correlated with predicted MSI scores.

Our results demonstrate potential benefits of multi-target DL models in improving the predictive power and efficacy of histology-based biomarker extraction compared to single-target DL models. However, our results crucially highlight the importance of considering potential confounders, such as MSI status in CRC, and emphasize the need for extensive analysis beyond AUROC in studies focusing on DL-based biomarker detection.

#4925 Spatial heterogeneity of tumor boundary in mammograms is prognostic of recurrence in triple negative breast cancer (TNBC).

S. Ghose[1], C. Davis[1], S. Cho[1], Y. Polar[2], F. Ginty[1], S. Badve[2],
[1]GE Healthcare, Waukesha, WI, [2]Emory University School of Medicine, Atlanta, GA

Introduction: Despite standard-of-care therapies, at least 25% of all TNBC patients will develop recurrence or metastasis within 3-5 years and die due to breast cancer. Early prediction of recurrence in TNBC patients from clinical mammograms would allow more aggressive intervention for higher risk patients. The tumor boundary represents the heterogeneous invasive front where malignant cells interface extracellular matrix (ECM) and contribute to invasion. In this study, we investigated role of the irregular infiltration of the normal tissue by tumor in heterogeneity of radiomics features at the boundary of the tumor.

Method: Surgically treated patients with pathologically confirmed diagnosis of TNBC of any tumor size were included. All cases had node negative status and were treated with adjuvant chemotherapy. Patients with node positive or metastatic TNBCs at diagnosis, receiving neo-adjuvant chemotherapy or non-chemo regimens were excluded. Manually segmented breast lesions in mammograms from a cohort of 29 patients with 5-year outcomes were used to automatically determine the tumor boundary as a zone of 1 mm from both intra-tumoral and peritumoral regions in concordance with prior studies. Over 2000 radiomics features from the tumor boundary and the central regions of the tumor were extracted to quantify heterogeneity, obscure margins, spiculations, texture, breast fat percentage, shape, and size of the tumor. Recursive feature elimination using random forest classifier was used to reduce feature dimensionality to prevent over-fitting and predict recurrence in TNBC patients.

Results: We observed that tumor boundary heterogeneity as quantified by continuous gradient magnitude features at pixel level was significantly better at predicting lethality for TNBC patients when compared to usual radiomic features (gradient, texture, and shape features) extracted from the entire tumor, as done in prior radiomics analyses. Continuous gradient magnitude features quantifying spatial heterogeneity of the tumor boundary were found to be superior to texture features in providing estimation of local changes in pixel-level heterogeneity. In a three-fold validation framework, continuous gradient features were associated with a mean AUC of 0.82 (std 0.17) and better differentiated patient lethality risk *as compared to* gradient, texture, and shape features of the *entire tumor* (mean AUC of 0.27 (std 0.11)).

Conclusions: To the best of our knowledge, this is the first time that heterogeneity features of a tumor quantified by continuous gradient magnitude features from tumor boundary, as observed in routine clinical mammograms, have been shown to predict TNBC lethality. This model will be validated in a larger cohort in future studies.

#4926 Advancements in somatic variant calling from UG100 whole genome and whole exome sequencing data.

D. Shem-Tov[1], M. Levy[1], G. Hornung[1], I. Soifer[1], H. Benjamin[1], A. Jaimovich[1], A. Blattler[2], W. Brandler[2], R. Sugar[2], I. Kinde[2], O. Barad[1], D. Lipson[1];
[1]Ultima Genomics, Fremont, CA, [2]Exact Sciences Corporation, Madison, WI

Somatic variant calling involves the identification of genomic alterations that occur in somatic cells, requiring deep coverage to enable high sensitivity for low-frequency variants. Characterizing somatic variants across the entire genome therefore benefits from novel cost-efficient sequencing platforms, such as UG100. Here, we present optimization of variant calling tools for short and structural variants on WGS and WES data from UG100.

For calling short variants, we optimized DeepVariant (DV) for somatic calling using data from matched tumor-normal sample pairs, improving both variant calling accuracy and pipeline running time (up to 10-fold). We defined the task of somatic variant calling as deciding if the pileup image containing reads from the tumor and normal samples represents a true somatic variant (vs a germline variant or artifact).

The challenge of robust variant calling using deep learning models is exacerbated in somatic calling, where sequencing depth and coverage variability are typically high. Our optimized DV overcomes these challenges by several data sampling strategies. First, allele-frequency preserving down-sampling reduces randomness of read sub-sampling in high coverage regions. Second, alternative allele prioritization samples alt-allele supporting reads first allowing to call variants at very high coverage loci without sacrificing sensitivity and computational efficiency. Finally, a Panel-of-Normals based on targeted WES data provides an additional improvement of precision for this assay type. We used these strategies to train two models, one for tumor characterization using WGS (T/N coverage: 40x-150x/40x-100x), and one for deep WES (T/N coverage: >500x/>120x).

We called variants on simulated tumors using the WGS model. For VAF>10% the model showed SNV recall >98% and indel recall >95% with false-positive rate of 0.2/Mb. For VAF range of 5-10%, indel recall was 67% and SNV recall was 86%. To demonstrate the utility of our somatic variant calling, we applied the models to call somatic variants from well characterized cancer cell lines: COLO829, HCC1395 and HCC1143. Results showed F1>90% for variants with VAF>10%. The WES model was used to reliably call variants at VAF>5% on simulated tumors with average SNV recall of 99% with precision >99% and indel recall >86% with precision >94%.

To analyze structural and copy-number variations, we optimized the assembly engine of GRIDSS to enable fast calling of structural variations and demonstrate that Control-FREEC can be used to call copy number variants. SV calling on COLO829/COLO829BL achieved sensitivity >95%.

In conclusion, our research highlights the utility of UG100 within the field of oncology, demonstrating its capacity for comprehensive and precise somatic variant detection, both on WGS and WES data.

#4927 Combining single-cell ATAC and RNA sequencing for supervised cell annotation.

Jaidip Gill[1], **Abhijit Das Gupta**[2], Brychan Manry[2], Natasha Markuzon[3]

[1]School of Public Health, Imperial College, London, United Kingdom,[2]AstraZeneca US, Gaithersburg, MD,[3]AstraZeneca US, Waltham, MA

Background: Analysis of samples at the single-cell level offers insights into cellular heterogeneity and cell function. Cell type annotation is the first critical step for performing such an analysis. While current methods primarily utilize single-cell RNA sequencing (scRNA-seq) for annotation, several studies have demonstrated improved classification accuracy by combining scRNA-seq with transposase-accessible chromatin sequencing (ATAC-seq) using unsupervised methods. However, the utility of ATAC-seq features for supervised cell-type annotation has not been explored.

Aims/Objectives: The objective of this study was to evaluate the relative performance of supervised cell-type classification using scRNA-seq alone vs. in multimodal combination with ATAC-seq; and how these data interplay with choice of classification and dimensionality reduction methods.

Methods: A peripheral-blood mononuclear cell multi-omic dataset from a single, healthy female donor wasanalysed in this study. Ground truth annotations were generated using unsupervised annotation with the weighted nearest neighbour clustering method. Two dimensionality reduction methods (principal component analysis (PCA), single-cell Variational Inference (scVI) autoencoder) and four classification models (logistic regression, random forest, support vector machine (SVM)) were implemented and performance metrics (F1 score, precision, and recall) were compared over 10 bootstrap samples.

Results: ATAC-seq features improved annotation quality and prediction confidence when using scVI embeddings, independent of the classifier. The best-performing model (SVM with scVI embeddings) showed an increase from a median macro F1 score of 0.907 (IQR = [0.902, 0.910]) using scRNA-seq alone to 0.946 (IQR = [0.940, 0.949], $p < 0.05$) with ATAC-seq added. For PCA embeddings, improvements in macro F1 score were insignificant.

All cell types (B, T, monocytes, natural killer and dendritic cells) showed significant improvements when using ATAC-seq with scVI embeddings. CD4 T effector memory cells showed the largest gain in F1 score (0.112, $p < 0.01$), whilst type-2 conventional dendritic cells showed the smallest improvement (0.006, $p < 0.05$). Prediction confidence was improved in B cells, monocytes, natural killer cells, CD4 and CD8 naïve cells, CD4 T central memory cells and CD8 T effector memory cells. Improvements in F1 scores were lost when only classifying major cell types rather than subtypes.

Conclusions: Employing ATAC-seq embeddings with scVI autoencoder enhances supervised annotation quality over scRNA-only methods. Further studies should explore the use of ATAC to improve the annotation of highly heterogeneous tissues such as tumours.

#4928 REFINE Method: Novel strategy for signal enhancement.

M. Wang[1], J. Ahn[2], J. Lee[2], D. Kim[2], E.-H. Cho[2], B. Lee[1], A. Carson[1];
[1]Genece Health, Inc., San Diego, CA, [2]GC Genome, Yongin, Korea, Democratic People's Republic of

Fragmentomics has emerged as a powerful tool in the detection of early cancer malignancies. One of the challenges for fragmentomics is the low signal to noise ratio in early stage cancer samples. Fragmentomic sequencing data is also inherently noisy and susceptible to batch effects. Common strategies to address these challenges include using normalization methods, such as frequency or Z-score normalization, to scale data. However, these existing methods struggle to differentiate true signals from noise and are susceptible to experimental bias. To address the need for a strategy that removes noise and batch effects, Genece Health is employing a novel normalization technique, the REFINE method, to improve the results of fragmentomic cancer detection. Whole genome sequencing (Illumina) fragmentomic data were generated at an average 2.5x coverage from 3,669 normal and 1,346 cancer samples. Six different cancer types were represented: colorectal, esophageal, liver, lung, ovarian, and pancreatic. Fragment end-motifs and fragment sizes (FEMS) data were then extracted from the sequence data. REFINE first establishes a baseline FEMS signal from a representative and random panel of normals (PoN) comprised of 100 healthy samples. This baseline, which represents the normal background FEMS noise in healthy donors, is subsequently decomposed using truncated singular value decomposition. Next, REFINE then eliminates this decomposed baseline FEMS signal from the raw FEMS data in all other samples using linear regression. A convolutional neural network (CNN) was trained (2,206 normal and 1,000 cancer samples) using frequency normalized data versus REFINE normalized data using 5-fold cross validation. The performances of both models were then assessed using the remaining 1,463 normal with 346 cancer samples. With a training dataset specificity threshold of 90%, REFINE significantly improves the sensitivity performance of the CNN model >30% (from 50.4% to 83.0%). REFINE also improves the auROC from 0.753 to 0.944. We also show that increasing the size of the PoN to 812 samples and including hyper-parameter optimizations further improves the sensitivity to 85.9% (with an auROC of 0.955). The REFINE method demonstrates a dramatic enhancement in the detection of ctDNA from fragmentomic data, overcoming the limitations of conventional normalization techniques. REFINE effectively enhances the signal to noise ratio, facilitating more accurate cancer detection. Future work will focus on validating the REFINE method across diverse datasets and exploring its application in other areas of oncology.

#4930 Identification of CBX7 and PCDHB18 as novel prognostic biomarkers of cervical cancer: RNA-sequencing and machine learning analysis.

G. Pourali[1], M. Zeinali[2], M. Arastonejad[3], N. Khalili-Tanha[4], E. Nazari[5], G. Khalili-Tanha[6], A. T. Toriola[1];

[1]Washington University in St. Louis, Saint Louis, MO, [2]Islamic Azad University Khomeinishahr Branch, Isfahan, Iran, Islamic Republic of, [3]Virginia Institute for Psychiatric and Behavioral Genetics, Virginia Commonwealth University, Richmond, VA, [4]Western College of Veterinary Medicine, University of Saskatchewan, Saskatoon, SK, Canada, [5]School of Allied Medical Sciences, Shahid Beheshti University of Medical Science, Tehran, Iran, Islamic Republic of, [6]School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran, Islamic Republic of

Background- Cervical cancer, ranking fourth in prevalence among women worldwide, is highly preventable when diagnosed early. The advent of innovative technologies including bioinformatics and machine learning, is revolutionizing the discovery and development of novel biomarkers for cancer. Our study uniquely integrates artificial neural networks with RNA-sequencing data of cervical cancer patients. This combination enhances the accuracy and reliability of biomarker predictions, providing a better understanding of the potential clinical utility of the identified biomarkers.

Methods- RNA-sequencing data and clinicopathological details of 304 Cervical Squamous Cell Carcinoma and Endocervical Adenocarcinoma (CESC) were obtained from the GDAC database (https://gdac.broadinstitute.org/). Differentially expressed genes (DEGs) were identified ($P<0.05$, $|\log2 \text{ fold change (FC)}| > 1.5$, false discovery rate (FDR) < 0.05). Pathway enrichment analysis was performed and protein-protein interactions of DEGs were constructed using the STRING database. Prognostic biomarkers were identified using Kaplan-Meier and Cox proportional hazard methods adjusted for potential confounders such as age, disease stage, and comorbidities ($HR<1$, $p<0.05$). Deep learning algorithms were applied for predictive marker identification, utilizing Weight by Correlation feature selection. The model used AUC (Area Under the Curve), accuracy, MSE (Mean Squared Error), and R2 (R-squared) as evaluation metrics in a 70-30 training-test split. A combined ROC curve assessed diagnostic biomarkers, validated externally with a GEO dataset on cervical cancer patients.

Results- In our study, 4153 DEGs were identified. Pathway analysis revealed that key dysregulated genes play a pivotal role in extracellular matrix organization. The survival analysis identified that six upregulated genes (CT62, SLC7A5P1, C10orf110, FDPSL2A, TNFSF15, and TTLL13) and seven downregulated genes (BAI3, CBX7, DKFZp566F0947, PCDHB18, GRAPL, PCDHB19P, and C4orf38) decreased the overall survival in patients. The machine learning model demonstrated high predictive accuracy (AUC=1, accuracy=99.02%, R2=0.99), identifying twenty genes with a positive correlation to cervical cancer risk. Notably, CBX7 emerged as a prognostic and diagnostic biomarker (AUC=0.99, sensitivity=0.93, specificity=1.00).

Conclusion- Our study uncovers the prognostic significance of two novel genes in cervical cancer: CBX7, a vital regulator of tumor suppression, and PCDHB18, a member of the protocadherin beta gene cluster functioning as a cell adhesion molecule. Downregulation of these genes is associated with decreased overall survival. Further functional analyses and validation of these candidate biomarkers are crucial to fully assess their potential clinical value in cervical cancer.

#4931 The Cancer Proteome Atlas: Expanded datasets and empowered with an AI-driven chatbot.

H. Liang, W. Liu, J. Li, Y. Tang;
UT MD Anderson Cancer Center, Houston, TX

Reverse-phase protein arrays (RPPAs) represent a powerful functional proteomic approach to elucidate cancer-related molecular mechanisms and develop novel cancer therapies. To facilitate community-based investigation of the large-scale protein expression data generated by this platform, we have developed a user-friendly, open-access bioinformatic resource, The Cancer Proteome Atlas (TCPA, http://tcpaportal.org), which contains several applications. The first one focuses on RPPA data of patient tumors, which contains >8,000 samples of 32 cancer types from The Cancer Genome Atlas (TCGA) and other independent patient cohorts. The second application focuses on the RPPA data of >1,500 cancer cell lines with publicly available, high-quality DNA, RNA and drug screening data. The third one focuses on perturbed RPPA profiles of >14,000 samples given drug treatments. We recently expanded our RPPA protein set from 200 to 500 proteins Importantly, this highly selected set is enriched in therapeutic targets and biomarkers and covers key oncogenic pathways such as PI3K/AKT, RAS/MAPK, Src/FAK, TGFβ/SMAD, JAK/STAT, epithelial-mesenchymal transition, DNA damage repair, Hippo, Notch, cell cycle, apoptosis, and immune-oncology. Using this upgraded RPPA platform, we generated an harmonized, expanded RPPA dataset of 8000 TCGA patient samples and 1000 CCLE cell line samples. To further address the informatic challenges of analyzing such large, diverse datasets, in addition to the GUI interfaces, we recently developed a chatbot through which users can analyze the RPPA data through human nature languages and obtain the results and related analytic reports without a learning curve. Such a chatbot empowers a broad research community to explore high-quality RPPA datasets and generate testable hypotheses in an effective and intuitive manner, representing the direction of next-generation data analytics.

#4932 UltiAnalyzer.AI: An automatic and robust AI-Driven tool for the quantification of multiplex immunofluorescence whole slide images.

R. Cardenes[1], D. Wood[1], M. Schulze[2], J. Lee[1], L. Rognoni[1];
[1]Ultivue, Inc., Cambridge, MA, [2]Slash-m GmbH, Harth-Pollnitz, Germany

Introduction: Whole slide multiplexed immunofluorescence (mIF) facilitates in-depth study of the tumor microenvironment with multi-channel images resulting in an enormous amount of protein expression and spatial data across millions of single cells. Therefore, it has become crucial to process this huge amount of data automatically and reliably. Here we introduce UltiAnalyzer.AI, a software tool that integrates a set of artificial intelligence (AI) models specifically designed for the analysis of whole slide mIF slides, that is fully automatic, highly accurate, highly efficient, and fully scalable.
Methods: UltiAnalyzer.AI processes are specialized for 1) tissue segmentation, in which tissue regions are identified using a semantic segmentation AI model on low magnification versions of the DAPI channel, 2) tiling, where slide images are divided into 512x512 overlapping tiles for efficient image processing and lower memory requirements, 3) tumor region segmentation based on a semantic segmentation AI model, 4) nucleus segmentation using the open-source StarDist model, and 5) marker-positive cell detection, in which AI object detection models are employed to classify nuclei as positive or negative in each marker channel using the Faster R-CNN architecture. Here, we take advantage of the full 16-bit dynamic range of images produced using Ultivue InSituPlex® amplification technology, although our approach could be applied to other platforms. Intensity thresholding is no longer necessary, and identification of a positive cell mainly considers the morphology of the cell in the context of its cellular neighborhood.
Results: Trained on over 60 mIF slides and validated with manual annotations, UltiAnalyzer.AI has demonstrated strong performance, achieving f1-scores between 0.8 to 0.91 for cell detection, and average correlations of 0.9 for cell counts across 15 markers. Processing time is around 3s per tile, enabling the processing of large slides in under an hour. It has been tested on over 1000 slides, and in a comparative study, it matched a VisioPharm-based quantification with 0.95 correlation in positive counts for 8 markers. Cloud deployment allows for processing thousands of slides simultaneously and in considerably less time.
Conclusions: UltiAnalyzer.AI represents a significant advancement in the field of whole-slide mIF analysis, offering high accuracy and scalability using fully automated processes. By utilizing the full dynamic range of Ultivue's mIF technology and avoiding traditional thresholding methods, the tool also increases robustness and reproducibility. The incorporation of cutting-edge AI technology and scalable cloud computing capabilities positions UltiAnalyzer.AI as a leading-edge solution for mIF analysis in digital pathology.

#4933 A workflow for cloud-based AI development of multiplex IF image analysis using the OMERO Plus platform.

R. Cardenes[1], E. Diel[2], D. Wood[1], J. Lee[1], A. Vasaturo[1], M. Schulze[3], L. Rognoni[1];
[1]Ultivue, Inc., Cambridge, MA, [2]Glencoe Software. Inc,, WA, Seattle, WA, [3]Slash-m GmbH, Kockritz, Harth-Pollnitz, Germany

Background: The advancement of AI in digital pathology is essential for analyzing image data containing billions of cells. This is true for digital pathology workflows using bright-field images, but this is even more critical for multiplex immunofluorescence (mIF) whole-slides due to the increased number of fluorescent channels and bit-depth per pixel. These complexities necessitate improved data management, and efficient visualization for both the mIF image and AI-based analysis results. We present a workflow using OMERO Plus, AWS SageMaker, and Ultivue software for AI model development in mIF. *Method*: Images were uploaded to AWS S3 and imported to the data management system OMERO Plus, where they were organized into training and validation groups.
Annotations: PathViewer was used to place rectangular fields of view (FOV) in locations selected by the pathologist where all positive cells for each target marker were manually annotated.
Data Preparation: Using the OMERO Plus API, annotation coordinates, image tiles, and image metadata were extracted and formatted for model training. All training data is under a version control system using Gitlab and Data Version Control tools using AWS S3. Additionally, strict quality checks were performed to ensure data integrity.
Training: For both semantic segmentation and cell object detection, the training data was used in a customized training workflow using AWS SageMaker, including modern deep learning architectures, data augmentation, training logging, evaluation, and deployment. All AI models were trained using Pytorch and deployed with the open model format ONNX.
Results Visualization: AI segmentation results of cells and regions are visualized using PathViewer as overlays on the original images by converting them to the OME-NGFF label image format that uses Zarr multidimensional arrays. *Results*: We utilized 58 and 24 mIF images for training and validation, respectively, on 15 markers using ISP Ultivue technology with 1681 and 296 FOVs, encompassing over 60K cells. Using this data and methodology we trained 3 semantic segmentation models and over five object detection models suitable for all twenty-four OmniVUE markers. For instance, the CD3 positive cell detection model, trained with 390 FOVs, achieved highly accurate results: f1-score of 0.915 evaluated on 34 FOVs.
Conclusions: The combination of OMERO Plus, PathViewer, AWS SageMaker, and internal tools can successfully address mIF Big Data data management complexities in a cloud environment for digital pathology. The architecture is highly scalable, cost effective, and reliable, enabling a very efficient AI workflow.

#4936 An ultrahigh-throughput synergy screening platform enables discovery of novel drug combinations.
W. C. Wright, P. Geeleher;
St. Jude Children's Research Hospital, Memphis, TN

The battle against many cancers and infectious diseases has long been hindered due to the complexity of finding potent and effective drug combinations. With each new drug considered, the number of combinations to potentially test increases exponentially, posing substantial challenges in screening throughput. These challenges further intensify when accounting for the number of doses of each drug that need to be tested in a drug combination matrix (known as matrix density). There is a pressing need to screen large amounts of combinations at sufficient density to discover new therapies for diseases like cancer, but this has traditionally been out of reach. However, the recent widespread adoption of acoustic liquid handling robots has shown promise to overcome these obstacles by allowing for intricate drug screening template designs which were previously not possible to make. Despite these advances, the throughput achieved by these technologies has been limited due to lack of broadly accessible protocols and analytical tools for drug combination screening.
We present Combocat, an end-to-end platform that allows for substantial increases in throughput of drug combination screens by combining experimental protocols that can be deployed for acoustic liquid handlers, machine learning algorithms for data imputation, and software that allows for in-depth analysis of results. We first generated a reference dataset of over 250,000 unique drug combination measurements in multiple cancer cell lines. The combination data were collected in a dense format (10×10 combination matrices) using a novel drug-drug template and achieved a dramatic increase in throughput compared to conventional methods. We then used this dataset to build a computational model which allowed us to accurately estimate drug combination effects using sparse measurements and imputing non-measured values with machine learning. The sparse measurements are collected in 1536-well microplates and substantially boost the throughput capabilities of drug-drug screens. As proof-of-concept, we used our method to screen a preclinical model of neuroblastoma with 9,045 drug combinations. This represents 10% the scale of the largest drug combination studies ever reported, achieved using a fraction of the resources, and in dense formats. We validated our findings by re-screening top hits using the fully-measured, non-imputed method and demonstrate the accuracy of our platform.
The Combocat platform’s documentation and codebase is open-source, and we also make a GUI available for interactive exploration of screening results. By integrating advanced experimental and computational methods, we provide a generalizable pipeline that will expedite synergy screens and the drug combination discovery process for many diseases.

#4937 Potential therapeutic targets with anti-inflammatory activity spectrum(COX-2/PGE2) of compounds associated with anti-cancer activityagainst oral and colorectal cancers.

S. Sampoornam Pape:
Kalinga Institute of Industrial Technology (KIIT), Bhubaneswar, India

Introduction: COX-2 and PGE2 are prevalent inflammatory cytokines that exert influence on several cancer-related pathways throughout the gastrointestinal tract, spanning from oral cancers to colorectal cancers. One of the tactics being developed for the treatment of oral and colorectal malignancies is the identification of drugs that can selectively target receptors associated with COX-2 and PGE2.
Materials and Methods: The objective was to identify potential therapeutic targets for oral cancer and colorectal cancer, specifically focusing on drugs that act as inhibitors or antagonists of the COX2/PGE2 pathway and its related receptor. A method for systematic data mining was created with a total of 32 targets associated with the COX-2/PGE2 pathway which were identified using the KEGG database. These targets were shown to be linked to both the oral cancer pathway and the colorectal cancer pathway. The compounds of interest were obtained from the Chembl25 database and their similarity was assessed using the Tanimoto similarity index, which was generated based on the Morgan fingerprints. The study employed molecular docking techniques to examine the interaction between the chosen drugs and the anticipated targets. A systematic data mining approach and computational methodology were devised utilizing the KNIME platform.
Results: A total of 16,900 compounds were extracted for a set of 32 targets. Following the implementation of rule-based filters, the number of compounds was reduced to 13,800. The compounds that have a similarity index greater than 0.7 were chosen for inclusion in final analysis. Among various targets examined, empirical evidence was found to support the inhibition of expected target for PI-3 kinase-mTOR, GSK-3CD1, GSK3-AKT and PI3kinase-AKT pair. However, no evidence was found to support the inhibition of GSK3-Ikappa B-kinase. In order to examine the likelihood of the compound's interaction with anticipated target, molecular docking was employed to explore the interaction of one inhibitor compound for each pair. This investigation was conducted in contrast to the existing inhibitor compound and the subsequent findings were analyzed and discussed.
Conclusion: The implemented data mining technique has demonstrated a notable decrease in the duration needed for comparable investigations, enabling the execution of experiments including numerous targets and a substantial number of ligands within a cumulative timeframe of 30 minutes. The findings of this study have the potential to be utilized in the identification of targets and the discovery of lead compounds for the purpose of managing oral as well as colorectal malignancies.

#4938 Prediction of gene mutation from colorectal adenocarcinoma whole slide images via integrated deep learning pipeline.

G.-Y. Tien[1], L.-C. Lai[2], T.-P. Lu[3], M.-H. Tsai[4], H.-H. Chen[5], E. Y. Chuang[1];

[1]Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, [2]Graduate Institute of Physiology, College of Medicine, National Taiwan University, Taipei, Taiwan, [3]Institute of Health Data Analytics and Statistics, National Taiwan University, Taipei, Taiwan, [4]Institute of Biotechnology, National Taiwan University, Taipei, Taiwan, [5]Institute of Computer Science and Information Engineering, National Taiwan Normal University, Taipei, Taiwan

Colorectal cancer (CRC) stands as one of the deadliest cancer types worldwide. Identifying specific gene mutations crucial for targeted therapy is pivotal for CRC treatment. However, the current genetic testing method involves liquid biopsy, which is often cumbersome and cost-intensive. Histopathological whole-slide images (WSIs) are routinely generated for diagnostic purposes and can offer valuable insights into cellular heterogeneity. In this study, we aim to develop an integrated deep learning pipeline for predicting TP53 mutations in CRC, one of the most frequently mutated genes in CRC.

We commenced by collecting 424 diagnostic WSIs from the TCGA-COAD cohorts. Each WSI was split as small patches at a resolution of 0.5 micrometers per pixel for following analyses. Quality control was implemented using Otsu thresholding and Gaussian blur filtering, both at the slide-level masking and patch-level filtering stages. Additionally, we applied the Macenko algorithm for color normalization to eliminate systematic errors. Following image preprocessing, we constructed a tissue-type classification model based on VGG19, which was trained and tested using the NCT-CRC-HE-100K and CRC-VAL-HE-7K datasets, both containing pixels with tissue types labeled by human experts. The trained classifier was then used to identify adenocarcinoma epithelium patches from TCGA-COAD. Subsequently, we applied multiple pre-trained Convolutional Neural Network (CNN) models, including ResNet-101, DenseNet-201, and Inception-ResNet-v2, to predict TP53 mutations for the identified adenocarcinoma epithelium patches from TCGA-COAD. A novel integration approach was employed to aggregate patch-level predictions into slide-level outcomes.

We evaluated the trained models using various metrics, including accuracy, precision, recall, F1 score, AUC (Area Under the Curve), and Cohen's Kappa coefficient. The tissue-type classification model exhibited robust performance, achieving an overall accuracy of 94.7%, a Cohen's Kappa coefficient of 94%, a precision of 95.3%, a recall of 99.76%, and an F1 score of 97.48% for identifying adenocarcinoma epithelium patches. Regarding the TP53 mutation prediction models, ResNet-101, DenseNet-201, and Inception-ResNet-v2 exhibit the predictive ability to both patch level (AUC=65%) and slide level (AUC=70%).

In summary, the proposed deep learning pipeline offers an efficient way to acquire gene mutation information from WSIs. Moreover, it demonstrates a capability to discover potential molecular aberration from the clinical images.

#4939 Computational pathology approach for prognostic advancements and therapeutic benefits in gastrointestinal cancer: A multi-centric retrospective study.

T. Zhang[1], Z. Sun[1], Z. Li[2], M. Ahmad[3], M. Islam[3], F. Yang[4], Z. Li[5], **Y. Jiang**[6];

[1]Southern Medical University, Guangzhou, China, [2]Northwestern Polytechnical University, XIAN, China, [3]Stanford University School of Medicine, Palo Alto, CA, [4]Wake Forest University, Winston Salem, NC, [5]Yunnan Cancer Hospital, Kunming, China, [6]Wake Forest University School of Medicine, Winston Salem, NC

Background: The current cancer staging methods cannot accurately predict survival and therapeutic benefits in cancer patients. Digital pathomics is an emerging field with potential to revolutionize disease evaluation. The present study aims to develop and validate a deep learning pathomics signature from digital hematoxylin-eosin (H&E) staining slides to predict the survival of pan-gastrointestinal cancer, and further investigated its associations with chemotherapy and immunotherapy response. P

atients and Methods: This international multicenter study included 2,463 patients with pan-gastrointestinal cancer from twelve cohorts of seven cancer centers, among which 1653 patients were diagnosed with GC. We proposed a deep learning pathomics signature (DLPS) by integrating information on three scales from the whole slide images (WSIs) of H&E, including pathomics nucleus, pathomics microenvironment, and single-cell spatial distribution features. Next, we evaluated the predictive accuracy of DLPS for prognosis, chemotherapy response, and immunotherapy response. To interpret the predictive ability of the DLPS, we analyzed multi-omics data and employed the Shapley value strategy to provide its biological insights and importance ranking.

Results: The DLPS was significantly associated with overall survival in patients with GC (hazard ratio range: 1.203-2.717, all $p < 0.001$), which was further validated in other gastrointestinal cancers (all $p < 0.02$). The DLPS remained an independent predictor of prognosis in multivariable analysis (all $p < 0.001$). Furthermore, a nomogram incorporating the DLPS and TNM stage shows significantly improved accuracy in predicting cancer prognosis compared to that with TNM stage alone (all $p < 0.05$). Shapley value analysis highlighted DLPS as the strongest predictor for prognosis. Importantly, GC patients with a low-DLPS (but not those with a high-DLPS) exhibited substantial benefits from adjuvant chemotherapy (all $p < 0.05$). Furthermore, we found the objective responses of anti-PD-1 immunotherapy is significantly higher in the low-DLPS group (29.6%) than in the high-DLPS group (8.3%, $p < 0.05$). Upon analyzing multi-omics data, we found that a higher DLPS was positively correlated with tumor promoting, chemotherapy resistance, immune tumor microenvironment and metabolic signaling.

Conclusion: The DLPS enabled improved assessment on prognosis, and has the potential to identify patients who will benefit from adjuvant chemotherapy and immunotherapy, which can further be extended to many gastrointestinal cancers or other solid tumors.

#4940 Unraveling ctDNA features in high-grade serous ovarian carcinoma and insights from genomic and transcriptomic integration.

Mai TN Nguyen[1], Jaana Oikkonen[1], Yilin Li[1], Daria Afentave[1], Veli-Matti Isoviita[1], Anni Virtanen[1], Johanna Hynninen[2], Sampsa K. Hautaniemi[1]

[1]University of Helsinki, Helsinki, Finland, [2]Department of Obstetrics and Gynaecology, University of Turku and Turku University Hospital, Turku, Finland

High-grade serous carcinoma (HGSC) is often diagnosed at advanced stages with less than 40% of patients surviving for five years after diagnosis. Circulating tumor DNA (ctDNA) is a minimally invasive technology that can provide crucial insights into tumor biology. Unique features from ctDNA, fragment patterns and nucleosome footprints at transcription start sites (TSS), complement genomic variants. Our study explored ctDNA features in HGSC, integrating with tumor biopsies' genomic and transcriptomic profiles. We focus on two aspects in HGSC: understanding how ctDNA features assist genomic profiling and track dynamic changes during treatment and exploring the biological factors impacting ctDNA release. We used 500+ longitudinal plasma and 400+ pretreatment tissue samples from HGSC patients in the DECIDER study (NCT04846933). Shallow whole-genome sequencing (sWGS) with 0.4x average coverage was conducted on plasma. Integration of DNA and RNA pretreatment tissue data was performed for 98 and 91 patients with available plasma before treatment, respectively. Plasma samples underwent analysis for fragment patterns and TSS signals. Somatic mutations and mutational signatures were retrieved for patients with available WGS tissue data. Pathway enrichment analysis was applied to diverse gene expression profiles. WGS data from 29 healthy individuals (Zhu, G. et al. (2023)) served as controls. DNA fragment profiles and TSS signals distinguish ctDNA from healthy samples. The ability to cluster sample phases based on ctDNA features facilitates tracking longitudinal changes. Integrating tissue DNA and RNA data reveals a positive correlation between high ctDNA release and mutational burden, single-base substitution signature SBS1 as a marker for cell division/mitotic clock and doublet-base substitution signatures linked to late replication. These mechanisms help explain why high ctDNA release group (n=40) is associated with a shorter progression-free survival. Additionally, transcriptomics data indicates associations with proliferation pathways in cancer cells and ctDNA release. The concordance in results from DNA and RNA points to a higher proliferation rate in patients with high ctDNA release, suggesting the need for alternative treatment compared to those with low ctDNA release. In conclusion, our results provide a multifaceted perspective on ctDNA in HGSC. The identification of longitudinal ctDNA features signifies the capability to stratify sample states and show the potential findings through fragment profiles and the discernment of key TSS regions. The proposed aetiologies and enriched pathways associated with ctDNA release, mutation burden and proliferation, shed light on potential treatment avenues. These findings contribute to our understanding of ctDNA in HGSC and offer insights for personalized treatment strategies and monitoring approaches.

#4942 Unraveling a prognostic and predictive 8-gene signature related to cuproplasia in pan-cancer.

V. Pham[1], T. Jue[1], J. Bell[1], F. Luciani[1], F. Michniewicz[1], G. Cirillo[2], L. Vahdat[3], C. Mayoh[4], O. Vittorio[1];
[1]UNSW Sydney, Sydney, Australia, [2]University of Calabria, Rende, Italy, [3]Dartmouth-Hitchcock Medical Center: Lebanon, New Hampshire, NH, [4]Children's Cancer Institute, Sydney, Australia

This study aims at identifying a cuproplasia-related gene signature to predict outcome for cancer patients based on gene regulatory networks. Copper is a vital micronutrient involved in many biological processes. Copper influences tumor growth through a process called cuproplasia, defined as abnormal copper-dependent cell-growth and proliferation. Copper-chelation therapy targeting this process has demonstrated efficacy in several clinical trials against cancer. While the molecular pathways associated with cuproplasia are partially known, genetic heterogeneity across different cancer types has limited the understanding of how cuproplasia impacts patient survival. We proposed a novel framework based on gene regulatory networks to identify critical cuproplasia-related genes (CCGs) across different cancer types. Utilizing RNA-sequencing data from The Cancer Genome Atlas (TCGA) and the Genotype-Tissue Expression (GTEx) datasets, we generated gene regulatory networks for 23 different cancer types. We applied a network control method to discover critical genes in these networks and combined with copper metabolism related genes to identify CCGs across 23 cancer types. We then performed a comprehensive analysis on the identified CCGs to better understand their potential roles and associations with cancer patient survival. We discovered 30 CCGs which were enriched in pathways related to a wide range of biological processes supporting cancer progression and immune evasion processes. The specific processes related to the identified CCGs include autophagy, cell cycle regulation, cell proliferation, kinase signaling pathways, immune infiltration, and immune checkpoint regulation. From this, we identified a novel 8-CCG signature significantly associated with survival pan-cancer, including CDK1, AP1S1, CASP3, MAP1LC3A, SNCA, TMPRSS6, MAPT, and GSK3B. Although some of these genes are known for their important roles in various malignancies and are associated with poor survival, this is the first study defining their connection with high copper levels in cancer cells. Furthermore, in keeping with previous studies that have used metal regulatory genes to predict outcomes in a specific cancer type, we specifically used low grade glioma (LGG), a cancer type highly impacted by intracellular copper level, as an example to explore the role of CCGs in a specific cancer type. Through our proposed gene regulatory network methodology, we identified a 3-gene signature that overlapped with a 6-gene prognostic risk score model for LGG patients. These 6 genes included ALB, CASP3, CDK1, CP, CYP1A1, and MT-CO1. To our knowledge, this is the first pan-cancer analysis for genes related to cuproplasia. The findings from our study highlight the use of gene regulatory networks to identify CCGs which could be used to develop novel targeted therapeutic strategies.

#4943 Benchmarking unpaired single-cell RNA and single-cell ATAC integration.

J. Chen, W. Xiao, E. Zhang, X. Chen;
St. Jude Children's Research Hospital, Memphis, TN

The integration of single-cell RNA-sequencing (scRNA-seq) and single-cell ATAC-sequencing (scATAC-seq) data offers a unique opportunity to gain a comprehensive view of cellular identity with defining features and to infer gene-regulatory relationships. Despite the emergence of technologies that simultaneously capture both the gene expression and chromatin accessibility of individual cells (paired data), the practical challenges of these approaches (e.g., the unavailability in previous samples and prohibitive cost) have led researchers to turn to the existing trove of single-modality data generated from independent biological samples (unpaired data). Various computational tools have been developed to integrate these unpaired single modality datasets. However, the comparative performance of these tools has not been comprehensively evaluated, and a standard benchmark pipeline is still lacking. To address these challenges, we used pseudo-unpaired scRNA-seq and scATAC-seq data derived from publicly available paired single-cell multi-omics datasets to benchmark 14 publicly available integration methods. The primary goal of unpaired single-cell multi-omics integration is to narrow the omics gap while preserving cell type diversity. We therefore focused on pair-wise cell distance and cluster performance in the joint latent space constructed by various integration tools in our benchmarking pipeline. To ensure the robustness of these computational approaches, we examined their stability across a variety of scenarios, including variations in cell number, cell types, and biological and technical batch effects. A number of the integration methods tested produced promising results. While the widely used Seurat package was recently reported to have the best performance (Lee et al., Genome Biology 2023), other computational tools such as scVI, Cobolt, scJoint, scglue and scBridge performed equally well or better in reducing omics differences and facilitating the identification of cell clusters. Notably, scglue and Cobolt demonstrated strong performance in aligning the same cell from different modalities, and discrete clusters emerged in the joint latent space using scJoint and scBridge. These findings suggest that it may not be strictly necessary to use paired multi-omics data to guide integration to achieve favorable results. Our freely available benchmarking pipeline will empower researchers to identify the optimal data integration methods for their specific data, facilitate the benchmarking of new methods, and contribute to future method development in the field.

#4944 Divergent proteogenomic gene expression is driven by microenvironment across tumor types.

J. LaMorte[1], N. Bateman[2], T. Conrads[1], R. F. Browning, Jr.[1], C. D. Shriver[1], R. L. Kortum[1], **M. D. Wilkerson**[1];
[1]Uniformed Services University, Bethesda, MD, [2]Uniformed Services University; Henry M. Jackson Foundation, Bethesda, MD

Solid tumors develop through a complex series of genome and downstream expression alterations that interact with the local tissue microenvironment, leading to a transformed cell and malignant phenotype. With massive multi-omic data, recent proteogenomics studies have jointly analyzed RNA and protein expression to uncover new gene regulatory relationships; however, many of these studies focused on single tumor types and lack a generalizable view of joint RNA and protein expression. Here, we present the first pan-cancer analysis of sample-wise RNA to protein correlation (SRPC). We re-analyzed over 1,000 tumors across 10 tumor types from published proteogenomic data from the Clinical Proteomic Tumor Analysis Consortium (CPTAC) and the Applied Proteogenomics OrganizationaL Learning and Outcomes (APOLLO) Research Network. We identified a wide range of SRPC across all tumors (ρ range: -0.08 to 0.70, median: 0.45). We then analyzed tumor pathologic and molecular characteristics versus the range of SRPC. High SRPC tumors had high tumor purity by pathology review, by somatic DNA whole exome sequencing, and by RNA and protein purity scores. In contrast, low SRPC tumors had high immune cell and stromal cell expression scores as inferred by either protein or RNA based signatures. We observed marked differences in cell type populations estimated by expression in different SRPC tumor tranches (low SRPC: macrophages, endothelial cells, cancer-associated fibroblasts; high SRPC: CD4+ Th2 cells). Tumors expressed signaling pathways depending on their SRPC (low SRPC: hypoxia, inflammatory response, and KRAS signaling; high SRPC: DNA repair and E2F targets). SRPC also stratifies tumors with distinct somatic DNA alterations (low SRPC: HRAS and NF2; high SRPC: TP53, MEN1, high Tumor Mutational Burden and high DNA chromosomal instability). Finally, we found that cancer driver genes displayed divergent gene-wise RNA to protein correlations (GRPC) among tumor types with a median absolute deviation interquartile range of 0.1 - 0.2, suggesting tumor-type-specific regulation. In summary, divergent RNA and protein expression is driven, in part, by tumor microenvironment composition across tumor types. Tumors with a diverse cellular microenvironment display a summation of RNA and protein expression resulting from this cell type diversity leading to a low SRPC, while tumors predominated by tumor cells display coordinated RNA and protein expression levels resulting from a pure clonal or cell type leading to a high SRPC. This first deep analysis into sample-wise RNA to protein correlation represents a large proteogenomic community resource for informing biomarker analysis by modality and by tranches of tumor microenvironment. The views expressed in this abstract are solely of the authors and do not reflect the official policy of the Departments of Army/Navy/Air Force, Department of Defense, USUHS, HJF, or U.S. Government.

#4945 Computational modeling-based discovery of novel anticancer drug candidates targeting centromere-associated protein E.

P. Lu[1], R. Kamata[2], M. R. Weil[1], N. Ohashi[1], A. Ohashi[2], E. A. Stahlberg[1];

[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]National Cancer Center Japan, Kashiwa, Japan

Purpose: Centromere-associated protein E (CENP-E), a mitotic motor protein, is crucial for cell division. Inhibition of CENP-E can lead to chromosome misalignment and aneuploidy. Our recent studies revealed that the CENP-E inhibitor (CENP-Ei), Compound A, induces aneuploid-mediated cGAS-STING pathway activation in cancer cell lines, which is expected to trigger innate immune response and induce immunological conversion of the tumor microenvironment from cold to hot. However, known CENP-Eis exhibited limited efficacy, and none have gone beyond phase I trials since 2012. The aim of this study is to develop a workflow integrating structure and artificial intelligence-based modeling approaches to accelerate the discovery of novel CENP-Eis with improved efficacy and overcome related challenges.

Method: The inhibitor-bound CENP-E structure was modeled using chimeric homology modeling followed by induced fit docking with known CENP-Eis. Structure-based virtual screening (VS) was performed on large compound libraries in Enamine REAL, Synthetically Accessible Virtual Inventory, and MolPort databases. Consensus scoring methods were applied by averaging ranks of individual molecules obtained from VS against different CENP-E conformations. An active learning-enhanced VS pipeline was developed using ATOM Modeling PipeLine (AMPL) to find the best-ranked ligands more efficiently. CENP-E ligand candidates were further filtered based on their safety properties predicted by machine learning models trained with curated databases of adverse drug reactions using AMPL. The success of this study was measured by its ability to reveal novel chemotypes that could modulate CENP-E in kinesin ATPase assays.

Result: Conformations of CENP-E's ligand binding site were predicted for VS using the homology model. Structure-based VS was performed to select high-ranked compounds based on consensus scoring. The active learning-enhanced VS pipeline achieved 75% accuracy in ranking the top 20% of hit compounds. The graph convolutional network model with a ROCAUC, 0.76, was created using AMPL to filter ligand candidates based on their predicted safety properties. Seventy-three potential CENP-E ligands computationally prioritized from the Molport database were experimentally tested using kinesin ATPase assays from which 4 potential inhibitors and 8 potential activators were identified indicating overlapping binding sites of inhibitors and activators.

Conclusion: Our integrated workflow is effective in discovering novel CENP-E modulators. The discovery of CENP-E activators provides an opportunity to identify novel therapeutics in hepatocellular carcinoma malignancies known to experience decreased CENP-E activity leading to aneuploidy. The predictions generated by computational models combined with experimental validations could further accelerate anticancer drug discovery.

#4946 ssTimiGP: Equip the TimiGP system with a single-sample module, facilitating the cell-cell interaction inference of the tumor microenvironment in any sample.

C. Li[1], J. Zhang[1], C. Cheng[2],

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Understanding the tumor microenvironment (TME) is essential in cancer treatment and risk assessment. While single-cell RNA-seq (scRNA-seq) offers in-depth insights into the TME, its expensive cost results in limited data sets and size. In contrast, microarray and RNA-seq provide rich datasets from larger cohorts, but they yield bulk data with lower resolution. To leverage the strengths of both approaches and comprehensively study the TME, we developed the computational framework TimiGP (Tumor Immune Microenvironment Illustration through Gene Pairs). It is inspired by the dynamic balance of the immune system and extended to the entire TME. TimiGP utilizes scRNA-seq to define cell type of interest, and bulk transcriptomic profiles to deduce clinically relevant cell-cell interaction networks and cell functions. Our recent release includes both prognosis and response modules to study the association between TME and the corresponding clinical outcomes. However, their applicability is constrained by the necessity for paired clinical information.

In response to this limitation, we present a significant enhancement, a single sample module slightly modified from the TimiGP framework (ssTimiGP). This upgraded version enables TME analysis in any individual sample, requiring only bulk RNA-seq data and cell-type markers. It exports a cell-cell interaction network representing the relative expression of functional markers and the abundance of cells. This optimization expands the utility of TimiGP, making it more accessible across diverse samples and species.

We have further expanded the application of ssTimiGP from solid tumors to liquid samples (e.g., peripheral blood). To validate its performance, we conducted a comparative analysis between the interactions of eight immune cell types observed in experimental results using FACS and the computational results derived from ssTimiGP based on paired RNA-seq data. As a result, ssTimiGP not only successfully identified interactions between different cell types that exhibited a significant correlation with experimental findings (e.g., CD4+ naïve T cells → Monocyte, R=0.75, p< 0.001, accuracy = 0.8), but also demonstrated its capability to achieve higher resolution in capturing interactions between immune cell subpopulations (e.g., CD4 naïve T cells → activated CD4+ memory T cells, R=0.57, p=0.008, accuracy = 1.0). In our benchmark analysis, ssTimiGP demonstrated superior performance compared to CIBERSORTx (e.g., CD4+ naïve T cells → Monocyte, R=0, Accuracy=0.3).

In summary, ssTimiGP signifies an expansion of the TimiGP system, enabling the inference of the TME in individual solid tumors and liquid samples at various resolutions by integrating the strengths of both scRNA-seq and bulk RNA-seq. This approach offers substantial potential for advancing personalized cancer treatment.

#4947 Uncovering the molecular basis for clinically relevant sphingolipidomic subtypes in acute myeloid leukemia.

B. Paudel[1], S.-F. Tan[1], J. Ung[1], D. Claxton[2], D. J. Feith[1], T. P. Loughran, Jr.[1], K. A. Janes[1];
[1]University of Virginia, Charlottesville, VA, [2]Penn State Cancer Center, Hershey, PA

Acute myeloid leukemia (AML) has been extensively studied at the genomic level, resulting in various genomic classifications. Despite the progress, three key challenges remain: 1) a significant proportion of patients lack identified genomic features, 2) a discrepancy exists between genomic risk classification and clinical outcomes, and 3) many mutated targets remain non-druggable. There is an urgent need for an enhanced AML risk classification that goes beyond genomic aberrations to guide effective therapeutics. Recent research, including our own, has increasingly linked AML pathogenesis and therapeutic resistance with dysfunctional sphingolipid metabolism, a family of bioactive molecules crucial for cellular functions. In a recent manuscript, we identified two robust sphingolipidomic clusters in AML, characterized by reciprocal abundances of hexosylceramide (Hex) and sphingomyelin (SM) species (HexloSMhi, HexhiSMlo). These clusters correlate with latent transcriptional states and stratify patient groups in multiple independent datasets such as TCGA, and BeatAML, with the HexloSMhi cluster representing a high-risk subgroup associated with poor clinical outcomes. These findings underscore the role of sphingolipids in refining AML risk assessment and creating avenues for discovery and therapeutic intervention. However, the signaling states driving these sphingolipidomic clusters and the mechanisms elevating risk in the HexloSMhi cluster require further investigation. To identify regulatory genes for the AML subtypes, we constructed gene regulatory networks using differentially expressed genes. Focusing on the high-risk subtype, we identified highly connected genes ranked by connectivity, including KDM1A, GSK3β, LCK, and STAT5A. We found that higher STAT5A abundances in the HexloSMhi subtype, particularly correlated with pro-survival Bcl-xL proteins. Furthermore, we identified STAT5 protein abundance as a key variable associated with drug sensitivity from pharmacological screening with sphingolipid pathway inhibitors and AML therapeutics 30 AML cell lines and patient samples. This is encouraging as STAT5 is druggable as evidenced in the NIH-Pharos druggable genome database, and several small-molecule inhibitors are currently in clinical trials. Analysis of gene expression data suggest that STAT5 inhibition, through genetic or pharmacological means, downregulates cell cycle-related genes and significantly alters sphingolipid gene expression. Recent work by others indicates that sphingolipid-catalyzing enzymes regulate STAT5 activity in leukemias, with ceramides acting as a second messenger in cells. Taken together, this suggests a possibility of a positive feedback loop between sphingolipid homeostasis and activity of STAT5; the details of this interaction require further investigation.

#4948 Automated tumor microenvironment analysis for multiple samples by image-based spatial transcriptomics on tissue microarray.

Dongjoo Lee[1], Seungho Cook[1], Yeonjae Jung[1], Myunghyun Lim[1], Jae Eun Lee[1], Hyung-Jun Im[2], Daeseung Lee[1], Hongyoon Choi[3]

[1]Portrai, Inc., Seoul, Korea, Republic of,[2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of,[3]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, Korea, Republic of

Introduction. Tissue Microarrays (TMAs), widely utilized in the field of pathology, have now found a powerful ally in Image-based Spatial Transcriptomics (ST). By analyzing various gene expression data with high resolution, image-based ST data on TMA can provide the heterogeneous patterns of tumor microenvironment in multiple samples. However, an efficient method for processing multiple samples post-data acquisition is still under development. A streamlined process would expedite the discovery of spatial gene expression patterns, thereby enhancing our understanding of the tumor microenvironment and its implications for cancer diagnostics and treatment strategies.

Methods. Our automated pipeline is initiated by automatic segmentation of every core in the whole TMA, derived from the processed output of the MERSCOPE or Xenium platform. Then, it subsequently removes QC failed cells unrelated to any core. Each core receives sequential naming and undergoes automated cell type mapping utilizing a reference single-cell RNAseq data. Additionally, the pipeline computes neighborhood enrichment between cell types, providing a nuanced comprehension of spatial relationships and interactions among diverse cell populations within the tissue microenvironment from multiple samples on the TMA.

Results. The automated pipeline we've developed provides several key advantages. It enables the simultaneous analysis of multiple tissue cores, effectively minimizing batch effects and ensuring the reliability of results across diverse tissue samples. Furthermore, by automating core separation, labeling, and cell type mapping, our pipeline significantly streamlines the time and effort required for TMA data analysis. This cost-effective approach allows researchers to optimize resource allocation, making our automated pipeline a valuable tool in cancer research. It facilitates the exploration of gene expression patterns within specific tissue regions, ultimately contributing to the advancement of our understanding of cancer biology.

Conclusion. By seamlessly integrating TMA data with image-based ST technologies such as Xenium and MERSCOPE, we can perform comprehensive spatial transcriptomics analyses and provide detailed statistical information on cell type proportions within the tumor microenvironment. This automated pipeline not only ensures robust and reliable results across diverse tissue samples but also optimizes resource allocation by minimizing batch effects and reducing analysis time. This cost-effective solution empowers researchers to delve deeper into spatial gene expression patterns, enhancing our comprehension of the tumor microenvironment.

#4949 Multimodal analysis of metals, spatial transcriptomics, and histological structures in colorectal cancer.

A. Srivastava[1], N. Shaik[2], Y. Lu[3], M. Chan[3], A. Diallo[4], S. Han[3], R. Steiner[4], T. Punshon[4], B. Jackson[4], L. Vahdat[3], L. Vaickus[3], J. Hoopes[4], F. Kolling IV[4], J. Marotti[3], J. Levy[5];

[1]Grafton High School, Yorktown, VA, [2]Basis Independent Silicon Valley, San Jose, CA, [3]Dartmouth Health, Lebanon, NH, [4]Dartmouth College, Hanover, NH, [5]Cedars Sinai Medical Center, Los Angeles, CA

Colorectal Cancer (CRC) accounts for nearly 10% of all cancer cases and is the second-leading cause of cancer-related deaths worldwide. The increased incidence of CRC in younger demographics underscores the need for improved screening and prognostication. These enhancements are crucial to augment staging practices which focus on accurate evaluation of local lymph node involvement and distant metastasis. Essential trace elements such as copper and iron within the tumor microenvironment (TME) present novel therapeutic strategies- e.g., copper in cell proliferation/signaling and iron in pro-tumorigenic pathways, amongst other multifaceted roles. Despite advancements in spatial imaging/sequencing for detailed mapping of elemental abundance and gene expression profiles at near-subcellular resolution, the understanding of metal signaling and transport pathways in tumors is limited. This gap highlights the need for sophisticated informatics software for data integration and analysis. We developed a computational workflow for spatial multimodal analysis of elements, genes, cell-types, and histological features, applied to a unique CRC case (pT3) as proof-of-concept. Elemental imaging at 5-micron resolution was performed using laser ablation inductively coupled plasma time-of-flight mass spectrometry (LA-ICPTOF-MS). The 10x Genomics Visium spatial transcriptomic (ST) CytAssist assay captured spatial variation in gene expression within 55-micron spots, with 40X H&E-stained whole slide imaging (Leica Aperio GT450). Cell type proportions within spots were determined through integration of single cell RNASeq. Regions within, around and away from tumor were annotated by a pathologist. ST and LA-ICPTOF-MS were integrated through co-registration software developed at Biomedical National Elemental Imaging Resource. Local Getis-Ord spatial statistics defined hotspots with high elemental concentration. Wilcoxon tests were used to perform differential expression analysis based on metal hotspots, followed by identification of associated biological pathways through Enrichr with Bonferroni adjustment. Preliminary findings revealed distinct trace element distributions in the TME. For instance, Copper was localized within tumor, correlating with pathways related to immune response and activation (overlap=10/89, $p<0.0001$). Iron was found concentrated at the proliferative front of the tumor, associated with the epithelial to mesenchymal transition pathway and extracellular matrix remodeling (overlap=25/291, $p<0.0001$), as well as with a mesenchymal phenotype ($W=11.7$, $p<0.0001$), identified through cell type deconvolution. Future work will expand on these findings across multiple tissue contexts as means to capture biological processes governing tumor metastasis, recurrence and survival for biomarker discovery and therapeutics development.

#4950 Applying fragmentomics profiles of plasma cell-free DNA for breast cancer detection.

Y. Liu[1], S. Gan[2], **H. Dong**[2], H. Tang[2], N. Wang[1], X. Gui[1], A. Zhu[1], R. Zhang[1], P. Du[2], S. Jia[2];
[1]Peking University Cancer Hospital & Institute, Shanghai, China, [2]Huidu (Shanghai) Medical Sciences, Ltd., Shanghai, China

The liquid biopsy approach focusing on DNA molecules supports the non-invasive diagnosis of breast cancer. Low-pass whole genome sequencing(lpWGS) for breast cancer detection has been validated for accuracy and cost-effectiveness, especially with copy number variant (CNV) analysis. However, detecting breast cancer with cell-free DNA (cfDNA) CNV was limited by tumor fraction. Utilizing cell-free DNA fragmentation characteristics for cancer detection has shown potential in plasma with high precision and applicability with low tumor fraction. In this study, 217 patients with breast cancer and 10 healthy individuals were enrolled. The cfDNA was extracted and performed using PredicineSCORE, a low-coverage whole genome sequencing assay to identify tumor-specific features. The cfDNA fragmentomics profiles including the coverage at specific regions, length and end-motif of fragment were implemented. We also investigated the copy number variation and the inferred tumor fraction which was adjusted by the Expectation-Maximum (EM) algorithm. Combining, an ensembled machine learning model was constructed for the classification of breast cancer and normal control. We observed a high correlation between tumor fraction and features. The absolute correlation coefficient scores between tumor fraction with the LYL1, MAF, FOXA1, and GRHL2 bonding sites' relative depth were over 0.82, 0.71,0.89,0.87. The insert size ratio of short reads and the CCCA end motif were over 0.77 and 0.72, respectively. We then diluted the tumor samples of tumor fraction at 0.1% to 50% by manually mixing reads from tumor samples into normal samples. By applying the XGBoost algorithm, the performance (F1 score > 0.95) showed a promising ability to distinguish tumors from normal samples. The limit of detection (LOD) was less than 1% which is more sensitive than previously proposed models. Those samples detected mutations with high through panel which can confirm the accuracy of the assay. Our results discovered that profiling the cell-free DNA fragment could facilitate the way of non-invasively detection of breast cancer with high precisions.

#4951 Integrative multi-omic machine learning model predicts neoadjuvant immunotherapy response using molecular data and deep learning-derived features from digital pathology.

L. V. M. Leek[1], V. Botha[1], V. A. Baxi[2], J. Teuwen[1], H. M. Horlings[1], S. D. Chasalow[2], J. van de Haar[1], C. U. Blank[1], L. F. A. Wessels[1], A. DebRoy[2], E. E. Voest[1];

[1]Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Bristol Myers Squibb, Princeton, NJ

Background: Over the past decade, there has been an exponential accumulation of digital patient data through molecular profiling and digitization of pathology slides. However, integrating this to advance diagnostics and cancer patient care remains a significant challenge. By integrating information from diverse modalities to capture aspects of the tumor microenvironment (TME) and immune landscape, we aim to improve patient stratification for immunotherapy.

Methods: We collected data from baseline biopsies from patients with palpable melanoma stage III (*n*=195) who received neoadjuvant immunotherapy followed by surgical resection of largest lymph node metastasis. The different modalities included clinical information, whole-genome sequencing (WGS), RNAseq, laboratory tests of blood, haematoxylin and eosin (H&E) images, and PDL1 immunohistochemistry (IHC) images. Cell detection and classification models were trained to identify tumor-infiltrating lymphocytes and tumor cells on H&E whole-slide images (WSI), deriving spatial features to quantitatively describe the tumor-immune interaction. Various biomarkers, including tumor mutational burden, BRAF status, expression of inflammatory gene signatures, systemic neutrophil-to-lymphocyte ratio, and tumor-lymphocyte spatial measures, were collectively integrated using machine learning models (random forest, elastic-net regularized logistic regression, CatBoost, support vector machine (SVM), and an ensemble classifier combined from the other models) within a 5x5-fold nested cross-validation scheme to predict pathologic response.

Results: Pathologic response to immunotherapy is associated with multi-omics biomarkers which were integrated using machine learning. The ensemble approach showed that when all modalities were combined a higher AUC (AUC=0.69, 0.61-0.77) could be achieved than for the clinical modality alone. RNA plus clinical emerged as the most predictive standalone modality with an AUC of 0.62 (0.50-0.75). The overall highest AUC was achieved using a SVM (AUC=0.72, 0.66-0.82).

Conclusions: Immunotherapy efficacy depends on diverse tumor microenvironment components, which were comprehensively assessed through data integration. A multi-omic predictive model holds promise for refining personalized and effective immunotherapy strategies.

#4953 A proposal to extend standardized organ mapping antibody panels (OMAPs) to integrate protein and RNA analysis in spatial biology.

Werner Muller[1], **Julia Femel**[1], Emily Neil[2], Dongju Park[2], Rebecca C. Hennessey[2], Eric C. DiBiasio[2], Michael DiBuono[2], Hanna Lafayette[2], Erica Lloyd[2], Hsinyi Lo[2], Alex Makrigiorgos[2], Sameh Soliman[2], Dominic Mangiardi[2], Paurush Praveen[1], Silvia Ruberg[1], Fabian Staubach[1], Ryan Hindman[2], Thomas Rothmann[1], Hansueli Meyer[2], Tanya Wantenaar[1], Jinling Wang[2], Robert Pinard[2], Andreas Bosio[1]

[1]R&D, Miltenyi Biotec, Bergisch Gladbach, Germany,[2]R&D, Miltenyi Biotec, Waltham, MA

The HubMap consortium has developed a new standard to report on normal histological samples using multicolor immunofluorescence imaging. An Organ Mapping Antibody Panel (OMAP) currently describes in a table the antibodies used, the cycle number assigned to a given reagent, and provides the rationale for using a particular antibody to better understand features of the tissue. This table is accompanied by antibody validation templates that show example images from the tissue described for the OMAP table. In addition, links to existing databases, gene symbols, the antibody features and colors are included. For each tissue, a further table called "Anatomical Structures, Cell Types, plus Biomarkers" (ASCT+B), which contains structures of the tissue, cell types in a given tissue structure, key RNA transcripts for a given cell type, and antibody stains as used in the OMAP table, is created. So far, this process has not been established for spatial multiomic datasets including protein and RNA detected on the same tissue section.

We have extended spatial biology methodology to combine cyclic RNA transcript detection with cyclic antibody-based protein detection using the MACSima Imaging Cyclic Staining (MICS) technology as well as H&E-staining on the same tissue section. For such datasets, the current OMAP data table needs to be extended by adding information on the RNA detection, cycle IDs and RNA validation templates, demonstrating the correct performance of a given RNA probe detection.

This poster will demonstrate a proposal to extend the OMAP table structure on an extended version of the “tonsil OMAP (OMAP-10)”, which was published on the Zenodo data repository page (https://zenodo.org/records/7875938). In addition, we will apply this extended OMAP to a colorectal cancer sample, to highlight the applicability and relevance of the OMAP structure for tumor tissue.

#4954 Improving microbial detection in cancer tissue samples with computational host depletion using the pangenome.

C. Guccione[1], L. Patel[1], D. McDonald[1], C. Martino[2], A. Gonzalez[1], G. D. Sepich-Poore[3], R. Knight[1], K. Curtius[1],
[1]University of California San Diego - UCSD, San Diego, CA, [2]Leaven Foods, San Diego, CA, [3]Northwestern University, Chicago, IL

Sensitive removal of host genetic information (i.e., host depletion) is a key first step towards accurate classification of potential microbial DNA sequences in low-biomass samples, such as human tumors. Inadequate filtration of human reads prior to microbial classification can cause false positives, biasing biological conclusions. Previous computational host depletion pipelines predominantly employed the human reference genome GRCh38 (hg38), which lacks genetic diversity of the human population and excludes substantial portions of the Y-chromosome. To address these deficiencies, we constructed a pipeline to maximally remove human reads that incorporates hg38, the first complete genome build T2T-CHM13v2.0 (T2T), and the 47 diploid genomes from the Human Pangenome Reference Consortium (HPRC) [1]. Reads passing maximal host depletion and quality control are considered sufficiently cleaned for downstream microbial analyses.

We first evaluated the specificity of our pipeline by simulating Illumina whole genome sequencing (WGS) data from 10 heldout HPRC humans, whose genomes were excluded from the host depletion pipeline. We found significant improvement in the median number of human reads remaining across successive host depletion methods (hg38, 0.05369%; hg38+T2T, 0.00535%; hg38+T2T+HPRC, 0.00093%). For sensitivity, we applied our pipeline to simulated data from 962 microbes in the FDA-ARGOS dataset and found minimal removal of true microbial reads (median 99.9390% reads retained). As a real world example, we evaluated our pipeline on 583 metastatic colorectal cancer tissue (WGS) samples from the Hartwig Medical Foundation (HMF) database (median 106X coverage)[2] and found successive decreases in median number of reads retained (hg38, 185,135; hg38+T2T, 92,951; hg38+T2T+HPRC, 10,314). Using Woltka for taxonomic classification against database RefSeq210, we assessed biological sex similarity across the HMF samples using Robust Aitchison PCA (RPCA). Notably, microbial data following hg38-only host depletion showed significant microbial differences between male and female-labeled samples ($p=0.00001$), which was biologically unexpected. However, our updated pipeline (hg38+T2T+HPRC) removed the false sex-based separation in the microbial data ($p=0.1837$).

Thus, utilization of diverse sets of complete human genomes for computational host depletion can mitigate artifactual bias, enabling more sensitive and specific host-microbe conclusions in cancer research.

#4955 An analytic pipeline of neoantigen selection for both MHC-I and MHC-II pathways.

Ko-Han Lee, Timothy Sears, Andrea Castro, Maurizio Zanetti, Hannah Carter

University of California San Diego, La Jolla, CA

Background: Accurate neoantigen selection is pivotal for assessing mutation burden and optimizing cancer vaccine formulation thereby playing a crucial role in cancer immunotherapy. The concurrent activation of CD4+ and CD8+ T cells engenders a robust immune response, which is key to effective treatment. However, currently analytic tools predominantly focus on the MHC-I pathway, typically relying on metrics such as gene expression level and MHC-binding affinity of mutated peptides. To address this gap, our study presents a comprehensive pipeline that encompasses both MHC-I and MHC-II pathways and integrates three critical dimensions of immune response: neoantigen abundance, presentation, and immunogenicity.

Methods: We estimated mutated peptide abundance by analyzing genomic allelic frequency, transcriptomic allelic frequency, and RNA expression level. Antigen presentation was assessed using the patient harmonic binding rank (PHBR, a composite binding score for all potential MHC-peptide pairs) and MHC diversity (the variety of MHC alleles involved in peptide binding), with additional consideration for the loss of heterozygosity of MHC-I alleles, potentially indicative of immune escape. For immunogenicity, we factored in agretopicity (comparison of MHC-binding affinity between mutated and wild-type peptides), foreignness (similarity to immunogenic foreign antigens), and dissimilarity (sequence disparity with self-peptides, reflecting T cell negative selection process).

Results: Implementing our pipeline on a dataset from Parkhurst et al. (2019), we analyzed immune reactivity in relation to 11,537 somatic mutations from 75 gastrointestinal cancer patients. Key metrics—RNA expression, transcriptomic allelic frequencies, PHBR, and MHC diversity—demonstrated significant correlations with both CD4+ and CD8+ activity ($p<0.05$). Notably, genomic allelic frequency was a significant factor in CD8+ reactivity, whereas agretopicity was crucial for CD4+ reactivity.

Conclusion: Our pipeline elucidates the necessity for implementing both MHC-I and MHC-II pathway analyses to effectively select neoantigen candidates for CD8+ and CD4+ T cells respectively. The study confirms that abundance and antigen presentation metrics are robust indicators of neoantigen immunogenicity, supporting their use as potential markers in crafting more effective cancer vaccines. The findings highlight the critical role of this dual-pathway selection approach in generating a comprehensive immune response through neoantigen vaccination.

#4956 A fast and efficient bioinformatics analysis workflow for processing reads from single-cell multiomics assays captured on a microwell-based platform.

R. Padmanabhan, B. Weichel, A. Radenbaugh, Y. Jiang, C. Weeks, T. McCarthy, Y. Kim, A. Berno, D. Jensen;
Becton Dickinson & Company, San Jose, CA

Here, we present a significant update: version 2.0 of our sequencing analysis, it is a comprehensive primary analysis workflow that is up to 7X faster and consumes 2X less disk space than the previous release. We used it to process a library with 20,000 human PBMCs sequenced to a depth of 1.2 billion reads in 2.5 hours of wall-clock time. The pipeline can be used with reads from single-cell whole transcriptome, targeted mRNA, surface antigens (AbSeq), TCR/BCR and Sample Tag libraries captured on the BD Rhapsody™ System platform. The major processing steps include Quality Filtering, Cell Barcode Identification, Read Alignment, Feature Assignment, UMI Error Correction, Identification of Putative Cells, Sample De-Multiplexing, Dimensionality Reduction for Visualization and VDJ Contig Assembly and Annotation. Output files and metrics are available in easy-to-digest formats, including an html report with dynamic visualization. Integrated outputs in Seurat and Scanpy formats combine expression matrices and all cell annotation metadata (e.g., predicted cell type, sample assignment, TCR/BCR sequence and gene segments). These pre-generated files are ready to load into popular single-cell analysis tools. The pipeline uses CWL as the workflow manager and makes use of custom code written in C++ and Python along with various open-source packages for data processing. The pipeline can also process reads from non-human species and includes built-in support for specifying and building custom reference genome indices. In support of high-throughput multiomic discovery studies enabled by the BD Rhapsody™ HT Xpress System, this pipeline has been tested with datasets containing more than 800,000 putative cells and 14.5 billion reads.

#4957 DNA quality control metrics in cryopreserved tissue outperform DNA extracted from FFPE tissue.

Jared James Barrott[1], Nikole O'Neal[2], Jeffrey Okojie[1], David Booker[3], Ken Dixon[3]

[1]Brigham Young University, Provo, UT,[2]Idaho State University, Pocatello, ID,[3]Specicare, Inc, Gainesville, GA

Personalized cancer care requires molecular characterization of neoplasms. While the research community accepts frozen tissues as the gold standard analyte for molecular assays, the source of tissue for testing of tumor tissue in clinical cancer care comes primarily from formalin-fixed, paraffin-embedded tissue (FFPE). Specific to genomics assays, numerous studies have shown significant discordance in genetic information obtained from FFPE samples and frozen samples. To explain the discordance between FFPE samples and cryopreserved samples, a head-to-head comparison between FFPE and cryopreserved tissues was performed to analyze the DNA yield, DNA purity and DNA quality in terms of DNA length. Additionally, short-read sequencing was performed on matched samples and quality control metrics were compared between the two sample types. Matched human tumors (n = 50) were processed either by formalin fixation and paraffin embedding or placed in cryovials containing cryopreservation medium. These cryovials were cooled slowly to -80°C and stored in liquid nitrogen. DNA was extracted using the same protocol for both tissue types with the exception that tissues embedded in paraffin were first dewaxed followed by a multistep rehydration protocol. Samples were weighed and calibrated for mass. After the column purification and elution, sample concentration and purity were measured. DNA fragment length was measured on a fragment microelectrophoresis analyzer. Graded amounts of tumor tissue were used to determine the lowest starting material needed to extract 200 ng of DNA. The average of all the samples reached the minimal threshold of 200 ng. However,74% of FFPE specimens failed to meet the minimum 40 ng/mg, whereas only 21% were below the threshold in the cryopreserved samples. In the cryopreserved group, the average DNA yield was 222.1 ng/mg, whereas 52.8 ng/mg was obtained from FFPE tissue. For DNA purity in cryopreserved tissues, the 260/280 ratio was 1.76, and in FFPE tissues the mean was 1.78. The DNA Quality Number (DQN) is a measurement of DNA fragment length and the percentage that exceeds the threshold of 300 bp. For FFPE, the DQN was 4.4 compared to a DQN of 9.8 for the cryopreserved samples. Setting a higher threshold of DNA length to 40,000 bp and measuring the area under the curve (AUC), it was observed that cryopreserved samples were 9-fold higher in fragments greater than 40,000 bp. Cryopreserved cancer tissue provides superior quality assurance measurements of DNA over FFFPE. Treatment decisions based on molecular results demand accuracy and validity. The pathology community should support efforts to cryopreserve cancer biospecimens in the clinical setting to provide valid molecular testing results. The automatic pickling of tumor specimens in formalin is no longer an acceptable default.

#4958 Optimizing transcriptome-based synthetic lethality predictions to improve precision oncology in breast cancer: BC-SELECT.

Y. Kim[1], M. Nagy[2], R. Pollard[3], N. U. Nair[1], L. Ray[1], E. Ruppin[1], P. S. Rajagopal[1];

[1]National Institutes of Health (NIH), Bethesda, MD, [2]Boston Children's Hospital, Boston, MA, [3]Maret High School, Washington DC, DC

Introduction: Precision oncology currently focuses on targeting specific mutations in cancer driver genes as predictors of treatment response. Clinical application of tumor transcriptomics is similarly limited to using specific RNA-based fusions for using therapy. SELECT (Lee et al, Cell 2021) is a computational tool that characterizes synthetic-lethal and/or synthetic-rescue genetic interactions of potential drug targets by using expression data, then uses these interactions to predict drug response in cancer patients. SELECT was initially developed using pan-cancer data from The Cancer Genome Atlas (TCGA), with limited evaluation on agents in breast cancer. We therefore sought to optimize SELECT for patients with breast cancer in an adaptation named BC-SELECT.
Methods: The standard SELECT comprises two steps: (1) Using an in-vitro screen, a patient tumor data screen, and a phylogenetic screen to build a library of clinically relevant candidate synthetic-lethal / synthetic-rescue gene partners; and (2) Generating scores based on gene partners' expression levels in a given sample. Scores are then used to predict the likelihood of response to a given therapy. For BC-SELECT, we modified this framework as follows: We incorporated the METABRIC dataset, comprising 1,989 samples and used only the breast cancer-specific TCGA dataset (1,075 samples) (which outperformed training on pan-cancer TCGA). To enhance the survival screening process, we include up to 5 clinical covariates for each training dataset, and prioritized gene pairs based on survival. Furthermore, we introduced new scoring controls to confirm prediction accuracy. All parameters have been standardized to optimize performance.
Results: BC-SELECT predicted treatment response in our initial cohort of breast cancer trials with immunotherapy or targeted therapy and expression data, where the same treatment / treatment target was present in more than one trial. BC-SELECT prediction was more accurate for immunotherapy and PARP inhibitors compared to trastuzumab. The AUC ranges for immunotherapy are between 0.67 and 0.83. For PARP inhibitors, the AUC ranges from 0.5 to 0.78, and for trastuzumab, it falls between 0.5 and 0.75.
Discussion: BC-SELECT advances transcriptome-based synthetic lethality prediction for translational use in patients with breast cancer. This tool demonstrates analytic and clinical validity to begin to improve therapy stratification and prioritization in patients.

#4959 Immunopipe: A comprehensive and flexible scRNA-seq and scTCR-seq data analysis pipeline.

P. Wang[1], H. Dong[2], Y. Yu[2], S. Zhang[2], Z. Sun[2], J.-P. A. Kocher[2], J. Wang[3], L. Yi[2], Y. Li[4];
[1]Mayo Clinic, Scottsdale, AZ, [2]Mayo Clinic, Rochester, MN, [3]The University of Hong Kong, Hong Kong, Hong Kong, [4]Mayo Clinic, Jacksonville, FL

Introduction: Single-cell RNA-sequencing (scRNA-seq) pairing with single-cell T-Cell-Receptor-sequencing (scTCR-seq) enables profiling of gene expression and TCR repertoires in individual T cells, elevating our understanding of T-cell-mediated immunity. Here, we present immunopipe, a comprehensive and flexible pipeline (https://github.com/pwwang/immunopipe) for analyzing the paired data. Besides the command-line tool, it offers a user-friendly web interface that allows users with varying programming expertise to configure, initiate, and monitor the pipeline. By combining extensive functionality with ease of use, immunopipe empowers users to unlock valuable insights from the data, which notably advances our understanding of immune response and fosters the development of innovative immunotherapies.

Results: *Immunopipe* is a comprehensive analytical pipeline for scRNA-seq and scTCR-seq data, offering various modules leveraging existing tools and novel methods to ensure data quality and enable downstream analytics. It performs quality control for scRNA-seq data, clusters cells based on gene expression to facilitate the identification of cell populations and provides insights into T-cell heterogeneity and functional diversity through T-cell selection and clustering. Enrichment analysis identifies markers and pathways for T-cell characterization. Our automated T-cell annotation tool annotates cell types accurately and hierarchically. For scTCR-seq data, *immunopipe* analyzes TCR clones, including clonality, diversity, gene usage, and repertoire overlap. Clone residency analysis examines the presence of clones across samples. Integrative analyses combine scRNA-seq and scTCR-seq data, providing a comprehensive understanding of the cellular landscape. *Immunopipe* incorporates diverse cell group information to analyze T-cell populations, which enables granular perspectives of the data for comprehensive insights. *Immunopipe* offers a flexible platform, allowing users to customize the analyses as needed. It supports both core and optional analyses through configuration, where users have control over the adjustable parameters. The pipeline relies on cell grouping information that can be referenced from metadata or modified to generate new variables for analysis and data filtering. *Immunopipe* can be executed locally or on scheduler platforms, and a docker image is provided for compatibility and simplified installation. It also offers a web interface that facilitates configuration, execution monitoring, and access to results.

Conclusion: *Immunopipe* is a flexible and user-friendly pipeline for analyzing scRNA-seq and scTCR-seq data. It empowers researchers to gain valuable insights that could enhance the understanding of immune responses and facilitate the development of innovative immunotherapies.

#4960 PIONEER initiative: Providing patient access to functional precision medicine.

Ken Dixon[1], Jared James Barrott[2], David Booker[3]

[1]Specicare, Inc, Gainesville, GA,[2]Brigham Young University, Provo, UT,[3]Specicare, Gainesville, GA

Eighty-five percent of patients receive medical care in cancer centers without National Cancer Institute (NCI) designation or significant ongoing research. The ability to access fresh tumor tissue for immediate functional testing is now available with appropriate logistical coordination. Cryopreservation of these tissues also allows testing to be done at a later date. We hypothesize that patient access to and ownership of each individual's tissues will facilitate personalized testing, thus bridging the chasm between research and the clinical cancer care for the individual patient. The PIONEER Initiative stands for Precision Insights On N-of-1 Ex vivo Effectiveness Research. In this Initiative we save cancerous tissue for any patient at any location, with subsequent cryopreservation and functional testing as needed and as able within an environment in which neither are standard. Our endpoint was to determine if this process serves to alter care for individual patients, and to what degree. The SpeciCare PIONEER Initiative: Precision Insights On N-of-1 Ex Vivo Effectiveness Research Based on Individual Tumor Ownership Trial (MYCT001) received human subjects IRB approval (Approval Number: 33943/1) from Quorum Review. The PIONEER Initiative is our lead clinical trial designed to provide the foundation for subsequent adaptive trials. Our mission with this trial was to demonstrate the utility of carrying out functional precision medicine in that cohort of patients who receive local cancer care at institutions that do not have significant research capabilities or are not NCI-designated cancer centers. Most cancer patients (~85%) are in this category. It is imperative to open the possibility of the best-in-class functional precision medicine testing to these patients. Core aspects of the PIONEER Initiative involve scaling up this process to approximately 200 patients, showing that our proof of concept in a more limited set of patients can ultimately scale to arbitrarily large numbers of patients. We see this capacity filling an important unmet need within the cancer community. The primary endpoint was the return of actionable information to positively impact care as assessed by the patient's clinical team and the patient. The underlying basic assumption of the PIONEER Initiative is that the ability to receive the best in cancer care should not come with restriction as to location, age, or medical condition. The PIONEER Initiative design facilitates inclusion of subjects across all these divides, thus providing beneficence to all participants. Among the 60 patients whose tumors had ex vivo drug testing performed, none of the data was included in the clinical decision making of the healthcare team. We conclude that physicians are not adequately prepared to use ex vivo drug testing data and the more likely acceptance of molecular characterization is primarily driven by genomic sequencing.

#4961 Large-scale CyTOF data modeling of leukemia patient cohorts.

G. Kong, T. Vu, E. Lind, **O. H. Nikolova**;
OHSU, Portland, OR

Introduction: Cytometry by Time-of-Flight (CyTOF) is a single-cell proteomic assay that uses antibody-lanthanide metal conjugates to tag surface or intracellular proteins, quantified via mass spectrometry. Compared to flow cytometry, CyTOF significantly reduces overlapping signals and increases the maximum protein features from 8 to 50. CyTOF data is commonly analyzed with the 'gating' workflow, which is the iterative process of plotting cells by two protein features to select discrete cell populations. While CyTOF can comprehensively profile nuanced cell types, gating does not scale well in the number of features. Biases in gating often arise from the forced discretization of cell populations, subjectivity of gate boundaries, and intrinsic sample-sample variation. Contemporary challenges in CyTOF data analysis can be attributed to data volume and gating bias, which can lead to oversight of disease-related cell populations while hindering reproducibility.

Methods: We developed a computational platform that enables the processing and analysis of large-scale CyTOF data. Our workflow includes modular components for data harmonization, normalization, transformation, batch correction, quality control, subsampling, and dimensionality reduction via UMAP of input sample files in Flow Cytometry Standard (FCS) format. Further, additional analytical modules are currently being integrated to deploy large-scale machine learning models for cell type identification. We use the results of these models as input for multi-scale analysis, where we aim to link single-cell CyTOF data with clinical outcomes. We test our workflow on previously published datasets and apply it to new leukemia patient cohorts of blood and bone marrow samples and a variety of marker panels.

Results: We tested our workflow on previously published datasets of 4.7 M peripheral blood mononuclear cells from healthy donors (N= 20) and T cells (N = 8). We observed that samples mixed well upon integration and separated into major cell types like monocytes, CD4+/CD8+ T-cells, naïve/mature B-cells, and natural killer T-cells. We then applied it to a bone marrow cohort of healthy donors (N = 10), where we observe good mixing of samples but less clear separation of cell types. Finally, we applied our workflow to 9.3 M cells from 51 chronic lymphocytic leukemia (CLL) patients and 4 healthy donors, using a lymphocytic marker panel. Here, we observed a clear resolution of a major clonal B-cell population and immune T-cells. We are in the process of applying it to Acute Myeloid Leukemia (AML) patient data with myeloid and immune marker panels.

Conclusions: We developed a computational platform that facilitates the simultaneous analysis of large-scale CyTOF data, both in the number of samples and cells per sample, a variety of marker panels, while minimizing gating biases common in traditional gating analysis.

CLINICAL RESEARCH: Artificial Intelligence and Data Science on Real World Data
Poster Session

#4965 Detection of status of cancer in radiology notes using artificial intelligence.
A. Arya, A. Niederhausern, N. S. P. Bahadur, N. J. Shah, C. Nichols, A. Chatterjee, J. Philip;
Memorial Sloan Kettering Cancer Center, New York City, NY

Introductory Statement: The goal is to use an AI model to replicate the human curator's response on cancer status in radiology notes of ~20,000 cancer patients.
Introduction: MSKCC currently has ~100,000 patients with genomic testing (IMPACT) and continues to accrue more. Clinicians use this genomic data for research but lack clinical structured data to analyze alongside the genomic data. We use a vendor called VASTA Global to manually curate unstructured paragraph text. Depending on the data model, we found that a patient's full cancer history can take up to 8 hours to curate. Therefore, we want to implement AI to automate the curation of this data to save time and cost.
We hope to achieve a faster curation process that allows us to accomplish more than 1 patient a day to catch up to the 100,000 MSK-IMPACT cohort. To decrease the average curation time per patient, we investigated the use of an NLP model to replicate manual curation of the PRISSMM™ ontology field for change in cancer status from radiology reports. Manual curation of radiology reports is time intensive due to curators understanding their cancer status and the volume of scans patients undergo.
Methods:A pre-trained Bidirectional Encoder Representations from Transformers (BERT) model is fine-tuned using training data using GPUs in IBM Cloud Pak for Data (CPD) platform. The hyperparameters were adjusted using accuracy and F_1 metric of evaluation data. Using one vs. rest approach the model is evaluated on held out test data with results shown in table 1.Table 1 includes class 1-5: Progressing/worsening/enlarging, stable/no change, improving/responding, not stated/indeterminate or mixed.
Summary: The weighted AUCROC ~ 0.97, F1 ~ 0.85 and accuracy ~ 93%. These metric scores improve by choosing notes with higher class probabilities only.
Conclusion: Due to the above 0.9 calculated accuracy this NLP model is successful in replicating the curated results of cancer status and the next steps will be to run this model on a new cohort of patients not yet curated.

Cancer Status Metrics

Class	Prevalence	Precision	Recall	F_1 Score	AUCROC	Accuracy
1	38.9%	88.7%	87.0%	87.9%	96.5%	90.7%
2	24.7%	89.9%	88.2%	89.1%	98.3%	94.6%
3	15.9%	87.6%	90.7%	89.1%	98.7%	96.5%
4	15.7%	77.0%	72.6%	74.7%	94.4%	92.3%
5	4.8%	68.1%	74.4%	71.1%	97.9%	97.1%
Weighted Average		85%	86%	85%	97%	93%

#4966 Machine learning and large language model approach to pancancer data elements.

A. Niederhausern[1], N. S. P. Bahadur[1], G. Wallace[2], G. E. Saadawi[2], **J. Philip**[1];
[1]Memorial Sloan Kettering Cancer Center, New York City, NY, [2]Realyze Intelligence Healthcare Solutions, Pittsburgh, PA

Introductory Statement: The goal is to use machine learning (ML) and large language model (LLM) to augment the manual curation of cancer data elements.
Introduction: Memorial Sloan Kettering Cancer Center (MSKCC) has ~100,000 cancer patients and counting with genomic testing. Clinicians use genomic data for research but lack clinical data to analyze together. We use a vendor, VASTA Global to hire curators to manually curate cancer patient's core clinical data elements (CCDE) within unstructured/paragraph text in electronic medical record (EMR) notes.
CCDE encompasses 122 data elements that include a patient's full cancer history that can take up to 1 working day to curate. We collaborated with the Realyze Intelligence Healthcare Solutions vendor to use their AI pipeline to generate the manual curated dataset.
Realyze generated the CCDE data elements such as histology, pathology site, MMR, TNM staging, ECOG, and KPS for a pilot lung cancer cohort of 150 patients. We manually validated the generated data for 74 out of 150 patients.
Methods:The Realyze platform uses a combination of LLMs, ML algorithms and standard terminologies to create a cancer patient model. These models are flexible enough to address the unique needs and challenges of a pan-cancer oncology model. By using standardized FHIR export, results were delivered to a data lake solution and written into a REDCap database to enable human review.
Summary: We manually assessed 74 patients. The NLP gave concordant values for MMR, KPS and TNM staging for 100% of the instances. For MMR these were all null values with false negative (FN) of 100% accuracy. Pathology site had 92.15% accuracy while histology has 97.5% accuracy.
Conclusion: Will work on refining pathology site and histology's ICDO3 list to increase the percentage of accuracy. Once Realyze refines their model for these data elements we will re-run it on a larger cohort of cancer patients and calculate the accuracy.

Accuracy Results

Clinical data elements	74 patients assessed: Accuracy %
ECOG	98.6
KPS	100
T (path)	100
T (clinical)	100
N (path)	100
N (clinical)	100
M (path)	100
M(clinical)	100
MMR	100
Histology (path)	97.5
Path site	92.15

#4967 Predicting progression-free survival (PFS) in first-line (1L) immune checkpoint inhibitor (ICI)-treated patients (pts) with advanced non-small cell lung cancer (aNSCLC): Machine learning (ML) application in real-world data.

D. K. Hathi[1], J. Harnett[1], N. Wu[1], Z. Xu[2], W. Pan[2], T. G. Hager[1], R. G. W. Quek[1], S. Aggarwal[1], Y. Kim[1], P. Rietschel[1], F. Seebach[1], F. Wang[2], Y. Li[1]; [1]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [2]Cornell University, New York, NY

Introduction: Anti-programmed cell death (ligand)-1 ICIs are the standard of care 1L treatment for pts with aNSCLC without actionable oncogenic driver mutations. Heterogeneity in ICI utilization and outcomes is observed in real-world pts. By leveraging ML in electronic health records (EHRs), we identified predictors influencing key clinical outcomes, and developed a nomogram to predict likelihood of median PFS in 1L ICI-treated aNSCLC pts for potential risk stratification for interventions.

Methods: 1L ICI-treated aNSCLC pts without *ALK*/*ROS1*/*KRAS*/*BRAF*/*EGFR* alterations were identified in a US oncology EHR database (ConcertAI; Jan 2015-Feb 2023). Survival ML models were trained on 112 clinical and demographic features with 5-fold nested cross-validation. The top predictors, determined by the best-performing ML model through SHapley Additive exPlanations and clinical judgement, were used to create a Cox proportional hazard (CPH) nomogram of median PFS. All models were evaluated using the concordance index (c-index). Patients were categorized as having high and low risk of progression/death at median PFS according to median risk predicted by the nomogram.

Results: The study cohort had 4668 pts (median PFS: 6.1 months; 3811 events). The CPH nomogram predicting 6-month PFS had a c-index of 0.60 with the top 10 predictors identified using the XGBoost model (c-index: 0.62). Nomogram predictors included increased number of metastases, ECOG PS, cough suppressant use, WBC counts, and NLR (**Table**). Median probability of 6-month PFS for low- and high-risk groups was 35.9% and 19.4%, respectively.

Conclusions: Future research should validate these findings and evaluate the opportunity to guide clinical practice to optimize outcomes in aNSCLC pts treated with 1L ICIs.

Summary of top 10 clinical predictors at baseline

	Mean HR (95% CI)	Max nomogram points
Total metastases, n	1.15 (1.11-1.19)	100
ECOG PS, ordinal	1.14 (1.10-1.19)	55
Basophils, %	0.81 (0.73-0.90)	52
Albumin, g/dL	0.81 (0.75-0.87)	46
Chloride, mmol/L	0.98 (0.97-0.99)	46
Cough suppressants/expectorants, n	1.08 (1.03-1.14)	42
NLR	1.03 (1.02-1.05)	33
WBC counts, 10^3 cells/mL	1.02 (1.01-1.03)	29
PD-L1 expression, %	1.00 (1.00-1.00)	28
Presence of liver metastases	1.26 (1.15-1.39)	24
ECOG PS, Eastern Cooperative Oncology Group performance status; NLR, neutrophils-to-lymphocytes ratio; PD-L1, programmed cell death-ligand 1; WBC, white blood cell.		

#4968 Discovery of cancer-associated factors in 293.5 million diagnosis records using statistical machine learning analysis.

M. Alam, N. Duesbery, D. Daniel Fort;
Ochsner Health System, New Orleans, LA

Cancer, a leading global public health issue, ranks as the second leading cause of death in the United States, with projections indicating 1,958,310 new cases and 609,820 deaths in 2023. Accurately quantifying specific pre-disease diagnosis factors associated with cancer, as well as predicting cancer through disease trajectories and imaging modalities, presents a complex and formidable challenge. A comprehensive temporal trajectory analysis of cancer diseases, using disease trajectories as an insight within large cohorts in the USA, has not yet been developed. Our analysis used a comprehensive EHR dataset stretching back to 1999, encompassing 293,501,891 records and involving 3,019,978 patients within Ochsner Health, a large integrated health system across the State of Louisiana. According to our investigation, those diagnosed at the ICD chapter level with diseases of the genitourinary system (genitourinary diseases, ICD-10 Chapter 14, relative risk (RR=1.65)) or endocrine nutritional and metabolic diseases (obesity, ICD-10 Chapter 4, RR=1.35) have an elevated risk of being diagnosed with cancer in the subsequent five years. The top four individual diagnosis ICD-10 codes associated with increased risk are N60 (Benign Mammary dysplasia, RR=7.80), M34 (Systemic sclerosis, RR=7.72), R43 (Disturbances of smell and taste, RR=6.93), and R92 (Abnormal and inconclusive findings on diagnostic imaging of the breast, RR=6.59). Furthermore, in our investigation of specific types of cancer risk across 17 cancer types (Breast, Skin, Prostate, Lung, Pancreatic, etc.), we observed that the most common diseases associated with breast and skin cancer involved immune mechanisms (RR=8.35 and 8.68), genitourinary issues (RR=4.13 and 2.48), obesity (RR=3.42 , 3.35), and cardiovascular conditions (ICD-10 Chapter 9, RR=1.73 and 2.19). For prostate cancer, associations were found with obesity (RR=3.50), human immunodeficiency virus (HIV, ICD-10 Chapter 1, RR=2.39). Across lung cancer, involvement with chronic viral hepatitis (ICD-10 Chapter 1, RR=4.00), cardiovascular issues (RR=3.52), genitourinary problems (RR=4.13), and obesity (RR=3.42) were indicated. Our comprehensive analysis has the potential to contribute to the early detection, diagnosis trajectories, and improved understanding of the pathological processes underlying cancer in patients worldwide.

#4969 Investigating digital pathology tumor microenvironment features for immunotherapy outcome in patients with advanced non-small cell lung cancer.

E. M. Ebot, K.-T. Chen, M. Biggs, D. I. Lin, J. A. Elvin, G. M. Frampton, J. J. Pao;
Foundation Medicine, Inc., Cambridge, MA

Introduction
The composition of the tumor microenvironment (TME) has been shown to influence response to immunotherapy (IO). In this study, we investigated digital pathology TME features of IO outcomes among patients with non-squamous, non-small cell lung cancer (NSCLC) within a real-world dataset.
Methods
From the nationwide de-identified Flatiron Health-Foundation Medicine NSCLC clinico-genomic database, a cohort of 50 *EGFR*/*ALK*-negative, non-squamous NSCLC patients treated with first-line pembrolizumab monotherapy (mono-IO) or pembrolizumab in combination with carboplatin/cisplatin and pemetrexed (chemo-IO) that had available whole slide images of H&E-stained tissue resection specimens were included. The de-identified data originated from approximately 280 US cancer clinics (~800 sites of care). AI-powered TME characterization models developed by PathAI (Boston, MA; commercially available as PathExplore™) were deployed on scanned H&E slides to extract a panel of cell- and tissue-level human interpretable features (HIFs). Cox proportional hazards regression was used to identify digital pathology features or HIFs associated with overall survival.
Results
17 HIFs were associated with better survival and 19 HIFs were associated with worse survival among patients treated with mono-IO ($p < 0.05$). Lymphocyte features were among the HIFs associated with favorable survival, including density of lymphocyte cells in cancer epithelium (hazard ratio (HR) per unit standard deviation (SD) = 0.46 [0.24, 0.88], p-value = 0.02) and proportion of lymphocyte cells relative to total immune cells in cancer epithelium (HR per unit SD = 0.61 [0.39, 0.95], p-value = 0.03). Cell-level features associated with worse survival included density of fibroblast cells in stroma (HR per unit SD = 1.51 [1.01, 2.25], p-value = 0.05). These associations remained after adjusting for tumor mutational burden (TMB) (N = 29 low, 21 high) and PD-L1 status (N = 0 negative, 1 low-positive, 17 high-positive, 32 unknown). Additionally, similar associations were not observed among patients treated with chemo-IO. High lymphocyte density was associated with better survival compared to low lymphocyte density in mono-IO treated patients (adjusted HR per unit SD = 0.36 [0.18, 0.74], p-value = 0.01) but not in chemo-IO treated patients (adjusted HR per unit SD = 1.10 [0.76, 1.60], p-value = 0.6).
Conclusion
These results indicate that the composition of TME assessed via digital pathology may have utility in identifying NSCLC patients that will respond to first-line immune checkpoint inhibitors beyond the established IO biomarkers.

#4970 Multi-modal machine learning approaches for predicting cancer type and Gleason grade leveraging public TCGA data.

C. Wohlfart[1], E. Klaiman[1], J. Witkowski[2], M. King[1], J. Gildenblat[3], O. Etz-Hadar[3], M. Ashtari[4], **A. Vladimirova**[5];
[1]Roche Information Solutions, Penzberg, Germany, [2]Roche Information Solutions, Warsaw, Poland, [3]DeePathology.ai, Ra'anana, Israel, [4]Roche, Toronto, ON, Canada, [5]Roche Information Solutions, Santa Clara, CA

Introduction: To better understand the complex and challenging nature of diseases such as cancer and for improved diagnosis, it may require the combination of multiple data modalities, such as histopathological images and omics data such as RNA-seq. By integrating these heterogeneous but complementary data, a multimodal approach unites both worlds and could achieve better synergistic results compared to using a single modality. The growing availability of large datasets such as The Cancer Genome Atlas (TCGA) with more than 10000 patients made it possible to combine different modalities to train machine learning algorithms which offers great potential to address challenging cancer related research. In this proof of concept initiative we use machine learning approaches within an open-source framework in order to leverage the potential of multimodality (Histopathology Whole Slide Images (WSI) and Genomics/RNA-seq) to build predictive AI models for cancer type and prostate Gleason score, and provide a potential to develop a quality control step.
Method: We used matched WSI and RNA-Seq profiles from TCGA, including 11093 samples and 30 cancer types to develop a pancancer classification model using both modalities. For prostate Gleason score prediction 401 patients were available. Both datasets were split into a train (70%) and test (30%) components. We used a late fusion approach where we combined the RNA-seq model (linear SVM) with the WSI model (Resnet18) by multiplying the probability scores of each single-modality model. Model performance was measured with the F1 metric.
Results: For cancer type prediction, the multimodality model achieved an F1 score of 0.95 on the test set. About 40% of the cancer types benefited from a synergistic effect by combining the two modalities. Cancer types and percent increase in F1 scores, respectively, that benefit most by combining modalities are: Cervical squamous cell carcinoma and endocervical adenocarcinoma (4.23%), Cholangiosarcoma (6.66%) and Uterine carcinosarcoma (4%). Interestingly, in other cancer types the combination did not result in improved predictive scores compared to a single modality model, e.g. in Rectum adenocarcinoma, Sarcoma or Stomach adenocarcinoma. For Prostate cancer grading, Gleason score prediction of patterns 3/4/5, combined multi modality model earned 0.73 F1 outperforming the single modality models.
Conclusion: By combining histopathology imaging and omics modalities we demonstrated synergistic effects in predictive power for both cancer-related research questions. We show improved predictive performance in 40% of the classified cancer types by taking both modalities. Imaging or omics modalities alone can be sufficient in some cases and their strengths are very problem-specific.

#4971 Integrating artificial intelligence and functional precision oncology for individualized cancer therapies.

F. Eguiarte-Solomon, R. Prendergast, B. Carapia, J. Rodriguez, K. Buck, D. Gorospe, E. Valencia, J. Lopez-Ramos, I. Gutierrez, R. Pippa, Y.-H. Chien, W. Andrews, L. Do, J. Sperry, **J. K. Nakashima**;
Certis Oncology Solutions, San Diego, CA

Precision oncology seeks to tailor cancer treatments to individual patients. Patient-derived xenografts (PDXs) have emerged as a promising platform for selecting efficacious, personalized therapies and developing new oncology drugs. Here, we present a workflow for selecting and validating treatments for patients with colorectal cancer (CRC) that integrates orthotopic PDX (O-PDX) models, molecular profiling, machine learning, and in vivo pharmacological validation. Of the nine tumor biopsies collected, seven were successfully developed into O-PDX models (78%) with a median time to establishment of 119 days. Models were molecularly profiled for gene expression and were serially passaged to perform orthotopic pharmacology studies to validate test agents selected by oncologists as well those suggested by CertisAI™, a novel ensemble of machine learning models for the prediction of drug response in human cancers. The correlation between CertisAI's predicted therapy responses and the actual observed tumor growth inhibition (TGI) was r = 0.7, encompassing 37 distinct treatments across studies from six patients. This research collectively illustrates that the integration of artificial intelligence with functional in vivo assays offers a powerful platform for precision oncology, enabling the identification and validation of tailored treatments for individual cancer patients.

#4972 Bioinformatic analysis of an annotated genomic database is clinically useful in a private cancer center.

C. E. Zuazo, S. Darabi, D. R. Braxton, P. Stafford, M. J. Demeure;
Hoag Family Cancer Institute, Newport Beach, CA

Background: Sequencing of patient solid tumor tissue is not a common service provided by community cancer centers. Our community cancer center has collected and sequenced over 5,000 tumor tissue samples from patients with various types of cancer. Since April 2019, we have conducted whole-exome and whole-transcriptome sequencing and stored this data in an internal genomics database. To analyze large patient cohorts, we must first optimize bioinformatic workflows on a smaller scale, which can then be applied to studies of larger populations. Previous studies have shown *BRAF* mutations are associated with an increased activation of the mitogen-activated protein kinase (MAPK) pathway. We analyzed transcriptomes of a cohort of 30 patients with thyroid cancer, 15 with V600E *BRAF* mutations and 15 wild-type for *BRAF*, for MAPK Pathway Activation Scores (MPAS). MPAS serves as a transcriptomic measure of the activation state of the MAPK pathway and has been shown to be a reliable prognostic biomarker of MAPK activity.
Method: We conducted a retrospective analysis of data from FFPE tumor samples sent to a commercial CLIA-certified laboratory from April 2019 to October 2023. Samples were profiled by whole exome, whole transcriptome sequencing and immunohistochemistry (IHC). Whole transcriptome sequencing (WTS) was executed using Illumina NovaSeq along with the Agilent SureSelect Human All Exon V7 bait panel. Resulting data were reported in transcripts per million (TPM) using the Salmon expression pipeline. MPAS was calculated using the expression profile of 10 MAPK-associated genes.
Results: There was no significant difference in *BRAF* expression levels or MAPK activation between patients with *BRAF* mutant and *BRAF* wild-type thyroid cancer (median MPAS scores: -0.09 vs. 0.11, p=0.9). This analysis workflow will be repeated with a larger patient population of patients with melanoma in the future; however, the consistency of expression between the groups, the rank-order, and the low variability per group suggest that expression changes related to this *BRAF* mutation may occur upstream or via differential regulation of an indirect pathway. Rank-order statistics and percentiles become more precise as data per tumor type grows.
Conclusions: Our community cancer center began building an internal genomics database including whole-exome and whole-transcriptome sequencing since 2019. This resource facilitates analysis of patient samples for tumor mutational burden, gene fusions, transcriptomic data, and other important characteristics which could reveal patterns or trends that inform cancer diagnosis and prognosis of other patients. Analysis of expression data for patients with advanced solid tumors who have mutations in genes of interest could inform on potential targeted treatments in the future. This study represents a single example of the potential of our internal clinically annotated genomics database.

#4973 Impact of technology on quality of thoracic multidisciplinary cancer conferences.

O. Ibekwe, C. Gaudioso, K. M. Attwood, S. Pokharel, C. L. Roche, C. E. Nwogu;
Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Complex cancer cases require discussion at Multidisciplinary Cancer Conferences (MCCs) to determine the best management. The study aim was to assess the impact of navify® tumor board solution (NTBS) technology on the quality of information presented, case discussions, and care plans at thoracic MCCs.

Methods: Between September 2020 and February 2022, using a before-after study design, we prospectively collected data through direct observation of thoracic MCCs at an academic cancer center. The NTBS technology was introduced in March of 2021. Additionally, we reviewed medical records to assess several factors including the rate of change in care plans as decided by the MCC, compliance of all care plans with national guidelines, and concordance of treatment received with MCC recommendations. Observational data was collected via a validated tool “Metric for the Observation of Decision-Making". We used SAS v9.4 (Cary, NC) for statistical analyses.

Results: We identified 151 and 166 thoracic cancer cases before and after implementation of NTBS, respectively. The overall quality of case presentation and discussion, represented by a mean composite score (the summation of individual variables scored on a 1-5 scale, poor to excellent), increased from 56.8 to 82.0 ($p<.001$). This improvement was also observed across multiple sub-components of the composite score including case history (3.4 vs 4.6), reason for presentation (3.2 vs 4.6), comorbidities/performance status/psychosocial information (2.8 vs 4.2), patient views (1.2 vs 3.3), radiology and pathology presentations (3.5 vs 4.8 and 3.2 vs 4.4, respectively), and contribution from surgical, medical, and radiation oncologists (3.9 vs 4.3, 3.3 vs 3.8, and 3.5 vs 3.8, respectively), as well as the moderation by the MCC chair (4.9 vs 5.0). All these results were statistically significant with $p<.001$. There was no statistically significant difference between the two cohorts in rate of change in care plans by the MCC, care plan compliance with national guidelines, and concordance of treatment received with MCC recommendations.

Conclusion: Technology improves the quality of information and discussion at tumor boards. However, this study did not demonstrate an impact on compliance with practice guidelines. Practitioners should explore the available tumor board technology platforms to optimize the conduct of MCCs in their respective institutions.

#4974 Development of an ovarian cancer diagnosis score using electronic health records.

M. Phung[1], K. McLean[2], G. E. Hanley[3], C. Pearce[1];

[1]University of Michigan, Ann Arbor, MI, [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [3]University of British Columbia, Vancouver, BC, Canada

Background: Diagnosis of invasive epithelial ovarian, fallopian tube, and primary peritoneal cancers (hereafter referred to as ovarian cancer) is often delayed, worsening both survival and quality of life for ovarian cancer patients. Diagnosis is delayed in ovarian cancer both because there is no effective screening method and because the symptoms commonly associated with ovarian cancer (i.e., abdominal/pelvic pain, bloating, loss of appetite, urinary symptoms) are non-specific to the disease. It would be beneficial to develop a flag in the electronic health record (EHR) when a patient's healthcare utilization indicates further investigation for possible ovarian cancer is warranted. Thus, we used EHR data to develop a diagnosis score that identifies people who should be further assessed for potential ovarian cancer.

Methods: EHR data from 211,123 female patients, including 135 ovarian cancer patients, at the University of Michigan Medical System during 2012-2023 were analyzed. Time-varying Cox proportional hazard models were fit to identify the association between ovarian cancer and the diagnostic codes recorded for healthcare visits in the EHR, including the temporal sequence of the diagnostic codes. The beta coefficients for the diagnosis codes from the Cox models were summed to create a weighted diagnosis score for each patient. The weighted diagnosis score was tested for association with ovarian cancer in the same population.

Results: A total of 79 diagnostic codes were statistically significantly associated with ovarian cancer after applying a Bonferroni correction ($p<9x10^{-5}$). The temporal sequence of the diagnoses was not associated with ovarian cancer. There were 11 pairs of diagnosis codes that were correlated (correlation coefficient ≥0.25); the diagnosis code with the higher p-value was excluded from further consideration. The remaining 68 codes were used to construct the diagnosis score. There was a statistically significant trend of increasing rate of ovarian cancer per quartile of the diagnosis score (hazard ratio=3.75, 95% confidence interval 3.50-4.03).

Conclusion: A score for ovarian cancer diagnosis was developed based on 68 diagnostic codes in the EHR. The next step is to validate the diagnosis score in an external dataset. This validation is underway using administrative data from British Columbia, Canada.

#4975 Stretching the boundary of Oncotype DX testing.

Z. Al-Saheli, V. Dabak;
Henry Ford Health System, Detroit, MI

Background: The predictive value of Oncotype DX in early-stage breast cancer had been well established. Strongest data support the use of chemotherapy for Recurrence Score (RS) > 30, with 25-30 deriving some benefit. Those with intermediate RS 16-25 are thought to have a small benefit from chemotherapy, especially premenopausal patients. Tumor size >5 cm is viewed as a high-risk feature regardless of RS. Our goal is to investigate how patients with uncertainty regarding their anticipated recurrence risk were managed at our institution.
Methods: We conducted a retrospective analysis to explore the management of non-metastatic HER-2 negative hormone sensitive breast cancer patients diagnosed between 01/2018 &12/2020 stratifying them into the following study groups of interest: premenopausal (age <50), RS 16-25 compared to RS 26-30 and tumor size >5cm. Patients were compared based on whether they received adjuvant chemotherapy or not. The primary endpoint was the rate of local recurrence.
Results: The results of our analysis are illustrated in the table. Studying the premenopausal group, 91.3% had RS < 16; yet 35% of them received chemotherapy. Patients with RS > 25 represented 3.2% of the premenopausal group, 12.5% of which did not receive chemotherapy. The six recurrences in the premenopausal group were all from the RS <16 subgroup. Comparing the RS 26-30 to the RS 16-25 group, patients were on average older with tumors being on average smaller, yet more patients were treated with chemotherapy; and there were no recurrences noted in both subgroups. Finally, in the tumor size >5 cm group, 91.4% had RS <16, almost all were premenopausal with many patients being lymph node negative, yet more than half received chemotherapy.
Conclusions: In our study we demonstrate that in certain subgroups of early-stage breast cancer there is inconsistency in clinical practice when prescribing chemotherapy to patients factoring in their Oncotype DX scores. There is need for larger trials to guide clinicians on using Oncotype DX in those subgroups of patients.

Characteristics, Treatment Pattern and Outcomes of Patient Groups of Interest

Characteristics	**Premenopausal (N=506)**	**RS 16-25 (N=28)**	**RS 26-30 (N=36)**	**Tumor Size >5 cm (N=47)**
Age, Mean (SD)	42.65 (5.46)	44.71 (3.85)	63.56 (9.65)	42.02 (6.14)
Age, Range	19 - 49	36 - 49	45 - 79	28 - 57
Mean Tumor Size, mm (SD)	29.66 (52.21)	29.57 (33.88)	16.88 (11.19)	83.61 (37.52)
Lymph Nodes Positive, n (%)	91 (18.0%)	2 (7.1%)	0 (0.0%)	16 (34.0%)
Received Chemotherapy, n (%)	184 (36.4%)	7 (25.0%)	13 (36.1%)	25 (53.2%)
Local Recurrence, n (%)	6 (1.2%)	0 (0.0%)	0 (0.0%)	0 (0.0%)
Mean Follow- Up, months (SD)	19.28 (8.20)	19.39 (7.07)	21.21 (11.04)	19.26 (8.93)

#4976 The impact of obesity on survival in epithelial gynecological tumors.

A. Badran[1], M. Elshenawy[1], W. Fallatah[2], A. K. Hinkston[2], S. S. Ali[2], M. Ali Omar[2], A. M. Alaklabi[2], H. M. Abdalla[2], T. Z. Arabi[2], **B. N. Sabbah**[2], H. Alhusaini[1]; [1]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, [2]Alfaisal University, Riyadh, Saudi Arabia

Background: The impact of obesity on the survival of patients with epithelial gynecological tumors is not yet clear. We aim to elucidate the impact of body mass index (BMI) on epithelial gynecological tumors in a large tertiary center at Saudi Arabia.
Methods: We retrospectively reviewed the medical files of all patients with pathologically confirmed epithelial gynecological tumors at our center. Then, we assessed the difference in overall survival (OS) according to primary tumor location, BMI, stage at presentation, and performance status (PS) at presentation using log-rank tests.
Results: 400 patients were included in the analysis. The mean age at diagnosis was 56.1±13 years. 242 (60.5%) patients were diagnosed with uterine carcinomas, 137 (34.3%) with ovarian carcinomas, and 21 (5.3%) with cervical carcinomas. 278 (69.5%) patients were obese at presentation, 74 (18.5%) were overweight, 43 (10.8%) were within normal range, and 7 (1.8%) were underweight. The PS at presentation was 0, 1, 2, 3, and 4 in 351 (87.8%), 17 (4.3%), 10 (2.5%), 16 (4%), and 6 (1.5%) patients, respectively. Cervical cancer was associated with long OS, while ovarian cancers demonstrated poor prognosis ($p=0.0159$). There was no difference in OS between different BMI groups ($p=0.072$). Patients with stage 4 cancers had significantly shorter OS ($p<0.0001$). Patients with PS 4 at presentation was associated with the worst prognosis ($p<0.0001$).
Interpretation: Shorter OS was associated with ovarian carcinomas, advanced staging, and poor PS at presentation. BMI classification had no impact on OS. Further studies are needed to confirm our findings.

#4977 The prevalence of key oncogenic driver mutations in stage I-III non-small cell lung cancer: Results from the AACR GENIE BPC dataset.

K. Zu, J. Ma, C. Chen, C. Pierce;
Merck & Co., Inc., Rahway, NJ

Background: While there is growing interest in targeted therapy for non-small cell lung cancer (NSCLC) in perioperative settings, data on key oncogenic driver mutations is limited in early-stage NSCLC. This real-world database study aims to evaluate the prevalence of select genomic alterations in stage I-III NSCLC.
Methods: From the American Association for Cancer Research (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) Biopharma Collaborative (BPC) V2.1-consortium dataset, we included adult patients with a confirmed diagnosis of NSCLC who had genomic testing using stage I-III NSCLC tissue samples. Descriptive statistics were used to summarize baseline characteristics and the prevalence of select genomic alterations.
Results: A total of 465 patients were included in this study, of whom 61% were female, 85% were white, 19% were never smokers, and 77% had adenocarcinoma. Less than 2% of the study population had BRAF V600E, HER2 activating mutations, HER2 amplification, MET amplification, HER3 amplification, RET fusion, ALK fusion, or ROS1 fusion. Among genomic alterations with a prevalence of 2% or higher, such as EGFR sensitizing mutations, KRAS G12C, MET exon 14 skipping, STK11, KEAP1, and TP53, some variations in prevalence were observed across baseline patient and disease characteristics such as race, smoking status, and histology (Table 1).
Conclusion: The prevalence of key oncogenic drivers and its relationship to select baseline disease characteristics among patients with early-stage NSCLC are similar to those of advanced NSCLC observed in other real-world clinico-genomic databases.

Table 1. Prevalence of Select Genomic Alterations in Stage I-III NSCLC (N=465)

	Prevalence of Positive Biomarker Status (%)					
	EGFR	KRAS G12C	MET Exon 14 Skipping	STK11*	KEAP1*	TP53
Overall	17.6	12.7	4.5	16.0	11.0	52.7
Gender						
Male	7.1	9.3	5.5	18.5	18.5	59.6
Female	24.5	15.9	3.9	14.3	6.3	48.2
Race						
White	15.6	14.1	4.5	16.5	12.0	53.7
Black	15.0	5.0	5.0	22.2	11.1	60.0
Asian	44.0	4.0	8.0	8.3	4.2	44.0
Smoking Status						
Never smoker	41.4	1.2	6.9	4.7	1.2	36.8
Former smoker	13.7	16.0	4.6	17.4	12.9	52.4
Current smoker	5.7	12.9	1.4	23.9	15.4	72.9
Histology						
Adenocarcinoma	20.1	14.3	4.6	18.1	10.4	46.0
Squamous cell carcinoma	0	2.9	4.4	4.6	14.1	86.8
*The numbers of patients tested for STK11 and KEAP1 were 457 and 445, respectively.						

#4978 Genomic characterization of metastatic pancreatic cancer according to tumor sample sites.

S. Y. Goksu[1], M. Ozer[2], B. Bacik Goksu[3], N. N. Sanford[4], A. Jones[4], N. Verma[4], S. Kazmi[4];

[1]West Suburban Medical Center, Oak Park, IL, [2]Dana Farber Cancer Institute, Harvard Medical School, Boston, MA, [3]University of Illinois at Chicago, Chicago, IL, [4]UT Southwestern Medical Center, Dallas, TX

Background: Our research aimed to evaluate and compare the genetic variations in the primary and metastatic sites of patients with metastatic pancreatic cancer.

Methods: In this study, we selected individuals with metastatic pancreatic cancer from the data provided by the American Association for Cancer Research Project GENIE (version 14.1). The comparison of genetic mutations between primary and metastatic tumor sites was conducted using the Fisher exact test, augmented with the Benjamini-Hochberg adjustment technique.

Results: In a study of 3,108 patients with metastatic pancreatic cancer, 38.9% had metastatic site tumor samples, while 61.1% had samples from the primary tumor. The most frequent mutations were KRAS (89.4%), TP53 (72.9%), SMAD4 (21.2%), and CDKN2A (17.4%). Metastatic samples showed higher rates of CDKN2A, CDKN2B, and MTAP mutations compared to primary site samples (40.1% vs. 29.1%; 20.3% vs. 10.4%; and 20.8% vs. 8.9%, respectively, all with $p<0.001$ and $q<0.001$). In patients with young-onset pancreatic cancer (younger than 50 years), there was no notable difference in gene mutations between the two sample groups.

Conclusion: Our findings corroborate the notion that identifying the precise genes that contribute to the development of metastatic pancreatic cancer is vital for gaining a more comprehensive understanding of the biological mechanisms. Moreover, genomic profiling could be a key in pinpointing potential biomarkers for diagnosis and therapy.

#4979 Genomic profiling of early-onset metastatic colorectal cancer based on tumor sample location.

M. Ozer[1], S. Y. Goksu[2], B. Bacik Goksu[3], N. N. Sanford[4], A. Jones[4], N. Verma[4], S. Kazmi[4];
[1]Dana Farber Cancer Institute, Harvard Medical School, Boston, MA, [2]West Suburban Medical Center, Oak Park, IL, [3]University of Illinois at Chicago, Chicago, IL, [4]UT Southwestern Medical Center, Dallas, TX

Background: Here, we describe analyses towards identifying and comparing genetic variations between the primary and metastatic sites in early-onset metastatic colorectal cancer patients.
Methods: We selected patients with early-onset metastatic colorectal cancer (under 50 years old) using data from the American Association for Cancer Research Project GENIE (version 14.1). We used the Fisher exact test to compare genetic mutations between the primary tumor and metastatic sites, complemented by the Benjamini-Hochberg adjustment method.
Results: In a total of 1,791 patients with early-onset metastatic colorectal cancer, 27.1% had tumor samples from metastatic sites, while the majority, 72.9%, were from the primary tumor location. The most common mutations found were in the TP53 gene (77.6%), followed by APC (76.0%), KRAS (42.4%), and PIK3CA (19.0%). Notably, the metastatic samples had a significantly higher occurrence of SMAD4 mutations compared to their primary site counterparts (20.8% vs. 14.0%, $p<0.001$, $q<0.001$). Conversely, the primary tumor samples exhibited higher frequencies of TCF7L2 and ARID1A mutations (16.9% vs. 10.6%, $p<0.001$, $q<0.001$, and 13.0% vs. 6.4%, $p<0.001$, $q<0.001$, respectively).
Conclusion: Determining the specific genes responsible for the formation of metastatic tumors is crucial for a deeper understanding of the disease's underlying biology in early-onset metastatic colorectal cancer. Such genomic details are crucial to pave the way to the discovery of potential biomarkers for diagnosis and the development of new cancer therapeutics.

#4980 Genomic and clinical characteristics of advanced pancreatobiliary cancer, stratified by KRAS mutation status.

H. Miyashita, P. S. Shah, G. A. Brooks;
Dartmouth Cancer Center, Lebanon, NH

Mutations in KRAS are common in pancreatobiliary cancer, occurring in 90% of advanced pancreatic ductal adenocarcinomas (PDAC) and 20% of advanced cholangiocarcinomas (CCA). We analyzed clinico-genomic databases to evaluate the hypothesis that KRAS mutation status defines subsets of PDAC and CCA with similar genomic characteristics and clinical behavior. Using the genomic data of PDAC and CCA from AACR Project GENIE Cohort version 14.0-public, we analyzed the genomic landscape of four cohorts of pancreatobiliary cancer: KRAS mutated PDAC, KRAS wild-type PDAC, KRAS mutated CCA, and KRAS wild-type CCA. Excluding KRAS mutations, there were 53 gene alterations observed in ≥2.5% of cases in at least one of the four cohorts. The three most common gene alterations in each cohort were; TP53, SMAD4, and CDKN2A mutations (KRAS mutated PDAC), TP53, ARID1A, and SMAD4 mutations (KRAS wild-type PDAC), TP53 mutation, CDKN2A deletion and SMAD4 mutation (KRAS mutated CCA), and TP53, ARID1D and IDH1 mutations. (KRAS wild-type CCA) The similarity of gene alteration patterns was evaluated by principal component analysis (PCA) 3D plot and calculation of average Euclidean distance. The PCA plot suggested heterogeneous genomic profiles in KRAS wild-type CCA in contrast to relatively monotonous profiles in KRAS mutated PDAC. The average Euclidean distance between KRAS mutated CCA and KRAS wild-type CCA was significantly longer than that between KRAS mutated CCA and KRAS mutated PDAC (2.00 vs. 1.89, $p < 0.001$), suggesting that KRAS mutated CCA is more genomically related to KRAS mutated PDAC than KRAS wild-type CCA. The average Euclidean distance between KRAS mutated PDAC and KRAS wild-type PDAC was significantly shorter than that between KRAS wild-type CCA and KRAS wild-type PDAC. To compare the clinical characteristics of the four cohorts, we evaluated the data of patients with stage IV pancreatobiliary cancer, using cBioPortal. The number of cases in each cohort was 1544 (KRAS mutated PDAC), 121 (KRAS wild-type PDAC), 91 (KRAS mutated CCA), and 459 (KRAS wild-type CCA). Median overall survival (OS) was 14.7, 21.5, 10.7, and 15.4 months, respectively. Compared to KRAS wild-type CCA, KRAS mutated CCA had a significantly shorter OS (hazard ratio [HR] = 1.45, 95% confidence interval [CI] = 1.12 - 1.89). The OS of KRAS mutated CCA was shorter than KRAS mutated PDAC (HR 1.32, 95% CI 1.03 - 1.68). KRAS wild-type PDAC had a significantly longer OS compared to KRAS mutated PDAC. (HR 0.72, 95% CI 0.57 - 0.92) In conclusion, KRAS mutated CCA has a poor OS and a genomic landscape distinct from KRAS wild-type CCA; it is genomically more similar to KRAS mutated PDAC. KRAS wild-type PDAC has a better OS than KRAS mutated PDAC, though it was not genomically similar to KRAS wild-type CCA. Therapeutic approaches stratified by KRAS mutation status should be considered for pancreaticobiliary cancers.

CLINICAL RESEARCH: Chemotherapy, Radiation, and Vaccine Mediated Immunity
Poster Session

#4984 TCR-CD3 bispecifics kill tumor cells in a caspase- and gasdermin-dependent manner by inducing multiple cell death pathways.

S. Varadarajan, A. Raczka, S. Khakoo, L. Collins, A. Benlahrech;
Immunocore Ltd., Abingdon, United Kingdom

Background:ImmTAC® (immune-mobilizing monoclonal T cell receptor against cancer) molecules are soluble bi-specific TCR molecules that redirect T lymphocytes to kill tumor cells. Tebentafusp, which targets the melanocyte lineage gp100, is the first ImmTAC molecule approved for the treatment of HLA-A*02:01 adult patients with metastatic uveal melanoma.[1] While the roles of Granzyme B and Perforin in the anti-tumor activity of CD3 T cell engagers are well described, the contribution of other apoptotic pathways, e.g. pyroptosis (inflammatory apoptosis), is poorly understood. For this reason, we explored apoptosis mechanisms induced by ImmTACs *in vitro* and their relevance to the anti-tumor activity of tebentafusp in a Phase 2 clinical trial.
Methods: Cell lines derived from different malignancies, MP41 (uveal melanoma), MEL624 (cutaneous melanoma) and NCI-H1755 (non-small cell lung carcinoma) were co-cultured with PBMC and ImmTAC molecules for defined time periods, followed by cytolysis measurements (xCelligence) and protein expression analysis (western blotting). Relevant cell death pathways were targeted by genetic (CRISPR knockout) or pharmacological inhibition. Translational relevance of *in vitro* experiments was assessed using RNAseq of tumor biopsies at baseline (N=70) and matched on-treatment at 16 days post treatment [N=35] or at progression [N=14]) from a Phase 2 trial of tebentafusp in HLA-A*02:01^{+} mUM patients (NCT02570308). Clinical data cut-off: 17-Oct-2022.
Results: ImmTAC-mediated tumor killing *in vitro* occurred in a caspase-dependent manner and accompanied a profound induction of several apoptotic, necroptotic and pyroptotic proteins, such as GZMB, Caspases 8 and 7, RIPK3, MLKL and GSDMD in several cell lines. In NCI-H1755 cells, genetic knockout of GSDMD significantly diminished ImmTAC-mediated cytolysis (92% reduction), thereby confirming the involvement of pyroptosis in ImmTAC-mediated tumor killing in these cells. In agreement, RNAseq analysis of tumor biopsies from mUM patients after 3 doses of tebentafusp revealed enhanced expression of genes involved in different cell death pathways, including Caspase 7, RIPK3, MLKL and GSDMD (fold changes of 1.2-2). In addition, patients exhibiting above-median tumor expression of GSDMD at progression had longer overall survival (Hazard ratio = 0.074 95% C.I. 0.01-0.64).
Conclusions: ImmTAC redirection of T cells resulted in a caspase-dependent, pyroptotic cell death of tumor cell lines and enhanced gene expression of necroptotic and pyroptotic pathways in tumor biopsies. GSDMD, induced during ImmTAC-mediated cytolysis, also correlated with better overall survival in tebentafusp-treated patients. Induction of multiple cell death pathways, particularly pyroptosis, helps to explain the anti-tumor activity of tebentafusp.

#4985 Pivotal roles for cancer cell-intrinsic mPGES-1 and autocrine EP4 signaling in suppressing anti-tumor immunity.

N. Markosyan[1], I. Kim[1], C. Arora[2], N. Cheng[1], E. Schechter[1], J. W. Tobias[1], B. Z. Stanger[1], R. H. Vonderheide[1];
[1]University of Pennsylvania, Philadelphia, PA, [2]University of Pittsburg, Pittsburg, PA

Tumor cell-derived prostaglandin E2 (PGE_2) is a tumor cell-intrinsic factor that supports immunosuppression in the tumor microenvironment (TME). Using a genetically engineered mouse model of pancreatic ductal adenocarcinoma, we demonstrate that deleting the terminal PGE_2 synthesis enzyme or disrupting autocrine PGE_2 signaling through cognate EP4 receptors on tumor cells reverses the T cell-low, myeloid cell-rich TME to activate T cell immunity and suppress tumor growth. Knockout (KO) of *Ptges* (the gene encoding PGE_2 synthesis enzyme mPGES-1) or the EP4 receptor gene (*Ptger4*) in KPCY (*Kras*^{G12D}/*P53*^{R172H}/*Yfp*/*Cre*^{Pd}) pancreatic tumor cells abolished growth of implanted tumors in a T cell-dependent manner (KO vs control $p<0.0001$ for both). Blockade of the EP4 receptor in combination with immunotherapy, but not immunotherapy alone, induced complete tumor regressions and immunological memory. Mechanistically, *Ptges* and Ptger4 KO tumor cells exhibited altered T and myeloid cell attractant chemokines, became more susceptible to TNF-α killing, and exhibited reduced adenosine synthesis. In hosts treated with an adenosine deaminase inhibitor, *Ptger4* KO tumor cells accumulated adenosine and gave rise to tumors. These studies reveal an unexpected role for autocrine mPGES1-PGE_2-EP4 signaling axis in pancreatic cancer cells, nominating mPGES-1 inhibition and EP4 blockade as immune-sensitizing approaches in cancer therapy.

#4986 Single-cell multimodal characterization of ovarian cancer microenvironment under neoadjuvant niraparib treatment informs an effective therapeutic strategy of suppressing HRD-dependent eTreg hyper-expansion.

Y. Luo[1], Y. Xia[2], D. Liu[2], X. Li[3], H. Li[2], Y. Zhao[4], D. Ma[2], Y. Fang[2], H. Liang[1], Q. Gao[2];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Tongji Hospital, Tongji Medical College, Wuhan, China, [3]Central Hospital of Wuhan, Tongji Medical College, Wuhan, China, [4]Precision Scientific (Beijing) Co., Ltd., Beijing, China

Homologous recombination deficiency (HRD) is a widespread hallmark in cancer, rendering tumors susceptible to PARP inhibition. Despite this well-established tumor-intrinsic vulnerability, the effects of HRD and related therapies on the tumor microenvironment (TME) remain poorly understood. In this study, utilizing single-cell RNA and T cell receptor profiling (scRNA/TCR-seq), we characterized 79 high-grade serous ovarian cancer (HGSOC) samples, both pre- and post-treatment, from 46 patients treated with neoadjuvant niraparib or chemotherapy in a phase II clinical trial (NCT04507841). This effort established the most comprehensive HGSOC TME atlas to date, encompassing over 700,000 cells. By integrating multiplex immunofluorescence imaging, flow cytometry, and bulk TCR-seq data from additional tumors and matched peripheral blood samples, we systematically assessed HRD-induced and treatment-perturbed dynamics of tumor-infiltrating and circulating immune cells. Surprisingly, among over 120 cell states across 10 cell types, effector regulatory CD4$^{\pm}$ T cells (eTreg) exhibited the strongest enrichment in treatment-naïve HRD tumors and a marked treatment-induced reduction. Further analyses of transcriptional states and clonal kinetics revealed HRD-driven functional coordination between eTregs and exhausted CD8$^{\pm}$ T cells (Tex), both displaying uniquely heightened tumor reactivity signatures and clonal co-expansions. The intra-population heterogeneity analysis of Tregs and Texs further demonstrated an effectiveness gradient, wherein the terminal subsets had a greater presence in HRD and were reversed by both niraparib and chemotherapy treatments. Delineating the clonal evolution of Tregs and Texs, we identified their notable crosstalk with other tumor-infiltrating T cell populations while remaining remarkably isolated from the peripheral blood repertoire, in line with their terminally differentiated status. Furthermore, we observed widespread, chronic activation of interferon signaling across TME components, downstream of HRD. This orchestrated CD4$^{\pm}$ T cell anergy induction into Tregs, mainly through direct engagement by cancer cells that upregulated MHC-II molecules but lacked essential co-stimulatory ligands. Finally, we experimentally validated a therapeutic strategy to conjunctively and effectively break down these factors in HGSOC by combining PARP inhibition and eTreg deletion through a humanized therapeutic anti-CCR8 antibody in multiple syngeneic HGSOC mouse models. Our study unravels a key immunoregulatory role of eTregs in the HGSOC TME amplified by HRD. These findings underscore the underappreciated value of eTreg-focused therapeutics as novel immunotherapies for HGSOC and other genomically unstable cancers.

#4987 TREM2 is a radiation-induced target for immunomodulation of tumor-associated macrophages in the prostate cancer tumor microenvironment.

J. A. Villa-Pulgarin[1], U. Chan[1], F. Khani[1], F. Socciarelli[1], J. Wu[1], R. Carelli[2], J. Kraynak[1], S. C. Formenti[1], L. Marchionni[3], M. Loda[1], H. Nagar[1], **A. E. Marciscano**[4], C. E. Barbieri[1];

[1]Weill Cornell Medical College, New York, NY, [2]Replit, New York, NY, [3]Weill Cornell Medical College, Boston, MA, [4]Harvard Medical School/Massachusetts General Hospital, Boston, MA

Background: The prostate cancer (PCa) tumor microenvironment (TME) is characterized by a predominance of myeloid cells that may have a key role in immunosuppression and disease progression. Stereotactic Body Radiation Therapy (SBRT) is utilized for treatment of localized and metastatic PCa and promotes inflammatory remodeling of the TME. We analyzed human PCa specimens at acute post-SBRT timepoints to identify radiation-induced targets in the PCa TME and used *in vitro* and *in vivo* models to test and validate our findings.

Methods: We performed 10X single-cell RNA sequencing (scRNA-seq) on prostatectomy specimens from men with high-risk localized PCa; 12,988 cells from 4 patients that underwent pre-operative SBRT and 47,314 cells from 6 patients that underwent prostatectomy alone. THP-1 monocytes polarized into macrophage (Mϕ) states [M0, M1, M2 and tumor-associated macrophages (TAM), were used to characterize TREM2 expression and immune responses to radiation or conditioned media (CM) derived from irradiated PC3 cells. In vivo studies with C57BL/6 mice inoculated with MC38 flank tumors or $PTEN^{-/-}$ $SPOP^{mut}$ $CHD1^{del}$ mouse prostate organoid line were used to analyze intratumoral myeloid populations in response to SBRT (37.5Gy in 5 fractions).

Results: scRNA-seq analysis (Cell Ranger 7.1.0 pipelines; Seurat v5 R package) revealed enrichment of a cluster of myeloid cells defined by a damage-associated Mϕ gene signature (TREM2, APOE, SPP1, LGALS3, CD9) in response to SBRT compared with non-irradiated specimens (35.6% vs 5.7%). TREM2 expression was significantly upregulated in THP-1 cells polarized in M2 ($p<0.001$) and TAM ($p<0.001$) conditions, compared to M1 conditions. Irradiation (20Gy x1) of THP-1 cells significantly increased TREM2 expression in M0 ($p<0.01$), M1 ($p<0.001$), and TAM ($p<0.01$) conditions. Proliferation of PC3 cells exposed to CM from irradiated TAMs was significantly increased ($p<0.0001$) compared to CM from non-irradiated TAM. Alternatively, CM derived from irradiated PC3 cells significantly increased ($p<0.05$) TREM2 expression in M0-polarized Mϕ. In vivo studies, in MC38 and organoid models, noted a significant reduction ($p<0.0001$) in tumor volume at day 7 post-SBRT. Multi-parametric flow cytometry demonstrated robust myeloid infiltration in response to SBRT dominated by $CD11b^{+}F4/80^{+}$ TAMs in irradiated tumors. Among irradiated tumors, TREM2 expression was markedly elevated in TAMs (organoid and MC38, $p<0.0001$).

Conclusion: Preliminary data in human irradiated PCa and validation studies in preclinical models suggest TREM2 expression on myeloid cells is a radiation-induced target. Further studies are underway to understand the functional and immunological implications of SBRT-induced TREM2 expression on TAMs and whether this can be therapeutically targeted to enhance anti-tumor immunity in PCa.

#4988 Responders to combination radiation and PD-1 blockade demonstrate reduced myeloid immunosuppression and enhanced interferon signaling in oligometastatic prostate cancer patients.

Z. Fan[1], D. Y. Oh[1], A. Wong[1], K. Shinohara[1], H. Nguyen[1], C. Hwang[1], H. Chang[1], A. Starzinski[1], T. Li[1], C. De Leon[1], M. Gin[1], E. Van Allen[2], L. Zhang[1], R. R. Aggarwal[1], T. W. Friedlander[1], E. J. Small[1], F. Y. Feng[1], L. Fong[1];

[1]University of California San Francisco, San Francisco, CA, [2]Center for Cancer Genomics, Dana-Farber Cancer Institute, Boston, MA

Background: Prostate cancer is unresponsive to current immunotherapies such as checkpoint inhibitors. Overcoming this “cold” environment requires rational combination of therapeutic modalities that can prime anti-tumor immunity. Radiation is a potential candidate; however it remains unclear how it should be most productively combined with immunotherapies.

Methods: We completed an investigator-initiated clinical trial of newly diagnosed men with oligometastatic, hormone-sensitive prostate cancer (mHSPC, NCT03007732). Patients were randomized to receive anti-PD-1 x 13 cycles (pembrolizumab, Arm 1, n=12), or anti-PD-1 with intraprostatic injections of TLR9 agonist SD-101 (Arm 2, n=11). All patients received SBRT to the prostate tumor during cycle 1, and concomitant hormonal therapy with a GnRH agonist and abiraterone. Response was assessed as PSA < nadir + 2 ng/mL at 15 months after ceasing all cancer therapies. For unbiased correlative immune interrogation of these patients, fresh paired biopsies of primary prostate tumor and PBMCs both before and after radiation and immunotherapy were analyzed by multi-omic single-cell genomics to assess changes with treatment, including T cell repertoire changes.

Results: Fourteen of 21 evaluable patients responded by PSA criteria with 3 patients not yet reaching 15 months of post-treatment follow-up. Adverse events included expected IRAEs from anti-PD-1, and flu-like symptoms from SD-101, with no unexpected AEs. Single-cell analysis of tumor biopsies reveals treatment-induced decreases in cytotoxic T cell populations and increases in both immunostimulatory LAMP3+ dendritic cells and immunosuppressive SPP1+ myeloid populations. Treatment increased interferon (IFN) signaling in most myeloid subsets while strongest in LAMP3+ DCs. Compared to non-responders, responders showed less immunosuppression at baseline with depletion of myeloid cells and enhanced IFN activity on LAMP3+ DCs, and treatment-induced IFN activity on cytotoxic T cells. TLR9 agonism also specifically enhanced IFN responses, persistence of cytotoxic T cell clonotypes, and enhanced antigen presentation in tumor cells. Circulating T cells in blood detected shared clones with tissue showing enrichment in cytotoxic phenotype and association with responders.

Conclusions: Responders to combination radiation and anti-PD-1 blockade have decreased myeloid immunosuppression and enhanced IFN activity prior to treatment in oligometastatic prostate cancer. This may identify patients likely to respond, and baseline immune setpoints that can be enhanced with improved immunotherapy strategies.

#4989 Targeting IL-1β mitigates radiation induced MDSC expansion & improves survival in glioblastoma.

S. Ghosh[1], J. Huang[2], D. DeNardo[2], D. Hallahan[2], J. Jaboin[1], D. Thotala[1];

[1]Stephenson Cancer Center, The University of Oklahoma, Oklahoma City, OK, [2]Washington University School of Medicine in St. Louis, St. Louis, MO

Background: Our previous research demonstrated that radiation therapy (RT) for glioblastoma (GBM) induces aberrant myelopoiesis, increasing production of myeloid derived suppressor cells (MDSCs) and exacerbating T-cell suppression. However, the precise biological mechanisms underlying this phenomenon remain unclear. This study aims to elucidate the role of the pro-inflammatory cytokine interleukin-1beta (IL-1β) in RT-induced myelopoiesis and its correlation with poor prognosis in GBM patients.

Methods: We conducted an extensive analysis of circulatory immune cells and pro-inflammatory cytokines in GBM patients treated with chemoradiotherapy. Using an orthotopic mouse model of GBM, we investigated the impact of IL-1β on myelopoiesis and survival. Functional assays were employed to examine MDSC expansion. Multi-color flow cytometry was used for immune profiling.

Results: We found that RT elevated the plasma IL-1β concentration in both GBM patients and GBM-bearing mice, which also corresponded with an increase of MDSC in blood. In the murine GBM model, RT appeared to promote hematopoietic stem (HSPC) differentiation towards myelopoiesis. This led to increased MDSC precursor cells in the bone marrow, elevated circulating MDSCs in blood, and more infiltration of MDSCs in the tumor microenvironment (TME). Similar effects were observed in GBM-bearing mice following the administration of exogenous IL-1β. In contrast, inhibition of IL-1β using anti-IL-1β antibody during RT led to reduced myelopoiesis. When anti-IL-1β antibody was combined with functional inhibition of MDSCs using phosphodiesterase-5 inhibitor-tadalafil during RT, we observed decreased MDSC infiltration and increased CD8+ T cell infiltration in the TME. The combination approach also extended the survival of GBM-bearing mice after RT longer than either drug alone.

Conclusions: Irradiation of GBM appears to induce IL-1β to promote aberrant myelopoiesis and MDSC expansion. A multi-pronged approach to inhibit MDSC production using IL-1β inhibitor and MDSC function using tadalafil during RT may be a promising approach to overcome the immune-suppressive TME of GBM.

#4990 Genotoxic chemotherapy impedes antibody-mediated complement dependent cytotoxicity (CDC), via a Chk1-CD59 axis.

Allison S. Y. Chan[1], Patrick W. Jaynes[1], Nurulhuda B. Mustafa[2], Akshaya A. Anbuselvan[1], Charmaine Z. Y. Ong[1], Anand D. Jeyasekharan[1]

[1]National University of Singapore, Cancer Science Institute of Singapore, Singapore, Singapore,[2]Department of Pharmacology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Monoclonal antibodies such as rituximab exert targeted tumor cell lysis via complement dependent cytotoxicity (CDC). These antibodies are often combined with chemotherapy in clinical treatment protocols. However, the impact of chemotherapy on cell-intrinsic pathways that regulate antibody-mediated CDC is not known. Through a phage display screen, we identified that genotoxic stress caused upregulation of a membrane complement regulatory protein (mCRP), CD46, prompting further investigation into its implications and mechanism.

Using cell lines from diffuse large B cell lymphoma (DLBCL) as our model, we confirmed that genotoxic chemotherapy upregulates CD46, as well as other mCRPs such as CD55 and CD59. We hypothesized that upregulated mCRPs could impede Rituximab-mediated CDC. We assessed this in-vitro using rituximab and complement human serum. Aligned with our hypothesis, chemotherapy treatment of DLBCL cells significantly impeded rituximab-induced CDC. Using blocking antibodies to each mCRP, reversal of the effect of chemotherapy on CDC only occurred after co-treatment with a CD59 blocking antibody, suggesting that CD59 is a key player for chemotherapy-invoked resistance to CDC.

To further elucidate the underlying cellular pathway, we performed a high-throughput small molecule screen using rituximab-induced CDC as a readout, with or without cotreatment of a genotoxic chemotherapeutic (etoposide). We identified Chk1 inhibitors as consistent top rescuers. qPCR and flow cytometry revealed that Chk1 inhibition prevented the upregulation of mCRPs transcriptionally. Sp1 is a known transcription factor driving constitutive CD59 expression. Inhibiting Sp1 similarly prevented chemotherapy-induced upregulation of CD59 and resistance to CDC. However, CHIP-qPCR showed no increased binding of total Sp1 protein to the CD59 promoter after chemotherapy. Instead, positive co-immunoprecipitation of pATM and p300 with Sp1 only with etoposide and not with co-treatment of Chk1 inhibitor suggests Chk1-mediated activation of Sp1. Mechanistically, we have found that chemotherapy-activated Chk1 modulates Sp1-mediated CD59 transcription and that the induced upregulation of CD59 is able to prevent antibody-mediated CDC.

Overall, these results indicate novel immune regulation by DNA damage response, particularly in the context of complement regulatory proteins. Our results advocate consideration when using simultaneous administration of chemotherapy with CDC-inducing monoclonal antibodies, and suggest Chk1 blockade as a possible therapeutic addition.

#4991 Radiotherapy-induced immunological and therapeutic response depends on stem-like TCF-1$^{\pm}$PD-1$^{\pm}$CD8$^{\pm}$ T-cells.

H. Koksal, M. Herbst, N. Marti, M. van den Broek;
Universitat Zurich, Zurich, Switzerland

Radiotherapy is a frequently used treatment for cancer. Recent data, including ours, showed that radiotherapy promotes an inflammatory response in the tumor that supports tumor-specific immunity, and in fact, the efficacy of radiotherapy in pre-clinical models depends on CD8$^{\pm}$ T-cells. According to our preliminary data, the response to radiotherapy is independent of de novo recruited CD8$^{\pm}$ T-cells, suggesting that radiation drives differentiation and proliferation of preexisting intratumoral CD8$^{\pm}$ T-cells. Intratumoral CD8$^{\pm}$ T-cells are heterogeneous concerning phenotype and function. Under conditions of chronic stimulation by antigen, a subset of CD8$^{\pm}$ T-cells expressing PD-1 and the transcription factor TCF-1 was described. These so-called stem-like CD8$^{\pm}$ T-cells, which give rise to effector cells, were shown to be essential for the clinical response to PD-1 blockade. How radiotherapy influences the different CD8$^{\pm}$ T-cell subsets in the tumor microenvironment has not been comprehensively investigated. We propose that the efficacy of radiotherapy depends on the presence of stem-like CD8$^{\pm}$ T-cells, presumably by giving rise to effector cells. To address this, we selectively depleted TCF-1$^{\pm}$ cells from tumor-bearing mice immediately before radiotherapy. Subsequently, we correlated tumor regression with the immunological response using single-cell analyses of intratumoral CD8$^{\pm}$ T-cells. In the absence of TCF-1$^{\pm}$ cells, we found a reduced efficacy and reduced number of intratumoral effector cells after radiotherapy. We currently analyze our single-cell RNA-sequencing data and expect to discover novel radiotherapy-induced pathways in CD8$^{\pm}$ T-cells that contribute to therapeutic efficacy.

#4992 Baseline and alteration in pre vs post standard of care management serum-derived inflammatory markers are associated with radiation treatment volumes and patient outcomes in patients with GBM in a large-scale proteomic panel.

S. V. Jagasia[1], T. Joyce[1], S. Chappidi[2], E. Tasci[1], T. Cooley Zgela[1], M. Mackey[1], M. Sproull[1], K. Camphausen[1], A. V. Krauze[1];
[1]National Cancer Institute, Bethesda, MD, MD, [2]National Cancer Institute / University of Cambridge, Bethesda, MD / Cambridge, United Kingdom

Glioblastomas (GBM) are the most aggressive central nervous system tumors with near universal recurrence following resection and chemoradiation (CRT). Inflammation plays a multifaceted role in GBM development and progression through disruption of the brain barrier, immunosuppression, angiogenesis, and release of inflammatory mediators. Previously established serum inflammatory markers (IM) have been studied in baseline measures obtained prior to surgical resection, making it difficult to establish patterns for potential treatment-induced alteration of IM. We tested the hypothesis that serum-derived IM measured post-resection, prior to and following completion of CRT, may be related to residual tumor burden and response to treatment. IM was analyzed in serum collected pre and post-CRT from 82 individuals with a pathologic confirmed diagnosis of GBM using aptamer-based SOMAScan® proteomic assay. Clinical variables were collected or derived from electronic health records and included RT (radiation therapy) gross tumor volumes GTVT1 (enhancing tumor volume on T1 gadolinium MRI pre CRT), GTVT2 (T2 FLAIR tumor volume on MRI pre CRT), the volume receiving the higher prescribed RT dose (60Gy) (PTVHD) and lower dose (46Gy) (PTVLD), and outcomes (overall survival (OS), progression-free survival (PFS)). Cox regression analyses were performed with pre and post IM levels significant associations ($p<0.05$) were identified. GTVT1 and PTVHD correlated positively with pre-CRT Fibrinogen level and negatively with alteration in CD23. GTVT2 and PTVLD correlated negatively with Kininogen alteration ($p<0.05$ for all). GTVT1 correlated positively with pre IL-6 level. PTVLD correlated negatively with pre TNFb level and PTVHD with CD14 alteration. High alteration in Albumin and a2-HS glycoprotein, lower pre HLA-G and pre IL-6, high pre IgE, pre PD-1 and pre TNF-b and lower altered TNF-b were all associated with longer OS ($p<0.05$). Accounting for age, tumor volumes and RT volumes, fibrinogen was the most prevalent signal associated with outcomes, the pre CRT level associated with OS (*HR: 0.66, p: 0.04*) and pre, post, and alteration significant for PFS (pre (*HR : 0.60, p : 0.01*), post (HR: 1.6, p: 0.01), alt (*HR : 1.52 , p < 0.005*). SAA pre CRT level was associated with OS (*HR : 1.46, p: 0.02*) and its alteration with PFS (*HR : 1.62, p : 0.02*). Additional IM alterations associated with OS CRP (*HR: 0.57, p: 0.01*), PD-1 (*HR : 3.52, p , 0.005*) and PFS, post CRT IL-10 level (*HR : 0.04 , p : 0.02*). GTVT1/PTVHD, GTVT2/PTVLD have distinct IM correlates in serum. Serum IM are associated with OS ad PFS and tumor volumes. Potential associations of previously literature-described inflammatory markers including Fibrinogen, SAA, IL-6, TNF-b and PD-1, were identified and are undergoing further analysis.

#4993 CJRB-101 induces immune responses through the GUT-TME axis in immune cell-driven mechanism in lung cancer models.

A. Min[1], B.-e. Kwon[1], S.-s. Kang[2], S. Baek[3], J. Yang[1], H. Park[1], J. Im[1], H. Kim[1], J. Kim[1], J. Kwon[1], D. Kim[3], J. Lee[3], H. Oh[1], S. Yang[3], Y. Han[3], M. Kim[3], H. Han[3], K. Na[3], Y. Kim[3], M. Yun[3], J. Kim[3], Y. Byeon[3], Y. Kim[3], M. Hong[3], S. Lim[3], K.-H. Pyo[3], B. Cho[3];

[1]CJ Bioscience Inc., Suwon, Korea, Republic of, [2]JEUK Co, Seoul, Korea, Republic of, [3]Yonsei University College of Medicine, Seoul, Korea, Republic of

Background Live biotherapeutic products (LBPs) are known to enhance immune responses through the GUT-TME axis. Here, we investigate the GUT-TME-related immune cell profiling and signals associated with the anti-cancer effects of CJRB-101.

Methods Tumors from NSCLC patients (anti-PD-1 refractory) were transplanted in Hu-CD34-NSG to establish humanized patient-derived xenograft (PDX) models. CJRB-101 was administered at $1x10^9$ CFU (*p.o.*, BID) or combination with anti-PD-1 (10 mpk, *i.p.*, BIW). TME was analyzed using multiplex IHC, flow cytometry and scRNA sequencing. Samples were collected from C3PQ syngeneic mice at multiple timepoints for GUT-TME immune cell profiling. For depletion assay, immune cells were individually depleted during the combination treatment. TLR4-mediated mechanism was evaluated using ex vivo and in vivo assay treated with CJRB-101 or cell membrane of CJRB-101.

Results CJRB-101 combined with pembrolizumab effectively suppressed tumor growth in anti-PD-1 resistant PDX models. Further analysis revealed a correlation between the activity of NK cells and angiogenesis inhibition. Abundance of NK/NKT was higher in the CJRB-101 treated group compared to the vehicle group in multiple PDX models. The expression of GZMB and IFNG in NK/NKT cells was significantly higher in the CJRB-101 treated group compared to the vehicle group in YHIM2014 ($p<0.001$). CJRB-101 treated group showed significantly higher expression of antiangiogenic IL1B ($p<0.001$) while the expression of pro-angiogenic VEGFA ($p=0.002$) was lower compared to the vehicle group in YHIM2014 cancer cells. Macrophages in the intestine were increased at Day 3 in the CJRB-101 group compared to anti-PD1, while NK cells, granulocytes, $CD3^{\pm}$, $CD4^{\pm}$, $CD8^{\pm}$ T cells increased at Day 10 in the syngeneic model. Depletion assay confirmed that macrophages, $CD8^{\pm}$ T cells and neutrophils were pivotal in the anti-cancer effects of CJRB-101. We observed that TAK242 and MD2 reduced the IL-6 secretion of Raw264.7 in a dose-dependent manner. The cell membrane played a key role in increasing BMDM M1 polarization and repolarization of M2 to M1, and that inhibition of TLR4 resulted in a decrease in BMDM repolarization. TLR inhibition also demonstrated that TGI decreased from 34% to 20% when treated with cell membrane + TAK242 compared to cell membrane monotherapy.

Conclusions This study showed that macrophages were the dominant immune population in the early stages then T cells (CD3, CD4, CD8), NK cells and granulocytes became more active in the latter stages of the GUT-TME-axis immune response. In vivo results indicated that anti-cancer efficacy of CJRB-101 is immune-cell driven by TLR4-dependent stimulation of key immune cell populations (macrophages, CD8+ T cells, neutrophils) modulated by the cell membrane of CJRB-101. CJRB-101 is currently undergoing clinical investigation for treatment of patients with advanced NSCLC.

#4995 Impact of radiotherapy on extracellular vesicle mediated anti-tumor immunity in oligometastatic prostate cancer.

C. J. Uzendu[1], Y. Kim[2], R. R. Lavoie[2], H. Dong[2], S. Park[2], F. Lucien-Matteoni[2];
[1]Mayo Clinic Graduate school of biomedical Sciences, Rochester, MN, [2]Mayo Clinic, Rochester, MN

Metastasis-ablative radiotherapy is a new therapeutic approach that prolongs survival in patients with advanced cancers. Tumour irradiation can elicit an immunogenic cell death resulting in the expansion of tumour-reactive T cells and eradication of both irradiated and distant non-irradiated metastases, referred to as the “abscopal effect”. This abscopal response, nevertheless, is observed in a minority of patients suggesting uncharacterized mechanisms that prevent robust systemic anti-tumor immune response. Tumour-derived extracellular vesicles (TdEVs) have recently emerged as mediators of antitumor immunity but their immunomodulatory role in response to radiotherapy remains largely unknown. Recent clinical studies by our lab have demonstrated that circulating levels of tumour-derived extracellular vesicles (tdEVs) are elevated in response to radiotherapy and high tdEV concentrations are associated with reduced levels of peripheral cytotoxic CD8+ T cells and higher risk of disease recurrence in advanced prostate cancer. Based on our findings, we hypothesize that radiotherapy induces the release of tumor-derived EVs that suppress anti-tumor immunity. Prostate cancer cells (PC3 and DU145) were irradiated with clinically used doses of ionizing radiation (20Gy x 1 or 10Gy x 3 fractions) and tdEVs were co-cultured with human CD8+ T cells to measure their proliferation and cytotoxic activity. Increased levels of tdEVs were released by tumour cells treated with radiotherapy. A higher frequency of impaired T cell cytotoxic activity and a reduction in CD8 T cell proliferation was found in the 10Gy x 3 radiation regimen. Proteomic analysis and western blot showed an increased expression of the immune checkpoint molecule B7-H3 on the tumour cell surface and tdEVs in response to radiotherapy. While coculture of CD8 T cells with B7-H3 depleted tdEVs led to recovery of T-cell cytotoxic ability, overexpression of the B7-H3 in tdEVs inhibited cytotoxic activity. This study provides a rationale for future studies in which we will test the immune-mediated effects of radiotherapy-induced tdEVs in immunocompetent mouse models and investigate B7-H3 blockade as a therapeutic approach to boost abscopal response in the treatment of advanced prostate cancer.

#4996 Analysis of the effect of eribulin on tumor immunity against triple-negative breast cancer.

S. Tadafumi, T. Oba, K.-i. Ito;
Division of Breast and Endocrine Surgery, Department of Surgery, Shinshu University School of Medicine, Matsumoto, Japan

Purpose: Chemotherapeutic agents may induce immunomodulatory effects on immune cells and cancer cells in patients with triple negative breast cancer (TNBC). Recent studies have demonstrated that absolute lymphocyte count in peripheral blood can predict response to eribulin in patients with breast cancer, suggesting that eribulin have some favorable effects on immune cells. However, there have been no reports demonstrating the mechanisms of how eribulin affects the immune cells of patients with breast cancer. This study aimed to analyze the effect of eribulin on T cells *in vitro* and *in vivo*.

Materials & Methods: Using human peripheral blood mononuclear cells (PBMCs) from healthy donors and patients with TNBC, we investigated the effects of eribulin on proliferation of these cells, changes in the expression of surface markers, and antitumor effects on TNBC cells. Three TNBC cell lines (MDA-MB-231, Hs578T, MDA-MB-157) were used in this study. Human PBMCs were activated by CD3/CD28 stimulation *in vitro* for six days and analyzed for T-cell surface markers by flow cytometry. For three patients with TNBC who underwent eribulin treatment, blood was collected at baseline and on days 8, 22, and 64 after treatment, and PBMCs were isolated, and analyzed by flow cytometry.

Results: The proliferation of activated $CD8^+$ T cells from healthy donors and patients was facilitated when cultured with 1nM of eribulin compared to the control. Moreover, eribulin significantly decreased CD4/8 ratio in T cells ($p< 0.05$). In PBMCs from healthy donors, the frequency of $CD45RA^+$ $CD45RO^-$ cells and $CCR7^+$ cells in $CD8^+$ T cells was significantly increased by eribulin treatment ($p< 0.05$). Furthermore, eribulin significantly increased $CD127^+$ $KLRG1^-$ cells (memory precursor effector cells) and $TCF1^+$ cells in $CD8^+$ T cells ($p< 0.01$). Furthermore, the anti-tumor effect of activated T cells from PBMCs of healthy donors and patients with TNBC was enhanced when cultured with eribulin in all three TNBC cell lines compared to control, and $IFN\gamma^+$ $CD8^+$ T cells were significantly increased by eribulin treatment ($p< 0.05$). However, in TNBC patients treated with eribulin in clinical practice, there were no significant changes in the CD4/8 ratio, the frequency of $CD45RA^+$ cells or $CCR7^+$ cells in $CD8^+$ T cells before and after treatment of eribulin.

Conclusions: Our findings suggest that eribulin can facilitate the proliferation of $CD8^+$ T cells and potentiates T cell-mediated anti-tumor activity against triple-negative breast cancer cells *in vitro*. Further analysis of the effects of eribulin on TNBC cells and immune cells *in vivo* is required, and we continue to analyze immunomodulation in patients treated with eribulin.

#4997 Auranofin enhances the efficacy of anti-PD1 immunotherapy.

Zichen Zhao[1], Shichuan Hu[2], **Yan Zhang**[1]

[1]Lung Cancer Center, West China Hospital, West China School of Medicine, Sichuan University, Chengdu, China,[2]State Key Laboratory of Biotherapy, West China Hospital, West China School of Medicine, Sichuan Univeristy, Chengdu, China

Anti-PD-1 immunotherapy brings hope for the treatment of malignant tumors, but its overall response rate is low. Therefore, how to sensitize anti-PD-1 therapy to make more patients benefit from immunotherapy is an urgent clinical demand. PKCι, a classical oncogene that affects cell proliferation and differentiation, has recently been found to be involved in the recruitment of immunosuppressive cells MDSCs and Tregs, which leads to anti-PD1 immunotherapy resistance. Our study is consistent with previously reported results that interfering with PKCι expression in tumor cells significantly enhances the anti-tumor effect of anti-PD1 therapy. Immunological mechanistic analyses demonstrated that the inhibition of PKCι expression significantly reduced the infiltration of tumor-associated macrophages (TAMs) rather than MDSCs or Tregs. Further studies revealed that PKCι enhanced the expression of macrophage chemokine CCL7 by promoting the formation of the YAP1/TEAD transcriptional complex. Interference in vitro and pharmacological inhibition of PKCι in tumor cells both significantly reduced CCL7 expression and TAMs invasion. Auranofin is a commonly used anti-inflammatory agent in clinical practice, which has been recently found that it directly induces tumor death by modulating the cellular redox system in tumor cells and remodels the tumor immunosuppressive microenvironment by specifically inhibiting PKCι expression. The results of our study showed that the anti-tumor effect of Auranofin combined with anti-PD1 therapy was superior to that of monotherapy in lung adenocarcinoma. Auranofin exerted synergistic anti-tumor effects with anti-PD1 immunotherapy by inhibiting the expression of PKCι-YAP1/TEAD-CCL7, reducing the recruitment of TAMs, and promoting the infiltration of effector CD8+ T cells. In summary, Auranofin is a potent candidate for sensitizing anti-PD-1 immunotherapy, reversing immunotherapy blunting by remodeling TIME, which provides new ideas and theoretical basis for immunotherapy of sensitizing malignant tumors.

#4998 Pralsetinib induces opportunistic infection in RET fusion-positive NSCLC patients via inhibition of IL-2 production by blocking Jak3-Stat5 activation.

S. Yoon[1], H.-M. Ryu[2], S.-W. Kim[1], **K.-S. Park**[1], D. Lee[1];

[1]Asan Medical Center (AMC), Seoul, Korea, Republic of, [2]University of Ulsan College of Medicine, Seoul, Korea, Republic of

Background: Oncogenic alteration in RET, representing 1-2% of non-small cell lung cancer (NSCLC), is one of the important targets. Pralsetinib is a selective RET inhibitor that targets RET fusions. We present a case series on opportunistic infections and the mechanism of immunosuppression.
Methods: From October 2021 to March 2022, we administered pralsetinib to a total of 15 patients with NSCLC harboring RET fusion. We retrospectively analyzed the clinical efficacy and adverse event related to pralsetinib. To investigate the potential impact of pralsetinib on T-cells, we examined cytokine release from Jurkat T (JT) cells after pralsetinib treatment. To test if Stat5 bind to IL-2 promotor, we conducted Chromatin Immunoprecipitation (ChIP).
Results: Out of a total of 18 patients with measurable disease, 14 patients (93%) achieved a partial response. With the median follow-up duration of 8.7 months, four cases of opportunistic infections were occurred. Notably, three patients (16.6%) experienced invasive pulmonary aspergillosis, and one patient (5.5%) experienced cytomegalovirus pneumonia. To mimic conditions akin to activated T cells, we treated JT cells with PMA and ionomycin, inducing IL-2 release through the binding of NFAT, AP-1, and NF-κB to the IL-2 promoter. Following approximately two weeks of pralsetinib treatment, a decrease of IL-2 releases, the inhibition of Jak3 and the reduced-expression of JunB and c-Jun was observed. Additionally, to investigate the direct correlation between Jak3 and IL-2 release, JT cells were treated with ritlecitinib, the Jak3-selective inhibitor, for approximately two weeks. Like pralsetinib, a reduction in IL-2 release was observed. Furthermore, based on the evidence that Stat5 inhibition leads to reduced IL-2 release, we also showed that the transcription factor Stat5, a direct downstream signaling component of Jak3, binds to the IL-2 promoter during the activation of Jurkat T cells.
Conclusion: Pralsetinib inhibits additional IL-2 production by blocking Jak3/Stat5 activation triggered by IL-2 released during early T cell activation. As a result, the Jak3 inhibition induced by pralsetinib leads to a decrease in JunB/c-Jun expression and blocking Stat5 activation by reducing IL-2 release. Consequently, Pralsetinib-related opportunistic infections may be caused by inhibition of the JAK3 pathway and IL-2 release.

#5000 Low dose ionizing radiation elicits the extrusion of neutrophil extracellular traps.

Alvaro Teijeira, Ana Martinez-Riano, Beatrice Pinci, Almudena Manzanal, Paula Molero, Maria E. Rodriguez- Ruiz, Ignacio Melero

Center for Applied Medical Research (CIMA), Pamplona, Spain

The majority of cancer patients undergo radiotherapy interventions at some point in their clinical management with unintended irradiation of blood vessels. We show that very low γ-irradiation doses (0.5-1 Gy) of human and mouse neutrophils elicit neutrophil extracellular trap (NET) formation in a manner dependent on oxidative stress, NADPH oxidase activity and autocrine interleukin-8. Radiation-induced NETs interfere with NK- and T-cell cytotoxicity-repelling effector lymphocytes away from tumor cells. As a consequence, pre-injection of irradiation-induced NETs increases the number of successful metastases in mouse tumor models. Increases in circulating NETs are readily detected in series of patients following radiotherapy interventions. Our results reveal new mechanisms whose knowledge may help to improve the efficacy and safety of radiotherapy, especially when used in combination with immunotherapy approaches.

#5001 Personalized neoantigen/cancer-testis antigen nanovaccine for advanced solid tumors, a single-arm, open-label pilot study.

J. Wei, Q. Liu, L. Zhu, J. Shao, J. Yang, G. Xu, N. Wu, H. Wang, R. Li, H. Sha, Q. Xu, J. Shen, L. Xie, L. Wang, J. Du, L. Cen, M. Tian, L. Yu, B. Liu; Department of Oncology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China

Background: Neoantigens, derived from somatic mutations in tumor cells, have been identified as promising targets of immunotherapy. A personalized neoantigen/cancer-testis antigen (CTA) nanovaccine (PNVAC) platform has been established by us previously, and demonstrated its feasibility, safety and efficacy in preventing recurrence of high-risk resected gastric/gastroesophageal junction (G/GEJ) cancer in both preclinical and clinical studies. This study aims to explore the universality of PNVAC monotherapy or combined with anti-angiogenesis drugs or anti-programmed death 1 (PD-1) in patients with multiple advanced solid malignancies.

Methods: Patient-specific neoantigens were selected based on tumor-specific mutations identified by whole-exome sequencing (WES) and RNA sequencing of paired blood and tumor tissues. Bioinformatic analysis for neoantigen prediction, including sequencing read filtering, human leukocyte antigen (HLA) typing and neoantigen filtering was performed. PNVAC is an amphiphiles nanovaccine loaded with multiple personalized neoantigens designed to induce specific T cell responses. PNVAC is administrated to patients with metastatic solid tumors on days 1, 4, 8, 15, 22, 43 (prime phase) and 64, 85 and 169 (boost phase) alone, or combined with anti-angiogenesis or anti-PD-1 drugs. Safety, immunogenicity and clinical efficacy are evaluated.

Results: Of the 30 enrolled patients, no treatment-related severe adverse events (AEs) occurred and the vast majority of AEs were limited to grade 1-2, only 1 patient developed grade 3 thrombocytopenia. The objective response rate (ORR) was 26.7% (8/30), including 2 cases of complete response (CR) and 6 cases of partial response (PR), and a disease control rate (DCR) of 66.7% achieved. The median progression-free survival (PFS) was 9.90 months (95% CI, 3.46-16.34 months), while the median overall survival (OS) was not reached (range, 0.80-43.53 months), and the estimated 1- and 2-year survival rates were 86.2% and 60.6%. Notably, among the 21 patients who had relapsed disease after previous ICB and/or anti-angiogenesis, disease control was asserted in 14 (66.7%) of them (7 of SD, 5 of PR, 2 of CR). ORR of this set was 33.3% (7/21), higher than that of all the enrolled patients (26.7%), and the set without prior ICB and/ or anti-angiogenesis treatment (11.1%). For immune analysis, PNVAC elicited robust and persistent immune responses against neoantigens/CTAs. Additionally, peripheral T cells with a cytotoxic phenotype tended to increase after vaccination, and immune memory was also detected in some representative patients.

Conclusions: These data supported the safety, immunogenicity, and efficacy of this regimen in patients with advanced solid malignancies, thus broadening the application and combined strategies of neoantigen-based vaccines. Clinical trial information: ChiCTR1800017319.

#5002 Next-generation mRNA-LNP vaccine prototype achieves tumor clearance in a GBM mouse model.

R. Nechanitzky[1], S. Snelling[2], K. Ellestad[2], X. Lun[2], K. Olsen[1], Y. Wu[1], Y. Karpov[1], J. Liu[1], M. Gold[1], H. Menon[1], R. Krishnan[1], R. Georgantas[1], P. S. Ohashi[3], D. J. Mahoney[2], J. A. Chan[2], N. Martin-Orozco[1];

[1]Providence Therapeutics Inc, Calgary, AB, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]Princess Margaret Cancer Centre, Toronto, ON, Canada

Glioblastoma (GBM) is the most prevalent and aggressive primary brain tumor type with an abysmal prognosis, featuring an immunologically dampened tumor microenvironment and limited neoantigen production. Novel therapeutic strategies are urgently needed. A well-characterized GBM-associated mutation that can elicit an anti-tumor immune response is EGFRvIII mutation. The cancer-driver mutation is detected in approximately 30% of patients at the time of diagnosis and plays a pivotal role in the emergence of GBM. EGFRvIII is an in-frame epidermal growth factor receptor (EGFR) deletion generating a constitutively active oncogenic protein. Its highly immunogenic nature represents an ideal focal point for cutting-edge mRNA-LNP candidate therapeutics. To evaluate proprietary lipid nanoparticle (LNP) compositions for their capacity to induce anti-GBM immunity, we developed a murine transplantable GBM tumor model by neonatal electroporation. The somatically engineered glioblastomas harbor two targeted CRISPR knockouts and stably overexpress EGFRvIII to yield transplantable cell lines for orthotopic tumor initiation. One week after intracranial tumor cell implantation of 6-8 week-old female mice (day 0; n=10), half the animals were administered either buffer (control cohort) or our novel anti-EGFRvIII mRNA-LNP vaccine (experimental cohort). The regimen involved four intramuscular injections before monitoring tumor progression by MRI on day 30. The imaging revealed a high tumor burden in all control group animals, compared to no detectable tumor cells in vaccine-protected mice. All control group animals were humanely euthanized by day 38 due to symptoms associated with the growing brain tumor mass. The asymptomatic experimental animals received a fifth anti-EGFRvIII vaccination before MRI-based examinations on day 43 and day 78 confirmed that no tumor cells could be detected in vaccine-protected mice. The results highlight the potency and potential of our proprietary anti-EGFRvIII mRNA-LNP vaccine as a novel anticancer therapeutic. In addition, the established tumor model represents a valuable tool to test future mRNA-LNP designs. Outstanding cellular and molecular investigations will reveal vaccine-mediated mechanistic insights, allowing for the co-advancement of the tumor model and next-generation multi-target mRNA-LNP vaccine candidates.

#5003 Efficacy of the STC-1010 a new allogenic cancer vaccine in different colorectal cancer models.

G. Alzeeb[1], C. Gongora[2], C. Richard[3], R. Boidot[3], T. Fortin[4], Y. Wang[5], A. Bessede[6], B. Pinteur[1], L. Chalus[1], C. Tortorelli[1], P. Bravetti[1], F. Ghiringhelli[7]; [1]Brenus Pharma, Lyon, France, [2]INSERM U1194, Montpellier, France, [3]CNRS 6302, Dijon, France, [4]Anaquant, Lyon, France, [5]Inovotion, La Tronche, France, [6]Explicyte, Bordeaux, France, [7]Inserm 1231, Dijon, France

Colorectal cancer (CRC) is the 2nd cause of cancer-related death worldwide. Recent tremendous progress has installed immunotherapy as a treatment option and opened multiple ways to address therapeutic challenges for CRC patients. Accordingly, Brenus-Pharma developed a therapeutic cancer vaccine, based on stimulating tumor cells (STC) technology with physical (irradiation and heat shock) or chemical (chemotherapy) stress, coupled to haptenization making vaccine more immunogenic. We first validated STC technology using a “one cell line” mouse surrogate vaccine in CT26 mouse model showed an efficacy of the combination of stress plus haptenization. We next prepared a mouse surrogate vaccine using three murine tumoral cell lines the mSTC-1010 (CT26, CMT93 and LTPA), and confirmed the value of using 3 cell lines to increase the antigenicity. In addition, mSTC-1010 associated with immunostimulant (cyclophosphamide and mGM-CSF), combined or not with chemotherapy (FOLFOX or FOLFIRI) led to a significant decrease of tumor volume, a M1-oriented macrophage response (immunohistochemical, iNOS/CD163 >1), and an increase of T lymphocyte infiltration. Following, we confirmed these proofs-of-concept with the human vaccine, STC-1010, composed of 6 drug substances (DS) derived from 3 CRC human cell lines (HCT116, HT29 and Lovo), stressed physically or chemically and then haptenized. Transcriptomic analysis showed the induction of stress-related pathways with a certain specificity for each DS, allowing their quantification in the STC-1010 by deconvolution strategy. Moreover, proteomic analysis showed specific protein expression modification of each DS and confirmed the rationale of using 3 cell lines with 2 stresses to cover the CRC heterogeneity. More than 200 cancer-related proteins from the Atlas proteins’ database were identified in theSTC-1010 including CRC-specific proteins, tumor plasticity and tumor-associated antigens. In ex vivo model, the efficacy of the vaccine was shown, through that CD8+ T cells primed by the STC-1010 treated DCs (versus control), induced massive apoptosis of cancer cells ($p<0,001$). In chicken embryo Chorio-Allantoid Membrane (CAM) model, STC-1010 significantly increased IL-12, IL-2 and IFN-gamma expression (versus control $p<0.02$). Results from this immune reactive model showed a significant increase of tumor necrosis ($p=0,0267$), metastasis regression (-49%), and increased infiltration of CD4+, CD8+ (versus control). The good tolerability and reproducible efficiency of the STC-1010 vaccine in these different clinical models allow to plan a first-in-human phase I/II clinical trial for metastatic CRC(mCRC) patients. A dose-escalation and cohort extension phase I followed by a phase IIa with STC-1010 plus immunostimulant, associated to mFOLFOX6 w/o bevacizumab, will be performed for MSS mCRC patients to evaluate the safety and preliminary effectiveness in human.

#5004 Oncolytic Jurona-driven systemic and intratumoral immunotherapy combined with immune checkpoint blockade boost immune response and survival in hepatocellular carcinoma models.

M. Z. Tesfay, K. U. Ferdous, A. Cios, R. S. Shelton, C. C. Simoes, S. R. Post, T. J. Kelly, M. J. Cannon, A. Basnakian, B. M. Nagalo;
University of Arkansas for Medical Sciences, Little Rock, AR

The members of the vesiculovirus genus have recently become attractive immunotherapeutic agents due to their natural selectivity for tumors and lack of toxicity in humans. Here, the research shows Intratumoral (IT) or Intraperitoneal (IP) injection of JURV was found to induce dynamic tumor regression in human hepatocellular carcinoma (HCC) xenografts and syngeneic models. Furthermore, IT injections of JURV were also shown to recruit and activate cytotoxic T lymphocytes and decrease tumor-associated macrophage infiltration, resulting in the delay of tumor growth in both local and distant murine HCC tumors established in a syngeneic model. Additionally, the concurrent use of JURV and anti-PD-1 antibodies was found to synergistically modulate the tumor microenvironment (TME) via increased tumor-infiltrating CD4+ T cells and depleted CD8+ PD-1+ and NK cells. Furthermore, using RIL-175, an aggressive metastatic HCC tumor mouse model, we show that intraperitoneal (IP) (systemic) administration of JURV and anti-PD1 significantly improved long-term survival (90%) compared to the (20%) JURV or anti-PD1 alone. Through proteogenomic analysis, the activation of different effectors of the immune system was observed to cooperate to alter the TME to a favorable anti-tumor immune state. These findings further support the development of JURV as an immunovirotherapy platform for HCC, with the potential to induce abscopal effects via the activation of several tumor suppressor genes and the mechanism regulating the T helper cell responses.

#5005 Safety and tolerability of multi-epitope HER2 peptide vaccines in combination with trastuzumab emtansine in HER2-positive breast cancer patients with residual disease after neoadjuvant chemotherapy.

S. Chumsri[1], S. Giri[2], A. J. Ness[2], D. W. Hillman[2], N. Norton[1], D. Cogen[1], B. M. Necela[1], A. Nassar[1], D. W. Northfelt[3], P. Advani[1], R. Rao[1], K. Sideras[1], A. Moreno-Aspitia[1], B. J. Ernst[3], K. J. Ruddy[2], M. P. Goetz[2], K. L. Knutson[1];

[1]Mayo Clinic Florida, Jacksonville, FL, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic Arizona, Phoenix, AZ

Background: Residual disease after neoadjuvant chemotherapy (NAC) in breast cancer (BC) confers poor outcomes. Trastuzumab emtansine (T-DM1) is approved for HER2+ patients with residual disease after NAC. However, many patients still develop recurrence. H2NVAC is a multi-epitope CD4 helper T cell activating vaccine that includes a pool of 4 degenerate HER2-derived HLA-DR epitopes admixed with GM-CSF. Our previous phase I trial showed that this vaccine was safe and generated robust, long-lasting T and B cell immune responses.

Method: We conducted a safety run-in phase of H2NVAC in combination with T-DM1 in stage II-III HER2+ BC with residual disease after NAC. Patients were treated with H2NVAC and T-DM1 for 6 cycles, followed by 2 boosters at 3 and 12 months. Dose-limiting toxicity (DLT) was defined as any grade (G) ≥ 3 toxicity occurring within 21 days after the first vaccination.

Results: 20 patients were enrolled (median age 51; 27-69 years), including 80% White and 15% Black. 90% had hormone receptor-positive disease. There was no DLT observed in the safety run-in cohort. All adverse events (AEs) during the DLT period were grades 1 and 2, with fatigue being the most common (60% G1, 5% G2), followed by peripheral sensory neuropathy (55% G1, 5% G2), and injection site reaction (50% G1). Across all treatment cycles, the 10 most common AEs that were at least possibly related to treatment in all cycles are summarized in the table below. The injection site reaction was the most common AE, with 85% G1 and 15% G2.

Conclusion: H2NVAC, in combination with T-DM1, was safe, with a favorable side effect profile. There was no DLT observed. The most common AE was injection site reaction, with the majority being G1. A multicenter, randomized, placebo-controlled, phase II trial of H2NVAC vs. placebo in combination with trastuzumab emtansine is currently ongoing through the ACCRU consortium (NCT04197687).

Adverse Events	**Grades**			
1	**2**			
N	**%**	**N**	**%**	
Injection site reaction	17	85.0	3	15.0
Aspartate aminotransferase increase	13	65.0		
Alanine aminotransferase increase	9	45.0		
Fatigue	7	35.0	2	10.0
Peripheral sensory neuropathy	7	35.0	2	10.0
Alkaline phosphatase increase	8	40.0		
Nausea	7	35.0	1	5.0
Arthralgia	7	35.0		
Myalgia	5	25.0	1	5.0
Platelet count decrease	6	30.0		

#5006 Discovery of immunogenic neo-peptides from actionable RNA fusions for developing cancer vaccines.

S. Rankothgedera[1], M. Castillo[1], S. Thevasagayampillai[1], C. Woody[1], A. Kandasamy[1], A. Diaz III[2], M. Wick[2], P. Gunaratne[1];
[1]University of Houston, Houston, TX, [2]XenoSTART, San Antonio, TX

The global surge in cancer cases, with a staggering 20 million new instances reported in 2023 alone, underscores an urgent demand for advanced and reliable cancer therapeutics. Immunotherapies centered around neoantigens have emerged as a promising avenue for enhancing treatment efficacy and have become a focal point in cancer research. We hypothesize that the tumor cells present a rich neoantigenic repertoire and the immunogenic neoantigens arising from the junctions of proteins translated from chimeric RNAs present viable targets for peptide and mRNA vaccines, offering a promising approach to impede tumor progression. To validate our hypothesis, we acquired a dataset of RNA fusions detected through RNAseq of tissue extracted from patient-derived xenograft (PDX) models established by XenoSTART, a global non clinical oncology contract research organization. This comprehensive dataset encompassed 985 PDX models across 27 cancer types, revealing three fusions associated with the neuregulin-1 (NRG1) gene. NRG1 gene fusions have been identified as a clinically actionable target for multiple solid tumors as they result in ErbB-mediated pathway activation. CD74-NRG1 has emerged as the most frequently reported NRG1 fusion across many cancers such as pancreatic ductal adenocarcinoma, triple negative breast cancer and ovarian cancer. The CD74-NRG1 fusion was identified in two PDX models harboring lung cancer (ST2891 and ST3204) and in an ovarian cancer model (ST088). The lung cancer PDXs displayed a notable abundance of fusion junction-crossing reads. We generated the CD74 (Exon 1-6) -NRG1 (Exon 6-12) fusion transcript model, where the first 6 exons of CD74 fused to exon 6 of NRG1 leading to an in-frame fusion. Validation of this fusion in PDX tissue was accomplished through PCR and Sanger sequencing of the PCR product. We assessed the affinity of the 9-mer neo peptide sequences formed by the translated junction of CD74-NRG1 to Major Histocompatibility Complex (MHC) Class I molecules using the in-silico prediction pipelines MHCNuggets and MixMHCPred-2 and found HLA-A*68:23 to be the MHC allele with highest binding affinity. HLA-Arena was used to investigate the binding affinity between the peptides and the MHC molecules via molecular docking, which revealed 4 peptides to be strong binders to HLA-A*68:23.The immunogenicity of these neoantigenic peptides to HLA-A*68:23 matched Peripheral Blood Mononuclear Cells (PBMCs) will be assessed by the IFN-γ Enzyme Linked Immunosorbent Spot (ELISpot) assay. To elucidate the specific T-cell clonotypes responding to the neo peptides, the 10X Genomics single-cell 5’ Gene Expression Assay, coupled with T Cell Receptor mapping, will be employed. The objective of the study is to establish a robust combinatorial therapeutic strategy leveraging peptide and mRNA vaccine technology to support an effective framework for personalized cancer treatment.

#5007 *Ex vivo* evaluation of mRNA lipid nanoparticle cancer vaccines.

Tommy Lidstrom, Mara Blanco Arauzo, Nickolas Karlowatz, Mikael Johansson, Mattias Forsell, Jonas Nilsson

Radiation sciences/Oncology, Umea University, Umea, Sweden

Lipid nanoparticle vaccines have recently been developed broadly against pathogens and recently, in precision medicine targeting mutations in different tumors. Evaluating vaccine candidates typically require animal models using orthotopic or allogenic transplantations to evaluate efficiency. Evaluating vaccine efficacy using ex vivo systems is faster and less technically demanding. Here we aim to develop individualized cancer vaccines based on neoantigen identified within established human organoids or directly from patient tissue. The selected neoantigens are enriched for epitopes identified on gene fusions. Identified gene fusions encoding predicted immunogenic proteins are inserted into a vaccine backbone and used to make mRNA lipid nanoparticle vaccines. The neoantigen candidates are then evaluated in a personalized ex vivo testbed. Within the *ex vivo* testbed personal tumor neoantigens are tested on the patients own isolated CD8+ T cells and monocytes. Monocytes are *in vitro* differentiated into monocyte derived dendritic cells (moDCs), which specialize in antigen cross presentation. The moDCs are inoculated with mRNA lipid nanoparticle vaccines or loaded with peptides. The moDCs are then co-cultured with syngeneic T cells. Vaccine candidates are evaluated based on CD8+ T cell activation and cytotoxicity in the co-culture ex vivo testbed. Our pipeline offers a fast and efficient means of evaluating individualized vaccine candidates. Effective vaccines developed through this process can be administered as a standalone therapy or in combination with checkpoint inhibitors, to generate a strong durable immune response against a variety of solid tumor types.

#5009 Deciphering anticancer mechanisms of oncolytic virus-loaded stem cells.

M. Hammad[1], A. Seth[1], Y.-C. Yuan[1], H. Ngai[1], R. Mooney[1], J. Lara[1], Y. Kang[2], I. Minev[2], D. Nguyen[2], B. Minev[2], A. Santidrian[2], K. Aboody[1];
[1]City of Hope National Medical Center, Duarte, CA, [2]Calidi Biotherapeutics, San Diego, CA

Background: Oncolytic viruses (OVs) selectively trap, replicate, and eradicate tumor cells without endangering healthy cells. However, any virus that enters the body will be found and rendered inactive by our immune system. Therefore, cancer-killing viruses don't function properly when given by themselves. Loading therapeutic viruses into stem cells is a promising solution since they shield the OVs from the immune system until they reach tumor cells and eventually destroy them. Stem cells are potent immunomodulators and, apart from protecting and delivering the cancer-killing viruses may release additional cell factors that may regulate tumor microenvironment favoring the effect of the therapy. In this study, we analyze these factors secreted by clinically relevant stem cells loaded with oncolytic viruses CLD-101 (Neuronova platform) and CLD-201 (Supernova platform)
Method: In our studies, we loaded neural stem cell line (NSCs) with tumor-selective oncolytic adenovirus CRAD-s-PK7 (CLD-101) and adipose-derived stem cells (AD-MSC) with tumor-selective oncolytic adenovirus vaccinia virus CAL1 (CLD-201), and studied their secretome transcriptomic and proteomic profile.
Results: The transcriptomic analysis demonstrated that immunomodulatory cytokines, chemokines, and their receptors are induced after three and twenty-four hours of OV infection. The proteomic analysis of the virus-loaded stem cells revealed a notable distinction from the naive stem cells indicating a potential immunotherapeutic role of the stem cells in addition to the delivery and protection of the OVs.
Conclusions: Our findings suggest that the enhanced therapeutic efficacy of stem cells loaded with OV is, at least partially because of qualitative and quantitative alterations in stem cells' secretome (including immunostimulatory cytokines and chemokines), These findings advance our knowledge of the molecular mechanisms underlying the immunostimulatory role of OV-loaded stem cells and specifically help to understand the mechanism of action of the promising clinical immunotherapies CLD-101 and CLD-201.

#5010 Development of a universal cancer vaccine using common cancer antigens cocktail that targets various cancer patients and overcomes the heterogeneity of individual cancer.

T. Nakatsura, K. Takenouchi, H. Kinoshita, N. Tsukamoto, K. Ohnuki, T. Suzuki;
National Cancer Center, Kashiwa, Japan

In clinical trials of the glypican-3 (GPC3)-derived peptide vaccine targeting hepatocellular carcinoma (HCC), hepatoblastoma, etc., peptide-specific CTL were detected in many patients. There have been some partial response advanced cancer cases, and it is expected to be effective in prolonging the prognosis after HCC surgery. Five children with refractory hepatoblastoma who had repeated relapses and remissions are all surviving for more than 9 years without relapse by only peptide vaccine therapy. On the other hand, several patients have experienced recurrence of hepatocellular carcinoma that does not express GPC3 despite the detection of a large number of peptide-specific CTLs in the blood after administration of peptide vaccines. GPC3 is highly expressed in many hepatocellular carcinomas, but there are GPC3-negative cancer cells, so it is difficult to prevent recurrence of hepatocellular carcinoma with a single type of GPC3 peptide vaccine. In other words, to cure cancer, it is necessary to combine multiple common cancer antigens. Through immunohistochemical analysis, we identified 10 common cancer antigens, including GPC3, that are frequently expressed in various solid cancers but rarely expressed in normal tissues. Five of these antigens are membrane protein antigens, and we have confirmed that at least one of these antigens, and often more than one, is expressed in many cancers investigated. We synthesized peptides predicted to be presented at HLA-A*24:02 or HLA-A*02:01 from the full-length amino acid sequences of 10 types of common cancer antigen proteins. These peptide vaccines were administered to HLA-A*24:02 or HLA-A*02:01 transgenic mice once a week for a total of three times, and a number of peptide-reactive CTLs were identified in the splenocytes. These peptides have better CTL-inducing ability than the peptides of the GPC3 peptide vaccine used in clinical trials. Among these 10 types of common cancer antigens, we will use 5 types of membrane protein common cancer antigens in particular to develop a cocktail mRNA vaccine with the goal of preventing cancer recurrence after surgery. Of course, it is also possible to develop cocktail peptide vaccines. At the same time, we are developing a cocktail CAR/TCR-T cell therapy targeting these common cancer antigens for the treatment of advanced cancer.

CLINICAL RESEARCH: Circulating Nucleic Acids 4
Poster Session

#5014 Analytical validation of a complete system for detection and characterization of genomic aberrations in circulating tumor DNA.

E. Stamper[1], W. Shen[1], A. Pruthi[1], C. Nagel[1], M. Piechota[2], K. Tomala[2], Q. Wei[1], D. Willoughby[1];
[1]Frontage Laboratories, Inc., Deerfield Beach, FL, [2]Intelliseq, Inc., Krakow, Poland

Cell-free DNA (cfDNA) fragments are readily detected at a low concentration in the human blood stream. In healthy patients cfDNA is primarily derived from apoptosis of hematopoietic cells. In cancer patients circulating DNA derived from tumor cells (ctDNA) undergoing apoptosis, shedding, and necrosis contribute to total cfDNA. Next generation sequencing (NGS) of cfDNA isolated from patient plasma can be used to fully characterize cancer driven changes in the tumor DNA including the relative contribution of cfDNA, single nucleotide variants (SNVs), small insertions and deletions (Indels), larger deletions, regions of amplified DNA, and structural rearrangements.

Frontage has developed a complete lab system for analysis of circulating cfDNA including automated sample extraction, preparation and sequencing of libraries targeting exon sequences of 293 oncology-related genes, and a bioinformatic reporting system. The Frontage sample extraction process uses a post-extraction size selection step to remove high molecular weight DNA derived from lysed blood cells in the plasma sample to increase the sensitivity of detection of ctDNA. The NGS platform couples hybridization-based selection of genomic DNA fragments derived from protein-coding exons with deep sequencing to ~4,000X gross coverage on the NextSeq 2000. The bioinformatic pipeline integrates unique molecular barcode-based generation of consensus reads for each template molecule, somatic variant calling with GATK Mutect2 and FreeBayes, and removal of false positive variants by comparison to a 60 samples healthy patient data set.

Analytical validation was performed for each component of the system. For verification of the sample extraction process, cfDNA was extracted in duplicate from four lots of pooled K2 EDTA plasma of healthy patients as well as individual K2 EDTA plasma of colorectal cancer (CRC) patients in four independent extraction runs. The mean yields of cfDNA from healthy samples ranged from 2.3 - 4.2 nanograms per ml plasma and all 32 of the isolated cfDNA aliquots from healthy patient plasma showed a prominent peak around 167 nt with minimal contamination from high molecular weight DNA. For validation of the NGS and bioinformatics platform a set of 8 different reference cfDNAs were processed through four independent runs of library preparation, sequencing, and analysis. For each of the validation runs, greater than 97% of 208 SNVs and Indels with expected allele frequencies (AF) between 2-3% were detected by the platform with higher levels of accuracy for variants at above 3% AF. Two or less false positive variants per run were detected out of 278,000 nucleotides of verified non-mutated sequence that overlapped with the 293 gene panel. Four known DNA amplification events were detected in each of the validation runs. Data from characterization of CRC and other clinical samples with the system will be presented.

#5015 Genomic profiling of colorectal cancer - insights from liquid biopsy comparisons between U.S. and China cohorts.

H. Tang[1], C. Jia[1], F. Xie[1], Y. Zhang[1], X. Dong[2], Y. Huang[2], S. Jia[2];

[1]Huidu (Shanghai) Medical Sciences, Ltd., Fengxian District, Shanghai, China, [2]Predicine, Inc., Hayward, CA

Background: Molecular characteristics play a pivotal role in cancer diagnosis, treatment selection, and disease monitoring across various tumor types. While previous research has elucidated the molecular classification of colorectal cancer using tissue NGS, limited investigation has explored the molecular profile of colorectal cancer through liquid biopsy, especially across diverse human races. This study presents a comprehensive genomic profiling analysis of colorectal cancer patients, using a globally harmonized liquid biopsy assay to compare patient cohorts from both the U.S. and China.

Methods: The prospective study is part of Predicine's Phoenix Program, a global molecular biomarker screening initiative across multiple solid tumors. At present, the study has enrolled 57 patients in the U.S. and 62 patients in China, all presenting with advanced colorectal cancer. A 10ml blood sample was collected from each patient and tested using PredicineCARE, an NGS-based liquid biopsy assay, to profile somatic mutations, copy number variations, and gene fusions among these patients.

Results: The assay, validated in both the U.S. and China using the same reference materials, achieved a LOD of 0.25% mutation allele frequency, with a positive predictive value exceeding 99%. Subsequently, the assay was applied to profile molecular aberrations in colorectal patients in both the U.S. and China. Among U.S. patients, the most commonly altered genes were APC (60%), KRAS (56%), TP53 (54%), MYC (25%), PIK3CA (16%), and EGFR (14%). In Chinese patients, the predominant altered genes were TP53 (48%), APC (42%), KRAS (32%), GNAS (21%), EGFR (16%), and PIK3CA (11%). The prevalence of GNAS variations was significantly higher in China than in the U.S. ($p < 0.05$), while the prevalence of APC ($p < 0.05$), KRAS ($p < 0.01$), and MYC ($p < 0.001$) variations was significantly higher in the U.S. than in China.

Conclusions: This study reveals the extensive mutational landscape in advanced colorectal cancer patients through liquid biopsy. Distinct prevalence patterns in certain genes between the U.S. and China cohorts offer novel biomarkers for clinical diagnosis and provide insights for targeted therapy mechanism studies.

#5016 Building better contrived samples to properly evaluate Next-generation MRD and LBx assays.

P. Labrousse[1], H. Russell[1], D. Shera[1], D. Stetson[1], B. Nuttall[1], B. Dougherty[1], D. Hodgson[2], J. Hadfield[2];
[1]AstraZeneca R&D Boston, Waltham, MA, [2]AstraZeneca R&D, Cambridge Biomedical Campus, United Kingdom

Circulating tumor DNA (ctDNA) is a component of cell-free DNA (cfDNA) that originates from tumor tissue in the plasma of cancer patients. Although ctDNA is a broadly applicable tumor biomarker, the absolute amount of ctDNA varies across indication and stage, with the level of ctDNA present reflective of tumor volume. As novel methods for the characterization of ctDNA develop, there is need to evaluate these assays with appropriate samples. But current commercial reference standards, generated from modified cell lines or oligonucleotides lack important features such as DNA methylation, fragmentation pattern and nucleosome positioning, whilst clinical trial samples lack the required volume to perform multiple tests and often lack proper consent. We have created a framework for generating contrived samples containing the biological features of clinical samples and the attributes of a reference standard. The *plasma-in-plasma* contrived samples are generated from commercially purchased and fully consented matched tumor and plasma from cancer patients with age and gender matched healthy donor plasma. Samples are characterized by an internally validated 700 gene NGS panel to identify somatic variants and copy number alterations, which establishes 'ground truth'. A contrived plasma dilution range based on the mean variant allele frequency (VAF) of the concordant somatic variants identified is generated. Using these methods, we have been able to generate sample sets for pan-cancer and disease specific evaluations. We have tested these samples through many novel high sensitivity assays that utilize both tumor-informed and tumor agnostic methods. We have confirmed that *plasma-in-plasma* contrived samples are amenable to all evaluated assays to date. The FFPE tumor tissue provide results matching clinical trial samples and the extraction yields of cfDNA are within the range of plasma samples from clinical trial data. Each dilution can be generated with replicates for reproducibility metrics. Current models of the sample dilutions have been generated to increase the number of replicates at relevant levels of tumor burden (i.e., 0.01% VAF). Negative samples consisting of the background plasma were also generated for each sample used. These *plasma-in-plasma* contrived samples have greater commutability to clinical samples than other commercial reference standards, however there are limitations. The complexity of generating these samples restrict the number of unique patients that can be utilized. Also, due to the volume of healthy plasma used as diluent, it is difficult to generate volumes greater than 4ml. To our knowledge, this is the first report examining the generation and usage of a contrived sample set that can be applied to evaluating novel high sensitivity MRD assays with clinical sample commutability.

#5017 Analytical performance of contrived samples for validation of liquid biopsy assays.

A. E. Harvey[1], C. K. Maddox[1], S. O. Dillon[1], O. T. Khawar[1], E. L. Verner[1], A. Greer[1], K. C. Valkenburg[1], B. J. Caveney[2], S. Ramkissoon[2];
[1]Labcorp, Baltimore, MD, [2]Labcorp, Durham, NC

Introduction: Cell-free DNA (cfDNA) extracted from plasma is critical for the analytical validation of liquid biopsy assays. cfDNA is comprised of genetic material from tumor and non-tumor cells, which can be highly variable across tumor types and disease stage. Relative to tumor tissue, cfDNA yield is lower and may not always capture all clinically relevant variants (e.g. gene fusions). Supplementing analytical validation studies with contrived samples prepared from cell line derived DNA to mimic the features of cfDNA allows for more robust testing of rare variants in clinical samples. To determine the commutability of contrived sample DNA to clinical plasma sample cfDNA, a retrospective analysis of sensitivity studies using two methods of contrived sample preparation was performed.
Methods: The PGDx elio Plasma Focus assay was used to compare sample base size post library preparation and limit of detection (LoD) of clinically relevant variants. Both methods used fragmented cell line DNA with a variant of interest and for method #1, cell line DNA was spiked into noncancerous donor plasma, which was then extracted resulting in a cfDNA and cell line DNA mixture. This contrived sample was diluted using wild-type (WT) DNA extracted from noncancerous donor plasma to obtain a target variant allele frequency (VAF). Method #2 used fragmented cell line DNA diluted with fragmented WT cell line DNA to obtain a target VAF. This retrospective data analysis will include a minimum of 28 samples run in replicate (3-20) across multiple studies.
Results: Data obtained from a DNA fragment analyzer post library preparation show similarities between fragmented cell line DNA spiked into plasma, fragmented cell line DNA, and clinical plasma cfDNA, with fragment peaks ranging from 290-320 base pair (bp). The median LoDs across the three sample types (n=28) were also similar for single nucleotide variants (SNVs) at VAFs of 0.70%, 0.76%, 0.72%, indels at VAFs of 0.70%, 1.0%, 0.78%, amplifications at folds of 1.4, 1.3, 1.5, and translocations at fusion read fractions of 0.5%, 0.61%, 0.55%. When comparing the same variants in a contrived sample functional characterization study, the call rates of various dilution levels were similar. A Fisher's Exact Test of the Hit Rate showed no significant difference for *KRAS G12V* SNV, *ERBB2* amplification, and *RET* translocation between cell line DNA and clinical cfDNA.
Conclusions: This data demonstrates that contrived samples perform with general equivalence to and may be an appropriate substitute for clinical plasma samples, though certain DNA sources may influence overall performance. Overall, fragmented cell line DNA spiked into plasma and fragmented cell line DNA diluted with WT fragmented cell line DNA performed similarly to clinical cfDNA samples representative of the intended use population.

#5018 Evaluation of whole blood fractionation conditions for optimal liquid biopsy NGS applications.

M. JASTI, S. Hernandez, N. Siepert, L. Kodandaramaswamy, T. Jayaweera, J. Schageman, A. Cheng, S. Lopez, M. Chen;
Thermo Fisher Scientific, Austin, TX

"For research use only. Not for diagnostic procedures."

Introduction: Liquid biopsy is a non-invasive alternative to tissue biopsies for cancer profiling using cell-free total nucleic acids (cfTNA; including cell free DNA (cfDNA) and cell free RNA (cfRNA)), the biological analytes derived from tumor cells floating in blood. However, it is crucial to optimize the whole blood fractionation workflows, since limited access to a suitable centrifuge at blood collection sites poses a challenge to this critical fractionation step, causing delays in processing the blood, leading to decreased sensitivity of variant detection and increased occurrence of false positives. Current study shows a systematic comparison of the effects of 8 different blood fractionation conditions for spin speeds, temperatures and duration on the levels of cfTNA derived from K2-EDTA-derived blood from multiple healthy and non-small cell lung cancer (NSCLC) donors, using next generation sequencing (NGS).

Methods: CfTNA from K2-EDTA derived plasma was isolated using the MagMAX™ Cell-Free Total Nucleic Acid kit and the Genexus™ Cell free total nucleic acid kit, utilizing the KingFisher™ Flex and Genexus™purification systems. Yield and integrity of cfTNA isolated was evaluated by Qubit™, Agilent Tapestation and quantitative real time PCR (qRT-PCR). Furthermore, the impact of these test conditions on quality control specifications of DNA and RNA was assessed by performing sequencing on an Ion Torrent™ Genexus™ sequencing instrument using the AmpliSeq™ HD target amplification assay, that reports sequence variations in DNA for 42 cancer related genes and RNA in 7 cancer related genes.

Results: Results showed comparable performance for all the 8 blood fractionation conditions tested, for yield and cfDNA profiles compared to control condition, indicating that there is no significant impact of these conditions on either yield or integrity of the cfDNA isolated. In addition, NGS data also showed that on target reads and median molecular coverage for DNA are comparable for all the conditions tested. However, sequencing data demonstrated that one test condition showed significantly better performance for RNA quality control specifications in terms of RNA mapped reads and molecular coverage for process controls used in the assay, compared to all other conditions tested.

Conclusion: Data suggests that one of the whole blood fractionation conditions tested impact the cfRNA recovery from plasma without negatively affecting the yield, and integrity of isolated cfDNA and shows increased sensitivity for RNA process controls in NGS.

#5019 Comprehensive pan-cancer analysis of cfDNA methylation marks in tumors reveals complex epigenetic regulatory circuits and diagnostic biomarkers.

Early detection of tumor activity in clinically asymptomatic patients has the potential to improve quality of life and prevent unnecessary exposure to toxic therapies. DNA methylation is one of the most studied, stable, and fundamental epigenetic marks and represents a prominent alteration in most cancers. Analysis of DNA methylation, particularly in liquid biopsies has been introduced in cancer diagnosis and risk stratification. Despite indisputable achievements, translation into clinical practice is lagging behind, primarily due to 1) challenges associated with the analysis of DNA methylation, 2) the fragmented nature of cell-free DNA (cfDNA), aggravated by bisulfite treatment, 3) lack of clinical validation of reported cfDNA methylation marks, and 4) the paucity of knowledge about the functional consequences of cfDNA methylation marks within tumors. Using a sample pooling strategy, complemented with robust whole genome and reduced representation methylation sequencing, we establish a pan-cancer cfDNA methylation resource encompassing 12 cancer entities with diverse clinical phenotypes and treatment modalities. We built this compendium using a robustly performing whole genome and reduced representaion enzymatic methylation sequencing of more than 150 cfDNA and tumor DNA. We complement our data by analyzing DNA methylation data from 15 cancer entities (more than 7,000 patients) within the TCGA. We developed an enzymatic digital PCR (dPCR) approach for pan-cancer but also entity-specific analysis of cfDNA methylation at single base-resolution. Using this dPCR assay, we analyzed cfDNA and tumor DNA samples from more than 400 patients and compared enzymatic digestion with bisulfite treatment. We demonstrate that this resource can allow for the identification of entity-agnostic and specific markers, and that cfDNA methylation patterns are mirrored in tumor samples. The approach can be applied for methylation profiling of yet unanalyzed entities. Finally, we demonstrate unconventional epigenetic regulation of gene expression by methylated DNA-binding transcription factors whose activities are tissue- and context-specific and dosage-dependent. This work, therefore, provides a reference resource to identify minimally invasive, entity-specific and pan-cancer markers applicable for diagnostics, surveillance and patient stratification. It also sets the stage for further investigation of tissue- and context-specific epigenetic regulation of gene expression in health and disease by methylated DNA-binding transcription factors.

#5020 Pre-analytical characterization of cell-free DNA to enable liquid biopsy for solid tumors.

R. J. Summersgill[1], J. M. Fox[1], J. S. Dickey[1], L. T. Cox[1], C. D. Palumbo[1], K. C. Valkenburg[1], B. J. Caveney[2], S. Ramkissoon[2], J. B. Jackson[1];
[1]Labcorp, Baltimore, MD, [2]Labcorp, Durham, NC

Background: The integration of liquid biopsy in oncology has transformed clinical management of patients with cancer. Cell-free DNA (cfDNA) represents extracellular nucleic acid fragments shed during cellular apoptosis, necrosis, or secretion, and can be extracted from whole blood. PGDx elio plasma focus analyzes cfDNA to enable non-invasive genomic profiling with next-generation sequencing. In this study, we characterized the cfDNA fraction (%) and yield (ng) across multiple tumor types and stages.

Methods: cfDNA fraction was obtained using automated electrophoresis (Agilent 4200 TapeStation System) to assess a region of 50-700 bp across 293 clinical plasma samples (tumor stages I - IV). The fraction of cfDNA to total DNA present was then calculated to determine overall cfDNA percentage. The overall DNA yield (ng) was quantified via Qubit fluorometer immediately following extraction from plasma and normalized to volume of plasma (ng of cfDNA/mL of plasma). In addition, data was evaluated from 100 clinical plasma cases with strict extraction conditions allowing for yield normalization to plasma volume. Sequencing metrics were evaluated for all clinical cases with a recommended input of 25 ng DNA using PGDx elio plasma focus.

Results: Average cfDNA fraction for individual tumor types ranged from 78.0% - 91.4%, with a mean (n=293) of 84.8%. When examining the yield normalized cohort (n=206), the average yield was 23.4 ng of cfDNA/mL of plasma. cfDNA yield and fraction varied across tumor types and increased with cancer stage. Despite these differences, the majority of cases (99.7%) yielded sufficient cfDNA to proceed with PGDx elio plasma focus testing. No statistical differences in sequencing performance (variants reported and coverage for each tumor type) were observed and the PGDx elio plasma focus assay success rate was 97%. There was a slightly higher failure rate (17.6% (3/17)) for samples below 60% cfDNA, indicating that high amounts of contaminating genomic DNA from white blood cells may obscure the number of available cfDNA fragments for analysis.

Conclusions: These data characterize pre-analytical factors that impact performance of PGDx elio plasma focus using cfDNA isolated from plasma of patients with solid tumors. We showed cfDNA yield and fraction varied across tumor types and increased with cancer stage. The overall success rate for testing was 97% while failed samples were associated with higher levels of genomic DNA contamination.

#5021 Circulating mutated and methylated tumor DNA detection for colorectal cancer diagnosis.

P. K. Bains, M. Kulak, Z. Cui, A. Babu, S. Tran, A. Zhang, M. Sha;
DiaCarta, Inc., Pleasanton, CA

Introduction: Detection of mutation and methylation patterns in liquid biopsies has emerged as a promising approach for screening early-stage cancers. We have developed a targeted next-generation sequencing (NGS)-based assay "OptiSeq™ Colorectal Cancer Detection Panel", a combined platform for assessing mutation and methylation in both low-quantity (plasma cfDNA) and low-quality formalin-fixed paraffin-embedded (FFPE) tissue for colorectal cancer (CRC) detection.

Methods: The OptiSeq™ Colorectal Cancer Detection Panel targets 442 SNVs and 434 CpG sites to detect circulating tumor DNA (ctDNA) in early-stage patients. With this panel, we profiled 6 early-stage and 6 metastatic CRC samples (matching cfDNA and FFPE) along with 2 primary colon specimens with adjacent normal tissue DNA. We also profiled 2 matching cfDNA and FFPE samples from precancerous adenomas (advanced adenomas (AA)) and 6 AA FFPE tissue DNA. In addition, we characterized the mutation and methylation pattern in 10 CRC fresh-frozen tissue DNA samples. For healthy individuals, we profiled 12 normal colon FFPE samples and 10 plasma cfDNA. The clinical performance for the CRC detection panel was calculated using AA, CRC, and cancer-free individuals.

Results: For CRC early and metastatic matching cfDNA and FFPE samples, clinical samples testing showed that the CRC detection panel had a sensitivity of 100% (95% CI: 69.8-100.0) and specificity of 100% (95% CI: 81.5-100). For precancerous AA FFPE tissues, combined DNA mutation and methylation increased the CRC detection sensitivity to 100% (95% CI: 51.6-100.0) and specificity to 100% (95% CI: 61.8-100). More clinical samples testing is underway.

Conclusion: We have developed the targeted NGS-based panel to detect clinically relevant mutation and methylation patterns and demonstrate its potential using the combined genetic and epigenetic markers making it a highly sensitive assay for early CRC diagnosis.

#5022 MEDOCC-CrEATE trial: Feasibility of measuring circulating tumor DNA after surgery to guide adjuvant chemotherapy in stage II colon cancer patients.

I. Franken[1], S. Schraa[1], K. van Rooijen[1], D. van der Kruijssen[1], C. Rubio-Alarcon[2], S. Ketelaars[2], S. van Nassau[1], T. Snetselaar[1], B. Adriaans[1], J. Phallen[3], S. Angiuoli[4], A. Greer[4], E. Verner[4], V. Coupe[5], H. Verkooijen[1], M. van Dongen[2], L. Bosch[2], M. Lanfermeijer[2], D. van den Broek[2], G. Meijer[2], V. Velculescu[3], M. Sausen[4], M. Koopman[1], R. Fijneman[2], G. Vink[6], on behalf of the PLCRC-MEDOCC group;

[1]UMC Utrecht, Utrecht, Netherlands, [2]Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Personal Genome Diagnostics (LabCorp), Baltimore, MD, [5]Amsterdam UMC, Amsterdam, Netherlands, [6]Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands

Introduction: Patients with stage II colon cancer not classified as high risk (pT4 microsatellite stable) do not receive adjuvant chemotherapy (ACT) according to Dutch guidelines. However, 15-20% of patients with stage II colon cancer experience a disease recurrence, indicating that there is an unmet clinical need to identify patients who could benefit from adjuvant treatment. Observational studies demonstrate that postoperative circulating tumor DNA (ctDNA) is indicative of minimal residual disease (MRD) and a strong prognostic biomarker for disease recurrence.

Aim: The MEDOCC-CrEATE trial aims to assess 1) the proportion of stage II colon cancer patients with detectable postoperative ctDNA accepting ACT and 2) whether ctDNA-guided ACT reduces 2-year recurrence rate (RR).

Methods: MEDOCC-CrEATE is an interventional trial following the 'trial within cohorts' design. Participants of the Prospective Dutch Colorectal Cancer cohort with stage II colon cancer and no indication for ACT randomized to the intervention arm undergo postoperative tumor-informed ctDNA testing using next-generation sequencing of 33 genes through the PGDx elio™ liquid biopsy assay. If ctDNA is detected, they are offered 4 cycles of adjuvant capecitabine plus oxaliplatin. Patients in the intervention arm who test ctDNA negative and patients in the control arm receive standard of care follow-up. For all patients, blood is collected every 6 months for 3 years to monitor disease recurrence.

The primary endpoint is the proportion of patients with detectable postoperative ctDNA willing to receive ACT. Secondary endpoints include 2-year RR, disease-free and overall survival, quality of life and cost-effectiveness of ctDNA-guided ACT. The study is powered for 2-year RR, randomizing 660 patients to each study arm in order to treat 30 patients in the intervention arm with detectable postoperative ctDNA, assuming 5% ctDNA detection and 10% noncompliance.

Results: Logistics for timely multicenter collection of tumor tissue and blood have been optimized across 28 Dutch hospitals. At present, 240 patients have been randomized. Of the 119 patients in the intervention arm, 98 provided consent for immediate postoperative ctDNA analysis (82%). Of the 92 currently available results, 5 (5 %) had detectable ctDNA. The median time from surgery to blood collection was 15 days (IQR 11-19), with a median turnaround time from surgery to ctDNA result of 47 days (IQR 39-54).

Conclusion: Multicenter postoperative tumor-informed ctDNA testing for MRD is operationally and technically feasible within the clinically relevant 8-12 week window to start ACT. The observed ctDNA detection rate is in accordance with expectations and the study design. Upon study finalization, the results will be used for health technology assessment to demonstrate the putative clinical utility of ctDNA-guided ACT in stage II colon cancer.

#5023 Analytical validation of the Oncomine™ Dx Express Test using liquid biopsy samples as an IUO assay in a CAP/CLIA lab.

J. C. Espinoza[1], R. Ramsamooj[2], A. Yuki[1], J. Williamson[1], D. Hassell[3], M. Jasti[3], S. Salazar[1], D. Ginzinger[1];
[1]Thermo Fisher Scientific, West Sacramento, CA, [2]Consultant, West Sacramento, CA, [3]Thermo Fisher Scientific, Austin, TX

Introduction: The Oncomine™ Dx Express Test (ODxET) is a next-generation sequencing (NGS) test. It can be used as an investigational use only (IUO**) test to detect somatic DNA and RNA alterations in human cell-free total nucleic acid (cfTNA) isolated from plasma samples. This study outlines the analytical validation of the ODxET for relevant single nucleotide variants (SNV) and insertion/deletions (INDEL) in liquid biopsy specimens. The Ion Torrent Genexus™ platform has a short turnaround time with minimal operator input. This study was performed in a College of American Pathologists (CAP™) accredited and Clinical Laboratory Improvement Act (CLIA) licensed laboratory.

Methods: Forty-seven unique samples (39 clinical, 3 derived, 2 reference and 3 commercially available DNA controls) were analyzed. All experiments began with sample extraction, except the lower input limit of detection (LLOD). We evaluated limit of detection, variant calling accuracy, and precision. Two control NIST™ samples were sequenced with 3 technical replicates each for INDEL and SNVs analytical accuracy. The LOD was evaluated at both the target input of 2ng/µl (40ng), and the minimum input,0.33ng/µl (6.6ng) with allele frequency (AF) levels at 1%, 0.5%, and 0.25%. The 39 clinical plasma samples were used for variant calling accuracy. Inter-assay reproducibility was assessed by sequencing DNA controls across four runs by different operators over multiple days/systems. Intra-assay repeatability was assessed by sequencing 4 samples in replicate on the same run by one operator on the same day/system.

Results: The analytical accuracy and NPV was 100% for SNV/INDEL variants. The 40ng input LOD sensitivity was 96% for SNVs at 0.5% AF and 100% for INDELs at 0.25% Minimum AF. The lower input LOD sensitivity was 89% for SNVs and 100% for INDEL at 1% AF. Variant calling accuracy on samples with pre-characterized data was 100% for the 13 positive samples. Specificity was >99% for all samples including both healthy donor and positive samples. Repeatability was 100% for INDELs and >96% for SNVs, reproducibility was 100% for both variant classes.

Conclusion: This validation study to estimate analytical accuracy, limit of detection, variant calling accuracy and precision has demonstrated that the ODxET assay is highly robust in detecting SNV and INDEL mutations in plasma samples and is suitable for use in a CAP/CLIA laboratory as an IUO assay.**=In Vitro Diagnostic use only. Not available in all regions including North America.

#5024 Analytical performance of a genome-wide methylome enrichment platform to detect minimal residual disease from plasma-derived cell-free DNA.

S. Shen[1], I. Cirlan[1], F. Vincelli[1], B. Brown[2], J. Min[2], J. Burgener[1], J. Zhang[1], Y. Newton[2], M. Gruca[2], A. Licon[2], J. Zhang[2], A.-R. Hartman[2], A. Williams[2], **H. Mellert**[2], D. D. De Carvalho[1];

[1]Adela, Inc., Toronto, ON, Canada, [2]Adela, Inc., Foster City, CA

Introduction: Plasma-derived cell-free DNA (cfDNA) can be used to identify cancer signals, including minimal residual disease (MRD), in patients who have undergone curative cancer treatments. The cell-free methylated DNA immunoprecipitation and high-throughput sequencing (cfMeDIP-seq) methodology is combined with custom algorithms that leverage differentially methylated regions (DMRs) found in cfDNA to distinguish between cancer and non-cancer signals. This novel non-degradative, tissue-agnostic approach was developed to bypass the limitations of bisulfite-sequencing and tissue-informed methods used in other liquid biopsy technologies. Here we present preliminary analytical performance metrics of an algorithm in development for detecting MRD.

Methods: In the genome-wide methylome enrichment platform, plasma-derived cfDNA is subjected to standard library preparation, combined with DNA filler, denatured, and immunoprecipitated using an anti-5-mC antibody. Captured DNA is amplified and sequenced. For this study, a candidate algorithm comprised of differentially methylated regions (DMRs) and 12 cancer types was used to quantify cancer-specific methylation. Control samples from 12 non-cancer donors were used to establish a selected 95% true negative rate threshold. This threshold was used to determine assay sensitivity, which was evaluated using contrived cancer samples intended to mimic low-level circulating tumor DNA (ctDNA) representative of MRD. Samples were contrived by titrating fragmented DNA from three immortalized tumor-derived cell-lines into plasma-derived cfDNA in a titration series targeting <1% ctDNA levels. Cell-lines were of non-small cell lung cancer and head and neck squamous cell carcinoma origin; titration series were replicated for a total of 65 tests.

Results: All non-cancer and contrived cancer samples met in-process quality control metrics. This included ≥98.5% methylation specificity and ≥80 million unique molecules. Limit of detection calculations at 95% sensitivity (LoD95) were <0.1%.

Conclusions: Tissue-agnostic approaches for detecting cancer signals from plasma have significant benefit, especially in settings where tissue is not accessible for evaluation. However, these tests must have highly sensitive methods of cancer signal detection for clinical applications. Our preliminary analytical data demonstrates the use of a blood-based, tissue- agnostic genome-wide methylome enrichment platform utilizing non-degradative methodology combined with specific algorithms and DMRs for MRD quantification and prognostic prediction, using treatment-naïve plasma samples. Future studies in post-treatment and longitudinal samples are ongoing to evaluate the utility of this genome-wide methylome enrichment platform for cancer management.

#5025 Extracellular vesicle DNA as a potential biomarker for cancer detection: A comparative analysis with ctDNA.

T. Wu, T. Tsering, Y. Chen, A. Nadeau, J. V. Burnier;
McGill University Health Centre Research Institute, Montreal, QC, Canada

Background: Liquid biopsy testing has been implemented in clinical practice because of recent advancements in detecting and characterizing circulating tumor DNA (ctDNA). The Food and Drug Administration (FDA) has approved three ctDNA liquid biopsy tests that detect mutations in cancers, which can aid clinicians in choosing the most effective treatments. While ctDNA has been validated for clinical applications, the same is not true for extracellular vesicle (EV)-associated DNA, which is another promising biomarker. Previously, our laboratory developed the Extracellular Vesicle-Associated DNA Database (EV-ADD) to provide validated experimental details and data extracted from peer-reviewed published literature on EV-DNA. The aim of our study was to investigate the potential clinical utility of EV-DNA in liquid biopsy for tumor detection by surveying studies on EV-ADD that compared ctDNA and EV-DNA.
Methods: We searched the entire EV-ADD to selectively identify studies that compared cell-free DNA (cfDNA) or ctDNA and EV-DNA in cancer patients (inclusion criteria). The sensitivity and specificity of cancer detection, the concentrations of DNA, and the methods of detection were compared between ct/cfDNA and EV-DNA. We define sensitivity as the ability to detect mutations in ctDNA/EV-DNA from patient blood when the mutations are known. Specificity is defined as the proportion of true negatives from the sum of true negatives and false positives. A true negative case occurs when no driver mutation is detected in ctDNA/EV-DNA of a patient whose tumor does not have the mutation either. A false positive case occurs when a driver mutation is detected in ctDNA/EV-DNA of a patient whose tumor does not have the mutation.
Results: Of 97 studies in the database, 20 met our inclusion criteria. From 12 studies that matched our definition of sensitivity, the sensitivity of EV-DNA and ctDNA ranged from 19% to 95% and 14% to 97%, respectively. From the same 12 studies, the specificity of EV-DNA and ctDNA ranged from 89% to 100% and 80% to 100%, respectively. Other studies that met our inclusion criteria but did not match our definition of sensitivity either calculated sensitivity differently (2 studies), calculated sensitivity the same way in pleural effusions (2 studies), in bronchoalveolar lavage fluid (2 studies), analyzed mitochondrial DNA (1 study), or did not calculate sensitivity (1 study). The concentrations of EV-DNA and ctDNA in blood ranged from 0.8 - 118.4 ng/ml and 4.0 - 236.5 ng/ml, respectively. Digital droplet PCR (ddPCR) and sequencing were the most common methods (45% and 35%, respectively) for detecting cancer mutations.
Conclusions: Since EV-DNA performed comparably to ctDNA in detecting cancer DNA in the blood of patients, EV-DNA should be seriously considered as a potential biomarker and complementary tool for detecting and monitoring cancer tumors.

#5026 Microfluidic capillary electrophoresis optimization of high-throughput cfDNA and pDNA measurements for enabling cancer diagnostics and gene therapy development.

James Geiger[1], Dipti Mehta[1], Gayatri Gautam[1], Adriana Coll de Pena[2], Menel Ben Frej[1], Anubhav Tripathi[2], James White[1]

[1]Applied Genomics, REVVITY, Hopkinton, MA,[2]Biomedical Engineering, Brown University, Providence, RI

Rapid and accurate electrophoresis characterization can be an important tool for cancer researchers and therapy manufacturers. Advances in NGS of low molecular weight cfDNA for diagnostics may benefit from high-throughput checks of cfDNA sample quality with ultra-low quantities of sample. On the other hand, high molecular weight pDNA characterization and separation of supercoiled, linear and open-linear conformations aids in quality control of these payloads for personalized medicine and in particular cancer vaccines and gene therapies. This work shows optimization of established microfluidic capillary electrophoresis to enable the measurement of cfDNA and pDNA. cfDNA study was completed on plasma reformatted from whole blood tubes using Janus G3 Blood iQ workstation. The cfDNA samples were extracted using commercial cfDNA extraction kits. Using a LabChip GX Touch Biologics Characterization system: gel optimization, marker solution dilution, and inclusion of a low molecular weight DNA standard improved the sensitivity of cfDNA detection. This afforded a new electrophoresis assay with linear dynamic range of 50-1000 pg/uL and sensitivity of <25 ng/uL. pDNA, supercoiled DNA and linear DNA standards were prepared according to published procedures and measured on the LabChip GX Touch Biologics Characterization system. A new ladder system was developed along with gel optimization to develop a new High Sensitivity Assay platform capable of baseline resolving each conformation and providing fragment DNA sizing and purity information. Taken together, this work provides researchers new tools to leverage automated microfluidic capillary electrophoresis for DNA analysis in both upstream and manufacturing processes.

#5027 Simplified selective electrochemical detection of ctDNA differentiates between cancer progression and regression.

M. J. Russo[1], K. Arnold[1], S. Tunney[1], S. Wright[1], F. Taub[1], C. S. Henry[2];
[1]aiGENE, Inc., Aurora, CO, [2]Colorado State University, Fort Collins, CO

Advanced cancers therapies, including personalized ones, often fail. Rapid evaluation of treatment efficacy is therefore critical to reduce medical and financial side effects and, most importantly, facilitate the implementation of a therapy most appropriate for that individual. Current approaches for evaluating treatment are too slow and expensive to rapidly modify therapy. The previously documented selective affinity of DNA to Au surfaces, albeit cumbersome, unsuitable for point-of-care (PoC) applications and having poor discrimination ability, suggested a solution to this clinically important problem. Methods presented herein potentially solve the problem as first illustrated by a studies of plasma from those with and without cancers. Multiple improvements, most notably optimized buffer conditions dramatically changed and enhanced the difference in adsorption between ctDNA and normal cfDNA drastically improving assay performance. The enhanced sensitivity of this Therascape™ assay was not only able to better detect the difference between healthy and cancer cfDNA but demonstrated potential for the monitoring of cancer treatment efficacy. De-identified clinical samples of the few patients that the Scripps Biorepository and University of Colorado supplied had samples before and after treatment, and were known to have progressed or responded in the interim, were analyzed. This initial group included 6 lymphoma patients and two NSCLC patients (in one case the cfDNA was isolated from urine). One of the patient samples taken before initiating therapy was in the healthy range and considered ineligible for the assay. Ten before and after pairs were then evaluated in a blinded fashion. TheraScape correctly correlated with the change in cancer burden in each pair (10/10 times, p = 0.00016, paired t-test). In some cases the “after” specimen was ~1 month after therapy began. The presentation will include additional patients. The CVs of repeat electrodes were less than 10%, interoperator variability did not increase this. The novel method of detecting cfDNA using disposable electrodes presents a significant advancement in monitoring the efficacy of treatments for advanced cancers, and may be particularly critical for immunotherapy. This approach reduced expenses by 10 to 50 times compared to current reimbursement rates for sequence dependent methods, even more critical is the same day turn around would allow rapid, truly individualized, patient therapy optimization.

#5028 Detection of non-small cell lung and bladder cancer signatures in peripheral blood using a novel antibody-free chromatin capture assay.

K. Lai, K. Dilger, R. Cunningham, T. Barnes, K. Truong, K. Lam, R. Boquiren, **M. C. Louie**, D. Abdueva;
Aqtual Inc., Hayward, CA

Immune checkpoint inhibition (ICI) via anti-PD-1/PD-L1 has improved clinical outcomes for multiple cancers, including bladder and non-small cell lung cancer (NSCLC). Yet, the response rates remain low highlighting a significant knowledge gap in the mechanisms driving response and resistance. While the expression of PD-L1 has been established as a predictive biomarker of ICI response, other features, including molecular tumor burden, tumor microenvironment (TME), and the host's immune mechanisms may contribute to overall response. The complex interactions between a tumor and the immune system underscore the need for a more comprehensive approach to explore novel biological and immunological insights of cancer progression.

Circulating tumor DNA assays, while integral to contemporary decision-making in oncology, fall short in delineating the transcriptional programs that dictate cancer phenotypes and their evolution over the disease trajectory. To bridge this gap, we have developed a plasma-based active chromatin capture method that enables the comprehensive epigenetic and transcriptomic interrogation of both tumor and immune components.

In this study, we quantified epigenetic profiles from plasma samples (n=100) of patients with bladder cancer (n=20) and NSCLC (n=24) undergoing ICI therapy, along with samples (n=70) from healthy individuals (n=5). As expected, the total cfDNA yield (ng) of lung (1.7x, p=2.3e-08) and bladder (1.98x, p=1.6e-11) cancer samples were higher than those of healthy individuals. More Interestingly, the longer cfDNA fragments derived from regulatory-active chromatin, also showed a significantly higher abundance in plasma samples from both lung (2.0x, p=2.5e-09) and bladder (3.2x, p=3.2e-14) cancer patients. Furthermore, the patterns of epigenetic regulations across cancer and healthy conditions showed distinct and stable clusters, consistent between gene bodies and transcription start sites, highlighting the epigenetic changes that may be driving cancer progression. We also observed a common enrichment of immune epigenetic signatures in both lung and bladder cancer samples, likely attributed to shared mechanisms associated with the modulation of the tumor microenvironment and immune interactions. Understanding these changes at an epigenetic level could provide insights into novel therapeutic approaches that target the tumor microenvironment and the immune interactions.

#5029 VAF in ctDNA correlated with advanced breast cancer tumor burden and prognosis.

J. Zhong[1], H. Li[1], B. Shao[1], H. Jiang[1], X. Liu[1], H. Tang[2], S. Jia[2];

[1]Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Breast Oncology, Peking University Cancer Hospital & Institute, Beijing, China, [2]Huidu (Shanghai) Medical Sciences, Ltd., Shanghai, China

Purpose: In patients with first-line advanced breast cancer (ABC), the correlation between ctDNA variant allele frequency (VAF) and tumor disease burden, and its prognostic value remains poorly investigated.

Methods: This study included patients with ABC diagnosed at Peking University Cancer Hospital who performed ctDNA test before receiving first-line treatment. Baseline plasma samples were collected for assessing ctDNA alterations and VAF with next-generation sequencing. The sum of tumor target lesion diameters (SLD) was measured with imaging methods according to RECIST 1.1 criteria.

Results: The final cohort included 184 patients. The median age of the cohort was 49.4 (IQR: 42.3-56.8) years. The median VAF was 15.6% (IQR: 5.4%-33.7%). VAF showed positive correlation with SLD in patients with relatively large tumor lesions ($r = 0.314$, $p = 0.003$), but not in patients with small tumor lesion ($p = 0.226$). VAF was associated with multiple metastasis sites ($p = 0.001$). Multivariate Cox regression analysis showed that high VAF was associated with shorter overall survival (OS) (HR: 3.519, 95% confidence interval (CI): 2.149-5.761), and first-line progression-free survival (PFS) (HR: 2.352, 95%CI: 1.462-3.782).

Conclusion: ctDNA VAF associated with tumor disease burden, and was a prognostic factor for patients with ABC. A combination of ctDNA test and radiographic imaging might enhance tumor burden evaluation, and improve prognosis stratification in patients with ABC.

#5030 Evaluation of different blood collection tubes for liquid biopsy NGS applications.

N. Siepert, E. Ostrowska, L. Qu He, M. Jasti, K. Lea, T. Jayaweera, A. Cheng;
Thermo Fisher Scientific, Austin, TX

Intro: Liquid biopsy is fast becoming a standard practice in oncology research due to recent advancements in Next Generation Sequencing (NGS). To detect genetic variants, whole blood samples are collected in blood collection tubes (BCTs) and fractionated to obtain plasma which is then used to isolate cell free nucleic acid (cfNA) for analysis. While the limited availability of cfNA is a challenge in liquid biopsy, storage condition and duration between blood collection and fractionation have a significant impact on the quantity and quality of the cfNA due to degradation and genomic DNA and RNA contamination. There are several BCTs available on the market offering stabilization of cfNA profiles to overcome the above challenges.

Methods: Here we compare the NGS performance of cfNA derived from three commonly used BCTs on the market, BD Vacutainer™ K_2EDTA Tubes, Streck™ Cell-Free DNA, and PAXgene® Blood ccfDNA tubes. Matched whole blood samples collected in the above-mentioned tube types were obtained from commercial vendors which were derived from 38 healthy donors as well as 6 cancer research samples. Whole blood samples were fractionated as per manufacturer recommendations and cfNA was isolated and quantified using Genexus™ Cell-Free Total Nucleic Acid Purification Kit on Genexus™ purification system. Isolated cfNA was then sequenced using Ion Ampliseq™ HD target amplification assay on Genexus™ Integrated sequencer.

Results: Data shows that K_2EDTA collected samples contain slightly higher amounts of cfNA compared to PAXgene® and Streck™ samples. When the cfDNA profiles were analyzed by Agilent™ BioAnalyzer™, K_2EDTA derived cfDNA showed varying degrees of genomic DNA contamination which can inflate the cfDNA concentration. However, both Streck™ and PAXgene® derived cfDNA showed little to no detectable genomic DNA contamination. As a result, a higher percentage of PAXgene® and Streck™ samples did not meet the minimum input requirement (5ng) for the sequencing assay. Sequencing data for DNA showed that K_2EDTA samples had higher total reads and median molecular coverage compared to the other two BCT types. However, all samples had passing QC metrics, and mean read length, on target reads, and uniformity were comparable between the three tube types. When DNA variant detection was evaluated using cancer research samples, no significant difference was observed in performance between K_2EDTA and PAXgene® samples. Interestingly, sequencing data for RNA shows that PAXgene® samples had slightly higher mapped reads on average, and significantly higher internal process control coverage compared to both K_2EDTA and Streck™ samples. Whereas Streck™ samples had significantly lower internal process control coverage.

Conclusion: In summary, this study demonstrates the advantages and disadvantages of using different BCTs for liquid biopsy applications, in terms of cfNA yields, isolated DNA profiles, and sequencing performance.

#5031 Identification of predictive/prognostic biomarkers in metastatic castration-resistant prostate cancer patients using plasma cell-free total RNA-sequencing.

G. Gurioli, M. Urbini, A. Virga, C. Casadei, E. Giunta, N. Brighi, M. Cortesi, M. Zanoni, S. Bravaccini, G. Martinelli, P. Ulivi, U. De Giorgi;
IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy

Background Metastatic castration-resistant prostate cancer (mCRPC) is a heterogeneous disease that is still lacking an optimal patient selection strategy and a validated sequence of therapies. Therefore, there is an urgent need to identify non-invasive biomarkers to guide treatment choice in a perspective of personalized medicine. Plasma cell-free RNA profiling has emerged as a tool to investigate potential liquid biopsy biomarkers. In this study, we aimed to evaluate a method to capture total RNA content deriving from plasma and to identify potential biomarkers for mCRPC.
Methods Plasma samples of 41 mCRPC patients treated with first line Abiraterone or Enzalutamide and 7 healthy donors were collected and stored from 2015 to 2022. Plasma cell-free RNA was purified using miRNeasy Serum/Plasma Advanced Kit (Qiagen) with DNase treatment. Bioanalyzer (Agilent) was used for the evaluation of RNA content and integrity profile of the samples. Sequencing libraries were generated using SMARTer Stranded Total RNA-Seq Kit v3 - Pico Input Mammalian (Takara Bio). An average of 80 millions reads pairs were sequenced on Novaseq 6000 (Illumina) using 100 bpx2 approach. After demultiplexing, reads were trimmed and aligned on hg19. Sequencing metrics were evaluated using Picard. Kallisto was used for gene expression analysis.
Results A median of $10x10^9$ bases per sample were aligned on hg19, of which a mean of 45% were located on coding or UTR regions. Storage time was investigated as a potential variable for RNA content and sequencing metrics, but no difference related to the year of storage was found. Unsupervised principal component analysis confirmed the absence of batch effects (including storage and sequencing analysis). PC1 seemed to reflect the different tumor RNA content of each sample, in which healthy donors and cancer patients were distinguished. Higher androgen receptor (AR) gene expression was found in mCRPC patients compared to healthy donors.
Conclusions Despite enormous interest in extracellular nucleic acids, RNA-sequencing methods for total RNA content outside cells are rare and not standardized. In this study, we found a method to identify plasma non-invasive RNA biomarkers in mCRPC samples, retrieving coding and non-coding RNAs. Case series enlargement and differential gene expression analyses are ongoing.

#5032 Analysis of analytical variables in the cancer detection assay utilizing cfDNA fragmentomics.

J. Lee, **J.-w. Kim**, J. Kim, S. Oh, D. Kim, J. Park, J. Lee, C.-S. Ki, E.-H. Cho;
GC Genome, Yongin, Korea, Republic of

Introduction: Recent studies have increasingly employed the fragmentation pattern of cfDNA-WGS to enhance the cancer detection rate. The control of experimental variables can exert a significant influence on the outcomes. In this study, our objective was to assess the stability of cfDNA from a fragmentomics standpoint in practical experiments involving diverse scenarios. Utilizing our proprietary fragmentomics-based algorithm, we conducted data analysis, confirming the stability of plasma cfDNA in blood across various storage periods. Furthermore, we assessed the robustness of fragmentomic profiles concerning the library's storage duration.

Method: To confirm the stability of cfDNA in plasma within Streck tubes, two experiments were conducted. In Experiment 1, three samples were stored at 4°C and room temperature (0, 3, 7, 14 days). Experiment 2 involved eight samples stored at room temperature (1, 2, 3, 4 days). To validate the stability of the library based on its storage period, 17 samples were sequenced using the library stored at -80°C for a period ranging from 3 to 88 days. All samples and libraries were utilized to generate low-depth whole-genome sequencing (WGS) using Novaseq, and the data were analyzed using our algorithm, which incorporates fragment size and end motifs.

Result: Regardless of the storage temperature of the Streck tube, the insert size exhibited less than a 3bp difference up to 7 days, but a rapid increase in insert size was observed on day 14 under room temperature conditions. The heatmap of 256 end-motif frequencies showed consistent patterns up to 7 days. The difference in insert size according to the library storage period was less than 2bp, and the analysis of density distribution based on fragment size confirmed no significant differences between the data. The heatmap of 256 end-motif frequencies showed similar patterns up to 88 days regardless of the library's storage period.

Conclusion: Results of this study showed that cfDNA of end motifs and size in Streck tubes remained stable for up to 7 days at both room temperature and 4°C, and libraries were stable for up to 88 days when stored at -80°C.

#5033 Sub-0.01% KRAS G12C dPCR variant detection by mutation specific blocker (MSB) cassettes.

A. Beams, K. Lee, S. Addison, N. Riccitelli;
Navigate BioPharma, Carlsbad, CA

Purpose: Kirsten rat sarcoma viral oncogene homologue (KRAS) is one of the most well-known oncogenes and is found commonly mutated in numerous cancer subtypes. Despite its prevalence as a driver of disease state, until recently KRAS-targeting therapeutics have proven difficult to develop due to lack of specificity (Huang 2021). Now, several treatments have been approved for KRAS mutated cancers that are driven specifically by the G12C variant, and additional compounds are under investigation. Enrollment on these therapies is conditional on the G12C mutation presence, and thus accurate, sensitive detection of G12C is critical. Herein, we describe the development of KRAS G12C-targeting MSB dPCR assays capable of detecting G12C variants down to less than 0.01% variant allele frequency in whole blood, FFPE, and cfDNA samples.

Methods: Multiple KRAS G12C MSB cassettes were developed, composed of four components: a mutation-specific forward primer with an engineered penultimate nucleotide mismatch, a non-extendable blocking oligo for the wild-type (WT) KRAS G12 sequence, a TaqMan probe, and a standard reverse primer. Initial cassette performance was assessed using synthetic KRAS G12C and KRAS G12 WT sequences inserted into an IDT plasmid backbone and tested directly or spiked into whole blood or extracted genomic DNA obtained from healthy donors prior to testing. Data obtained with the MSB cassettes across multiple matrices was compared to a BioRad off-the-shelf KRAS G12C droplet digital PCR (ddPCR) assay for accuracy. Cassette designs achieving the desired specificity and sensitivity were subsequently run on cell-free DNA samples possessing KRAS G12C, KRAS G12D, and WT sequences to evaluate performance in patient material.

Results: The enhanced WT suppression design of the assay allowed the lower limit of detection and limit of blank to remain at 6 copies/reaction (cps/rxn) and 3 cps/rxn, respectively, across 30 ng/rxn to 350 ng/rxn gDNA background. At the theoretical maximum input of 200,000 cps/rxn, the assay can achieve 0.003% frequency detection in a single well, with robust detection down to 5 ng/rxn input, making it ideal for samples with limited availability. The assay demonstrated high accuracy, with a correlation coefficient ≥ 0.95 to known values and the BioRad reference assay, and high precision, with less than 10% coefficient of variation among allele frequencies of the same sample.

Conclusion: With the emergence of targeted therapies for KRAS G12C driven cancers, detection of this mutation has become crucial in the diagnosis. While multiple methods are available for variant identification, MSB cassettes represent a powerful approach to achieve a sensitivity of molecular detection not possible with other techniques. This enhanced sensitivity directly impacts patient access to potentially life-saving therapies, ensuring all possible options are available to diagnose the patients sensitively and early.

#5034 Analytic validation of an ultra-sensitive tumor-informed circulating tumor DNA assay based on whole genome sequencing.

J. Northcott, G. Bartha, J. Harris, S. Ma, M. Hong, Q. Zhang, R. Chen, J. Lyle;
Personalis, Inc., Fremont, CA

Monitoring of circulating tumor DNA (ctDNA) levels has demonstrated utility in the detection of residual and recurrent disease after tumor resection, and as a prognostic indicator of patient outcome following initial therapy, in a wide range of cancers. Here we describe the analytic validation of the NeXT Personal® assay, an ultra-sensitive, quantitative, tumor-informed ctDNA assay for use in patients diagnosed with solid tumors. NeXT Personal utilizes whole genome sequencing (WGS) of tumor and normal samples and advanced noise suppression to accurately identify somatic variants and generate a patient-specific diagnostic panel based on up to ~1,800 single nucleotide variants. This personalized panel is used to test for the presence of ctDNA in the patient's blood samples. The NeXT Personal validation was performed using 123 matched tumor, normal and plasma clinical sample sets representing 9 cancer types. The assay achieved 100% specificity on donor normal plasma samples with an in silico approach giving us a confidence interval of 99.87% to 100%. The analytical range measurements were performed using two paired tumor and normal cell lines, one of which is a commercially available MRD control. The detection threshold for the analytical range measurement was 1.68 parts per million (PPM) with a limit of detection at 95% (LOD95) of 3.52 PPM. Furthermore, NeXT Personal showed linearity over a range of 0.8 PPM to 300,000 PPM (Pearson correlation coefficient= 0.9998) with a limit of quant (LOQ) of 10 PPM. The assay also demonstrated strong performance across varying cfDNA input amounts from 2 ng to 30 ng. These studies demonstrate that NeXT Personal is an ultra-sensitive, highly specific, quantitative and robust assay, giving it the potential to detect residual disease and recurrence earlier than less sensitive assays.

#5035 Use of Streck nucleic acid BCT with plasma nucleic acid next-generation sequencing workflows.

N. M. George, L. Bartron;
Streck Laboratories, Inc.R, La Vista, NE

Introduction: Liquid biopsies, which interrogate body fluids in search of analytes released by cancer cells, are becoming increasingly common in clinical oncology. Foremost among the technologies used are those that employ nucleic acids, such as cell-free DNA (cfDNA) and cell-free RNA (cfRNA). Currently, many NGS-based tests perform near the limit of assay detection, making the identification of critical mutations, fusions, or expression patterns like finding a needle in a haystack. Further hindering successful assay development is the variability in analyte availability and detectability that can occur prior to analysis due to blood collection, transport, and storage. Here, we demonstrate that Nucleic Acid BCT stabilizes draw-time levels of plasma nucleic acids for downstream use with NGS-based assays.

Methods: Blood from self-proclaimed healthy donors was drawn into EDTA and Nucleic Acid BCT and stored at ambient temperature for up to 7 days before plasma isolation with a general double-spin protocol and storage at -80 °C. Plasma nucleic acids were isolated using the MAGicBead cfDNA Kit (Zymo, cfDNA) or the QIAamp Circulating Nucleic Acid Kit (QIAGEN, cfRNA). Library prep for cfDNA was carried out with added synthetic mutant spike-in oligonucleotides using the Illumina TruSight Tumor 15 kit (Illumina). cfRNA library prep was done with the NEBNext Ultra II RNA Library Prep Kit for Illumina with upfront rRNA depletion (New England Biolabs). Sequencing was performed using an Illumina NextSeq 500 system, and all data were saved in and analyzed with Illumina BaseSpace applications.

Results: When blood samples were stored in EDTA tubes for up to 7 days, spiked mutant alleles ($EGFR^{L858R}$, $EGFR^{del19}$, $KRAS^{G12D}$, and $PIK3CA^{E545K}$) were no longer detected, likely due to a dilution of the spiked DNA concentration following the release of genomic DNA containing wildtype alleles during white blood cell degradation. In contrast, equivalent blood samples stored in Nucleic Acid BCTs displayed mutant allele frequencies reflective of draw-time levels. Interrogation of plasma RNA expression patterns in samples stored in Nucleic Acid BCT versus EDTA revealed similar results, where differentially expressed plasma transcripts in blood samples stored in EDTA were found at high levels (>1,000 transcripts) versus donor-matched blood samples stored in Nucleic Acid BCT (<50 transcripts).

Conclusions: Our data demonstrate that Nucleic Acid BCT maintains mutant allele frequencies and the plasma transcriptome profile of blood samples during ambient temperature storage. This provides precious sample integrity during whole blood storage and transport, offering laboratories and assay developers reduced preanalytical variability for NGS-based analysis of gene mutations, fusions, indels, and the plasma transcriptome. Nucleic Acid BCT is for Research Use Only. Not for use in diagnostic procedures.

#5036 Analytical and clinical validity of Northstar Select, a quantitatively enhanced liquid biopsy assay for comprehensive genomic profiling of solid tumors.

X. Bower, J. Wignall, J. Zhu, N. Searle, M. Varga, E. Rosas-Linhard, J. Luong, E. Lin, M. Simon, J. ten Bosch, W. Zhou;
BillionToOne, Inc., Menlo Park, CA

Background: Liquid biopsy assays have emerged as vital tools in precision oncology. Among these assays, Comprehensive Genomic Profiling (CGP) tests in particular have improved treatment selection for late-stage solid tumor cancer patients by allowing for the detection via circulating tumor DNA (ctDNA) of somatic mutations in the tumor, many of which have corresponding targeted therapies. However, technical restrictions in the performance of such tests have limited their utility when ctDNA signal is low. BillionToOne's Northstar Select assay is a new CGP test that achieves increased performance by addressing these limitations.
Innovation: By using Quantitative Counting Template (QCT) technology, Northstar Select is able to track the yield of multiple processing steps, contributing to the higher sensitivity of the assay by maximizing the number of decoded molecules after sequencing. In addition, it employs chemistry and panel design optimizations, as well as novel algorithms for SNV, indel, CNV, fusion, and MSI calling to increase sensitivity and specificity.
Analytical Performance: The performance of Northstar Select surpasses that of other commercially available tests for multiple mutation types, detecting more pathogenic and actionable mutations at low tumor DNA fraction while maintaining similarly high specificity. In analytical validation (N=103), limit of detection was determined to be 0.13-0.16% variant allele fraction (VAF) for SNVs and indels, 2.11 copies for copy number amplifications, 1.8 copies for copy number losses, 0.35% VAF for fusions, and 0.07% tumor fraction for MSI.
Clinical Performance: Northstar Select was determined to have high clinical utility as well, with a study of clinical samples (N=481) from a variety of tumor types yielding <2% of reports with 0 mutations detected. A head-to-head comparison with other commercial liquid biopsy assays on a subset of the clinical samples (N=192) showed that the assay detected 115 additional pathogenic mutations in total, leading to a higher proportion of patients with at least one pathogenic mutation detected (90%) compared to comparators (79%).
Conclusion: These results demonstrate that the Northstar Select assay is an innovative and high-performing diagnostic for treatment selection in oncology, leveraging quantitative approaches in process design, chemistry, and bioinformatics to offer superior analytical and clinical performance compared to the current landscape of liquid biopsy CGP tests.

#5037 Development of multiplexed Absolute Q digital PCR assays to rapidly quantify EGFR and KRAS genotype in advanced non-small cell lung cancer (NSCLC) patients' plasma.

B. Hanna, S. Xu, C. P. Paweletz, **Y. Kuang**;
Dana-Farber Cancer Institute, Boston, MA

Introduction: There are needs to identify and serially monitor driver and resistance mutations (muts) in therapy-treated cancer patients (pts). Quantitative liquid biopsy in cell-free (cf)DNA has been widely adopted. We have developed and clinically validated droplet digital PCR (ddPCR) assays to detect common driver/resistance muts such as *EGFR* del19, L858R, T790M and *KRAS* G12X in the cfDNA of advanced NSCLC pts. We have established ddPCR assays for 30+ driver/resistance muts in multiple genes (*BRAF, MET, ESR1,* etc.) relevant to melanoma, breast, and colorectal cancer. Our assays use tumor/cell line DNA as positive controls and serve as benchmarks to develop newer assays such as plasma NGS. In this study, we converted existing/validated *EGFR* and *KRAS* G12X ddPCR assays to the QuantStudio Absolute Q digital PCR (dPCR) system. The selected mutations maximize actionable clinical information and are designed to study oncogenic and resistance mutations in NSCLC efficiently. dPCR's accuracy and efficiency enables target multiplexing, providing comprehensive information from limited materials and contributing to liquid biopsy research progress.

Methods: Plasma from pts with tumors harboring *EGFR* and *KRAS* muts was collected at progression with advanced disease following consent to protocol DFCI #14-147. We designed a multiplex dPCR assay that identifies the most common and therapy-relevant *KRAS* muts in NSCLC, G12C/D/V, and detects other G12X using a drop-off probe. We also designed 2 *EGFR* kits, one identifying driver muts, the other resistance muts.

Results: To validate assay performance, we used gDNA derived from cell lines with *EGFR* or *KRAS* muts. We serially diluted mut gDNA samples in background wt gDNA (16 ~ 1000 mut copies in 1000 wt copies) and performed *KRAS* and *EGFR* dPCR assays. We detected 16 mut copies with sensitivities similar to those of ddPCR assays. We then studied 48 cfDNA samples from plasma of NSCLC pts with tumor confirmed *KRAS* G12X or *EGFR* L858R, del19, T790M muts. No samples had both *EGFR* and *KRAS* muts detected, suggesting our assays are specific. We detected muts in samples with an allele frequency median of 0.9% for *KRAS* mut, 11.9% for *EGFR* driver mut, 2.9% for *EGFR* T790M. The concordance rate is 91.3% between dPCR and ddPCR results. Our findings suggest these assays are as sensitive and specific as our validated ddPCR assays. Multiplexed Absolute Q dPCR saves cfDNA and cuts turnaround time (TAT) to 90 min for *KRAS* assay and 3hr for *EGFR* assays.

Conclusions: We developed rapid, sensitive and specific quantitative dPCR assays for *KRAS* and *EGFR* muts on the QuantStudio Absolute Q platform to quantify plasma genotyping in NSCLC. We will clinically pilot our validated rapid genotyping approach and quantify TAT advantage of multiplexed genotyping in NSCLC pts undergoing standard-of-care tumor genotyping.

#5038 Validation of a comprehensive next-generation sequencing liquid biopsy assay for clinical diagnostics and clinical trial applications.

X.-X. Tan, T. Peters, M. Berry, K. Barber, K. Jeter, B. Lovell, P. Elizondo, Y. Mou, B. Thomas, H. Xie, J. Guo;
NeoGenomics Laboratories, Inc., Houston, TX

Liquid biopsy next generation sequencing (NGS) provides a powerful non-invasive approach to detect solid tumor derived somatic variants in a massively parallel manner. Liquid biopsy NGS has rapidly become an invaluable choice of testing technologies for clinical utility where invasive tissue biopsy is inaccessible and/or inadequate for molecular characterization. We present here a targeted NGS gene panel assay designed and validated specifically for liquid biopsy characterization. The assay was designed to test cell free DNA and cell free RNA from blood plasma for detection of single nucleotide variants (SNV), insertion/deletion (Indel), copy number variants (CNV), and gene fusions present in 52 most commonly mutated genes in cancers. The validation was performed to assess assay accuracy, specificity, sensitivity, repeatability, and reproducibility, with including pre-characterized reference controls, retrospective plasma samples from cancer patients, and prospectively-collected clinic blood specimen. Triplicates were included and testing was performed at different times and by different operators to assess the assay precision. Over 100 clinic blood specimens were collected in Streck cfDNA tubes from multiple trial centers, including treatment naïve phase III-IV patients with solid tumor (lung cancer, breast cancer, brain cancer, prostate cancer, kidney cancer, melanoma, etc) as well as heathy donors, processed within 7 days for plasma separation and total nucleotide acid (TNA) extraction, and assessed by the NGS assay for mutation detection. The identified mutations and wild-types were verified with orthogonal ddPCR. Assay sensitivity as low as 0.1% for SNV and Indel, 1.3 fold change for CNV, and 10 copies for gene fusion were observed, with near-perfect assay specificity (>99.99%) at these sensitivity levels. In conclusion, a targeted NGS liquid biopsy assay was analytically validated under medical oversight, with a demonstrated rigor of the test by its high sensitivity/specificity and robust reproducibility. The validated assay has been utilized for clinical diagnostics and to support research and development efforts in clinical trials.

#5039 Preanalytical workflow enabling cfDNA analysis from urine samples.

D. Mancarella, J. Rutsch, L. Erkelenz, M. Meyer, L. Witthaus, M. Rath, T. Voss;
QIAGEN GmbH, Hilden, Germany

Introduction: Urine has become an important source of information in the liquid biopsy field. In contrast to blood, specifications for the collection, storage, transport and processing of urine intended for molecular examination are not widely established. Preanalytical specifications were published for urine cell-free DNA (cfDNA) only recently (CEN/TS 17811:2022). In this study, we investigated post-collection changes to cfDNA profiles in urine samples and present the performance of an optimized preanalytical workflow for cfDNA analysis.
Methods: Urine from apparently healthy, consented female individuals was spiked with processed cell-free male urine or with a cfDNA standard containing PIK3CA mutations (SensID). The urine was stabilized with a urine collection/ stabilization solution under development at PreAnalytiX or was left unstabilized. Urine samples were stored for varying durations at different temperatures in a time course experiment to simulate different urine storage conditions. After storage, urine samples were centrifuged to remove cells and cfDNA was isolated from the supernatant via the QIAsymphony® platform (QIAGEN). Autosomal and male-specific targets were quantified using the Rotor-Gene® Q instrument and the therascreen® PIK3CA qPCR Kit (both QIAGEN) or the QIAcuity® Digital PCR System and a dPCR LNA PIK3CA Mutation Assay (both QIAGEN). Fragment size distribution was determined by TapeStation® Cell-free DNA ScreenTape® (Agilent Technologies).
Results: Analysis of cfDNA profiles in unstabilized urine stored for varying durations and temperatures highlighted changes which create artificial cfDNA profiles. The yield of cfDNA drastically decreases over time. Furthermore, the size distribution of cfDNA isolated from unstabilized urine was impacted by release of gDNA as well as DNA degradation. Urine stabilization minimized cfDNA degradation and gDNA release and allowed isolation of cfDNA that was analyzed with qPCR and dPCR even after urine storage. Analysis of isolated cfDNA revealed positive detection of PIK3CA mutations in spiked urine samples.Conclusions: Changes in post-collection cfDNA profile can hinder downstream analysis, resulting in artificial or failed outcomes. Urine stabilization with a collection/stabilization solution under development at PreAnalytiX minimized DNA degradation and gDNA release. It enabled urine storage, allowed analysis of urine cfDNA and target detection by qPCR and dPCR.

#5040 Evaluation of commercially available cell free DNA extraction kits using biosynthetic reference materials.

D. Ruminski Lowe, S. Jamindar, A. Anfora, D. Merriam, C. Huang, R. Garlick, B. Anekella;
LGC Clinical Diagnostics, Gaithersburg, MD

Extraction of cell free DNA (cfDNA) from a patient's blood sample is a crucial preanalytic step of the liquid biopsy process. Whether testing is being performed for early disease diagnosis, therapy selection, or disease and treatment surveillance, the input material must be of sufficient quantity as well as high quality to return informative data. In addition, accurate capture of the full cfDNA content from a sample is necessary to evaluate tumor growth or recurrence. Fragmentomics is an emerging field that can indicate tumor origin among other information, and again, accurate and precise cfDNA content is critical. The cfDNA content in patient plasma is highly variable, and sample mass is quite limited compared to that of resected tumors. Healthy donor plasma, though abundant, varies in cfDNA levels batch to batch and should not contain any somatic variants relevant to liquid biopsy assay development or validation. Despite the challenges associated with cfDNA isolation and ctDNA analysis there are few reference materials available to optimize laboratory process for these preanalytic challenges. Here we evaluate various commercially available extraction kits using novel Seraseq® cfDNA Extraction Reference Materials. Genomic DNA from the GM24385 cell line was blended with 4 biosynthetic DNA EGFR variants targeted at 1% allele frequency and verified using the Bio-Rad QX-200 Droplet Digital PCR (ddPCR) System. The mixed DNA was fragmented and size selected to create ctDNA-like size profiles. The ctDNA was mixed into a synthetic plasma matrix to simulate native cfDNA samples and diluted to three distinct concentrations (20, 50, and 80 ng/mL). Verification of concentration was performed using the QIAGEN QIAamp Circulating Nucleic Acid Kit for extraction. The final materials were also extracted with other kits: the Maxwell RSC ccfDNA Plasma Kit, the MagMAX Cell-Free DNA Isolation kit, the Zymo MAGicBead™ cfDNA Isolation Kit, and the Takara NucleoSnap cfDNA Kit. Yields were measured with Qubit dsDNA BR assay and EGFR variants were measured using Bio-Rad ddPCR. Other sites evaluated the materials as well, using various kits. The kits showed variable yields, but there was a clear difference between the cfDNA extracted from each reference material correlating with the intended increasing concentration. The EGFR variants were all present at ~1% regardless of the cfDNA concentration and the kit used for extraction. Seraseq ctDNA Plasma Reference Materials serve to evaluate extraction of cfDNA in liquid biopsy testing workflows without having to source donor plasma, which is limited and variable in cfDNA content. The consistency and availability of these biosynthetic materials allow for optimization without risking patient samples.

#5041 Next generation liquid biopsy reference material performance across NGS assays and platforms.

D. Ruminski Lowe, S. Jamindar, Y. Konigshofer, A. Anfora, K. Nahilk, D. Xia, E. S. Davis, D. Merriam, C. Huang, R. Garlick, B. Anekella;
LGC Clinical Diagnostics, Gaithersburg, MD

Liquid biopsy testing has grown to support early disease diagnosis, therapy selection, and disease and treatment surveillance in cancer survivors. Recent advances in next generation sequencing (NGS) have enabled larger panel sizes, pan-cancer target sets, and wider ranges of genomic alterations. More inclusive analytical validation materials are needed to assess assay sensitivity, specificity, and limit of detection of all variant types to serve the expanded utility of liquid biopsy testing. Here we describe the development and multisite evaluation of expanded Seraseq® ctDNA Mutation Mix v4 reference materials. Genomic DNA from the GM24385 cell line was blended with 93 clinically relevant biosynthetic DNA variants including single nucleotide variants (SNVs), insertions and deletions (indels), structural variants (SVs), copy number variations (CNVs), and mono- and dinucleotide biomarkers for microsatellite instability (MSI). Variant allele frequency (VAF) was targeted to 0.5% and total copy number for CNVs was targeted to 2.5 and verified using the Bio-Rad QX-200 Droplet Digital PCR (ddPCR) System. The DNA mix was fragmented and purified to create ctDNA-like size profiles. Wild-type (WT) material was prepared for comparison and identification of background variants. Agilent Bioanalyzer High Sensitivity DNA and TapeStation Cell-free DNA ScreenTape analyses were used to assess fragment size. The ctDNA mixes were analyzed with the Illumina TruSight™ Oncology 500 (TSO 500) ctDNA assay, the Thermo Oncomine™ Precision assay, and additional assays. All biosynthetic SNVs, indels, SVs, and CNVs in the 0.5% ctDNA mix were detected near target values. The average fragment size was about 190 bp, similar to native ctDNA. The VAFs and CNVs observed in the TSO 500 data correlated well with those that were obtained by dPCR. Variants reported by all evaluation site assays showed good concordance of VAF values. The two sites that tested the materials with TSO 500 revealed consistency in both VAF and total copies with an average CV of 16.1% and 2.5%, respectively. The sequencing performance of the reference material was similar to patient samples and showed comparable levels of background noise. The performance of the Seraseq ctDNA v4 mutation mix across NGS assays, supported by robust digital PCR data, demonstrated that these materials will allow for assessment of complex and sensitive liquid biopsy tests. Comparing data measured at different sites highlights the variability in liquid biopsy assay performance and the importance of highly multiplexed and consistent reference materials. Remnant samples are typically not an option due to limited yields from a standard blood draw, thus contrived standards are especially needed. Expanded variant content and improvements in the methods used to produce the Seraseq ctDNA Mutation Mix v4 materials will enable advancements in the blood-based NGS clinical diagnostics space.

#5042 Urine as a non-invasive proxy for plasma in prostate cancer-related liquid biopsy applications.

Nafiseh Jafari[1], Jason Saenz[1], Lauren Lee[1], Carlos Hernandez[1], Andrew Dunnigan[1], Amit Arora[2], Rafal Iwasiow[2], Mayer Saidian[1]

[1]nRichDX, Irvine, CA,[2]DNA genotek, Ottawa, ON, Canada

Introduction: The non-invasive collection of urine renders it an attractive and pragmatic substitute for plasma in liquid biopsy applications, fostering the creation of diagnostic methods that are more patient-friendly and less cumbersome for clinicians. This study investigates the feasibility of urine-derived cfDNA as a non-invasive option for acquiring vital diagnostic insights, further enhancing the liquid biopsy field.

Methods: Paired male first void urine (FVU) and venous blood samples were collected from healthy donors (n=40) using Colli-Pee UAS devices (Novosanis) and BD K2EDTA Vacutainer tubes, respectively. Out of these, 20 paired urine and blood samples were spiked with 10 ng of cfDNA reference standard containing the KRAS p.G12V mutation. ~35 ml of urinary cell-free supernatant and ~3.5 ml of plasma were obtained after centrifugation of FVU and blood sample, respectively, and used as input material for cell-free nucleic acids extraction using the nRichDX Revolution Max20 cfDNA Isolation Kit. The extracted cfDNAs profile was assessed on 4200 TapeStation System, Agilent, using cfDNA ScreenTape. Extracted nucleic acids from urine samples were subjected to a qPCR assay to quantify endogenous human cfDNA content using 2X iTaq Universal SYBR Mastermix (Bio-Rad). Human cfDNA quantity was assessed using Ct values obtained from the qPCR assay. The actionable cfDNA molecules recovery was determined by qPCR mutation detection assay using TaqMan Genotyping.

Results: Male FVU collected in Colli-Pee UAS device showed the presence of 100-250 bp cell-free DNA fragments similar to plasma obtained from whole blood collected in 10 ml vacutainer tubes as demonstrated by the Agilent cfDNA ScreenTape analysis. The cfDNA yield was similar when comparing one tube of blood (~3.5 mL of plasma) to one Colli-Pee of urine (~35 mL) shown by endogenous cfDNA qPCR assay. Additionally, the amplifiability of the KRAS G12V mutation was consistent in both plasma and urine samples, with comparable Ct values.

Conclusion: The nRichDX Revolution Sample Prep System demonstrates the ability to extract cfDNA from both plasma and urine samples, with comparable extraction efficiency observed between matched samples from the same donor. This study provides evidence supporting the viability of first void urine samples as a non-invasive alternative for prostate cancer-related liquid biopsy applications. It indicates that cfDNA can be recovered from a sample collected with a single BCT or Colli-Pee UAS urine collection device. Future investigations will be required to assess clinical samples and biomarkers to establish a robust correlation between cfDNA levels and various cancer types and stages. This study reinforces the utility of first void urine samples as a reliable proxy for blood-based liquid biopsy applications.

#5043 Achieving sensitivity of 0.1% variant allele frequency (VAF) in plasma and urine with the nRichDX revolution sample prep system evaluated on the the MassARRAY system.

Nafiseh Jafari[1], Mayer Saidian[1], Jason Saenz[1], Lauren Lee[1], Andrew Dunnigan[1], Carlos Hernandez[1], Jessica Mendoza[2], Francisco Hernandez[2], Darryl Irwin[2]

[1]nRichDX, Irvine, CA,[2]Agena Bioscience, San diego, CA

Introduction: Achieving high sensitivity in detecting cancer variants is essential for accurate diagnosis and monitoring of diseases. In this study, we explore the effectiveness of the nRichDX Revolution Sample Prep System in conjunction with the MassARRAY System for enhancing sensitivity and achieving 0.1% VAF in plasma and urine samples. The ability to detect such low-frequency variants is significant in clinical applications.

Methods: Whole blood from healthy donors was collected in K2EDTA tubes. Plasma aliquots were extracted from 5mL (6) and 20mL (6) inputs using the Revolution Max20 cfDNA Extraction Kit. Replicate samples were extracted using the QIAamp Circulating Nucleic Acid kit from QIAGEN. Urine from healthy donors was extracted from 10mL (3) and 20mL (3) inputs using the Revolution Max20 cfDNA Extraction kit. (12) Replicate samples were extracted using a MagMAX cfDNA Isolation kit from Thermo Fisher Scientific. All the samples were spiked with a cfDNA standard containing a KRAS p.G12V mutation at 0.1% VAF. The quantity and quality of extracted cfDNA were determined using the LiquidIQ Pro Panel on the MassARRAY System, which measures amplifiable cfDNA copies. Recovery and frequency of the spiked ctDNA standard were performed with the UltraSEEK LungPanel v2.0, capable of detecting variants as low as 0.1% VAF.

Results: The spiked KRAS mutation was recovered consistently by all nRichDX 5mL plasma samples with an accepted mutation frequency and high mutation significance z-score (z-score>10). However, 3/6 of the QIAGEN 5mL plasma samples did not detect the mutation. The spiked KRAS mutation was recovered consistently by all nRichDX 10 and 20mL urine samples with an accepted mutation frequency and high mutation significance z-score. However, all the MagMAX 10 and 20mL urine samples did not pass the QC (5) or detect the mutation (1). The amplifiable copies of cfDNA recovered from nRichDX 20mL plasma samples are significantly higher than Qiagen ($p < 0.0001$). The amplifiable copies of cfDNA recovered from nRichDX 10 and 20mL urine samples are significantly higher compared to MagMAX ($p < 0.0063$.)

Conclusion: The evaluation of the nRichDX Revolution Sample Prep System on the MassARRAY System has demonstrated its effectiveness in achieving 0.1% VAF detection in plasma and urine samples. The nRichDX System extracts cfDNA and ctDNA with consistently high yields. Two sample T-Test analysis shows that the nRichDX System performed significantly better than the QIAGEN and Thermo Fisher Scientific extraction kits. The results demonstrate the capability of the nRichDX system to recover more amplifiable copies with consistent cfDNA quality and ctDNA frequency with high z-scores. This advancement in sensitivity enhances our ability to detect rare cancer variants, leading to the potential for better patient outcomes in precision medicine.

#5047 Identifying genomic features associated with pathologic lymph node metastasis in lung adenocarcinoma patients.

S. Wang[1], **Z. Zhou**[1], S. Wang[2], R. Guo[2], Z. Ma[1], D. Zhao[1], L. Wang[1], Y. Liu[1], Y. Ma[1], J. Zhang[1], S. Wang[2], Y. Chen[2], H. Tang[2], Q. Ou[2], J. Chen[1];
[1]Peking University Cancer Hospital & Institute, Beijing, China, [2]Nanjing Geneseeq Technology Inc., Nanjing, China

Introduction: Lymph node metastasis evaluation in solid tumors is mainly complicated by the diagnostic yield of standard imaging modalities and tumor size contradictions. Exploring clinical/molecular features that complement the use of radiologic and bronchoscopy findings may provide significant values for a more accurate pathologic determination of nodal metastasis.
Methods: We analyzed surgery-resected tumor samples from 72 treatment-naïve lung adenocarcinoma (LUAD) patients via whole-exome sequencing (WES). Mutational profiles of patients categorized based on their pathologic lymph node metastasis (pN) status were assessed, and the association between metastatic-driving features and overall survival (OS) was then explored in both the study cohort and the Cancer Genome Atlas Program (TCGA) external cohort.
Results: Among all 72 patients, 41 (56.9%) were pathologically confirmed as positive for lymph node metastasis (pN-positive), while 31 (43.1%) were categorized as pN-negative. The most frequently mutated gene was *TP53* in both subgroups (54.8% and 53.7%, respectively), and the aberrant KEAP1-NRF2 signaling pathway was found significantly more enriched in pN-negative patients. Copy-number variant analysis showed that chromosome 7p amplifications (X7p_amp) at the arm level and *EGFR* amplifications at the focal gene level were more frequently identified in pN-positive patients (P=0.008 and P=0.004, respectively). Importantly, these amplifications were associated with worse OS in both the study cohort and the TCGA external dataset. Consistent with the unfavorable prognosis, pN-positive patients demonstrated a higher chromosome instability score (CIS) (median: 0.32 vs. 0.14, P=0.14) and a lower tumor mutation burden (TMB) (median: 1.83 vs. 3.85 muts/Mb, P=0.048) compared to pN-negative patients.
Conclusion: Our findings suggest that X7p_amp, particularly *EGFR* amplification, might be associated with pathologic involvement of lymph nodes and an unfavorable prognosis in LUAD patients. Our study highlights the importance of integrating clinical and genomic data into conventional radiologic modalities for a more accurate determination of pathologic nodal involvement.

#5048 NF2 mutations are enriched in FH deficient renal cell cancer.

K. Bin Satter, L. Xi, C. Rickets, W. M. Linehan, M. J. Merino;
National Cancer Institute, Bethesda, MD

Introduction: NF2 is a tumor suppressor gene in charge of producing a protein called Merlin that controls cell growth and division. Mutations in the NF2 gene affect predominantly the nervous system causing the development of benign tumors. NF2 mutations have been reported in Renal cancers with morphologically specific tumor types and in aggressive tumors. We studied a cohort of 16 cases of RCC in which the NF2 mutation was identified and describe other molecular changes as well as morphology and clinic-pathological correlation.

Materials and Methods: Sixteen patients had been consented and treated for renal masses in protocols of the UOB division of the NCI. Next generation sequencing was performed with tumor DNA from FFPE tissue using the Illumina TruSight Oncology 500 Kit (TSO500) NextSeq 550DX. TSO500 assay was designed to detect single nucleotide variations, small insertions/deletions, copy number variations from 92 genes, TMB and MSI. Morphology and IHC stains were performed.

Results: Nine patients were female and 7 males, ranging in age from 21 to 87 years. Fourteen patients underwent partial or total nephrectomies, one case had a biopsy and in 1 case a metastatic tumor to a lymph node was studied. Morphologically, nine cases were diagnosed as HLRCC, three clear cells, two cases with clear and papillary cell, one medullary and one oncocytoma. Genetic findings revealed mutations in NF2, FH,VHL, SMARCB1, HOBB13, ARID1B, B2M, EP300, BCORL1 and MGA. Concurrent coexistence of NF2 and FH mutations was present in 9 cases. Three patients with concurrent FH and NF2 mutations died of the disease.

Conclusions: NF2 mutations have been identified in a variety of morphologic types of Renal cell cancer. However, we were surprised by the number of cases with NF2 mutation in tumors that also harbor the FH (HLRCC) mutation. NF2 tumors have been reported to have an aggressive behavior, and FH cancers are also known to have poor survival. Genomic studies of renal cancers is recommended since some genetic alterations are targetable and may provide adequate therapies that will lead to longer survivals.

#5049 Detecting chromosomal copy number variations and point mutations in Glioma using a single assay; sparing tissue while significantly reducing testing time and cost.

M. L. Mimosa[1], J. T. Simpson[1], K. Boissinot[2], M. Tiab[2], R. Fattouh[1], R. M. Saleeb[1];
[1]University of Toronto, Toronto, ON, Canada, [2]St. Michael's Hospital, Toronto, ON, Canada

We aimed to develop a single streamlined assay to detect all Glioma biomarkers. The current diagnosis of Gliomas incorporates molecular biomarkers that include whole chromosomal copy number variations (CNVs) and single nucleotide variations (SNVs). Testing CNVs and SNVs are traditionally done using different large platforms and are performed in large genomic facilities that have the suitable infrastructure. This creates delays in testing, where samples undergo lengthy referrals and the tissue is often split between institutions, which also adds substantially to the costs. We have previously used Nanopore sequencing to develop an assay to detect *IDH* SNVs from formalin-fixed paraffin-embedded (FFPE) tissue. Nanopore sequencing platform uses small inexpensive tools and can test for both CNVs and SNVs. However, combining both targets efficiently in FFPE tissue remains a challenge.
While nanopore whole genome sequencing can detect CNVs, it does not allow for enough coverage to accurately detect small SNVs. Also, raw FFPE DNA is not compatible with the nanopore technology. To fix both challenges we used a PCR based approach that allows enrichment of the SNV targets, as well as creates new nanopore compatible DNA copies. To counteract the bias that PCR creates with uneven amplification, we used a SNP based method to call chromosomal gains and losses. Statistical analysis of probability showed that targeting 15 heterozygous SNPs per chr arm is sufficient for accurate CNV detection (error rate <0.1%). A total of 57 amplicons targeting CNVs on Chr 1,7, 10, 19, and *EGFR* gene; and *IDH1 and IDH2* SNVs were pooled together in one assay and tested on 4 Glioma samples. Variant calling was performed with a custom Python script.
All CNV targets were accurately detected on all samples. Losses in chr 1p, 19q and chr 10 were evident with a loss of heterozygosity (LOH) pattern on the SNP analysis. The gain in chromosome 7 was also observed as an allele gain 2:1 SNP pattern on the corresponding samples. The SNV statuses of these samples were also accurately detected when compared to reference results. Finally, the SNV and CNV calling analysis were streamlined using custom shell script, further reducing total turnaround time (including sequencing and data analysis) to less than a day for the entire batch of samples. Initial cost analysis shows <50% of the traditional testing costs for the assay.
This work is the first to develop a streamlined single test to detect CNVs and SNVs in Gliomas using FFPE DNA on the nanopore sequencing platform. The shorter testing time, streamlined workflow, and low assay/capital cost could positively influence the care of brain cancer patients. Notably, nanopore-based sequencing tools can also be implemented in other types of tumor diagnosis, especially by smaller labs, helping to overcome many of the existing diagnostic challenges.

#5050 Germline variants in *CDKN2A* wild-type melanoma prone families.

S. Knappskog[1], G. T. Iversen[1], M. Loeng[2], A. L. Holth[2], P. E. Lonning[1], J. Geisler[2];
[1]University of Bergen, Bergen, Norway, [2]Akershus University Hospital, Lorenskog, Norway

The presence of germline pathogenic variants in *CDKN2A* is a well-established underlying cause of familial malignant melanoma. While pathogenic variants in several other genes have also been linked to melanoma development, many familial cases remain unexplained. We analyzed for pathogenic germline variants in a panel of 360 cancer related genes in a set of 56 Norwegian melanoma prone families. The index cases and families were selected based on familial history of melanoma and/or multiple primary melanomas in the same individual, along with previous negative tests for pathogenic *CDKN2A* variants. We found 6 out of 56 index individuals to carry germline pathogenic or likely pathogenic variants. These variants were found in *BRCA2*, *MRE11*, *ATM*, *MSH2*, *CHEK2* and *AR*. In addition, one family member with a melanoma diagnosis (not index case) carried a pathogenic variant in *MAP3K6*. In genes typically linked to xeroderma pigmentosum, we found a high fraction of variants previously considered benign and/or as variants of uncertain significance. In particular the XPC^{L48F} variant was found in 8 out of 56 indexes, thus, the allele fraction (0.07) was significantly higher than in comparable healthy populations (p-values from 0.007 to 0.014). Similarly, we found presumed benign or uncertain variants in *MC1R* to be significantly enriched or numerically higher in index cases versus comparable healthy populations (p-values from 0.009 to 0.1). The common $MC1R^{Arg151Cys}$ variant was highly enriched in our cohort (p=0.001).In conclusion, we found that several melanoma prone families harbored pathogenic variants in genes not usually linked to melanoma.

#5051 Evolutionary characterization and refinement of copy-number high endometrial carcinoma.

C. J. H. Kramer[1], D. Ruano[1], A. Hawari[2], F. Blanc-Durand[3], C. D. de Kroon[1], J. R. Kroep[1], G. Ortoft[4], E. Hogdall[5], A. Leary[3], C. L. Creutzberg[1], M. P. G. Vreeswijk[1], N. Horeweg[1], D. N. Church[6], D. C. Wedge[2], T. Bosse[1];

[1]Leiden University Medical Center (LUMC), Leiden, Netherlands, [2]Manchester Cancer Research Centre, Manchester University, Manchester, United Kingdom, [3]Institute Gustave Roussy, Villejuif, France, [4]Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, [5]Copenhagen University Hospital, Herlev and Gentofte Hospital, Copenhagen, Denmark, [6]University of Oxford, Oxford, United Kingdom

Copy-number (CN)-high endometrial carcinoma (EC) is characterized by abundant CN-alterations, thought to be driven by *TP53* aberrations, and is the subgroup with the poorest prognosis. CN-high EC exhibit substantial heterogeneity in histotypes, molecular markers, and mutational profiles. Here, we aimed to refine this subgroup by assessing the evolution and identifying CN-signatures (Drews et al. Nature) to establish CN-clusters. We used whole-genome sequencing (WGS;100X) data from 146 CN-high cases from Genomics England (GeL) as discovery cohort. We then performed shallow WGS (sWGS;0.1X) of FFPE tumor DNA of *n*=307 CN-high EC from (non-)trial cohorts. Timing of canonical driver mutations by MutationTimer in CN-high GeL revealed that *TP53* mutations were: (i) not ubiquitous and (ii) not consistently identified as early clonal events (Table), challenging conventional belief that *TP53* inactivation is necessary for initiation of CN-high EC. Evolutionary analyses (Plackett-Luce) are ongoing to identify carcinogenesis trajectories and assess how driver mutations other than *TP53* influence CN-phenotypes. Unsupervised clustering of 307 EC by CN-signatures identified five clusters (E1: 19%; E2: 2%; E3: 20%; E4: 19%; E5: 40%), characterized by CN-signatures linked to biological phenomena. Clusters E1/E4 reflect homologous recombination deficiency (CX3), while cluster E5 seems driven by chromosomal missegregation (CX1). Notably, there was no one-to-one relationship between CN-clusters and histotypes, suggesting CN-evolution is independent of morphology. In conclusion, we have identified *TP53*-dependent and -independent pathways in CN-high EC evolution. Potentially clinically relevant CN-clusters were identified using cost-effective sWGS. sWGS of additional *n*=475 CN-high EC are ongoing. Furthermore, we will analyze in-depth clinicopathological relationships of clusters, including prognosis/prediction, using PORTEC trials prior to the meeting.

Table. Timing of canonical driver mutations in CN-high EC

	Clonal - early	Clonal - late	Subclonal	Clonal - NA	Total
1. *TP53*	87 (67%)	4 (3%)	3 (2%)	36 (28%)	130 (100%)
2. *PIK3CA*	42 (76%)	1 (2%)	1 (2%)	11 (20%)	55 (100%)
3. *PPP2R1A*	18 (47%)	1 (3%)	2 (5%)	17 (45%)	38 (100%)
4. *PTEN*	17 (59%)	1 (3%)	2 (7%)	9 (31%)	29 (100%)
5. *PIK3R1*	11 (46%)	0 (0%)	3 (13%)	10 (42%)	24 (100%)
6. *FBXW7*	14 (61%)	0 (0%)	0 (0%)	9 (39%)	23 (100%)
7. *KRAS*	9 (64%)	0 (0%)	2 (14%)	3 (21%)	14 (100%)
Abbreviation: NA, timing not applicable.					

#5052 Novel drug resistance mechanisms and drug targets in *BRAF* mutated peritoneal metastasis from colorectal cancer.

C. Lund-Andersen[1], A. Torgunrud[1], C. Kanduri[2], V. J. Dagenborg[1], I. S. Froysnes[1], M. M. Larsen[2], B. Davidson[1], S. Larsen[1], K. Flatmark[1];
[1]Norwegian Radium Hospital, Oslo University Hospital, Oslo, Norway, [2]University of Oslo, Oslo, Norway

Objective: Patients with peritoneal metastasis (PM) from colorectal cancer (CRC) have inferior prognosis and respond poorly to chemotherapy compared to other metastatic locations. This study aims to identify the molecular explanation for the observed clinical behavior and suggest novel treatment strategies in PM-CRC.

Design: Tumor samples from a Norwegian national cohort of 230 patients undergoing surgery and hyperthermic intraperitoneal chemotherapy (HIPEC) with mitomycin C (MMC) for PM-CRC were subjected to targeted DNA sequencing, and associations between molecular findings and clinical data were analyzed. mRNA sequencing was conducted on a subset of thirty samples to compare gene expression in tumors harboring mutations in the *BRAF* or *KRAS* oncogenes and wild-type tumors.

Results: Almost one-third of the patients had mutations in the *BRAF* oncogene, which were associated with *RNF43*/R-Spondin aberrations and low expression of negative Wnt regulators (ligand dependent Wnt activation). This molecular profile, with high abundance in PM, could be an underlying mechanism promoting aggressive tumor biology that facilitates metastasis to the peritoneal cavity, and could contribute to the observed poor overall survival of this patient subgroup. *BRAF* mutations were also associated with gene expression changes in transport solute carrier proteins and drug metabolism enzymes that could influence the efficacy of MMC and irinotecan, commonly used in PM-CRC treatment. *BRAF*-mutated tumors exhibited increased expression of BTN immune checkpoint molecules, and targeting these checkpoints in addition to ligand dependent Wnt activation could be two novel targeted therapy approaches.

Conclusion: *BRAF* mutations were associated with particularly poor survival in this cohort, possibly related to altered drug transport and metabolism conferring resistance to MMC and irinotecan. Two potential novel therapeutic approaches were identified, suggesting specific targeting of BTN immune checkpoint molecules and the use of inhibitors to target ligand-dependent Wnt activation.

#5053 Clinicopathologic and molecular genetic features of STAT3-mutated myeloid neoplasms.

M. T. Ye, Z. Zuo, S. Calin, F. Ye, H. He, W. Kamata, M. You;
UT MD Anderson Cancer Center, Houston, TX

STAT3 is a key transcription factor that can mediate cancer progression through phosphorylation or gain-of-function mutations. *STAT3* mutations have been mainly associated with large granular lymphocytic T-cell leukemia. Whereas STAT3 activation is common in myeloid neoplasms, it is primarily mediated through STAT3 phosphorylation. *STAT3* mutation has only rarely been reported in myeloid neoplasms. We assessed the clinicopathologic and molecular genetic features of 32 *STAT3*-mutated myeloid neoplasms. Twenty (62.5%) cases were classified as acute myeloid leukemia (AML), 7 (21.9%) as myelodysplastic syndrome (MDS), and 5 (15.6%) as chronic myelomonocytic leukemia (CMML). It is of note that *STAT3* mutation was not detected in myeloproliferative neoplasms (MPN). *STAT3* mutations were detected at the initial diagnosis in 22 of 25 (88%) cases, suggesting *STAT3* mutation is an early event in pathogenesis. However, *STAT3* mutations represented the dominant clone in only 6 (18.8%) cases, all classified as AML. Most are missense mutations, located at the SH2 domain. The median variant allele frequencies were 6.8%, 4.6% and 3.1% for AML, MDS and CMML, respectively, and in a case of CMML, the VAF increased from 2.4% to 34.8% upon leukemic transformation. *STAT3* mutation was accompanied by co-existing mutations in all cases, with *SRSF2* (40.6%), *TET2* (40.6%), *ASXL1* (37.5%), and *SETBP1* (34.4%) being most common. Cases with *STAT3* mutations were usually associated with morphologic dysplasia and increased blasts. Monosomy 7/del7q was the most common cytogenetic abnormality, seen in 11 (34.4%) cases. With a median follow-up of 24.5 months, 21 patients died, 6 had persistent disease, and 5 achieved complete remission. We summarize that *STAT3* mutation is present in a variety of myeloid neoplasms, but not seen in MPN. It is often an early events and always with concurrent mutations. It may play an important role in the pathogenesis and progression of myeloid neoplasms by activating JAK-STAT pathway, and may serve as a potential therapeutic target.

#5054 Optimization and evaluation of an FFPE dual extraction protocol for next-generation sequencing applications.

R. Hong[1], J. Chu[2], S. Hsiao[1], D. Whang[1], S. P. Rivera[2], H. Xie[1], J. Guo[2];
[1]NeoGenomics, San Diego, CA, [2]NeoGenomics, Aliso Viejo, CA

Formalin-fixed paraffin-embedded (FFPE) biopsies are highly valuable and widely used tissue specimens for clinical diagnostics. However, obtaining sufficient and high-quality nucleic acid material from limited FFPE samples presents a challenge for downstream molecular analysis, such as next-generation sequencing (NGS). We present an optimized sequential extraction method that generates high-quality DNA and RNA from a single set of input tissues that is automatable and operation-friendly. This workflow performs well with reduced FFPE tissue input and efficiently supports various high-throughput clinical NGS applications. The DNA/RNA yield, quality, purity, and impacts on NGS assay performances were on par or better than an existing validated comparator extraction method. With comparable FFPE input, the new method demonstrated a superior extraction performance with significantly higher yield, quality, and purity. For DNA, NGS libraries were made with two different library preparation methods: a TA-ligation-based method and a single-strand-based method, followed by hybrid capturing and sequencing. The DNA from the new extraction method demonstrated a superior library conversion rate and improved target enrichment uniformity with both chemistries. This provides the potential of reduced input requirements, allowing very limited tissue, such as fine needle aspirate or core needle biopsy, for clinical NGS testing. The sequencing results were highly concordant between the existing and new extraction methods when the extracted DNA was subjected to a validated comprehensive genomic profiling (CGP) clinical test, demonstrating the quality and robustness of the extraction. For RNA, NGS libraries were made following the validated CGP clinical test with hybrid capturing, and the results were comparable between the two extraction methods. In conclusion, an FFPE extraction method was optimized to allow more clinical biopsy samples to be tested with different NGS workflows, providing a better diagnostic value for patient care.

#5055 Genetic background of recurrent uterine leiomyomas.

S. Khamaiseh[1], A. Ayravainen[1], M. Arffman[1], S. Reinikka[1], A. Pasanen[1], R. Butzow[1], P. Harkki[2], P. Vahteristo[1];
[1]University of Helsinki, Helsinki, Finland, [2]Helsinki University Hospital, Helsinki, Finland

Uterine leiomyomas, also known as fibroids, are common benign smooth muscle tumors in women of reproductive age. Leiomyomas can cause symptoms that can significantly reduce the quality of life. Treatment mainly involves hysterectomy or myomectomy, the latter for women who wish to preserve their uterus. Most leiomyomas harbor one of the three driver mutations affecting either *MED12*, *HMGA2*, or *FH*. Recently identified rare subtypes include tumors with mutations in genes linked to the neddylation of the Cullin 3-RING E3 ligase or SRCAP complex. Recurrence of leiomyomas is poorly understood in relation to their clonal origins and molecular factors. The aim of this study was to characterize the mutational profiles of leiomyomas from recurrent operations and to identify the frequency of clonally related tumors. We utilized a retrospective cohort of 234 women who underwent laparoscopic or open abdominal myomectomy, with 46 (20%) of them experiencing multiple procedures related to leiomyomas. We examined the mutation profiles of 133 leiomyomas (62 index and 71 recurrent tumors) from 33 patients who required multiple tumor removal surgeries. We screened the tumors for the three primary leiomyoma drivers—*MED12* mutations, HMGA2 overexpression, and FH-deficiency—to identify potentially clonal tumors. We found that 21 out of 33 (64%) patients had tumors from multiple operations with identical leiomyoma driver alterations. To further assess the clonal relationship, we executed whole exome sequencing on these 52 tumors. We identified three patients with two clonally related tumors each through shared somatic copy number alterations and point mutations. The clonally related tumors included HMGA2, FH, and wild-type tumors. Notably, leiomyomas with *MED12* mutations—the most common molecular leiomyoma subtype—were not found among the clonally related tumors. Three patients harbored numerous FH-deficient tumors from recurrent operations. In all those patients, we found *FH* germline mutations, characteristic of Hereditary Leiomyomatosis and Renal Cell Cancer syndrome (HLRCC). Moreover, we identified somatic mutations in *YEATS4*, a member of the SRCAP complex, in four recurrent tumors from three patients. Interestingly, all *YEATS4* mutations were different, and the tumors were not clonally related. Further research is required to elucidate the role of *YEATS4* in leiomyoma recurrence. In conclusion, our systematic study confirms that reinterventions are common after myomectomy, and while uterine leiomyomas typically develop independently, some share a clonal origin. Additionally, we show that recurrence may be due to genetic predispositions, such as germline *FH* mutations.

#5056 Molecular characterization of microsatellite stable (MSS) colorectal cancer (CRC) patients with a BRAF V600E mutation.

Y. van der Pol[1], B. Yilma[1], V. K. Morris[2], C. Chao[1], M. Harris[1], J. Guinney[1], S. Kopetz[2];
[1]Tempus Labs, Chicago, IL, [2]MD Anderson Cancer Center, Houston, TX

Introduction: A $BRAF^{V600E}$ mutation is an unfavorable prognostic biomarker for CRC and is associated with short-lived treatment response to BRAF and EGFR blockade. Anti-PD-1 therapies are ineffective in MSS CRC but demonstrate efficacy in combination with BRAF + EGFR inhibition for MSS $BRAF^{V600E}$ CRC. A comprehensive characterization of MSS $BRAF^{V600E}$ CRC as an immunologically distinct subpopulation of MSS CRC has not been performed. Here, we characterize the clinicopathological and transcriptomic features of MSS $BRAF^{V600E}$ CRC patients, relative to $BRAF^{WT}$ MSS CRC patients.Methods: De-identified records of 12,009 MSS CRC patients were retrospectively analyzed from the Tempus clinicogenomic database. CMS subtypes were derived using the CMScaller algorithm. Survival was assessed using Kaplan-Meier survival analysis with risk set adjustment (RSA) method; log-rank test was used to compare survival. Categorical and continuous variables were compared using chi-squared test and Wilcoxon rank sum test, respectively.
Results: $BRAF^{V600E}$ was found in 5% (n=630) of the patients. Demographics and clinicopathological features varied significantly between the $BRAF^{WT}$ and $BRAF^{V600E}$ cohorts (Table 1). Relative to the $BRAF^{WT}$ cohort, $BRAF^{V600E}$ tumors were enriched for the immune-activated CMS1 signature (53% vs 11%, p< .001), PD-L1 detection (9.5% vs 3%, p<0.001), and CD8+ T-cell infiltration (4.6% vs. 2.5%, p<0.001). CMS4 was linked to an unfavorable prognosis in the $BRAF^{WT}$ cohort (HR=0.58 compared to CMS1, p=0.026), yet this was not observed in the $BRAF^{V600E}$ cohort (HR=2.60 compared to CMS1, p=0.083).
Conclusions: $BRAF^{V600E}$ MSS CRC exhibited immune activation characteristics that were not observed in the $BRAF^{WT}$ group, including greater CMS1 status, PD-L1 expression, and CD8-T cell infiltration. Our findings support investigation of novel immune-based therapeutic strategies of MSS $BRAF^{V600E}$ CRC as an immunologically distinct subpopulation of MSS CRC.

Cohort characteristics

			$BRAF^{WT}$	$BRAF^{V600E}$	P-value
Demographics	Age (median)		60 (51,69)	65 (55,74)	<0.001
	Ethnicity	Not Hispanic or Latino	3,444 (83%)	200 (93%)	0.001
		Hispanic or Latino	699 (17%)	16 (7.4%)	
	Gender	Female	4,771 (42%)	345 (55%)	<0.001
		Male	6,608 (58%)	285 (45%)	
	Race	White	5,050 (75%)	318 (87%)	<0.001
		Black or African American	888 (13%)	19 (5.2%)	
		Other	517 (7.7%)	20 (5.4%)	
		Asian	297 (4.4%)	10 (2.7%)

#5057 microRNA profiling in combination with whole exome sequencing reveals insights into long-term recurrence patterns in chordoma.

S. R. Ullmann[1], F. Karras[1], J. Schreier[1], K. Korber-Ferl[2], D. A. Ullmann[3], S. Franke[1], A. Roessner[1], D. Jechorek[1];

[1]Otto von Guericke Univ. of Madgeburg, Magdeburg, Germany, [2]Martin-Luther-Universitat Halle-Wittenberg, Halle, Germany, [3]Berufgenossenschaftliches Universitatsklinikum Bergmannsheil Bochum, Bochum, Germany

While few studies on miRNA profiling in primary chordomas have been published, there is no data on the miRNA landscape of long-term recurrences. Therefore, we performed a miRNA analysis and whole exome sequencing (WES) investigating four patients with multiple recurrences over seven to 16 years and eight patients with non-recurrent tumors (NRTs), conventional, sacral chordomas in order to compare both groups as well as the recurrence cases (RCs) to each other. Our aim was to find typical miRNA patterns distinguishing the recurrences from the NRTs. After histopathological classification, immunohistochemical and morphometric analysis, DNA and miRNA were extracted from formalin-fixed-paraffin-embedded tissue samples and analyzed by WES and Nanostring. The microRNA regulation patterns showed similarities within RCs differing from NRTs. In unsupervised clustering there is a tendency of recurrences clustering apart from the NRTs. The differential expression between cases developing recurrences and NRTs showed highly significant differences between both groups with 32 miRNAs upregulated in the RCs being downregulated in NRTs. The miRNA expression of long-term recurrences of each patient are quite homogenous differing only from their primary tumor. Comparing NRTs with primary tumors that would later develop long-term recurrences showed significant up-regulation of 5 miRNAs in the RCs. This suggests a pivotal molecular difference between singular and long-term recurring chordomas. Our WES analysis confirmed known and revealed possible new driver genes. Recurring tumors had a higher number of mutations classified as pathogenic as well as increased proliferation rates and pleomorphic changes. Recurrences displayed a change in mutational distribution, showing considerably more disturbances in embryonic signaling and our proposed driver genes. Intriguingly, our study found a progress in number of alterations throughout the recurrences most of all affecting chromatin regulation and the new drivers.

Less disruption of these pathways in primary cases than in recurrences implies their pivotal role not only in chordoma formation, but also in recurrence evolution. The miRNA alterations were correlated with the genomic differences. Validated affected genes of miRNAs deregulated primarily in the recurrences are involved in those pathways as well. As current targeted therapy options are only sporadically altered in few patients, the progress in number of pathogenic mutations throughout the recurrences as well as the drastic change in miRNA expression could present new research approaches for chordomas with long-term recurrences. Combined clinical and molecular studies of miRNA patterns and genetic alterations could expand the understanding of recurrence development leading to new therapeutic targets inhibiting or delaying recurrence formation.

#5058 Genomic alterations predictive of outcome in early staged cervical cancer: *A translational investigation from the SENTICOL III trial*.

M. El Gani[1], S. Ibadioune[2], Z. El Beaino[3], A. Hamza[2], S. Vacher[2], E. Jeannot[2], J. Masliah-Planchon[2], A. Salomon[2], A. Degnieau[2], A.-S. Bats[4], M. Koskas[5], V. Fourchotte[2], E. Wafo[6], N. Bourdel[7], R. Fauvet[8], M. Plante[1], P. Mathevet[9], **M. Kamal**[2], F. Lecuru[10], I. Bieche[2];

[1]CHU de Quebec, Universite Laval, Quebec, QC, Canada, [2]Institut Curie, Paris, France, [3]Hopital St Joseph, Paris, France, [4]Hopital Europeen Georges Pompidou, Paris, France, [5]Hopital Bichat Claude Bernard, Paris, France, [6]Grand Hopital de l'Est Francilien, Jossigny, France, [7]CHU Estaing, Clermont Ferrand, France, [8]CHU Cote de Nacre, Caen, France, [9]CHUV - Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, [10]Universite Paris, Institut Curie, Paris, France

Background: The risk of relapse in patients with early-stage cervical cancer (ESCC) ranges from 4-14% (LACC study). Risk-factors for recurrence are mainly derived from histopathological factors. Senticol III is a large multicenter international randomized prospective study aims to validate sentinel lymph node biopsy in the surgical management of ESCC. Our objective is to characterize prognostic and actionable biomarkers in ESCC.

Methods: FFPE-fixed tumoral slides of the first 150 randomized patients were analyzed based on SEDLIS criteria. We characterized TIL's infiltration, PD-L1 expression and HPV status. Sequencing of tumor DNA was carried out using an in-house targeted next-generation sequencing panel (571 genes). Relapse-free survival (RFS) was defined as the time between randomization and relapse of any type. We performed Fisher's exact test and Student's t-test to compare distributions of categorical variables and Log Rank test.

Results: The sequencing quality control criteria were met for 135 samples. *PIK3CA* was the most commonly altered gene (17%). Loss-of-function variants in *KMT2*-family genes (*KTM2C* 9%, *KMT2D* 6%, *KMT2A* 1%) were found in 16% of samples. The loss-of-function variant of *ARID1A* was mostly non-sense mutation (6%). Activations of *ERBB2* (5%) were 3 focal amplifications and 4 hotspot missense mutations. Two samples were found to have microsatellite instability due to an alteration of *MLH1*. The Pik3/AKT/mTOR (26%) and the chromatin remodeling (23%) pathways were the most altered pathways. The median follow-up period was 20 months. There were 6 relapses, of which 80% were considered as low risk based on SEDLIS criteria. Recurrences were local and occurred 9-23 months following surgery. Multiparity was the only clinical feature associated with RFS ($p < 0,001$). Tumor size, histological subtypes, PD-L1 status, number of TIL's, presence or absence of lymphovascular emboli and deep stromal invasion were not associated with RFS in our cohort.*KMT2C* ($p=0,018$) and *ARID1A* ($p < 0,001$) pathogen variants were significantly associated with RFS. The pathway chromatin remodeling ($p=0,063$) showed a trend toward association with RFS. We found 32% of genomic alterations actionable for a target therapy including mutations of PIK3CA, ERBB2, ARID1A, PTEN, BRCA2, KRAS, BRAF, CDK12, FGFR2, NF1, AKT1, BRCA1, TP53 and MSI-high.

Conclusion: Our prospective, randomized and multicentric study suggests a genomic profile from a homogeneous cohort of 150 patients. We identified genes involved in chromatin remodeling (*ARID1A* and *KMT2C*) as prognostic biomarkers of clinical interest and suggesting the relevance of epidrugs in ESCC. Theranostic annotations of variants identify a matched to target therapy for 32% of alterations. Those targets represent multiple tracks for personalized therapy in ESCC.

#5059 Robust single sample consensus molecular subtype classification for primary and metastatic colorectal cancer.

A. J. Sedgewick, T. Chandra, T. Taxter, J. Guinney;
Tempus Labs, Chicago, IL

Introduction Consensus Molecular Subtypes (CMS) represent a well-established molecular stratification framework for colorectal cancer (CRC). Existing methods for CMS classification rely on a representative input cohort as a preprocessing step (CMScaller) or have difficulty generalizing to metastatic samples (CMSclassifier). We developed Tempus CMS to overcome these limitations. Our method normalizes gene expression data from input samples to a static reference cohort to enable single sample classification of both primary and metastatic tumors. We evaluated the performance of this classifier on a large, de-identified CRC cohort comprising 8,489 samples from primary and metastatic sites.

Methods To normalize input data, our method shifts and scales each gene expression value based on the mean and standard deviation of the expression of that gene in the reference cohort (n=2,787 primary and metastatic CRC). CMS calls are then generated via nearest template prediction similar to CMScaller (Eide et al., 2017). The analysis cohort was selected from clinical biopsies within 30 days of primary or metastatic diagnosis excluding reference cohort samples. CMS calls were assessed by comparing subtype prevalence to reported rates and by testing for known enrichments of pathways and genomic markers.

Results Subtype prevalences for lower gastrointestinal (GI) biopsies and resections (n=5,090) were comparable to reported rates for primary CRC tumors: CMS1 - 12%, CMS2 - 28%, CMS3 - 19%, and CMS4 - 33% with 7.6% no calls. Biopsies from metastatic tissue showed site-specific changes in prevalence: CMS2 increased to 43% in liver samples (n=1,715) and CMS4 was identified in 49% of samples from metastatic sites excluding the liver (n=1,684). In addition, we found that purity had an effect on prevalence: in lower GI tumors with ≥ 50% tumor purity rates of CMS2 and CMS4 were 34% and 26%, respectively, while rates in tumors with purity between 20% and 50% were 20% CMS2 and 41% CMS4.

Across all tissue groups, pathway enrichment showed significant associations, including TGF-□ signaling in CMS4 (adj *P* ≤ 4.4e-15) and cell differentiation in CMS3 (adj *P* ≤ 3.0e-27). Expected enrichments of CMS markers were also observed: *BRAF* mutations and microsatellite instability in CMS1 and *KRAS* mutations in CMS3. In liver tissue, higher *KRAS* mutation rates were noted in CMS1 (57%) and CMS3 (83%) compared to GI tissue (35% and 67%, respectively).

Conclusions In this study, we developed an enhanced, single sample CMS-calling algorithm optimized for primary and metastatic sites. Application of this algorithm in a large cohort recapitulated known biology, which suggests that the tool can be used to support clinical studies requiring robust molecular stratification.

#5060 Role of molecular driver mutations in recurrence of early stage laryngeal cancer following narrow field definitive radiotherapy.

Aaron Segura[1], Emily Nissen[2], Chris Lominska[3], Ryan Morse[4], Deri Morgan[3], Prakash Neupane[5], Dong Pei[2], Devin Koestler[2], Randall Kimple[6], Umamaheswar Duvvuri[7], Kevin Sykes[8], Sufi Thomas[8], Rohit Nallani[8], Lisa Shnayder[8], Kiran Kakarala[8], Andres Bur[8], Emrullah Yilmaz[9], Gregory Gan[10]

[1]Department of Internal Medicine, Division of Radiation Oncology, University of New Mexico Health Sciences Ctr., Albuquerque, NM,[2]Department of Biostatistics & Data Science, University of Kansas Medical Center, Kansas City, KS,[3]Department of Radiation Oncology, University of Kansas Medical Center, Kansas City, KS,[4]Department of Radiation Oncology, University of North Carolina, Chapel Hill, NC,[5]Division of Medical Oncology, Department of Internal Medicine, University of Kansas Medical Center, Albuquerque, KS,[6]Deparment of Human Oncology, University of Wisconsin School of Medicine and Public Health, Madison, WI,[7]Department of Otolaryngology, Head and Neck Surgery, NYU Grossman School of Medicine, New York, NY,[8]Department of Otolaryngology, Head & Neck Surgery, University of Kansas, Kansas City, KS,[9]Department of Hematology and Medical Oncolgy, Cleveland Clinic, Cleveland, OH,[10]University of Kansas Cancer Center, Kansas City, KS

PURPOSE/OBJECTIVES

Recurrent early-stage laryngeal cancer poses profound clinical and prognostic dilemmas. The primary endpoint of this study was to identify patient exome differences between early-stage laryngeal cancer patients who responded or rapidly progressed following definitive, narrow field radiotherapy. Our study offers the first exploration of mutation patterns in early-stage laryngeal head and neck squamous cell carcinoma (HNSCC) patients receiving curative radiation therapy.

MATERIALS/METHODS

We identified 36 early-stage laryngeal (T1 = 8, T1a = 4, T1b = 2, T1c = 1, T2 = 20, NA =1) HNSCC patients from the University of Kansas Medical Center treated with definitive narrow field radiotherapy to 63-70 Gray (gy) dose. Whole exome sequencing was performed in all patients. Patients were stratified into “responders” (never failed, N=14) and “non-responders” (recurrence <12 months, N=21). Most non-responder patients with local recurrence underwent total salvage laryngectomy (TSL, N=18). All patients underwent whole exome sequencing. The Genome Analysis Toolkit (GATK) was used for pre-processing and functional annotation of variants. Cancer driver genes were detected for each group using the OncodriveCLUST algorithm. Differentially mutated genes were assessed using Fisher’s exact or exact McNemar’s test at $P < 0.05$. Tumor mutational burden (TMB) comparisons employed the Wilcoxon rank-sum test with the same threshold. For pathway analysis in Reactome and Ingenuity, a $P < 0.1$ was used for exploratory significance.

RESULTS

Mutation analysis identified distinct cancer driver genes between responders, (N=3), non-responders (N=36), and post-TSL (N=4). Among 75 genes with significant pre-treatment mutation differences between responders and non-responders, KCNT2 and AGAP6 were exclusively mutated in non-responders (OR=0, P=0.005 and OR=0, P=0.027, respectively). ADAMTS7 was solely mutated in responders (OR=inf, P=0.019), and PLEC showed more mutations in responders (OR=11.6, P=0.006). Pathway analysis showed these genes were involved in the RND2 GTPase cycle, protein O-glycosylation related diseases, and apoptotic pathways. Post-treatment analysis indicated an enrichment of mutations in apoptosis regulation pathways, with genes like PLEC being more frequently mutated in responders than in non-responders or TSL patients. In addition, we observed in non-responders that they trended towards higher median pre-treatment TMB compared to responders (7.98 vs 6.16, P=0.072). There was no significant difference in TMB between TSL patients and responders or non-responders pre-treatment.

CONCLUSION

Our analysis reveals distinct mutation patterns in early-stage laryngeal cancer patients by response to radiotherapy and the potential role of these mutated genes in apoptosis related pathways.

#5061 Improved survival and unique mutational signatures in small cell lung cancer arising in patients with limited tobacco use.

K. Concannon[1], M. Sahu[2], W. Lewis[1], H. Tran[1], L. Diao[1], Y. Xi[1], B. Morris[1], S. Heeke[1], X. Tang[1], J. Stewart[1], I. Valiev[3], G. Raso[1], J. Wang[1], K. Sasaki[1], C. Gay[1], J. Heymach[1], L. Byers[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]The University of Texas Health San Antonio Long School of Medicine, Houston, TX, [3]BostonGene LLC, Waltham, MA

Small-cell lung cancer (SCLC) remains the deadliest histologic lung cancer subtype with a median survival of only 12.3 months among trial-eligible patients with extensive-stage (ES-SCLC) disease, as demonstrated in the IMPower133 trial. Heavy tobacco use, >40 pack-years, is strongly associated with developing SCLC, which near universally harbors *RB1* and *TP53* co-mutations. However, there is a paucity of information regarding SCLC tumors that occur in patients with minimal tobacco use. This represents an unmet need given an increasing appreciation for low pack-year and never-smoker SCLC with some studies, like the CAPSTONE-1 trial, demonstrating an incidence of never-smoking SCLC >20%. To address this, we clinically characterized the treatments and outcomes of a 164 SCLC patient cohort with ≤10 pack year smoking histories treated at the University of Texas MD Anderson Cancer Center; 22 of which underwent whole-exome sequencing (WES).

The overall survival of limited-stage (LS-SCLC) and extensive-stage (ES-SCLC) disease in the low pack-year cohort were 33.6 and 16.6 months, respectively (P=0.003); superior to historic medians of roughly 17.0 and 12.3 months, respectively. Among those with ES-SCLC, those who reported 1-10 pack-years had significantly improved median overall survival as compared to never-smokers; 19.5 vs 15.8 months, respectively (P=0.02). This trend was observed in LS-SCLC as well with 1-10 pack-year and never-smokers demonstrating median overall survivals of 88.6 vs 26.2 months, respectively (P=0.2). Demographic differences including age were similar across these cohorts.

WES of tumors from 22 patients demonstrated significantly fewer mutations in *RB1* and *TP53* than was observed in previously reported cohorts of SCLC from smokers. Among the low-pack year cohort, 7/22 (32% vs 98.2%:P<0.001) harbored an *RB1* alteration, 7/22 (32% vs 90.9%: P<0.001) harbored a *TP53* mutation, and 4/22 (18% vs 90.9%: P<0.001) had co-occurring *RB1/TP53* mutations. No patients harbored mutations in *EGFR, HER2*, or *RET*. Mutations in potentially targetable pathways were observed throughout the cohort including the DNA-damage repair pathways, RTK/RAS, and PI3K.

Taken together, these data demonstrate that patients with low pack-year SCLC have improved overall survival compared to historic averages for SCLC patients with a history of heavy tobacco use. Paradoxically, however, light-smokers with SCLC live longer than never-smokers, and these patients may harbor a higher frequency of targetable alterations than typical SCLC patients, highlighting the importance of molecular profiling in SCLC patients with minimal tobacco use.

#5062 Evaluation of genetic mutations in non-small cell lung cancer patients.

M. Rothstein[1], P. Broughton[1], E. Markalunas[2], A. Funkhouser[1], L. Allen[3], J. Martin[3], W. Edenfield[3], A. V. Blenda[1];
[1]Univ. of South Carolina School of Medicine Greenville, Greenville, SC, [2]Brown University, Providence, RI, [3]Prisma Health, Greenville, SC

Lung cancers represent the second most common cancer and Non-Small Cell Lung Cancer (NSCLC) constitutes 80-85% of all lung cancers. Genes within several cellular pathways have been previously evaluated for their clinical impact in NSCLC. In this investigation, we evaluate genetic mutations found in 50 cancer-critical genes implicated in the signaling pathways RTK/RAS/MAP, TGFβ, PI3K, Wnt, GPCR, p53, JAK/STAT, Notch, and the cell cycle pathway. Some of these mutations have not yet been described or have not been described in NSCLC. The intent of our study is to evaluate these mutations and allow further research into their impact, specifically highlighting mutations that are involved in clinically important pathways.

We evaluated mutations found in 59 NSCLC patients at the Prisma Health Cancer Institute. These mutations are part of 2,800 COSMIC (Catalogue of Somatic Mutations in Cancer) hotspot mutations in 50 cancer-critical genes. Each mutation was investigated further using the ClinVar database to identify whether it had been described in NSCLC or other cancers/conditions, its genetic consequence, pathogenesis, possible variations, and origin.

A total of 73 unique mutations in 59 NSCLC patients were evaluated. Of the 73 mutations, 17 had not been described at all, 40 had been described in other cancers/conditions, and 16 had been previously described in NSCLC. The known mutations' effects in other cancers/conditions were categorized as pathogenic, likely pathogenic, likely benign, benign, or uncertain. Novel mutations were found in genes that provide a druggable target, help predict treatment response, are under investigation for their ability to predict treatment response or confer additional clinical utility.

Medical management of cancer has benefitted greatly from studies of genetic mutations. Most mutations identified in our patient population had not been described in NSCLC, and a smaller number of those had not been described at all. Further elucidation of these mutations may lead to additional discoveries relevant to NSCLC prognostication and treatment.

#5063 Exploring the mutational landscape of *KRAS* and *NRAS* in tumors with non-V600 *BRAF* mutations.

C. L. Mukonoweshuro, E. Rousselle, A. A. N. Rose;
Lady Davis Institute at Jewish General Hospital, Montreal, QC, Canada

Background: BRAF, a key modulator of the Mitogen-Activated Protein Kinase (MAPK) pathway, is observed in 7% of all cancers. Therapeutic response to MAPK inhibition (MAPKi) often relies on molecular distinctions between members of varying classes: Class 1 (V600), Class 2 and 3 (non-V600) BRAF mutants. Preliminary data indicates that co-occurring *RAS* mutations in non-V600 BRAF mutant cancers are less responsive to MAPKi treatment. This emphasizes the need to investigate the characteristics of *RAS* co-mutations in non-V600 BRAF mutant tumors.

Methods: Genomic data was obtained from a cohort of 183,292 patients provided by the AACR GENIE database (v14.1). Patient samples were clustered according to their *BRAF* mutation status and co-occurring *K/NRAS* mutations: WT BRAF (n=60,845) vs. non-V600 *BRAF* (n=1009). Samples were grouped based on cancer type: melanoma (n=3841), colorectal (n=15,434), and non-small cell lung cancer (n=14640) and were further categorized according to key biochemical features of RAS GTPase function and overall GTPase activity.

Results: This dataset revealed a diverse array of allelic variants of *K/NRAS* between cancer types and their underlying *BRAF* mutation status (Table 1). Non-V600 BRAF mutant cancers showed an enrichment for *KRAS* mutations linked to amplified nucleotide exchange (37.9% vs. 13.4%; p<0.0001) and hydrolysis-impairing *NRAS* mutations (41.9% vs. 23%; p<0.0001), compared to WT BRAF cancers. Rare allelic variants including *KRAS* L19F, *KRAS* A146T, and *NRAS* G60E were seen in Class 2/3 BRAF mutants.

Conclusion: This data suggests that non-V600 BRAF mutant tumors are characterized by a unique distribution of *RAS* mutations. More research into the difference in downstream effectors of *RAS* mutants overrepresented in non-V600 BRAF mutant tumors could provide important insights into how these tumors develop and resist targeted therapies.

Table 1. Classification of *KRAS* and *NRAS* mutations in WT BRAF vs. non-V600 BRAF mutant tumors

	Cancer Type		**All cancers**			**NSCLC**			**Colorectal**			**Melanoma**		
	BRAF mutation		**WT**	**non-V600**	**p-value**	**WT**	**non-V600**	**p-value**	**WT**	**non-V600**	**p-value**	**WT**	**non-V600**	**p-value**

#5064 Wild type *KRAS* amplification as *de novo* oncogenic driver in non-small cell lung cancer.

B. Ricciuti[1], S. V. Michelina[2], J. Alessi[1], X. Wang[3], F. Pecci[1], A. Di Federico[1], M. Gandhi[1], G. Lamberti[1], E. Patrucco[1], L. Sholl[1], A. Aguirre[1], C. Ambrogio[1], M. M. Awad[1];

[1]Dana-Farber Cancer Institute, Boston, MA, [2]University of Turin, Turin, MA, [3]Harvard T.H. Chan School of Public Health, Boston, MA

Introduction: Oncogenic *KRAS* mutations define subsets of non-small cell lung cancer (NSCLC) with unique clinicopathologic and genomic features, and the recent development of direct KRAS inhibitors has changed the treatment landscape of these patients (pts). However, whether *KRAS* amplification is oncogenic and defines unique subset of potentially targetable NSCLCs is currently unknown.

Methods: Clinicopathologic and genomic data were abstracted from multiple independent cohorts of NSCLCs which underwent tumor genomic profiling at the Dana-Farber Cancer Institute (Cohort 1), AACR-GENIE v.13, TCGA, and other 212 studies (Cohort 2). Whole transcriptome sequencing and quantitative proteomics data from the The Cancer Genome Atlas (TCGA) and the Cancer Cell Lines Encyclopedia (CCLE) were used to correlate *KRAS* amplification with KRAS RNA levels and protein expression. KRAS doxycycline-inducible models were generated to determine *in vitro* and *in vivo* oncogenicity of wild-type KRAS overexpression.

Results: Among 15,341 pts with NSCLC identified, *KRAS* amplification was identified in 355 (2.4%) cases. Compared to *KRAS* not amplified cases, pts with *KRAS* amplified NSCLC were more likely to be males (52.4% vs 45.6%, p=0.01), have a history of smoking (82.1% vs 64.2%, p<0.01), and higher median pack-years (35 vs 23.5, p<0.01). *KRAS* amplification was also associated with higher median aneuploidy levels (as fraction of genome altered) (30.4% vs 14.3%, p<0.01), tumor mutational burden (p<0.01), and increased median PD-L1 expression (20% vs 5%, p=0.01). KRAS amplified cases were enriched with *KRAS*, *POLE2*, *SLC34A2* and *PALB2* mutations, while *EGFR* mutations were mutually exclusive (Q<0.1). Among NSCLC samples with transcriptomic and proteomic profiling from the TCGA and CCLE cohorts, *KRAS* amplification was associated with significantly increased KRAS mRNA (p<0.01) and protein expression (p<0.01), compared to *KRAS* diploid samples. Among pts with clinical outcomes data available (N=9,335), median overall survival (OS) from the date of diagnosis was significantly shorter in pts with *KRAS* amplified vs *KRAS* diploid genotype in both KRAS mutant (HR: 0.71, P=0.02) and KRAS WT (HR: 0.74, P=0.02) NSCLCs. In KRAS doxycycline-inducible models (BEAS-2B cells) we demonstrated increased cell proliferation and MAPK activation upon doxycycline-induced KRAS expression. *In vivo*, sustained expression of KRAS in animals constantly fed with doxycycline-diet triggered tumor formation and development of metastasis, indicating that WT KRAS overexpression is oncogenic.

Conclusion: *KRAS* amplification defines a novel subset of NSCLCs characterized by distinct clinicopathologic and genomic features, and worse survival. Developing novel therapeutic strategies to target *KRAS* amplification may improve outcomes in pts with NSCLC.

#5065 Integrating blood based liquid biopsies with TNM stage improves survival prediction model for non-small cell lung cancer.

L. Schmalz[1], C. Urtis[1], L. Liu[1], E. Forbes[1], F.-C. Hsu[1], N. Steuerwald[2], A. de Hoyos[1], T. Lycan[1], J. Ruiz[1], W. Petty[1], W. Zhang[1];
[1]Atrium Health Wake Forest Baptist, Winston Salem, NC, [2]Levine Cancer Institute, Charlotte, NC

Introduction: Stage is the most important prognostic factor for survival in non-small cell lung cancer (NSCLC). The current TNM (Tumor, Node, Metastasis) staging system for NSCLC uses physical exam, histology, imaging, and surgical findings to define the extent and spread of a patient's cancer. Despite advances in molecular testing which can impact treatment and prognosis for NSCLC patients, the current system does not incorporate molecular data into staging. We proposed a novel predictive model for survival analysis which integrates molecular analysis of liquid biopsies (B) into the TNM staging system (1). In this study, we tested this new staging system and our predictive model shows TNM + B (TNMB) provides a better predictive model for survival compared to TNM alone.

Methods:176 patients were identified at Atrium Health Wake Forest Baptist with Guardant 360 liquid biopsies sent at diagnosis for NSCLC. Clinical data was obtained through retrospective chart review. Molecular analysis was performed on 81 genes across all Guardant 360 liquid biopsies. Using Cox proportional hazards model, we identified significant gene mutations or genes with significant magnitude of variant allele frequency (VAF) that improved survival prediction. We then designed a novel staging system incorporating whether a patient had a positive liquid biopsy test (B1), defined by the presence of these impact gene variables, to TNM stage.

Results: Three impact genes STK11 (p=0.0253), NFE2L2 (p = 0.0025), TP53 (p=0.0129) and one gene with a magnitude of VAF, ARID1A (p=0.0082) was identified which significantly improved the predictive model for survival. Patients with negative liquid biopsy test, B0, had improved survival compared to patients with a positive liquid biopsy test, B1 (p<0.005). In our cohort, TNM staging alone did not show a significant survival difference between stage II and III (p = 0.19). Whereas TNMB staging showed a significant survival difference between stage II, III and IV.

Conclusions: While TNM stage remains a major prognostic factor for NSCLC patients, it fails to incorporate molecular data which has a critical impact on management and prognosis. We designed a novel method to analyze molecular data obtained by liquid biopsy to identify significant gene mutations and gene magnitude of VAF that impacts survival prediction. In our cohort, we showed 4 impact genes which we used to create a new TNMB staging system which led to improved survival prediction compared to TNM alone.

#5066 Integrating spatial and single cell transcriptomics to identify and characterise biologically driven subgroups in invasive lobular carcinoma.

M. Serra[1], A. Papagiannis[1], M. Rediti[1], F. Lifrange[2], N. Occelli[1], L. Collet[1], D. Vincent[1], G. Rouas[1], D. Fimereli[1], L. Craciun[1], D. Larsimont[1], D. Venet[1], M. Vikkula[3], F. P. Duhoux[4], F. Rothe[1], C. Sotiriou[1];

[1]Institut Jules Bordet, Bruxelles, Belgium, [2]University Hospital Center of Liege, Liege, Belgium, [3]de Duve Institute, Universite Catholique de Louvain, Bruxelles, Belgium, [4]Institut Roi Albert II, Cliniques universitaires Saint-Luc and Institut de Recherche Experimentale et Clinique (pole MIRO), Bruxelles, Belgium

Background: Invasive lobular carcinoma (ILC) is the second most common histological breast cancer subtype; however, little is known about its tumor microenvironment (TME). Here, we aimed to identify and to characterise ILC subgroups based on TME heterogeneity by combining spatial transcriptomics (ST) and single cell RNA-sequencing (scRNA-seq).

Methods: We performed ST (Visium 10x Genomics) on frozen tumor samples from 41 primary hormone receptor positive (HR+), HER2-negative (HER2-) ILCs. Information coming from the morphological annotation of ST slides and the gene expression-based clustering of ST spots was integrated and used as input for a patient level classification (using intNMF algorithm). Subgroups of patients were annotated using morphology, gene set enrichment analysis and ST deconvolution based on scRNA-seq data (CARD software). SCAN-B bulk RNA-seq dataset was used as validation set (HR+, HER2- ILC samples, n = 853).

Results: Four subgroups of patients were identified: proliferative (P, n = 12, enriched in tumor cells and proliferation-related pathways), normal-stroma enriched (NSE, n = 10, enriched in fibroblasts, stroma-related pathways and showing an higher level of colocalization between invasive and in situ carcinoma), metabolic (M, n = 9, enriched in metabolic related-pathways) and metabolic-immune enriched (MIE, n = 10, enriched in adipocytes, metabolic and immune-related pathways). Deconvolution of ST spots with single cell data revealed matching results with morphology (in terms of cell types). We observed an enrichment of myofibroblasts in NSE, an enrichment of cancer epithelial in P and, interestingly, an enrichment of endothelial cells in M subgroup (fdr < 0.25). MIE was characterized by perivascular like-endothelial cells and myeloid cells (monocytes and macrophages, fdr < 0.25). Of note, at the level of the ST slide, myeloid cells in MIE subgroup were more present in the adipose tissue compartment (fdr < 0.25) compared to the rest of the slide. NSE subgroup showed a trend for association with better prognosis. Gene signature-based assignment identified the same four subgroups in SCAN-B: GSEA analysis and comparisons among the four subgroups showed matching results between our dataset and SCAN-B. Of note, in SCAN-B, we observed differences in prognosis among the subgroups, with NSE showing better, M and MIE intermediate and P worse prognosis for overall survival and relapse free interval (p < 0.01).

Conclusions: Four subgroups of ILC based on TME heterogeneity and showing differences in prognosis were identified and validated in external cohort. Of note, two of these groups were related to metabolism, highlighting the value of such process in ILC biology. Importantly, myeloid cells were the predominant immune cell types in ILC, and they showed a specific compartmentalization inside the TME. Further validation is needed.

#5067 Exploring the genomic landscape of de novo neuroendocrine prostate cancer: Insights for innovative therapies from spatial gene expression analysis.

R. Watanabe[1], N. Miura[1], M. Kurata[1], R. Kitazawa[2], T. Kikugawa[1], T. Saika[1];
[1]Ehime University Graduate School of Medicine, Toon, Japan, [2]Ehime University Hospital, Toon, Japan

Introduction & Objectives Neuroendocrine prostate cancer (NEPC) accounts for less than 1% of all prostate cancers but has a worse prognosis than androgen receptor-positive prostate adenocarcinoma (ARPC). Rare cases exist where both de novo NEPC and ARPC are found in the same tissue sample. Our study examines one such unique case: a 78-year-old male treated at Ehime University Hospital who was diagnosed with both ARPC and adjacent de novo metastatic NEPC. This case provides an excellent opportunity for studying gene expression in these two types of prostate cancer. Materials & Methods We used Visium CytAssist Spatial Gene Expression technology from 10x Genomics to analyze formalin-fixed, paraffin-embedded (FFPE) tissue samples from this unique patient. Results We observed elevated expression levels of specific neuroendocrine markers like PEG10, DLL3, NCAM1, SYP, and CHGA in de novo NEPC regions. In contrast, androgen receptor markers such as KLK3, ACPP, TMPRSS2, and NKX3.1 were more prevalent in ARPC areas. Furthermore, genes like Chek1, BRCA1/2, TOP2A, and FANCA were also elevated in NEPC, suggesting that PARP and TOP2 inhibitors could be effective. Expression levels of Rbfox3 and SFRTM2 were lower in NEPC areas, implying possible roles in epithelial-mesenchymal transition (EMT) and Wnt signaling pathways. Additionally, fibrotic markers like HGF, HMOX1, ELN, and GREM1 were upregulated, suggesting that de novo NEPC tumors might be 'immune cold,' thus requiring treatments to boost the effectiveness of immune checkpoint inhibitors. Conclusion The data from additional cases could open the door for new treatment options for NEPC and improve survival rates for castration-resistant prostate cancer patients. Our research serves as a pioneering application of Visium CytAssist on FFPE samples and is the first to examine gene expression in both ARPC and de novo NEPC. A subset of these findings was published in the International Journal of Molecular Science (IJMS) in May 2023.

#5068 Clonal Hematopoiesis of indeterminate potential (CHIP) in patients with advanced solid tumors treated with immune checkpoint blockers (ICB) as monotherapy: Analysis of the PREMIS study.

J. E. Rodriguez, F. X. Danlos, A. Larive, A. Marabelle, Y. Loriot, C. Robert, L. Albiges, M. Frelaut, M. Aldea, B. Besse, M. Ducreux, C. Even, J. B. Micol, S. Ponce, C. Marzac, N. Chaput, C. Massard, C. Baldini;
Gustave Roussy, Villejuif, France

Introduction: Clonal Hematopoiesis of indeterminate potential (CHIP) is a clonal expansion of mutations affecting genes involved in hematologic malignancies in patients without a hematological disease per se. It has emerged as a significant risk factor for cardiovascular events via skewing innate immune cells towards a pro-inflammatory state. Recently studies have shown its potential detrimental impact on overall survival in patients treated with chemotherapy. However, its impact on patients treated with immune checkpoint blockers in monotherapy remains unclear.
Objective: Our aim is to evaluate CHIP prevalence in a prospective cohort of patients treated with ICB for advanced solid tumors and its impact on patient outcomes.
Materials and methods: We performed a Next-Generation Sequencing (NGS) panel of 74-genes dedicated to hematological alterations on DNA extracted from whole blood collected before first administration of an ICB for an advanced solid tumor, within the PREMIS trial (NCT03984318). CHIP prevalence was assessed according to a variant allele frequency (VAF) threshold ≥ 2%.
Results: We included 127 pts in the analysis; 88 pts (69%) were male with a median age of 70 years [range 37-100]. Most common tumor locations were skin (29%), genitourinary (25%) and lung (19%). ICB setting was 1°L in 40% of patients; 2°L in 43%; > 3°L in 17%, and the most used ICB was Nivolumab in 39% of patients. At least 1 CHIP mutation was found in 55 pts (43%). The most frequent mutations were found in *DNMT3A* (40%), *TET2* (18%) and *PPM1D* (13%). Co-mutations were found in 20% of patients. Median PFS was 7.7 months (m) for CHIPm patients compared to 5.7 m in non-CHIPm patients (p=2.2) and median OS was 16.2 m in CHIPm patients compared to 14.9 m in non-CHIPm patients (p= .5). No pts developed hematological disease during the follow up.
Conclusion: CHIP is commonly found in pts with solid tumors, with a prevalence in our cohort of 43% with no statistical significance neither in PFS nor in OS in the CHIP-mutated population.

#5069 Retrospective analysis of acute myeloid leukemia using next generation cytogenomics identifies variants missed at diagnosis.

S. Eacker[1], M. Malig[1], M. Wood[1], A. Muratov[1], O. Sala-Torra[2], I. Liachko[1], C. Yeung[2], J. Radich[2];
[1]Phase Genomics, Inc., Seattle, WA, [2]Fred Hutchinson Cancer Center, Seattle, WA

Cytogenetics forms the cornerstone of diagnostic genetic testing in leukemia, providing both prognostic and diagnostic information to help guide treatment. Currently, standard-of-care cytogenetics in acute myeloid leukemia (AML) is composed of a combination of karyotyping, FISH testing, and in some cases chromosomal microarray analysis, each test offering a unique combination of advantages and weaknesses. A particular challenge for this combination of tests is the delivery of results in a timely and comprehensive manner. To overcome these limitations, we have developed OncoTerra, a proximity-ligation-sequencing based method which can rapidly detect all classes of variants detected by cytogenetics tests in a single assay. We applied OncoTerra to a cohort of more than 100 samples from a SWOG AML trial (S0106), benchmarking sensitivity and specificity of the variants. We observed an overall >0.95 sensitivity and a specificity of 1 for the variants identified by cytogenetics and identified numerous cryptic variants. Overall, we identified variants that changed the diagnostic risk stratification of 15% of the patient involved in the trial based on the ELN 2022 criteria. This translated into better overall prediction of outcomes of patients in the trial and has identified both known and novel variants missed by standard-of-care tools.

#5070 Landscape of clonal hematopoiesis prior to PARP inhibitor treatment in patients with ovarian cancer.

A. Asare, S. Corvigno, J. Yao, L. Zhao, N. D. Fleming, J. Celestino, R. A. Hajek, M. S. Kim, A. Flores Legarreta, K. H. Lu, K. Takahashi, P. A. Futreal, A. A. Jazaeri, S. N. Westin, A. K. Sood, S. Lee;
UT MD Anderson Cancer Center, Houston, TX

Background: Poly (ADP-ribose) polymerase inhibitors (PARPi) are an important tool for treatment of ovarian and other cancers, particularly for those with mutations in BRCA1 or 2 genes or homologous recombination deficiency. The risk of developing secondary hematologic malignancy, particularly myelodysplastic syndrome or acute myeloid leukemia (MDS/AML), is substantially higher (4-12%) after PARPi maintenance or treatment in the second line and beyond in patients with ovarian cancer. This elevated risk necessitates additional investigation into the pathogenesis of PARPi-related secondary malignancy. Clonal hematopoiesis of indeterminate potential (CHIP) has been associated with the development of therapy-related myeloid neoplasms. We aim to understand the patterns of CHIP in patients with high grade serous ovarian carcinoma who receive PARPi therapy.
Methods: We performed ultra-high-depth whole exome sequencing of plasma derived cfDNA or white blood cells (WBCs) barcoded with unique molecular identifiers from patients with high grade serous ovarian carcinoma who were treated with multiple lines of chemotherapy (n=6) or with PARPi in addition to chemotherapy (n = 10). Using spike-in mutated DNAs as positive controls, we detected variant alleles as low as 1% variant allele frequency. Gene set enrichment analysis was performed on identified groups.
Results: We identified 7162 recurrent variants among our patients. We began by comparing quantities of CHIP between the samples from patients who eventually receive PARPi and those who do not. Samples contained a median of 2030 recurrent CHIP variants and 4300 total variants. No differences in total CHIP quantity or mutation type was discernable among samples from patients who will receive PARPi (BRCA1/2 enriched) vs those who will not. Among our 16 patients, 14 ultimately developed secondary hematologic malignancy (t-MN+ Comparison of t-MN+ (n=14) and t-MN- (n=2) defined a group of 14 variants enriched in the t-MN+ population and a group of 85 variants depleted in the t-MN+ population. The t-MN+ enriched variants we identified were not previously associated with CHIP and had significant overlaps with alkyl transferase activity (FDR q val < 0.01) and nucleotide binding gene sets (FDR q val < 0.01).
Conclusions: We used a novel methodology to identify unbiased low variant mutational changes in the hematopoietic system. These results suggest that baseline clonal hematopoiesis variants are similar among patients newly diagnosed with ovarian carcinoma. We have also identified a signature potentially related to future risk of leukemia requiring further validation.

#5071 Minimal residual disease (MRD) status by peripheral blood mononuclear cells (PBMCs) and circulating tumor DNA (ctDNA) demonstrates rapid, deep, and sustained response in patients (Pts) with relapsed/refractory follicular lymphoma (R/R FL) treated with subcutaneous (SC) epcoritamab monotherapy in the pivotal phase 1/2 EPCORE™ NHL-1 trial.

D. Soong[1], I. Altıntaş[2], J. Karavitis[1], K. M. Linton[3], W. Jurczak[4], C. Thieblemont[5], K. Zhao[6], E. Szafer-Glusman[6], D. Hoehn[1], E. Favaro[7], M. Sacchi[1], M. Jure-Kunkel[1];

[1]Genmab, Plainsboro, NJ, [2]Genmab, Utrecht, Netherlands, [3]The Christie NHS Foundation Trust and Manchester Cancer Research Centre, Manchester, United Kingdom, [4]MSC National Research Institute of Oncology, Krakow, Poland, [5]Assistance Publique & Hopitaux de Paris (APHP), Hopital Saint-Louis, Hemato-oncologie, Universite de Paris, Paris, France, [6]AbbVie Inc, South San Francisco, CA, [7]Genmab, Copenhagen, Denmark

Introduction: Outcomes in high-risk R/R FL are poor. Epcoritamab SC, a CD3xCD20 bispecific antibody, demonstrated promising efficacy with a manageable safety profile in pts with R/R FL after ≥2 prior lines of therapy (phase 1/2 EPCORE NHL-1; NCT03625037). Here we evaluated MRD with PBMCs and ctDNA in pts with R/R FL and correlated the results with clinical findings.

Methods: Adults with R/R FL 1-3A enrolled in EPCORE NHL-1 received epcoritamab SC in 28-day cycles. MRD analysis was performed on longitudinal plasma and PBMC samples collected at prespecified timepoints (clonoSEQ assay, Adaptive Biotechnologies). Screening tumor biopsies were used to identify trackable tumor clones; samples were quantified as tumor clones detected per mL plasma for ctDNA and per one million nucleated cells for PBMC. Overall response and progression-free survival (PFS) were assessed using Lugano criteria by independent review committee.

Results: Of 128 pts in the R/R FL 1-3A cohort, 91 with PBMC data and 100 with ctDNA data were MRD evaluable. Overall MRD negativity was achieved in 67.0% [95% CI: 56.4-76.5] of pts per PBMC and 68.0% [95% CI: 57.9-77.0] of pts per ctDNA. Concordance of subject-level MRD status was high (79 of 89 with PBMC and ctDNA data; 88.8%). In most pts, MRD negativity was reached prior to radiographic complete response (PBMC, 76.4%; ctDNA 58.5%). MRD negativity by PBMC preceded ctDNA (median days to MRD negativity, 28 [PBMC] vs 57 [ctDNA]), suggesting a difference in methodology in detecting tumor DNA. Pts who became MRD negative had prolonged PFS (median not reached). Baseline MRD levels were not associated with clinical outcomes (PBMC; Wilcoxon *P*=0.59, ctDNA *P*=0.39). PFS was similar in pts achieving MRD negative status (median not reached, PBMC and ctDNA), independent of high-risk/difficult-to-treat disease (≥4 prior lines, Ann Arbor stage III-IV, bulky disease, double refractory, FLIPI 3-5, and POD24). The overall MRD negativity rate was also similar in high-risk pts, except those with ≥4 prior lines of therapy.

Conclusions: Based on the EPCORE-NHL-1 study, one of the first pivotal studies to report MRD in pts with R/R FL, epcoritamab drives rapid, deep, and sustained responses as supported by MRD assessment by both PBMC and ctDNA. MRD results correlate with clinical outcome, and achieving MRD negativity is associated with longer PFS. PFS was similar among all pts who achieved MRD negativity, including those with high-risk disease.

#5072 Multi-omic, multi-scale characterisation of colorectal cancer defines spatiotemporal patterns of recurrence.

C. S. Wood[1], J. Da Silva Filho[2], A. Cameron[1], A. Legrini[1], H. Leslie[1], T. Zhang[1], Y. Doncheva[1], C. Kennedy-Dietrich[1], M. Marti[2], J. Edwards[1], P. Horgan[1], C. Roxburgh[1], C. Steele[1], N. Jamieson[1];

[1]University of Glasgow - Institute of Cancer Sciences, Glasgow, United Kingdom, [2]University of Glasgow - Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom

Aim: Patients who undergo intended curative resection of colorectal cancer (CRC) have a 20-25% chance of metachronous recurrence, the site and timing of which are unpredictable and resistant to current treatment. The biological basis for such heterogeneous disease behavior remains to be elucidated. Bulk transcriptomic profiling and subsequently single-cell RNAseq have provided insight in the epithelial subtypes and immune microenvironment. Recently spatially resolved transcriptomic assessment allow molecular profiling of tissue while preserving tissue architecture. Utilizing ST technology we sought to perform deep characterization of a large cohort of patients with primary CRC with the intention to decipher the biological determinants of spatio-temporal patterns of recurrence.

Methods: 750 patients who underwent resection of CRC with mature follow up were studied. Bulk transcriptomic, genomic and multiplex immune characterization was performed using a TMA format. Of these, 28 patients were assessed using single cell spatial transcriptomics (Nanostring CosMx Spatial Molecular Imager (SMI, 1000plex gene panel)), 120 tumors underwent regional whole transcriptome profiling of epithelium and TME (Nanostring GeoMx Digital Spatial Profiler using FFPE tissue). We used image analysis and bioinformatics to integrate these complex datasets in over 120000 single-cells in the context of their spatial tissue architecture and clinicopatholgical outcome and recurrence data.

Results: Using the CosMx SMI we characterized cells with complete topographic detail and defined 2 unique epithelial cell states defined. Each epithelial state had distinct spatial properties including cell size and morphology, average distance to nearest lymphocyte, neighboring cell types and stromal neighborhood. This epithelial signature was integrated in GeoMx samples and were found to predict recurrence ($p<0.05$). The Epithelial, Fibroblast and Immune GeoMx transcriptomic compartments were expanded and grouped using unsupervised clustering. Each compartment demonstrated groups of patients where specific spatially derived signatures could predict site and time of recurrence ($p<0.05$).

Conclusions: By maintaining the tissue structure, we have directly measured cellular interactions and captured cells commonly missed during dissociative studies whilst defining novel molecular subtypes of CRC with clinical relevance. Novel platforms such as CosMx allow deeper characterization of unique cell types and cellular interactions that may pave the way for novel therapeutics and precision medicine for patients with CRC.

#5073 Advancing precision oncology: Insights from pan-cancer proteogenomic signatures.

Y. Li, N. V. Terekhanova, M. C. Wendl, F. Chen, L. Ding;
Washington University School of Medicine in St. Louis, St. Louis, MO

Somatic mutations in cancer genomes arise from diverse mutational processes, leaving distinct mutational signatures. However, the proteogenomic implications of these signatures and their connections to environmental influences and immune interactions remain largely unexplored. In this study, we comprehensively investigated these signatures from a broader proteogenomic perspective to further discern their genetic, proteomic, phosphoproteomic, and environmental ramifications. The harmonized dataset of 1064 samples across ten cancer types from the Clinical Proteomics Tumor Analysis Consortium (CPTAC) pan-cancer resource was utilized for this investigation. Beyond genetic alterations and mutational signatures, we harnessed high-throughput multi-omics data to detect critical changes and infer expression signatures associated with the transitions to seven tumor-linked phenotypes: aging, Apolipoprotein B mRNA Editing Catalytic Polypeptide (APOBEC), Homologous Recombination Deficiency (HRD), Microsatellite Instability (MSI), Polymerase Epsilon (POLE), smoking, and ultraviolet (UV) light exposure at the pan-cancer level. We prioritized the top differentially expressed markers uniquely found at the protein and phosphoprotein levels and developed a quantitative score predicting each phenotype status, such as MSI. Respectively, we pinpointed potential candidates as actionable therapeutic targets by linking the identified markers to druggable databases. This offers additional cues to optimize therapeutic options for patients. Specifically, directing attention to genes up-regulated in HRD tumors treated with PARP1 inhibitors shows potential promise in overcoming resistance. Moreover, we explored environmental exposure-related tumor proteogenomic signatures and their association with immune infiltration levels and phenotypes. Notably, smoking strongly influenced the tumor microenvironment (TME) and prognosis in lung cancer. In summary, our identification of expression signatures facilitates phenotype prediction and unveils their molecular mechanisms. We anticipate clinical utility in classifying samples using proteogenomics, particularly in cases where a solely genomic assessment is inconclusive.

#5074 Profiling the splicing landscape in solid tumors in a large, real-world dataset.

M. G. Rosasco, A. J. Sedgewick, J. Guinney, M. M. Stein;
Tempus, Chicago, IL

Introduction Aberrant pre-mRNA splicing is common across cancers. Molecular regulation of splicing is an attractive drug target and clinical trials are currently evaluating splice-targeted therapies (STTs). Due in part to the complex and pleiotropic nature of splicing regulation, molecular biomarkers to identify patients who may benefit from STTs are lacking. While mutations in splicing factors (SFs) are promising biomarkers, these are rare, leaving many patients with unmet need. In this study, we identified and characterized splicing patterns (SPs) in a large, multi-cancer cohort.

Methods De-identified patient records with splicing data from the Tempus xR whole transcriptome assay were extracted from the Tempus clinicogenomic database (N=2918). A total of 1052 alternative splicing events were detected in at least 90% of the samples with at least 10 supporting reads. Leiden clustering was applied to the percent spliced-in (PSI) values of these events to identify SPs. Fisher's exact test was used to assess clinical and molecular enrichment in SPs, and Cox proportional-hazards models were used to assess associations with rwOS and derive hazard ratios (HRs).

Results From a list of 404 SF genes 7.7% of patients had one or more pathogenic or likely pathogenic (P/LP) SF variants, and 2.2% had variants in the key biomarker SF genes *SF3B1*, *SRSF2*, or *U2AF1*. Clustering revealed 15 SPs containing 43 to 353 samples. One SP had a significant enrichment of SF variants (19.7% of SP, P < 0.0005). SPs were associated with significant differences in rwOS, and many were enriched for samples from a single cancer type, biopsy, or histology - principally by prostate cancer (97.5% of SP), melanoma (94.3% of SP), urothelial carcinoma (93.4% of SP), and renal clear cell carcinoma (93.0% of SP), as well as samples collected from liver biopsies (93.9% of SP). In contrast, colorectal and lung adenocarcinoma samples were present in a wide variety of SPs. One SP was enriched for squamous histologies (66.6% of SP, P < 0.0005) and associated with shorter rwOS (HR = 1.33, 95% CI [1.11, 1.59], P < 0.0005). This association remained after controlling for squamous histology (HR = 1.45, 95% CI [1.02, 2.05], P = 0.04). Samples in this SP were characterized by increased expression of *MYC*- and proliferation-related genes, and lacked enrichment for SF variants (P = 0.51, 6.6%).

Conclusions Mutations in SFs were rare in our cohort, highlighting the need for additional biomarkers related to STTs. This work revealed the presence of multiple SPs - characterized by distinct clinical and molecular traits. Further work will be able to contextualize STT response data using SPs to facilitate STT biomarker discovery.

#5075 Transcriptomic landscape of tumor microenvironment in gastric cancer in treatment with different types of cancer drugs.

H. Yamashita[1], J. G. Zhang[2], C. Mashima[3], R. Kamata[3], T. Yamamori[3], I. Nakayama[1], A. Kawazoe[1], K. Shitara[1], T. Yano[1], Q. Xu[2], A. Ohashi[3], T. Saito[2]; [1]National Cancer Center Hospital East, Kashiwanoha, Kashiwa, Chiba, Japan, [2]Astellas Pharma Global Development, Inc, Northbrook, IL, [3]National Cancer Center, Kashiwanoha, Kashiwa, Chiba, Japan

Gastric cancer (GC) in the fifth-leading types of cancer and the third-leading cause of death from cancer. Characterization of tumor microenvironment (TME) in GC is important not only to comprehensively understand tumor biology in GC but also to develop a novel cancer therapeutics targeting TME. In this study, we conducted multi-omics analyses of single-cell RNA sequencing (scRNA-seq), bulk RNA sequencing (bulk RNA-seq), and whole exome sequencing (WES) using biopsied tumor samples through endoscopy from 23 GC patients: 3 treatment-naïve patients, 7 patients in treatment with chemotherapy (Chemo), 5 patients in combination treatment with chemotherapy and immune checkpoint blockade (Chemo+CPI), 3 patients in combination treatment with chemotherapy and Her2-antibody targeted therapy (Chemo+Her2i), and 5 patients in third-line or later treatment. We initially classified the GC samples into 4 molecular subtypes (CIN, GS, MSI, and EBV) using datasets of WES, bulk RNA-seq and scRNA-seq, showing that our samples were mainly composed of CIN (n=7) and GS (n=16) types. In scRNA-seq, we revealed that drug treatments profoundly modulated not only proportions of TME components but also their molecular characteristics. For instance, Chemo+CPI treated patients showed higher proportion of CD8+ cytotoxic T cells with activation and/or exhaustion markers. Combination treatments with Chemo+Her2i, in addition, resulted in higher Trail and Estrogen signaling pathways in epithelial cells of TME components. These findings suggest that interventions with certain cancer therapeutic drugs could substantially convert transcriptome landscape and reconstitute GC TME components. High-resolution of GC TME analyses should provide a clue for developing a next generation of cancer therapeutic drugs.

CLINICAL RESEARCH: Novel Immunotherapies and Immune Modulation
Poster Session

#5079 Comparative studies of chemotherapy and immuno-oncology combinations in multiple mouse syngeneic tumor models.
E. Park, M. Hinton, M. Cai, M. A. Gil, G. Hebert, L. Cui, D. Linn, B. J. Long, E. R. Barry;
Merck, Boston, MA

The development of immune checkpoint inhibitors (ICIs) and combinations of immuno-oncology therapies with standard-of-care (SoC) chemotherapeutic agents has shifted therapeutic paradigms for patients with multiple cancer indications. For many patients, these combinations have shown a beneficial effect on clinical outcomes and disease management. However, additional combination therapies are still needed. Preclinically, a comparison of responses from SoC chemotherapies and ICI combinations in multiple disease models may be helpful in identifying optimal treatment combinations in the clinic. Here we report the results of multiple SoC/ICI in vivo combination efficacy studies in a large panel of mouse syngeneic models spanning seven tissue origins: 1) Colon: CT26, MC38; 2) Breast: EMT6, 4T1; 3) Kidney: Renca; 4) Bladder: MB49, MBT2; 5) Skin: B16F10, CM3; 6) Lung: TC1, LL/2, M109; 7) Brain: GL261. The advantage of using syngeneic models is not limited to the rapid and reproducible tumor growth, but importantly that the animals also have an intact immune system and clinically relevant tumor microenvironment, which are required for ICI combination studies. We tested > 10 chemo SoC combinations with a murinized anti-PD-1 antibody (DX400) in 14 syngeneic mouse models. We found that multiple SoC regimens combined well with DX400 treatment, including FOLFIRI, FOLFOX (colon), Carboplatin/Paclitaxel, Carboplatin/Pemetrexed (lung), Capecitabine/Docetaxel, Cisplatin/Gemcitabine (bladder), Cisplatin/5-FU/or capecitabine, and Oxaliplatin/5-FU/ or capecitabine (gastric). Specifically, we observed that the SOC/ICI combinations resulted in enhanced antitumor activities compared to single-agent treatments in many of the models. These data, particularly specific SoC combination regimens that combine well with ICIs in each disease, are useful for optimizing promising combination approaches for clinical development and will be presented here.

#5080 Antibody drug conjugate trastuzumab deruxtecan suppresses leptomeningeal brain metastasis cells and is potentiated by addition of immune check point inhibitor.

E. C. Smith, S.-Y. Wu, R. P. Deshpande, A. Tyagi, K. Watabe;
Wake Forest University School of Medicine, Winston Salem, NC

Leptomeningeal disease (LMD) is defined by dissemination of metastatic cancer cells into the subarachnoid space with subsequent involvement of the cerebrospinal fluid and leptomeninges. LMD is an aggressive, late-stage development of cancer, which is increasing in prevalence as improved treatments for systemic malignancies are discovered. It leads to significant neurological morbidity and mortality, and outcomes remain poor despite improving cancer treatment strategies. There is a large population of patients with human epidermal growth factor receptor 2 (HER2) expressing cancers, such as breast and lung cancers, who suffer from leptomeningeal metastasis. There has been evolving research looking at antibody drug conjugates for treatment of these primary pathologies, such as Trastuzumab Deruxtecan (TDxd), which shows improved progression free survival and overall survival in those with HER2 expressing primary cancers, as well as in intraparenchymal brain metastasis. However, as of yet there has been no study of its utility in LMD. Additionally, use of immune check point inhibitors (ICI) for treatment of LMD has been studied, showing some efficacy, but less robust response than that in intraparenchymal brain metastasis. Given the significant population of patients who continue to be affected by leptomeningeal metastasis, there is significant need for an improved treatment regimen. We hypothesize that TDxd will have a killing effect on HER2 expressing LMD cells, which can be further potentiated by the addition of ICIs. To test this hypothesis, we developed breast and lung cancer cell lines (SKBrM-LMD, and H2030BrM-LMD) that express HER2 and preferentially metastasize to leptomeningeal space. These cell lines were also labeled with luciferase. We then treated these cell lines with TDxd and found that TDxd had significant growth inhibitory effect on these cells *in vitro* when compared to the control. Furthermore, we educated human T Cells against the SkBrM-LMD cells and treated these cells with the aforementioned T cells plus the ICI Anti-PD1. Our results showed that ICI had significant killing effect when compared to the control. We have also created an *in vivo* LMD model by performing intraventricular injection of HER2 expressing tumor cells into a mouse model, which can be used for testing the efficacy of TDxd and ICI by intrathecal injection. In conclusion, our results indicate that TDxd and ICI have significant killing activity against HER2 expressing LMD cells, and therefore intrathecal administration of these drugs is a promising treatment modality that will be demonstrated using a mouse LMD model.

#5081 Immune sensitization of melanoma to checkpoint inhibitor therapy using acoustically active nanoparticles.

M. I. Henderson, L. Xiang, S. Drennan, X. Yi, J. Fischer, A. Yildirim;
Cancer Early Detection Advanced Research (CEDAR), Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Advanced melanoma remains the most fatal form of skin cancer with novel therapeutic approaches required to treat inoperable metastatic lesions. While immunotherapies have shown promise in improving long-term melanoma survival, its treatment efficacy is limited, with only 50% of patients responding. Focused ultrasound (FUS) offers as a non-invasive strategy for targeted tumor ablation, thereby strengthening immunotherapy efficacy by release of tumor associated materials. However, control over tumor material release through FUS, without causing excessive thermal damage to surrounding healthy tissue remains challenging. To address this challenge, our group has previously developed acoustically active nanoparticles (AANPs) responsive to low intensity ultrasound for mechanical tumor ablation by generating strong and durable acoustic cavitation in the tumor tissue. Building upon previous success with AANPs, our current work focuses on sensitizing melanoma tumors to checkpoint inhibitor therapy by releasing tumor antigens into circulation using AANPs and FUS. Our findings revealed sensitization of an immunologically cold B16-F10 metastatic melanoma tumors following treatment, which resulted in a notable 12-day stall in tumor growth. When combined with immune checkpoint inhibitors α-PD-L1 and α-CTLA-4, this approach showed a complete response in B16-F10 bearing mice with impressive memory immune response upon a tumor rechallenge. Herein, these novel AANPs represent a promising advancement to enable accurate immune surveillance by boosting the release of tumor antigens and offers new strategies for improved immunotherapy of melanoma and other solid tumors.

#5082 Novel TSHR CAR T therapy for targeting oncocytic carcinoma.

J. J. Gleba[1], A. Alasonyalilar-Demirer[1], M. Pawlush[1], C. Manriquez-Roman[2], E. L. Siegler[2], R. C. Smallridge[1], A. Zubair[1], H. W. Tun[1], S. S. Kenderian[2], J. A. Copland III[1];

[1]Mayo Clinic Cancer Center, Jacksonville, FL, [2]Mayo Clinic, Rochester, MN

Oncocytic carcinoma (Hurthle cell carcinoma) has the highest incidence of metastasis among the differentiated thyroid cancers. Metastatic disease is reported at the initial diagnosis in 10-20% of patients and 34% overall. Thyroid-stimulating hormone receptor (TSHR) expression is limited to the thyroid gland. It is abundantly expressed on thyroid tumor cells, making TSHR a compelling target for advanced thyroid cancer diagnostics and therapeutics. We developed a potent anticancer strategy for treating oncocytic carcinoma using a novel thyroid hormone stimulating receptor (TSHR)- targeted (chimeric antigen receptor) CAR T cell therapy. TSHR CAR T was generated by transducing T cells derived from healthy donors. *In vitro* effector functions (cytotoxicity, proliferation, degranulation) were tested in TSHR+ tumor models, and subsequent *in vivo* studies using NSG mice were performed to assess anti-tumor activity efficacy. We observed strong anti-tumor activity against metastatic oncocytic carcinoma cell line XCT.UC1 using the TSHR CAR T therapy *in vivo*. Re-challenging treated mice with XCT.UC1 cells reactivated TSHR CART cells with enhanced proliferation and complete suppression of tumor growth of the newly injected tumor cells. Our work represents a promising strategy to improve treatment outcomes of patients with metastatic oncocytic carcinoma that may provide a durable response.

#5083 Discovery of an asymmetric IgG-like bispecific ADC targeting EGFR/HER3.

L. Chen[1], S. Peng[2], C. Wang[1], X. Miao[1], Y. Yan[1], J. Xing[1], W. Huang[2], A. Tsun[1], Y. Xu[1], X. Liu[1], **Y. Luo**[1];
[1]Biotheus Inc., Zhuhai, China, [2]Biotheus (Suzhou) Co., Ltd., Suzhou, China

Background: The epidermal growth factor receptor (EGFR) family, consisting of EGFR, HER2, HER3, and HER4, plays a critical role in tumorigenesis and tumor progression. Inhibition of ERBBs using either monoclonal antibodies (mAb) or small-molecule tyrosine kinase inhibitors have been approved for use for the treatment of various types of cancers. Despite relative success, many patients acquire resistance to long-term benefit due to alternative compensatory signaling pathways. Accordingly, activating mutations or overexpression of HER3 has been reported in many cancers, such as breast, ovarian, lung, colorectal, melanoma, head and neck, cervical and prostate cancers. Here, we report the discovery of a humanized anti-EGFR x HER3 IgG-like bispecific antibody-drug conjugate (ADC). The ADC takes a asymmetric 1+1 form through HC-HC and HC-LC charge-based heterodimerization, which is then conjugated to a topoisomerase 1 inhibitor (TOP1i) payload via a cleavable linker. The affinity of EGFR and HER3 was optimized to improve the therapeutical window, and has shown potent anti-tumor efficacy in various tumor models with limited toxicity supporting further development in clinic.
Methods: An anti-EGFR x HER3 bispecific ADC (PM1300) was generated by introducing unique mutations to the CH1-CL domains of each binding arm to avoid HC-LC mispairing. KIH mutations were also introduced to each CH3 domain to support HC/HC heterodimerization and generate an IgG-like bispecific with one arm binding to EGFR and the other to HER3. TOP1i payload was conjugated to the IgG-like bispecific by the endogenous cysteine residues at DAR 8 via a clearable linker.
Results: Through affinity optimization, PM300 was found to preferentially bind to EGFR/HER3 double-positive cells rather than EGFR single-positive cells. PM1300 showed significantly increased internalization and anti-proliferation activity against EGFR/HER3 double-positive cells, with limited activity towards single positive-cells. PM1300 used an optimized linker for better payload release and serum stability. PM1300 induced a potent anti-tumor efficacy in various CDX models representing different EGFR and HER3 expressing levels and mutations. Importantly, PM1300 exhibited a good safety profile in NHP consistent with the optimal affinity for EGFR and HER3. These results demonstrate that PM1300 has a promising efficacy/safety therapeutical window in preclinical models supporting further development in the clinic.
Conclusion: A bispecific ADC targeting EGFR x HER3 was discovered, named PM1300, which has an asymmetric 1+1 IgG-like structure and optimized affinity. This allows for preferential binding to EGFR/HER3 double-positive cancer cells, rather than EGFR single-positive cells. This may significantly contribute to minimizing safety risk that is common for EGFR-targeting agents.

#5084 A first-in-class bispecific antibody CPL976 with a dual PD-L1/AXL mechanism of action that promotes common biological antitumor effects in *in vitro* and *in vivo* models.

D. Popiel, D. Kołakowski, A. Bojko-Matuszek, K. Lacek, A. Jabłońska, A. Sowińska, F. Mituła, M. Bojko, B. Wiernicki, A. Mikołajczyk, T. Kornatowski, K. Flis, M. Skupińska, J. Hucz-Kalitowska, E. Mroz, M. Choroś, M. Wieczorek, J. Pieczykolan, O. Abramczyk;
Celon Pharma SA, Kazun Nowy, Poland

Background: Bispecific antibodies emerged as a leading drug class for cancer therapy and are becoming increasingly interesting for the therapeutic applications. The Gas6/Axl signaling pathway contributes to the immunosuppressive tumor microenvironment by increasing the expression of PD-L1 and tumor-derived chemokines. This results in increased infiltration of macrophages, monocytes, and myeloid-derived suppressor cells, but decreased infiltration of CD4+ and CD8+ T cells and dendritic cells in the tumor bed. The PD-1/PD-L1-mediated signaling pathway is a well-known mechanism responsible for T-cell inhibition, consequently disrupting their ability to eliminate tumor cells. In addition, AXL and PD-L1 are concurrently highly expressed in many tumors. Therefore, bispecific antibody that inhibits both axes seems like a promising therapeutic strategy engaging anti-proliferative effect by AXL inhibition, and cytotoxic properties of effector T cells by breaking the PD-1/PD-L1 axis.
Materials and Methods: Bispecific antibody CPL976 was designed as a VHH-Fc-VHH format, with two VHHs raised against PD-L1 and two against AXL. Activity, selectivity, and potential for internalization and degradation of targets were studied on cancer cell lines with different expression levels of the targets. In addition, CPL976 efficacy was verified in syngeneic mouse models, when antibodies were administered intravenously at different doses for 3 weeks.
Results: We confirmed the CPL976's innovative mechanism of action based on the strong and simultaneous engagement of both therapeutic targets, and potential internalization and degradation of target proteins in cancer cell lines with different expression levels of AXL and PD-L1 (MDA-MB 231, A375, A549, H1299). Potent and dose-dependent in vivo antitumor activity was observed in the syngeneic mouse model, where at a dose of 15mg/kg remission of the tumor was observed in 5/8 compared to 0/8 in the control group.
Conclusions: CPL976 is the bispecific antibody that combines the effects of cancer inhibition by interacting with AXL and immunotherapy by disrupting the PD-1/PD-L1 axis. The use of the bispecific antibodies simultaneously targeting PD-L1 and AXL provokes internalization of the targets to maximize the biological effect of the inhibition of the receptor/ligand complexes (AXL/cGAS6, PD-1/PD-L1) formation. Simultaneous action on both therapeutic targets may help achieve an enhanced immune response against cancer cells and lead to tumor eradication and overcoming the primary and secondary resistance to PD-1/PD-L1 targeted therapies.

#5085 Preclinical development of NaPi2b-PL2202, a novel camptothecin-based antibody-drug conjugate targeting solid tumors expressing NaPi2b.

E. Horsley[1], A. Jabeen[1], N. Veillard[1], K. Havenith[1], N. Janghra[1], P. Alves[1], C. Oblette[1], I. Kirby[1], P. W. Hogg[1], F. Zammarchi[2], L. de Haan[1], **P. v. Berkel**[1]; [1]ADC Therapeutics, London, United Kingdom, [2]Myricx Bio, London, United Kingdom

NaPi2b, encoded by the SLC34A2 gene, is a multi-transmembrane, sodium-dependent phosphate transporter expressed at high levels in tumors and low levels in normal tissues. Functionally, it is involved in trans-cellular flux of phosphate in the small intestine and in the synthesis of surfactant in lung alveoli. NaPi2b is reported to be expressed at a high frequency in ovarian carcinoma as well as in NSCLC, bladder, endometrial and papillary thyroid carcinoma[1], and its expression is associated with poor prognosis [2, 3]. The purpose of this study was to characterize the *in vitro* and *in vivo* anti-tumor activity and tolerability of NaPi2b-PL2202, an antibody-drug conjugate (ADC) composed of a humanized, Fc-silenced IgG1 antibody directed against human NaPi2b, to which PL2202, a novel payload containing a valine-alanine cleavable linker and a camptothecin warhead, has been site-specifically conjugated with a drug to antibody ratio of 6. In addition, the level of NaPi2b expression in selected human tumor specimens was evaluated by immunohistochemistry (IHC). *In vitro*, NaPi2b-PL2202 showed good binding affinity for mouse, rat, cynomolgus monkey and human NaPi2b, and displayed highly potent, targeted cytotoxicity against various NaPi2b-expressing tumor cell lines. NaPi2b-PL2202 also exhibited strong *in vitro* bystander activity. *In vivo*, intravenous (IV) administration of a single dose of NaPi2b-PL2202 at 6.6 mg/kg resulted in substantial tumor regression in the OVCAR-3 ovarian carcinoma xenograft model, with 3/10 partial responders (PR) and 7/10 complete responders (CR), and all CRs being tumor-free at the end of the study (Day 44). In the G-402 renal leiomyoblastoma xenograft model, administration of a single IV dose of NaPi2b-PL2202 at 3.3 mg/kg was associated with durable antitumor activity and resulted in 1/10 CR, with this animal remaining tumor-free by the end of the study (Day 42). With respect to toxicity, in single dose studies in male rats, NaPi2b-PL2202 was tolerated up to 300 mg/kg IV. Furthermore, in a dose-range finding study in male cynomolgus monkeys, NaPi2b-PL2202 was well tolerated up to 40 mg/kg IV given on Day 1 and 22. Finally, cell membranous NaPi2b expression was confirmed by IHC in a panel of tissue microarrays including ovarian, lung, bladder and endometrial cancers. In conclusion, NaPi2b-PL2202 demonstrated specific and potent *in vitro* and *in vivo* anti-tumor activity, and was tolerated at high doses in toxicity studies in rats and cynomolgus monkeys, indicating a good therapeutic index. Together, these observations support future clinical development of NaPi2b-PL2202 for the treatment of NaPi2b-expressing cancers. 1- Bodyak N. D. et al., 2021 2- Valsenkova R. et al., 2021 3- Hakim S. A. et al., 2021

#5086 Functional profiling in lung tumor explants show contributions of the tumor microenvironment to response of Dato-DXd*ex vivo*.

S. Yasuda[1], E. V. Ivanova[2], H. V. Vo[2], S. Kivlehan[2], I. Gjeci[2], M. Ha[2], P. Lizotte[2], R. Bueno[3], D. A. Barbie[2], **C. P. Paweletz**[2];
[1]Daiichi Sankyo, Baskin Ridge, NJ, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA

Background: Antibody drug conjugates (ADCs) have demonstrated significant antitumor activity against multiple treatment refractory cancers. While Trastuzumab deruxtecan, a HER2 directed ADC, has shown impressive clinical activity in HER2-expressing cancers, the ability to predict responses of ADCs by IHC has been limited. Dato-DXd is a TROP2 directed ADC that is currently being studied in a number of registrational phase 3 trial incld. TROPION-Lung01. In the phase 1b TROPION-Pan tumor 01 trial (TP01) response to Dato-DXd did not correlate to TROP2 IHC expression. Here we investigate molecular determinants of sensitivity to Dato-DXd using short-term microfluidic culture of patient derived organotypic tumor spheroids (PDOTS).
Methods: Surgical NSCLC cases collected from Brigham and Women's Hospital and St. Elizabeth's Medical Center under an IRB approved protocol were studied. PDOTS were generated as previously described. *Ex vivo* response was assessed by live/dead imaging, TROP2 antigen density on EPCAM+ cells by flow cytometry (FCM) and by immunofluorescence (IF). T cell and myeloid cell populations were analyzed by FCM of CD45+ cells isolated during tumor preparation. For a subset of samples single cell RNA sequencing (scRNAseq) was performed.
Results:Eleven NSCLC explants were studied. Two specimens were excluded due to excess of fibrotic material. Response to Dato-DXd was measured by change in raw live cell area compared to control samples. Median response to Dato-DXd was -48.5% (ranging from +33.9% to -77.8%). Using a cut-off of -40%, four cases were characterized as non-responders (NR) and 5 as responders (R). Tumor TROP2 expression by IF ranged from 0 to 3+ with no relationship between TROP2 expression and response being observed. TROP2 staining positivity by IF didn't correlate to Dato-DXd sensitivity *ex vivo*. TROP2 FCM, on the other hand discriminated between responsive and non-responsive models in 100% of the cases, using a cutoff of MFI >13000. Furthermore, we observed an increase of tumor CD8 abundance in Dato-DXd R compared to NR (median %CD8 in R 10.3% (range 5.1%-62.5%); median %CD8 of live cells in NR 2.3% (range 1.2%-3.7%) p-value 0.029). Conversely, we also observed a trend of higher granulocytic myeloid-derived suppressor cells abundance in NR compared to R (NR median %gMDSC of CD15+ cells 84.1% (range 73.4%-90.2%) ; R median %gMDSC 61.7% (range 54.3%-90.6%); p-value 0.069). In 2 cases with high and low TROP2 MFI available scRNAseq data showed TROP2 expression exclusively in tumor cells, with further analysis ongoing.
Conclusion: By functionally profiling NSCLC PDOTS that retain immune cells, we correlated multiple parameters with *ex vivo* response to Dato-DXd. Our results have important implications for precision deployment of ADCs and suggest that target tumor antigen density in conjunction with addition immune cell features may refine patient selection strategy.

#5087 ILB-3101, a novel B7H3-targeting ADC with Eribulin as payload, demonstrates strong tumor killing activities and favorable PK/TOX profile in preclinical evaluation.

Y. Shang, J. Qiu, Y. Xin, M. Zhao, Q. Liu, Z. Wang, X. Gong, **Y. Xu**, Y. Li, M. Xia, R. Chen;
Innolake Biopharm, Hangzhou, China

B7H3, a B7 family member of immune checkpoint proteins, is overexpressed in a broad spectrum of malignant tumors. It has become an attractive target for cancer therapies in recent years. ILB-3101, a potential best-in-class ADC, was constructed by conjugating a potent mitotic inhibitor Eribulin to a proprietary anti-B7H3 mAb through a proprietary linker. This ADC molecule has been developed and preclinically evaluated as both the 1st line ADC treatment with B7H3 expressed patients in Eribulin sensitive cancer types and the later line treatment for patients whose cancer are B7H3 positive but TopoI inhibitor resistant.
The humanized antibody of ILB-3101 is IgG1 type and shows high affinity to both human and monkey B7H3 proteins. It also shows better internalization than benchmark antibodies such as that of DS-7300 analog. The DAR value of ILB-3101 is 3.5. ILB-3101 has potent and dose-dependent cytotoxicity to B7H3-positive tumor cells and shows better activities than DS-7300 analog as positive control. *In vivo* studies based on xenograft tumor models reveal that ILB-3101 has potent anti-tumor activities in various tumor types including TNBC, sarcoma, ovarian cancer and AML etc., which are superior or comparable to DS-7300 analog. Furthermore, ILB-3101 shows strong anti-tumor activity on Dxd based ADC resistant tumors in xenograft tumor models. The PK study of ILB-3101 in cynomolgus monkeys shows dose-dependent exposure and desirable PK profile. ILB-3101 was well tolerated in cynomolgus monkeys with HNSTD at 6 mg/kg. No serious adverse events were observed, and the main safety findings were limited and reversible hematological and immunological effects, which are consistent with the safety profile of Eribulin as an approved chemotherapy.
The *in vitro* and *in vivo* preclinical results above demonstrate that ILB-3101 has good efficacy and safety profile and it is a promising and potentially best-in-class B7H3 targeting ADC drug candidate. ILB-3101 is worthy of further translational research and clinical trials. Its IND application has been submitted in China, followed by US FDA filing soon.

#5088 Evaluating TNF-receptor associated factor 2 (TRAF2) as a targetable driver of immune resistance in LKB1 deficient non-small cell lung cancer.

Bahareh Nourmohammadi[1], Joseph M. Amann[1], Rahul Shivahare[1], Qin Ma[2], Zihai Li[1], David P. Carbone[1], Jacob Kaufman[1]

[1]Division of Medical Oncology, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[2]Department of Biomedical Informatics, The Ohio State University College of Medicine, Columbus, OH

STK11 is a serine-threonine kinase and tumor suppressor lost in about 25% of NSCLC. It potently regulates a network of downstream effector kinases in the AMPK family, thereby exerting major effects on cell signaling, metabolic activity, and epigenetic patterning. Clinically loss of STK11 in NSCLC is associated with poor response to immune checkpoint blockade. Several mechanisms of immune resistance have been identified involving both tumor intrinsic pathways as well as changes in the immune microenvironment. Dysregulation of cellular inhibitor of apoptosis proteins, specifically cIAP1 has been identified as a specific resistance mechanism, which was shown to also influence the STING pathway in the context of STK11 loss. However, there is a gap in understanding how loss of STK11 influences cIAP1 signaling.We evaluated cIAP1, its TRAF family member binding partners, and downstream NF-kB and immune signaling using a multiomic approach. Using CPTAC multiomic data of 110 lung adenocarcinomas, we observe discordance between protein vs mRNA expression for cIAP1, which shows no significant association with STK11 loss in mRNA, but is significantly over-expressed at the protein level (P<1e-4). Conversely, we identify TRAF2 as the only TRAF member whose expression is increased in STK11-deficient NSCLC, with concordant increase in both mRNA (P<1e-8) and protein (P<1e-10). Further, on the protein level TRAF2 and cIAP1 levels were highly correlated (P<1e-12), strongly suggesting that TRAF2 is the proximal factor driving dysregulation of cIAP1 signaling in these tumors. We also observe a correlated pattern of phosphorylation sites within cIAP1, TRAF2, and other NF-kB signaling members that we putatively link to STK11 loss. We confirm that TRAF2 mRNA is consistently over-expressed in STK11 deficient NSCLC across multiple additional transcriptomic datasets together comprising >2000 tumors. Across this large dataset we observe that among STK11-deficient tumors, TRAF2 is anti-correlated with NF-kB signaling and immune infiltration signatures, a relationship that is strikingly absent among the STK11-WT subset. Using GEMM cell lines (KRAS, TP53, STK11 GEMM; Winslow lab, Stanford), we derived STK11 mutant vs WT isogenic pairs and performed T-cell co-culture experiments using ovalbumin antigen and OT-I CD8 T-cells. This showed that inhibition of cIAP1 using birinapant was synergistic to CD8 cytotoxicity, as previously known, but the synergy was much more pronounced in STK11 mutant vs STK11-WT context (Bliss index 38, P<1e-10). Together, these data demonstrate that the link between STK11-loss and cIAP1 dysregulation is likely through over-expression of TRAF2, and support the strategy of targeting TRAF2/cIAP1 to overcome immune resistance STK11-deficient NSCLC.

#5089 Therapeutically targeting endometrial cancer by ICAM1 antibody-drug conjugates.

H. Xie[1], L. Sun[2], S. Yao[3], P. Guo[3], Y. Zhang[2];

[1]Postgraduate training base Alliance of Wenzhou Medical University, HangZhou, China, [2]Zhejiang Cancer Hospital, Hangzhou, China, [3]Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, HangZhou, China

Background: Endometrial cancer is the most frequently occurring gynecologic cancer in developed countries and the third leading cause of cancer deaths among women. It remains one of the few malignant tumors with rapidly increasing mortality and morbidity. Patients with recurrent or metastatic endometrial cancer continue to experience poor outcomes. Antibody-drug conjugates (ADCs) represent a class of targeted therapeutic modalities that offer biomarker-based therapeutic options for patients with endometrial cancer. In this study, we proposed to identify a novel molecular target for the preclinical development of an ADC for endometrial cancer-targeted therapy.

Methods: Firstly, to determine the level of target expression within endometrial cancer tissue components as well as differences, we performed immunohistochemical staining of human endometrial cancer and paracancerous tissue. Secondly, the expression of the target on the cell membrane surface was quantitated and qualitatively verified using flow cytometry and single-photon confocal microscopy. In the third step, an endocytosis assay was used to verify the endocytosis of the target antibody by EC cells. Confocal imaging can directly observe the endocytosis of the target antibody, and flow cytometry can be analyzed and quantified. Co-localization experiments with antibody fluorescence can verify the specific site where the target antibody is endocytosed into cancer cells. We then designed and characterized two targeted ADCs. Next, the *in vitro* inhibitory activities of these ADCs against endometrial cancer cell lines and normal cells were evaluated using the CCK8 assay. Finally, we established a cell line-derived xenograft (CDX) model of endometrial cancer to validate the *in vivo* efficacy and bio-safety of the ADCs.

Results: We have determined a correlation between ICAM1 overexpression and EC, and IHC staining of patient tissues showed significantly higher levels of ICAM1 expression in endometrial cancer tissues than in paracancerous tissues. The high cell surface expression of ICAM1 was verified in a panel of various human endometrial cancer cell lines. Moreover, two ICAM1 ADCs were established using clinically-approved ADC linker and payload combinations. It was visually confirmed that ICAM1 ADCs selectively recognize endometrial tumors and efficiently enter endometrial cells via antigen-mediated endocytosis. We compared the anti-tumor activity of ICAM1 ADCs with standard-of-care chemodrugs, and ICAM1 ADCs outperformed chemodrugs in the CDX model of endometrial cancer without toxicity.

Conclusion: We identified that ICAM1 is a promising ADC target for endometrial cancer and confirmed the potent anti-tumor activity and biosafety of ICAM1 ADCs *in vitro* and *in vivo*, warranting further pre-clinical and clinical investigations.

#5090 Development of HSPG2 targeted glycoengineered antibody-drug conjugates.

X. Li, S. Prabha;
Temple Univ, Lewis Katz School of Medicine, Philadelphia, PA

Ovarian cancer is associated with poor outcomes and aggressive behaviors. Although surgical removal of tumors and chemotherapy can initially eradicate cancer, many patients eventually experience relapse with chemotherapy-resistant tumors, resulting in poor long-term outcomes and chemotherapy complications. Antibody-drug conjugates (ADCs) are formed by integrating the tumor specificity provided by antibodies (Ab) and small molecule cytotoxicity drugs and can facilitate highly targeted delivery with minimal toxicity to normal tissues. Our group has identified that the overexpression of a novel target, heparan sulfate proteoglycan 2 (HSPG2), is associated with poor prognosis and survival of high grade serous ovarian cancer (HGSOC) patients. We have developed a monoclonal antibody (AM6) that effectively targets HSPG2-expressing tumors. In this study, we used a novel glycoengineering strategy to introduce artificial azide groups at the N-glycan sites of AM6 without affecting its antigen affinity and intracellular localization. The azide groups were then used for site-specific conjugation of the cleavable dibenzyl cyclooctyne - monomethyl auristatin E (DBCO-PAB-MMAE) linker (drug conjugate) to form an AM6 antibody-drug conjugate (AM6 ADCs). Hydrophobic interaction chromatography (HIC) and liquid chromatography/quadrupole time-of-flight/mass spectrometry (LC/Q-TOF/MS) confirmed the successful conjugation of the DBCO-PAB-MMAE to the AM6. In-vitro cytotoxicity studies of AM6 ADCs in OVCAR8 (high HSPG2 expression) and CAOV3 (regular HSPG2 expression) showed the cell line dependent response with lower IC50 in OVCAR8. These results suggest that the effectiveness of AM6 ADCs is proportional to the HSPG2 expression levels of the cells. Future studies will be aimed at the in-vivo evaluation of optimized antibody-drug conjugates.

#5091 Response to neoadjuvant chemoimmunotherapy in resectable locally advanced oral squamous cell carcinoma: a single-center retrospective observational study.

Jinsong Li, Bowen Li, Shule Xie, Haotian Cao, Zhaoyu Lin, Qunxing Li, Song Fan

Sun Yat-Sen Memorial Hospital of Sun Yat-Sen University, Department of Oral and Maxillofacial Surgery, China

Background: This study aims to investigate the effectiveness of neoadjuvant chemoimmunotherapy (NACI) regimens in treating advanced oral squamous cell carcinoma (OSCC).
Methods: We analyzed clinicopathologic features of advanced OSCC patients who received PD-1 inhibitors in combination with carboplatin and paclitaxel before surgical tumor resection between 2020 and 2022. The Response Evaluation Criteria in Solid Tumors (RECIST, version 1.1) and pathologic response were used to evaluate the efficacy of the NACI treatment. Adverse events apparently related to NACI treatment were graded according to the Common Terminology Criteria for Adverse Events, version 4.0. Disease-free survival (DFS) and overall survival (OS) were calculated using the Kaplan-Meier survival curves and compared using the log rank test. Additionally, we calculated the area under curve (AUC) to compare the predictive value of PD-L1 expression with baseline serum lipid biomarkers for patient response.
Results: Our analysis involved 104 advanced OSCC patients who received NACI. Notably, the top three grade 1-2 treatment-related adverse events (TRAEs) were Alopecia (104; 100%), Anemia (81; 77.9%) and Pruritus (62; 59.6%). Only one patient developed grade 3-4 TRAEs due to increased aminotransferases. The pathological complete response (PCR) rate was 47.1%, and the major pathological response (MPR) rate was 65.4%. Importantly, patients achieving MPR exhibited higher CPS. The diagnostic value of CPS as a biomarker for NACI efficacy was enhanced when combined total cholesterol (TC) level. Our findings from DFS and OS suggested that patients who underwent NACI before surgery experienced improved survival compared to those who accepted the surgery alone.
Conclusions: The data from this study proved evidence that NACI treatment is safe and encouragingly efficacious in treating advanced OSCC patients.

#5092 Development of a priming approach to enhance antigen-directed therapies in hematological malignancies and solid tumors.

K. E. Vanderlaag, A. Dhar, M. Volkman, E. Werner, T. Nguyen, K. Ali;
Eigen Therapeutics Inc., Redwood City, CA

Clinical success of antigen-directed therapies in cancer has been limited by heterogeneous antigen expression and a narrow therapeutic window. In many patients, failure of antigen-directed therapies such as CAR T-cell therapies, antibody-drug conjugates (ADC) or radioligand therapies (RLT) has less to do with a lack of potency or specificity of the agent and more to do with variable and suboptimal antigen expression in the patient. We are developing combination therapies that introduce a priming agent designed to optimize antigen expression in the patient and improve the therapeutic window of existing antigen-directed therapies. Our high-throughput platform utilizes machine learning and automation to scale functional combinatorial screening for small molecule priming agents using cell lines and patient samples. Using this platform, we are identifying priming therapies for CD123, CD33, CD22, and CD19 in hematological malignancies including acute myeloid leukemia (AML), and HER2, HER3, and TROP2 in solid tumors including breast cancer.For our CD123 program, we have identified priming agents that selectively upregulate CD123 expression ≥2-fold on AML cells without increasing expression on normal myeloid progenitor cells, which also express CD123. AML cells treated with a CD123 priming agent in combination with a CD123 ADC showed greater tumor-cell killing compared to the ADC alone. In comparison, normal myeloid progenitor cells from healthy bone marrow treated with the same CD123 priming-ADC combination treatment did not show an increase in ADC-mediated cell killing. From our mechanistic studies, we have identified a somatic mutation associated with CD123 upregulation that may lead to selective upregulation on cancer cells and not on normal cells. Additionally, this marker can be used for patient selection. We have also observed CD123 upregulation in vivo using mouse models of AML and are currently conducting additional in vivo proof of concept studies to demonstrate that CD123 priming therapy enhances efficacy.There are two distinct advantages of a priming approach paired with an antigen-directed therapy, which include: (1) improving the durability of patient responses and (2) expanding the patient population. Our priming combination approach has the potential to overcome antigen heterogeneity and thereby improve the clinical success of antigen-directed therapies.

#5093 Analysis of protein expression in head and neck cancers as therapeutic targets for antibody drug conjugates.

J. T. Moyers[1], S. L. Smith[1], M. M. Mora[1], R. Carmagnani Pestana[2];

[1]The Angeles Clinic and Research Institute, A Cedars-Sinai Affiliate, Los Angeles, CA, [2]Hospital Israelita Albert Einstein, Sao Paulo, Brazil

Introduction: Antibody Drug Conjugates (ADCs) represent a new category of therapeutic molecular targeting for solid tumors. To date 6 ADCs have been approved in solid tumors against 5 targets (HER2/ERBB2, Folate alpha, Tissue Factor, Nectin-4, and Trop-2). Thus far, no ADCs have been approved for head and neck cancers.

Methods: We queried protein expression data from a publically available consortium of datasets (TNMPlot.com) containing protein expression data from over 56,000 tumor and normal samples from GEO, GTex, TCGA, and TARGET databases. Genes examined for protein targets, included those with ADC targets of both presently approved and investigational drugs from clinical trials.The level of overexpression was determined as the percent of tumors over the 75th percentile of expression in normal tissue.

Results: Protein expression data were available for 99 HNSCC samples. Among targets with ADCs available, increased protein expression was seen in HNSCC for 0% of ERBB2 (n=0/99), 38% of FOLR1 (n=38/99), 0% of TACSTD2 (n=0/99), and 42% of F2 (n=42/99) genes.Among gene targets with investigational ADCs, increased protein expression was seen in HNSCC for 35% of of AXL (n=35/99), 13% of B7H3/CD27 (n=12/99), 50% of EGFR (n=50/99), 63% of VTCN1 (n=63/99), 10% of MSLN (n=10/99), 77% of CDH3 (n=76/99), and 39% of PDGFRA (n=39/99).

Conclusion: Increased protein expression for approved ADC targets were infrequent in HNSCC. However, increased protein expression is seen for several ADCs under clinical investigation supporting the potential therapeutic approaches for investigational ADC targets.

#5094 Immunotherapy in advanced cutaneous non-melanomatous spindle cell neoplasms.

L. S. McLean[1], A. M. Lim[1], C. Angel[1], R. J. Young[1], A. Pizzolla[1], S. Archer[2], A. A. Thai[1], B. Solomon[1], J. Lewin[1], D. Rischin[1];
[1]Peter MacCallum Cancer Centre, Melbourne, Australia, [2]Monash Bioinformatics Platform, Melbourne, Australia

Background: Non-melanomatous cutaneous spindle cell neoplasms (NMCSpC) are a rare group of malignancies including pleomorphic dermal sarcoma (PDS) and spindle-cell cutaneous squamous cell carcinoma (SpSCC). They present a diagnostic challenge with overlapping morphological features and variable patterns of immunohistochemical (IHC) staining. There is a lack of consensus on how to best manage advanced NMCSpC and limited reports of immunotherapy (IO) responses. This study reviews the efficacy of IO in NMCSpC and performs comprehensive tumor profiling to identify biological rationale for IO use in this rare group of tumors.

Methods: We performed a single-center retrospective review of all locally-advanced or metastatic NMCSpCs treated with IO. Blinded histopathology reviews occurred to confirm each diagnosis. Overall response rates (ORR) were collected as per Response Evaluation Criteria in Solid Tumors 1.1 or Positron Emission Tomography Response Criteria 1.0. Comprehensive tumor profiling included whole exome sequencing for tumor mutational burden (TMB) and ultraviolet(UV)-signatures, and IHC for immune-cell infiltration (CD103/CD4/CD3/CD8/CD20) and immune-checkpoint expression (PD-L1/TIGIT/LAG3).

Results: 7 patients were identified. Median follow up was 18.1 months (range: 5.3-34.7). ORR 86% (6/7) with five complete responses (CR). One patient who achieved stable disease progressed. Responses were durable with two patients in CR >30 months after IO commencement. Blinded pathological review identified 3 SpSCC, 2 PDS and 2 spindle cell tumors of unclear sub-classification. All patients had high TMB and UV-signatures. One patient had PD-L1 100% (combined positive score) with abundant immune-cell infiltration and LAG3 expression (Table 1).

Conclusion: In advanced NMCSpC, excellent responses to IO with durable disease control was observed. IO is worthy of further exploration in these patients. UV-signatures and high TMB could be used to help select patients for treatment.

Immunohistochemistry (IHC)^, tumor mutational burden and ultraviolet signatures

Patient	T-cell markers				B-cell marker	Immune-checkpoints			Tumor mutational burden (mutations/megabase)	Ultraviolet-mutational signature	Best response assessment#
	CD103	CD4	CD3	CD8	CD20	PD-L1	TIGIT	LAG3			
1	1	20	1	1	0	7	0	0	17.94	Yes	Stable metabolic response
2	1	20	30	10	0	100	0	10	35.34	Yes	Complete metabolic response
3	1	10	10	5	0	5	0	0	104.87	Yes	Complete metabolic response
4	1	0	1	0	0	0	0	0	74.04	Yes	Partial metabolic response
5*	NA	NA	NA	NA	NA	NA	NA	NA	29	Yes	Complete metabolic response
6	1	0	0	5	0	0	0	4	12.02	Yes	Complete metabolic response
7	1	0	5	1	0	0	0	0	41.17	Yes	Complete response

^IHC scores are % of positively stained cells, except for PD-L1 which is combined positive score (CPS). *Insufficient tissue for IHC on Patient 5. #As per PERCIST 1.0 on FDG-PET/CT or RECIST1.1 on CT.

#5095 Characteristics of patients with advanced renal cell carcinoma (aRCC) who received first-line (1L) nivolumab plus cabozantinib (NIVO+CABO), pembrolizumab plus lenvatinib (PEM+LEN), or nivolumab (NIVO) monotherapy in the real-world (RW) setting.

K. K. Zarrabi[1], B. Miron[2], X. Yin[3], L. Rosenblatt[3], S. B. Guttenplan[3], W. John[4], T. A. Miller[4], P. Asgarisabet[4], P. Pathak[4], M. Ahlquist[4], Y. Gash[4], D. M. Geynisman[2];

[1]Thomas Jefferson University, Philadelphia, PA, [2]Fox Chase Cancer Center, Philadelphia, PA, [3]Bristol Meyers Squibb, Princeton, NJ, [4]Cardinal Health, Dublin, OH

Background: Recent advances in immunotherapy have introduced new treatment modalities for aRCC. In absence of guideline recommendations, it is unclear what factors drive providers in selecting 1L treatments for aRCC. To address this gap, we described the baseline demographic and clinical characteristics of patients with aRCC who received 1L NIVO+CABO, PEM+LEN, or NIVO monotherapy in the RW setting.

Methods: In this retrospective cohort study, treating oncologists from a US nationally representative network abstracted electronic health record data from patients with aRCC who initiated 1L NIVO+CABO or NIVO monotherapy (off-label in the US) between 2/1/2021 and 6/12/2023, or PEM+LEN between 9/1/2021 and 6/12/2023. Patient demographic and clinical characteristics were summarized descriptively.

Results: Compared with patients who received NIVO+CABO (n = 200) or PEM+LEN (n = 100), patients who received NIVO (n = 147) were relatively older at 1L initiation (Table). Sex, race, and region of residence were comparable across cohorts. Patients who received NIVO were more likely to have an ECOG PS score of ≥ 2 (59.2%) compared with NIVO+CABO (14.5%) or PEM+LEN (20%) cohorts. The distribution of MSKCC or IMDC risk scores at 1L initiation was comparable across cohorts . Grade 3 or 4 tumors were reported among 56.5%, 41.0%, and 43.5% of those who received NIVO+CABO, PEM+LEN, and NIVO, respectively.

Conclusions: This study suggests that 1L treatment for aRCC using IO monotherapy may be more likely to be considered than IO-TKI therapy for older patients and those with poorer ECOG PS, possibly reflecting perceived tolerability of TKI combinations in these patient populations. Further research is needed to understand the impact of these 1L treatment selection patterns on outcomes.

Table: Key patient characteristics at 1L initiation.

	PEM+LEN	**NIVO+CABO**	**NIVO**
	n = 100	**n = 200**	**n = 147**

#5096 Clinical feature of immune checkpoint inhibitor-induced pancreatic injury.

J. Itani, T. Ishikawa, T. Doi, D. Sone, R. Morita, N. Iwai, R. Hirose, K. Inoue, O. Dohi, N. Yoshida, K. Uchiyama, T. Takagi, H. Konishi, Y. Itoh;
Kyoto Prefectural University of Medicine, Kyoto, Japan

Immune checkpoint inhibitors(ICIs) cause multiple adverse inflammatory reactions known as immune-related adverse events(irAEs), but ICI-related pancreatic injury(ICI-PI) is rare. ICI-PI ranges from asymptomatic hyperamylasemia to acute pancreatitis(ICI-AP), and its clinical features are not fully understood. We investigated the frequency and clinical features of ICI-PI and ICI-AP as well as their possible risk factors. Of the 186 consecutive cases who received ICI for GI cancers in our hospital from January 2020 to May 2022, 185 could be evaluated for serum amylase(AMY) levels pre- and post- ICI treatment. We retrospectively examined the clinical features and predictors of ICI-PI. Hyperamylasemia of grade 2 or higher according to CTCAE(v.5.0) was considered ICI-PI, and cases with other obvious factors were excluded. In the case of ICI-AP, we analyzed the pathological features of the tissues collected by EUS-FNA as well as the clinical features. The median of ICI doses was 6.0(range, 1-64), and the median duration of observation was 236 days(range, 17-1162). There were 25 cases of hyperamylasemia (higher than ULN) before starting ICI treatment. After starting ICI treatment, 14 patients(7.6%) developed ICI-PI, in all cases grade 2. The median time to onset of ICI-PI was 37.5 days(7-715). No cases discontinued ICI dosing due to ICI-PI, and no cases developed obvious pancreatic endocrine or exocrine insufficiency during the observation period. Overall survival was significantly longer in cases with ICI-PI than in those without ICI-PI(MST; 855 vs. 347days, p=0.029) and there was a trend toward longer PFS(MST; 160 vs. 96 days, p=0.057). Multivariate analysis revealed that only pretreatment serum AMY level(≥80 U/L) was a significant independent predictor of developing ICI-PI(HR: 5.00, 95% CI: 1.057-23.668, p=0.04). ICI-AP occurred in 2 cases(1.1%), both of them discontinued ICI treatment. Both cases showed enlarged pancreas on CT scan, negative serum IgG4 level, and responded well to steroid therapy. Pathological findings showed lymphoplasma cell infiltration, flower-like fibrosis, and obstructive phlebitis, which were similar to type 1 autoimmune pancreatitis(AIP) in one case. In the other case, neutrophil infiltration was observed in the stroma and epithelium, similar to type 2 AIP. The best overall response was PR in both cases with ICI-AP. The findings of this study indicate that higher pretreatment serum AMY levels may increase the probability of ICI-PI. ICI-PI cases without pancreatitis did not show any pancreatic endocrine or exocrine insufficiency during the observation period without interruption of ICI treatment and had favorable prognosis, but a more long-term evaluation of the impact on pancreatic function is needed. The clinical implications of ICI-related hyperamylasemia and its differences from ICI-AP remain uncertain and need to be explored in the future.

#5097 Effectiveness and safety of atezolizumab plus bevacizumab in unresectable hepatocellular carcinoma: A multicenter, retrospective real-world study in China.

H. Zhang, M. Shao, B. Tan, Y. Fu, Y. Yuan, H. Chen;
Southwest Hospital, Third Military Medical University, Chongqing, China

Background: Atezolizumab plus bevacizumab (Atezo+Bev) has shown better benefits than sorafenib as the first-line treatment for unresectable hepatocellular carcinoma (uHCC) in IMbrave 150. However, the real-world evidence of Atezo+Bev in uHCC is limited, especially in China. We aimed to investigate the real-world effectiveness and safety of Atezo+Bev in Chinese patients with uHCC.

Methods: Patients with uHCC treated with Atezo+Bev were included at 5 centers in China from Jan. 2021 to Jan. 2023. Overall response (ORR), organ-specific response rate (OSRR), disease control rates (DCR), time to disease progression (TPP), progression-free survival (PFS), metastasis-specific PFS and overall survival (OS) were calculated.

Results: Among 48 patients, the median age was 58.4 years with 85.4% being male. A total of 35 and 13 patients received Atezo+Bev as 1st and 2nd line treatment, respectively. The median number of treatment cycles were 8, and 27 (56.3%) patients received locoregional therapies. Detailed treatment response is in the Table. The overall ORR and DCR assessed by mRECIST were 60.4% and 75.0%, while the intra- and extrahepatic OSRR were 59.4% and 62.5%, respectively. With a median follow-up of 14.5 months, the median PFS was 8.5 months (95%CI: 4.4, 11.2) in 1st line setting and 5.1 months (95%CI: 2.1, 7.9) in 2nd line setting. Median intra- and extrahepatic metastasis-specific PFS were 7.9 and 7.6 months, respectively. Median overall TTP was 7.6 months. The median OS was not reached. A total of 36 patients (75%) experienced any grade adverse events, most commonly being thrombocytopenia (27.1%, n=13), lymphopenia (25%, n=12) and abnormal liver function (14.6%, n=7).

Conclusion: This study confirmed effectiveness and safety of Atezo+Bev in the 1st line treatment of uHCC, and observed its potential in 2nd line in a real-world setting. Further studies are warranted to confirm these observations and refine treatment strategies.

Table. Treatment response

N (%)	Response Evaluation Criteria in Solid Tumors (RECIST) 1.1(N=48)	Modified RECIST(N=48)
Complete response (CR)	7 (14.6)	9 (18.8)
Partial response (PR)	12 (25.0)	20 (41.7)
Stable disease (SD)	15 (31.2)	7 (14.6)
Progressive disease	11 (22.9)	12 (25.0)
Not evaluated	3 (6.2)	0
ORR (CR+PR)	19 (39.6)	29 (60.4)
DCR (CR+PR+SD)	34 (70.8)	36 (75.0)

#5098 Second-line treatment outcomes in Extensive Stage Small Cell Lung Cancer (ES-SCLC) patients after first-line immuno-chemotherapy.

R. Wan, L. Fan, J. Zhong, J. Duan, Z. Wang, X. Hao, J. Wang;
Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Background: First-line immune checkpoint inhibitors (ICIs) has significantly improved overall survival (OS) of ES-SCLC. However, second-line treatment options are still controversial with limited overall survival. This study aims to evaluate the efficacy of different second-line regimens for relapsed ES-SCLC after first-line immuno-chemotherapy.

Patients and Methods: We retrospectively reviewed 96 ES-SCLC patients receiving first-line immuno-chemotherapy in Cancer Hospital Chinese Academy of Medical Sciences, from Jan 2019 to Dec 2022. Clinical data were collected from electronic medical records. The clinical outcomes, including objective response rate (ORR), progression-free survival (PFS) and overall survival (OS) were assessed by Kaplan-Meier method and standard log-rank test.

Results: From January 4, 2019 to December 18, 2022, a total of 96 ES-SCLC patients received first-line immuno-chemotherapy and 49 of them went through second-line treatment in our center. Patient characteristics were listed as follows : median age 63 (31-79), male 76 (79.2%) , heavy smoker 59 (61.5%), liver metastasis 40 (41.7%), brain metastasis 33 (34.4%) and refractory recurrence 58 (60.4%). Second-line treatments included immunotherapy crossover and combination with chemotherapy (n=40), anlotinib with or without chemotherapy (n=5), chemotherapy alone (n=4). ORR of the whole group in the second-line setting was 22.4%. Median PFS was 3.23 months (95% CI 1.96-4.50). Cross-line immunotherapy failed to improved survival for relapsed ES-SCLC compared with those without ICIs (mPFS 3.23 vs 3.13m, *p*=0.829). Anlotinib based treatment showed numerically superior PFS for relapsed SCLC compared with those without anlotinib therapy (mPFS 6.00 vs 3.13m, p=0.089).

Conclusion: This retrospective study indicated cross-line ICIs failure to improve clinical outcome for relapsed ES-SCLC, and implied the potential benefits of anlotinib in second-line setting.

#5099 Prevalence of fibroblast growth factor receptor (*FGFR*) alterations (alts) and programmed death-ligand 1 (PD-L1) expression (exp) in Chinese solid tumor patients (pts).

M. Qing[1], F. Yang[1], X. Chen[1], X. Lyu[1], A. Wang[2], Y. Yu[2], S. Thomas[3], **L. Zhou[1]**;

[1]Janssen Research & Development, Shanghai, China, [2]OrigiMed Co., Ltd, Shanghai, China, [3]Janssen Research & Development, Spring House, PA

Background: PD-L1 expression drives anti-PD(L)-1 treatment decisions across many cancer indications. *FGFR* inhibitors have been approved for the treatment of metastatic urothelial cancer (UC) and cholangiocarcinoma with *FGFR* alts. BALVERSA (erdafitinib), a selective pan-*FGFR* kinase inhibitor, has shown clinical activity against *FGFR* altered solid tumors in pts who exhausted standard treatment options. It is important to understand the prevalence of *FGFR* alts and relationship between *FGFR* alts and PD-L1 expression levels in different cancer types.

Methods: In this real-world study, 9937 Chinese solid tumor pts with the PD-L1 (22C3) immunohistochemistry and OrigiMed 450-gene next-generation sequencing panel results were selected. Chi-square test and Fisher test were used to explore the association between the *FGFR* alts and PD-L1 expression.

Results: *FGFR1-4* somatic alts were found in 9.0% of Chinese cancer pts evaluated. *FGFR1* amplification (amp) was the most prevalent alts identified (1.9%). There were no significant differences in frequency of FGFR alts between the Chinese cohort and MSK-IMPACT cohort in each cancer type tested. Up to 40.6% of pts evaluated were PD-L1 positive (CPS ≥1 or TPS ≥1%). The PD-L1 positive rate (TPS ≥1%) in SCLC (12.4%, n=121) and NSCLC adenocarcinoma tumors (LUAD) (26.1%, n=2902) was relatively low. In few tumor types, higher expression of PD-L1 in FGFR altered samples was observed compared with FGFR unaltered samples in pan-tumor (mean TPS 14.8% vs.8.6%, *P*=6.0*E-9; mean CPS 6.3 vs. 6.1, *P*=3*E-4). Those includes LUAD (mean TPS 14.2% vs. 7.4%, *P* = 1.7*E-16), colorectal tumor (mean CPS 4.6 vs. 3.9, *P* = 4.6*E-8), and uterine tumor (mean CPS 8.1 vs. 6.5, *P* = 9.6*E-5). While PD-L1 expression is lower in FGFR altered samples than FGFR unaltered samples in UC (n=154; mean CPS 3.9 vs. 6.8, *P* = 0.004). No relationship was observed between FGFR alts and PD-L1 expression in cholangiocarcinoma (n=610). Specific *FGFR* alts eligible for erdafitinib UC treatment were further investigated in UC and observed with rate 10.4%, including *FGFR3* short variants (9.7%) as main alts. Specific FGFR altered tumors showed similar trend with lower PD-L1 expression than *FGFR* unaltered tumors in UC. The inverse relationship between *FGFR* alts and PD-L1 expression in UC compared to other solid tumors may explain variable role of *FGFR*s since the predominant *FGFR* alt types vary among different cancer types (*FGFR3* short variants enriched in UC vs no such predominant *FGFR* alt types in other cancer types).

Conclusion: The large Chinese solid tumor cohort analysis showed comparable *FGFR* alts prevalence between Chinese and Western population. Differences in relationship between *FGFR* alts and PD-L1 expression across tumor types reflect the differential role of predominant *FGFR* types in each tumor type.

#5100 Multimodal real world data reveals immunogenomic drivers of acquired and primary resistance to immune checkpoint blockade.

M. Keddar[1], S. Carrasco Pro[2], K. Burke[2], A. Camelo Stewart[1], M. Cobbold[3], R. Stewart[1], S. Khosla[1], B. Sidders[1], S. Hammond[4], D. C. Palmer[4], J. Dry[2], **M. L. Miller**[1];

[1]Astrazeneca, Cambridge, United Kingdom, [2]Tempus Labs Inc, Boston, MA, [3]Astrazeneca, Waltham, MA, [4]Astrazeneca, Gaitherburg, MD

Background: Why some patients fail or have short lived response to immune checkpoint blockade (ICB) immunotherapy remains largely unknown. While baseline molecular assessments have provided clues to prognostic factors, insights into resistance drivers remains elusive. This is partially due to the difficulty in getting access to post progression samples from patients that were either primary resistant or developed acquired resistance after an initial response to ICB. Thus, the tumor-intrinsic and -extrinsic features that are selected for during progression and potentially drive primary and acquired resistance to immunotherapy remain underexplored.

Methods: To compare clinical features and immunogenomic drivers of acquired and primary resistance to ICB across major cancers, we analysed and annotated de-identified patient records in the Tempus real-world database. We built an immuno-oncology cohort consisting of >2500 multimodal (DNA, RNA and clinical outcome data) pre-treatment baseline with >1500 post-treatment tumour biopsy samples from mainly NSCLC, TNBC, HNC and Bladder cancer patients. We used bulk RNA-seq data to estimate activation of the hallmark oncogenic pathways and immune cell composition and used panel DNA-seq data (>500 genes) to quantify mutation selection at the gene and pathway levels using *dndscv*.

Results: Compared to acquired, primary resistant patients tended to have a higher observation of liver lesions at progression. Post-ICB, acquired resistant NSCLC and HNC patients showed a significantly inflamed tumour microenvironment (TME) characterised by higher estimation of infiltration of T cells and myeloid cells and higher activation of interferon gamma (IFNg) signalling as compared to primary resistant patients. In addition, in post-ICB acquired resistance in NSCLC we observed selection for mutations in genes involved in known immunomodulatory pathways, including loss-of-function mutations in *B2M*. Consistently, acquired resistance patients showed stronger selection for mutations in Hedgehog and Notch pathways as compared to primary resistance patients across NSCLC, HNC and TNBC post-ICB.

Conclusions: Acquired and primary ICB resistant patients have distinct clinical and molecular features at progression. Their tumours' TME is fundamentally different with acquired resistance TMEs being infiltrated with immune cells albeit escaped post progression. In addition, ICB selects mutations that potentially activate pathways such as Notch and Hedgehog. This multi-modal Real-World Data with post therapy biopsies has given insights for patient selection strategies and provides rational into combination treatment options for acquired resistant patients.

#5101 Comparative genomic analysis reveals distinctive immune profiles in MET exon 14 mutated and MET amplified lung cancer.

S. Javeri[1], R. Minne[1], S. Ramesh[1], A. Baschnagel[1], R. Kimple[1], L. Lamb[2], S. Tomlins[2], B. Johnson[2], N. Khazanov[2];
[1]University of Wisconsin-Madison, Madison, WI, [2]STRATA Oncology, Ann Arbor, MI

Background: In non-small cell lung cancer (NSCLC), the MET tyrosine kinase receptor can be mutated or amplified resulting in dysregulation of receptor function leading to tumor proliferation. MET exon 14 (METEx14) mutated and MET amplified NSCLC tumors have shown varied response to immunotherapy. Therefore, we sought to compare the genomic and immune landscape of MET-altered NSCLC.
Methods: The genomic profiles of 3,821 NSCLC tumors sequenced using the Strata Select assay on the Strata Oncology Platform were analyzed. Tumors were sorted based on METex14 mutations, MET amplification (METamp) defined as copy number gain (CNG) ≥6 and MET wild-type (METwt). The RNA expression of 19 immune regulatory genes, tumor mutation burden (TMB), Strata Immunotherapy Response Signature (IRS) score and the frequency of gene co-alterations were compared across groups. Statistical comparisons of medians were done with Kruskal-Wallis testing and categorical comparisons with Chi square using R Studio version 4.3.2.
Results: 122 (3.2%) METex14, 70 (1.8%) METamp, and 3,629 (95.0%) METwt were identified. Patients with METex14 were older and more frequently female. MET gene expression was found to be higher in METamp (median 14.4) compared to METex14 (median 12.3) ($P<0.01$). TMB was lowest in METex14 (median 2.7) group compared to METamp (median 7.1) and METwt (median 5.1) ($P<0.001$). High PD-L1 expression occurred in 71.4% of METamp, 68.0% of METex14 and 41.3% of METwt ($P<0.001$). Overall, METamp tumors had a greater proportion of high IRS scores (52.9%) compared to METex14 (35.2%) and METwt (45.4%) ($P<0.01$). mRNA expression of immune checkpoints CTLA4, PD-1, LAG3, IDO1, TIGIT and HAVCR2 were all higher in METex14 compared to METamp and METwt ($P<0.001$ for all). METex14 tumors also exhibited higher gene expression of CD4, CD8A and FOXP3 compared to METamp and METwt ($p<0.001$). METex14 had higher prevalence of MDM2 amplification (34% vs 3% vs 4%) and lower prevalence of alterations in EGFR (0.8% vs 22% vs 21%), KRAS (0.8% vs 10% vs 26%), CDKN2A (17% vs 29% v 28%) and TP53 (34% vs 87% vs 64%) compared with METamp and METwt tumors, respectively ($p<0.05$).
Conclusion: METex14 and METamp tumors harbor distinct immune-gene expression profiles and co-occurring gene alterations that distinguish themselves from each other and METwt tumors. Further analysis must be conducted to determine how these variations impact immunotherapy in MET-altered NSCLC.

CLINICAL RESEARCH: Pediatric CNS Tumors, Leukemia, and Neuroblastoma: Translational
Poster Session

#5105 Aberrant CLK1 splicing is a key dependency factor in pediatric high-grade gliomas.

Children's Hospital of Philadelphia, Philadelphia, PA

Pediatric brain cancer is the leading cause of disease-related mortality in children. With a paucity of therapeutically targetable alterations, there is a pressing need to identify effective strategies for many of these tumors. In this study, we systematically examine aberrant alternative splicing in pediatric brain tumors from the Open Pediatric Brain Tumor Atlas, and additional tumors from the Children's Brain Tumor Network and the Pacific Pediatric Neuro-Oncology Consortium (n = 1831). Notably, high-grade gliomas (HGGs), including those with and without H3 histone mutations, were enriched in the upper quartile of all tumors with high splicing burden (SB). HGGs demonstrated the greatest SB heterogeneity of all tumor types and we identified a total of 19,229 aberrant splicing events in 8,577 genes in midline tumors compared to non-tumor brainstem controls (ΔPSI >= |.20|, p < 0.05). We next integrated protein annotations from the UniProt Knowledgebase to assess and prioritize differential alternative splicing events affecting protein function. This approach led to the discovery of 3,754 splice variants in 5,036 genes resulting in the gain or ablation of functional sites. The protein kinase *CDC-like kinase 1 (CLK1)*, a recognized master splicing factor and cell-cycle modulator, exhibited aberrant splicing of exon 4, whereby inclusion promoted the gain of two known phosphorylation sites. Additionally, we observed a strong correlation between *CLK1* splicing, its own RNA expression and proteomic activity of the Serine/Arginine-rich (SR) family of splicing factors. The distribution of exon 4 splicing was significantly different (p = 0.019) between tumors with low vs high splicing burden; tumors with high splicing burden had increased exon 4 inclusion. Further, we performed experimental modulation of *CLK1* exon 4 aberrant splicing in the brain tumor cell line KNS42 and demonstrated that forced exon 4 skipping leads to reduced CLK1 protein abundance and significantly reduces cell proliferation (p < 0.01 vs. control). Following bulk RNA-Seq analysis of these cell lines, we identified that forced *CLK1* exon 4 skipping resulted in 4,518 dysregulated genes enriched for known cancer pathways such as mitotic spindle, E2F targets, and G2M checkpoint. Our data suggest a role for *CLK1* in driving transcriptional dysregulation in pediatric high-grade gliomas and uncover a potential therapeutic vulnerability.

#5106 Pharmacological targeting of LSD1 prolongs animal survival times in patient derived orthotopic xenograft models of posterior fossa ependymoma in combination with fractionated radiation.

M. M. Suarez Palacios[1], S. Zhao[2], H. Zhang[2], L. Qi[2], H. Lindsay[2], M. Kogiso[2], F. Braun[2], A. M. Adesina[2], Y. Du[2], Y. Song[2], X.-N. Li[2];
[1]Northwestern University - Chicago, Chicago, IL, [2]Baylor College of Medicine, Houston, TX

Background: Posterior Fossa Group A Ependymoma (PFA EPN) constitute one of the most aggressive and highly recurrent molecular subtypes of childhood Ependymomas. We recently performed a comprehensive genome-wide DNA methylation analysis in recurrent pediatric EPN tumors from patients that were followed up for over 13 years. Integrative analysis between tumor DNA methylation and histone modification identified LSD1 as a druggable driver of PFA EPN recurrence. In this study, we examined the therapeutic efficacy of our newly developed LSD1 inhibitor SYC-836 in PDOX models of recurrent PFA EPN.
Methodology: To determine the *in vitro* anti-tumor activities of SYC-836, paired PFA EPN xenograft cell cultures (monolayer and 3D neurospheres) were treated with SYC-836 at 8 concentrations (0.02-25 µM) and examined for changes of cell proliferation every 3-4 days through day 14. To validate the drug's *in vivo* efficacy, two established posterior fossa EPN PDOX models, ICb-4423EPN and ICb-2002EPN, were utilized. Forty 8-week old SCID mice of both genders received intra-cerebellar tumor cell implantation and were divided into 4 treatment groups (n=10 per group): 1) control, 2) radiation (2 Gy/day x 5 days), 3) SYC-836 (15 mg/kg, daily intra-peritoneal injection for 28 days), and 4) combination (radiation + SYC-836). Animal survival times were analyzed using log-rank analysis. Changes in LSD1 protein expression and histone lysine methylation were examined through western hybridization.
Results: SYC-836 strongly suppressed PFA EPN cell growth *in vitro,* in both, a time- and dose-dependent manner. While there was no survival benefit with either SYC-836 only (P=0.186) or XRT only (P=0.205); combining SYC-836 with XRT significantly (P=0.04) prolonged the median survival time of ICb-4423EPN, from 46 days in the untreated group to 59 days; and in ICb-2002EPN, even more prominent, from 136 days to 180 days (P=0.007). SYC-836 was well tolerated in mice with no loss of body weight or other toxicities. Changes in LSD1 protein expression and H3K4me2 were detected through western hybridization during and after SYC-836 treatment.
Conclusion: Our data support LSD1 as a druggable driver of PFA recurrence and highlights strong anti-tumor activities of SYC-836 in combination with radiation, a standard therapy of pediatric EPN. SYC-836 may have a role in the clinical setting by either reducing radiation dosages or be an adjuvant agent to other chemotherapy drugs in our treatment approach for ependymoma.

#5107 Targeting CTPS1 and nucleotide biosynthesis pathways as a novel therapeutic approach in MYC-amplified medulloblastoma.

M. Hathaway[1], H. Jagana[1], M. Meechan[1], J. Hemenway[1], **K. E. Gadek**[1], A. Miyaki[1], I. Terrones[1], B. Slusher[2], S. Pattwell[1], N. Vitanza[1], M. K. Evans II[1];
[1]Seattle Children's Research Institute, Seattle, WA, [2]Johns Hopkins School of Medicine, Baltimore, MD

Although leukemia is the leading pediatric oncology diagnosis, brain tumors are the leading cause of pediatric cancer-related death. Medulloblastoma is the most common pediatric brain tumor, representing approximately 20% of all diagnoses. Of all four defined subgroups, MYC-amplified Group 3 medulloblastoma (G3 MB) tumors are the deadliest, with a < 50% 5-year overall survival rate. High risk patients receive large doses of chemo- and radio- therapy (CT/RT) with most survivors experiencing debilitating neurological and cognitive sequelae making the identification of novel targets of the utmost importance. Utilizing whole-genome CRISPR screening from the Pediatric Cancer Dependency Map, we identified the enzyme CTPS1 as a strong G3 MB-specific vulnerability. Recent studies corroborate our findings and suggest a dependence on the *de novo* pyrimidine biosynthesis pathway in MB. Targeted knockdown of CTPS1 restricts sphere formation and reduces proliferation of G3 MB tumor lines. We confirmed this genetic approach using a specific CTPS1 inhibitor, which also reduced proliferation but did not induce cell death, suggesting a cytostatic mechanism. Strikingly, we demonstrate that G3 MB is only dependent upon de novo pyrimidine synthesis and not de novo purine synthesis, despite regulation of both pathways by oncogenic MYC signaling. Previous work has shown that triggering an imbalance in pyrimidine and purine levels leads to replication stress and activation of the ATR/CHK1 pathway. Both genetic and pharmacologic inhibition of CTPS1 leads to CHK phosphorylation, allowing for cell survival despite lack of dNTPs. Previously, the CHK1 inhibitor, prexasertib, demonstrated robust brain accumulation and targeting of G3 MB in pre-clinical models. Dual inhibition of CHK1 and CTPS1 synergizes to significantly reduce cell viability *in vitro* and tumor growth *in vivo*. We further demonstrated robust synergy of CHK1 inhibition with either glutamine antagonists or other inhibitors of the *de novo* pyrimidine synthesis pathway, prolonging *in vivo* survival in an orthotopic xenograft G3 MB model. The results of this investigation confirm CTPS1 as a novel target in G3 MB, pinpoint a dependency on *de novo* pyrimidine rather than purine biosynthesis, and identifies a novel rational combination for treatment in MYC-amplified MB patients.

#5108 Immunomodulatory and anti-tumor effect of radiation and induced telomere damage to treat pediatric high-grade gliomas.

U. Banlanjo[1], S. Senthil Kumar[1], S. Gryaznov[2], **R. Drissi**[1];
[1]Nationwide Children's Hospital, Columbus, OH, [2]MAIA Biotechnology Inc., Chicago, IL

Pediatric high-grade gliomas (pHGGs), including diffuse intrinsic pontine glioma (DIPG) are among the most treatment refractory cancers in children. Despite multimodal therapy, prognosis is dismal with survival of <1 year for DIPG and a 5-year overall survival <10% for other pHGGs. Radiotherapy remains the only standard of care for DIPG that extends the survival by few months. In recent years, immunotherapy is emerging as a potential alternative treatment option. However, several factors have hindered the use of immunotherapy for pHGGs including “cold” immune environment with lack of immune cells infiltration, low tumor mutational burden, and lack of neo-antigen expression that prevents tumor recognition by the immune system. Therefore, novel therapies that activate the immune system while evading the tumor immunosuppression are highly needed. Here, we aim to demonstrate the immunomodulatory anti-tumor effects of THIO (6-thio-2’deoxyguanosine), a nucleoside analog and a telomerase-dependent telomere targeting agent, in DIPG mouse models. Our preclinical *in vitro* and *in vivo* data have demonstrated the efficacy of THIO in inducing telomeric damage, G_2/M cell cycle arrest, and apoptosis in high-risk medulloblastoma and DIPG. Importantly, we have demonstrated that THIO crosses the blood-brain barrier and specifically targets tumor cells in an orthotopic mouse model of DIPG. THIO was shown to induce anti-tumor immunity through micronuclei formation leading to cGAS-STING pathway mediated activation of the innate and adaptive immune response in colon, lung, and hepatocellular carcinoma tumor models. Our preliminary data demonstrate the THIO-dependent induction of micronuclei formation co-localizing with cGAS and leading to STAT1 activation in DIPG cell lines. We have also shown that THIO synergistically sensitizes DIPG cells to ionizing radiation (IR), significantly decreasing cell proliferation. We are currently testing the combination of THIO+IR in an orthotopic mouse model for DIPG. We will present results on the potential of THIO and IR treatments to stimulate anti-tumor immunity through the activation of STING pathway in a syngeneic mouse model of DIPG. These preclinical studies will support the potential use of THIO and IR to treat children with high-risk pediatric brain tumors.

#5109 Novel acylfulvene LP184 shows single agent and combinatorial efficacy with PARP inhibitors in atypical teratoid rhabdoid tumors.

Abigail Tindall, Hyuk J. Kwon, Istabraq Musa, Tyler Findlay, Su Chan Lee, Charles Eberhart, Eric Raabe

Pediatric Oncology, Johns Hopkins University School of Medicine, Baltimore, MD

Atypical Teratoid Rhabdoid Tumor (AT/RT) is an aggressive form of pediatric brain cancer that spreads quickly and leads to survival rates of less than 40%. Current treatments are insufficient at reducing this poor prognosis. A hallmark feature of ATRT is a SMARCB1 mutation. Illudins are a class of cytotoxic compounds with activity against pediatric solid tumors, including AT/RT. LP-184 is a novel synthetic illudin with improved brain penetration and activity against adult high-grade glioma orthotopic xenografts. We tested LP-184 against a battery of AT/RT cell lines including BT37, CHLA06, CHLA05, and CHLA266. LP-184 decreases viability at nanomolar concentrations with IC50s ranging from 9.91nM - 23.92nM. LP-184 decreased proliferation as measured by immunofluorescence and confirmed by western blots (BT37 p=0.0001, CHLA06 =0.0001, CHLA05=0.033). LP-184 also induced apoptosis as demonstrated in immunofluorescent images and western blots (BT37 p=0.0001, CHLA06 =0.0001, CHLA05=0.0015, CHLA266 p=0.002). Furthermore, LP-184 shows strong synergy with the PARP inhibitor Rucaparib, suggesting that inhibition of DNA repair potentiates LP-184 activity. LP-184 reduces viable cell count by as much as 50% and combination with Rucaparib further decreases viability by 75% (BT37=0.0001, CHLA06=0.0002, CHLA05=0.0077). The dual therapy also demonstrates cytostatic and cytotoxic effects as confirmed by immunofluorescence and western blots (BT37 BrdU = 0.0004, BT37 CC3 = 0.0002, CHLA06 BrdU = 0.0033, CHLA06 CC3 = 0.0117 compared to control). Further studies *in vivo* are being conducted to test single agent and combination therapies of LP-184 and Rucaparib in ATRT, as our data indicates that the two could provide a compelling treatment option for patients with this poor prognosis brain tumor.

#5110 Exploring the effects of Indirubins in pediatric diffuse high grade glioma models.

J. S. Clark[1], J. Jimenez-Macias[1], P. Vaughn-Beaucaire[1], S. Zhang[1], W. El-Deiry[1], R. Lulla[2], S. Lawler[1];
[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]Hasbro Children's Hospital, Providence, RI

Diffuse midline glioma (DMG) is an invasive pediatric brain tumor which grows in the pons of the brainstem. The current course of treatment is focal radiation however, DMG continues to have a very poor prognosis with a median survival of less than 10 months. A major barrier for chemotherapeutic treatment of DMG is the blood brain barrier (BBB) which tightly controls access of molecules to the brain. This limits the efficacy of drugs to treat brain cancer and other diseases of the central nervous system. Previous studies from the Lawler lab and others have shown that the indirubin derivative, 6-bromoindirubin-3′-acetoxime(BIO-acetoxime/BIA), has anti-invasive properties and can enhance survival in glioblastoma xenograft models. Here, we investigated the effects of BIA on pediatric glioma models using a range of relevant assays. In an *in vitro* collagen migration assay, BIA was observed to significantly slow cell migration at a concentration of 1μM in DIPG 36 cells, over 72 hours. Furthermore, we have also shown that BIA modulates the tumor vasculature, which could limit tumor growth, and improves drug delivery to tumors by targeting tight junctions in tumor associated endothelium. The effect on BBB drug penetration was assessed in a multicellular 3D *in vitro* BBB model and effects of BIA on endothelial barrier functions was determined using trans-endothelial resistance assays (TEER). BIA treatment increased dextran uptake into 3D BBB models, and also lowered endothelial cell permeability *in vitro* via a reduction in the expression of tight junction proteins as shown by staining and a decrease in TEER values. In order to assess potential synergistic interactions, a drug screen was performed on a panel of distinct pediatric glioma cell lines (DIPG 36 and KNS42). This identified several FDA approved drugs that combine well with BIA. From this screen, BIA was shown to synergize with DNA damaging chemotherapy to enhance toxicity and in combination with cisplatin promote DNA damage in pediatric glioma cell lines. Other drugs identified in the screen are currently under investigation and details will be reported. Thus, our hypothesis is that BIA may provide an effective approach for further development as a DMG therapeutic through targeting invasion and enhancing drug potency and delivery via modulation of endothelial cell tight junctions. Interrogating the mechanisms involved and developing drug formulations informed by the drug screen for *in vivo* studies to determine the translational potential of this approach is our focus for future studies.

#5111 Rational synergistic radiosensitization strategies for group 3 medulloblastoma.

J. Povilaikaite, K. Stitz, N. Austin, V. Ramaswamy;
The Hospital for Sick Children, Toronto, ON, Canada

Medulloblastoma (MB) is the most common malignant pediatric brain tumor. MB is comprised of 4 groups, termed Wnt, Shh, Group 3 and Group 4, each characterized by distinct molecular and clinical profiles. *MYC*-amplified Group 3 MB is associated imminent fatal metastatic relapse following standard treatment approaches, which currently include surgery, craniospinal irradiation and chemotherapy, highlighting an urgent need for identification of therapeutic vulnerabilities for these tumours. As such, using 4 novel patient-derived models of Group 3 MB that faithfully recapitulate the molecular and histological tumor characteristics, we characterised response to radiation of Group 3 MB *in vitro* to show that these tumors do not possess intrinsic radiation resistance. Furthermore, cumulative radiation experiments do not increase bulk radiation resistance in MB cells, highlighting the contribution of dynamic cell states to radiation response. In contrast, exposure to radiation leads to changes in cell clonogenic capacity as measured by limited dilution assays. Furthermore, RNA-seq data uncovered altered transcriptomic programs in response to cumulative radiation treatment. In particular, we observe differential regulation of genes encoding potassium ion channels and their regulators as well as genes encoding ECM and cell adhesion proteins. As part of our goal to evaluate the current multimodal treatment strategy of MB, we also show that a set of standard chemotherapeutic agents (etoposide, thiotepa and lomustine) currently used in the clinic do not produce a potent response at optimal doses *in vitro*, potentially accounting for abysmal survival outcomes seen in chemotherapy treated MB patients. As such, we conducted a screen of 144 FDA approved cancer drugs and identified therapeutics that selectively target Group 3 MB cells in contrast to normal tissue controls (foetal neural stem cells) in the low nanomolar dose range. In particular, topoisomerase inhibitor topotecan produces a potent response specific to MYC-amplified Group 3 MB, and sensitizes 2 patient-derived MB models to gamma irradiation. Altogether, our data characterizes Group 3 MB molecular and cellular responses to current treatment modalities and provides rationale for new clinical strategies to sensitize patients to radiation that will potentially allow to reduce the required radiation doses to treat these aggressive tumors, reduce the incidence of radiation treatment-related morbidity as well as improve cure rates.

#5112 Discovery of nuclear envelope mislocalization in *MYC*-driven group 3 medulloblastoma.

Y. Suk[1], J. Ibanez-Vega[2], I. Chaudhry[1], M. Rossotti[3], M. Subapanditha[1], P. Miletic[1], S. Custers[1], L. Escudero[1], A. Delaidelli[4], T. Nakashima[5], Y. Xiao[6], J. Moffat[6], H. Suzuki[5], P. Sorensen[4], K. Henry[3], C. Venugopal[1], G. Krenciute[7], S. Singh[1];

[1]McMaster University, Hamilton, ON, Canada, [2]St. Jude Children's Hospital, Memphis, TN, [3]National Research Council Canada, Ottawa, ON, Canada, [4]University of British Columbia, Vancouver, BC, Canada, [5]National Cancer Center Research Institute (Japan), Tokyo, Japan, [6]University of Toronto, Toronto, ON, Canada, [7]St. Jude Children's Research Hospital, Memphis, TN

Medulloblastoma (MB) is the most common malignant pediatric brain tumor, comprised of four distinct molecular subgroups (WNT, SHH, Group 3, and Group 4). A subset of Group 3 MB tumors harbor focal amplifications of the *MYC* oncogene and are particularly prone to tumor recurrence and leptomeningeal spread which currently remains incurable. Therefore, there is an urgent need for the development of therapeutic modalities that can spare the vulnerable, developing brain while having potent antitumor efficacy against recurrent MB. Through proteomic profiling of cyclophosphamide-resistant patient-derived *MYC*-driven Group 3 MB cell line SU_MB002, we identified nuclear envelope (NE) proteins to be highly abundant and enriched in Group 3 MB compared to normal tissue. We discovered that LBR, an inner nuclear transmembrane protein, while present in all cells at the NE, is aberrantly presented to the cell surface in *MYC*-driven Group 3 MB cell lines. Immunohistochemistry analysis of LBR on MB patient tumor samples identified that positive LBR staining correlated with a significantly worse prognosis and was also identified to be enriched in recurrent tissue compared to their matched primary samples. Cell surface expression flow cytometry analysis identified highly abundant cell surface expression in all MYC-driven Group 3 MB cell lines with low to no expression in human neural stem cells and other MB subgroups. Mechanistically, high resolution microscopy of endogenously HALO-tagged LBR reveals LBR cell surface presentation to be linked to ER or ER-like vesicles that are directly trafficked to the cell surface. Transcriptomic analysis of LBR cell surface positive and negative cells identify that cell surface positivity is significantly linked to cell division and mitotic processes (cell cycle process, mitotic cell cycle process, chromosome segregation, cell division, nuclear division). LBR mislocalization stems from mitosis at the time of nuclear envelope dissolution and is enriched in the hyperproliferative, therapy-resistant subpopulation of MB cells following exposure to chemotherapy and radiation *in vitro* and *in vivo* and may act as a marker for the brain tumor initiating cells that seed recurrence. Therefore, we demonstrate that LBR is an ideal therapeutic target for patients facing relapsed or treatment-refractory MB and have generated single domain antibodies in an effort to engineer LBR-specific CAR T cells. The development of therapies against NE proteins like LBR may provide patients a novel therapeutic opportunity that may be able to treat therapy-resistant, hyperproliferative *MYC*-driven Group 3 MB cells.

#5113 Fractionated radiation therapy alters energy metabolism and induces cellular quiescence exit in patient-derived orthotopic xenograft models of high-grade glioma.

Z.-L. Huang[1], Z.-G. Liu[2], Q. Lin[1], Y.-L. Tao[3], X. Li[1], P. Baxter[2], J. Su[2], A. Adesina[4], C. Man[2], M. Chintagumpala[2], W. Teo[2], Y.-C. Du[1], Y.-F. Xia[3], X.-N. Li[1]; [1]Program of Precision Medicine PDOX Modeling of Pediatric Tumors, Ann & Robert H. Lurie Children's Hospital of Chicago; Department of Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL 60611., Chicago, IL, [2]Texas Children's Cancer Center and Department of Pediatrics, Baylor College of Medicine, Houston, TX, houston, TX, [3]State Key Laboratory of Oncology in Southern China, Department of Radiation Oncology, Sun Yat-Sen University Cancer Center, Guangzhou 510060, China, Guangzhou, China, [4]Department of Pathology, Texas Children's Hospital, Houston, TX, houston, TX

Radiation is one of the standard therapies for pediatric high-grade glioma (pHGG), of which the prognosis remains poor. To gain an in-depth understanding of the biological activities beyond the classic DNA damage, we treated 6 patient-derived orthotopic xenograft (PDOX) models, including one with DNA mismatch repair (MMR) deficiency, with fractionated radiations (2 Gy/day x 5 days). Extension of survival time was noted in 4/6 PDOX models (P<0.05) and widespread γH2AX positivity in >95% tumor cells in tumor core and >85% in the invasive foci, accompanied by ~30% apoptotic and mitotic catastrophic cell death. The model with DNA MMR (IC-1406HGG) was the most responsive to radiation with a reduction of Ki-67(+) cells. Altered metabolism, including mitochondria number elevation, COX IV activation and reactive oxygen species buildup, were detected together with the accumulation of $CD133^{\pm}$ tumor cells. The latter was caused by the entry of quiescent G_0 cells into cell cycle and the activation of self-renewal (SOX2 and BMI1) and epithelial mesenchymal transition (fibronectin) genes. These novel insights about the cellular and molecular mechanisms of fractionated radiation in vivo should support the development of new radio-sensitizing therapies.

#5114 Deciphering the implications of THOC7 in medulloblastoma: Unraveling its role in tumor growth and progression.

S. M. Abdulsahib, S. Timilsina, S. Nirzhor, D. Medina, P. V. Pitta, P. Subbarayalu, M. K. Rao;
UT Health Science Center at San Antonio, San Antonio, TX

Background: Medulloblastoma (MB) is the most common malignant brain cancer in children. Despite the progress made in treating MB, the 5-year survival rate for high-risk tumors remains poor and risk of recurrence within 2 years of treatment is still high. Unfortunately, patients who do survive have reduced quality of life because of the highly toxic side effects of radiation and chemotherapy. Those facts underline the importance of identifying new drivers of MB and understanding the mechanism by which those drivers may promote MB. Using CRISPR-based dependency analysis, we discovered THO Complex Subunit 7 Homolog (THOC7) as one of the highly differentially expressed genes that may uniquely provide survival advantage to MB cells. THOC7 is a component of the THO subcomplex of the TREX complex, which is known to couple mRNA transcription, processing and nuclear export associated with spliced mRNA.
Methods: To understand the role of THOC7 in MB, we silenced the expression of THOC7 using siRNAs in multiple MB cell lines. The knockdown efficiency was confirmed by western blot and qPCR. The effect of THOC7 silencing on the viability of MB cells was assessed by short-term viability and long-term colony formation assays. The effect of THOC7 silencing on MB cell proliferation was measured using an IncuCyte. To assess whether THOC7 may affect MB progression, we performed Transwell migration assay. To understand the mechanism by which THOC7 may play a role in medulloblastomogenesis, we measured the effect of THOC7 silencing on the cell cycle progression and apoptosis. As presence of cancer stem cells is linked to relapse and makes MB refractory to radiation therapy, we asked whether THOC7 may support MB stem cell proliferation using neurosphere assay.
Results: Our analysis revealed that MB is highly addicted to THOC7. Importantly, higher expression of THOC7 is strongly correlated with lower overall survival of MB patients. We showed that depletion of THOC7 inhibited the short- and long-term viability as well as proliferation of MB cells. In addition, silencing of THOC7 inhibited migration/invasion of MB cells. THOC7 depletion led to cell cycle arrest and increased apoptosis of MB cells. Furthermore, our neurosphere assay demonstrated that silencing of THOC7 blocked the MB stem cell proliferation.
Conclusion: Our results suggest that THOC7 may be a novel driver of MB growth and progression. Inhibition of MB stem cell proliferation in THOC7 depleted cells indicates that THOC7 inhibition may sensitize refractory MB to radiation therapy. Experiments are currently underway to understand the mechanism by which THOC7 may support MB growth and progression. In conclusion, our results showing no effect of THOC7 silencing on normal cell viability suggest that approaches aimed at silencing THOC7 may be a safe and viable approach for treating MB.

#5115 Designing targeted approaches for recurrent medulloblastoma.

J. Rodriguez Blanco;
The Medical University of South Carolina (MUSC), Charleston, SC

Designing targeted therapies for recurrent medulloblastomaPediatric brain tumors are the leading cause of cancer-related death in children, with medulloblastoma (MB) being the most common type. Despite significant progress in the field, approximately 30% of children with MB will relapse. Recurrent MB is commonly metastatic and virtually none of these patients will live beyond the one-year hallmark. These sobering statistics highlight the significant unmet need for effective therapies for recurrent MB. The likely underlying cause of the constant failure of our current clinical approaches, which are based on data obtained from disease models recapitulating primary tumors, is the disparity in genomic and transcriptomic data between primary and relapsed disease. Because of these disparities, we hypothesize that by conducting mechanistic studies and drug screens in relapse disease models, we can improve the outcomes for children with recurrent MB. Our data, obtained through a bioinformatics mining approach to predict tumor response, enabled us to identify a clinically relevant candidate drug for the treatment of recurrent MB: Minnelide. This compound acted on MYC to reduce tumor growth and the metastatic dissemination of tumors with the genetic background often found in relapsed MB patients. Additionally, to further support the translational relevance of our data, Minnelide increased the efficacy of adjuvant therapeutics used in the clinical management of MB. Our findings not only highlight the potential for repurposing Minnelide to treat children with recurrent MB, but also the potential of our research approaches aimed at identifying novel therapeutics for relapsed cancers.

#5116 Stress-induced AMPK interactome analysis reveals novel protein-protein interactions associated with chromatin remodeling in acute lymphoblastic leukemia..

A. Shvab, G. J. Leclerc, J. C. Barredo;
University of Miami, Miami, FL

Acute lymphoblastic leukemia (ALL) is a leading cause of cancer-related death among children, adolescents and young adults. We previously reported that ALL cells are vulnerable to metabolic stress conditions following AMP-activated protein kinase (AMPK) activation, leading to cell death. AMPK is the master metabolic regulator, and we and others have reported it interacts with chromatin-associated proteins to regulate gene expression in response to metabolic stress. To investigate AMPK's mechanistic role in epigenetic gene regulation under metabolic stress, and identify new AMPK partners, we performed a comprehensive interactome analysis using TurboID-based proximity labeling proteomics. We generated HEK293T cells stably expressing TurboID fused to the AMPKα1, AMPKα2, AMPKβ1 or AMPKγ1. Following treatment with the allosteric AMPK activator PF-06409577 (PF064) for 1h, to mimic the cell's rapid response to energy/metabolic stress, the samples underwent mass spectrometry-based proteomics. Proteomics data analysis identified novel altered (enhanced or reduced) AMPK protein-protein interactions (PPI) following PF064 treatment. The GO analysis of proteins interacting with AMPK showed that metabolic stress enhances PPIs involved in regulating gene expression, cellular metabolic processes, DNA repair, chromatin organization, histone modifications, etc. More importantly, we identified that AMPK interacted with members of the non-canonical Polycomb repressive complex 1 (PRC1.1) such as PCGF1, RING1, KDM2B, BCORL1, USP7. PRC1 is a known epigenetic regulator that monoubiquitinylates histone H2A at Lys119 (H2AK119ub) to control transcription and regulate gene expression. Using Co-IP, we confirmed these interactions in KASUMI-2 (Bp-ALL) and KE-37 (T-ALL) cells. When cells were treated with PF064 or 991 (another AMPK activator), we found that the interactions of AMPK with the catalytic core of PCR1.1 (PCGF1, RING1) were increased compared to untreated cells. To examine the effect of activated AMPK on PCR1.1 activity, we determined the level of H2AK119ub in ALL cells treated with PF064 and 991 for 1h. We found that the level of H2AK119ub protein expression was increased in ALL-treated cells indicating the PRC1.1 was activated. Together, these data suggest that stress-induced AMPK activation increased the catalytic activity of the PRC1.1 via PPI in ALL. Our findings are consistent with our previous published RNA-Seq and ChIP-Seq data indicating an epigenetic role for AMPK in altering gene expression examined under metabolic stress (two thirds exhibited downregulation), and provide insights into the AMPK-driven mechanism(s) involved. Further elucidation of the uncovered PPIs and its mechanistic role(s) may lead to potential epigenetic-based strategies to overcome resistance/refractoriness in ALL and other malignancies.

#5117 CK2 inhibiton exhibits synergistic effect in acute lymphoblastic leukemia.

Daniel Gary Bogush, Joseph Schramm, Katarina Dovat, Yali Ding, Chingakham Singh, Sinisa Dovat

Penn State College of Medicine, Hershey, PA

Survival for pre-B cell Acute lymphoblastic leukemia (B ALL) has improved greatly, however. High risk (HR) subgroups continue to result in significant mortality and morbidity of pediatric oncology patients. Pediatric T-cell acute lymphoblastic leukemia (T-ALL) is a lethal disease, often associated with high-risk clinical features. T-ALL therapy has made less improvement than B ALL and continues to represent a significant number of high-risk outcomes. Novel treatment strategies are required to overcome chemotherapy resistance and improve morbidity for HR B ALL. The development of treatments that can overcome chemotherapy resistance is essential for improving survival in T-ALL. Deletions of *IKZF1,* resulting in decreased IKAROS function, are present in High-risk ALL patients. Casein kinase 2 (CK2), a protein kinase upregulated in ALL, phosphorylates IKAROS preventing DNA binding reducing transcriptional regulation in ALL patients. Past studies have shown that pharmacologic inhibition of CK2 with CX-4945 rescues IKAROS function as a transcriptional regulator. Receptor tyrosine kinase c-KIT is transcriptionally regulated by IKAROS and is often upregulated in cancer. The purpose of this study was to determine whether restoration of IKAROS via CX-4945 would act in a synergistic manner with c-KIT inhibitor imatinib in ALL.Methods/results B-ALL Nalm6 cells were treated with imatinib over 72-hours to establish the half-maximal inhibitory concentration (IC_{50}). The IC_{50} was used to determine the concentration range of imatinib to be used in combination with CX-4945 in a 72-hour synergy analysis of cytotoxicity.. Cell viability was measured using WST-1 cell proliferation assay. The data were analyzed using Calcusyn and synergy was defined as a combination index below 0.85. The study was repeated to determine a more precise range of synergy. The cytotoxicity of single drug c-KIT inhibitor, Imatinib, in Nalm6 B-ALL yielded an IC_{50} of 25uM while CK2 inhibitor CX-4945 resulted in 4uM. When a combination was administered with a constant dose of CX-4945 at 4uM and varying concentrations of imatinib, synergy was observed at multiple dose combinations. Conclusion: The data shows that CK2 inhibitor, CX-4945, and c-KIT inhibitor, imatinib, exhibit a synergistic therapeutic effect. Imatinib is indicated for use in Philadelphia positive (Ph+) acute lymphoblastic leukemia so future studies will include testing CX-4945/imatinib synergy in Ph+ BALL where we expect to see more potent synergistic effect.

#5118 Neuroblastoma extracellular vesicles present GPC2 and activate GPC2 CAR T cells in an antigen-dependent manner.

A. M. Giudice, S. Matlaga, G. Pascual-Pasto, P. M. Schuerch, G. Rouin, B. McIntyre, V. P. Zecchino, K. R. Bosse;
Children's Hospital of Philadelphia, Philadelphia, PA

Glypican 2 (GPC2) chimeric antigen receptor (CAR) T cells are safe and efficacious in neuroblastoma and are currently being tested in a first-in-human Phase 1 clinical trial at the Children's Hospital of Philadelphia. Tumor-derived extracellular vesicles (TEVs) are nanosized vesicles secreted by cancer cells, often enriched with glypicans. However, the presence of GPC2 on neuroblastoma TEVs and any interaction with GPC2 CAR T cells has not been explored. High-levels of GPC2 were found on TEVs isolated from neuroblastoma preclinical models [7 cell lines, circulating EVs from 6 patient-derived xenograft (PDX)-bearing mice] and from the peripheral blood of 16 neuroblastoma patients, but not on circulating EVs from 7 non-tumor bearing mice or 12 healthy human donors. The level of circulating GPC2+ EVs isolated from the peripheral blood of PDX-bearing mice positively correlated with PDX size ($R=0.96$; $P<0.0001$) and parent PDX GPC2 expression. To evaluate how GPC2 on EVs modulates CAR T cell functionality, we generated EVs with varied levels of GPC2 (Hi/Lo/Neg) and co-incubated each EV subset with GPC2 CAR T cells. Here using immunofluorescence and flow assays we found that EVs bind GPC2 CAR T cells proportional to the amount of GPC2 on their surface. Further, $GPC2^{Hi}$ EV-CAR T cell synapses induced potent T cell activation shown by CD69/Granzyme B expression and release of IL-2/IFN-γ. $GPC2^{Hi}$ EV pre-incubated CAR T cells also displayed enhanced target neuroblastoma cell cytotoxicity, inducing 4-fold more specific cytotoxicity than CAR T cells incubated with control $GPC2^{Neg}$ EVs. *In vivo* we observed that injection of $GPC2^{Hi}$ EVs into $GPC2^{Lo}$ neuroblastoma SK-N-AS xenografts genetically altered to have significantly decreased endogenous EV production (via *RAB27A* knock-out) greatly enhanced the efficacy of co-infused GPC2 CAR T cells ($p<0.05$). Similarly, in an isogenic SK-N-AS-GPC2 xenograft murine model treated with a limiting number of GPC2 CAR T cells concurrently with the EV-inhibiting drug GW4869, GPC2 CAR efficacy was dependent on the presence of $GPC2^{Hi}$ EVs. Here, pharmacologic EV inhibition in mice decreased GPC2 CAR efficacy which could be rescued by intratumoral injection of $GPC2^{Hi}$ EVs. In both *in vivo* models, the presence of intratumoral $GPC2^{Hi}$ EVs resulted in a significantly enhanced tumor infiltration of activated (CD69+/CD25+) GPC2 CAR T cells ($p<0.05$).
Taken together, $GPC2^{Hi}$ EVs are selectively secreted from neuroblastomas and bind and activate GPC2 CAR T cells enhancing their anti-tumor cytotoxicity. To further capitalize on these findings, we engineered $GPC2^{Hi}$ EVs to have an extended circulation half-life through albumin binding or tumor targeting via GD2 binding that are currently being tested *in vivo* and results will be reported. EVs offer a versatile platform for CAR antigen presentation and should be further validated as a strategy to enhance CAR T cell efficacy for solid tumors.

#5119 Exploring the relationship between metabolism and the epigenome in *MYCN*-amplified neuroblastoma.

K. M. Dalton, T. L. Lochmann, C. Coon, M. L. Calbert, M. Dozmorov, L. Shock, J. Koblinski, A. C. Faber;
Virginia Commonwealth University, Richmond, VA

Background: Neuroblastoma (NB) is the most common cancer of infancy and is responsible for the most cancer-related deaths in children under the age of five. The transcription factor MYCN is the most studied oncogene in NB and automatically confers high-risk. MYCN drives numerous effects in the cell, including metabolic changes that are critical for oncogenesis. NB has also been demonstrated to be a highly methylated cancer, with DNA methyltransferases (DNMTs) largely responsible for these modifications. Epigenetics and metabolism are closely connected, with oncogene-driven metabolic rewiring modifying the epigenetic landscape through increases of metabolites that are critical for the activities of epigenetic enzymes, and conversely the enhanced epigenetic activity further regulating the activity of metabolic enzymes.
Aims: As metabolism is believed to be a key regulator of the epigenome, the objective of this proposal is to understand the connection between MYCN-DNMT1-driven epigenetic alterations and dysregulated metabolism in *MYCN*-amplified NB.
Methods: RNA-seq and mass spectrometry analyses were performed to explore the MYCN-driven metabolome in NB and changes that occur with DNMT1 inhibition. The efficacy of DNMT1 inhibition in *MYCN*-amplified NB was tested in vivo.
Results: Our data demonstrate that sensitivity to DNMT1 inhibition is linked to MYCN status in NB. We found that MYCN indeed dysregulates metabolism in NB, and DNMT1 inhibition led to a global decrease in oxidative phosphorylation and exacerbated mitochondrial dysfunction in *MYCN*-amplified NB. Expression of MYCN was linked to an increase in methionine and subsequently SAM, the universal methyl donor, further supporting reliance on DNMT1. Most importantly, we have found that treatment with DNMT1 inhibitors in vivo inhibited tumor growth, even after treatment had stopped.
Conclusion: We have found a correlation between MYCN and metabolism that supports DNMT1 activity. This relationship allows for a potential treatment for a high-risk disease in which there is few clinically actionable targets.

#5120 Direct targeting of the COMPASS complex inhibits neuroblastoma growth by inhibiting cancer stem cells.

Rameswari Chilamakuri, **Saurabh Agarwal**

St. John's University, College of Pharmacy and Health Sciences, Queens, NY

Epigenetic regulator COMPASS Complex, a histone H3K4 methyltransferase has recently been shown to be involved in multiple cancers and attaining focus as a novel therapeutic target. High-risk neuroblastoma (NB) is a heterogeneous pediatric cancer with high mortality and relapse rates. The relapse of refractory cancer is shown to be driven by cancer stem cells (CSCs), which are maintained by epigenetic malfunctions. In the present study, we determined the effects of inhibiting the COMPASS complex on NB CSCs and overall NB growth. A high-throughput shRNA screening of methyltransferases and demethylases reveals the role of COMPASS complex partners MLL1 and Menin in NB proliferation. We found that both MLL1 and Menin are overexpressed in our previously identified CD114+ NB CSCs. Further, *MEN1* (gene coding Menin) expression showed an inverse correlation with overall NB patient survival and cancer progression in a comprehensive analysis of 1235 primary NB patient data. Our ChIP results show that the *CSF3R* gene which codes for CD114 and maintains CD114+ NB CSCs, is regulated by the presence of high H3K4me3 activating marks. Further, we used MI-503 to inhibit MLL1-Menin interaction and also developed *MEN1* stable knockdown and found that both strategies significantly inhibit H3K4me3 activity in NB, particularly at the *CSF3R* gene promoter. This led to decreased *CSF3R* expression and NB CSC levels. MI-503 significantly inhibits proliferation in different NB cell lines and primary patient-derived xenograft (PDX) lines, with minimal effect on non-cancerous fibroblasts. MI-503 significantly inhibits NB cell cycle progression at the S phase, induces apoptosis, and inhibits NB 3D spheroid growth and development. Interestingly, we overserved differential selectivity of MI-503 in inducing apoptosis and in blocking the cell cycle in NB CSCs in contrast to non-CSCs. *MEN1* knockdown also inhibits NB proliferation and 3D spheroid growth. Furthermore, MI-503 in a dose-dependent manner synergistically sensitizes NB to chemotherapy doxorubicin and significantly inhibits NB proliferation and spheroid growth compared to either agent alone. Further, by using the NB xenograft *in vivo* tumor model, we established that MI-503 significantly inhibits NB tumor growth and tumor metastasis by directly inhibiting tumor NB CSCs, without any observed toxicities. Similar results of significantly reduced tumor growth, metastasis, and NB CSCs were shown by the *MEN1* knockdown *in vivo*. Overall, our data show that the MLL1-Menin of the COMPASS complex directly activates the *CSF3R* gene to maintain NB CSCs and drive NB pathogenesis. Our data show that MI-503 or *MEN1* knockdown leads to significant inhibition of NB growth by directly inhibiting NB CSCs in both *in vitro* and *in vivo* tumor models. Further developing these epigenetic-based therapeutic strategies and combining them with current therapies will pave the way for effectively managing NB.

#5121 Next-generation immunocompetent and humanized neuroblastoma murine models for the discovery and validation of novel immunotherapies.

T. T. Spear[1], E. Posthill[1], D. Groff[1], A. M. Giudice[1], K. R. Bosse[1], L. Ma[2], S. P. Schoenberger[3], J. M. Maris[1];
[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [3]La Jolla Institute for Immunology, La Jolla, CA

The success of CD19-directed chimeric antigen receptor (CAR)-T cell therapy for ALL has yet to be matched in solid pediatric malignancies. Moreover, immune checkpoint blockade has shown limited benefit in pediatric cancer. Despite this unmet need, there is a lack of reliable preclinical models to facilitate novel target discovery, validate therapeutic benefit, anticipate on- or off-target toxicity, and understand mechanisms of resistance.

Syngeneic murine model systems are a critical intermediate for preclinical translation, preserving the complex and heterogenous immune landscape and host-immunotherapy interactions. However, model interpretation and validity are limited as expression and function of murine targets and immune effector cells are not always conserved. We have developed a syngeneic immunocompetent C57BL/6 neuroblastoma system to study CAR efficacy, toxicity, and mechanisms of resistance, as well a variety of vaccination strategies. Specifically, we have built two murine CAR T constructs containing a 100% conserved antigen-directed scFv joined to orthologous murine TCR signaling machinery. In parallel, we engineered the murine neuroblastoma cell line 9464D to stably express surface antigen Gpc2 (Bosse, *Cancer Cell* 2017), or a novel chimeric single chain trimer of a 9mer peptide from intracellular oncoprotein PHOX2B discovered on HLA-A*24:02 (Yarmarkovich, *Nature* 2023) as Phox2b/A24*02/H2-k^{b} to generate tumor-bearing B6 or B6-A24-Tg mice. We are currently using this system to demonstrate how vaccination approaches enhance the persistence and potency of CART directed to both targets and are extending our syngeneic murine constructs to additional TH-MYCN allograft models.

To further study the innate and adaptive immune response to various therapeutics, we have developed peripheral blood mononuclear cell (PBMC) humanized models. Our autologous humanized PDX mouse models of neuroblastoma use immunocompromised NSG mice engrafted with a PDX and humanized with patient-matched PBMCs to evaluate personalized vaccines *in vivo.* We have shown the ability to stably engraft both lymphoid and myeloid populations in various human cytokine transgenic NSG variants (i.e. SGM3, Flt3L), allowing for T/B cell and APC crosstalk, thus providing a robust means to study targeted interventions. We are currently using this autologously humanized PDX model to test the ability of multivalent, personalized neoantigen vaccines developed specific to the neoantigen landscape of individual PDXs, with a focus on endogenous T cell responses of patient PBMC against their own PDX *in vivo.*

#5122 Modulating anti-GD2 immunotherapy via dual DFMO and TGF-β inhibition in neuroblastoma.

O. H. Gandhi, C. S. Turn, K. Liu, A. T. Vu, H. Bassiri, M. D. Hogarty;
Children's Hospital of Philadelphia/Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Neuroblastoma (NB) is an often-lethal childhood solid tumor. Anti-GD2 immunotherapy improves survival but not all responses are durable. Transforming growth factor-beta (TGFβ) has been implicated in solid tumor immunoresistance. High-risk NBs harbor activated *MYC or MYCN* to coordinately expand intratumoral polyamines (PA), oncometabolites with immunomodulatory roles, to support tumor progression. Difluoromethylornithine (DFMO) is an inhibitor of ornithine decarboxylase, the rate-limiting enzyme in PA synthesis, and has shown activity in preclinical NB models, including *TH-MYCN*$^{+/+}$ transgenic mice, and is in clinical trials in children. We sought to augment anti-GD2 therapy using DFMO and the small molecule TGFβ-receptor inhibitor, galunisertib. We randomized *TH-MYCN*$^{+/+}$ mice in two experiments (10 therapy arms; n=6-10 mice/arm) to receive combinations of DFMO, galunisertib, and anti-GD2 antibody m14G2a and to assess impact on survival. We measured 770 genes using nCounter Immuno-Oncology 360 (Nanostring), 36 cytokines using xMap bead-arrays (Luminex), and tumor-infiltrating leukocytes using flow cytometry in harvested tumors. Cell line TGFβ signaling was evaluated in tissue culture. In vitro, galunisertib consistently suppressed the upregulated TGFβ-Smad2/3 signaling cascade in *MYCN*-amplified neuroblastoma cell lines. In vivo, DFMO alone extends mouse survival and increases intra-tumoral neutrophils and natural killer (NK) cells. These NK cells increased surface expression of activation receptors like NKG2D ($p<0.05$), while tumor cells increased surface expression of NK-ligands. Tumor cells also expressed increased latency-associated peptide (LAP; $p<0.05$), a TGFβ precursor, suggesting NK cells were poised to kill but restrained by TGFβ. Cytotoxicity assays showed reversal of this inhibition with TGFβR1 inhibitor galunisertib in vitro. In a proof-of-concept trial, DFMO and galunisertib (DFMO/gal) demonstrated a clinical anti-tumor synergistic effect. DFMO/gal treated tumors had upregulated NK cell activity genes and downregulated TGFβ signaling genes. Cytokine analysis confirmed DFMO induced upregulation of TGFβ1 and TGFβ2 ($p<0.01$) that was modulated by galunisertib. IL6, GCSF, and GMCSF were markedly downregulated in tumors treated with both DFMO and galunisertib ($p<0.05$). An expanded trial showed DFMO/gal added to m14G2a showed no significant survival benefit over the DFMO and m14G2a combination. Ultimately, DFMO creates a pro-inflammatory cellular and cytokine milieu in *TH-MYCN*$^{+/+}$ NBs. DFMO and TGFβR1 inhibition via galunisertib activate NK cells further and decrease the anti-inflammatory cytokine IL6. Ongoing studies are further characterizing the gene expression and cytokine levels of the NB TME under these treatment conditions.

#5124 A CRISPR-drug perturbational map for identifying compounds to combine with commonly used chemotherapeutics.

W. C. Wright, P. Geeleher;
St. Jude Children's Research Hospital, Memphis, TN

Combination chemotherapy is crucial for successfully treating cancer. However, the enormous number of possible drug combinations means discovering safe and effective combinations remains a significant challenge. To improve this process, we conduct large-scale targeted CRISPR knockout screens in drug-treated cells, creating a genetic map of druggable genes that sensitize cells to commonly used chemotherapeutics. We prioritize neuroblastoma, the most common extracranial pediatric solid tumor, where ~50% of high-risk patients do not survive. Our screen examines all druggable gene knockouts in 18 cell lines (10 neuroblastoma, 8 others) treated with 8 widely used drugs, resulting in 94,320 unique combination-cell line perturbations, which is comparable to the largest existing drug combination screens. Using dense drug-drug rescreening, we find that the top CRISPR-nominated drug combinations are more synergistic than standard-of-care combinations, suggesting existing combinations could be improved. As proof of principle, we discover that inhibition of PRKDC, a component of the non-homologous end-joining pathway, sensitizes high-risk neuroblastoma cells to the standard-of-care drug doxorubicin in vitro and in vivo using patient-derived xenograft (PDX) models. Our findings provide a valuable resource and demonstrate the feasibility of using targeted CRISPR knockout to discover combinations with common chemotherapeutics, a methodology with application across all cancers.

CLINICAL RESEARCH: Predictive Biomarkers 3
Poster Session

#5128 Circulating H3K27me3 modified nucleosomes as a biomarker to monitor anti EZH2-based treatment in advanced solid tumour patients: Translational analyses from CAIRE trial.

Francesca Salani[1], Mark Eccleston[2], Lola-Jade Palmieri[3], Simon Pernot[4], Sophie Cousin[3], Gianluca Masi[5], Francesco Crea[6], Antoine Italiano[7]

[1]LHCS (The Open University), The Open University Milton Keynes, Universita di Pisa and Scuola Superiore Sant'Anna, Pisa, Italy,[2]Belgian Volition SRL, Isnes, Belgium,[3]Department of Medicine, Institut Bergonie, Bordeaux, France,[4]Department of Medical Oncology, Institut Bergonie, Bordeaux, France,[5]Ricerca Traslazionale e Delle Nuove Tecnologie in Medicina e Chirurgia, Universita di Pisa, Pisa, Italy,[6]Cancer Research Group-School of Life Health and Chemical Sciences, The Open University, Milton Keynes, United Kingdom,[7]Faculty of Medicine, University of Bordeaux, Bordeaux, France

CAIRE is a phase 2 umbrella study which assessed activity of combined anti-EZH2 tazemetostat and anti-PDL1 durvalumab (T+D) in advanced pretreated pancreatic, colorectal and sarcoma cancer patients. The are currently no plasma biomarkers for anti-EZH2 treatment monitoring or outcome. EZH2 catalyzes tri-methylation of Lysine 27 (K27me3) on nucleosomal histone 3 (H3, H3K27me3). Circulating, cell free H3K27me3 modified nucleosomes are thus a potential biomarker for tazemetostat activity. We evaluated the concentration of circulating H3K27me3 modified nucleosomes normalized to H3.1 nucleosomes (the most common isoform of H3) in T+D treated patients, irrespective of the tumor primary site, to determine target engagement during anti-EZH2 treatment. Plasma from patients receiving T+D was collected before the first cycle administration (C1D1), on the following two cycles administration (C2D1, C3D1) and at end of treatment (EOT). H3.1 and H3K27me3 containing nucleosomes were quantified by Nu.Q®-H3.1 and Nu.Q®-H3K27me3 Chemiluminescent Immunoassays. Concentrations are reported as ng/ml and the comparison of their median values at the different timepoints were tested with Kruskal-Wallis and Mann Whitney (independent samples) or Wilcoxon tests (paired samples), with SciPy.stat package (1.6.2). Bonferroni correction was applied to multiple comparisons. Of 197 total samples, 191 were evaluable for both biomarkers (6 higher than top standard after 5x dilution): 69 at C1D1, 63 at C2D1, 50 at C3D1 and 9 at EOT. For 58 patients paired C1D1 and C1D2 levels were available, 46 from C1D1 to C3D1 and 8 from C1D1 to EOT. The normalized Nu.Q®-H3K27me3 C1D1 median value (0.56) was significantly higher than C2D1 (0.31, p: e^{-12}), C3D1 (0.31, p: e^{-12}) and EOT ones (0.28, p: 0.001). Conversely, Nu.Q®-H3.1 levels were similar from C1D1 to C3D1 (range of the medians: 122.16-133.25 ng/ml) and increased at EOT (290.09 ng/ml), but with no significant difference between pairwise timepoints. Regarding paired-samples comparison, the normalized Nu.Q®-H3K27me3 was significantly higher at C1D1 than at C2D1 (p: e^{-8}) and C3D1 (p: e^{-9}) and at EOT (p: 0.02). Conversely, H3.1 concentration was significantly higher at EOT than at C1D1 (p: 0.02), at C2D1 (p: 0.02) and C3D1 (p: 0.05).In conclusion, we described for the first time that normalized circulating nucleosomal H3K27me3 values significantly decrease during T-based treatment in metastatic solid tumor patients, irrespective of the primary disease site, supporting its potential role as a pharmacodynamic biomarker for EZH2 inhibition. Moreover, total nucleosomal H3.1 seems to represent a surrogate of disease burden in metastatic pancreatic, colorectal and sarcoma cancers, as suggested previously in other hematological malignancies.

#5129 Subcellular MLH1 protein as first in class biomarker for CDK4/6 response in endocrine resistant ER+/HER2- breast cancer.

A. Mazumder, E. Oropeza, N. Punturi, S. Haricharan;
Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA

Over 175,000 diagnoses of estrogen receptor-positive breast cancer are made every year in the US. Of these, >40,000 patients will go on to die of their disease. We recently identified defects in a principal mismatch repair (MMR) gene, MLH1, as a driver of resistance to standard-care treatment and poor patient outcomes. Moreover, we demonstrated increased sensitivity to palbociclib, a CDK4/6 inhibitor, in experimental model systems *in vitro* and *in vivo* and in clinical trial data. MLH1 is mutated in 5-10% of treatment-resistant tumors, i.e., 4,000 patient tumors every year. However, most of these mutations are missense and variants of unknown significance (VUS). The impact of these mutations on mismatch repair capability and on treatment resistance remains uncertain. Here, we use experimental model systems to phenotype MLH1 VUS´ *in vitro* and *in vivo* using xenograft systems.Specifically, we use nuclear localization of MLH1 and repair of mismatches through a mismatch repair deficiency assay to test for mismatch repair capability in ER+ breast cancer cells engineered to express mutations in MLH1 that are found in patient tumors associated with poor survival. Second, we assess the ability of variants of MLH1 to induce activation of G1/S cell cycle checkpoints by activating Chk2. Lastly, we directly test the ability of variants in MLH1 to induce resistance to standard-care endocrine therapies and sensitivity to palbociclib, using 2D and 3D growth assays and xenograft experiments. Results from these experiments serve to systematically catalog VUS´ in MLH1 based on their predictive potential. We identified for the first-time specific mutation in MLH1 that induces resistance to endocrine therapy by stalling nuclear translocation of MLH1 which inhibits Chk2 activation. Cells with impaired Chk2 activation maintain a high CDK4/6 levels and are therefore more sensitive to CDK4/6 inhibition. Currently, there are few tests available in the clinic to predict response to therapies early in the timeline of ER+ breast cancer patients. Due to the nature of the disease, this can result in years of overtreatment. Overtreatment comes at great financial, physical, and emotional cost to patients and their families. Simultaneously, a lack of predictive markers can result in missed opportunities of presenting patients likely to relapse on standard care with personalized alternative therapeutic strategies. Based on our findings, cytoplasmic MLH1 may serve as first in-class biomarker for CDK4/6 response in ER+/HER2- patients.

#5130 Phospho-proteomic dynamics reveal DNA damage and repair signatures of drug sensitivity.

G. Arad, A. Hay-Koren, N. Simchi, D. Kovalerchik, D. Daitchman, A. Manor, O. Givton, E. Lezmi, I. Alchanati, Y. Katzenelenbogen, S. Herman, A. Shtrikman, G. Otonin, E. Seger, **K. Pevzner**;
Protai, Tel Aviv, Israel

There are numerous drug development efforts of DNA damage response (DDR) targets, such as PARP, ATR, ATM, CHK1, where the ability to accurately identify responsive sub-populations for monotherapies and combinations is a major challenge. Patients are routinely assigned to these drugs based on BRCA mutation, or BRCAness profile, encompassing homologous recombination deficiencies (HRD) which do not always represent the responsive sub-populations. Since DNA replication and DNA repair mechanisms are dominated by signaling events, we hypothesized that HRD extends beyond the genomic status, and is manifested also in the level of protein expression and protein modification.
To that end, we created a harmonized data atlas consisting of phenotypic drug sensitivity and basal and dynamic phosphoproteomics of multiple cell lines before and after treatment of multiple DDR drugs. Proteogenomic analysis of cell lines showed that some cell lines are sensitive to DDR drugs despite being DDR-proficient at the genomic level. Proteomic analysis of these cell lines showed that at least a third of them exhibit proteomic DDR deficiency, explaining DDR sensitivity beyond mutation status. We then utilized our proteogenomic atlas and computational platform to address challenging clinical needs, namely discovery of a predictive ATR biomarker and identifying potential combination treatments to overcome ATRi resistance. Using basal state and protein dynamics of ATR coupled with ATRi sensitivity, we developed a novel predictive ATR biomarker, and tested it using two independent validation datasets. Our ATR biomarker exhibited improved precision and recall compared to genomic biomarkers represented by mutations commonly used in the clinic, and was not confounded by mutations. In addition, integrated analysis of basal and dynamic data of multiple cell lines treated with ATRi, highlighted both known (e.g. ATM) and novel resistance mechanisms and suggested potential drug combinations.
Altogether, we demonstrate here the benefit of utilizing (phospho)-proteomic data to tackle clinical challenges in DDR drug development, such as predictive biomarkers and combination strategies. We provide a proteomics-based framework that would enable future patient selection in DDR clinical trials.

#5131 TYMS overexpression - but not copy number alteration - is associated with cancer aggressiveness in urothelial bladder cancer.

H. Plage[1], S. Hofbauer[1], K. Furlano[1], S. Weinberger[1], A. Franz[1], A. Fendler[1], F. Ro?ner[1], S. Schallenberg[1], S. Elezkurtaj[1], A. Frericks[2], M. Lennartz[2], A. H. Marx[3], H. Samtleben[3], M. Fisch[2], M. Rink[4], M. Slojewski[5], K. Kaczmarek[5], T. Ecke[6], S. Koch[6], N. Adamini[7], R. Simon[2], G. Sauter[2], H. Zecha[7], J. Weischenfeldt[8], T. Klatte[6], S. [1]Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany, [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [3]Academic Hospital Fuerth, Fuerth, Germany, [4]Marien Hospital Hamburg, Hamburg, Germany, [5]Pomeranian Medical University, Szczecin, Poland, [6]Helios Hospital Bad Saarow, Bad Saarow, Germany, [7]Albertinen Hospital, Hamburg, Germany, [8]Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany, Biotech Research & Innovation Center (BRIC), University of Copenhagen, Copenhagen, Denmark

Background: Thymidylate Synthetase (TYMS) is an import enzyme in the early stage of DNA biosynthesis. It is coded by the TYMS gene at 18p11.32, a region which has been found amplified in urothelial carcinoma. TYMS is a target enzyme for 5-fluorouracil (5-FU) and methotrexate. Elevated TYMS expression has been associated with poor prognosis and unfavorable therapy response in different cancer types. The aim of this study was to clarify the clinical relevance of TMYS expression in urothelial carcinoma and to determine the relationship between TYMS expression and gene amplification.

Design: TYMS expression was analyzed by immunohistochemistry and TYMS copy number status was determined by fluorescence in-situ hybridization on a tissue microarray (TMA) containing more than 2,700 urothelial carcinomas of the urinary bladder including >600 patients who had undergone cystectomy for muscle-invasive disease and for which follow-up data were available.

Results: TMYS immunostaining was detectable in 83.1% of 1,799 analyzable bladder cancers, including 56.4% with weak, 14.4% with moderate, and 12.3% with strong staining. The rate of strongly TMYS positive cancers increased markedly from pTaG2 low (0.3%) to pTaG2 high (4.1%), and pTaG3 cancers (11.8%; p<0.0001) and was even somewhat higher in pT2-4 cancers (16.7%; p=0.6401; pTaG3 vs pT2-4). In muscle-invasive cancers, the frequency of strong TMYS immunostaining increased with tumor stage (p=0.0011) and grade (p=0.0007) but was lower in lymph node positive cancers (p=0.0018). No association was found between TYMS expression and patient prognosis. TYMS amplification was found in 3.1% and TMYS deletion in 1.2% of 1,775 analyzable bladder cancers. The rate of TYMS amplification increased from pTa (0.6%) to pT2-4 (3.7%; p<0.0001) cancers whereas TYMS deletion was only found in pT2-4 (1.4%) cancers. In muscle invasive-cancers, TYMS copy number alterations were unrelated to tumor phenotype and patient prognosis. Strong TYMS positivity was significantly associated with TYMS amplification (p=0.0096) but only 28.6% of 42 amplified cancers showed a strong TMYS staining and only 7.2% of strongly TYMS positive cancers had a TYMS amplification.

Conclusion: The significant association between TYMS overexpression and parameters of aggressive phenotype are consistent with a role of TYMS in bladder cancer progression. The incomplete association between TYMS amplification and overexpression demonstrates that TYMS is not the critical target of 18p11 amplification in bladder cancer and that TYMS upregulation is in most cases due to other mechanisms than amplification.

#5132 Multi-omics analysis uncovers predictive biomarkers for the efficacy and outcomes of immune checkpoint inhibitor in combination with chemotherapy in advanced unresectable biliary tract cancers.

J. Ying[1], Q. Xu[1], J. Ni[1], H. Chen[2], C. Li[3], Y. Xie[4], Q. Zheng[5], J. Jin[6], J. Yan[2], X. Wu[2], Q. Ou[2], L. Yuan[1], W. Zhuo[7], **H. Tang**[2];

[1]Zhejiang Cancer Hospital, Hangzhou Institute of Medicine, Chinese Academy of Sciences, Hangzhou, China, [2]Nanjing Geneseeq Technology Inc., Nanjing, China, [3]Wenzhou Medical University, Wenzhou, China, [4]Lishui Municipal Central Hospital, Lishui, China, [5]Quzhou Affiliated Hospital of Wenzhou Medical University, Quzhou People's Hospital, Quzhou, China, [6]Taizhou Hospital of Zhejiang Province, Taizhou, China, [7]Zhejiang University School of Medicine, Hangzhou, China

Background: Biliary tract cancer, typically diagnosed at advanced stages with a poor prognosis, has witnessed a glimmer of hope in the progress of immune checkpoint inhibitors (ICIs). Yet, their limited response rates necessitate the search for effective biomarkers to refine patient selection.

Methods: A total of 125 patients with a confirmed histological diagnosis of unresectable advanced or metastatic biliary tract cancers (BTC) who received first-line ICIs in combination with chemotherapy (chemoimmunotherapy) were prospectively enrolled. All baseline samples from 125 patients underwent targeted DNA sequencing, with an additional 62 patients undergoing RNA sequencing, and 85 patients had accessible mIHC data. The associations between molecular characteristics and the response to chemoimmunotherapy, progression-free survival (PFS) and overall survival (OS) were evaluated.

Results: The cohort had a median age of 63 years (range from 34 to 82) and 52.8% (66/125) were male, including 54 with gallbladder cancer, 57 with intrahepatic cholangiocarcinoma, and 14 with extrahepatic cholangiocarcinoma. The median duration of follow-up was 14.8 months for the entire cohort, with the median PFS and OS of 6.9 months (95%CI: 6.2-7.9) and 11.8 months (95%CI: 10.3-14.8), respectively. The most mutated genes were *TP53* (64/125, 51.2%), *KRAS* (34/125, 27.2%), *ERBB2* (18/125, 14.4%), and *ARID1A* (17/125, 13.6%). Mutations of *TP53* (51.2%, p = 0.042), *BRCA2* (4.8%, p = 0.002), cytokine genes (6.4%, p = 0.004), and high tumor mutation burden (p = 0.072) demonstrated significant correlation with chemoimmunotherapy response. *KRAS* G12D mutations (PFS: P < 0.001; OS: P = 0.034) and *ARID1A* loss-of-function mutations (PFS: P = 0.009; OS: P = 0.012) were adverse survival factors, while high *CXCL9* or *CTLA4* expression was associated with response (*CXCL9*, P = 0.014; *CTLA4*, P = 0.067), improved PFS (*CXCL9*, P = 0.018; *CTLA4*, P = 0.008), and longer OS (*CXCL9*, P = 0.010; *CTLA4*, P = 0.008) under chemoimmunotherapy. Patients were classified into three subtypes using the identified survival biomarkers. Among them, Type I patients, characterized by the absence of *KRAS* G12D or *ARID1A* mutations but expressing high levels of *CTLA4* or *CXCL9*, demonstrated the best outcomes under chemoimmunotherapy. Interestingly, further RNA analysis suggested that elevated *CXCL9* expression correlated with heightened immune checkpoint expressions, including *CTLA4*, *PD-L1*, and *PD-1* (all P < 0.001), as well as increased tumor microenvironment immune activity, findings validated in two additional independent patient cohorts both internal and external.

Conclusions: Our study revealed predictive biomarkers relevant to the response and efficacy of immune checkpoint inhibitors in combination with chemotherapy in advanced biliary tract cancer.

#5133 Gastric cancer carrying FAT4 mutations associated with favorable prognosis in comparison to wild-type: Results from Real-World Cohorts.

S. Wang[1], H. Wang[1], Y. Ma[1], Y. Wang[1], Y. Zhao[1], C. Peng[1], W. Duan[2], F. Zhao[2], **J. Yang**[1];

[1]Department of Digestive Surgery, Xi Jing Hospital, The Fourth Military Medical University, Xi'an, Shaanxi, China, Xi'an, China, [2]3D Medicines Inc., Shanghai, China, Shanghai, China

Introduction: Gastric cancer (GC) is a complex and heterogeneous disease with variable clinical outcomes. Identifying prognostic factors that can reliably predict patient outcomes is crucial for personalized treatment strategies. In this study, we aimed to investigate the impact of mutations in the FAT4 gene as potential prognostic factors in gastric cancer.

Methods: We conducted a comprehensive analysis of genomic data from a cohort of 236 gastric cancer patients to identify mutations in the FAT4 gene and validated it using the TCGA cohort. The mutational landscape of FAT4 was analyzed using next-generation sequencing (NGS) techniques. Clinical data, including patient demographics, tumor characteristics, and survival outcomes, were collected and correlated with the presence of FAT4 cadherin mutations.

Results: In the real-world cohort, the occurrence of mutations of FAT4 was 19.1% (45/236), while in the TCGA cohort, it was 21.0% (89/423). Specifically, the mutation rates in the single cadherin functional domain of FAT4 were 10.2% (24/236) in the real-world cohort and 8.0% (34/423) in the TCGA cohort. The mutation rates for multiple cadherin sites were 2.5% (6/236) and 2.1% (9/423) in the real-world and TCGA cohorts, respectively. Survival analysis revealed that patients with FAT4 mutations had a significantly better prognosis compared to those with wild-type FAT4 ($p=0.0357$). Patients with multiple cadherin mutations had a better prognosis compared to those with single cadherin mutations in real-world cohorts ($p=0.0651$). No significant difference was observed in the TCGA cohort between single and multiple cadherin mutations ($p = 0.2003$), although FAT4 mutations exhibited a significant improvement in prognosis compared to wild-type patients in the TCGA cohort ($p = 0.0226$).

Conclusion: Our findings indicate that FAT4 mutations confer a favorable prognosis in gastric cancer patients. The presence of FAT4 mutations was associated with improved survival compared to patients with wild-type FAT4. These findings underscore the potential value of FAT4 mutation status as a prognostic factor, guiding personalized treatment approaches for individuals with gastric cancer.

#5134 Immunohistochemistry expression of membrane targets for novel therapeutic agents in RET-rearranged NSCLC.

A. Marinello[1], M. Ghigna[1], W. Zrafi[1], M. Mandarano[2], I. Monnet[3], C. Genova[4], A. Russo[5], S. Terrisse[6], G. Metro[7], J. Remon[1], A. Gazzah[1], F. Barlesi[1], D. Planchard[1], J.-Y. Scoazec[1], B. Besse[1], M. Aldea[1];

[1]Gustave Roussy, Villejuif, France, [2]University of Perugia, Perugia, Italy, [3]Centre Intercommunal Hospitalier de Creteil, Creteil, France, [4]IRCCS Policlinico San Martino, Genova, Italy, [5]Centro Oncologico Ospedale Papardo, Messina, Italy, [6]St Louis Hospital APHP, Paris, France, [7]Ospedale Santa Maria della Misericordia, Perugia, Italy

Background: *RET* fusions are found in 1-2% of patients (pts) with advanced non-small cell lung cancer (aNSCLC). RET inhibitors (RETi) are effective, but resistance occurs. Scarce data are available on treatment after progression (PD) to RETi. Antibody-drug conjugates and bispecific antibodies are promising therapies in NSCLC, possibly employed at resistance. Data on the expression of membrane targets and the impact of novel agents are lacking.
Methods: This is a multicentric retrospective study of 6 European centers. We collected archival tissue samples from pts with RET+ aNSCLC, treated or not with RETi. Membrane expression of cMET/TROP2/HER2/HER3/EGFR was centrally evaluated by immunohistochemistry (IHC). Expression was scored from 0 to 3+. cMET was assessed with EP1454Y clone, TROP2 with EPR20043, HER2 with 4B5, HER3 with D22C5, EGFR with DAKO EGFR pharmDx kit. IHC 2+ and 3+ were considered as high expression. cMET FISH testing was performed on cMET 3+ cases with available tissue. PFS was calculated from RETi start to PD or death, OS from diagnosis to death/last follow up in pts treated with RETi.
Results: 52 pts were included. Median age was 65 years, 63% were female, 92% had adenocarcinoma, median PD-L1 expression was 10% (IQR 0-62.5). All samples were collected before RETi start. IHC 2/3+ scores were observed in 80% of evaluable cases (25/31) with TROP2, 60% (30/50) with cMET, 39% with HER3 (19/48), 31% with EGFR (15/48), and 4% (2/48) with HER2. 31 patients had more than 1 highly expressed target, mostly TROP2/cMET (n=17) and cMET/HER3 (n=13). FISH testing was negative for *MET* amplifications (N=5). PFS and OS of pts with low vs high target expression are presented in the Table.
Conclusion: cMET and TROP2 were frequently expressed in RET+ aNSCLC, EGFR and HER3 were present in a lower proportion, HER2 was rarely found. These markers were not associated with a prognostic or predictive impact on RETi outcomes. The activity of novel therapeutic agents should be evaluated in this setting.

PFS and OS of pts with low versus high target expression.

Marker	cMET	TROP2	HER2	HER3	EGFR
Treated with RETi, n	Total=38 low=17 high=21	Total=22 low=4 high=18	Total=36 low=34 high=2	Total=37 low=24 high=13	Total=36 low=27 high=9
PFS of low vs high, median in months	12.88 vs 15.05 (HR 0.90, 95%CI 0.34-2.05, p=0.77)	3.99 vs 6.06 (HR 2.44, 95%CI 0.54-11.3, p=0.10)	13.96 vs 10.10 (HR 0.57, 95%CI 0.91-3.63, p=0.445)	7.55 vs 17.12 (HR 1.54, 95%CI 0.65-3.67, p=0.356)	12.88 vs 13.96 (HR 1.29, 95% CI 0.47-3.52, p=0.64)
OS of low vs high, median in months	38.75 vs 51.6 (HR 1.29, 95%CI 0.53-3.14, p=0.55)	22.17 vs 51.6 (HR 2.09, 95%CI 0.50-8.71, p=0.19)	NE	51.5 vs 62.6 (HR 1.31, 95%CI 0.50-3.46, p=0.59)	51.6 vs 62.45 (HR 0.97, 95% CI 0.32-2.96, p=0.96)

#5135 Tertiary lymphoid structures and T-cell aggregates signal a robust anti-tumor immune response in a subset of leiomyosarcoma patients.

Aditya Suru, Alexandre Maalouf, Lingling Chen, Ada Tam, William Villasi, Kaushal Sharma, Lindy Zhang, Christian Meyer, Jonathan Greer, Fabian Johnston, Carol Morris, Sophia Strike, Adam Levin, Daniel Rhee, Brian Ladle, Kornel Schuebel, Yan Zhang, Rulin Wang, Srinivasan Yegnasubramanian, John Gross, Robert Anders, Andrew Pardoll, Nicolas Llosa

Johns Hopkins, Baltimore, MD

Cancer immunotherapy has ushered in a new era for treatment of many difficult to treat cancers such as Leiomyosarcoma (LMS), one of the most common subtypes of sarcomas. There are few biomarkers which can be used to identify patients who might benefit from immunotherapy. There is an urgent need to discover novel biomarkers which might be prognostic of a strong anti-tumor response. We thus sought to comprehensively profile the microenvironment of LMS tumors to identify features which might be suggestive of an active immune response and molecular features prognostic of response to immunotherapy. We began our analysis by classifying the LMS tumors from The Cancer Genome Atlas (TCGA) into 4 subtypes based on previously identified molecular features and comparing the enrichment of various immune gene signatures. Two of the subtypes had a high expression of various immune gene signatures including B Cells, M2 macrophages and Cytotoxic T cells. Visual inspection of the Hematoxylin and Eosin-stained tissue slides available with TCGA pointed to a presence of lymphoid aggregates or Tertiary lymphoid structures (TLS) in 10-15% of the tumors - predominantly belonging to one of the two subtypes. This subtype displayed features of smooth muscle differentiation and was also associated with improved survival. To validate our findings, we performed immunohistochemistry (IHC) and bulk RNA sequencing of LMS specimens (n=66) obtained from surgical resections from the Johns Hopkins Hospital. We identified mature CD21+ TLS in 15% of these cases and non-germinal center T cell aggregates present in more than 30% of the cases and these features were associated with improved survival. We digitally merged the different IHC sections to study if the markers were spatially correlated. Interestingly, spatial analysis showed that these CD8 T cells aggregates co-localized with neighborhoods of high density of PD-L1+ cells, hinting at the possibility of immune mediated upregulation of PD-L1 as means of immune suppression. The deconvolution of the transcriptome of these samples showed a marked presence of cytotoxic CD8 T cells and plasma B cells in this subset of patients, an enrichment of pathways related to T cell trafficking, activation and proliferation. Single cell RNA sequencing of tumor infiltrating immune cells showed an oligoclonal expansion of B and T cells. Taken together, this study shows that a subset of LMS patients have a strong anti-tumor immune response which is characterized by the presence of Tertiary Lymphoid Structures and patches of high density of PD-L1 expressing cells. These features might serve as biomarkers in screening LMS patients which might benefit from immunotherapy.

#5136 Development of a highly specific NAPRT monoclonal antibody for the detection of tumors sensitive to pharmacological inhibition of NAMPT.

J. Spurrier[1], E. S. Burgos[1], M. R. Lundquist[1], K. Tanaka[1], S. Brook[1], M. Gozzi[1], J.-S. Yi[1], J. Edmonds[2], M. Raponi[1];
[1]Alphina Therapeutics, Inc., New Haven, CT, [2]Yale School of Medicine, New Haven, CT

Introduction: A key component of targeting synthetic lethality in cancer is identifying specific biomarkers, such as sources of NAD+ synthesis, that differentiate between healthy and diseased tissue. In mammals, NAD+ can be synthesized from nicotinamide via nicotinamide phosphoribosyltransferase (NAMPT) or from nicotinic acid (niacin, NA) via nicotinic acid phosphoribosyltransferase (NAPRT). NAPRT loss has been identified across tumor indications as a synthetic lethal sensitizer to small molecule inhibitors of NAMPT. Given the reliance of cancer cells on NAD+ synthesis, blocking NAD+ production is a compelling target for anti-cancer therapeutics. However, identifying tumors with NAPRT loss has been a challenge as NAPRT can be expressed by as many as 14 transcripts, only some of which code for the active enzyme. This complicates transcript-based analyses and necessitates proteomic assessment. Here, we have developed a mouse monoclonal antibody (4A5D7) to specifically detect active NAPRT and to identify indications enriched for NAPRT loss in patients through an IHC-based assay. We further confirm that loss of NAPRT makes cells susceptible to NAMPT inhibition, and ultimately show that our antibody can identify patient-derived xenograft (PDX) models that respond to NAMPT inhibition.
Methods We utilized a hybridoma system to produce antibodies against epitopes in the NAPRT active site; clones were subsequently screened for their ability to selectively recognize active NAPRT. After identifying clone 4A5D7, we validated our proprietary antibody against FFPE specimens across multiple cancer indications (TNBC, NSCLC, SCLC, CRC, gastric, ovarian, and prostate). Stained samples were scored by a pathologist and assessed for percent of positive tumor cells, nuclear and/or cytoplasmic staining, and staining intensity. CCLE and TCGA datasets were mined for indications enriched for suspected NAPRT-loss and sensitivity to NAMPT inhibitors. We then selected cell lines and pan-tumor PDX tissue microarrays (TMAs) from indications of interest and characterized samples by western blot and IHC to determine NAPRT status. Cell lines and PDX tumor tissue were exposed to increasing ranges of NAMPTi in the presence or absence of NAPRT-substrate NA to validate our approach.
Results: We validated that our proprietary NAPRT monoclonal antibody clone 4A5D7 only detects functional NAPRT and demonstrated improved performance over previous antibodies. We used our antibody to characterize cell lines and PDX tumor samples, and subsequently show that NAPRT-null cell lines and tumor samples are susceptible to NAMPT inhibition, while samples with functional NAPRT can be rescued by NA.
Conclusion: Our proprietary antibody can identify NAPRT null tumors and identify samples that will respond to NAMPT inhibition, a critical advancement for patient selection in clinical trials.

#5137 BRAF mutations in primary central nervous system tumors.

J. B. Blaquier, F. D'Angelo, D. Tejera, R. A. Nasany, G. Saigal, A. Iavarone, M. I. de la Fuente;
Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL

Background: *BRAF* alterations are present in a variety of primary central nervous system (CNS) tumors from 3% in glioblastomas to 60% in pleomorphic xanthoastrocytomas. BRAF V600E mutation is the most common *BRAF* alteration found in tumors and has been successfully targeted by combining BRAF/MEK inhibitors in different tumor types, including gliomas. We aimed to describe the clinical and genomic features of primary CNS tumors harboring BRAF alterations and real-world data on BRAF-targeted therapy including our experience sequencing BRAF-directed therapies (BDI) in gliomas.
Methods: Single-center retrospective analysis of patients with diagnosis of primary CNS tumors with NGS testing. Clinical, histological and molecular characteristics were analyzed.
Results: 44 patients with *BRAF* mutant primary CNS tumors were included. 28 (64%) were male. 24 (55%) had histology consistent with high-grade glioma (HGG), 14 (32%) low grade glioma (LGG), 4 (9%) low grade neuroepithelial tumors and 2 (4%) others. Missense mutations were found in 77%, followed by amplifications (9%), fusions (9%) and in/del alterations (5%). V600E was the most common mutation (63%), followed by class 2 (16%) and 3 (7%) mutations and amplifications (9%). Co-occurring mutations were found in *CDKN2A/B* (22), *TERT* (20) and *MTAP* (12). median TMB was 2 mut/mb and only 2 patients had high TMB. 4 patients had commuted *IDH1* (3 R132H), non-concurring with a V600E mutation. For patients with HGG, median age at diagnosis was 47 years and 16 (66%) were male. Lesions were more frequent in left hemisphere (70%) and temporal lobe (54%). V600E was found in 50% of cases. KIAA1549-BRAF fusion was found in 1 case. Median follow-up was 40 months (95% CI 11-68) and median overall survival (OS) was 22 months (3.4-40) for the whole population, and 56 (4-109) months for patients treated with BDI (n=4). All 4 patients had an OS >30 months. In the LGG cohort, median age at diagnosis was 34 years (IQR 24-46). 8 (57%) were male. 50% of the lesions were in the left side and 21% of the tumors were in the posterior fossa. 78% had a V600E mutation, with no statistical difference with HGG cohort (p=.082). Median follow up was 11 months, median OS was not reached. For 5 patients treated at recurrence with BDI, median PFS was 15 months (3-27).5 patients were treated with plixorafenib (PLX8394) on clinical trial achieving disease control (PR +SD) in 4 cases. Upon progression, 4 were rechallenged with dabrafenib + trametinib and 1 with another BDI. 4 patients had a partial response with duration of response >6 months in 3 cases.
Conclusion: BRAF mutant CNS tumors are a heterogeneous disease. Longer survival was observed in the small group of HGG patients treated with BDI compared to SoC (56 months vs 22months). BDI rechallenge showed durable responses in heavily pretreated patients. Further molecular characterization of these patients is ongoing. The best therapeutical sequencing strategy for BDI remains uncertain.

#5138 Proteomic analyses of the urothelial cancer landscape reveal highly distinct prognostic and predictive subtypes.

F. F. Dressler[1], F. Diedrichs[1], D. Sabtan[1], S. Hinrichs[2], P. Mackedanz[2], M. Schlotfeldt[2], C. Krisp[3], M. Hennig[2], H. Schlueter[3], U. Wetterauer[4], R. Zubarev[5], D. Horst[1], S. Perner[2], P. Wolf[4], A. Vegvari[5],

[1]Charite - University Medicine Berlin, Berlin, Germany, [2]University Medical Center Schleswig-Holstein, Luebeck, Germany, [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [4]University of Freiburg - Medical Center, Faculty of Medicine, Freiburg, Germany, [5]Karolinska Institutet, Stockholm, Sweden

Introduction: Urothelial cancer (UC) is a challenging disease with a wide tumor-biological spectrum. Most molecular classifications cover only muscle-invasive bladder cancer and are transcriptome-based, relating only indirectly to the therapeutically relevant and more stable protein level. Also, the recent introduction of antibody-drug conjugates (ADCs) requires quantitative data about the tumor specificity of their target proteins. We turned to the proteome to address these questions.

Methods: We performed deep proteomic profiling of a comprehensive cohort by optimized tandem mass tag-labelled liquid chromatography-coupled tandem mass spectrometry. Data acquisition was validated internally with immunoblotting and externally by bioinformatic reclassification within existing, filtered transcriptomic data. After bioinformatics, the top cluster defining proteins were quantified immunohistochemically under real-world conditions. Protein profiles were individualized and separately evaluated with drug repurposing libraries. Cell viability assays were performed for a panel of twelve UC cell lines to validate these predictions in vitro.

Results: We analyzed 434 samples with 242 tumors and 192 paired normal mucosae, covering all stages of UC. 9542 proteins were quantified and revealed five distinct proteomic subtypes. These were validated internally and externally, showing relevant survival stratification also in the TCGA dataset. The proteomic subtypes were independent from pathological groups with relevant stratification of progression- free and overall survival (low vs. high-risk: median 103 vs. 27 months). Tumor specificity of all proteins was highly heterogeneous across stages and subtypes. As an example, the ADC target NECTIN4 was generally overexpressed mainly in non-muscle-invasive UC. Drug repurposing revealed several new candidate drugs, each specific to different proteomic subtypes. In vitro data showed increased sensitivity by subtype in line with four out of seven representative predictions.

Conclusions: Proteomic subtypes add independent prognostic information and carry predictive value for several newly identified adjuvant drug candidates. The actual tumor specificity of biomarkers and ADC targets is highly dependent on stage and subtype and calls for individualized patient-specific predictive testing.

#5139 PD1-PDL1 interaction as a superior predictor for response to immune checkpoint therapy in NSCLC patients.

P. Micke[1], A. Lindberg[1], R. Artursson[1], L. Hellberg[1], H. Yu[1], M. Backman[1], J. Botling[1], H. Brunnstrom[2], A. Mezheyeuski[3], J. Isaksson[1], **C. Strell**[1];
[1]Uppsala University, Dept of Immunology, Genetics and Pathology, Uppsala, Sweden, [2]2Department of Clinical Sciences Lund, Division of Pathology, Lund University, Lund, Sweden, [3]Molecular Oncology Group, Vall d'Hebron Institute of Oncology, Barccelona, Spain

Background: Immune checkpoint therapies (ICT) are now widely introduced in clinical oncology and most often guided by PDL1 expression in diagnostic biopsies. However, the predictive value of this testing is only modest, leading to over- and undertreatment. Conceptually, the prevention of binding of ligand PDL1 to PD1 receptor is decisive for the efficacy of ICT. Therefore, directly detecting the spatial PD1-PDL1 interaction would provide more predictive information.

Methods: A second-generation *in situ* proximity ligation assay (isPLA; Navinci Diagnostics) was established to detect PD1-PD-L1 interactions in diagnostic patient samples and linked to an automated analysis pipeline (QuPath). For basic validation, we used pan-cancer tissue microarrays (TMA) including 16 solid tumor types, and a non-small cell lung cancer (NSCLC) TMA (359 ICT-naïve surgically treated patients). In addition, we analyzed diagnostic tissue biopsies from 75 advanced NSCLC patients treated with anti-PD1-PDL1 regiments.

Results: The pan-cancer analysis revealed varying levels of PD1-PDL1 interaction among the solid cancer types, with the lowest levels detected in liver cancer and the highest in testicular cancer. A general positive association was observed between the literature-reported objective ICT response rate (ORR) per tumor type and its corresponding PD1-PDL1 interaction status. Conventional immunohistochemical analysis of the ICT-naïve, surgically treated NSCLC cohort revealed variable protein expression level for both, PDL1 and PD1, for 200 cases, but only 108 (54%) of them demonstrated a detectable PD1-PDL1 interaction with our isPLA assay. EGFR mutated cases showed generally lower PD1-PDL1 interaction scores (p=0.01). PD1-PDL1 interaction was not associated with survival (p=0.46). A subsequent analysis of the ICT-NSCLC cohort revealed a significant positive association between PD1-PDL1 interaction status and prolonged overall survival upon ICT (median survival 14.8 vs 32.3 months; p=0.022). The standard tumor proportional score (TPS) of membranous PDL1 expression did not correlate with ICT-specific survival (p=0.40).

Conclusions: The second generation isPLA successfully distinguishes a previously difficult-to-define patient subset with positive PD1-PDL1 interaction status. Our data suggest that the PD1-PDL1 interaction is a superior clinical biomarker for patient selection for ICT in NSCLC. The interaction analysis is applicable to sections from minute diagnostics biopsies and accessible by light microscopy either semi-quantitatively by a pathologist or by an automated image analysis program. Thus, the assay holds great potential to be integrated into routine clinical pathological workflow to stratify cancer patients for ICT.

#5140 ITGB6 as a predictive biomarker for overall prognosis and PD-(L)1 immune checkpoint blockade response in various cancer types.

W. J. MacDonald, P. R. Srinivasan, M. Pinho-Schwermann, V. Tajiknia, C. Purcell, L. Carlsen, W. S. El-Deiry;
Legorreta Cancer Center at Brown University, Providence, RI

Our previous work studying the effects of integrin αvβ6 knockdown in cancer cells demonstrated αvβ6 as a method of T cell suppression in a co-culture model. ITGB6, the gene encoding the β6 subunit of αvβ6, is a potent prognostic marker across multiple cancer types. As a major activator of latent TGFβ, αvβ6, and consequently, ITGB6, has considerable therapeutic implications due to the immunosuppressive effect that activated TGFβ has on the tumor microenvironment. A Human Protein Atlas search of ITGB6 expression surveyed the upregulation of ITGB6 across cancer types. Cancer ITGB6 expression was then compared to expression in paired adjacent normal tissue using the TNMplot tool (Bartha, 2021) on a concatenated set of GEO, GTex, TCGA, and TARGET RNA-seq databases. Kaplan-Meier curves were generated using TCGA mRNA data through the cBio portal, splitting the cohorts according to an ITGB6 mRNA expression threshold of one standard deviation above the mean (z-score ± 1.0). ITGB6 expression and immune checkpoint blockade (ICB) response were evaluated with the Kaplan-Meier Plotter tool (Kovacs, 2023). ITGB6 expression levels between ICB responders and non-responders were quantified using the ROC Plotter tool (Fekete, 2023), and the figures were generated using Matplotlib in Python. Lung, bladder, head and neck, pancreatic, and cervical cancer all demonstrated high expression of ITGB6. Head and neck squamous cell carcinoma (median fold change 2.70, $p<0.0001$), bladder urothelial carcinoma (FC 2.41, $p<0.001$), cholangiocarcinoma (FC 5.33, $p<0.01$), and esophageal carcinoma (FC 2.72, $p<0.03$) showed strong upregulation of ITGB6 compared to normal tissue. Interestingly, lung adenocarcinoma (FC 0.77, $p<0.04$) and lung squamous cell carcinoma (FC 0.55, $p<0.0001$) showed downregulation of ITGB6 compared to normal tissue. Survival data revealed that ITGB6 was a potent marker of a poor prognosis in pancreatic adenocarcinoma (high ITGB6 median survival 16.79 mos, vs. low ITGB6 21.88 mos, $p<0.004$) and head and neck squamous cell carcinoma (high ITGB6 30.06 mos vs. low ITGB6 57.42 mos, $p<0.03$). However, no significant prognostic difference was observed in non-small cell lung cancers. Finally, high pan-cancer expression of ITGB6 led to poorer response to αPD-1 (high ITGB6 Hazard Ratio 1.37, $p<0.05$) and αPD-L1 (high ITGB6 HR 1.50, $p<0.001$). In vitro and in vivo experiments to validate the benefit of ITGB6 as a biomarker and as a therapeutic target are underway.

#5141 Autoantibody profiling for predictive biomarkers for immune-related adverse events and clinical benefit in rare tumors treated with anti-PD-1 therapy.

M. H. Derbala[1], J. Hajjar[2], B. Stephen[1], S. A. Gurses[1], E. Kwiatkowski[1], P. Budde[3], H.-D. Zucht[3], M. Brautigam[3], A.-S. Schubert[3], B. Ahangarianabhari[3], E. Rodriguez[1], M. Gouda[1], L. Castillo[1], A. Zarifa[1], J. A. How[1], J. T. Moyers[4], D. S. Hong[1], F. Meric-Bernstam[1], A. Naing[1];
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [3]Oncimmune Germany GmbH, Dortmund, Germany, [4]Angeles Clinic and Research Institute, Cedars-Sinai Affiliate, Los Angeles, CA

Background: Immune checkpoint inhibitors (ICIs) have changed the cancer treatment paradigm; however, with high frequency of immune-related adverse events (irAEs) and limited response rates in select patients. This underscores the unmet need for the development of biomarkers predictive for the development of irAEs and ICI response. Herein, we conducted autoantibody (AAb) profiling to assess baseline (BL) AAb associations with clinical benefit (CB) and irAEs in patients (pts) with rare tumors (RT) treated with programmed cell death protein 1 (anti-PD-1) therapy.
Methods: AAbs against 1168 antigens were analyzed using the SeroTag antibody discovery technology. The study included 41 pts with RT who received anti-PD-1 therapy. We conducted a Significance Analysis of Microarray (SAM) to analyze the association between BL AAbs with irAEs and CB (defined as pts achieving complete response (CR), partial response (PR), or stable disease (SD) for ≥4 months by Response Evaluation Criteria in Solid Tumors (RECIST) v1.1). AAb biomaker candidates were discovered based on filtering for SAM hits with $p < 0.05$ and a delta score $|D| > 2$.
Results: Table 1 outlines patients' demographics. CB and irAEs were observed in 34% and 39% of patients, respectively. Eighteen BL AAbs were significantly associated with CB such as DNA ligase III (LIG3) and small nuclear ribonucleoprotein polypeptide (SNRPA) ($p = 0.002$ and $p = 0.003$, respectively). Likewise, 13 BL AAbs showed significant associations with any-grade irAEs, particularly AAbs to breast cancer 2 (BRCA2) DNA repair associated antigen and chromatin-modifying protein 4A (CHMP4A) ($p = 0.001$ and $p = 0.003$, respectively).
Conclusion: The predictive potential of autoantibodies as biomarkers is promising. Further evaluation in larger cohorts is needed for validation of our findings and understanding the underlying mechanism.

Table 1. Patients' demographics

Total patients		n=41
	Median age in years (range)	66 (35-84)
	Male	n=19
	Female	n=22
Tumor type	Carcinoma of unknown primary	n=13
	Squamous cell carcinoma of the skin	n=9
	Small cell malignancies of non-pulmonary origin	n=7
	Adrenocortical carcinoma	n=6
	Vascular sarcoma	n=5
	Other rare histology	n=1
Clinical benefit	CR, PR, or SD ≥ 4 months	n=14
	SD <4 months or progressive disease (PD)	n=23
	Not evaluable	n=4
irAEs	Yes	n=16
	No	n=25

#5143 Molecular investigation of a polymorphic variant in *JMJD1C* that associates with chemoradiotherapy outcomes in locally advanced rectal and head and neck cancer.

Adria Hasan[1], Elena V. Demidova[1], Philip Czyzewicz[1], Shreya M. Shah[1], Karthik Devarajan[2], Thomas J. Galloway[3], Margret B. Einarson[4], Barbara Burtness[5], Erica A. Golemis[6], Joshua E. Meyer[3], Sanjeevani Arora[1]

[1]Cancer Prevention and Control Program, Fox Chase Cancer Center, Philadelphia, PA,[2]Program in Biostatistics and Bioinformatics, Fox Chase Cancer Center, Philadelphia, PA,[3]Department of Radiation Oncology, Fox Chase Cancer Center, Philadelphia, PA,[4]Program in Cancer Signalling and Microenvironment, Fox Chase Cancer Center, Philadelphia, PA,[5]Department of Internal Medicine, Yale Cancer Center, Yale School of Medicine, New Haven, CT,[6]Department of Cancer and Cellular Biology, Lewis Katz School of Medicine, Temple University, Philadelphia, PA

Background: Neoadjuvant chemoradiotherapy (nCRT) is standard therapy for locally advanced rectal cancer (LARC). While only a minority of patients are expected to have a complete response, all are at risk of toxicity. Currently no biomarkers reliably predict response to nCRT in LARC. Further, standard therapy in locally advanced head and neck squamous cell carcinoma (HNSCC) is adjuvant CRT. A major cause of poor outcomes in HNSCC is regional persistence or recurrence post-CRT. No biomarkers, apart from HPV, predict CRT response in HNSCC. CRT causes double-strand breaks (DSBs) and methylation of histones on lysine residues is known to affect chromatin, influencing DSB repair. We hypothesized that single nucleotide polymorphisms (SNP) in the histone 3 lysine 9 (H3K9) demethylase-encoding *JMJD1C* influenced CRT response.

Methods: LARC patients (n=84) were divided into poor (PoR) and complete (CR) responders based on Neoadjuvant Rectal score. Lymphocyte DNA was sequenced, and LARC patient-derived cells were treated with DSB-inducing agents to assess viability. Sequencing was confirmed in an independent cohort of CRT-treated HNSCC patients (n=90) divided into: disease-free (n=30), recurrent disease (n=28), and never-disease-free (n=32). HNSCCs were in the larynx or oral cavity. Not all patients received HPV-testing; p16 expression was positive for 19/43 tumors. CRISPR/Cas9 editing of HPV-negative HNSCC lines (SCC9, Cal27) generated JMJD1C WT or SNP isogenic pairs. Bulk RNA-sequencing, colony survival, and immunofluorescence studies were performed.

Results: In LARC patients, CRs were enriched for a coding, missense germline SNP in *JMJD1C* versus PoRs (discovery n=30, p<0.00001; validation n=54, p=0.001, Fisher's Exact). When subjected to DSB, LARC patient-derived cells with the SNP displayed greater sensitivity than their WT counterparts (n=12, p<0.001, Mann-Whitney). In HNSCC, a correlation was identified between the same *JMJD1C* SNP and no recurrence (p=0.0003, Fisher's Exact). HNSCC SNP cells showed changes in mRNA levels of DNA repair and immune response genes versus HNSCC WT cells (q-value<0.05). Upon irradiation, kinetics of foci resolution of the DNA damage response protein MDC1, specific to DSBs, were slower in SNP versus WT HNSCC cells (p<0.05, Mann Whitney). Further, there was reduced colocalization of BRCA1 with RAP80, a crucial factor for homology-directed DSB repair, in SNP versus WT HNSCC cells (p<0.01, Mann-Whitney).Targeted introduction of the SNP into HNSCC cell lines reduced viability and radiation response.

Conclusion: Our study identifies a polymorphic coding variant in *JMJD1C*, as a predictive biomarker for CRT effectiveness in LARC and HNSCC, and defines a DNA repair mechanism by which JMJD1C influences response to irradiation.

#5145 Association of a ctDNA biomarker of treatment response with clinical outcomes in a real-world pan-cancer cohort treated with tyrosine kinase inhibitors.

A. Mitra[1], J. Guittar[1], R. Schwind[1], T. Driessen[1], M. Berginski[1], C. Lo[1], M. M. Stein[1], J. Freaney[1], S. Won Hyun[1], C. Sangli[1], K. Sasser[1], H. Nimeiri[1], A. Chaudhuri[2];

[1]Tempus Labs, Chicago, IL, [2]Washington University in St. Louis, St Louis, MO

Clinical evidence suggests that early changes in circulating tumor DNA tumor fraction (ctDNA TF) is predictive of patient response to immune checkpoint inhibitors, but the extent to which this approach can be used for patients on Tyrosine Kinase Inhibitors (TKIs) is not known. Here, we use xF Monitor to estimate ctDNA TF in patients that received TKIs and show that changes in circulating TF correlate with outcomes in a real-world pan-cancer cohort.

Tempus xF Monitor is a ctDNA assay that measures quantitative molecular changes in ctDNA TF by utilizing diverse genomic events, dynamically weighting somatic variant allele frequencies and copy number variants, while using germline information to inform these estimates and providing single nucleotide variant (SNV) results on 105 genes. Molecular responders (MR) were defined as patients with ≥50% reduction in ctDNA TF between baseline and on-treatment time points, consistent with our previously established threshold. Deidentified patient records from the Tempus multimodal database were analyzed if patients had an xF test ≤ 15 weeks prior to the start of their first TKI regimen and an xF test 15 -180 days post-TKI initiation. Patients received TKI agents as classified in the Tempus Medical Ontology, which assigns a unique ID to key clinical concepts, validated and harmonized across industry standard terminologies. The TKI list was further validated using the NCI Metathesaurus (https://ncim.nci.nih.gov/ncimbrowser/) TKI concept (NCI Code C1967). Clinical endpoints were defined from TKI start to the first progression event or death (rwPFS) or death (rwOS), both censored on the last follow-up in event-free patients. Kaplan Meier analysis and Cox proportional hazard models were fitted to compare MR status and survival outcomes on TKI.

The evaluable pan-cancer cohort N=69, median age = 61.5 yo, advanced/metastatic disease = 72%, 65% were female, consisted of > 10 cancer diagnoses (35% NSCLC, 26% BC), 41% 1L. In this cohort, 49% of patients received a TKI combination regimen, 21% with CT, 18% with ICI. 68% of patients with NGS testing received matched targeted mutation therapies based on NCCN guidelines. Patients classified as MR based on xF Monitor results had improved survival outcomes with a median rwOS of 951 days (vs 439 days for non-MRs). MR patients had significantly longer rwPFS (HR = 0.383, p = 0.005, CI = 0.12 - 0.75) and rwOS (HR = 0.205, p = 0.004, CI = 0.07 - 0.61) than non-MRs.

xF Monitor is a novel tumor naive serial quantitative ctDNA TF algorithm off the Tempus xF assay that has the potential to be used clinically as a monitoring biomarker to stratify patients who are likely to benefit from TKI therapy. xF monitor can be used as a strategy to identify patients at a high risk of progression who could benefit from early switch or intensifying therapy. Results need to be prospectively validated in a larger cohort.

#5146 Clinical significance of inter-assay discrepancy in PD-L1 expression evaluation for the efficacy of pembrolizumab in advanced NSCLC patients with high PD-L1 expression.

J. Miyakoshi, J. Kashima, M. Shirasawa, M. Torasawa, Y. Matsumoto, K. Masuda, Y. Shinno, Y. Okuma, T. Yoshida, Y. Goto, H. Horinouchi, K. Shiraishi, T. Kohno, N. Yamamoto, Y. Yatabe, Y. Ohe;
National Cancer Center Hospital - Japan, Tokyo, Japan

Introduction: The expression of programmed cell death ligand-1 (PD-L1) is a predictive biomarker for the efficacy of pembrolizumab in advanced non-small cell lung cancer (NSCLC). While several assays have been approved for evaluating PD-L1 expression status, the inter-assay discordances are observed. The clinical significance of these discrepancies is still unclear.

Methods: We retrospectively reviewed treatment-naïve NSCLC patients with available PD-L1 expression status by both 22C3 and SP142 assays. Among these patients, efficacy analysis was performed in those with PD-L1 tumor proportion score (TPS) ≥ 50% (22C3) who received the first-line pembrolizumab monotherapy. Additionally, we conducted RNA-sequence analysis in the patients with TPS ≥ 50% to investigate the distinct immune profiles with the inter-assay discordance.

Results: A total of 611 patients were evaluated for PD-L1 expression status by both assays. Of 198 patients with TPS ≥ 50%, 91 (46%) had TC score ≤ 1 (SP142, i.e., inter-assay discrepancy). In 52 patients who received the first-line pembrolizumab monotherapy, the efficacy in patients with the inter-assay discrepancy was significantly lower than those without the discrepancy (shown in Table). While there was no difference in tumor microenvironments such as the tumor-infiltrating lymphocytes, the transcriptome analysis revealed significantly more *CD274* splicing variants with aberrant 3'-terminal sequences in tumors with the inter-assay discrepancy than those without discrepancy, leading to the suppressed PD-1/PD-L1 pathway in those with the discrepancy.

Conclusion: The inter-assay discrepancy in the PD-L1 expression status on tumor cells between the 22C3 and SP142 assays, reflecting an imbalance of the *CD274* splicing variants, could be a primary-resistance mechanism to the pembrolizumab monotherapy in highly PD-L1-expressing NSCLCs.

PD-L1(22C3)	Discrepancy	Pts.	ORR(%)	p value	Median PFS(months)	95%CI	p value
TPS ≥ 50%	yes	17	18	< 0.001	3.2	0.8–5.5	< 0.001
	no	35	83		8.3	5.7–24.2	

#5147 Identification of pharmacodynamic biomarkers in PBMCs and cancer cells for SIK2 kinase inhibitor therapy.

H. Yang[1], W. Mao[1], P. Rask[1], M. Peter[2], G. Swaminath[2], S. W. Morris[2], Z. Lu[1], R. C. Bast[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Greenfire Bio, Frisco, TX

Salt-inducible kinase 2 (SIK2) is an AMPK family kinase involved in multiple signaling pathways including the LBK1-SIK-HDAC, LKB1-SIK-CRTC/CREB, PI3K-PKA-mTOR and Hippo pathways. The expression of SIK2 is significantly upregulated in fraction of ovarian and breast cancers, and associated with poor prognosis. Inhibition of SIK2 kinase activity suppresses growth of ovarian and breast cancers as well as progression of acute myeloid leukemia. SIK2 inhibitors synergistically enhance sensitivity of ovarian and breast cancer cells to paclitaxel, carboplatin and PARP inhibitors. Utilization of SIK2 inhibitors to treat cancers has been investigated in preclinical studies and in a Phase I clinical trial (NCT04711161). To enable pharmacodynamic (PD) analysis in clinical studies, we have developed biomarkers that measure the effect of GRN-300, a SIK2/3 inhibitor, on SIK2 signaling in ovarian cancer cells. Class IIa histone deacetylases (HDAC4/5/7) are SIK2 substrates in cancer cells; and are also expressed in peripheral blood mononuclear cells (PBMCs). We found that GRN-300 decreased phosphorylated HDAC4/5/7 levels in ovarian and breast cancer cells (Lu et al. J Clin Invest, 2022) and now report that this SIK2 inhibitor also decreases pHDAC4/5/7 in PBMCs *ex vivo* in a dose-dependent manner using Western blot analysis. We also identified three mRNA markers in PBMCs by RNAseq analysis - SEPP1, RNASE1 and MS4A6A - which are up-regulated by GRN-300 in PBMCs isolated from healthy donors. However, these mRNA markers were either expressed at very low levels or not dramatically changed in cancer cells. We identified an additional mRNA marker panel using RNAseq technology by screening seven ovarian and six breast cancer cell lines: A2780, Caov3, IGROV1, OC316, OVCAR3, OVCAR8, SKOv3ip, BT549, Cal51, HCC1937, MDA-MB-231, MDA-MB-436 and MDA-MB-468. mRNA expression of three genes - DDIT4, NUPR1 and IL6 - is upregulated by GRN-300 in more than 9 of 13 cell lines tested. Five genes - ID1, ID2, ID3, ID4 and TGFBI - are down-regulated in response to GRN-300 treatment in more than 10 of 13 cell lines. The decrease in HDAC4/5/7 phosphorylation, and alterations in mRNA markers we discovered could serve as PD biomarkers for clinical trials to evaluate the effects of SIK2 inhibitors and provide insights in the mechanisms of drug action.

#5148 Analysis of HER2 prevalence by RNA expression across solid tumors.

K. Moxley[1], E. Scherrer[2], M. Bontrager[3], S. Whitman[2], N. R. M. Schwartz[2], C. Sangli[3], S. Won Hyun[3], H. Nimeiri[3], J. Ball[3], C. Aggarwal[4]; [1]Oklahoma Cancer Specialists and Research Institute, Tulsa, OK, [2]Seagen, Inc., Bothell, WA, [3]Tempus Labs, Inc., Chicago, IL, [4]University of Pennsylvania, Philadelphia, PA

Background: The frequency of HER2 expression in solid tumors other than breast (BC) and gastric cancer (GC) is not well defined. This study describes the frequency of HER2 expression by correlating HER2 IHC/ ISH and ERBB2 mRNA levels by NGS in tumor samples of patients with locally advanced/metastatic (LA/m) BC or GC and applying those findings to predict HER2 expression in other solid tumors.

Methods: De-identified records from NGS-tested patients with LA/m BC, GC, HNSCC, NSCLC, endometrial, and ovarian cancers in the Tempus database from 2015 - 2021 were analyzed. Patients with BC and GC who underwent HER2 IHC/ISH testing were categorized as: RNA-zero (IHC0), -low (IHC1+, IHC2+/ISH-), and -positive (HER2+; IHC2+/ISH+, IHC3+). To identify thresholds separating HER2 subgroups, a logistic regression model was fit to NGS and IHC status data in BC and GC. These thresholds were applied to other solid tumors to predict the distribution of HER2 expression. HER2 amplification and mutation rates were evaluated in the Tempus NGS data.

Results: Logistic regression modeling used 3,898 samples. HER2+ samples had the highest IHC-to-RNA agreement at 80% (BC) and 81% (GC) compared to HER2 low and zero samples which ranged ~56-75% agreement. When applying thresholds identifying RNA-low and RNA-positive sample to other tumors (N = 4,726), the models predicted up to 33% (BC thresholds) or 56% (GC thresholds) of tumors express HER2 at levels that may be detectable (Table 1).

Conclusions: A notable amount of solid tumors apart from BC or GC have RNA expression that may correspond to HER2 IHC ≥1+. This opens the possibility for novel agents such as HER2-directed antibody drug conjugates to impact patient care in several tumor types. Further IHC testing in these populations are needed to corroborate our results.

Table 1. ERBB2 (HER2) Categories in Solid Tumors

HER2 Status	**HNSCC** (N = 630)	**NSCLC** (N = 2945)	**OC** (N = 855)	**EC** (N = 295)
NGS BC thresholds ERBB2 Log2(TPM+1)				
RNA-Zero	589 (93.5%)	1,974 (67.0%)	626 (73.2%)	205 (69.5%)
RNA-Low	33 (5.2%)	853 (29.0%)	214 (25.0%)	64 (21.7%)
RNA-Positive	8 (1.3%)	118 (4.0%)	15 (1.8%)	26 (8.8%)
RNA-Low + RNA-positive	41 (6.5%)	971 (33.0%)	229 (26.8%)	90 (30.5%)
NGS GC thresholds ERBB2 Log2(TPM+1)				
RNA-zero	492 (78.1%)	1,345 (45.7%)	395 (46.2%)	130 (44.1%)
RNA-Low	124 (19.7%)	1,190 (40.4%)	384 (44.9%)	127 (43.1%)
RNA-Positive	14 (2.2%)	410 (13.9%)	76 (8.9%)	38 (12.9%)
RNA-Low + RNA-positive	138 (21.9%)	1,600 (54.3%)	460 (53.8%)	165 (55.9%)
DNA Amplification				
Unamplified	622 (98.7%)	2,911 (98.8%)	843 (98.6%)	277 (93.9%)
Amplified	8 (1.3%)	34 (1.2%)	12 (1.4%)	18 (6.1%)
DNA mutation				
Wild-Type	623 (98.9%)	2,916 (99.0%)	850 (99.4%)	287 (97.3%)
Mutated	7 (1.1%)	29 (1.0%)	5 (0.6%)	8 (2.7%)

NGS: next-generation sequencing; HNSCC: head and neck squamous cell carcinoma; NSCLC: non-small cell lung cancer; OC: ovarian cancer; EC: endometrial cancer; TPM: transcripts per million

#5149 Extracellular matrix remodeling in metastatic mismatch repair deficient endometrial cancer:Implications for immune checkpoint inhibitor response prediction.

J. Grau[1], C. Aime[2], M. Mehnert[3], E. Yaniz-Galende[1], C. Genestie[1], A. Le Formal[1], E. Edmond[1], A. Lachaud[3], P. Pautier[1], J. Michels[1], S. Gouy[1], A. Maulard[1], E. Colomba-Blameble[1], F. Blanc-Durand[1], M.-C. Schanne-Klein[4], A. Leary[1];

[1]Institut Gustave Roussy, Villejuif, France, [2]Ecole Normale Superieure, PSL University, Sorbonne University, CNRS, Paris, France, [3]Biognosys AG, Schlieren, Switzerland, [4]Ecole Polytechnique CNRS - INSERM - Institut Polytechnique de Paris, Palaiseau, France

Mismatch repair deficient (MMRd) status is a predictive biomarker for Immune checkpoint inhibitors (ICI) in endometrial cancer (EC), however, half of these patients (pts) do not respond. Most studies exploring biomarkers of response to ICI have focused on tumor or immune cell factors. We aimed to describe the extracellular matrix components of the tumor microenvironment (TME) in ICI-Responder (R) versus Non-Responder (NR) MMRd EC pts to identify new predictive biomarkers of response.

Clinical data and outcomes of metastatic MMRd EC pts, treated with ICI (2016-2021), were retrospectively collected. Pts were classified as Rs (CR, PR, or SD ≥12 months) or NRs (PD or SD <12 months). Pre-ICI FFPE tumor samples were subjected to Biognosys UltraDeep TrueDiscovery™ Mass Spectrometry (MS) for identification of differentially regulated protein expression between R and NR. Criteria for protein candidate selection were p-value < 0.01 and average absolute log2 fold change (AVG Log ratio) > 0.58. Collagen was visualized on whole slides using Masson's trichrome and quantified by Qupath. Collagen density was expressed as % positive surface in the intratumoral area. Second-harmonic generation (SHG) microscopy plus polarimetry (p-SHG) was used to estimate collagen content and describe the spatial orientation of fibrillar collagen in the intratumoral area. intraepithelial (ie) and stromal (s) CD3+ and CD8+ cells were quantified by Qupath. Non-parametric t-tests and Spearman's rank coefficient (r) for linear correlation were used.

Twenty-five tumor samples were included in the analysis: 17 from Rs and 8 from NRs. MS identified collagen type V alpha-2 (AVR Log ratio 2.9, p 0.008) and type XXII alpha-1 chains (AVR Log ratio 1.14, p 0.006) as significantly upregulated in NRs. Using spatial imaging, collagen density in the intratumoral area was significantly higher in NRs (median: 14.2% vs 4.6%, p 0.01). Intratumoral collagen density was positively correlated with collagen type V expression (r 0.54, p 0.016), and negatively correlated with ie and s CD3+ cell (r -0.39, p 0.054; r -0.4, p 0.048, respectively) and ie and s CD8+ cell (r -0.39, p 0.053; and r -0.29, p 0.166) infiltration. SHG confirmed that fibrillar collagen content in the tumor area was significantly greater in NRs (p 0.02). p-SHG revealed that NR tumors tended to show a highly disorganized collagen matrix. In contrast, a linear collagen pattern was associated with response to ICI: 89% of tumors displaying this pattern were Rs.

Both MS and two different spatial approaches consistently demonstrated that increased collagen expression or density may serve as a potential predictive biomarker of resistance to ICI in MMRd metastatic EC, contributing to create an immunosuppressive TME. The spatial orientation pattern of collagen fibers may also be crucial in shaping immune TME and influencing the response to ICI.

#5150 An immunohistochemical survey of predictive biomarkers for immunotherapy in ampullary carcinoma identifies strata with unique prognostic signatures.

S. E. Kalloger[1], J. Karasinska[2], J. Topham[2], D. J. Renouf[2], D. F. Schaeffer[2];

[1]University of British Columbia Faculty of Medicine, Vancouver, BC, Canada, [2]Pancreas Centre BC, Vancouver, BC, Canada

Introduction: Carcinomas located in the ampulla of Vater are a low incidence malignancy. Therapeutic options for early stage disease largely consist of pancreaticoduodenectomy followed by adjuvant chemotherapy with or without radiation. We explored the localization of CD8 and CD3 positive cells in addition to PDL-1 staining and mismatch repair deficiency markers to gain insight into the potential applicability of immunotherapy for patients with this disease.
Methods: Excess material from clinically diagnosed cases collected between 1997 - 2013 were used to construct a duplicate 0.6mm core tissue microarray (TMA). All cases were derived from the Vancouver Coastal Health Region. Immunohistochemical staining was performed with the following markers: CD8, CD3, PD-L1, and the mismatch repair (MMR) markers: MSH2, MSH6, MLH1 and PMS2. CD3 and CD8 were quantified using localization within the tissue. PD-L1 was considered positive with >1% of cells stating positive. MMR markers were confirmed using full section and cases with convincing loss of any MMR marker were considered MMR deficient. Univariable disease specific survival analysis was performed to identify unique prognostic signatures and contingency analysis was performed to identify co-expression of the aforementioned biomarkers.
Results: Ninety-eight cases were evaluable for all markers. The median age of the cohort was 69 [41 - 84] years. Forty-two percent were female. Adjuvant chemotherapy was provided to 15% of patients with the remainder undergoing post-surgical observation. Almost 90% were pT3 or pT4 and 48% had regional lymph node metastasis. CD3+ T-cells were either localized in the tumor stroma only (59%) or in both the stroma and epithelial compartments (41%). CD8+ T-cells were principally located in the stroma (66%) and both the epithelial and stroma (24%). Ten percent of cases had no CD8+ T-cells. PD-L1 staining was found in 10% of cases. MMR deficiency was found in 5% of cases. Improved prognostic signatures were found for cases with CD3+ and CD8+ T-cells in both the epithelial and stromal compartments ($p <= 0.02$). A trend towards a negative prognostic signature was observed for MMR deficient cases and for PD-L1 positive cases. The only significant positive association between biomarkers was found for CD3+ and CD8+ in both the epithelial and stromal compartments.
Conclusions: The results of this analysis suggest that enhancement of an immune response yielding an increase CD3+ and CD8+ T-cells in the epithelial compartment may have a beneficial effect on prognosis. The relative scarcity of MMR deficiency in this disease is within the expected prevalence supported by other studies. Further exploration of the potential role of immunotherapy in immune enhanced subgroups of ampullary cancers is warranted.

#5151 High serum kidney injury marker-1 and high baseline tumor PD-L1 protein expression levels are independently associated with treatment effect in adjuvant nivolumab plus ipilimumab vs placebo in localized clear cell renal cell carcinoma.

S. Vemula[1], W. Xu[2], Y. Wang[1], X. Liu[3], J. Somocurcio[3], D. McDermott[3], J. Li[1], R. Bhatt[1], C.-W. Lee[1], B. Simsek[1], S. Gupta[1], R. Motzer[4]; [1]Bristol Myers Squibb, Princeton, NJ, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Beth Israel Deaconess Medical Center, Boston, MA, [4]Memorial Sloan Kettering Cancer Center, New York City, NY

Introduction: CheckMate 914 (CM-914) Part A is a double-blind, phase III randomized trial of the Nivolumab (NIVO) plus Ipilimumab (IPI) vs placebo (PBO) in localized ccRCC. Our prior report from this study suggested a disease-free survival (DFS) benefit for NIVO+IPI among patients with Fuhrman grade 4, TNM stages PT2a and PT4, or sarcomatoid features, although the sample size was limited. It is known that high circulating KIM-1 is associated with worse DFS after nephrectomy. In this exploratory post hoc analysis, we investigated whether high KIM-1 may help identify a subset of patients who benefit from adjuvant NIVO+IPI.

Methods: Patients (n=816) with RCC after nephrectomy were randomized in CM-914 Part A to receive NIVO+IPI or PBO as previously described. Assessment of KIM-1 levels was performed using enzyme linked immunoassay (ELISA) on pre-treatment (n=584) and matched on-treatment blood samples (n=584). We used pre-treatment tumor samples to assess PD-L1% tumor cell expression (%TC) in an PD-L1 IHC 28-8 pharm Dx assay. The association between biomarkers and DFS outcomes was investigated by Kaplan-Meier (KM) and Cox proportional hazards analysis.

Results: Median baseline serum KIM-1 level was 102 (9.9 - 1055.7) pg/mL. Serum KIM-1 levels were higher in males vs females, ≥65 yrs vs <65 yrs, Asian vs white patients, and patients with partial vs radical nephrectomy. In the PBO arm, subjects with highest quartile of pre-treatment KIM-1 had significantly worse DFS than those from the three lower quartiles. In contrast, this DFS risk among the subjects within the highest KIM-1 quartile was mitigated with NIVO+IPI treatment. Among patients within the highest quartile of pre-treatment KIM-1, there was trend for better DFS for NIVO+IPI versus PBO, HR=0.6 (0.34-1.04). Increase in KIM-1 during study therapy was positively associated with higher DFS rate in both arms. Multivariable analysis showed that PD-L1 %TC was predictive at predefined PD-L1 cutoffs (>=1%, >=5%, and >=10%), associating with improved DFS compared to placebo. Subjects with high PD-L1 expression had a DFS benefit from NIVO+IPI independent of KIM-1.

Conclusion: Circulating KIM-1 and tumor PD-L1 expression may enrich for benefit from IO therapy in adjuvant ccRCC and hence holds promise for informing risk stratification and patient inclusion in neoadjuvant or adjuvant clinical trials.

#5152 Co-expression and prognostic significance of HER family members and EGFRvIII in patients with hepatocellular carcinoma.

O. Sherif[1], S. Khelwatty[1], I. Bagwan[2], A. Seddon[1], A. Dalgleish[3], S. Mudan[3], **H. Modjtahedi**[1];

[1]Kingston Univ. London School of Life Sci., Kingston upon Thames, United Kingdom, [2]The Royal Surrey County Hospital, Guildford, United Kingdom, [3]St Gerorge's University of London, London, United Kingdom

Hepatocellular carcinoma is one of the most common type of liver cancer. Despite advances in its treatment including the approval of several targeted agents in the past few decades, many patients do not respond or have a response of short duration to such therapeutic interventions. As a result, liver cancer is the third leading cause of cancer-related deaths worldwide. Therefore, it is essential to identify additional therapeutic targets and to develop more effective therapeutic interventions. In the past few decades, increased expression, and activation of the human epidermal growth factor receptor (HER) family members have been detected in various cancer types and of these, EGFR and HER2 are important therapeutic targets for the treatment of patients with a wide range of cancers, but currently not in liver cancer. In some studies, cross-talk between different members of the HER family has been associated with tumor progression and resistance to therapy with EGFR inhibitors but there has been no comprehensive study of the expression of all members of the HER family in patients with hepatocellular carcinoma. In this study, we examined the relative expression of all members of the HER family, type-III deletion mutant of EGFR (i.e.EGFRvIII), which is a tumor specific antigen, and two putative liver cancer cell biomarkers (i.e. CD44, EpCAM) in 43 patients with hepatocellular carcinoma by immunohistochemistry. The prognostic significance of such antigens was also investigated. Of these, the expression of EGFR, HER2, HER3, HER4 and EGFRvIII was found in tumor specimens from 35%, 58%, 0%, 19%, and 26% of the cases, respectively. Interestingly, at a cut off value of >5% of tumor cells with staining, 23%, 14% and 9% of the patients had co-expression of EGFR with HER2, EGFRvIII, and HER2/EGFRvIII. In addition, 40% and 33% of the cases were CD44 and EpCAM positive. Of these, the expression of EGFRvIII positivity at >5% (HR=3.35, p=0.002) and 20% (HR=7.22, p=0.003) of tumour cells and membranous CD44 (HR=2.12, p=0.04) were associated with a poorer survival in patients with hepatocellular carcinoma. In contrast, the expression of cytoplasmic CD44 was associated with a better overall survival (HR=0.30, p=0.02). These were found to be independent prognostic markers in multivariate analysis. Interestingly, the co-expression of EGFR with EGFRvIII was associated with a poorer overall survival (59.5 vs 21.0 months, p=0.004). Taken together, our results suggest that the expression of EGFRvIII occurs in patients with hepatocellular carcinoma and highlight its importance as biomarker for tumor progression and as a potential target for therapeutic intervention with drugs targeting EGFRvIII and other members of HER family.

#5153 Pyramidobacter-DMMR synergy in colorectal cancer: Unveiling prognostic impact, mechanistic insights, and tumor microenvironment dynamics.

S. LI[1], Y. LI[1], H. Ma[2], S. Qin[2], F. Zhao[3], J. Li[1];

[1]The First Affiliated Hospital of Air Force Medical University, Shannxi, China, [2]Air Force Medical University, Shannxi, China, [3]3D Medicines Inc,, Shanghai, China

Background: Colorectal cancer (CRC) exhibits a heightened presence of intratumoral bacteria, and deficient DNA mismatch repair (dMMR) contributes to nucleotide mismatch accumulation, fostering mutagenesis. However, the combined impact of intratumoral bacteria and dMMR on the tumor immune microenvironment (TIME) in CRC, and its consequential influence on patient prognosis, remains elusive.

Methods: We utilized samples from the Cancer Microbiome Atlas project (TCMA), collecting tumor and matched paracancer tissues from colorectal cancer patients. Phyloseq in R was employed to scrutinize microbial abundance differences. The effects of microbial enrichment on prognosis were assessed through survival analysis, and GSEA enrichment analysis provided mechanistic insights.

Results: A total of 173 samples, including 28 dMMR tumors, 112 proficient MMR (pMMR) tumors, and 22 paired para-cancer tissues, were collected. Following stringent filtration, we analyzed 230 bacterial genera. Notably, 26 genera, including Fusobacterium and Streptococcus, showed significant enrichment in dMMR tumors compared to para-cancer tissues. Furthermore, 18 genera were enriched in dMMR tumors compared to pMMR tumors. Of these, 8 genera like Desulfovibrio and Pyramidobacter consistently exhibited enrichment in dMMR CRC compared to either para-cancer tissues or pMMR tumors. Survival analysis highlighted Pyramidobacter as the only genus significantly associated with prognosis in dMMR CRC. Increased Pyramidobacter abundance correlated with decreased overall survival (OS) (P value: 0.049). Stratifying dMMR CRC patients based on Pyramidobacter abundance further emphasized the significantly worse survival in the Pyramidobacter-High group (HR 0.93, 95%CI 1.03-9.60, log-rank p = 0.015). Exploring the impact of Pyramidobacter infection on tumor progression, we assessed TIME and oncogenic pathways between Pyramidobacter-Low and Pyramidobacter-High groups. While overall immune infiltration was higher in the Pyramidobacter-High group, it primarily stemmed from increased B cell and naive CD8+ T cell infiltration. Importantly, pathways enriched in the Pyramidobacter-High group included inflammatory response, epithelial-mesenchymal transition (EMT), and KRAS signaling, while those enriched in the Pyramidobacter-Low group encompassed IFNα response, IFNγ response, and DNA damage repair. These findings suggest Pyramidobacter's role in inducing inflammation, promoting tumor proliferation and metastasis, and suppressing interferon response.

Conclusion: Pyramidobacter emerges as a key player in the development of dMMR CRC, exerting a pivotal influence on patient prognosis through the induction of inflammatory responses and EMT.

#5154 Bacterium LF-3: A dual player in colorectal cancer, shaping prognosis and immune responses.

K. Du[1], F. Zhao[2], F. Feng[1];

[1]Xijing Hospital, the Fourth Military Medical University, Shannxi, China, [2]3D Medicines Inc, Shanghai, China

Background: Colorectal cancer is distinctive for its heightened intra-tumor bacterial presence. While previous studies concentrated on the genus level, the impact of unclassified bacteria, identified through extensive genome sequencing, has been underexplored.

Methods: Utilizing samples from colorectal cancer patients in the Cancer Microbiome Atlas project (TCMA), we applied phyloseq for a nuanced analysis of microbial abundance disparities between tumor and paracancer tissues. Prognostic implications of microbial enrichment were explored through survival analysis, with mechanistic insights gleaned from Gene Set Enrichment Analysis (GSEA).

Results: We meticulously examined 151 colorectal cancer tumors and 22 corresponding para-cancer tissues, scrutinizing a total of 1217 microbial species. We observed that 240 species exhibited a statistically significant enrichment in tumor samples. A focused investigation involving 22 tumor and para-cancer tissue pairs unveiled 35 species with notable enrichment specifically within tumors. A subset of 25 species, including well-documented entities like Fusobacterium sp. oral taxon 370 and Streptococcus oralis, emerged consistently across both comprehensive and paired analyses. We then delved into the prognostic implications of these enriched bacteria. Strikingly, patients with bacterium LF-3 positivity exhibited significantly improved prognoses compared to those without (HR 0.40, 95% CI 0.18-0.91, log-rank p = 0.024). Considering the pivotal role of Microsatellite Instability (MSI) status in the context of Tumor Immuno-Microenvironment (TIME) and prognosis, our analysis of bacterium LF-3 encompassed both MSI-H and MSS CRC cases, with proportions of 12/28 (43%) and 55/102 (54%), respectively. Even after meticulous adjustments for MSI status, bacterium LF-3 maintained a robust correlation with prognosis (HR 0.42, 95% CI 0.18-0.99, p = 0.048), highlighting its independent prognostic significance. Further exploration among MSS patients (N = 112) unearthed intricate details about the impact of bacterium LF-3 on tumor signaling pathways. TNF-α and IFN-γ pathways were significantly up-regulated in bacterium LF-3-positive cases, while the MYC pathway, PI3K pathway, and various cell cycle-related pathways (G2M checkpoint, The E2 factor [E2F] targets, and mitotic spindle assembly) were down-regulated. As for TIME, bacterium LF-3 positivity correlated with the significant enrichment of CD4+ Th2 cells, suggesting a potential role in modulating immune responses.

Conclusion: Bacterium LF-3 in colorectal cancer reveals a dual role, instigating inflammation and tumorigenesis, yet simultaneously activating the innate immune system and promoting cellular immunity. This dual functionality contributes to improved patient prognosis, highlighting the intricate interplay between microbes, immune responses, and colorectal cancer outcomes.

#5155 CD8$^{\pm}$ T cells and CD4$^{\pm}$central memory T cells as biomarkers of perioperative anti-PD-1 therapy in combination with concurrent chemoradiotherapy for locally advanced G/GEJ adenocarcinoma.

Y. Wang[1], Y. Chen[1], J. Yang[1], X. Zhou[2], Y. Wei[2], Q. Liu[1], Y. Yang[1], W. Guan[3], B. Liu[1], J. Wei[1];

[1]Department of Oncology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China, [2]Department of Oncology, Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, China, [3]Department of General Surgery, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China

Background: Gastric or gastroesophageal junction (G/GEJ) adenocarcinoma is one of the most common lethal malignancies in the world. Near half of the G/GEJ adenocarcinoma are locally advanced at diagnosis and with poor prognosis. Several clinical trials including SHARED (ChiCTR1900024428), which conducted in our center, demonstrated that perioperative anti-PD-1 therapy in combination with concurrent chemoradiotherapy for locally advanced G/GEJ cancers, could raise the pCR rate over 30%. However, the biomarkers for patients with pCR are nor clear.

Methods: Baseline tumor biopsies and post-treatment surgical tissues were collected for next-generation sequencing (NGS) and mass cytometry (CyTOF). The overall survival (OS) was measured from the date of surgery to the date of death or the last follow-up visit.

Results: 34 patients with locally advanced G/GEJ cancer received anti-PD-1 therapy (Sintilimab) in combination with concurrent chemoradiotherapy in our center. Our results met the pre-specified primary endpoint, with a pCR rate of 38.2% (13/34) and median DFS of 17.0 months. Tumor mutation burden (TMB) analyzed by NGS was higher in the pCR group than those not achieving pCR (non-pCR). Deletion of cytoband 7q35, where TPK1 locates, was significantly enriched in pCR groups. The RNA sequencing data revealed an enrichment of dendritic cells (DC), CD8$^{\pm}$ T cells and cytotoxic cell signatures in the pCR group. Conversely, the signature for CD4$^{\pm}$ central memory T cells (TCM) was observed to be lower in the pCR group. On the other hand, CyTOF data also demonstrated that the proportion of CD8$^{\pm}$ T cells, CD8$^{\pm}$ effector memory T cells (TEM) were both higher in pCR group at baseline, while CD4$^{\pm}$ TCM was lower. Moreover, the proportion of specific subtype characterized by CD127$^{\pm}$CD27$^{\pm}$CD45RO$^{\pm}$CXCR5^{-}CD4$^{\pm}$ TCM was significantly lower in pCR patients and significantly reduced after treatment. As continuous variable, only CD8$^{\pm}$ T cells correlated with OS.

Conclusions: It seemed that CD8$^{\pm}$ T cells and CD4$^{\pm}$ TCM cells could be predictive biomarkers of perioperative anti-PD-1 therapy in combination with cCRT for locally advanced G/GEJ. Furthermore, we found a new CD4$^{\pm}$ TCM subtype defined with CD127$^{\pm}$CD27$^{\pm}$CD45RO$^{\pm}$CXCR5^{-} could be novel biomarkers.

#5156 Is the formation of Stroma AReactive Invasion Front Areas in colorectal cancer driven by characteristic extracellular matrix reorganization processes based on the plasmin/plasminogen system?.

B. Grosser[1], N. G. Reitsam[1], F. Sommer[2], J. Hardt[3], B. Markl[1];

[1]Pathology, Medical Faculty, Augsburg, Germany, [2]General and Visceral Surgery, Medical Faculty, Augsburg, Germany, [3]Laboratory Medicine and Microbiology, Medical Faculty, Augsburg, Germany

Background: As patient stratification still needs to be refined in colorectal cancer (CRC), we established SARIFA (Stroma AReactive Invasion Front Areas) as a novel H&E-based prognostic biomarker that is defined by a direct tumor-adipocyte interaction with a lack of desmoplastic reaction. Even though we could prove the high prognostic relevance of SARIFA now in multiple cohorts in gastric, colorectal, and pancreatic cancer, as well as could link an upregulation of lipid metabolism and immune alterations to this specific aggressive tumor biology, it remains an open question how SARIFAs are formed mechanistically.
Materials/Methods: Based on the results of our recently established SARIFA-scores in the TCGA-CRC (TCGA-COAD & TCGA-READ cohorts; SARIFA-positive n=69, SARIFA-negative n=138) and the corresponding differential gene expression analysis, which are part of a previous study, protein levels (in ng/mL) measured by commercially available uPA and PAI1 enzyme-linked immunosorbent assays (ELISAs) were compared between SARIFA-positive and SARIFA-negative CRC patients (SARIFA-positive n=35, SARIFA-negative n=62). Additionally, immunohistochemistry for FABP4 as a key player in lipid metabolism was performed. Moreover, spatial transcriptomics (digital spatial profiling, DSP) was performed with tumor and stroma section segmentation on a subset of cases.
Results: In TCGA-CRC, *SERPINE1* (PAI1), as well as *PLAU* (uPA), are both significantly upregulated on mRNA level (LFC: 1.14 and 0.74, respectively; both adjusted p-values ≤0.001). Logically, *SERPINE1* and *PLAU* are highly expressed in mesenchymal CMS4 CRCs, which overlap with SARIFA-positivity. This is reflected by an upregulation of matrix metalloproteinases in predicted functional protein networks (*STRING* analysis). In our local cohort, we could now validate this upregulation of uPA in SARIFA-positive CRCs on protein level (p=0.0027). For PAI1, a trend towards higher protein levels in SARIFA-positive CRCs could be observed (p=0.209). Moreover, SARIFA-positive CRCs show a higher number of tumor buds (p=0.013) as well as increased FABP4 expression at the invasion front (p<0.001) in our local cohort. In DSP analysis, the stroma fraction of SARIFA-positive CRCs showed significant changes compared to SARIFA-negative cases.
Conclusion: Our current data shows that the formation of SARIFAs and the consecutive direct tumor-adipocyte interaction with a tumor-promoting increase in lipid metabolism may rely on alterations in the plasmin/plasminogen system, which could be a novel potential drug target in the aggressive subset of SARIFA-positive CRCs.

#5157 Development and evaluation of a high-throughput method for rapid detection of surface antigen expression in fixed cells.

Kaja Holtorf[1], Anne-Lise Peille[2], **Daniel Feger**[1], Vincent Vuaroqueaux[2], Jan Erik Ehlert[1], Nadine Obier[1]

[1]Cellular Pharmacology, Reaction Biology Europe GmbH, Freiburg, Germany,[2]4HF Biotec GmbH, Freiburg, Germany

Cell surface proteins are increasingly considered in the development of novel anticancer agents, as demonstrated by recent clinical successes in the field of immuno-oncology and antibody-drug conjugates (ADCs). These conjugates specifically target antigens present on the surface of tumor cells, enabling the delivery of cytotoxic agents to specific tumor sites. During the preclinical development of such compounds, for example, when they are tested on a wide panel of cell lines, it is essential to have a rapid and reliable method for monitoring target expression and distribution.

Complementing our 160 Cell line panel ProLiFiler™, we report here the development of a novel method named oncoFLOW-Profiler™ which includes steps of cell fixation, micronic storage, staining, and measurement by flow cytometry. This method is applied in a 96-well format, enabling screening of all cell lines in parallel and analysis of the expression of different targets in just one day.

In this proof-of-concept study, we investigated the level of ERBB2 expression across the ProLiFiler panel of 160-cell lines in order to validate this methodology. We first compared the impact of fixation methods and sample storage on knowingly positive and negative control cell lines over a period of several months. ERBB2 measurements from the oncoFLOW-Profiler™ will be analyzed and validated by comparison with various OMICs datasets from the Cancer DataMiner platform (4HF Biotec), including RNA expression, mutational status, and protein expression levels. To determine the expression cutoff of ERBB2 amplified models, results will be analyzed according to gene copy number variation. Finally, the flow cytometry data generated will be investigated for use as a predictor of response to clinically approved ADCs targeting ERBB2: Kadcyla and Enhertu.

Here we present a method that we have demonstrated is feasible for investigating cell surface receptor/antigens during preclinical phase of drug development. Our method has enabled us to successfully assess ERBB2 in biological samples and to identify models sensitive to ADCs targeting ERBB2. We will also discuss the results of ongoing experiments analyzing the applicability of this screen to intracellular targets and carbohydrate-based surface antigens, which cannot be analyzed either by transcriptomics or proteomics.

CLINICAL RESEARCH: Predictive Biomarkers 4
Poster Session

#5160 Evaluation of circulating microRNAs as predictive and prognostic biomarkers for advanced melanoma patients.

G. Durante[1], F. Comito[2], M. Naddeo[2], S. De Matteis[2], M. Bonafe[3], E. Dika[3], A. Ardizzoni[3], **M. Ferracin**[3];
[1]University of Bologna, Bologna, Italy, [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, [3]University of Bologna, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Introduction Metastatic melanoma is the deadliest form of skin cancer whose incidence has been rising dramatically over the last few decades. The advent of Immune checkpoint inhibitors (ICIs) has strongly improved the survival of melanoma patients. However, a high fraction of patients shows primary resistance or will develop secondary resistance during therapy. For these reasons, it is of utmost importance to develop biomarkers that could predict response or resistance to therapies. Among the most promising biomarkers analyzed in peripheral blood there are circulating microRNAs (miRNAs). The aim of this study is to identify a miRNA signature able to predict prognosis and clinical relapse in advanced melanoma patients treated with ICIs.
Methodology We collected longitudinal blood draws from metastatic melanoma patients treated with ICIs at Bologna University-Hospital (Italy). We separated plasma from whole blood, extracted RNA and determined the absolute levels of miR-155-5p, miR-424-5p and miR-320a using EvaGreen-based droplet digital PCR. Moreover, in the subset of first-line anti-PD-1 treated patients, we performed cytofluorimetric leukocyte analysis.
Results and discussion We found that patients with pre-therapy (baseline) high expression of circulating miR-155-5p, miR-320a and mir-424-5p had longer progression-free survival (PFS), and overall-survival (OS). In patients treated with anti PD-1 as first-line treatment, we found that baseline miR-155-5p levels were significantly higher in patients who responded to therapy, and therefore miR-155-5p could have a predictive value. Moreover, using a flow cytometric approach, we noted that baseline miR-155-5p levels correlated with CD4+Naïve (r:-0.91, p:0.027) and CD4+PD1+ T-cells (r:0.94, p:0.015) in patients treated with first-line anti-PD-1 treatment.
Conclusion These preliminary findings propose baseline circulating miRNAs as potential predictive and prognostic biomarkers in the setting of advanced melanoma patients treated with immunotherapy.

#5161 Integrating patient's derived organoids and liquid biopsy: An exploratory study of early stage pancreatic cancer.

M. Cortesi[1], T. Rossi[1], M. Zanoni[1], S. Bandini[1], C. Pacilio[2], A. Cucchetti[3], M. Valgiusti[1], C. Gallio[1], A. Passardi[1], G. Gurioli[1], S. Bravaccini[1], A. Dubini[4], G. Frassineti[1], P. Ulivi[1], G. Martinelli[1], G. Ercolani[3], I. Rapposelli[1];

[1]Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST S.r.l., Meldola, Italy, [2]Morgagni-Pierantoni Hospital, AUSL Romagna, Forli, Italy, [3]Alma Mater Studiorum - University of Bologna; Morgagni-Pierantoni Hospital, Ausl Romagna, Bologna, Italy, [4]GB Morgagni L. Pierantoni Hospital, Forli, Italy

Background: Pancreatic cancer (PC) has a 5-year survival of 12% despite recent therapeutic advancements. There is a desperate need to discover novel ways of treating PC since a large proportion of patients do not benefit from therapy and experience significant toxicity. A major cause of therapy failure is therapy resistance due to tumor heterogeneity. Nowadays, a deeper understanding of tumor heterogeneity could be assisted by the use of patients-derived organoids (PDOs). Furthermore, the use of liquid biopsy may allow for the investigation of circulating factors with predictive value and for disease monitoring over time. Methods: Patients were enrolled in the comprehensive, multiomic study of pancreatic cancer CONTAINER. Patients with early stage PC treated with preoperative chemotherapy or undergoing surgery first were selected for the present study. When possible, a surgical specimen was collected to obtain PDOs. Tissue from resected tumors was dissociated by GentleMACS™ dissociator (Miltenyi Biotec), fragments were embedded in Matrigel™ and cultured in PancreaCult™ human Organoid Media (stemcell technologies). PDO histological features were investigated by H&E staining and IHC. Blood samples were collected before and one month after surgery. From blood samples circulating tumor cells (CTCs) were enriched and isolated, extracellular vesicles (EVs) were isolated from plasma with size-exclusion chromatography and their concentration and size distribution was evaluated with NanoSight NS300. Then, EV surface antigens were characterized by flow cytometry. A panel of inflammatory cytokines was finally evaluated through Ella Automated Immunoassay System. Results: In CONTAINER study 113 patients were enrolled and 30 of them underwent surgery. 21 surgical specimens were received from which 18 PDOs were successfully established. EVs with diameter ≥ 70nm were isolated from plasma, EV mean size was similar before and after surgery whereas individual variations in particle concentration and in surface antigen exposure were observed. Correlation with clinical and pathological characteristics of patients will be performed once reached an adequate sample size for statistical analyses. A panel of inflammatory cytokines (IL1β-, IFNγ, TNFα, IL6, IL8, TGFβ1, CRP and Leptin) was assessed in plasma samples obtained before and after surgery. Except for IL1β, a significant individual variation of circulating cytokines before and after surgery was observed. Conclusions: This study will contribute to unveil mechanisms of disease progression and drug resistance in PC. Possible predictive factors and mechanisms of drug resistance will be investigated taking advantage of the information derived from both in vitro models and circulating tumor-related entities.

#5162 Tumor transcriptional identity as a key predictor of clinical outcome in EGFR-Mutant non-small cell lung cancer.

S. Heeke, M. Nilsson, D. Gibbons, J. Zhang, I. I. Wistuba, K. Park, J. V. Heymach, X. Le;
UT MD Anderson Cancer Center, Houston, TX

Background: EGFR tyrosine-kinase inhibitors (TKIs) produce significant clinical benefit in patients (pts) harboring *EGFR*-activating mutations, however, patient outcomes remain heterogeneous, highlighting the need to identify novel biomarkers for treatment response prediction. We aim to investigate the association of tumor transcriptional identity with clinical outcomes in *EGFR*-mutant NSCLC.

Methods: We used consensus classification to derive unsupervised transcriptionally distinct clusters in *EGFR*-mutant NSCLC from the TCGA (N= 44). Then, we built a predictive model using extreme-gradient boosting to (1) classify an additional 88 surgically resected tumors from the LCCS study and analyzed for overall survival (OS) prediction; (2) classify metastatic *EGFR*-mutant NSCLC from the RELAY trial with available RNAseq data (N = 106) and analyzed for progression-free survival (PFS) with erlotinib treatment.

Results: Consensus clustering revealed two distinct clusters, one associated with more lineage-preserving features and one with more lineage-independent features that could transcriptionally distinguish *EGFR*-mutant lung cancer. No differences in primary *EGFR* mutations were detected across the two clusters. Ingenuity Pathway Analysis revealed TGFB1 as the most significantly enriched pathway in the lineage-independent cluster which was also significantly more mesenchymal (p = 0.0028). For surgically resectioned *EGFR*-mutant NSCLC, OS was consistently shorter in the lineage-independent cluster for TCGA (23.6 vs 58.3 mo; p = 0.049; HR = 0.4) and the LCCS cohort (55.7 vs not-reached; p = 0.0073; HR = 0.27). In the metastatic setting with erlotinib treatment, there was a trend for PFS to be shorter in the lineage-independent cluster (15.2 vs 19.4 mo; p = 0.12; HR = 0.61).

Conclusions: Transcriptional identity in *EGFR*-mutant lung cancer are prognostic of clinical outcome. The lineage-independent tumors have inferior benefit to EGFR TKI as well as inferior OS, indicating that transcriptional biomarkers can be independent of oncogene biomarkers. These transcriptional biomarkers may help identify pts with poor outcome for future intensification of therapies.

#5163 Determining the role of septin expression in response of breast cancer patients to microtubule targeted chemotherapy.

T. Aldawoodi, J. N. Essif, A. Naqvi, L. D. Boyle, D. Urueta Portillo, K. Lathrop, A. L. Risinger;
UT Health Science Center at San Antonio, San Antonio, TX

Drugs that disrupt the microtubule cytoskeleton, including both microtubule stabilizing taxanes and destabilizers like eribulin, are regularly used in the treatment of metastatic breast cancer. However, there are currently no molecular biomarkers to guide their use. Septins, a class of small GTPases, interact with both microtubules and actin to functionally link these cytoskeletal components and regulate cell biological processes shown to be critical for the invasion and migration of cancer cells. In particular, septin 9 (SEPT9) directly interacts directly with microtubules through an N-terminal domain on the longest isoform, SEPT9i1, which is sufficient to promote migration and invasion of breast cancer cells in vitro. We hypothesized that the relative expression of septin9 isoforms in breast tumors could play a role in their response to treatment with microtubule-targeted chemotherapy, particularly in the metastatic setting. A retrospective investigation of the relationship between septin expression and response to taxane chemotherapy was conducted utilizing full transcriptome sequencing data from biopsies of 75 breast cancer patients treated at our NCI-Designated Mays Cancer Center who received molecular profiling through Caris Life Sciences. Levels of total SEPT9 expression as well as the expression of specific variants that encode mechanistically distinct septin9 isoforms, SEPT9v1, v2, and v3, were determined for each sample and correlated with demographic, treatment, and outcome data for these patients. The oncogenic sept9_v1 variant (which produces the septin9_i1 isoform) was detected in over half of tumors and those with the highest total septin9 expression also expressed significantly higher levels of this isoform. Strikingly, the expression of total septin9, as well as the v3 variant, was significantly increased in taxane-treated patients who survived over a year after diagnosis with metastatic breast cancer, suggesting that septin9 expression could be a molecular correlate of response to taxane chemotherapy. We found that the expression of total septin9 and its variants was not significantly correlated with race, ethnicity, or cancer type suggesting that our findings would apply to our patient population as a whole, which is over 50% Hispanic. These data were used to support an ongoing prospective study to determine effect of septin expression on response to taxane chemotherapy in the neoadjuvant setting and determine the effect of taxane treatment on septin expression by comparing samples pre and post treatment. Together this work supports our overall goal of identifying predictive biomarkers to facilitate the use of microtubule targeted chemotherapy in a more personalized manner.

#5164 Deployment of ASPYRE-Lung targeted variant panel across three sites and testing with FFPE tissue and cytology-derived nucleic acid samples.

S. E. Herlihy[1], C. Gentile[1], S. J. Scott[2], B. A. Smith[2], K. A. Stoll[2], K. F. Schilter[2], J. Mordaka[3], R. Palmer[3], C. Xyrafaki[3], E. Gillon-Zhang[3], C. King[3], R. Evans[3], A. Green[3], A.-L. Silva[3], M. Stolarek-Januszkiewicz[3], K. von Bargen[3], I. Turner[3], C. Ho[3], A. Collazos[3], N. Potts[3], D. Nugent[3], J. Jose[3], E. Gray[3], E. Shapiro[3], **W. J. Levin**[3], A. Cooke[3], B. Balmforth[3], R. Osborne[3], H. V. Reddi[3], V. M. Van Deerlin[1];

[1]University of Pennsylvania, Philadelphia, PA, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Biofidelity, Morrisville, NC

While there is no shortage of approved targeted therapeutics to address driver mutations in NSCLC, many patients are not tested for these alterations due to gaps in biomarker testing access. Challenges in NSCLC molecular testing include the need for assessment of multiple variants in both DNA and RNA, samples are often small specimens, cost, and clinical need for rapid turn-around time when patients are deteriorating and require timely treatment initiation. ASPYRE-Lung detects a targeted panel of 114 actionable genomic variants across 11 genes, covering NCCN treatment guideline-recommended biomarkers for samples that are associated with NSCLC. The assay simultaneously analyzes DNA and RNA with inputs of only 20 ng and 6 ng respectively. ASPYRE-Lung is easily adoptable by standard clinical laboratories, requiring only PCR and qPCR thermocyclers, with no specialist bioinformatics skills required for analysis and a run time of 2 days from specimen to result. We established the assay at two external sites and Biofidelity laboratories, with multiple operators at each site. We first determined that the assay had acceptable performance at each site, using a panel of contrived control samples. We then examined 56 matched DNA and RNA samples extracted from clinical FFPE lung tissue specimens. We also tested 29 unmatched samples derived from FFPE tissue (13), fine needle aspirate (FNA, 4), FNA rinse (5), peritoneal fluid (1), pleural effusion (1), pleural fluid (1) and fresh tissue (4), at all 3 sites. Data were analyzed using a simple cloud-based turnkey analysis solution. All samples yielded valid results across all runs. We assessed reproducibility (inter-run precision) using all 85 clinical samples, across new and experienced users, achieving a positive percent agreement (PPA) of 100% and negative percent agreement (NPA) of 99.99%. We then assessed concordance with NGS results, investigating any discrepancies. The 69 FFPE tissue-derived samples (56 matched DNA/RNA, 7 unmatched DNA, and 6 TNA) had PPA 96.55% and NPA 99.98%. The 16 cytopathology-derived samples had PPA 100% and NPA 99.96%. Together, these results demonstrate high concordance of ASPYRE-Lung and NGS across different types of clinical samples, alongside ease of adoption of the ASPYRE-Lung assay with simple training and no specialist expertise required. ASPYRE-Lung promises to enable all patients with NSCLC to start appropriate treatment in a cost-effective and timely manner.

#5165 Development and validation of an assay for the characterization of SSTR2 expression on CTCs from liquid biopsies.

E. G. Bayer[1], R. N. Ponting[1], C. M. Kelly[2], A. Lutfi[3], M. K. Afghan[3], A. B. Ramirez[1], P. M. Kasi[3];

[1]RareCyte, Inc., Seattle, WA, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]Weill Cornell Medicine, Cornell University, New York, NY

Background: Expression of Somatostatin Receptor subtype 2 (SSTR2) is observed in multiple cancers, including breast and colorectal cancer. Its role as a prognostic or predictive marker is cancer-type dependent. Recently, there has been renewed interest in assessing this biomarker since it plays a critical role as a target for radiotherapeutics (peptide receptor radionuclide therapy - PRRT) in patients with neuroendocrine tumors (NETs). Blood-based liquid biopsies are a non-invasive tool with proven effectiveness in characterizing cancer biomarker expression in patients. In this study, we describe the development and validation of a novel assay to analyze circulating tumor cells (CTCs) for expression of SSTR2 using the RareCyte platform.

Experimental Procedures: Using AccuCyte®, an unbiased density-based method for collecting nucleated cells from whole blood, we transferred nucleated cells to slides and stained for SSTR2, CD45, and CK/EpCAM to identify CTCs (CK+/EpCAM+, CD45-), and evaluate SSTR2 expression. Slides were imaged with CyteFinder®, an automated multiparameter immunofluorescent (IF) microscopy system that applies machine learning algorithms for rare cell identification. Both clinical and spike-in samples were used for assay validation. Single-cell SSTR2 mean fluorescence intensities (MFI) were analyzed to determine protein expression levels. Colorectal cancer with neuroendocrine features and Merkel cell cancer (neuroendocrine tumor of the skin) patient samples were evaluated for CTC enumeration and SSTR2 expression.

Results: The assay's performance metrics for SSTR2 expression were 90+% accuracy, 85% sensitivity, 100% specificity with repeatability and intermediate precision CVs of 14.4% and 16.4%, respectively. A small cohort of colorectal cancer (1) and Merkel cell cancer (2) patient blood samples were tested using the assay. All 3 patients had high CTC levels (300+ per 7.5 mL). The percentage of SSTR2-positive CTCs ranged from 20-60%, reflective of tumor heterogeneity.

Conclusions: SSTR2 is an important target now in the advent of theranostics - PRRT. Prognostic and therapeutic implications of SSTR2 expression is an area of active clinical research. SSTR2 targeted therapeutics like 177Lu-dotatate illustrate the possible utility of SSTR2 as a predictive biomarker of treatment response. To date, most of the work has been focused on assessing SSTR2 on tissue. Herein, we show how a CTC platform can be adapted to assess a clinically relevant cell surface protein biomarker. This is now included as an important correlative in a clinical trial for Merkel Cell Cancer patients called iPRRT that is actively accruing (NCT05583708).

#5166 A multiplexed immunofluorescence assay to assess Rb and phospho-Rb as predictive biomarkers for CDK4/6 inhibitors in HR+/HER2- breast cancer.

M. Tabassum[1], S. Suresh Kanna[1], W. Cao[1], M. Rimawi[2], G. Miles[2], M. Trivedi[1];
[1]University of Houston, College of Pharmacy, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Introduction: Cyclin-dependent kinases 4/6 inhibitors (CDK4/6i) are used as the first-line treatment of advanced/metastatic or high-risk HR+/HER2- breast cancer (BC) that make up about 60-70% of all cases. However, nearly 50% of patients exhibit drug resistance. Therefore, biomarkers that predict CDK4/6i response are needed to spare patients from toxicities and high costs. Resistance to CDK4/6i [palbociclib, ribociclib, and abemaciclib] is associated with the aberrant or loss of Retinoblastoma (Rb). A decline in phospho-Rb (pRb) levels on therapy is also associated with CDK4/6i response. We aimed to develop a multiplex immunofluorescence (IF) assay to assess Rb and pRb levels that can be used on circulating tumor cells (CTCs) to predict tumor response to CDK4/6i. Here, we report the selection of internal controls for Rb and pRb, assay repeatability and reproducibility, as well as compatibility of the CTC isolation protocol with the assay.
Methods: Rb and pRb expression was evaluated by western blotting (WB) and IF in parental (P), estrogen deprivation-resistant (EDR), palbociclib-resistant (PalboR), and EDR/PalboR derivatives of two HR+/HER2- cell lines (MCF7 and T47D), Rb1 KO cells of MCF7 and T47D, as well as triple-negative cell lines, BT549 and MDA-MB-468. IF-stained cells were imaged using Leica STED SP8 confocal microscope and Zeiss Axioscan 7. The concordance between IF and WB results was assessed using a Bland-Altman plot. Selectivity and specificity of the assay as well as repeatability and reproducibility between investigators were also assessed. Blood from healthy subjects was used to test the compatibility of the ScreenCell® filtration system to isolate CTC with the IF assay.
Results: Our initial approach utilized indirect IF staining for Rb and pRb using the same primary antibodies as WB. On the Bland-Altman plot, most data points were relatively close to the bias line, suggesting that the difference between the two methods was acceptable. The analytical range for mean Rb and pRb staining intensity was 0.744 - 46.779 and 1.001 - 52.919, respectively. Based on WB and IF data, we nominated T47D PalboR and MDA-MB-468 cells as negative controls for Rb and pRb expression. The selectivity and specificity were 100% and 70%, respectively, for the Rb expression and 99% and 61% for pRb, respectively. The IF assay was repeatable and reproducible between two investigators. The ScreenCell® CTC isolation method was not compatible with the assay, as Rb and pRb expression was either not detected or limited when processed using FC2 or PBTFC buffer, irrespective of the antigen retrieval.
Conclusion: We have selected internal cell line controls for Rb and pRb and are in the process of optimizing signal-to-noise ratio and specificity using conjugated antibodies. We are also testing the compatibility of other CTC isolation methods with the IF assay.

#5167 Barriers to tumor mutational burden (TMB) testing in oncology care - U.S. Physician Survey.

G. Jones[1], E. Szamreta[1], B. Jackson[2], N. Ning[2], J. Stephens[2], A. Hussain[3];
[1]Merck & Co., Inc, Rahway, NJ, [2]OPEN Health, Bethesda, MD, [3]University of Maryland, Baltimore, MD

Background: Genomic technologies have become increasingly available in oncology; however, barriers remain in terms of TMB use. This study aimed to identify barriers to physicians' adoption/use of TMB testing.
Methods: A cross-sectional online survey was conducted with a representative sample of U.S. general medical, surgical, and/or gynecologic oncologists, including both users and non-users of TMB testing. Physician demographics, practice characteristics, barriers (reimbursement, knowledge, logistics), and approaches to alleviate barriers were collected. Quotas were put in place to ensure a distribution of diverse physician characteristics such as academic affiliations, geography, TMB use, etc. Descriptive analysis was conducted via SASv9.4.
Results: Three hundred physicians participated (47.6 mean years of age and 15.2 mean years in clinical practice on average; 50% medical oncologists, 31% surgical oncologists, and 19% gynecologic oncologists). Ninety percent of respondents reported using TMB testing. The most common barrier to TMB testing use was test turnaround time (All: 74.3%; TMB users: 72.3%; non-TMB users: 93.1%). Other commonly reported barriers included unawareness of corresponding therapy and/or clinical trials that may benefit a patient with mutation (All: 68.3%; users: 66.1%; non-users: 89.7%), obtaining prior authorizations (All: 65.7%; users: 62.7%; non-users: 93.1%), and difficulty obtaining a biopsy for testing (All: 57.3%; users: 57.6%, non-users: 55.2%). Increased coverage of TMB testing, access to educational content, and the establishment of minimally acceptable technical standards were reported as key approaches to increasing adoption/use of TMB testing.
Conclusions: These results suggest that challenges around reimbursement, knowledge, and logistics are key barriers to use of TMB testing for physicians and provide insights for solutions to alleviate the barriers to TMB testing in oncology.

Table 1. Barriers to TMB Test Adoption Reported by Physicians, %

		All N=300	TMB user N=271	Non TMB user N=29	p-value
Reimbursement	Obtain prior authorizations	65.7	62.7	93.1	0.003
	TMB not covered by insurance	53.7	53.5	55.2	>0.99
	Coverage policy refers to TMB as “experimental”/”unproven”	52.7	51.7	62.1	0.26
	Insurance policy restricts genomic tests to particular lab/test provider	51.3	50.6	58.6	0.79
Knowledge/awareness	Unaware of therapy/clinical trials that may benefit a patient with mutation	68.3	66.1	89.7	0.03
	Unaware of approved indications for TMB	51.3	51.3	51.7	>0.99
	Lack of training on TMB	48.7	47.2	62.1	0.28
Logistics	Test turnaround time	74.3	72.3	93.1	0.02
	Difficulty obtaining biopsy	57.3	57.6	55.2	0.87
	Inaccessibility to personnel/lab	49.0	48.3	55.2	0.84

#5168 Analysis of biomarker and outcomes data: 7-year update from COLUMBUS.

Background: In the randomized, 2-part, phase 3 COLUMBUS study (NCT01909453), encorafenib (enco) + binimetinib (bini)—an approved regimen in the US, EU, and other countries—improved 7-year PFS and OS vs vemurafenib (vemu) in patients (pts) with BRAF V600E/K-mutant locally advanced unresectable or metastatic melanoma. We investigated genetic and transcriptional correlates of outcomes in an exploratory biomarker analysis of COLUMBUS Parts 1 and 2.
Methods: In Part 1, 577 pts were randomized 1:1:1 to enco 450 mg QD + bini 45 mg BID, enco 300 mg QD, or vemu 960 mg BID; in Part 2, 344 pts were randomized 3:1 to enco 300 mg QD + bini 45 mg BID or enco 300 mg QD. Baseline tumor samples were analyzed using the ACE ImmunoID NeXT whole exome sequencing/whole transcriptome sequencing (WES/WTS) assays (Personalis). PFS and OS were analyzed (cutoff: Jan 13, 2023) by treatment arm and presence of specific genetic or transcriptomic alterations.
Results: Among treated pts, 668 had WES or WTS data. K-means clustering identified 3 major transcriptional clusters: (1) microphthalmia-associated transcription factor (*MITF*)-low (invasive dedifferentiated tumor cell phenotype), (2) *MITF*-high (proliferative melanocytic phenotype), and (3) immune-high. Cluster assignments were significantly associated with biopsy site ($P<0.001$), with cluster 1 enriched in skin biopsies and cluster 3 in lymph node metastases; biopsy site-independent characteristics were also captured. Improved PFS with enco + bini vs vemu was most pronounced in cluster 3 (Table 1). *ERBB2* expression and *PI3KCA* pathway mutation, previously found to be associated with reduced survival benefit with enco + bini vs vemu, were enriched in clusters 1 and 2 vs cluster 3.
Conclusions: Enco + bini showed benefit across molecular subtypes in BRAF V600E/K-mutant melanoma. The contribution of bini was most pronounced in the immune-high cluster. Improved outcomes in this cluster support ongoing trials of combinations with immune checkpoint inhibitors, such as STARBOARD and PORTSIDE.

Table 1. Hazard ratios of PFS and OS for enco + bini or enco vs vemu by cluster

	HR (95% CI) vs vemu			
	PFS		**OS**	
	Enco + bini	**Enco**	**Enco + bini**	**Enco**
Overall	n=255 vs 100	n=159 vs 100	n=255 vs 100	n=159 vs 100
	0.47 (0.35, 0.63)	0.78 (0.57, 1.07)	**0.66 (0.50, 0.86)**	0.85 (0.63, 1.13)
Clusters				
Cluster 1: *MITF*-low	n=72 vs 34	n=44 vs 34	n=72 vs 34	n=44 vs 34
	0.74 (0.44, 1.26)	0.92 (0.51, 1.66)	**0.63 (0.40, 1.00)**	**0.57 (0.34, 0.96)**
Cluster 2: *MITF*-high	n=120 vs 46	n=76 vs 46	n=120 vs 46	n=76 vs 46

Numbers are given as the number of pts included in the treatment arm vs the number of pts in the comparator arm (vemu-treated). Statistical significance ($P<0.05$) is shown by bold font. Bini, binimetinib; enco, encorafenib; MITF, microphthalmia-associated transcription factor; pts, patients; vemu, vemurafenib.

#5169 Circulating levels of ANGPTL3, PCSK9, apoCIII and lipoprotein (a) in high-grade serous ovarian cancer.

E. Wong Chong[1], F.-H. Joncas[1], P. Douville[1], D. Bachvarov[1], F. Calon[1], N. G. Seidah[2], C. Diorio[1], A. Gangloff[1];
[1]CHU de Quebec - Universite Laval, Quebec, QC, Canada, [2]Institut de Recherches Cliniques de Montreal, Montreal, QC, Canada

Background: Ovarian cancers require abundant amounts of lipids for their growth. Recent years have highlighted the role of ANGPTL3, PCSK9, ApoCIII and Lp(a) as key players in lipid metabolism. But circulating levels of these factors in ovarian cancers have not been thoroughly investigated to date.
Objective: We assessed the profiles of plasma ANGPTL3, PCSK9, ApoCIII and Lp(a) in ovarian high-grade serous carcinoma (HGSC).
Methods: Plasma samples collected from women diagnosed with an HGSC (n=31) or a benign ovarian lesion (BOL, n=40) were analyzed for plasma lipid profile (ApoB, total cholesterol, HDL, triglycerides, Lp(a) levels) on a clinical modular platform (Roche). ApoCIII, ANGPTL3 and PCSK9 levels were measured with commercially-available ELISA kits. Differences between HGSC and BOL were assessed by two-group comparisons. Pairwise correlation strength between variables was evaluated with Spearman's rank order tests. Logistic regression modelling was used to further examine the associations between selected variables and HGSC diagnoses.
Results: ANGPTL3 levels increased in HGSC (84.1 ng/ml, SD=29.2ng/ml, n=31) compared to BOL (66.9ng/ml, SD=30.7 ng/ml, n=40; HGSC *vs* BOL p=0.02). Receiver operating characteristic (ROC) curve suggested that plasma ANGPTL3 levels were moderately associated with HGSC (AUC=67.7%, p=0.005 1) and did not increase predictive performance of ovarian tumor biomarkers CA125 and HE4 in multivariable model. Associations between ANGPTL3 levels and cholesterol (HDL, non-HDL, LDL and total) could be observed in the control group but not in the HGSC group. The same dissociation was observed for the inverse correlation between HDL and triglycerides in HGSC. Furthermore, moderate associations were observed between PCSK9 & CA19-9 in the entire cohort (rho=0.34, n=53, p=0.013) and Lp(a) & CA125 in HGSC cases (rho=0.51, p= 0.017).
Conclusion: In this cohort of 71 women, we report increased levels of ANGPTL3 in HGSC with an effect size (Cohen's D) of 0.57. Confirmation of this result in larger cohort studies (minimal n>50 in each group) would warrant further investigation into the roles of circulating ANGPTL3. Its inhibition may allow to tackle deregulated lipid metabolic pathways contributing to ovarian cancer progression.

#5170 Novel dSTRIDE-HR assays can accurately assess DNA repair defects in human cancers and distinguish HR status of tumors.

M. Jarosz[1], Z. Prucsi[1], F. Sierpowski[1], K. Stepien[1], S. Ostrowska-Paton[1], S. Koman[1], N. Riaz[2], S. Powell[2], F. Pareja[2], E. da Silva[2], M. Kordon-Kiszala[1], K. Solarczyk[1];

[1]intoDNA, Krakow, Poland, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Accurate patient stratification is crucial for the successful application of targeted anti-cancer therapeutic approaches. It has been shown that PARP inhibitors are synthetic lethal with defective homologous recombination (HR) repair, with genes such as BRCA1 and BRCA2 identified as conferring therapy resistance or sensitivity, depending on their mutational status. Moreover, there is evidence of patient benefit of carboplatin-based therapy in HR deficient (HRD) tumors. With a growing emphasis on HRD in cancer treatment, efforts have been made to define the HRD phenotype. Nonetheless, the current approaches employed in the clinic, such as Next Generation Sequencing (NGS), HRD score or RAD51 assays have significant limitations and their interpretation can be unclear.

To answer the need for a functional HR-specific biomarker, we have recently developed and introduced two new assays, called collectively dSTRIDE-HR. The assays are based on the STRIDE platform technology that enables direct and sensitive detection of single- or double-strand DNA breaks *in situ* in fixed cells. Novel dSTRIDE-HR explicitly detect double-strand DNA breaks localized in close proximity to RPA (dSTRIDE-RPA) or RAD51 (dSTRIDE-RAD51) proteins. The assays have been shown to be reliable reporters of HR activation in cellular models after exogenous DNA damage induction, yet their potential to predict HR status in an *in vivo* setting has not been tested so far.

To assess the suitability of the dSTRIDE-HR assays for determining the HR status of patients' tumor cells, we applied these assays in FFPE sections from biopsies derived from breast cancer patients with a different mutational status of BRCA1 and BRCA2 genes. The assays showed low dSTRIDE-RPA and dSTRIDE-RAD51 readouts in BRCA1/2 mutated tumors in comparison to wild type tumors, as well as a great concordance of readouts within a given genetic background. Additionally, the cell cycle analysis proved nearly twofold increase in foci numbers of dSTRIDE-RPA and dSTRIDE-RAD51 in G2/S phase.

Our study unveils a potential of dSTRIDE-HR assays to become predictive biomarkers reporting on the status of HR repair in breast tumors, although more patient samples need to be tested to confirm initial findings.

#5171 CD39, CD73 and CD38 as potential biomarkers for monitoring the response to mogamulizumab in Sézary syndrome.

Yuliya Yakymiv[1], **Sara Marchisio**[1], Erika Ortolan[1], Verdiana Pullano[1], Chiara Leso[1], Rebecca Senetta[2], Lorenzo Marega[1], Gabriele Roccuzzo[1], Pietro Quaglino[1], Ada Funaro[1]

[1]Medical Sciences, University of Torino, Torino, Italy,[2]Oncology, University of Torino, Torino, Italy

We demonstrated aberrant expression of CD39 or CD73 and low expression of CD38 in circulating and skin-homing CD4+ T cells in patients with Sézary syndrome (SS), an erythrodermic cutaneous T-cell lymphoma (CTCL) with a leukemic component. The anti-CCR4 monoclonal antibody Mogamulizumab (Moga) has been shown to increase progression-free survival in patients with advanced SS. Here, we longitudinally explored the modulation of the expression of CD39, CD73 and CD38 in circulating CD4+ T cells from SS patients under treatment with Moga. Eight patients with relapsed/refractory SS were included in the study and prospectively followed up for two years (median duration of treatment 9,5 months, range 5-28 months). Seven out of eight (87,5%) patients showed early complete response in the blood and partial (5/7, 71,4%) or near complete response (2/7, 28,6%) in the skin. One patient (12,5%) showed no blood or skin response to the treatment. Flow cytometry analysis highlighted that the clinical response was accompanied by a rapid and remarkable increase in CD38 expression in the residual circulating CD4+ T cells, as well as in CD8+ T cells. Moreover, in six patients carrying the homozygous G/G or heterozygous A/G *ENTPD1* SNP rs10748643 genotypes, permissive to CD39 overexpression in T cells, the increased CD38 expression was paralleled by rapid reduction/loss of CD39. Notably, in one patient carrying the A/A genotype, characterized by low CD39 and high CD73 expression at the baseline, response to treatment was characterized by reduction of CD73 expression. The only one patient with A/A genotype who didn't respond to Moga showed no modulation of CD38 or CD39 expression, while CD73 expression increased. Noteworthy, Moga increases the expression of CD38 in responding patients, and influences the expression of CD39 only in patients with the permissive CD39 genotypes (G/G; A/G), but not in those with the A/A genotype. Two patients showing initial response to Moga experienced skin progression during treatment, which was associated with a significant increase of CD39 and simultaneous decrease of CD38 in residual circulating CD4+ T cells, although there was no evidence of blood relapse. These preliminary results suggest that partial or complete responses to Moga is paralleled by reduced CD39 and/or CD73 expression and increased CD38 expression. Instead, an opposite modulation of these markers is associated with disease progression hinting at the potential clinical utility of CD38, CD39 and CD73 as markers to monitor patients' response to Moga therapy.

#5172 miRNA lncRNA network associated with response to cemiplimab in cutaneous squamous cell carcinoma.

L. Porcelli, S. De Summa, R. Fasano, M. Guida, T. M. Marvulli, T. Rafaschieri, G. De Palma, S. Serrati, R. Di Fonte, I. De Risi, S. Strippoli, S. Tommasi, A. Azzariti;
IRCCS Istituto Tumori Giovanni Paolo II, BARI, Italy

Introduction: For advanced cSCC the use of immunological therapies relies on the biology of the tumor, characterized by high mutational burden. However, although the anti-PD1 cemiplimab showed to be a promising treatment option, future research focusing on the use of biomarkers to predict treatment response are needed. Since increasing number of studies has revealed the crucial roles of non-coding RNAs, such as miRNAs and lncRNAs in the development of SCC, the present study had the purpose to explore the lncRNA-miRNA-mRNA networks associated with response to anti-PD1. For this purpose the experimental procedure envisaged a preliminary in silico analysis followed by the investigation of identified miRNA and lncDNA in liquid biopsy.
Methods: For the in silico study, GSE139505 RNA-sequencing raw data have been retrieved from SRA, including 7 Healthy Samples and 9 cSCC biopsies. Two matrices have been prepared, including coding genes and lncRNAs. Normalized coding gene matrix have been used as input to perform GSEA. Coexpression analysis between lncRNAs and Core enrichment genes resulting from GSEA was performed. Biological network including validated miRNA-gene interactions (TarBase) and lncRNA-miRNA interactions (lncBase) has been built-up through Cytoscape. MCODE analysis to identify subnetwork with the closest relationships was performed. The quantification of identified miRNAs (miR-125a, miR-125b, miR-148a, miR-148b) and lnc (AF131217.1, RP11-362F19.1, PVT1, LINC00665) was performed in pre-therapy plasma samples of 34 cSCC patients, categorized according to clinical response to cemiplimab, in responders and non-responders. miRNA-specific RT primers were used for reverse transcription by ddPCR.
Results: The computational analysis revealed a significant enrichment of two gene sets related to immunotherapy, namely the Reactome_PD1_signaling and WP_Cancer_Immunotherapy_by_PD1_blockade. The coespression analyses highlighted more than 600 correlations gene-miRNA-lncRNA for the two above-mentioned genesets. CD4-miR-125a/b and AF131217.1/RP11-362F19.1 are strongly correlated for the first one; whilst, regarding the latter one, CD274/HLA-A with mir-148a/b and PVT1/ LINC00665 and JUN with mir-125a/b and AF131217.1/RP11-362F19.1 were found. The validation in cSCC plasma samples evidenced the significant correlation between mir-148a/b and PVT1/LINC00665 and an higher expression of all miRNAs in responders respect to non-responders. The longitudinal study assessing the correlation between miRNA expression and response to cemiplimab is ongoing.
Conclusion: Preliminary analysis in pre-therapy plasma samples of cSCC validated the in silico data highlighting the inverse correlation between miR-148a/b and lnc (PVT1 and LINC00665). Further investigation will confirm the role of miR125a/b and miR148a/b as predictors of cemiplimab response.

#5173 TRAIL expression in tumor cells predicts and drives poor response to neoadjuvant immunochemotherapy in esophageal squamous cell carcinoma.

W. Yang[1], F. Wang[1], J. Guo[1], J. Cai[2], Z. Wang[1], Y. Liu[1], Z. Fang[1], W. Chen[1], L. Xu[1], S. Zhang[1], B. Zeng[1], Z. Liu[1], S. Peng[1], S.-C. J. Yeung[3], **C. Cheng**[1]; [1]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, [2]Sun Yat-sen University, Guangzhou, China, [3]The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Neoadjuvant PD-1 blockade combined with chemotherapy has shown promising antitumor efficacy in the therapy of esophageal squamous cell carcinoma (ESCC). However, effective biomarkers and potential mechanisms of resistance to this treatment are still unclear.

Methods: We prospectively collected pre- and post-neoadjuvant treatment ESCC tissues from 40 patients who received PD-1blockade (camrelizumab, 200mg) and chemotherapy (albumin-paclitaxel, 260mg/m^2 and carboplatin, area under the curve = 5). Based on their pathological responses to neoadjuvant immunochemotherapy (NICT), patients were classified into “responder” and “non-responder” groups. All samples were subjected to bulk RNA-sequencing and whole-exome sequencing. Of note, samples from 14 patients in both groups were subjected to single cell RNA sequencing and TCR sequencing. We characterized and validated the changes in the immunological landscape of “responder” and “non-responder” groups using multi-omics sequencing data, multiplex immunofluorescence, *in vitro* and *in vivo* experiments. External validation cohorts of ESCC treated with NICT were analyzed to validate the predictive biomarkers for NICT.

Results: We found that TNF-related apoptosis-inducing ligand (TRAIL) signaling was significantly higher in pre-treatment non-responders than in responders, and was inversely correlated with T cell proliferation and TCR expansion. TRAIL was mainly secreted by tumor cells and bound to its specific receptor DR5 in T cells, thereby inhibiting the activation of T cells. Functional co-culture experiments and T cell cytotoxicity assays revealed that TRAIL$^+$ tumor cells mediated T cell suppression and caused CD8$^+$ T cell dysfunction. Furthermore, TRAIL inhibition could improve the efficacy of anti-PD-1 in a xenografted mouse model. In bulk RNA-seq (n=40), TRAIL expression was associated with worse disease-free survival and overall survival, however, these results were not observed in the ESCC cohort treated with upfront surgery from the TCGA database, suggesting that the predictive value of TRAIL is specific to NICT. In an external validation cohort of ESCC patients treated with NICT (n=81), multivariable Cox regression analysis showed that high TRAIL expression was an independent risk factor for unfavorable outcomes. Importantly, TRAIL expression exhibited a higher accuracy in predicting NICT response compared with PD-L1 expression in ESCC (AUC of ROC curves: 0.886 vs 0.607, respectively P<0.001). Meanwhile, the serum concentrations of TRAIL (measured by ELISA) in pre-NICT ESCC patients were also significantly higher in non-responders (n=58).

Conclusions: TRAIL expression in tumor cells is negatively correlated with the response of ESCC to NICT. TRAIL expression may serve as a promising biomarker to predict NICT response and guide NICT selection in ESCC patients.

#5174 Organoids to predict treatment response in metastatic colorectal cancer (OPTIC).

L. P. Smabers[1], E. Wensink[1], C. S. Verissimo[2], M. Doorn[2], T. Yang[2], T. Voskuilen[2], Y. Abouleila[2], M. A. Huismans[1], L. Valkenburg-van Iersel[3], G. A. Cirkel[4], E. C. Gootjes[5], F. J. Jeurissen[6], G. M. Bol[1], H. H. Nienhuis[1], M. M. N. Braat[1], B. Penning de Vries[1], S. G. Elias[1], E. Cuppen[7], R. G. Vries[2], O. Kranenburg[1], M. Koopman[1], S. F. Boj[2], J. M. L. Roodhart[1];

[1]UMC Utrecht, Utrecht, Netherlands, [2]HUB Organoids B.V., Utrecht, Netherlands, [3]Maastricht University Medical Center, Maastricht, Netherlands, [4]Meander Medical Center, Amersfoort, Netherlands, [5]Radboud University Medical Center, Nijmegen, Netherlands, [6]Haaglanden Medical Center, The Hague, Netherlands, [7]Hartwig Medical Foudation, Amsterdam, Netherlands

Introduction: The inability to predict treatment response results in unnecessary toxicity, decreased efficacy and survival. There is a clinical need for an effective biomarker to select patients for cancer treatment. A promising biomarker for treatment efficacy is response testing on patient-derived organoids (PDOs). For metastatic colorectal cancer (mCRC), larger prospective studies are needed to evaluate the predictive value of standardized PDO screens.

Methods: OPTIC is an ongoing prospective multicenter trial (NL61668.041.17, started 2018) that will evaluate the value of tumor PDOs in therapy response prediction. We establish PDOs for mCRC patients from newly obtained biopsies, prior to the start of treatment. We compare PDO sensitivity (area under drug response curve) with patient response measured by changes in biopsied metastatic lesion size on CT scans. Secondary outcome measures are RECIST response and progression-free survival. We evaluate the feasibility of using PDOs as a biomarker by examining drug screen availability in a clinically relevant timeframe of 4 weeks. From 2020 onwards, we incorporated whole genome sequencing (WGS) on fresh-frozen biopsies to correlate drug response in vitro and in vivo, to genetic tumor characteristics. Additionally, PDO screens with experimental drugs based on genetic alterations identified by WGS could be performed. Trial inclusion will continue until 85 PDOs from clinically evaluable patients for standard of care (SOC) treatment are established, with expected completion in Q1 2024.

Results: Currently, 206 patients were included in 5 hospitals and 180 biopsies were taken. PDO establishment success gradually increased from 22% in 2018-2020 to 75% in 2023, yielding an overall success rate of 50% (n=84 PDOs and 13 in culture). Critical factors in optimizing culture success were replacement of several growth factors in the culture medium, reducing time to processing and more frequent handling of biopsies. We have established PDOs for comparing with patient response for the following treatment categories: 5-fluorouracil (n=4), CAPOX/FOLFOX (n=23), irinotecan/FOLFIRI (n=11), FOLFOXIRI (n=12), trifluridine/tipiracil (n=14), panitumumab (n=14), encorafenib-cetuximab (n=2), non-SOC drugs (n=4). We have successfully screened the first 8 PDOs in consistent technical triplicates and biological duplicates ($R<0.88$, $p<0.02$). WGS succeeded in 76% (n=75), primarily failing when tumor percentage was <20%.

Conclusion: We improved PDO establishment success to 75% which is essential to facilitate the implementation of PDOs in clinical treatment. OPTIC will enhance the clinical application of PDOs by defining thresholds for PDO sensitivity and analyzing the diagnostic power for different treatments. To enable personalized treatment in clinical practice, PDO screening should guide mCRC treatment and result in enhanced chance of response and reduced over- and mistreatment.

#5176 TIGIT expression increases with advancing clinical stages and does not differ across racial groups in resected pancreatic cancer.

M. George, J. Clark, K. Gartrelle, G. Nassif, K. Hartway, D. Long, D. Salas-Escabillas, A. Wombwell, T. Pichardo, H.-J. Wen, S. Benitz, S. Zwernik, R. Shah, H. Park, P. Philip, G. Khan, H. Crawford, D. Kwon, B. Theisen, N. Steele;
Henry Ford Health, Detroit, MI

Pancreatic ductal adenocarcinoma (PDAC) has a dismal 12% 5-year survival rate (SEER) due to a lack of early detection biomarkers and resistance to standard therapeutic options (surgery, chemotherapy, radiation). Black African Americans (BAA) have 20% increased incidence of PDAC compared to those with European Ancestry (EA). TIGIT, an immune checkpoint receptor, is a marker of T cell exhaustion and plays a key role in the inhibition of anti-tumor immune responses. Recent studies have demonstrated that immune checkpoint receptor expression (PD-1 and TIGIT) on specific T cell populations correlates to worse overall survival (OS). TIGIT inhibitors are being explored in clinical trials in pancreatic cancer due to implications of its ligand (CD155) promoting immune evasion. We hypothesize that targeted anti-TIGIT therapy, in conjunction with other therapies targeting the tumor microenvironment, could reverse the immune suppression that is characteristic of PDAC. We performed RNAscope in situ hybridization (ISH) with a probe specific for human TIGIT mRNA (combined with a nuclear counterstain) on 79 tissue samples. The cohort of tissue samples included 8 biopsies (endoscopic-guided fine needle biopsies at time of diagnosis), 66 primary (from surgical resection), and 5 metastatic (liver core biopsies from patients with a primary PDAC diagnosis) formalin-fixed paraffin-embedded (FFPE) tissue sections from patients with histologically confirmed PDAC. After cells were segmented based on nuclear recognition, the presence of TIGIT probe within the cytoplasm of each cell was determined and quantified. Percent positive cell values were then exported for statistical analysis in R. De-identified clinical metadata was obtained from REDCap, a cloud-based HIPAA-compliant database used to compile patient data for research purposes. We tested for associations between %TIGIT present and clinical covariates, using linear regression for continuous outcomes, and logistic regression for binary outcomes. ScRNAseq revealed that TIGIT mRNA is enriched in, but not exclusive to the T/NK cellular compartments in PDAC. Staining analysis showed that TIGIT expression did not differ significantly between racial groups (comparing BAA to non-BAA). The mean percentage of TIGIT positive cells was 64.0%. High expression of TIGIT was associated with clinical stage, where an increase in stage was associated with increasing %TIGIT ($p < 0.05$).The TIGIT biomarker assay can be conducted at time of diagnosis, time of surgical resection, and time of metastatic biopsy. If patients' samples contain high levels of TIGIT expression, these patients may be candidates for anti-TIGIT drug therapy. Considering that TIGIT expression correlates with advancing clinical stage, patients with more advanced staging at diagnosis (stage IIB, III, IV) especially may benefit from anti-TIGIT therapy.

#5177 *Ex vivo* assessment of cellular mass response predicts clinical efficacy in solid tumors.

R. Kimmerling[1], M. Stevens[1], S. Olcum[1], M. Vacha[1], R. LaBella[1], K. Katsis[1], R. Aikens[1], C. Hannah[2], A. Guo[1], J. Fujii[3], Z. Shaheen[3], S. Sundaresan[3], A. Rainey[2], A. M. Blakely[2], J. Hernandez[2], A. Tamrazi[4], C. Reid[1];

[1]TRAVERA, Medford, MA, [2]NIH/NCI, Bethesda, MD, [3]Sequoia Hospital, Redwood City, CA, [4]Palo Alto Medical Foundation, Redwood City, CA

Introduction: Identifying personalized, efficacious therapies for cancer remains an urgent unmet need in oncology. While genomics-based biomarkers have demonstrated significant progress, they are not universally applicable, with most patients still treated using clinical guidelines.

Experimental procedures: We have previously demonstrated broad clinical applicability of a functional precision medicine (FPM) workflow that incorporates high-resolution measurements of single-cell mass changes in response to drugs. As a highly integrative biomarker of cellular state, mass change serves as a rapid and mechanism agnostic readout of drug response, demonstrating an ability to detect signal from over 100 different cytotoxic and targeted therapies within 24 hours of treatment *ex vivo*. As a single-cell assay that requires as few as 10,000 cells to assess drug response, this method does not require any *ex vivo* culture for cell expansion and is compatible with a range of clinically relevant tissue specimen formats. Together, these features have enabled this mass response framework to be implemented in a CLIA-certified laboratory with a reporting turnaround time of just two days.

Summary of the new, unpublished data: Having previously shown that mass response testing is compatible with various solid tumor specimen formats such as malignant fluids, core biopsies and fine needle aspirates, here we present preliminary results that demonstrate compatibility with surgically resected tissue specimens. Specifically, we demonstrate that mass response testing results correlate with clinical response across of broad array of solid tumors. In our cohort of 24 patients, we found that mass response measurements correlated with clinical response to therapy with an accuracy of 83% (OR=19.66, P=0.003). Within this group, we also found clear examples of how mass response testing can serve as a valuable complement to existing genomic approaches to guide therapy. Importantly, we demonstrate both concordant and discrepant results using small molecule inhibitors in the setting of known biomarkers of response, highlighting the need for functional testing in precision cancer medicine.

Conclusions: These results support that mass response testing is feasible and broadly applicable to solid tumor malignancies and may serve as a valuable complementary readout for informing therapeutic selection for cancer patients.

#5178 Guided by a predictive *ex vivo* test: Bringing the PLK1 inhibitor volasertib back into the clinic for venetoclax-HMA relapsed/refractory acute myeloid leukemia patients.

M. D. Lacher[1], G. Michelson[1], A. Ling[1], W. Anderson[1], J. Vinas[1], C. J. Gu[1], C. Leonardi[1], J. Wagner[1], G. N. Mannis[2];
[1]Notable Labs, Foster City, CA, [2]Stanford University, Stanford, CA

INTRODUCTION: Volasertib, a polo-like kinase 1 (PLK1) inhibitor, has a roughly 30% CR/CRi response rate in de novo acute myeloid leukemia (AML) patients when combined with low-dose cytarabine. However, its development was halted due in part to toxicity in a Phase 3 study. We have built a flow cytometry-based, high-throughput predictive precision medicine platform to forecast clinical responses to various treatments. Here, we present our design plan for a Phase 2a clinical trial with volasertib in relapsed/refractory (R/R) AML using a modified protocol to reduce toxicity and the development of a companion diagnostic to predict responders in a follow-up Phase 2b study.

METHODS: We will initiate an open-label clinical trial in AML with volasertib in venetoclax-hypomethylating agent (HMA) R/R patients while co-developing a companion diagnostic to selectively enroll predicted responders in a follow-up, Phase 2b, study. Primary and secondary objectives will focus on efficacy/safety of intravenous volasertib and *ex vivo* responses, respectively. To reduce the toxicity seen in the Phase 3 study, specific strategies like tailored dosing will be implemented. To develop the clinical trial assay, peripheral blood or bone marrow samples were collected from AML patients and treated *ex vivo* with volasertib for 3 days. Surviving blast cells were enumerated by flow cytometry. Using a dynamic separation model restricted to the 35% most sensitive samples, we estimated optimal blast cutoffs for volasertib sensitivity.

RESULTS: In single-agent experiments with 41 primary AML samples (31 de novo, 9 R/R, 1 with disease status unclear), we observed dose-response profiles consistent with volasertib's role as a cell cycle inhibitor. Irrespective of the disease status, median and mean EC_{50} values were about 10 nM (1st-3rd quartile from 7-12 nM). To identify an optimal concentration of volasertib for patient stratification, we compared the *ex vivo* resistant blast fractions at each concentration with the areas under the dose-response curves (AUCs), assuming that in our case, AUCs most accurately reflect clinical responses. At 31.6 and 100 nM, the Pearson correlation coefficients were highest ($r > 0.8$), suggesting that these are optimal stratifying doses. With these concentrations and corresponding blast cutoff values, 32-33% of the de novo and 25% of the R/R patients would have been predicted to be responders were they given volasertib, assuming a positive predictive value of 100%.

CONCLUSION: Volasertib's EC_{50} values clustered within a narrow range, suggesting that EC_{50} may not be a suitable metric to stratify patients into responders and nonresponders, in contrast to AUCs and residual blast fractions at 31.6 and 100 nM of volasertib, which displayed more heterogeneous distributions. Limitations include small sample sizes, especially for the R/R group.

#5179 Tumor microenvironment (TME) biomarkers of TIGIT and PD-L1 immune checkpoint blockade in cervical cancer: An exploratory biomarker analysis from SKYSCRAPER-04 (SKY04) study.

V. Krishnan[1], C.-W. Chang[1], E. Bader[1], R. Salani[2], B. J. Monk[3], Y.-M. Kim[4], S. Ghamande[5], S. L. Hall[6], D. Lorusso[7], L. Barraclough[8], L. Gilbert[9], A. Guzman Ramirez[10], C.-H. Lu[11], D. Berton[12], N. Colombo[13], M. Castro[1], Y. G. Lin[1], M. McCormack[14], L. Molinero[1],

[1]Genentech, Inc., South San Francisco, CA, [2]David Geffen School of Medicine, UCLA, Los Angeles, CA, [3]HonorHealth University of Arizona College of Medicine and Creighton University School of Medicine, Phoenix, AZ, [4]Gynecologic Cancer Center, Asan Cancer Institute, Asan Medical Center, University of Ulsan, Seoul, Korea, Republic of, [5]Georgia Cancer Center, Augusta University, Augusta, GA, [6]National Cervical Cancer Coalition, Research Triangle Park, Durham, NC, [7]Fondazione Policlinico Gemelli and Catholic University of the Sacred Heart, Rome, Italy, [8]The Christie NHS Foundation Trust, Manchester, United Kingdom, [9]Department of Gynecologic Oncology, McGill University Health Centre, Montreal, QC, Canada, [10]Instituto de Investigacion en Ciencias Medicas (ICIMED), San Jose, Costa Rica, [11]Taichung Veterans General Hospital, Taichung, Taiwan, [12]Institut de Cancerologie de l'Ouest, Saint Herblain, France, [13]Department of Medicine and Surgery, University of Milan-Bicocca and Gynecologic Oncology Program, European Institute of Oncology IRCCS, Milan, Italy, [14]Department of Oncology, University College London Hospitals, London, United Kingdom

Introduction: Immune checkpoint inhibitors are active in advanced cervical cancer. SKYSCRAPER-04 (NCT04300647) explored the clinical activity of Tiragolumab (T, anti-TIGIT) plus atezolizumab (A, anti-PD-L1) dual blockade (T+A) in patients (pts) with PD-L1+ cervical cancer. This study aimed to evaluate the histological, transcriptomic and genomic TME biomarkers associated with both immune checkpoint blockade (ICB: combined A and A+T arms) and predictive of T clinical outcome.

Methods: FFPE tumor biopsies were collected from patients with recurrent/persistent PD-L1+ cervical cancer (n=171). Samples were tested for PD-L1 (high [TAP ≥10%] vs low [TAP 5-9%]), stromal tumor infiltrating lymphocytes (sTIL by H&E, n=168), immune phenotypes (inflamed, excluded, desert) and total CD8 T cells by CD8/PanCK dual IHC (n=163), TIGIT IHC (n=166), tumor DNA NGS panel (FoundationOne CDx, n=95), and RNA sequencing (RNA Access, n=168) for biological pathways. Biomarker association with outcome was performed with chi-squared test for ORR and Cox-regression analysis for PFS and OS. Analyses are not adjusted for multiple testing.

Results: Biomarkers associated with PD-L1 and TIGIT biology were evaluated for association to clinical outcome in ICB or T analysis. Pts with PD-L1 high tumors had higher ORR and longer PFS and OS, while IFNg/IFNa pathways (RNA) were associated with higher ORR and TIGIT IHC was only associated with longer ICB OS. In contrast, RNA signatures of highly proliferative tumors were negatively associated with ICB ORR. sTILs (IHC) and PVR (RNA) were numerically linked to higher ORR, PFS and OS in T+A vs A arms. The subgroup of patients analyzed for genomic profile (55% of randomized population) showed that TMB high (≥10 mut/Mb; 26% of pts) had higher ORR for ICB and numerically longer PFS and OS than TMB low (<10 mut/Mb). Mutations (mut) of activated *PTEN/PIK3CA/AKT* pathway was the most prevalent feature (52%) and pts with *PIK3CA*-mut had higher ICB ORR, PFS and OS.

Conclusions: This exploratory analysis suggests that increased tumor immunity and mutation burden (TMB and *PIK3CA*-mut) correlates with improved ICB clinical outcomes. No biomarkers were clearly associated with tiragolumab outcome. These results are hypothesis generating and should be confirmed in an independent dataset.

#5180 Pharmacodynamic biomarker analysis of gastrointestinal cancer patients treated with metronomic chemotherapy in the Italian COMET Trial.

M. L. Manca[1], D. Prospero[2], S. Darvishi[2], A. Bandini[1], M. Banchi[1], P. Orlandi[1], H. Padilla[2], A. Sanchez[2], C. E. I. Perucho[2], N. de Avila[2], H. Padilla[2], B. E. Ortega[2], R. D. Stewart[2], M. Santillan[2], V. Lopez[2], R. Kirken[2], G. Allegrini[1], G. Bocci[1], **G. Francia**[2];

[1]The University of Pisa, Pisa, Italy, [2]The University of Texas at El Paso, El Paso, TX

Metronomic, or continuous low-dose, chemotherapy produces antitumor effects through multiple mechanisms. These include inhibition of angiogenesis and activation of the immune system. At AACR 2017 we presented a small, proof-of-concept, multiplex analysis of 14 cytokines specifically chosen by their association with activation of the immune system. The 14 cytokines were evaluated in 31 out of 38 patients with advanced refractory gastrointestinal tumors, enrolled in a phase II clinical trial of metronomic UFT (a 5-fluorouracil prodrug; 100 mg/twice per day p.o.) and cyclophosphamide (500 mg/mq2 i.v. bolus on day 1 and then 50 mg/day p.o.) plus celecoxib (200 mg/twice a day p.o.); the Italian COMET trial (Clinical Trial ID NCT02926911; Allegrini et al. Angiogenesis 2012: 15(2):275-86). We evaluated baseline (day 0) plasma levels with levels at days 28 and 56, and tested for correlations with observed Progression Free Survival, which we then reported (Valenzuela et al. Clin Exp Med. 2021: 21(1):149-159). We now present a comprehensive analysis of 75 cytokines in 34 of the 38 patients. Furthermore we extend the analysis to include baseline (day 0), days 28 and 56, and days 84 and 112 of the COMET trial, and we also correlated specific cytokines levels with Overall Survival. After an estimation of optimal cut-off points of plasma levels of the cytokines, survival analysis was performed, and log-rank tests and cox regression analyses were applied. We show that pre-treatment plasma level <435.46pg/ml of macrophage-derived chemokine (MDC), was a predictive marker for those patients with better progression-free survival at 3 and 6 months (log-rank test p=0.0046; Cox regression analysis p=0.016). Moreover, baseline plasma levels of three cytokines, including monocyte chemoattractant protein 2 (MCP-2), monocyte chemoattractant protein 4 (MCP-4) and TNF-related apoptosis-inducing ligand (TRAIL), were associated with an improved overall survival. MCP-2 values >26.21pg/ml (log-rank test p=0.0012; Cox regression analysis p=0.007), MCP-4 >72.97pg/ml (log-rank test p=0.012; Cox regression analysis p=0.019) and TRAIL >60.73pg/ml (log-rank test p=0.0059; Cox regression analysis p=0.011) were predictive markers for subjects with a better overall survival at 6 and 9 months. These results indicate that a methodology based on the detection of optimal cut-off points and survival analysis allowed the selection of potential biomarkers, such as MDC or MCPs. We propose that the systematic use of these statistical strategies, aimed at detecting potential biomarkers, could help to identify those patients that are likely to benefit from metronomic chemotherapy schedules. This would allow the stratification of such patients for future metronomic chemotherapy trials, and the potential identification of patients that should instead be offered alternative therapeutic strategies.

#5181 Early activity and biomarker evaluation of NT219 in combination with cetuximab in a Phase 1/2 study of recurrent/metastatic squamous cell carcinoma of the head and neck (R/M SCCHN).

A. J. Rosenberg[1], S. Kato[2], D. Johnson[3], A. Popovtzer[4], V. Chiu[5], R. Geva[6], H. Ben-David[7], T. Meirson[7], M. Schickler[7], **H. Reuveni**[7];
[1]The University of Chicago, Chicago, IL, [2]UCSD Moores Cancer Center, San Diego, CA, [3]Ochsner Health, New Orleans, LA, [4]Hadassa Medical Center, Jerusalem, Israel, [5]Cedars-Sinai, LA, CA, [6]Sourasky Medical Center, Tel Aviv, Israel, [7]Purple Biotech, Rehovot, Israel

Background. NT219 is a novel small molecule, dual inhibitor, that uniquely triggers the degradation of Insulin Receptor Substrates 1/2 (IRS) and the dephosphorylation and suppression of STAT3. These two major oncogenic targets in the tumor and tumor microenvironment (TME) play a key role in drug resistance, particularly to EGFR inhibitors. Previously, we demonstrated synergistic effect of NT219 and cetuximab in multiple SCCHN patient-derived xenograft (PDX) models. HPV-negative R/M SCCHN patients have poor survival and demonstrate IGF1R/IRS and STAT3 upregulation. We report biomarker results from dose escalation of NT219 in combination with cetuximab in patients (pts) with immunotherapy-refractory R/M SCCHN (NCT04474470).
Method. Biopsies from 11 enrolled SCCHN patients treated with different dose levels of NT219 (6, 12, 24 and 50 mg/kg) were obtained and evaluated using Immunohistochemistry and pathological analysis. Evaluation of potential biomarkers included measurements of IRS1/2 levels, as well as IGF1R and STAT3 phosphorylation (pIGF1R, pSTAT3) in tissue biopsies, and H-score was defined for tumor cells, infiltrating immune cells, and fibroblasts in the TME. Membrane completeness (mc) parameter was included in pIGF1R scoring.
Results. NT219 Cmax and AUC demonstrated a dose dependent increase, with 50mg/kg dose mean human AUC reaching Human Equivalent Dose efficacy of animal models. Indeed, at this dose, anti-tumor activity in humans was also demonstrated with 2 confirmed partial responses (PR) reported. At the 50 mg/kg NT219 dose, out of 4 SCCHN pts, for whom pre-treatment biopsies were available, 3 were HPV negative and 2 of them achieved PR. Pretreatment biopsies of these 2 pts demonstrated high activated IGF1R membranal staining (Avg. mcH-score: 285, p-value:) and high activated STAT3 nuclear staining (Avg. H-score: 285), in contrast to the non-responding SCCHN pts (30 and 33, with p-value 0.017, 0.004 respectively). Inhibition of intratumoral IGF1R/IRS and STAT3 was demonstrated in on-treatment biopsies. Analysis will be presented at the conference.
Conclusion. NT219 in combination with cetuximab demonstrated safety and early activity with 2 confirmed PRs at 50mg/kg dose level in R/M SCCHN pts. This dose level was the first dose at which the observed NT219 exposure was within the range of the efficacious dose levels in pre-clinical models. Detection of activated IGF1R and STAT3 in responding pts, compared to the non-responding pts, suggests a potential use of these targets as biomarkers for future patient selection. This notion is further substantiated by the demonstration of NT219 on-target effects in on-treatment tumor biopsies. Upregulation of NT219 targets, IGF1R and STAT3, in HPV-negative SCCHN pts and their response to the NT219+cetuximab treatment, support further evaluation of this patient population.

#5182 Exploiting tumor RNA-sequencing data for prediction of immune checkpoint inhibition response.

P. Mestdagh, P.-J. Van Dam, F. De Baene, C. Fierro, E. Van Hoof, E. Riviere, H. Dangreau, R. Van Cauwenberge, J. Vandesompele;
CellCarta, Antwerp, Belgium

Immune checkpoint inhibitors (ICI) have become the standard of care as a first- or second-line systemic treatment for patients with various cancer types. Unfortunately, many patients do not respond to this treatment and the occurrence of immune-related adverse events varies widely. There is an urgent need for robust predictive biomarkers for ICI response to identify patients with likely clinical benefit from this costly treatment. Several biomarkers, aimed at predicting response to ICI, have been proposed, including PD-L1 expression, tumor mutation burden (TMB), infiltration of cytotoxic T-cells in the tumor, Microsatellite Instability (MSI) and expression of various immune gene signatures. However, these individual biomarkers have suboptimal performance and multiple complementary omics technologies are required to properly quantify them. Integration of these multi-omic biomarkers has proven valuable in increasing the accuracy and robustness of ICI response prediction.We have developed a computational pipeline that determines the expressed mutation burden (eTMB), MSI status, fraction of infiltrating immune cells and various immune gene expression signatures directly from the RNA-sequencing profile of the tumor. Each biomarker is quantified using a dedicated algorithm that applies machine learning (eTMB and MSI) or computational deconvolution (infiltrating immune cells) and integrates external data sources to maximize performance. Algorithm performance has been validated on large cohorts of tumor RNA-sequencing data with matching gold standard quantification of said biomarkers.

As a proof of concept, we applied our pipeline to tumor RNA-sequencing data of 45 gastric cancer patients treated with pembrolizumab. Responders showed significantly higher eTMB scores and were enriched among the MSI-H patients. Fractions of CD8 T-cells and M1 Macrophages, together with interferon gamma and cytotoxic T-cell gene expression signatures, were significantly increased in responders. Notably, integrating these biomarkers into a single prediction model improved prediction of response to checkpoint inhibition therapy compared to predictions based on eTMB or MSI alone.

Taken together, our approach enables the quantification of various ICI response biomarkers from a single omics layer (RNA-sequencing) and can contribute to ICI response prediction.

#5183 Retrospective analysis of CCNG1 expression in tumors, a novel biomarker in development for partnering with DRG-101, a tumor targeted retrovector encoding a CCNG1 inhibitor gene.

N. Omelchenko[1], V. Kumar[1], S. Jeffrey[1], G. Haroun[1], D. Brigham[2], W. H. Isacoff[1], S. Chawla[1];
[1]Sarcoma Oncology Research Center, Santa Monica, CA, [2]Aveni Foundation, Santa Monica, CA

Background: CCNG1, a non-canonical cyclin, is a novel biomarker in development for partnering with DRG-101 (DeltaRex-G), a tumor targeted retrovector encoding a CCNG1 inhibitor gene. Expanded access using DRG-101 is currently open for an intermediate-size population of advanced pancreatic cancer, sarcoma and carcinoma of breast (NCT04091295). Therefore, it is important to identify patients who might respond favorably to DRG-101 gene therapy. Previously, we reported that CCNG1 expression is enhanced in sarcoma tumors (Ann Oncol 34, 1980P, 2023). In this report, we have expanded the analysis to 137 patients with all cancer types and describe patients with known CCNG1 expression levels who have been treated with DRG-101.
Methods: Archived formalin-fixed paraffin-embedded (FFPE) tumor specimens (n=137) from patients who were followed at the Sarcoma Oncology Research Center were collected, processed, and subjected to RNA sequencing. Briefly, RNA-seq libraries were sequenced to generate 50 million reads, aligned using Kallisto v0.42.4 to GENCODE v23 transcripts with default parameters. Only protein-coding, IGH/K/L- and TCR-related transcripts were retained for downstream processing, resulting in 20,062 protein-coding genes. Gene expression levels in patients of the reference cohorts are categorized as low/medium/high, defined by Low = < 17%; Medium-high = 50%-83%; Medium-low = 17%-49%; High = >83%.
Results: Seventy women and sixty-seven men, ranging in age from 16 to 87 years, were studied. All tumors showed enhanced CCNG1 expression. Thirty (22%) tumors exhibited high CCNG1 expression, 53 (39%) showed medium-high CCNG1 expression, 48 (35%) displayed medium-low CCNG1 expression, and six (4%) had low CCNG1 expression. One hundred (73%) patients had metastatic disease, and 37 (27%) had localized disease. There was no correlation between CCNG1 expression and disease stage. As a result of these findings, the FDA-CBER authorized the use of DRG-101 in an Expanded Access program as platform therapy upon which one or more FDA approved cancer drugs/immunotherapies may be added. Historically, one patient with metastatic pancreatic cancer, one with early stage, HR+ HER2+ invasive breast cancer and one with early stage triple negative breast cancer are alive 15, 3 and 2.5 years in sustained remission with DRG-101 therapy, and had 24%, 23% and 74% CCNG1 tumor expression levels respectively. Five patients with advanced pancreatic cancer, sarcoma and breast cancer and known CCNG1 expression levels are currently being treated with DRG-101.
Conclusions:(1) 100% of tumors tested showed enhanced CCNG1 expression at varying levels, and (2) the use of DRG-101 in combination with FDA approved cancer drugs/immunotherapies is on-going for an intermediate size population of advanced pancreatic cancer, sarcoma and carcinoma of breast.

#5184 Biomarker results from PEVENAZA, a randomized phase 2 study of venetoclax and azacitidine +/- pevonedistat in newly diagnosed AML patients unfit for intensive chemotherapy: Increased efficacy in a subset of patients with IDH1/2 mutations and other observations.

R. Ramesh[1], X. Fang[1], S. Li[1], S. Friedlander[1], F. Sedarati[1], L. Ades[2], N. Short[3], C. Papayannidis[4], T. Yeh[1];
[1]Takeda Development Center Americas, Inc (TDCA), Lexington, MA, [2]Hopital Saint Louis & Paris Cite University, Paris, France, [3]The University of Texas MD Anderson Cancer Center, Houston, TX, [4]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Background: Many newly diagnosed patients with AML are ineligible for intensive chemotherapy due to pre-existing comorbidities and older age. VIALE-A, a phase-3 trial with venetoclax (ven) and azacitidine (aza) established this combination as a new standard of care (SOC) for this patient population. The addition of pevonedistat (pevo) to this combination was evaluated in the same patient population in the current trial (NCT04266795). Here we present results of biomarker analyses from baseline and on-treatment bone marrow samples.

Methods: Molecular mutational analysis was performed using a next generation sequencing (NGS) panel on baseline bone marrow samples. Combining this data with cytogenetics allowed centralized assignment of risk category based on ELN2017 guidelines. Longitudinal bone marrow aspirate samples were also examined by multi-color flow cytometry for expression of select surface antigen expression and to identify AML leukemic stem cells (LSCs) from the blast population.

Results: Eleven genes were selected for analyses based on prevalence and scientific interest, including DNMT3A, ASXL1, TET2, FLT3, and IDH1/2. In contrast to other genes and ELN risk categories, we observed a statistically significant increase (p-value 0.013) in CR+CRi rates for IDH1/2 mutant patients when treated with pevo + ven + aza (95%, n=21) compared to ven+aza control arm (62%, n=21). In addition, we evaluated the prevalence of CD33, CD123 and CLEC12a, targets of current AML developmental therapeutics, in both the blast and LSC populations at baseline. The median (n=120 pts) % blast cells expressing CD33, CD123, or CLEC12a were 89.8%, 63.2%, and 66.0%, respectively. The median (n=78 pts) % LSCs expressing CD33, CD123, or CLEC12a were 48.2%, 90.9%, and 32.0%, respectively. Importantly, we did not see any significant difference in median fluorescence intensity (MFI) or % expression in any of the three proteins after treatment with ven and aza (+/- pevo). Finally, no strong associations were observed between expression levels and either mutations or ELN risk categories.

Conclusions: Analyses of biomarker samples as part of the PEVENAZA trial resulted in several insights for not only the pevonedistat program but also for other AML therapeutics in development. The observation that newly diagnosed patients with IDH1/2 mutations may benefit from the addition of pevo to ven+aza is certainly hypothesis-generating but would require further follow-up with higher patient numbers. In addition, baseline CD33, CD123, and CLEC12a expression levels were in line with published studies. Here we have also shown they remain similar after SOC treatment (ven+aza) supporting the development of agents that target these proteins in both first and second line settings for AML.

#5185 A multimodal, spatially defined, nanomechanical signature as predictive biomarker for breast cancer outcome: A 20 year survival study.

S. Nizzero[1], M. Pelaez Soni[2], G. Zaugg[3], Y. Xu[4], L. Zhang[4], J. Zheng[4], L. B. Jordan[5], C. A. Purdie[5], P. R. Quinlan[6], C. Nagi[7], K. A. Sepulveda[7], P. Oertle[3], T. A. Appenzeller[3], M. Loparic[3], S.-H. Chen[4], V. Cristini[4], M. Plodinec[3], A. M. Thompson[7];

[1]ARTIDIS Inc, Houston, TX, [2]Houston Methodist Resarch Institute, Houston, TX, [3]ARTIDIS AG, Basel, Switzerland, [4]Houston Methodist Research Institute, Houston, TX, [5]University of Dundee, Dundee, United Kingdom, [6]University of Nottingham, Nottingham, United Kingdom, [7]Baylor College of Medicine, Houston, TX

Background: With the recent advancement in perioperative treatment protocols, the search for clinical biomarkers that can predict overall response and long-term cancer outcome independent from treatment acquires even more importance. Recently, it has become clear that mechanical properties of the tumor microenvironment in solid tumors play a key role in driving outcome, mediating immune infiltration and activation, and response to therapy. Moreover, a growing body of evidence supports the understanding that mechanical changes induced by a plethora of therapeutic regimens should be leveraged to elicit favorable outcome.

Methods: In this work we propose a dual approach to reveal mechanical biomarkers predictive of long-term outcome in solid cancers. Our first approach is based on a newly developed, 60 channel, biomechanical imaging mass cytometry panel to elucidate biomechanical cues that drive tumor aggressiveness and immune infiltration. Our second approach utilizes the AFM-based Automated and Reliable Tissue Diagnostics (ARTIDIS) investigational device to measure mechanical properties of fresh clinical biopsy samples at a nanoscale resolution. Our analysis was performed on over 300 clinical samples, from routine baseline clinical biopsies collected from both the Breast Clinic, University Hospital Basel, and the University of Dundee, in the UK. Patients in these two cohorts were treated with either adjuvant or neoadjuvant approaches, including radiation, chemotherapy, hormonal, and surgical treatment regimens, with individual patient follow up as long as 20 years.

Results: We demonstrated with two complimentary technologies that biomechanical spatial patterns drive outcome in breast cancer. Our results include a multi-platform elucidation of the biomechanical phenotypes of epithelial to mesenchymal transitions driven by hypoxic environments. Furthermore, we identified several biomechanical subpopulations of cancer associated fibroblasts, and their role in mediating cancer outcome, in relationship with survival time and several clinical variables (e.g. metastasis, nodes, grade). We mechanistically corroborated these results by evaluating the immune modulatory effect of the identified biomechanical microenvironments in breast cancer. Lastly, we correlated the identified biomechanical microenvironments with the ARTIDIS nanomechanical signature as a clinically integrated, rapid, single biomechanics signature at the nanoscale.

Conclusion: Our results further validate the importance of biomechanics in driving tumor response and immune infiltration across a variety of clinical treatment setting. These result support the integration of ARTIDIS nanomechanical signature in clinical settings as a single predictive biomarker able to rapidly and accurately capture biomechanical alterations that drive cancer outcome.

#5186 Spatial single-cell deconvolution of the bone marrow microenvironment to define predictive biomarker for response to immunotherapy in patients treated with a check point inhibitor in smoldering multiple myeloma, phase II trial of nivolumab in combination with lenalidomide and low dose dexamethasone.

Y. Konishi[1], G. Tarantino[1], Y. He[1], R. Sklavenitis-Pistofidis[1], S. Shah[2], K. Towle[3], C. Cea-Curry[3], O. Zavidij[3], R. Carrasco[4], S. Rodig[2], J. Aster[2], D. Liu[1], G. Getz[5], I. Ghobrial[1];

[1]Dana-Farber Cancer Institute/Harvard Medical School/Broad Institute of Massachusetts Institute of Technology (MIT) and Harvard, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Dana-Farber Cancer Institute, Boston, MA, [4]Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA, [5]Massachusetts General Hospital/Harvard Medical School/Broad Institute of Massachusetts Institute of Technology (MIT) and Harvard, Boston, MA

Background:The immune system is critical for response and resistance in all cancer types and therapies. Patients with Smoldering Multiple Myeloma (SMM) have altered immune cell composition in the bone marrow (BM). However, little is known about the role of BM spatial immune profiling in patients treated with checkpoint inhibitors in MM.

Methods: We performed spatial profiling with imaging mass cytometry of trephine biopsies of the BM (n=15; pre-treatment n=7 and post-treatment n=8) from patients with high-risk SMM enrolled in a phase II trial of nivolumab in combination with lenalidomide and low dose dexamethasone (NCT02903381). Patients received 6 cycles of induction therapy of nivolumab (240mg) at days 1 and 15, in combination with lenalidomide (25mg) at days 1-21 and dexamethasone at days 1, 8, and 15. The induction phase was followed by nivolumab (240mg) and lenalidomide (25mg) maintenance for another 6 cycles. A treatment cycle was defined as 28 consecutive days for a total of 12 months period. Event monitoring was performed up to 3 years. The primary efficacy outcome was progression-free survival 2 years after treatment.

Results: Eight patients were enrolled on this study from January 2017 to June 2017. The study was put on hold due to the toxicity of checkpoint inhibitors observed in other trials of MM. The median age for all patients at enrolment was 60 years (range 49 to 81), with 5 males (62%) and 3 females (38%). All patients met criteria for high risk SMM disease. Median follow-up for all 8 patients was 38.7 months. Median overall survival was not reached; median progression-free survival was 33.8 months. Seven total patients had a response of Minimal Response (MR) or better, and 4 patients who initially responded eventually progressed. The total number of patients who were followed for at least two years and remained progression-free was 4 of 8 evaluable patients (50%; 90% CI: 19 - 81%).Spatial profiling with a panel of 37 markers on the pre-treatment samples allowed us to assess the states and abundances of multiple immune subpopulations, including rare regulatory NK cells. To assess the accuracy of our cell type annotation, we correlated the proportion of malignant plasma cells identified per patient with the value determined by pathologists for clinical diagnosis. These measures were significantly positively correlated ($R=0.92$, $p<0.01$). Spatial neighborhood analysis revealed statistically significant interactions enriched in the responders, even with our small sample size (t-test; $p < 0.05$).

Conclusions and future directions: This pilot study suggests that BM spatial immune profiling before receiving immune check point inhibitors can be a biomarker for response in patients with SMM.

#5187 VistaPlex immunofluorescence assay panels provide reliable deep spatial phenotyping for diverse immuno-oncology applications.

A. Christians[1], C. E. Jackson[2], J. Boog[1], M. H. Ingalls[2], A. Northcutt[2], K. E. Cashion[2], J. Rauer[1], K. Kwarta[2], J. S. Schwarz[2], O. Braubach[2];
[1]Canopy Biosciences-A Bruker Company, Hannover, Germany, [2]Canopy Biosciences-A Bruker Company, Saint Louis, MO

Multiplex immunofluorescence (mIF) is a powerful tool that enables deep phenotyping of immune and cancer cells across a wide variety of tissue types. The initial effort and cost required to develop high-plex mIF panels is significant and poses a considerable hurdle for adoption of spatial biology. To streamline high-plex assay development, we developed a process for creating and validating multiplex antibody panels for use in immuno-oncology applications that leverage CellScape™, an automated end-to-end platform for Precise Spatial Multiplexing. Our multiplex assay development was a rigorous, multi-stage, iterative process to evaluate antibodies for suitability, specificity, and reproducibility. These assay panels are formulated as ready-to-use VistaPlex™ assay kits and are intended to enable rapid, reliable spatial phenotyping of key immune populations.

To confirm the utility of VistaPlex, we deployed the Human FFPE Spatial Immune Profiling Panel to stain and image various FFPE tissue samples on the CellScape platform. With CellScape, tissues are mounted in enclosed fluidic chambers while on-instrument staining, imaging and signal erasure are conducted in iterative rounds. The panel presented here contains antibodies against 16 common biomarkers used in immune-oncology applications. Among these are CD3, CD4, CD8, CD20, and CD45 to detect cell lineages, PD-1 and PD-L1, to interrogate immune checkpoints, and markers that inform about cell state and activation. Spatial immune profiling data were obtained from human tonsil, colon, breast, and lung tissue samples. Deep immune phenotyping was performed using unsupervised clustering analysis and AI-assisted cluster labelling, and biomarker distributions were studied in the context of cellular neighborhoods and other proximity analyses. Overall, we identified more than 19 cell phenotypes with varying frequencies and spatial arrangements across tissue samples.

Our data are robust and demonstrate that VistaPlex Assay kits for spatial profiling present an efficient and cost-effective solution for users that want to break into spatial biology.

#5188 Defining PD-1/PD-L1 receptor-ligand interactions in the head and neck cancer tumor microenvironment identifies unique 'immune cell rivers' of cellular interactions.

H. Sadeghirad[1], V. Yaghoubi Naei[1], J. Monkman[1], S. Basu[2], A. Wicher[2], R. Ladwa[1], B. G. Hughes[3], **A. Kulasinghe**[1];
[1]University of Queensland, Brisbane, Australia, [2]Navinci Diagnostics, Uppsala, Sweden, [3]Royal Brisbane and Women's Hospital, Brisbane, Australia

Head and neck squamous cell carcinoma (HNSCC) is the 7th most common cancer globally with a poor 5-year survival rate of ~50%. With the emerging successes with immune checkpoint blockade (ICB) in the metastatic and recurrent setting, there is a need for predictive biomarkers to identify patients likely to achieve clinical benefit. Whilst PD-L1 expression on tumour cells and PD-1 on immune cells have been investigated, these remain inconclusive biomarkers. To better understand and map the PD-L1/PD-1 receptor-ligand interactions, we evaluated a novel in situ proximity ligation assay (is PLA) across whole tissue sections of pre-treatment HNSCC patients to received ICB therapy. Pre-treatment FFPE whole tissue samples were collected from n=25 advanced stage HNSCC patients across two major Queensland Hospitals (Royal Brisbane and Women's Hospital and the Princess Alexandra Hospital). Tissues were stained with multiplex immunofluorescence and the Navinci Diagnostics fluorescent is PLA assay for PD-1/PD-L1. Tissues were incubated with the PD1/PD-L1 antibodies and subsequent incubation with oligonucleotide-tagged secondary probes enabled PLA, which highlights PD1 and PD-L1 interactions. Following the application of secondary probes, the sections underwent a ligation step, then a post-blocking, and an amplification process to enhance the detection of protein interactions. Next, the sections were treated with a detection solution to visualize the amplification product. The PLA assay findings were measured against clinical endpoints (PFS/OS criteria). In n=5/25 HNSCC tissues, positive PD-1/PD-L1 interactions were measured across the tumour microenvironment (TME), specifically in the immune rivers on the immediate tumour periphery. These cells showed highly specific binding of the PLA product. These areas positive by the PLA assay were in stark contrast to the tumour bulk/nests which were absent in PD-1/PD-L1 interactions. Notably, the PLA PD-1/PD-L1 do not correlate with tumour PD-L1 expression or tumour proportion scores (TPS). Rather, our study highlighted the difference in spatially mapping PD-1/PD-L1 interactions which may better recapitulate the tumour-immune recognition and activity in the TME. Taken together, these data provide a novel approach for determining clinically relevant receptor/ligand interactions in the HNSCC TME.

#5189 The potential of minimal residual disease (MRD) in guiding adjuvant therapy (AT) decisions in non-small cell lung cancer (NSCLC).

S. Lei[1], H. Xu[2], Y. Yang[1], L. Tian[1], T. Ma[3], Y. Wang[1];

[1]Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical, Beijing, China, [2]Department of Comprehensive Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [3]Genecast Biotechnology Co, Ltd, Wuxi, China

Background: Circulating tumor DNA (ctDNA)-based minimal residual disease (MRD) detection has become a strong prognostic stratification factor in post-operation non-small cell lung cancer (NSCLC). Here we sought to investigate the guiding potential of MRD in informing adjuvant therapy (AT) decisions.
Methods: Patients with stage IA-IIIB NSCLC who had undergone confirmed R0 resection were enrolled. Blood samples were collected prospectively one month after surgery before initiation of AT (landmark) and longitudinally every 3-6 months since surgery. Postoperative AT was conducted according to the guideline recommendations and regular radiographical examinations were recommended for relapse surveillance. MRD detection was conducted via the MinerVa platform (Genecast Biotechnology Co., Ltd) using a tumor-informed strategy based on a fixed next-generation sequencing (NGS) panel spanning 769 cancer-related genes.
Results: 168 patients were included in this study, with 11 (6.5%) experiencing confirmed relapse. Positive MRD was detected in 10.2% (16/157) of patients at landmark and was associated with a significantly higher risk of shorter disease-free survival (DFS)(HR: 26.2[6.7-102.7], *P*<0.001), irrespective of disease stage or gene alteration. Dynamic changes in ctDNA status further stratified patients into three subgroups with different prognosis. Consistent negative MRD detected at the landmark and all longitudinal timepoints represented the group with the best prognosis, while positive MRD detected at either the landmark or one subsequent timepoint showed a worse prognosis (Neg-Pos vs. Neg-Neg, HR: 37[3.2-438], *P*=0.004; Pos-Neg vs. Neg-Neg, HR: 14[1.2-172], *P*=0.035). The group with the worst prognosis occurred with consistent positive MRD (Pos-Pos vs. Neg-Neg, HR: 50[5.3-473], *P*<0.001). For patients with negative landmark MRD, there was no significant difference between the DFS of patients who received AT and those who didn't(*P*=0.241), and the result was replicated in a highly controversial subgroup: stage I patients with high-risk factors (*P*=0.130). Besides, whether chemotherapy was applied before targeted therapy in the *EGFR*-mutant subgroup showed no influence on DFS provided that landmark MRD was negative (*P*=0.197). In multivariate analysis considering pathological high-risk factors, poor differentiation was identified as an independent risk factor for landmark MRD positivity (HR: 10.6[1.96-168.01], *P*=0.030).
Conclusions: MRD is a strong and steady prognostic factor in post-operative NSCLC. AT may be waved for stage I patients with high-risk factors given that they had negative landmark MRD, same as the adjuvant chemotherapy before targeted therapy for patients with sensitive *EGFR* mutation. More attention should be paid to poorly differentiated tumors, indicative of a high-risk subgroup with potential residual diseases.

CLINICAL RESEARCH: Prognostic Biomarkers 1
Poster Session

#5193 Molecular evolution of chemoresistance acquisition and predictive insights into the progression of bladder cancer.
G.-E. Yang, J.-J. Kim, T. Shin, S.-H. Leem;
Dong-A University, Busan, Korea, Republic of

Cancer heterogeneity arises from cellular features, suggesting that distinct molecular drivers may be latent within cancers diagnosed at different clinicopathological stages. We thoroughly assessed phenotypic traits and molecular alterations linked to chemoresistance and constructed chemoresistant bladder cancer cell lines representing the stepwise transformation. Model cell lines (5637GRCs, gemcitabine-resistant cells) with stepwise gemcitabine resistance representing early, intermediate, and late resistance phases were developed from non-muscle-invasive bladder cancer (NMIBC) cells. Notably, an increase in cell motility was observed at a relatively early phase. The results from the time-course analysis of molecular evolution showed changes in focal adhesion kinase signaling, PI3K-Akt signaling, and TGF-β signaling pathways during the phase of increasing cell motility. As chemoresistance increased, the levels of genes related to differentiation and MAPK signaling gradually increased. A 63-gene chemoresistance-motility (CrM) signature was constructed and weighted according to cell motility, and a strong correlation was observed between cancer metastasis and drug resistance; the signature also showed prognostic relevance in patients with NMIBC. This study affords a significant understanding of the molecular evolution of chemoresistance acquisition and enables prediction of cancer progression during chemotherapy treatment. Moreover, it provides insights into the progression of cells through all chemoresistance stages from NMIBC to MIBC. Therefore, this study proposes the feasibility of utilizing biomarkers correlated with cancer motility to predict cancer progression in the early phase of chemotherapeutic intervention in patients with non-muscle-invasive bladder cancer.

#5194 Pre-operative markers extracted from extracellular vesicles related with lung cancer relapse.

H. Koba, S. Nanjo, S. Yano;
Kanazawa Univ. Hospital, Kanazawa, Japan

Background: Pre- and post-operative immunotherapy have been a new standard of care for lung cancer patients. On the other hand, post-operative Osimertinib; EGFR-TKI therapy had obtained new evidence to the *EGFR* mutant lung cancer patients. Both treatments revealed to make patient survival prolonged. However, there are quite a lot patients who had experienced disease relapse, despite of multimodal therapy. Extracellular vesicles (EVs) have reported to have potent for searching a new target to cancers.
Purpose: Exploration of novel risk factors related with post-operative recurrence of lung cancer.
Methods: We retrospectively examined patient background, disease-free survival, overall survival, and preoperative liquid biopsy analysis in lung cancer patients who underwent surgery at Kanazawa University Hospital between January 2017 and May 2020, in whom preoperative chemotherapy was not administered. EVs were extracted from 500 µl serum within 7 days before surgery using MagCapture Exosome isolation Kit PS Ver.2 (FUJIFILM). First, we focused the six cases that had the 3 phase samples: preoperative, disease free and relapse phase. According to the EV concentrations calculated by BCA method, comprehensive protein assessment of these subjects was performed using shotgun mass spectrometry. Secondly, all cases' prognosis were analyzed in connection with the detected marker using Dot blotting.
Results: All EV samples from primary 6 cases were able to be detected and median concentration of those was 27 µg/ml (9-82). We focused on three factors (LCEV1-3) among the 6 cases analysis, when we disease fluctuation. Among LCEV1-3 examination to all preoperative samples, LCEV2 had been related with disease recurrence.
Discussions: EVs contain amount of information such as cancer biomarker. Not only that, these factors may have a potency for therapeutic target. Further investigations are needed.

#5196 Stepwise molecular mechanisms involved in chemoresistance in bladder cancer cells.

J.-J. Kim, G.-E. Yang, T. Shin, S.-H. Leem;
Dong-A University, Busan, Korea, Republic of

Bladder cancer (BC) is one of the most prevalent genitourinary tumors worldwide, with approximately 573,000 new cases reported. Approximately 80% of BC patients are diagnosed with non-muscle-invasive bladder cancer (NMIBC) with a high five-year survival rate, while the remaining 20% are diagnosed with muscle-invasive bladder cancer (MIBC). Although the surgical operation has been utilized to BC, patients with NMIBC frequently experience disease recurrence, of which about 20% progress to MIBC. However, the response rate of MIBC patients to gemcitabine treatment has been shown to be limited to less than 40% efficacy, and only a small number of patients have potential benefits.Chemotherapy resistance is an obstacle to cancer therapy and is considered a major cause of recurrence. Thus, understanding the mechanisms of chemoresistance is critical to improving the prognosis of patients. Here, we have established a stepwise gemcitabine-resistant T24 bladder cancer cell line to understand the molecular mechanisms of chemoresistance within cancer cells. The characteristics of the stepwise chemoresistance cell line were divided into 4 phases (parental, early, intermediate, and late phases). These four phase cells showed increasingly aggressive phenotypes in vitro and in vivo experiments with increasing phases
and revealed the molecular properties of the biological process from parent cells to phased gemcitabine-resistant cell line (GRC). Taken together, through the analysis of gene expression profile data, we have characterized gene set of each phase indicating the response to anticancer drug treatment. Specifically, we identified a multigene signature (23-genes including GATA3, APOBEC3G, NT5E, MYC, STC1, FOXD1, SMAD9) and developed a chemoresistance score consisting of that could predict eventual responsiveness to gemcitabine treatment. We suggest that our findings improve prognosis by predicting to acquiring of chemotherapy resistance in bladder cancer patients.

#5197 Identification of novel molecular biomarkers for predicting postoperative recurrence of ampulla of Vater carcinoma.

H. Kim[1], J. Choi[1], H.-o. Jeong[2], A. Kim[1], S.-H. Lee[1], K. Lee[1], K. Lee[1], J. Lee [1], S. Lee[2], J. Park [1];

[1]Samsung medical center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [2]Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of

Background: Ampulla of Vater (AoV) carcinoma is a rare tumor that accounts for 20 % of periampullary cancers. Surgical resection is the only treatment that can expect cure of disease, and there is still an unmet need to predict postoperative recurrence. In this study, we investigated the novel molecular biomarkers that can predict the risk of recurrence after surgery with AoV carcinoma.

Methods: In this retrospective study, we collected the surgically resected tissue and medical records of patients who were diagnosed with AoV carcinoma at Samsung Medical Center from January 2005 to December 2020. Patients were classified patients according to the initial stage and experience of tumor recurrence. Whole transcriptomic analysis using primary AOV tumor and recurred tumor tissue samples was conducted to identify the molecular biomarker for tumor recurrence.

Results: A total of 40 tumor tissue from primary site in non-recurrence group, 22 tumor tissue from primary site in recurrence group, and paired 22 tumor tissue from recurrence site were analyzed. A total of 1005 genes differentially expressed between primary tumor of non-recurrence group and recurrence group were found. Gene set enrichment analysis showed that pathways related to fatty acid metabolism, adipogenesis, oxidative phosphorylation, and hypoxia were upregulated, and pathways associated with interferon gamma response, and mTOR signaling were downregulated in recurrence group. These pathways were significantly affecting the recurrence free survival which was verified with TCGA data, and we further identified some candidate genes including PIM3, IGFBP4, SLC19A1, HIF1A and CXCL11 to predict tumor recurrence . Moreover, we found candidates for single gene level biomarkers to predict early tumor recurrence in N0 stage. Low expression of UQCC3 and high expression of CLCNKB was related to early tumor recurrence.

Conclusions: We found the candidates for novel molecular level biomarker to predict postoperative recurrence of AoV carcinoma. In the future, it is necessary to develop a predictive model for the risk of recurrence after surgical resection for AoV carcinoma.

#5198 Non-invasive biomarkers of ECM turnover are prognostic for combinations of checkpoint inhibition immunotherapy in solid tumors.

C. N. Bistrup[1], V. Araujo Barbosa de Lima[2], C. Jensen[1], M. A. Karsdal[1], I. Svane[3], U. Lassen[3], **N. Willumsen**[1];
[1]Nordic Bioscience, Herlev, Denmark, [2]Copenhagen University Hospital, Copenhagen, Denmark, [3]Copenhagen University Hospital, Herlev, Denmark

Background: Immune checkpoint inhibitors (ICIs) are investigated in many different combinations (Table 1). As only a fraction of patients responds to ICIs, prognostic biomarkers are needed to assess the likelihood of benefit. High collagen turnover in the tumor microenvironment are closely related to response to ICIs and survival outcomes. In this study, we explored the clinical utility of non-invasive biomarkers of type I collagen (reC1M), type III collagen (PRO-C3), type IV collagen (C4M), type XIX collagen (PRO-C19), type XX collagen (PRO-C20), TGF-β activity in metastatic cancer patients treated with ICIs.
Methods: PRO-C3, PRO-C19, PRO-C20, TGF-β, reC1M and C4M were measured with ELISAs in pre-treatment serum from 33 patients with metastatic disease in a basket trial comprising 14 different tumor types, treated with 8 different checkpoint inhibition regimens (Table 1). The association between biomarker levels and overall survival (OS) outcome was evaluated by Kaplan-Meier analysis and Cox regression analysis after dichotomizing patients at the 75th percentile (Q4).
Results: When evaluating the combined group of cancer patients, high levels (Q4) of PRO-C3 (HR=3.00, 95%CI=1.21-7.44, p=0.018), PRO-C19 (HR=2.49, 95%CI=1.04-5.99, p=0.041), PRO-C20 (HR=2.49, 95%CI=1.04-5.99, p=0.041), TGF-β (HR=2.52, 95%CI=1.05-6.04, p=0.039), reC1M (HR=2.79, 95%CI=1.16-6.67, p=0.021) and C4M (HR=2.52, 95%CI=1.05-6.04, p=0.039) were all associated with poor OS compared to low levels (Q1-Q3). The median OS was 4.7-6.1 months in biomarker-high patients compared to 8.7-11.4 in biomarker-low patients.
Conclusion: Across a diverse cohort of metastatic cancer patients treated with different checkpoint inhibition regimens, non-invasive biomarkers associated with tumor fibrosis and collagen turnover (PRO-C3, PRO-C19, PRO-C20, TGF-β, reC1M and C4M) could identify cancer patients with poor prognosis.

Table 1

Cancer type	**Number of patients**	**Treatment**
Esophageal	1	Nivolumab (Nivo) +Anti-LAG3

#5199 Protease-activated CDCP1 as a marker for aggressive primary prostate cancer and castration resistance.

R.-M. Merivirta, T.-P. Lehto, A. Rannikko, T. Mirtti, H. Koistinen;
University of Helsinki, Helsinki, Finland

CUB domain-containing protein 1 (CDCP1) is a type 1 transmembrane protein overexpressed in many cancers, including prostate cancer. CDCP1 has been associated with tumor progression, metastasis, drug resistance and poor prognosis in prostate cancer, making it a potential prognostic biomarker and therapeutic target. It has been shown to be overexpressed in a subset of castration resistant prostate cancers (CRPC) and cooperate with the loss of tumor suppressor PTEN to promote metastatic dissemination. Extracellular serine proteases activate CDCP1 by cleaving it into an N-terminal and C-terminal fragments. Proteolytic cleavage has been associated with the tumor-promoting functions of CDCP1. We studied the expression of full-length and cleaved form of CDCP1 in grade group 2-4 primary prostate cancer tissues and CRPCs using immunohistochemistry. Total CDCP1 staining was observed in 60% of primary prostate cancer samples, while the staining of cleaved CDCP1 was somewhat less frequently observed (45%). The results will be further analyzed regarding the PTEN status and for association with survival of the patients. In conclusion, so far, our results have indicated that cleaved CDCP1, which likely represents activated CDCP1, is detectable in GG 2-4 prostate cancers.

#5200 Multiparametric MRI along with machine learning informs on molecular underpinnings, prognosis, and treatment response in pediatric low grade glioma.

A. Nabavizadeh[1], A. Kraya[2], K. Rathi[2], M. Kim[2], N. Khalili[2], A. Familiar[2], V. Kesherwani[2], H. Anderson[2], D. Gandhi[2], A. Mahtabfar[2], S. Bagheri[1], X. Huang[2], Y. Zhu[2], A. Sickler[2], S. Phul[2], S. Mueller[3], M. Koptyra[2], P. Storm[2], J. Ware[1], Y. Song[2], M. Fisher[2], A. Vossough[2], C. Davatzikos[1], A. Resnick[2], A. Fathi Kazerooni[2];

[1]Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA, [2]CHOP, Philadelphia, PA, [3]UCSF, San Francisco, CA

We report a comprehensive radiogenomic analysis, including multiparametric MRI and RNA sequencing of 502 tumors across 13 histological types of pediatric low-grade glioma (PLGG). Through an unsupervised analysis of treatment-naïve imaging, we were able to identify 3 distinct imaging clusters that were associated with different molecular pathways according to transcriptomic pathway analysis. Using xCell enrichment scores as input for clustering, we discovered three distinct immunological groups based on immune cell infiltration. The results suggested the presence of an ‘immune-hot” cluster within the tumors with a poorer prognosis, which may potentially benefit from emerging immunotherapies. We subsequently generated a radiomic signature that was able to predict immunological profiles. We also developed a clinicoradiomic predictive model that can assess patients’ risk of progression and predict treatment response. Finally, we evaluated the transcriptomic pathways that were most predictive of clinicoradiomic risk scores and identified the biological pathways most predictive of risk of progression in PLGG, when adjusting for molecular subtype, race, reported gender, age at diagnosis, and the anatomic location of the tumor. This is the first large-scale radiogenomic analysis in PLGG that can aid in prognostication, assessing patients’ risk of progression, predicting treatment response in conventional therapies, and early stratification of patients to identify potential candidates for targeted therapies.

#5201 Characterization of *PDLIM2* in non-small cell lung cancer.

K. Ashouri[1], H. Krause[2], A. Elliott[2], S. V. Liu[3], P. C. Ma[4], B. Halmos[5], Z. Qu[1], G. Xiao[1], A. Vanderwalde[2], J. J. Nieva[1];
[1]University of Southern California, Los Angeles, CA, [2]Caris Life Sciences, Phoenix, AZ, [3]Georgetown University, Washington, DC, [4]Penn State College of Medicine, Hershey, PA, [5]Montefiore Medical Center, Bronx, NY

Introduction: PDZ and LIM domain protein 2 (PDLIM2) acts as tumor suppressor by downregulating NF-κB and STAT3 signaling, modulating inflammation, immune response, and cell survival. Mouse model studies have demonstrated that downregulation of *PDLIM2* leads to PD-1 immune blockade and chemotherapy resistance. We present a large clinical and molecular characterization of *PDLIM2* expression in non-small cell lung cancer (NSCLC).
Methods: NextGen sequencing of DNA (whole exome)/RNA (whole transcriptome) was performed for NSCLC (Total N = 29126; Adenocarcinoma [-A, N = 15765], Squamous [-S, N = 6416]) patient tumors submitted to Caris Life Sciences (Phoenix, AZ). Mutations were defined as pathogenic SNVs/indels. Samples were stratified by PDLIM2 expression quartiles (in transcripts per million [TPM]) for all NSCLC tumors (Q4: H, Q1: L). PD-L1 expression [22C3; Positive (+): tumor proportion score (TPS) ≥1%]was assessed by IHC. High tumor mutational burden (TMB-high) set as ≥10 mutations per Mb. Cell infiltration in the tumor microenvironment was estimated by QuantiSEQ. Gene expression profiles were analyzed for transcriptional signatures predictive of response to immunotherapy (T cell-inflamed). Real-world overall survival was assessed from insurance claims data and Kaplan-Meier estimates were calculated for molecularly defined subpopulations. Mann-Whitney U and X^2/Fisher-Exact tests were applied where appropriate, with P-values adjusted for multiple comparisons ($p < 0.05$).
Results: Median *PDLIM2* expression was higher in NSCLC-A compared to NSCLC-S (15.3 vs 13.6 TPM, $p < 0.001$). *PDLIM2*-A^L had a lower prevalence of *EGFR* mutations than *PDLIM2*-A^H (15.5% vs 19.4%, $p < 0.01$), but the opposite pattern was observed for *STK11* (21.5% vs 11.2%), *RB1* (7.5% vs 3.8%), *TP53* (62.9% vs 52.8%), *KEAP1* (18.4% vs 10.9%), and *SMARCA4* (9.15 vs 4.5%) alterations (all $p < 0.001$). *PDLIM2*-A^L tumors had decreased PD-L1+ (L: 52.4% vs H: 58.4% $p < 0.001$) but increased TMB-High status (L: 40.9% vs H: 28.5%, $p < 0.001$). PD-L1+ and TMB-H frequency did not vary with *PDLIM2* expression in NSCLC-S. In both NSCLC-A and -S tumors, *PDLIM2*^{H} had increased infiltration of NK cells, macrophages, dendritic cells, T cells, neutrophils, monocytes, and B cells compared to PDLIM2^L (all $p < 0.05$), in addition to increased T cell-inflammed scores ($p < 0.001$). *PDLIM2*-A^H was associated with improved overall survival (OS) (median 21.7 vs L: 15.6 months; $p < 0.001$; Hazard ratio [HR] = 0.825, 95% Confidence Interval [CI] 0.765 - 0.889) and time on pembrolizumab treatment (median 6.2 vs L: 5.6 months; $p = 0.009$; HR = 0.825 95% CI 0.714 - 0.953). No difference in OS was observed between *PDLIM2*-S^H vs ^{L} tumors (H: 14.8 vs L: 14.0 months; $p = 0.37$; HR = 0.95, CI 0.85-1.06).
Conclusions: NSCLC-A with high *PDLIM2* expression have a unique mutational profile, increased immune cell infiltration and favorable OS. Therapeutic strategies for targeting PDLIM2 to modulate NF-κB and STAT3 signaling should be further explored.

#5203 Identification of prognostic and predictive biomarkers for palbociclib add-on therapy using cancer panel sequencing of cell-free DNA in patients with HR-positive HER2-negative advanced and metastatic breast cancer with fulvestrant resistance.

T. Takeshita[1], T. Iwamoto[2], N. Niikura[3], K. Watanabe[4], Y. Kikawa[5], K. Kobayashi[6], N. Iwakuma[7], T. Okamura[3], H. Tada[8], S. Ozaki[9], T. Okuno[10], U. Toh[11], Y. Yamamoto[12], M. Tsuneizumi[13], H. Ishiguro[14], N. Masuda[15], S. Saji[16];

[1]Kumamoto City Hospital, Japan, Kumamoto, Japan, [2]Kawasaki Medical School Hospital, Okayama, Japan, [3]Tokai University School of Medicine, Kanagawa, Japan, [4]Hokkaido Cancer Center, Hokkaido, Japan, [5]Kansai Medical University Hospital, Osaka, Japan, [6]Saitama Red Cross Hospital, Saitama, Japan, [7]NHO Kyushu Medical Center, Fukuoka, Japan, [8]Tohoku University Graduate School of Medicine, Miyagi, Japan, [9]Hiroshima Prefectural Hospital, Hiroshima, Japan, [10]Kobe City Nishi-kobe Medical Center, Hyogo, Japan, [11]Kurume University Hospital, Fukuoka, Japan, [12]Kumamoto University Hospital, Kumamoto, Japan, [13]Shizuoka General Hospital, Shizuoka, Japan, [14]Saitama Medical University International Medical Center, Saitama, Japan, [15]Nagoya University Graduate School of Medicine, Aichi, Japan, [16]Fukushima Medical University, School of Medicine, Kumamoto, Japan

Purpose: The combination of cyclin-dependent kinase 4/6 inhibitors with endocrine therapies has shown promise for improving the survival of patients with hormone receptor (HR)-positive/human epidermal growth factor receptor 2 (HER2)-negative advanced and metastatic breast cancer (ABC/MBC). The FUTURE trial (UMIN000029294) demonstrated that adding palbociclib after acquiring fulvestrant resistance is potentially safe and effective. To further identify biomarkers for patient selection, this preplanned translational sub-study aims to use cancer panel sequencing of cell-free DNA (cfDNA) to discover prognostic and predictive biomarkers for additional palbociclib treatment after acquiring fulvestrant resistance in patents with HR-positive/HER2-negative ABC/MBC.

Methods: Herein, we utilized 149 cfDNA samples from 61 patients with disease progression after fulvestrant monotherapy and who subsequently received fulvestrant and palbociclib. Circulating cfDNA was analyzed at the time of palbociclib addition after fulvestrant resistance, on day 15 of cycle one (D15), and at the end of treatment (EOT) using the ThruPLEX ctDNA Assay, which can identify single or multi nucleotide variants, DNA insertions, and deletions in up to 34 cancer-associated genes.

Results: The genetic landscape of patients with BC undergoing palbociclib treatment was dynamic and changed over the course of treatment. Regarding progression-free survival, alterations in *NRAS* (Hazard Ratio (HR): 11.97, P < 0.005)), *MAP3K1* (HR: 6.86, P < 0.005), and *TP53* (HR: 3.6, P = 0.02) were identified in cfDNA on D15 and were linked to poor prognoses. Alterations in *CBFB* at baseline (HR: 5.15, P = 0.01), in *BRCA2* (HR: 7.17, P < 0.005) and *NRAS* (HR: 5.32, P < 0.005) at D15, and *ESR1* (HR: 4.37, P = 0.01) at EOT were also linked to poor prognosis, whereas alterations in *WEE1* (HR: -5.84, P = 0.02) at EOT were associated with a favorable prognosis. Alterations in *ESR1*, *WEE1, CBFB*, and *BRCA2* were prognostic factors at peak frequencies during treatment. Moreover, our research uncovered a novel observation that as treatment progressed, the relationship between prognostic factors focused on alterations in *ESR1* and *TP53* tended to weaken.

Conclusion: Cancer panel testing for cfDNA identified prognostic and predictive biomarkers for palbociclib add-on therapy after acquiring fulvestrant resistance in patients with HR-positive/HER2-negative ABC/MBC. These findings have important implications for patient selection and personalized treatment strategies in such patients.

#5204 Exploring the therapeutic potential of EGFR retreatment: A comprehensive analysis of T790m(+) conversion and prognosis in lung cancer patients.

Joong Jin Ahn[1], Jae Cheol Lee[2], Chang Min Choi[3], In Ae Kim[4], Kye Young Lee[4], Jeong Eun Lee[5], Seung Hoon Jang[6], Seong Hoon Yoon[7], In Jae Oh[8], Sang Hoon Lee[9], Eun Young Kim[9], Juwhan Choi[1], **Sung Yong Lee**[1]

[1]Korea University Guro Hospital, Seoul, Korea, Republic of,[2]Ulsan University Asan Medical center, Seoul, Korea, Republic of,[3]Ulsan University Asan Medical Center, Seoul, Korea, Republic of,[4]Konkuk University Medical Center, Seoul, Korea, Republic of,[5]Chungnam National University Hospital, Daejeon, Korea, Republic of,[6]Hallym University Medical Center, Anyang, Korea, Republic of,[7]Pusan National University Yangsan Hospital, Pusan, Korea, Republic of,[8]Chonnam National University Hwasun Hospital, Jeonnam, Korea, Republic of,[9]Yonsei University Severance Hospital, Seoul, Korea, Republic of

Background: T790M acquired resistance occurs in 30-40% of cases after first- or second-generation EGFR TKI treatment. However, some patients who did not develop T790M mutation are converted to T790M positive through EGFR TKI retreatment. We conducted a Phase II prospective study analyzing T790m (+) conversion and prognosis in patients who were not induced T790M mutation at 2nd biopsy and were re-treated with first-generation EGFR-TKI as the third-line or later therapy.

Methods: We re-administered first-generation EGFR-TKI to 63 patients (gefitinib n=34 or erlotinib n=29) who had previously been treated with first- or second-generation EGFR TKIs and cytotoxic chemotherapy because they were T790M-negative at the 2nd biopsy. Results: Among the 63 patients, a new T790m (+) mutation was identified in 20 patients (32%) with EGFR TKI retreatment. The first EGFR TKI treatment period and EGFR TKI retreatment period were significantly longer in the T790m (+) group than in the T790m (-) group (P-value=0.026, P-value=0.029, respectively). The best response to retreatment was also favorable in the T790m (+) group (P-value=0.038). The median overall survival (OS) in the T790m (+) group was 29.3 months, which was significantly better than the 6.0 months observed in the T790m (-) group (P-value<0.001). In an additional NGS analysis conducted on stored plasma samples from the 24 patients who were negative for T790M in the tumor tissue before retreatment, T790M was detected in five patients. These patients, who were subsequently treated with a third EGFR TKI, demonstrated very favorable overall survival (OS).

Conclusions: EGFR retreatment could induce T790m (+) conversion in approximately one-third of cases, and these patients exhibited favorable prognosis. Through NGS analysis using plasma samples, approximately 20% cases of T790m mutation, which were not detected through routine PCR tests at the tumor tissue, could be identified. Retreatment-EGFR TKI and NGS analysis through blood samples could improve patient prognosis through the additional discovery of T790m (+) mutation.

#5205 Beyond boundaries: ADRB3, a novel prognostic marker in pediatric neuroblastoma.

G. Mattei[1], C. Banella[2], F. Carrozzo[2], A. Pasha[2], A. Tondo[2], C. Favre[2], **M. Calvani**[2];
[1]University of Florence Department of Information Engineering, Firenze, Italy, [2]Meyer Children's Hospital-IRCCS, Firenze, Italy

Introduction: Neuroblastoma (NB) is a pediatric tumor arising from immature nerve cells originating from neural crest cells. This malignancy is characterized by a remarkably early onset, with only 10% of cases occurring beyond 5 years of age. According to the INRG classification, ~50% of patients are classified as low risk (L1/L2). Despite advances in treatment, around 20% of these experienced a relapse within 5 years with a mere 10% survival rate.
Methods: We investigated the role of the adrenoceptor beta-3 (ADRB3) as a prognostic factor for NB. The samples provided by IRCCS Meyer Children's Hospital allowed us to measure cytofluorimetric level expression of ADRB3 in tissue biopsies from 43 NBs, in the circulating tumor cells (CTCs) and in the bone marrow cells (BMCs) at onset and at the end of treatment. Further, to study the role of ADRB3 in NB, we used CRISPR-Cas9 to knock down ADRB3 expression in mice model.
Results: Results indicate that ADRB3 levels in biopsy at the onset are significantly higher (Wilcoxon test, $p = 0.026$) in patients with negative outcome than those who achieved complete remission. The R package survival was used to perform Survival curve analysis to further assess the impact of ADRB3 at the onset in biopsy tissues. Results confirmed a significant separation ($p = 0.031$) between survival curves of patients with high levels and those with low levels, reinforcing its importance as a prognostic factor. Moreover, the same results were found in survival curves ($p = 0.038$) in low-risk patients, corroborating the importance of ADRB3 levels to discriminate between unfavorable or favorable prognosis. Moreover, post-chemotherapeutic treatment analysis, in both residual CTCs and BMCs, indicated statistically differences in ADRB3 levels between fully recovered patients and deceased. Survival curves, stratified by ADRB3 levels in CTCs post-chemotherapy, a favorable prognosis for patients with low levels ($p = 0.0001$). Finally, the expression analysis showed that ADRB3 levels in NB cells led to increment of processes associated with the cellular migration and metastasization and in metabolism.
Conclusion: Our findings suggest that ADRB3 is a significant prognostic factor for NB. Patients with high ADRB3 expression in biopsy at the onset and after the treatment have a higher risk of unfavorable outcome, even for low-risk patients. In conclusion, our results challenge current classification and prognostic paradigms, highlighting ADRB3's crucial role in NB, contributing to refine risk stratification and unveil a new potential target for liquid biopsy of detecting, analyzing and monitoring CTCs.

#5206 High level STING expression in tumor and inflammatory cells is linked to microsatellite instability and favorable tumor parameters in a cohort of 1,900 colorectal cancer patients..

Elena Bady[1], Zhihao Huang[1], Maximilian Lennartz[1], Claudia Hube-Magg[1], Julia Ebner[2], Frank Jacobsen[2], Stefan Steurer[2], Christian Bernreuther[1], Till S. Cauditz[2], Andreas H. Marx[3], Till Krech[2], Eike Burandt[2], Guido Sauter[2], Ronald Simon[2], Sarah Minner[2], **Jan Hendrik Mueller**[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Department of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[3]Department of Pathology, Clinic Furth, Furth, Germany

Background: The stimulator of interferon genes (STING) is a transmembrane protein expressed on a variety of cell types including epithelial, inflammatory (lymphocytes and macrophages), and endothelial cells. STING expression has been described at variable levels in various tumor types where it might enhance anti-tumoral effects of the immune system and impact tumor angiogenesis. STING activating targeted therapies are currently evaluated in preclinical studies. However, the clinical significance of STING expression in tumor cells as compared to tumor-associated inflammatory cells is not fully resolved.
Methods: To evaluate the potential clinical significance of STING expression in different cell types of colorectal cancer (CRC) tissue (tumor cells, lymphocytes, macrophages and endothelial cells), more than 1.900 patients were analyzed by multiplex fluorescence immunohistochemistry (CKpan, STING, CD45, CD68 and CD31) in a tissue microarray format (TMA) in combination with a deep-learning based algorithm for automated cell detection.
Results: STING expression on colorectal cancer cells varied markedly. Of 1,905 evaluable cancers, 601 (31.5%) showed a strong expression in virtually all tumor cells and 428 (22.5%) lacked STING staining while 478 (25.1%) showed a weak, and 398 (20.9%) a moderate staining. High STING expression on tumor cells was associated with microsatellite instability (MSI, p<0.0001), low tumor stage (p=0.0013), absence of nodal metastasis (pN0, p=0.0003) and tumor localization in the right colon (p<0.0001). A multivariate analysis revealed that these associations were solely driven by the tight relationship between STING expression in tumor cells and MSI. Accordingly, subgroups of tumors with and without MSI lacked significant associations between STING expression on tumor cells and pT or pN categories. While the total number of lymphocytes and macrophages were related to MSI, low pT, and pN0, there were significant associations between a high percentage of STING positive macrophages and lymphocytes to low pT stage (p<0.0001 each) and absence of nodal metastases for high percentage of STING positive macrophages (p=0.0033). STING was regularly expressed on endothelial cells of small vessels. Although the intensity appeared to be variable, there was no link to tumor phenotype.
Conclusion: In summary, the significant link between high STING expression on tumor cells, lymphocytes and macrophages with a favorable tumor phenotype supports the concept of STING representing an enhancer of anti-tumoral effects of the immune system.

#5207 Hypermethylation of SOX17 is an important epigenetic mark in Afro-Brazilian breast cancers.

L. Delgado-Cruzata[1], D. J. Gomes de Paula[2], J. G. Vieira[3], A. L. Christianes[2], T. Simao[3], L. B. Gusmao[3], L. Ribeiro Pinto[2], S. Coelho Soares Lima[2]; [1]John Jay College, New York, NY, [2]INCA, Rio de Janeiro, Brazil, [3]UERJ, Rio de Janeiro, Brazil

Afro-Brazilian women suffer from higher excess breast cancer mortality after adjusting for age, level of education and stage at diagnosis. Limited studies have researched disease characteristics in this population, which can benefit from the identification of molecular markers that can provide an insight into who is at greater risk of mortality. Epigenetic biomarkers represent the combined effect of environmental and genetic factors. Particularly DNA methylation biomarkers can be valuable as biomarkers of breast cancer risk and prognosis. While studies in other populations have identified DNA methylation biomarkers associated with breast cancer and its clinicopathological outcomes, research on Brazilian cohorts has been limited in scope and focused on women of European descent. The goal of this work was to determine the epigenetic makeup of breast cancer in Brazilian women of African descent. To identify epigenetic biomarkers in Brazilian women who self-identified as Black or Brown, we conducted a case-series analysis investigating DNA methylation patterns in tumor (T) and adjacent non-tumor (NT) tissue. For this, we used the Illumina EPIC (850k) arrays to carry out DNA methylation profiling in 48 frozen tissue paired T and NT samples of breast cancer patients treated at the National Cancer Institute Breast Cancer Hospital in Rio de Janeiro, Brazil. We identified a total of 7,749 probes with Benjamini-Hochberg adjusted p-value < 0.0001 and differences between T and NT tissue above |0.3|. Of these, 5,976 or 77.12% had lower DNA methylation in T when compared to NT tissue; while 1,773 (22.88%) had higher DNA methylation. These were used to identify 21 differentially methylated regions (DMRs) that contained a minimum of seven cg sites, a mean difference larger than |0.2| and a maximum difference above |0.4|. DMRs were mostly (12) hypermethylated in T, and included PCDHGA, NKAPL, ZKSCAN4, SPAG6, CA3, DPP6, RGS22, NXPH1, ANK3, OTX2, SOX17, and CDO1. We used pyrosequencing to validate the levels of SOX17 in eighty-eight tumor and non-adjacent tumor tissue DNAs. We found SOX17 to be hypermethylated in T (44.5±19.1% vs 10.2±10.6, p<0.0001). Differences in DNA methylation in T and NT tissue we still observed by race/ethnicity categories, 43.9±18.6% vs 11.0.±13.2% (p<0.0001) for Brown, and 45.1±20.7% vs 8.8±3.0% for Black women (p<0.0001), respectively. Similarly to previously reported, SOX17 hypermethylation was found to be associated with Luminal A and B molecular subtypes (p<0.0001). To our knowledge, this is the first study to use a discovery approach to identify epigenetic biomarkers in Black and Brown Brazilian women. Our findings confirming previously reported data on SOX17 hypermethylation in breast cancer are encouraging. We expect to validate other epigenetic markers unique to this population that can ultimately aid in the molecular characterization of Brazilian breast cancers.

#5208 Dynamic changes in circulating tumor DNA and T cell receptor repertoire predict disease progression in patients with unresectable esophageal squamous cell carcinoma.

Baidong Zhang[1], Xiang Zhan[2], Qiang Li[1], Chenxuan Wang[3], Jiaohui Pang[3], Yaru Zhang[3], Song Wang[3], Qiuxiang Ou[3], **Haimeng Tang**[3], Alei Feng[1], Zhe Yang[4]

[1]Tumor Research and Therapy Center, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China, [2]Tumor Research and Therapy Center, Shandong Provincial Hospital, Shandong University, Jinan, China, [3]Nanjing Geneseeq Technology Inc, Nanjing, China, [4]Tumor Research and Therapy Center, Shandong Provincial Hospital, Shandong University, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: Patients with unresectable esophageal squamous cell carcinoma (ESCC) showed variations in their response to treatments and experienced inevitable disease progression. The development of non-invasive and clinically viable biomarkers is urgently needed. Therefore, this study aimed to investigate prognostic value of circulating tumor DNA (ctDNA) and T cell receptor (TCR) repertoire in these patients.

Methods: A total of 21 ESCC patients who underwent definitive chemoradiotherapy, radiotherapy, or immune checkpoint inhibitor (ICI)-combined therapy from October 2020 to March 2022 were retrospectively evaluated. Baseline tumor samples were collected for genomic profiling using targeted NGS. Baseline and post-therapy plasma were collected for genomic and TCR profiling.

Results: We found that ctDNA detection rates were significantly reduced after treatment ($P<0.001$). Post-treatment ctDNA positivity were associated with worse local recurrence-free survival ($P=0.001$) and progression-free survival ($P=0.001$), but not overall survival. Moreover, TCR clonality was significantly increased after treatment, including CDR3 diversity ($P=0.003$), TCR clonotype ($P=0.004$), and VJ pairs ($P=0.010$), indicating an increased T cell expansion and complexity. Specifically, we identified two increased and four reduced VJ rearrangements after treatment, and the four reduced VJ rearrangements (Vβ12-2Jβ2-4, Vβ6-9Jβ1-5, Vβ6-7Jβ1-5, and Vβ6-9Jβ1-1) were significantly associated with worse progression-free survival.

Conclusion: Our findings suggest the prognostic implication of plasma ctDNA and TCR profiles in patients with unresectable ESCC receiving definitive therapy, supporting the future development of non-invasive monitoring of disease progression in these patients.

#5210 The Prognostic value of serum TK1 protein determinations using AroCell TK210 ELISA in DLBCL patients treated with R CHOP.

K. Jagarlamudi[1], G. Hedstrom[2], P. Venge[2], S. Eriksson[3], D. Molin[2], G. Enblad[2];

[1]AroCell AB, Stockholm, Sweden, [2]Uppsala University, Uppsala, Sweden, [3]Swedish Agricultural University, Uppsala, Sweden

Background: Diffuse large-cell B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin's lymphomas (NHL) that accounts for approximately 25% of the patients. Earlier studies demonstrated the prognostic value of serum thymidine kinase 1 (STK1) activity determinations in different hematological malignancies. To date, the prognostic value of STK1 protein concentration in patients with DLBCL treated with R-CHOP has not been investigated. The purpose of this retrospective study was to determine the value of high TK levels on Overall survival among DLBCL patients treated with R-CHOP as first-line treatment.
Materials and Methods: The study included 146 patients diagnosed with DLBCL between 2010 and 2016 from the Uppsala-Umeå Comprehensive Cancer Consortium (U-CAN). All patients included were treated using the standard chemotherapy regimen R-CHOP. Serum samples were collected at the time of diagnosis, during the treatment, 1 year after treatment, and after relapse. Non-infected and apparently healthy persons, matched to the DLBCL patients (57 males and 88 females), served as controls. The TK1 protein levels in all serum samples were determined by using AroCell TK 210 ELISA (AroCell AB, Sweden). The TK1 protein concentration was expressed as µg/L.
Results: The TK1 concentrations in sera from DLBCL patients before treatment were significantly higher compared to the concentrations in healthy individuals, median 0.44 µg/L (IQ range 0.22 to 1.06 µg/L) vs. median 0.22 µg/L (IQ range 0.18 to 0.29 µg/L, P<0.00001). Serum TK1 was also significantly higher in patients with more advanced stages (P<0.00001), higher IPI (P<0.00001), and in patients with B-symptoms (P<0.0001). Patients with STK1 protein levels below the cut-off value (0.45 µg/L) had significantly better OS and DFS (P=0.04 and P=0.0006, respectively) compared to patients with STK1 concentration above the cut-off. In multivariate analyses, dichotomized S-TK1 measurements before treatment were found to be significant for the risk of relapse in combination with either aaIPI or IPI (p<0.01).
Conclusions: These results confirmed that STK1 concentration correlates with risk factors such as tumor burden, Ann Arbor stage, and IPI. In conclusion, patients with high TK1 concentrations at the time of diagnosis have short overall survival and STK1 concentrations are apparently a prognostic indicator for survival in patients treated with modern chemo-immunotherapy.

#5211 Somatic copy number variation as prognostic marker for recurrence in never-smokers with early-stage lung adenocarcinoma.

S. Vanstraelen, A. Reiner, B. H. Mastrogiacomo, K. Tan, J. Dycoco, B. J. Park, P. S. Adusumilli, M. J. Bott, D. R. Jones, G. Rocco;
Memorial Sloan Kettering Cancer Center, New York, NY

Objective: Lung cancer in never-smokers has a distinct genomic profile with low tumor mutation burden, more tumor promotor mutations and fewer somatic copy number variations (CNV) than smokers. CNVs have shown to be associated with poor outcome in advanced stage disease. However, the relationship between CNV and clinicopathologic features on prognosis in early-stage lung cancer is undefined. To address this knowledge gap, we assessed the impact of CNV on recurrence in never-smokers who underwent curative resection for pathological stage I-II lung adenocarcinoma using an integrated genomic and clinicopathological analysis.

Methods: We analyzed a cohort of 210 never-smokers with stage I-II lung adenocarcinoma treated from 2014 to 2022 who met the inclusion criteria (no neoadjuvant therapy, pathological stage I-II, complete resection, next-generation sequencing available). The patient cohort was stratified using unsupervised hierarchical clustering of arm-level CNVs. We assessed cumulative incidence of recurrence (CIR) between CNV groups using competing risk regression analysis, adjusting for SUVmax, pathologic stage, lymphovascular invasion, IASLC grade, and tumor mutation burden.

Results: Of the 210 patients, 159 patients were female (76%), and patients were primarily from Caucasian (n=140, 67%) or Asian decent (n=50, 24%). Based on arm-level CNV clustering, the cohort was stratified into three groups: CNV low (n=86, 41%), CNV moderate (n=75, 36%) and CNV high (n=49, 23%). The CNV low tumors were characterized by a low CNV burden. Conversely, the CNV moderate tumors primarily exhibited gains in chromosomes 1q, 5p and 7p, along with loss of heterozygosity in chromosome 9p, 9q and 13. CNV high tumors were characterized by whole-genome doubling. Whole-genome doubling was significantly more common in CNV high tumors (n=33, 66%) compared to CNV low (n=2, 2.3%) and CNV moderate tumors (n=2, 2.7%) (*p<.001*). *EGFR* (n=145, 69%) and *TP53* (n=61, 29%) were the most frequently altered genes, with *EGFR* alterations being significantly more prevalent in CNV high tumors (n=41, 84%) compared to CNV low tumors (n=46, 53%) (*p<.001*). In total, 42 patients (20%) developed recurrences. The CIR was lower in the CNV low group (5y-CIR, 14%, 95%CI: 6.5%-25%) compared to the CNV moderate (5y-CIR, 31%, 95%CI: 18%-44%) and CNV high group (5y-CIR, 48%, 95%CI: 27%-66%) (*p=.004*), with adjusted hazard ratios of 2.3 (95%CI: 0.93-5.71; *p=0.074*) and 2.65 (95%CI: 1.07-6.60; *p=.037*), respectively. The CIR for locoregional (n=11, 5%) and distant recurrence (n=31, 15%) remained lower in the CNV low group compared to the combined CNV moderate & high groups (Gray test *p=.020* and *p=.049*, respectively).

Conclusion: In never-smokers who underwent curative treatment of pathological stage I-II lung adenocarcinoma, copy number status seems a predictor of recurrence, with CNV low tumors associated with the best prognosis.

#5212 Prognostic biomarkers for breast cancer: Metabolic and inflammatory pathways.

A. N. McMahon[1], C. Takita[1], J. L. Wright[2], I. M. Reis[1], E. Lee[3], G. Yang[1], J. J. Hu[1];
[1]University of Miami Miller School of Medicine, Miami, FL, [2]Johns Hopkins University School of Medicine, Washington, DC, [3]University of Central Florida, Miami, FL

Objective: To assess the prognostic significance of molecular biomarkers, particularly metabolic and Inflammatory pathways using samples from a prospective study of breast cancer patients undergoing adjuvant radiotherapy (RT).
Methods: We used ultra-performance liquid chromatography-mass spectrometry (UPLC-MS/MS) for measuring urine metabolites. Following normalization to osmolality, log transformation, and imputation of missing values, we used Welch's two-sample t-test to identify biochemicals that differed significantly by progression status. We measured pre- and post-RT plasma high-sensitivity C-reactive protein (hsCRP) levels. Progression-free survival (PFS) was calculated from the date of diagnosis to the date of disease progression or last follow-up. Univariable and multivariable Cox proportional hazards regression models assessed the associations between hsCRP and PFS.
Results: In 120 breast cancer patients, carbohydrate metabolism, branch-chain amino acid (BCAA) metabolism, phosphatidylcholine metabolism, arginine metabolism, oxidative stress-related metabolites, androgenic steroids, and nucleotide metabolism had the most notable differences in patients with progression versus progression-free cases. In 488 breast cancer patients, RT significantly increased plasma hsCRP levels, and post-RT hsCRP levels were significantly higher in deceased vs. alive patients (p=0.031). In multivariable models, hsCRP had a prognostic value for all-stage and stage 0-II patients.
Conclusions: In our study of breast cancer patients receiving adjuvant RT, multiple metabolite biomarkers and post-RT plasma CRP levels were associated with a worse prognosis. BCAAs and fatty acids regulate cell metabolism by affecting mitochondrial function and inflammation signals. Thus, our findings suggest a potential role of metabolic and inflammatory pathways in breast cancer prognosis. These molecules may have potential utility as prognostic biomarkers for breast cancer patients undergoing adjuvant RT and targets for intervention.
Keywords: breast cancer, metabolomics, inflammation, prognosis

#5213 Evaluation of HER2DX risk-score in residual disease (RD) from HER2-positive (HER2+) early breast cancer (EBC) patients (pts) following neoadjuvant trastuzumab and pertuzumab (HP)-based therapy: An exploratory analysis from the PHERGain trial.

[1]Medica Scientia Innovation Research (MEDSIR), Barcelona, Spain,[2]Translational Genomics and Targeted Therapies in Solid Tumors, Institut D'Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain,[3]Medica Scientia Innovation Research (MEDSIR), Jersey City, NJ,[4]Reveal Genomics S L, Barcelona, Spain,[5]Cancer Genomics Group, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain,[6]Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC

Introduction:
HER2DX is a prognostic (risk-score) and predictive (pathological complete response-score) genomic assay validated in baseline (BL) tumor samples from HER2+ EBC pts. RD after neoadjuvant anti-HER2-based therapy is associated with worse outcomes. Whether HER2DX risk-score analyzed in RD provides additional prognostic information is unknown.

Methods:
This retrospective analysis included 14 pts from group B of the PHERGain trial (NCT03161353): 6 who developed distant recurrences and 8 matched controls with HER2DX high-risk score at BL who did not. Group B pts had centrally confirmed, stage I-IIIA, HER2+ EBC and were treated with HP (± endocrine therapy), with chemotherapy added for pts without PET response after 2 treatment cycles or pathological complete response (Perez-Garcia et al, Lancet Oncol 2021).HER2DX was evaluated on tumor samples collected at BL and surgery. The primary objective was to determine the association of HER2DX risk-score in RD with the development of distant recurrences. Secondary objectives were to assess gene expression and the HER2DX signatures in BL vs RD and their association with distant recurrences. Cox regression models evaluated the association of variables with distant recurrence. Paired SAM with a false discovery rate <5% identified differences in gene expression between BL and RD samples.

Results:
Median follow-up was 4.04 years. Five (83.3%) of 6 pts with distant recurrences had HER2DX high-risk scores at BL. The 8 control pts had HER2DX high-risk scores at BL but no relapse. In RD, all 6 pts (100%) who relapsed had a HER2DX high-risk score, while 4 (50%) of 8 pts without distant recurrence presented a HER2DX downstaging. Pts with HER2DX low-risk in RD had better 3-year distant disease-free survival than high-risk pts (100% vs 50%; hazard ratio = 4.34 [1.03-18.23], p=0.045). In RD, high expression of the proliferation signature and 15 genes, including proliferation genes, and low expression of 38 genes, including immune and luminal-related genes, were associated with poor prognosis. In paired analyses of BL and RD samples, 118 genes (63.8%) were differentially expressed in pts that did not relapse, while only 3 genes (1.6%) were differentially expressed in pts that relapsed.

Conclusions:
These data suggest that HER2DX risk-score in RD provides additional information on the likelihood of developing distant recurrences. In RD, high expression of immune and luminal genes was associated with a reduced risk, while high expression of proliferation genes was associated with a higher risk. Molecular changes after anti-HER2 therapy were mainly observed in RD of pts that did not relapse. Prognostic impact of HER2DX downstaging merits further evaluation.

#5214 HYAL4 splice variant induces treatment-resistance in advanced bladder cancer.

K. Aguilar, S. Panda, J. Van Der Eerden, L. Lopez, M. Terris, P. Santamaria, B. Lokeshwar, V. B. Lokeshwar;
Augusta University, Augusta, GA

Introduction and Objective: Precision-based treatment approaches could improve the prognosis of patients with bladder cancer (BC). We recently discovered a first-in-class human Chondroitinase (Chase) that degrades chondroitin sulfate. This Chase is a splice variant of HYAL4 (V1) and promotes a malignant phenotype and chemoresistance in BC cells. We evaluated V1/Chase expression and functions in BC and inhibitors to overcome V1/Chase-mediated Gemcitabine (Gem) resistance.

Methods: Cohort 1: 653 voided urine specimens (BC, 160; non-BC, 493); cohort 2: 40 cystectomy specimens from MIBC patients who received adjuvant Gemcitabine plus cisplatin (G+C) treatment. Gene expression was measured by q-PCR and urine was assayed by the Chase test. V1 was expressed in BC cell lines or silenced and the transfectants were analyzed for sensitivity to Gem and Cisplatin. The mechanism of Gem resistance was evaluated in preclinical *in vitro* and *in vivo* models.

Results: In cohort 1, Chase levels were 7-10-fold elevated in patients with BC compared to patients with benign genitourinary conditions, history of BC, or other cancers. Chase test detected BC with 94.4% and 87.4% specificity. Chase test had 84% accuracy in correctly diagnosing the cases with atypical cytology inference. Stem cell marker CD44 was the major substrate of Chase in BC cells. V1's Chase activity induced CD44 cleavage and shedding. Intracellularly, CD44 cleavage induced JAK2/Stat3 pathway and subsequently upregulation of cytidine deaminase. CDA induces Gem metabolism and efflux of dFdU, an inactive Gem metabolite. HPLC analysis showed, V1 transfectants have increased levels of dFdU and higher efflux. STAT3 and CDA inhibitors synergistically re-sensitized V1-expressing cells to Gem. In cohort 2, V1, p-JAK2 and CDA expression predicted failure to G+C treatment ($P<0.0001$). JAK2, STAT3 and CDA inhibitors synergistically re-sensitized V1-expressing cells to Gem. V1-induced muscle invasive tumors that were metastatic. While V1-expressing tumors were resistant, combination of Gem with a CDA or JAK-2 inhibitor abrogated V1 tumor growth with minimal toxicity.

Conclusion: V1/Chase is a potential diagnostic and prognostic biomarker for bladder cancer and drives muscle-invasion, metastasis, and Gem resistance in BC. Inhibitors of the Chase signaling pathway overcome V1-induced Gem resistance, suggesting a precision-based treatment approach to improve treatment response.

#5215 Orphan noncoding RNA (oncRNA) liquid biopsy assay is prognostic for survival in patients with triple-negative breast cancer (TNBC) and residual disease.

R. Yoder[1], J. Yen[2], M. Karimzadeh[2], J. M. Staley[1], I. Fernandez[3], A. C. Heinrich[3], F. Hormozdiari[2], J. Gregg[2], A. K. Godwin[4], I. Acerbi[2], R. Trivedi[2], B. Alipanahi[2], S. R. Stecklein[4], P. Sharma[3],

[1]The University of Kansas Cancer Center, Westwood, KS, [2]Exai Bio, Inc., Palo Alto, CA, [3]University of Kansas Medical Center, Westwood, KS, [4]University of Kansas Medical Center, Kansas City, KS

Introduction: Residual disease (RD) after neoadjuvant systemic therapy is associated with high recurrence risk in patients with TNBC. oncRNAs are a novel category of small RNAs that are largely absent in healthy tissue but enriched in tumors and can be detected using a blood-based assay. This study investigated impact of an oncRNA recurrence risk model on outcomes in TNBC patients with RD.

Methods: Study population included stage I-III TNBC patients with RD and available end-of-treatment (EOT) serum samples who were enrolled in a multisite prospective cohort study. EOT samples were collected after completion of all curative treatment (local/systemic). Small RNAs were isolated from EOT serum, sequenced at average depth of 76.5 ± 12.5 million 50bp single end reads, and annotated using a bespoke bioinformatics pipeline to identify oncRNAs. Cancer risk scores were generated using an oncRNA based tumor detection artificial intelligence model trained on 451 treatment naive breast cancer samples and 470 samples from individuals without known cancer diagnosis. Score cutpoint for high vs low recurrence risk was determined through ROC analysis. Impact of EOT oncRNA risk category on event free survival (EFS) and overall survival (OS) was estimated by Kaplan Meier method and compared by log rank test followed by Cox regression. Residual cancer burden (RCB) was determined according to classification by Symmans et al.

Results: oncRNA isolation/score generation was successful for 79 out of 80 TNBC patients with RD and available EOT serum sample. Median age was 48 years and 39% had node positive disease. RCB class distribution was as follows: RCB I=27%, RCB II=49%, RCB III=18%. Training set (n=39) was used to define oncRNA risk score cutpoint. In the testing set (n=40), 38% were classified as oncRNA high-risk and 62% as oncRNA low-risk. oncRNA risk category was not associated with baseline T stage, nodal status, or RCB class. oncRNA high-risk status was associated with lower EFS and OS; 3y EFS was 47% and 73% (HR 2.76, 95% CI 0.92-9.24, p=0.058) and OS 53% and 76% (HR 3.78, 95% CI 1.19-12.00, p=0.016) in high and low risk groups, respectively. In multivariable analysis including oncRNA risk status, T stage, nodal status, and RCB class, oncRNA high risk status retained significant association with lower EFS (HR 7.70, 95% CI 1.33-44.64, p=0.023) and OS (HR 7.99, 95% CI 1.36-47.00, p=0.022).

Conclusion: EOT oncRNA liquid biopsy assay was independently prognostic for outcomes in TNBC patients with RD. More than half of patients in the oncRNA high-risk group suffered an EFS event by 3 years. oncRNA risk score has potential to provide prognostic utility complementary to clinicopathologic characteristics in patients with TNBC. These findings should be confirmed in other TNBC studies and may provide insights for patient stratification/selection in RD adjuvant therapy intensification trials.

#5216 Peripheral T cell receptor repertoire diversity is associated with outcome in bladder cancer.

A. Kjar[1], N. Kristjansdottir[1], I. Nordentoft[1], R. Juul[1], K. Birkenkamp-Demtroder[1], J. Ahrenfeldt[1], D. Hodgson[2], C. Abbosh[2], H. Aerts[3], M. Agerbak[4], J. Jensen[4], N. Birkbak[1], L. Dyrskjot[1];

[1]Aarhus University, Aarhus, Denmark, [2]AstraZeneca, Cambridge, United Kingdom, [3]Harvard Medical School, Boston, MA, [4]Aarhus University Hospital, Aarhus, Denmark

Bladder cancer is the sixth most common cancer overall, and treatment often involves removal of the bladder, which comes with a significant reduction in quality of life. Within this cancer type, an easily applicable prognostic biomarker may have clinical utility, potentially stratifying patients into bladder-sparing treatments. Expansion of T cell populations targeting cancer-specific neoantigens is an early response to malignancy. To investigate if the T cell receptor (TCR) repertoire could serve as a biomarker for cancer progression, we analyzed the TCR landscape in a cohort of 119 patients with muscle-invasive bladder cancer, treated with neoadjuvant chemotherapy before undergoing radical cystectomy.

Peripheral and tumor TCR repertoires were produced using amplicon-based sequencing of the TCR beta chain. Additionally, T cell fraction was determined from whole exome sequencing data using TcellExTRECT, and latent viral DNA was investigated in plasma whole genome sequencing data using Kraken2. Antigen targets were estimated using GLIPH2. To explore the T cell repertoire subtypes, single-cell sequencing was performed on four fresh blood samples.

In pre-treatment peripheral blood, low-diversity TCR repertoires were associated with worse survival (HR=2.3, p=0.024). Particularly poor outcome was observed in a subset of patients with both low TCR diversity and low fraction of circulating T cells (HR=4.7, p=5e-4). Low-diversity repertoires were dominated by expanded T cell clones. TCR target annotation revealed that expanded T cell clones disproportionately targeted latent viral infections (p=2e-13), and cytomegalovirus DNA detection was strongly associated with decreased TCR diversity (p=5e-5). Additionally, tumor TCR sequencing revealed that expanded clones were rarely found in the tumor. Single-cell sequencing of peripheral blood found that most expanded clones consisted of cytotoxic T cells, while non-expanded clones mostly consisted of naive T cells. This indicates that low TCR diversity may represent a contraction of the naive T cell compartment, resulting in reduced immune competence. Finally, analysis of patient-matched longitudinal samples revealed that chemotherapy and cystectomy reduced TCR diversity in patients with high pre-treatment diversity (p=0.001), indicating that treatment negatively affected the immune system in the most immune-competent patients.

Our results suggest that both low TCR diversity and low T cell fraction represent decreased immune competency. This could be associated with an elevated risk of progression due to a reduced ability to control cancer growth and limit systemic cancer cell dissemination. These findings underline that immune health is an important factor during malignant disease, even when patients are not treated with immunotherapies. Therefore, improving immune health could be a potential future goal for cancer treatment and prevention.

#5217 Genome instability in renal tumors.

Hanbyul Cho, Ginny X. Li, Rahul Mannan, Noshad Hosseini, Yi Hsiao, Yuping Zhang, Aniket Dagar, Chandan Kumar-Sinha, Marcin P. Cieslik, Saravana M. Dhanasekaran, Alexey I. Nesvizhskii, Arul M. Chinnaiyan, Clinical Proteomic Tumor Analysis Consortium

University of Michigan Medical School, Ann Arbor, MI

Genome instability (GI), a recognized cancer hallmark, encompasses CNV burden, tumor mutational burden (TMB), and microsatellite instability and is variably associated with several clinical/ prognostic features in solid tumors. GI and intratumor mutational heterogeneity in clear cell renal cell carcinoma (ccRCC) were associated with poor prognosis in a large multi-site sequencing study. As 10-15% of renal tumors exhibit copy number burden associated GI, the development of proteogenomic biomarkers to identify this subset of tumors will be of high clinical value. In our in-depth analysis of CPTAC renal cancer cohorts namely, ccRCC discovery and rare RCC, we first estimated absolute copy number using CNVEX TPO analysis pipeline. Copy number burden-based genome instability was estimated by calculating whole genome instability index (wGII) from DNA sequencing data, in addition to the estimation of genome ploidy and purity of the tumors. Genome instability was associated with survival outcomes in both ccRCC and rare RCC (Ref. 1 and 2). Differential proteogenomic analysis identified IGF2BP3, IGF2BP1, PYCR1 RNA and protein, to be upregulated among high wGII tumors. High wGII tumors showed upregulation of cell proliferation and other cell cycle/proliferation concepts in gene set enrichment analysis. Interestingly, transcriptional module analysis revealed transcription factors and target genes specifically upregulated in GI cases and this pattern showed certain degree of overlap to 9p loss ccRCC tumors (another molecular ccRCC subset that is also associated with poor prognosis). Differential expression analysis also identified, kinases, phosphosites and co-regulated kinase-substrates that are dysregulated in genome instable renal tumors. IGF2BP3 immunohistochemistry staining showed specific overexpression in high wGII tumors and the high positivity was observed exclusivity in the tumor cells. Prognostic biomarkers IGF2BP3, IGF2BP1, PYCR1, and UCHL1 show great promise to be developed as clinical prognostic assays and warrants additional characterization.

#5219 Loss of chromosome Y is unrelated to the composition of the tumor microenvironment and patient prognosis in muscle-invasive urothelial bladder cancers.

M. Kluth[1], H. Plage[2], S. Hofbauer[2], K. Furlano[2], S. Weinberg[2], A. Franz[2], A. Fendler[2], F. Ro?ner[2], S. Schallenberg[2], S. Elezkurtaj[2], N. C. Blessin[1], M. Lennartz[1], A. H. Marx[3], H. Samtleben[3], M. Fisch[1], M. Rink[4], M. Slojewski[5], K. Kaczmarek[5], T. Ecke[6], S. Koch[6], N. Adamini[7], R. Simon[1], G. Sauter[1], J. Weischenfeldt[8], T. Klatte[6], S. Minner[1], D. Horst[2], T. Schlomm[2], D. Zecha[7];

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany, [3]Academic Hospital Fuerth, Fuerth, Germany, [4]Marien Hospital Hamburg, Hamburg, Germany, [5]Pomeranian Medical University, Szczecin, Poland, [6]Helios Hospital Bad Saarow, Bad Saarow, Germany, [7]Albertinen Hospital, Hamburg, Germany, [8]Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany, Biotech Research & Innovation Center (BRIC), University of Copenhagen, Copenhagen, Denmark

Background: Loss of chromosome Y (LOY) occurs commonly in cancers of male patients. It was recently proposed to be associated with cancer aggressiveness and altered T-cell function in bladder cancer and it was found to be linked to poor prognosis in a TCGA bladder cancer patient cohort of 300 patients based on a combined analysis of RNAs from Y-chromosome genes. In this study, we aimed to clarify the clinical relevance of LOY in a large cohort of urothelial bladder cancer patients by using fluorescence in-situ hybridization (FISH).

Design: X and Y chromosomes were analyzed by FISH on a tissue microarray (TMA) containing 1,819 urothelial carcinomas of the urinary bladder from male patients including 487 patients who had undergone cystectomy for muscle-invasive disease and for which follow-up data were available. Data of tumor microenvironment parameters were obtained in a previous study.

Results: LOY was found in 26.0% of 1,479 analyzable cancers. In the subset of non-invasive cancers, the frequency of LOY increased from pTaG2 (14.5%) to pTG3 (28.6%) but these differences were not significant (p=0.1015). In muscle-invasive cancers, the frequency of LOY increased slightly from pT2 (25.4%) to pT4 cancers (32.8%) but this association was again not significant (p=0.1868). Within pT2-4 cancers, LOY was associated with venous invasion (p=0.0010) but unrelated to pT, pN, and L-status, as well as to overall, recurrence-free, and cancer-specific survival. Muscle-invasive urothelial carcinomas with and without LOY did not show significant differences in the number of CD8 positive lymphocytes, the fraction of CD8 positive intraepithelial lymphocytes, the number of macrophages and dendritic cells, as well as the fraction of t helper and t regulatory cells.

Conclusion: FISH is the gold standard for determining LOY. That LOY was neither associated with histopathological parameters of cancer aggressiveness and patient prognosis nor with any parameters describing the tumor microenvironment strongly argues against a driving role of LOY for bladder cancer progression and cancer associated immune reaction. The slight increase of LOY from pTaG2 to pT4 cancers is consistent with a continuous (but clinically irrelevant) loss of the dispensable Y chromosomes during tumor evolution over time.

#5220 Reduced expression of Glutathione peroxidase 2 (GPX2) is an independent predictor of poor prognosis in muscle-invasive urothelial carcinoma of the bladder.

H. Plage[1], S. Hofbauer[1], K. Furlano[1], S. Weinberger[1], A. Franz[1], A. Fendler[1], J. Weischenfeldt[2], F. Ro?ner[1], S. Schallenberg[1], S. Elezkurtaj[1], M. Kluth[3], A. H. Marx[4], H. Samtleben[5], M. Fisch[3], M. Slojewski[6], K. Kaczmarek[6], T. Ecke[7], S. Koch[7], N. Adamini[8], R. Simon[3], G. Sauter[3], H. Zecha[8], T. Klatte[7], S. Minner[3], D. Horst[1], T. Schlomm[1], M. Rink[9], **M. Lennartz**[3];

[1]Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany, [2]Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany Biotech Research & Innovation Center (BRIC), University of Copenhagen, Copenhagen, Denmark, [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [4]Academic Hospital Fuerth, Hamburg, Germany, [5]Academic Hospital Fuerth, Fuerth, Germany, [6]Pomeranian Medical University, Szczecin, Poland, [7]Helios Hospital Bad Saarow, Bad Saarow, Germany, [8]Albertinen Hospital, Hamburg, Germany, [9]Marien Hospital Hamburg, Hamburg, Germany

Background: The Glutathione peroxidase 2 (GPX2) is a selenium-dependent glutathione peroxidase with a pivotal role in removing potentially harming reactive oxygen species (ROS) from cells by catalyzing the reduction process of hydrogen peroxide to water. GPX2 is strongly expressed in normal urothelium but can be reduced in urothelial cancer. The aim of the study was to evaluate the potential clinical significance of GPX2 expression in urothelial bladder cancer.
Design: GPX2 was analyzed by immunohistochemistry (IHC) in more than 2,500 urothelial bladder carcinomas in a tissue microarray format. Follow-up data were available for more than 600 patients with muscle-invasive disease.
Results: GPX2 staining occurred in 67.5% of urothelial carcinomas including 11.4% with weak, 11.9% with moderate, and 44.2% with strong staining. While GPX2 staining was always strong in normal urothelium, it decreased markedly during grade and stage progression. Within pTa tumors, GPX2 positivity continuously decreased from pTaG2 low grade (99.4% positive) to pTa G2 high grade (97.2% positive) and to pTa G3 (90.5%; p=0.0013) while there was a marked further drop of GPX2 positivity from pTaG3 to muscle-invasive cancers (56.6%; p<0.0001 for pT2-4 vs. pTa G3). Within pT2-4 carcinomas, low or absent GPX2 staining was significantly linked to poor overall survival (p=0.0140), V1 (p<0.0001), L1 (p=0.0014), and high grade (p=0.0091), but statistically unrelated to pT and pN. In a multivariate analysis, the prognostic impact of reduced GPX2 expression (p=0.0081) was independent of pT (p<0.0001) and pN (p<0.0001) in pT2-4 tumors. GPX2 expression loss was inversely related to the expression of the luminal subtype markers GATA3 (p<0.0001), uroplakin 1b (p<0.0001) and cytokeratin 20 (p<0.0001) in pT2-4 carcinomas.
Conclusion: GPX2 expression loss is a common event during bladder cancer progression which is strongly associated with poor prognosis in patients with pT2-4 urothelial carcinomas. GPX2 expression measurement - optimally together with other markers - could be useful for clinical risk assessment of bladder cancer patients.

#5221 TTF-1 status in early-stage lung adenocarcinoma is an independent predictor of relapse and survival superior to tumor grading.

S. Schallenberg[1], G. Dernbach[1], M. Dragomir[1], G. Schlachtenberger[2], K. Boschung[3], C. Friedrich[1], K. Standvoss[4], L. Ruff[4], P. Anders[5], C. Grohe[6], W. Randerath[3], S. Merkelbach-Bruse[2], A. Quaas[2], M. Heldwein[2], U. Keilholz[1], K. Hekmat[2], J. Ruckert[1], R. Buttner[2], D. Horst[1], F. Klauschen[7], N. Frost[1];
[1]Charite - University Medicine Berlin, Berlin, Germany, [2]University Hospital Cologne, Cologne, Germany, [3]Bethanien Hospital, Cologne, Germany, [4]Aignostics GmbH, Berlin, Germany, [5]Semmelweis University, Budapest, Hungary, [6]Protestant lung clinic Berlin, Berlin, Germany, [7]Ludwig-Maximilian University of Munich, Munich, Germany

Background: Thyroid transcription factor 1 (TTF-1) is expressed in 70% to 80% of lung adenocarcinomas (LUAD). Several papers revealed that TTF-1 expression is associated with better patient outcomes independent of the tumor stage. However, it is unknown whether the prognostic impact of TTF-1 only results from a different growth pattern (tumor grading) or is independently associated with a biologically more aggressive phenotype. Thus, we analyzed a large bi-centric cohort of LUAD to assume the true prognostic value of TTF-1 in relation to the tumor grade.
Methods: We collected a large, real-life cohort of 447 patients with completely resected LUAD from two large-volume German lung cancer centers. TTF-1 status, evaluated by IHC, and tumor grading were correlated with clinical, pathologic, and molecular data, as well as patient outcomes. Kaplan-Meier curves were used for comparison of TTF-1 status and different tumor grades in terms of the DFS. The impact of TTF-1 was measured by univariate and multivariate Cox regression. Finally, a causal graph analysis was performed to identify and account for potential confounders to improve the statistical estimation of the predictive power of TTF-1 expression for DFS in comparison to the tumor grade.
Results: Kaplan-Meier curves revealed that TTF-1 positivity is associated with longer DFS independent of tumor grade, whereas a strong association of DFS with the tumor grade is observed only in TTF-1-positive patients. In univariate analysis, TTF-1 positivity was associated with significantly longer DFS (median log HR -0.83 [-1.43; -0.20]; p=0.018), whereas higher tumor grade showed a non-significant association with shorter DFS (median log HR 0.30 [-0.58; 1.60]; p=0,62 for G1 to G2 and 0.68 [-0.24; 1.89]; p=0,34 for G2 to G3). In multivariate analysis, TTF-1 positivity resulted in a significantly longer DFS (median log HR -0.65 [-1.13; -0.09]; p=0.05) independent of all other parameters, including tumor grade. Applying the adjustment sets suggested by the causal graph analysis, the superiority of TTF-1 (median log HR -0.86 [-1.25; -0.41]) over tumor grade (median log HR 0.31 [-0.32; 1.30]/ 0.61[-0.07; 1.65]) in terms of prognostic power was confirmed.
Conclusion: This study draws three important conclusions: Firstly, it indicates that the prognostic power of tumor grade is limited to TTF-1-positive patients. Secondly, it underlines the independent prognostic value of TTF-1 expression for DFS regardless of tumor grade. Finally, our analyses reveal that the effect size of TTF-1 surpasses that of tumor grade. To transfer the results directly into the clinical area, we recommend distinguishing between TTF-1-positive and TTF-1-negative LUADs in the pathological report. Tumor grading should only be applied to TTF-1-positive LUADs (TTF-1+ / G1-3). TTF-1-negative LUADs should either not be graded or always be classified as high-grade (TTF-1- / G3).

#5222 AI-driven, mIF-based cell-omics reveals spatially resolved cell signature for outcome prediction in NSCLC patients.

S. Schallenberg[1], G. Dernbach[1], S. Ruane[2], C. Bohm[2], L. Ruff[2], K. Standvoss[2], S. Ghosh[2], M. Frentsch[1], M. Dragomir[1], R. Fritz[1], I. Koch[1], C. Friedrich[1], I.-K. Na[1], S. Merkelbach-Bruse[3], A. Quaas[3], N. Frost[1], K. Boschung[4], W. Randerath[4], G. Schlachtenberger[3], M. Heldwein[3], U. Keilholz[1], K. Hekmat[3], J. Ruckert[1], R. Buttner[3], A. Vasaturo[5], D. Horst[1], M. Alber[2], F. Klauschen[6],

[1]Charite - University Medicine Berlin, Berlin, Germany, [2]Aignostics GmbH, Berlin, Germany, [3]University Hospital Cologne, Cologne, Germany, [4]Bethanien Hospital, Cologne, Germany, [5]Ultivue, Cambridge, MA, [6]Ludwig-Maximilian-University of Munich, Munich, Germany

Background: Despite the rapidly increasing number of new targeted and immunotherapeutic options over the past two decades, the prognosis of patients with NSCLC, even with early-stage tumors, is still poor and novel biomarkers are needed to better stratify patients in terms of survival and treatment response. A novel approach is to gain a holistic understanding of the cellular composition and formation of the tumor microenvironment (TME). Therefore, we developed a miF-based, AI-driven approach for spatially resolved TME characterization at the cellular level and used this to successfully predict clinical outcome.

Methods: We assembled a large bicentric real-world sample group of 1168 patients with resected NSCLC from the Charite and the University Hospital Cologne. For tissue microarray construction, four 1.5 mm tissue cores were punched from each formalin-fixed and paraffin-embedded tumor block. Sections were stained with a 12-plex IF panel followed by H&E staining. All stains were scanned and co-registered with single cell accuracy. Next, we trained a H&E-based tissue segmentation model to detect the different tumor regions: carcinoma, stroma, and necrosis. In addition, we developed a nucleus-based cell detection model, and 12 cell classification models to categorize each detected cell by single-miF channels. Different cell phenotypes were derived from the marker-specific cell classifications. Finally, we trained a model on the Charité cohort using the spatially resolved cell readouts, spot-wise phenotype log-density, co-clustering of marker expression, and frequency of co-occurrence of marker expression through Delaunay triangulation, to predict patient survival on the Cologne cohort.

Results: The tissue segmentation model achieved a macro averaged F1 score of 92%. The cell detection model identified a total of 53 million cells that were classified marker-wise with an F1 score of at least 95% on hold-out data. Our final prediction model identified a stable spatially resolved cell signature, consisting of 10 different characteristic cell neighborhood niches, which could be used to predict overall patient survival. The model trained on the Charite cohort was validated with the Cologne cohort and achieved a high performance (C-score of 71). In comparison, the UICC8 stage and the immunoscore ($CD20^{\pm}CD3^{\pm}$/carcinoma cell ratio), which were used as a baseline, achieved C-scores of 63 and 54, respectively.

Conclusions: The combination of our large real-world clinical cohort, multiplex panel, and automated AI approach enabled a broad spatially resolved exploration of the TME in NSCLC at single cell resolution. Our model identified a specific cell neighborhood signature predictive of patient survival outperforming the commonly used prognostic scores, UICC8 stage and immunoscore. This allows for an improved patient stratification with potential implication for therapy selection.

#5226 A 3D ECM embedded tumoroid platform for testing antibody drugs and engineered TCRs for immune oncology.
E. H. Danen;
Leiden Univ., Leiden, Netherlands

We developed a screening platform for immune oncology using an assay based on automated image guided injection of tumoroids in wells of multi-well plates preloaded with a collagen-rich ECM. The identical x-y-z position and size of the ECM-embedded tumoroids in each well facilitates automated real time confocal microscopy and quantitative image analysis algorithms. The model is used to generate quantitative data for T cell recruitment to tumoroids and killing of tumoroids by T cells. We have applied this to screening a panel of CD3:Her2 bispecific antibodies (BsAb) binding with different affinities to CD3 or Her2 or displaying high affinity interactions with different epitopes on Her2. Exposure to fresh, non-activated peripheral blood mononuclear cell (PBMC) derived T cells shows an initial phase of random T cell movement throughout the ECM followed by a BsAb-dependent phase of active T cell recruitment to tumoroids (day 2-4) and a subsequent phase of tumoroid killing (day 4-6). We show that the wave of T cell recruitment following initial T cell-tumoroid contact involves chemotactic signaling. Decreased affinity at the Her2 or CD3 arm can be compensated for by increasing BsAb concentrations. However, we detect major differences in efficacy for different high affinity epitopes. I.e., of two BsAbs interacting with high affinity with distinct Her2 epitopes and each causing effective tumor cell killing in 2D co-culture, only one was able to trigger a wave of T cell recruitment and subsequent tumoroid killing in 3D. We have applied the same setup to testing the efficacy of T cells expressing engineered TCRs aimed at application in adoptive T-cell therapy. Kinetics of experiments using these activated engineered T cells are considerably shorter (24 hours instead of ~6 days) but show a similar pattern of T cell recruitment and subsequent tumoroid killing. We demonstrate successful generation of quantitative data for T cell recruitment and tumoroid killing for engineered T cells targeting tumor antigens expressed on TNBC and uveal melanoma tumoroids.

#5227 Gamma-delta (γδ) CAR-T cells lacking the CD3ζ signaling domain enhance targeted killing of AML cells and preserve healthy tissues.

L. Ding, Y. Li, J. Li, M. Ter Haak, L. Lamb, Jr.;
IN8bio, New York, NY

Chimeric antigen receptor T cell (CAR-T) therapy has shown remarkable efficacy against B cell malignancies, offering hope to patients with limited treatment options. However, extending this therapy to myeloid malignancies and solid tumors has proven challenging due to co-expression of targetable antigens on hematopoietic progenitors and healthy tissues. In this context, γδ T cells show promise, as they can directly identify and eliminate malignant cells via recognition of multiple tumor-associated stress antigens rarely expressed on normal tissues. We leveraged the tumor-sensing capabilities of γδ T cells with enhanced tumor localization by employing a non-signaling CAR (nsCAR) that excludes the CD3ζ domain, facilitating targeted tumor cell killing while sparing healthy tissues. We designed second-generation lentiviral constructs for anti-CD33-scfv for *in vitro* evaluation against acute myeloid leukemia (AML) lines HL-60, KG-1a, and MOLM-13 and the chronic myeloid leukemia (CML) line K-562 Additionally, we tested CD33/CD123 dual-targeting nsCAR constructs (ns-dCAR) to determine if the addition of CD123 targeting enhanced the therapeutic index. We also tested whether a secreted IL-15 (sIL-15) would enhance CAR-T cell fitness. We observed significant upregulation of CD69 in Jurkat cells transduced with signaling CARs in co-culture with KG-1a cells but not in those with nsCAR constructs. We also noticed a time-dependent reduction (43%) in the CD3ζ+ CD33CAR+ population over a 7-day extended coculture while the nsCAR+ Jurkat population remained stable, suggesting potential mitigation of activation-induced cell death (AICD). Expanded and activated γδ T cells from healthy donors were then transduced with nsCAR lentiviral vectors. The ns33CAR+ γδ T cells exhibited enhanced killing capability against HL-60 (up to 1.3x) and K-562 (up to 1.6x) compared to unmodified γδ T cells (UTD) in a 24-hour cytotoxicity assay. Incorporation of sIL-15 into the nsCD33 CAR construct also increased killing across all 4 cell lines (up to 1.8x for HL-60, up to 2.6x for KG-1a, up to 2.0x for MOLM-13 and up to 2.0x for K-562). Minimal cytotoxicity (<10%) was observed for nsCARs or UTDs against normal CD33+/CD123+ cells from healthy donor PBMC or CD34+ HPSCs. The ns-dCAR constructs did not improve in vitro AML killing compared to ns33CAR alone, although ns-dCARs generally exhibited lower transduction efficiency. In summary, our findings suggest that combining nsCAR constructs with γδ T cells may widen the therapeutic window to expand the reach of CAR-T therapy to cancers with limited target antigen expression on critical healthy tissues. Further optimization to improve integration and incorporation of membrane-bound IL-15 co-expression holds the potential to enhance both the efficacy and safety profiles of next-generation adoptive cell therapies against a broader spectrum of cancers.

#5228 Engineering CD123-targeting vδ1-enriched γδT cells with enhanced preclinical efficacy and safety profile.

M. Ng, S. L. Hayward, D. Zhang, G. Gu, B. Paulhus, D. Gjuka, C. Crowley, S. McLaughlin, A. Lublinsky, A. Mathew, E. Berreondo Giron, D. Mai, M. Lee, M. Wal, R. Alade, A. Simoes, R. Lytle, J. Gavin, S. Cramer, Z.-h. Yan, T. Hickman, R. Choudhary, C. Abikoff, Y. Wang, I. Kovacs, N. M. Sobhana, L. Cao; Takeda Development Center Americas, Inc, Cambridge, MA

Acute myeloid leukemia (AML) is an aggressive hematological malignancy that, despite advances in treatment, has an overall 5-year survival rate of less than 30%. There is an urgent unmet need for new and effective therapies for AML. Chimeric antigen receptor (CAR)-modified cell therapies are emerging as promising options. However, the selection of suitable antigens is challenging, due to the heterogeneous expression of potential antigen targets in AML. Most antigens, such as CD123, are expressed on both leukemic cells and normal hematopoietic stem and progenitor cells. In addition, conventional autologous or allogeneic T cell therapies present many limitations, such as cytokine release syndrome (CRS) and graft-vs-host disease (GvHD). We therefore evaluated CD123-targeting CAR designs in vδ1-enriched γδT cells, an innate immune cell platform that is inherently non-MHC restricted, has low risks of CRS and GvHD, and is capable of discriminating between malignant and healthy cells in preclinical models.

We engineered vδ1-enriched γδT cells from peripheral blood of healthy individuals to express various CD123-targeting CAR constructs. The CD123-targeting CAR-engineered vδ1-enriched γδT cells expressed high levels of natural cytotoxicity receptors, suggesting capability to target innate receptor ligands on AML cell surface. CD123-targeting CAR-expressing vδ1-enriched γδT cells demonstrated enhanced cytotoxicity in vitro against multiple AML cell lines, in both short-term co-culture and repeated antigen stimulation assays. CD123-targeting CAR-expressing vδ1-enriched γδT cells also showed enhanced efficacy and survival in vivo against mouse models of human AML. Interestingly, attenuation of CAR activity via novel designs preserved the inherent selectivity of vδ1-enriched γδT cells against AML cells relative to normal hematopoietic stem or progenitor cells, which also express CD123.

Together, our results demonstrated through rational CAR designing and engineering in vδ1-enriched γδT cells, an allogeneic cell therapy targeting CD123 can be generated with selective cytotoxicity against AML cells while sparing normal hematopoietic stem cells. Such product designs have the potential to be a transformative therapeutic option for a broad population of AML patients.

#5229 Enhancing solid tumor treatment with engineered blood-derived Vδ1 platform: Safe and effective targeting of mesothelin-expressing tumors with Vδ1 γδT cells.

N. Mohan Sobhana, A. Simoes, S. Edwards, S. Mishra, G. Gu, G. Papadopoulos, S. Kiesgen, R. Alade, L. Li, A. Venuso, J. Kumaran, K. Waddington, T. Huseni, R. Karattil, L. Reynolds, M. Sharif, D. Wotherspoon, C. Tudor, I. Kovacs, M. Rosa Ng, Y. Wang, L. Cao;
Takeda Development Center Americas, Inc., Cambridge, MA

Mesothelin (MSLN) is a solid tumor-associated antigen that has been thoroughly studied and is expressed in several tumor indications that have significant unmet therapeutic needs. Vδ1-enriched γδT cells differentiate themselves from other MSLN-targeted modalities by mitigating the challenges of targeting tumors with heterogeneous MSLN expression through their inherent capability to detect malignant cells while sparing normal cells. The ability to effectively combat cancer cells that express mesothelin is significantly increased by the expression of a chimeric antigen receptor (CAR). Novel armoring is being evaluated to improve engineered Vδ1 persistence in the solid tumor microenvironment. Cytokine armoring, through novel engineering, enhances sensitivity to cytokines and recovers cell fitness that is impaired by 'traditional' cytokine armoring options.

Extensive *in vitro* and *in vivo* safety and efficacy studies were carried out to validate the product's potency. These studies aimed to determine cytotoxicity, expansion, and persistence. MSLN CAR cytokine-armored Vδ1 cells exhibited high post-thaw viability and survival. Furthermore, cytokine-armored Vδ1 cells displayed elevated innate receptor expression and gene-engineered cells maintained their baseline innate phenotype, indicating that they can maintain their 'innate' effectiveness over time. *In vitro* studies demonstrated broad anti-tumor activity against multiple tumor cell lines expressing various levels of mesothelin. Additionally, in long-term cytotoxicity assays, cytokine-armored cells demonstrated improved tumor-clearance capabilities. The effector cells also exhibited an enhanced innate cytotoxic phenotype that equips the cells with the capability to persist and proliferate in response to soluble cytokines and upon cytokine trans-presentation by adjacent cells. *In vitro* studies further revealed that there is a distinction in the killing activity between tumor and normal cells, which is important for ensuring that the product is safe for use in patients. An orthotopic lung tumor-bearing mouse model was developed to confirm their anti-tumor effectiveness *in vivo*. The model's outcomes demonstrated that MSLN CAR cytokine-armored Vδ1 cells exhibit higher *in vivo* efficacy in comparison to their unarmored counterparts at low effector-to-target ratios. With no significant healthy tissue damage found, the histopathology report confirmed an excellent safety profile. Terminal biodistribution studies demonstrated that armored drug candidates preferentially home to and persist in tumor-bearing tissues.

Overall, these findings imply that the product might be highly effective in treating tumors that express mesothelin. This strategy could greatly advance our knowledge of how Vδ1-enriched γδT cells function as a platform against solid tumors.

#5230 A modified FcyRI expressing T cell (SolidT) exhibits profound anti-tumor activity followed by maturation into effector memory t cells that can be reactivated to kill a secondary tumor.

S. Dotan[1], N. Pilpel[1], P. Rider[1], H. Shpilt[1], D. Rasoulouniriana[1], Y. Carmi[2], J. E. Wooldridge[3];
[1]Gilboa Therapeutics Ltd., Rehovot, Israel, [2]Tel Aviv University, Tel Aviv, Israel, [3]Gilboa Therapeutics Inc., Cambridge, MA

We previously described a subset of cytotoxic FcyRI (CD64)-expressing T cells in tumors and inflamed tissues (PMID 31449054). We subsequently expressed an engineered modified CD64 into T cells ("SolidT") and demonstrated that these cells possessed greater specificity for tumor over normal tissues, reduced exhaustion, and attenuated cytokine secretion compared to other engineered cell therapies. SolidT activation correlates with surface tumor antigen density enabling the differentiation between tumor cells and normal cells by use of a specific antibody targeting tumor antigens. We previously showed that SolidT + mAb has anti-tumor activity *in vitro* and *in vivo* in several tumor models, including immunodeficient HER2 xenografts and an immunocompetent syngeneic B16-TYRP1 model (PMID 37070661). In this study, we further assessed the effect of SolidT on HER2+ tumors in a rechallenge model and extended the platform to CD20+ lymphoma models by combining SolidT with rituximab. In an *in vivo* experiment using HER2+, NCI-N87 cells in immunodeficient mice, several mice in the SolidT + trastuzumab group experienced complete tumor clearance. These mice were monitored until day 84, then rechallenged with NCI-N87 cells along with a new control group. After tumor establishment, mice were treated only with trastuzumab weekly for two weeks. While tumors in the control group progressed, the tumors in the rechallenged mice were completely cleared with a trastuzumab boost only, suggesting a SolidT cell memory response. Bone marrow from these rechallenged mice was analyzed and revealed the presence of effector memory SolidT cells. The SolidT model was then studied in a human, CD20+ lymphoma model *in vitro* and *in vivo* in immunodeficient mice. SolidT + rituximab was more potent *in-vivo* against CD20+ lymphoma cells than rituximab. *In vivo*, mice treated with SolidT + rituximab had significantly greater survival, lower tumor burden, and fewer sites of metastases than mice treated with rituximab alone. Bone marrow from these mice was analyzed and revealed the presence of effector memory SolidT cells in mice treated with SolidT + rituximab. We demonstrated that marrow resident SolidT cells developed an effector memory phenotype that positively correlated with outcome in HER2+ and CD20+ xenograft models, consistent with earlier data from a syngeneic B16 melanoma model. We further demonstrated that SolidT cells can be reactivated in a rechallenge model with only the addition of tumor targeting mAb, resulting in the eradication of the recurring tumors. This data further confirms that the SolidT platform can be targeted against different tumor antigens by using different tumor targeting mAbs. The SolidT platform could represent a paradigm shift in the approach to engineered cellular therapy for hematological malignancies and solid tumors.

#5231 NK and T cells armed with EVE16, a novel synthetic immune receptor, mediate robust anti-tumor responses through dual direct cytotoxicity and ADCC with minimal trogocytosis and exhaustion.

A. Ali[1], J. D. Ham[2], F. Zairi[3], V. Patel[3], M. Tarannum[1], K. Dinh[1], Y. Abdulhamid[1], J. Vergara[1], R. Soiffer[1], J. Ritz[1], J. Beadle[3], **N. A. Ivica**[3], J. Chen[4], R. Romee[1],

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]InnDura Therapeutics, Cambridge, MA, [4]2. Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Cambridge, MA

Despite the major advances, cancer patients treated with targeted chimeric antigen receptor (CAR)- based T and NK cell therapies often face the challenge of frequent disease relapse, and their efficacy in solid tumors is low. This is attributed to the inherent potency of the starting cell material, unique characteristics of CAR engineering resulting in trogocytosis and tonic signaling, and the notable absence of homogenously expressed surface markers, particularly in solid tumors.

To address these limitations, we engineered a novel synthetic immune receptor termed Enhanced-Valency Engineered CD16A (EVE16) and evaluated it in memory-like NK cells and T cells against liquid and solid tumors. We hypothesized that post-activation cleavage of CD16A by ADAM17 plays a crucial role in reducing trogocytosis and tonic signaling. EVE16 utilizes the inherent potential of CD16A to trigger an activation signaling cascade through the endogenous CD3ζ adaptor signaling protein. Unexpectedly, we discovered that, aside from the CD16A transmembrane domain, the Fc-binding domain is essential for proper surface expression. After multiple rounds of optimization, we developed a receptor that surpassed the activation potency of endogenous CD16A and allowed both direct binding to the tumor targets and retained antibody-dependent cellular cytotoxicity (ADCC), and this dual 'CAR-like' and ADCC function opens the potential for combination with clinically approved antibodies to prevent immune escape. Furthermore, in contrast to the conventional CAR(BBζ), the optimized EVE16 receptor exhibited minimal tonic signaling in both T and NK cells. This translated to enhanced sensitivity towards low antigen-density targets, as demonstrated by a cytotoxicity assay performed on polyclonal cancer cells engineered with target antigen knock-down. Additionally, EVE16, but not CAR transduced, protected T and NK cells from trogocytosis and allowed for the efficient disengagement of cytotoxic lymphocytes from cancer targets due to CD16A cleavage by ADAM17 upon immune cell activation. In *in vivo* mouse xenograft models, CD19-targeted EVE16 memory-like NK cells, rapidly manufactured using our approach, demonstrate outstanding performance in terms of robust expansion, prolonged persistence, and effective leukemic clearance, underscoring the effectiveness of our method.

In summary, we here describe a novel synthetic immune receptor called EVE16 which enables both direct (CAR-like) and ADCC functionality while preventing trogocytosis and exhaustion. Clinical trials are being planned for the near future.

#5232 Placental circulating T cells expressing CD16 in combination with trastuzumab demonstrate robust anti-tumor antibody-dependent cellular cytotoxicity (ADCC) against gastric cancer.

K. Karasiewicz-Mendez, J. Gleason, K. Tess, M. Djedaini, S. Lin, C. Huang, S. He, R. Hariri, A. Kilcoyne;
Celularity Inc., Florham Park, NJ

Introduction: Celularity is developing PT-CD16VS as a novel platform for use in combination with approved monoclonal antibodies for the potential treatment of multiple cancers. PT-CD16VS is an allogeneic cell therapy derived from human postpartum placental circulating T (P-T) cells that are genetically modified to express a proprietary CD16 variant and endogenous T cell receptor (TCR) knockout. Here we report the characterization and preclinical evaluation of PT-CD16VS against HER2+ gastric cancer cells in combination with Trastuzumab. *In vitro* safety studies evaluating the potential for on-target/ off-tumor activity of PT-CD16VS against HER2 low expressing lung epithelial cells (LEC) and human dermal fibroblasts (HDF) are also highlighted.
Methods: P-T cells were activated and transduced with a lentiviral vector containing a CD16 construct expressing a high affinity CD16 variant, CD16VS. Following transduction, P-T cells were transfected to knock out the TCR. *In vitro,* the functional activity of PT-CD16VS cells in combination with Trastuzumab was assessed against the HER2+ gastric cancer NCI-N87 cell line in cytotoxicity, cytokine release, and proliferation assays. For on-target/ off-tumor studies, similar assays were utilized to assess activity against the HER2 low expressing LEC and HDF cell lines. *In* vivo, PT-CD16VS with Trastuzumab was evaluated in a subcutaneous NCI-N87 xenograft model in NSG mice. Tumor volume was measured and tumor samples were evaluated for PT-CD16VS infiltration.
Results: High CD16 transduction efficiency (>60%) was achieved across donors. *In vitro*, PT-CD16VS plus Trastuzumab demonstrated potent cytotoxicity against NCI-N87 cells at low E:T ratios (0.625:1) and at 12 hours of co-culture with moderate cytokine secretion at 24-hour of co-culture. PT-CD16VS proliferated following 48-hour incubation with NCI-N87 cells and Trastuzumab, as compared to an IgG1 control. PT-CD16VS in combination with Trastuzumab did not elicit on-target/ off-tumor cytotoxicity or cytokine release in response to low HER2 expression on normal LEC or HDF cells. *In vivo*, PT-CD16VS with Trastuzumab demonstrated significant reduction in tumor volume compared to vehicle, Trastuzumab alone, and the positive control Enhertu groups. In addition, PT-CD16VS infiltration into the tumor was shown to be Trastuzumab dependent, with infiltrating cells expressing high levels of CD16 and Ki67.
Conclusions: Our results show that PT-CD16VS has robust *in vitro* and *in vivo* ADCC activity against gastric cancer tumor cells when combined with Trastuzumab. Furthermore, PT-CD16VS activity is specific to tumor HER2 antigen expression and does not target low HER2 expression on normal healthy cells. PT-CD16VS is being developed in combination with various monoclonal antibodies for the treatment of multiple cancers.

#5233 Engineered NK-like NKG2C+ CD8 T cells mediate superior anti-tumor efficacy over conventional CD8 T cells and NK cells.

K. Lupo, M. Panjwani, A. Daniyan, C. Klebanoff, K. Hsu;
Memorial Sloan Kettering Cancer Center, New York, NY

We have recently characterized a unique CD8 T cell subset that expresses NKG2C, as well as multiple other natural killer cell markers. These NKG2C+ CD8 T cells demonstrate NK-like effector functions against various tumor targets, can be efficiently expanded and engineered using GMP-compatible techniques, and most importantly, display beneficial qualities unique to T and NK cells while minimizing the therapeutic deficits of each. NKG2C+ CD8 cells can be easily expanded using a genetically modified K562 feeder line and can be efficiently engineered via retroviral transduction. We genetically engineered NKG2C+ CD8 T cells to express an anti-CD19-28-z CAR construct to target B cell malignancies and compared effector functions of the CAR-engineered NKG2C+ CD8 T cells against CAR+NKG2C- (conventional) CD8 T cells and CAR+ NK cells in vitro and in vivo. We examined expansion, engineering efficiency, tumor control, and extent of cytokine release syndrome (CRS). We also engineered NKG2C+ CD8 T cells with a transgenic NY-ESO-1 TCR to target melanoma and compared the functional responses and efficacy of TCR-engineered NKG2C+ CD8 T cells against TCR-engineered conventional CD8 T cells. CAR+NKG2C+ CD8 T cells demonstrated superior in vitro effector function when compared to CAR+ conventional CD8 T cells and CAR+NK cells and did not upregulate characteristic T cell exhaustion markers, such as PD-1, TIM-3, and LAG-3. These CAR+NKG2C+ CD8 T cells demonstrated superior control of a CD19+ NALM6 tumor model in NRG mice, which was further enhanced with administration of IL-15. CAR+NKG2C+ CD8 T cells with IL-15 demonstrate dramatic and enhanced persistence, as well as superior cytotoxicity and activation in vivo when compared to CAR+ conventional CD8 T cells and CAR+ NK cells. Using a SCID-beige CRS mouse model, we observed reduced CRS in mice treated with CAR+ NKG2C+ CD8 T cells than in mice treated with CAR+ conventional CD8 T cells, with lower levels of proinflammatory cytokines and minimal expansion of murine myeloid subsets. Similarly, TCR-engineered NKG2C+ CD8 T cells demonstrated enhanced tumor control and in vivo persistence in an A375 melanoma-bearing NRG mouse model compared to TCR-engineered conventional CD8 T cells. We have successfully demonstrated that CAR- or TCR-engineered NKG2C+ CD8 T cells have superior anti-tumor efficacy, in vitro and in vivo, to conventional CD8 T cell and NK cell counterparts due to their innate tumor killing and greater in vivo persistence. These cells mediate less CRS and provide a safer alternative to traditional engineered T cell therapeutics. Ultimately, our NKG2C+ CD8 T cells represent a unique platform for engineered T cell therapies to target both solid tumors and hematologic malignancies, that is easily expanded ex vivo, does not require CD4 T cells for in vivo persistence, and is resistant to exhaustion.

#5234 TGF*beta*-conditioned K-NK cells are able to counter immune suppression in the tumor micro-environment.

A. Kunert[1], A. Oja[1], I. Cesonyte[1], K. Franciszkiewicz[2], S. Sidhu[2], H. Jetani[1], G. Bocconcelli[1], R. Igarashi[1], V. R. Fantin[3];
[1]Sanofi Oncology, Amsterdam, Netherlands, [2]Sanofi Oncology, Vitry, France, [3]Sanofi Oncology, Boston, MA

Recent advances have enabled the use of autologous K-NK cells to treat patients suffering from hematological malignancies. When aiming to treat patients suffering from solid tumors however, the suppressive effects of the tumor microenvironment (TME) and the involvement of other immune cells need to be considered to make a cell therapeutic potentially more effective.
TGFβ-conditioning (TGFβ-c), the co-culture of K-NK cells with low-dose TGFβ while undergoing cytokine-mediated expansion, imbues these cells with unique qualities suitable to mitigate immuno-suppressive effects of the TME, making them more efficacious toward solid tumors. The exposure to TGFβ during expansion results in significant downregulation of SMAD3, rendering these cells insensitive to TGFβ-mediated down-regulation of NK cell receptors. TGFβ-c K-NK cells display enhanced in vitro cytotoxicity towards 2D, 3D cultured cell lines as well as against organoid models derived of various indications. These cells infiltrate into patient-derived tumor organoids at higher frequency and have increased IFNγ secretion upon target-specific activation. The effect of the higher IFNγ output on a complementary anti-tumor immune subset was investigated in complex immune cell cultures and was indeed shown to enhance DC maturation.
In vivo studies revealed prolonged persistence of TGFβ-c K-NK cells in mice while retaining both altered gene-expression and functional hallmarks for up to 28 days, indicating that the conditioning results in a stable phenotype.
In summary, TGFβ-c K-NKs are a platform with enhanced potency to transition cell therapy from treating hematological to solid tumor malignancies.

#5235 Combination STING agonist and NK cellular therapy in patient derived organotypic tumor spheroids.

P. H. Lizotte[1], E. Ivanova[1], S. Park[1], N. Spicer[1], S. Kivlehan[1], I. Gjeci[1], S. Kiesgen[2], V. Appleman[2], L. Talarico[2], M. Y. Tolstorukov[1], R. Bueno[3], D. A. Barbie[1], C. P. Paweletz[1];

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Takeda Pharmaceuticals, Cambridge, MA, [3]Brigham and Women's Hospital, Boston, MA

Background: Increasing the immunogenicity of solid tumors may potentiate durable anti-tumor immunity. Targeting innate pattern recognition receptor signaling is a promising strategy to repolarizing the suppressive tumor immune microenvironment (TME). A potential synergistic approach is the addition of cellular therapy. Tumor models expressing high levels of endogenous STING, but where the pathway is not active, were considered for evaluating STING agonism as a potential intervention. Additionally, prior work has demonstrated that STING induction is toxic to T cells; however, natural killer (NK) cells are unaffected, due to their differential regulation of autophagy. Here we investigate the immunomodulatory properties of STING agonism alone and in combination with NK cells using short-term microfluidic culture of fresh patient-derived organotypic tumor spheroids (PDOTS).

Methods: Surgical cases from Brigham and Women's Hospital under an IRB-approved protocol were studied. PDOTS were generated as previously described. Ex vivo response was assessed by fluorescent live/dead imaging, immunofluorescence (IF), multiplexed cytokine array, and single cell RNA sequencing (scRNAseq). Baseline immune phenotypes were analyzed by FACS from single cells isolated during tumor sample preparation.

Results: Twelve explants were studied. Two specimens were excluded from viability assessment due to excess of fibrotic material and low viability. Using a cut-off of -40%, three cases were characterized as responders (R) and seven as non-responders (NR). We observed significant induction of CXCL10 in all samples treated with STING agonist. IFN-β, IFN-γ, TNF-α, and MIP1-α were also consistently induced by STING agonist treatment. More detailed analysis of two samples by scRNAseq revealed a strong interferon stimulated genes (ISG) signature in STING agonist conditions; the cellular source of CXCL10 secretion in STING agonist treatment was tumor cells and fibroblasts. We also observed profound changes in myeloid biology, indicating that these cells polarized to a more pro-inflammatory and antigen-presenting phenotype with STING agonism. Interestingly, NK-based cell therapy added to PDOTS cultures displayed better persistence and enhanced effector function relative to endogenous NK cells, with and without STING agonism.

Conclusions: Using tumor explants and a variety of orthogonal techniques, we investigated the response to STING agonism and NK cellular therapy ex vivo. Our results indicate that STING agonism remodels the TME, creating a more immune-permissive environment. STING agonism induces secretion of chemoattractant CXCL10 by tumor cells and fibroblasts. STING agonism does not abrogate NK cell effector function and therefore, may synergize with NK cell therapies.

#5236 Adoptive natural killer therapy is effective for synovial sarcoma cell lines..

N. Oike[1], T. Miyazaki[1], Y. Murayama[1], T. Ariizumi[1], A. Ogose[2], M. Baba[1], H. Kawashima[1], C. Imai[3];
[1]Niigata Univ. School of Medicine, Niigata, Japan, [2]Uonumakikan Hospital, Niigata, Japan, [3]Toyama University, Toyama, Japan

Despite the development of multimodal therapy consisting of surgery, radiotherapy, and chemotherapy, the prognosis of patients with metastatic or relapsed synovial sarcoma (SS) remains poor. A novel treatment option including immunotherapy is urgently required. Natural killer (NK) cells are innate immune cells that can recognize and kill tumor cells. The cytolytic activity of NK cells is determined by the balance of signals from both inhibitory and activating receptors expressed on cell surface. Activating receptors include NKp30, NKp44, NKp46, NKG2D, and DNAM-1. Furthermore, tumor cells with low HLA class I expression are potentially even more sensitive to NK-mediated cytotoxic killing due to a lack of inhibitory signals. We previously reported that HLA class I expression was down regulated in one third of patients with synovial sarcoma, suggesting that NK cell therapy may be effective for patients with SS. However, the efficacy of NK cells treatment in SS was not well established. In this study, we evaluated surface ligands for NK cell activation on SS cell lines and demonstrated the effectiveness of activated allogenic NK cells for SS cell lines *in vitro*.The surface expression of ligands for NK cell-activating receptors including NKp30, NKp44, NKp46, NKG2D, and DNAM-1 in three SS cell lines (SYO-I, HS-SY-II, and Yamato-SS) was evaluated using flow cytometry. Peripheral blood from two healthy donors were ficoll-separated to collect peripheral blood mononuclear cells (PBMCs). Then, PBMCs were stimulated with irradiated K562 cells expressing the NK-stimulatory molecules 4-1BB ligand and membrane-bound Interleukin 15 in the presence of human Interleukin-2 in RPMI1640 with 10% FBS. The cells were expanded for 14 days, and the expanded NK cells are CD3-CD56+ NK cells. These expanded cells are reproducible in their function, and we have utilized these cells for *in vitro* cytotoxicity assays. 2x10E4 of SS cell lines (SYO-I, HS-SY-II, and Yamato-SS) were seeded in a 96 well plates and cultured overnight. Then, allogenic NK cells or activated T cells as a control at various tumor effector ratio. The cells were co-cultured with activated T cells or NK cells in the presence of low dose interleukin2. Forty-eight hours later, cell viabilities were measured using WST-8 assay.Ligands for NKp44, NKp30, NK2GD, were expressed in all three SS cell lines. It suggested that SS cells upregulate activating receptor ligands for NK cells. In addition, cytotoxicity of allogenic NK cells for SS cell lines was significantly higher than that of activated T cells. To determine whether cytotoxic activity was effect of allogenic NK cells, CD107a mobilization assay using flowcytometry was performed. CD107a mobilization assay demonstrated degranulation of NK cells, leading us that NK cells had an antitumoral effect on SS cell lines in vitro. Based on these initial findings, we were able to demonstrate that allogenic NK cells may be a promising immune therapy for SS.

#5237 Engineered probiotics direct the antigen specificity of CAR-T cells *in situ*.

R. L. Vincent, F. Li, A. Vardoshvili, C. Gurbatri, N. Arpaia, T. Danino;
Columbia University, New York, NY

Antigen-targeting therapies such as chimeric antigen receptor (CAR)-T cells have achieved unparalleled success in the treatment of hematological malignancies. However, broad success has remained bottlenecked by the lack of targets that are specifically, and uniformly, expressed on heterogenous solid tumors. In contrast, certain strains of bacteria are gaining recognition as a new class of antigen-agnostic cell therapies due to their selective growth within the immuno-suppressive niche of the solid tumor microenvironment (TME). Bridging these approaches, we developed a platform of probiotic-guided CAR-T cells (ProCARs) - in which tumor-colonizing probiotics release synthetic targets that efficiently tag tumor tissue for CAR-mediated lysis. Here, we engineered a well-characterized strain of probiotic bacteria, *E. coli* Nissle 1917, to sustain the intratumoral production of genetically encoded CAR targets and T cell attracting chemokines in multiple xenograft and syngeneic models of human and murine tumors. We design orthogonal CAR targets (Tags) as modified dimers of GFP that broadly anchor to collagens, fibronectins, and heparin sulfates found in high abundance within the solid TME to achieve antigen-agnostic tumor targeting. We demonstrate that Tags robustly coat the surface of cancer cell lines through interaction with cell surface matrix proteins, thus leading to the activation of GFP CAR-T cells and Tag-dependent killing across a panel of genetically distinct target cells. We additionally show that injected probiotics selectively grow within the tumor core and maintain the intratumoral production of Tags and human chemokines - leading to therapeutic efficacy across multiple subcutaneous and orthotopic tumor models. Moreover, we demonstrate a systemic antitumor benefit in immune-competent hosts, whereby unilateral treatment of primary tumors leads to a significant reduction in the growth rate of distal, untreated tumors. Finally, we show that intratumoral bacteria provide natural TLR agonists that trigger substantial activation of human and murine ProCAR-T cells. Our findings highlight the potential of the ProCAR platform to address the critical roadblock of identifying suitable CAR targets by providing an antigen *in situ* that is orthogonal to both healthy tissue and tumor genetics. Altogether, the use of a bacterial delivery platform in the ProCAR system offers a partner organism that naturally enhances CAR-T cell effector function and broadens the scope of CAR-T cell therapy to include previously difficult to target tumors.

#5238 uPAR as a novel immunotherapeutic target in recurrent glioblastoma.

William T. Maich[1], Muhammad Vaseem Shaikh[1], Anish Puri[1], Alisha Anand[1], Chirayu Chokshi[1], Sabra Salim[1], Neil Savage[1], Chitra Venugopal[1], Martin Rossotti[2], Thomas Kislinger[1], Kevin Henry[2], Sheila Singh[1]

[1]McMaster University, Hamilton, ON, Canada,[2]National Research Council, Ottawa, ON, Canada

Glioblastoma (GBM) is the common malignant brain tumor in adults, accounting for approximately 15% of all CNS tumors, and 48.6% of malignant brain tumors, with a median survival of approximately 15 months, and minimal clinical progress having been made in the past two decades. GBM is characterized by extensive inter- and intra-tumoral heterogeneity as well as an extremely immunosuppressive tumor microenvironment. Following Standard-of-Care (SoC) surgical resection and chemoradiotherapy at primary diagnosis, few therapeutic avenues exist at recurrence, owing in part due to a lack of clinically relevant targets. Data from our multi-institutional target pipeline shows that the extracellular urokinase plasminogen activator receptor (uPAR) is significantly upregulated at recurrence on putative GBM brain tumor initiating cells (BTICs), which are believed to drive *de novo* tumor formation, tumor recurrence, and therapeutic resistance. uPAR plays an important role in the plasminogen activation system, and in the context of cancer, has been implicated in numerous pro-tumorigenic processes such as invasion, proliferation, epithelial-to-mesenchymal transition, and therapy resistance. We used CRISPR-Cas9 to genetically delete uPAR from our in-house patient-derived GBM cell lines, and found that *in vitro*, knockout of uPAR expression in recurrent GBM cells significantly reduces proliferation and sphere formation capacity, two stem-like traits associated with BTICs. Additionally, we found that uPAR knockout significantly reduced the frequency of BTICs in a given population. Additionally, uPAR knockout cells display increased sensitivity to standard-of-care chemoradiotherapy, implicating uPAR expression in therapy resistance, as seen in recurrent disease. We orthotopically injected immunocompromised mice to generate patient-derived xenograft models of GBM, and found that knockout of uPAR significantly increases survival, and decreases tumor burden. Further, we generated novel anti-uPAR single domain antibodies (sdAbs) and found that they specifically bind uPAR at low nanomolar concentrations *in vitro*. Using these sdAbs, we created an anti-uPAR CAR T which showed potent cytotoxicity *in vitro*, and drastically reduced tumor burden and extended survival *in vivo*. From this work we believe uPAR to be a clinically relevant target in recurrent GBM, and further investigation into therapeutic strategies to target uPAR-positive GBMs should be investigated further.

#5239 Discovery of AML associated therapeutic targets.

Omar M. Ibrahim, Michael P. Rettig, Reyka G. Jayasinghe, Li Ding, John F. DiPersio

Washington University School of Medicine in St. Louis, St. Louis, MO

Chimeric Antigen Receptor T-cell (CART) immunotherapy has shown significant success in the treatment of hematological malignancies. However, their efficacy in AML is limited due to the disease's genetic diversity and lack of uniform antigen targets. To identify potential AML cell-surface markers, we employed a comprehensive approach that involved the utilization of 3' single-cell RNA sequencing (scRNA-seq), bulk RNA sequencing (RNA-seq), and enhanced whole exome sequencing (eWES). A total of 21 samples were analyzed, comprising 18 distinct AML patients and 3 healthy bone marrow aspirates, serving as controls. We conducted scRNAseq on 21 samples, yielding a total of 185,106 high-quality cells, which were effectively clustered into 38 unbiased groups. Notably, tumor clusters exhibited highest copy number variations and formed separate clusters from other non-tumor immune cells. To uncover key functional pathways, we conducted pathway enrichment analysis comparing tumor cells to non-tumor cells. Our findings demonstrated a significant overrepresentation of cellular processes related to Allograft rejection, IL2/STAT5 signaling, IFN-gamma response and apoptosis. To identify AML specific markers, we performed an unbiased systematic search of the scRNAseq dataset for genes with unique expression patterns in tumor cells compared to the healthy bone marrow controls. Our analysis identified differentially expressed genes, with many genes displaying relative cell and tissue specificity. Notably, among these genes, we unveiled key potential targets with cell surface specificity, including novel markers alongside previously known ones. Noteworthy candidates, such as *ADGRE2, CD33, CD123, CLEC12A*, and *FLT3* and understudied novel markers such as *CD86, CSF1R,* S100 proteins and *VMP1*, were prominently expressed, showcasing their potential significance as targets for engineered immunotherapy. To validate and consolidate our discoveries, we conducted a cross-referencing exercise by comparing our scRNAseq data against bulk RNA data from primary human AML samples and cell lines. Bulk global proteomics, flow cytometry-based and CART generation studies are ongoing to confirm our discoveries. Our rigorous computational and experimental approach provides valuable insights into tumor-specific cell surface proteins, which hold promise as potential targets for innovative and precision immunotherapeutic interventions in the realm of AML treatment.

#5240 Novel CD3-Fusion Receptor enables combination of T-cell engagers and allogeneic CAR T cells to promote enhanced antitumor activity and overcome antigen escape.

D. Lu, **E. Peralta**, H.-Y. Chu, S. Park, M. Tsuda, E. Avramis, M. Denholtz, A. Witty, T. Lee, B. Valamehr;
Fate Therapeutics, San Diego, CA

Chimeric antigen receptor (CAR) T cells have shown remarkable clinical success in the treatment of hematologic malignancies. However, the durability of response of CAR T therapy can be impaired by heterogenous expression of the CAR-specific target antigen (1° Ag) on tumors. In combination with a CAR, T-cell engagers (TCEs) that target additional tumor antigen (2° Ag) can be a unique approach to address tumor heterogeneity and overcome antigen escape. Engineered induced pluripotent stem cell (iPSC) master cell lines are a renewable source material from which iPSC-derived CAR T (CAR-iT) cells can be manufactured and administered in an off-the-shelf manner. In developing allogeneic CAR-iT cells, the T-cell receptor (TCR) must be eliminated to prevent graft-versus-host disease. However, the absence of TCR expression leads to loss of surface CD3 and a corresponding loss of TCE compatibility. Here we discuss a novel CD3ε fusion receptor (CD3-FR) with a modified transmembrane and endodomain, which allows for CD3 surface expression on TCR-less T cells and effective combination of off-the-shelf allogeneic CAR-T cells and TCEs. CAR$^{\pm}$ CD3-FR$^{\pm}$ iPSCs were differentiated into CAR-iT cells, uniformly expressing both modalities (>95% CAR$^{\pm}$, >90% CD3ε$^{\pm}$) and absent of TCR. To demonstrate that CD3-FR$^{\pm}$ CAR-iT cells can elicit TCE-dependent activity, 1° Ag^{-} (CD19^{-}) / 2° Ag$^{\pm}$ (EpCAM$^{\pm}$) target cells were used in cytotoxicity assays. As shown, CD3-FR^{-} CAR-iT cells failed to kill 1° Ag^{-} target cells. In contrast, CD3-FR$^{\pm}$ CAR-iT cells demonstrated potent activity toward the target cells (>80% cytolysis) but only in the presence of the TCE targeting 2° Ag.

To test the ability of CD3-FR$^{\pm}$ CAR-iT cells to mitigate antigen escape, we used a tumor cell population heterogenous for the CAR-specific target (50% 1° Ag^{-}) but homogenous for TCE-specific target (100% 2° Ag$^{\pm}$). In co-culture assays, CD3-FR^{-} CAR-iT cells failed to prevent tumor cell growth due to 1° Ag^{-} tumor escape. However, CD3-FR$^{\pm}$ CAR-iT cells in the presence of TCE exhibited robust control (80% cytolysis) of the heterogenous tumor, mitigating 1° Ag^{-} tumor escape via targeting of 2° Ag. Next, we tested the ability of CD3-FR$^{\pm}$ CAR-iT cells to control heterogeneous tumor *in vivo* in a disseminated leukemia model. As expected, CD3-FR$^{\pm}$ CAR-iT cells exhibited significantly better tumor growth inhibition in the presence of TCE (p-value <0.005) compared to controls lacking the CD3-FR modality. *Ex vivo* analysis of tumor in the bone marrow confirmed 1° Ag^{-} tumor escape in the control treated mice, but not in mice treated with CD3-FR$^{\pm}$ CAR-iT and TCE targeting 2° Ag.

Taken together, these studies present a novel opportunity to leverage a novel CD3 fusion receptor and enable combination of TCEs with engineered off-the-shelf CAR T-cell products, uniquely harnessing two potent therapeutic modalities for improving cancer therapy.

#5241 Generation of allogeneic CAR-T circumvents functional deficits in patient-derived autologous product for glioblastoma.

M. Shaikh[1], S. K. Salim[1], J. Wei[2], W. T. Maich[1], A. A. Anand[1], O. Y. Tang[3], M. K. Subapanditha[1], Y. Suk[1], M. Singh[1], Z. Alizada[1], B. Brakel[1], V. Dimitrov[2], Z. Tabunshchyk[1], K. Brown[2], P. Vora[1], Z. Binder[3], C. Venugopal[1], J. Moffat[2], S. K. Singh[1];

[1]McMaster University, Hamilton, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Perelman School of Medicine, University of Pennsylvania,, Phildelphia, PA

Glioblastoma (GBM) is the most common malignant primary brain tumor in adults. Despite an aggressive standard of care that includes maximally safe surgical resection, chemo-radiotherapy, median overall survival remains stagnant at 15 months. However, immunotherapeutic strategies have provided an exciting avenue of exploration to meet clinical need. Chimeric antigen receptor T-cell (CAR-T) therapy has shown promising results in liquid malignancies, but clinical trials in GBM targeting various tumor antigens have not shown durable clinical benefit. While this may be attributable to various tumor-intrinsic immune evasion strategies characteristic of GBM, little work has assessed whether the issue is due to the quality of the CAR-T treatment itself. Currently, CAR-Ts for clinical studies are manufactured in an autologous setting wherein T-cells are extracted from patients, engineered ex-vivo, and subsequently re-infused back. However, peripheral T-cells taken from untreated GBM patients have demonstrated qualitative and functional deficits, which may contribute to suboptimal treatment outcomes. Thus, we aimed to establish whether CAR-Ts generated from GBM patients would show reduced efficacy in comparison to healthy donors using our previously validated CD133 CAR-T. In this work, we show that in-spite of no inherent phenotypic differences, patient derived CAR-Ts shows pre-treatment exhaustion and upon preclinical evaluation using an orthotopic xenograft model of human GBM reduced survival advantage in autologous, patient-derived CD133-targeting CAR-T cell products was observed as compared to the controls. Transcriptomic analysis highlighted a decreased panel-wide enrichment in genes related to T cell and lymphocyte activation, lower prevalence of T cells (including Th1 and CD8+) and higher prevalence of exhausted CD8+ cells in T-cells products derived from GBM donors as compared to healthy donors. To overcome the functional and logistical considerations of autologous therapy, we additionally aimed to generate an “off-the-shelf” allogeneic CD133 CAR-T. Using CRISPR gene editing technology, we generated TCR-knockout CAR-T cells with comparable pre-clinical efficacy to our autologous models. In conclusion, this work highlights the need to reassess autologous CAR-T therapy for GBM and considers allogeneic approaches as promising alternatives. By addressing the inherent deficits in patient-derived CAR-Ts, allogeneic CD133 CAR-Ts may offer a more effective and logistically feasible therapeutic option for treating GBM.

#5242 In vitro cytotoxicity assays to support CAR T cell evaluation against solid tumors.

C. N. Castro, V. Bergo, H. Weber, **P. Metzger**;
Reaction Biology Europe GmbH, Freiburg, Germany

CAR T cells are donor/patient-derived T cells genetically engineered to express a chimeric receptor against a specific tumor antigen (TA), which allows an MHC-independent recognition and targeting of tumor cells. While CART cell therapies have been tremendously successful against hematological cancers, with 6 T cell products being approved up to date from the FDA (Sengsayadeth S etal, EJHaem. 2022), the activity on solid tumors is more difficult. Solid tumors remain a unique challenge in part due to trafficking problems of CAR T cells, a hostile TME and heterogenous antigen expression, which limits CART cell capacity to find their target. Several strategies are being developed at the moment with the aim to overcome these hurdles, such as multispecific CART cells, co-therapy with checkpoint inhibitors, or inhibition of DNA methylation enzymes to prevent exhaustion. To offer an in vitro platform to assess the effectiveness of upcoming cellular therapies we developed several pipelines to allow the investigation of cytotoxic potential in 2D and 3D formats.
We show here our results using a CART cell product expressing a coreceptor to enhance its activation potential upon recognition of the target. We next tested the capacity of these cells to kill solid tumor in vitro by coculturing with potential target cells cultured in a monolayer (2D). By measuring the luciferase expression of the target cells, we could track the cytotoxicity exerted by the effector cells. In vitro, the CART cells were able to kill in a dose dependent manner different solid tumor cell lines expressing the cognate antigen for the co-receptor. At Reaction Biology we have developed spheroid-based 3D killing assays in which target cells from solid tumor entities are pre-cultured to form spheroids prior to their coculture with effector cells. Using this technique, we challenged the capacity of these CART cells to recognize their antigen in a 3D format. This 3D assay system can be used as well in combination with co therapies such as PD1 inhibitors, in a sensitive and high throughput manner. Finally, we evaluated the therapeutic capacity of these CART cells in vivo in a subcutaneous THP-1 tumor model. Mice treated with these CART cells showed a marked reduction of tumor volume.
In summary we show here a pipeline to characterize in vitro the effectivity of new T cell products, in particular those designed to overcome some of the hurdles against solid tumors.

#5243 CAR B cells to accelerate antigen presentation in cancer.

M. Molloy, J. Balero, A. Contreras-Sandoval, M. Selby, H. Park, S. Kothakota, K. Boyle, R. Romano, S. Rajendiran, M. Hernandez, A. Pios, R. Williams; Walking Fish Therapeutics, South San Francisco, CA

Engineered B cells hold promise for multiple therapeutic applications. Walking Fish Therapeutics is engineering B cells to produce replacement proteins for deficiency diseases, antibodies of defined specificity and effector function, and Chimeric Antigen Receptor (CAR) B cells with and without therapeutic payloads for use in the oncology setting. B cells are professional antigen presenting cells (APCs) with the ability to present antigen to CD4+ T cells. Recent studies have found the presence of tumor infiltrating B cells are associated with favorable outcomes across multiple cancer types. Adoptive transfer of B cells has demonstrated antitumor activity in a syngeneic mouse model. B cells from OVA-vaccinated transgenic luciferase mice were adoptively transferred to mice bearing EG7.OVA-tumors. We observed B cells migrating to the tumor and tumor draining lymph node (TDLN), locations where B cells can engage with antigen. Further, we observed a strong anti-tumor response in mice receiving B cells from OVA-vaccinated donors. Based on these results, we hypothesized that B cells engineered to target tumor specific antigens may engage and activate the immune system leading to an enhanced antitumor immune response. We generated CAR B cells expressing synthetic BCRs with tumor-antigen specific scFvs fused to designated B cell signaling motifs. Expression of different CAR constructs were confirmed in both human and mouse B cells. Upon antigen engagement CAR B cells release pro-inflammatory cytokines. Importantly, we demonstrate *in vitro* that antigen-specific CAR B cells can recognize cognate cell surface antigen, leading to uptake, processing, and presentation on MHCII as detected by activation of peptide-specific CD4+ T cells. When administered *in vivo* by IV administration, we observed a significant increase in mouse CAR B cells at the tumor site compared to unengineered B cells. We are currently investigating additional CAR formats that may lead to enhanced anti-tumor activity.

#5244 SIRPα knockout iPSC-derived macrophages (iMACs) are resistant to CD47-dependent inhibition of phagocytosis and efficiently kill tumor cells in pre-clinical models.

K. Haake[1], M. Mirenda[2], Q. Bernard[2], P. Hublitz[1], L. Gouxette[2], M. Briscadieu[2], P. Scheinpflug[1], G. Singh[1], A. Hinkelmann[1], T. Schneider[1], M. Esquerre[2], A. Holtzinger[1], M. Epstein[3], D. Sommermeyer[1], M. Paillasse[2], A. Scheel[1], M. Dangl[1], M. Braun[1], **N. Wagner**[1];
[1]Evotec International GmbH, Gottingen, Germany, [2]Evotec France SAS, Toulouse, France, [3]Evotec (UK) Ltd., Abingdon, United Kingdom

The CD47-SIRPα axis is a critical checkpoint that prevents SIRPα-positive macrophages from phagocytosing CD47-expressing solid tumors. Several agents aiming to block this axis have recently entered early clinical trials including anti-CD47 and anti-SIRPα monoclonal antibodies (mAb). These checkpoint inhibitors (CPI) aim to modulate the phagocytotic activity of endogenous tumor associated macrophages (TAMs). However, the adoptive transfer of macrophages resistant to CD47-based inhibition in the tumor microenvironment (TME) could also increase clinical efficacy while avoiding side effects linked to the use of anti-CD47 mAb. Cell therapy based on autologous macrophages have gained increasing attention for cancer treatment due to their ability to infiltrate into the immunosuppressive TME and their unique immunomodulatory characteristics. However, due to required intricate genetic manipulation of autologous macrophage cell product for each patient, optimization and consistency of the cell product remains challenging. In contrast, the use of induced pluripotent stem cell (iPSC)-derived macrophages (iMACs) facilitates the introduction of genetic modifications to further optimize the iMAC cell product and limits the need for combination therapies. The knockout (KO) of the SIRPα gene in iMACs is a promising genetic modification that results in a potent iMAC cell therapy product resistant to phagocytosis inhibition by CD47-expressing tumor cells.

A SIRPα KO was introduced in a fully characterized GMP iPSC line that was then differentiated to iMACs using Evotec's 3D differentiation protocol. The SIRPα KO iMACs were then evaluated for their antibody-dependent cellular phagocytosis (ADCP) capacity in comparison to antibody-loaded wildtype (WT) iMACs when co-cultured with CD47-expressing tumor cells.

SIRPα KO iPSCs showed differentiation potential comparable to WT iPSC and resulted in iMACs expressing typical markers of fully differentiated macrophages. SIRPα KO iMACs exhibited increased phagocytic potency and killing capacity compared to WT iMACs when both cell types were exposed to CD47-positive tumor cells and loaded with the same tumor-targeting mAb. This increased phagocytosis of tumor cells by antibody-loaded SIRPα KO iMACs was also comparable to ADCP observed for WT iMACs in the presence of an anti-CD47 blocking antibody.

Using Evotec's gene editing platform we were able to efficiently generate SIRPα-deficient iPSCs that serve as the starting material to manufacture highly pure, genetically modified iMACs that lack SIRPα expression rendering them resistant to CD47-dependent inhibition of phagocytosis. This novel allogeneic *off-the-shelf* iMAC cell product overcomes the need to combine this cell therapeutic with CD47-SIRPα axis CPIs and provides the basis to develop innovative treatments for solid tumors.

#5245 Anti-CSPG4 CAR-Macrophages synergize with anti-CD47 in melanoma cytotoxicity.

D. Greiner, Q. Xue, T. Waddell, M. Roh-Johnson;
University of Utah School of Medicine, Salt Lake City, UT

While CAR T-cells have been a success in treating liquid tumors, these successes have not been replicated in solid tumors. There are several reasons for these challenges, including physical matrix barriers and increased tumor antigen heterogeneity in solid tumors. Macrophages are frequently found in melanoma tumors, even in those that have low T-cell infiltrate, suggesting macrophages are well equipped to penetrate the physical barriers surrounding solid tumors. Macrophages are also antigen-presenting cells, thus, if macrophages phagocytose the tumor, they will likely present additional antigens to T-cells, potentially enhancing the adaptive immune response in cancer treatment. Thus, we hypothesized that macrophages expressing chimeric antigen receptors (CAR-Macrophages or CAR-Ms) are able to access solid tumors, phagocytose cancer cells, and subsequently re-educate the tumor immune environment by directly polarizing tumor-associated macrophages and by presenting novel antigens to recruit and educate adaptive immune cells. To test these hypotheses, we generated CAR-Ms with primary human macrophages using an scFV specific to chondroitin sulfate proteoglycan 4 (CSPG4), a highly expressed antigen enriched and specific to melanoma tumors, and an intracellular activation domain to promote phagocytosis. We found that anti-CSPG4 CAR-Ms phagocytosed human melanoma cells at high efficiency, however, this phagocytosis did not result in high levels of melanoma cell cytotoxicity. To improve CAR-M-mediated melanoma cell death engulfment, we blocked the anti-CD47/SIRPα (“don’t eat me”) signaling axis with an anti-CD47 blocking antibody, which resulted in additive effects for phagocytosis, and a robust effect on the melanoma cell killing. Preliminary *in vivo* xenograft experiments suggest that anti-CSPG4 CAR-Ms alone delay melanoma growth. We are now testing whether combining anti-CD47 and CSPG4 CAR-Ms therapies *in vivo* can 1) further reduce primary tumor growth and 2) prevent recurrence following surgical resection by treating remnants of the tumor. Our work shows that CSPG4 CAR-M-mediated killing of CSPG4-positive cancer cells is significantly enhanced when in combination with anti-CD47 antibody treatment.

#5246 Therapeutic efficacy of glypican-3 peptide-linked chimeric antigen receptor-macrophages in hepatocellular carcinoma.

W. Leung, O. Leung, T. Wong, K. Lee;
The Hong Kong Polytechnic University, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) is the third most lethal cancer and sixth most diagnosed cancer worldwide. Recently, chimeric antigen receptor-T cell (CAR-T) therapy has been demonstrated to be a promising immunotherapy for the treatment of hematologic malignancies such as leukemia. However, its application in solid tumors has proven to be challenging. To overcome this limitation, chimeric antigen receptor-macrophages (CAR-Ms) have emerged as a new immunotherapy against solid cancers, capitalizing on the unique attributes of macrophages in penetrating the tumor microenvironment, promoting antigen presentation, and priming T cells. Traditionally, CAR-M therapy involves the transfer of an edited CAR gene into macrophages via viral infection. However, this method is expensive, involves tedious procedures, and has long-term safety concerns. In the present study, we employed peptides to mimic the genetic approach for producing CAR-Ms to reduce the above uncertainties. To achieve this, we developed a novel bioconjugation method called the phthalaldehydeamine capture (PAC) reaction to produce peptidic CAR-Ms (pCAR-Ms) targeting Glypican-3 (GPC3) in HCC cells. This was achieved by linking GPC3 specific peptides to Raw264.7 murine macrophages. Using an *in vitro* co-culture system, we demonstrated the specificity and efficacy of pCAR-Ms against GPC3, as evidenced by a significant increase in the number of phagocytosed cells with high GPC3 expression when compared to their low-expression counterparts, by flow cytometry and confocal microscopy. The specificity of pCAR-Ms was further proven in GPC3-knockdown HCC cells, with a significant decrease in the phagocytic rate. Using an HCC xenograft model derived from MHCC97L cells, we confirmed the specific homing of pCAR-Ms to tumor sites via intravenous injection of lipopolysaccharide (LPS)-differentiated pCAR-Ms. Strikingly, pCAR-Ms suppressed HCC tumor growth when compared with untagged macrophages and PBS control. In conclusion, we provided evidence of the potency and specificity of non-viral-based pCAR-Ms in targeting HCC with simple and short production time and increased flexibility.

#5247 Reprogramming tumor microenvironment with intratumor macrophage adoptive cell therapy in melanoma.

S. R. Noonepalle[1], N. Gajendran[1], M. Suresh[1], X. Li[1], M. D. G. Hernandez[2], C. Z. Delgado[3], N. Aghdam[4], M. Berrigen[5], T. Knox[1], K. Tan[1], M. Durr[1], E. Sotomayor[6], K. B. Chiappinelli[2], D. Wardrop[7], A. Horvath[2], B. A. Shook[2], N. H. Lee[2], A. Dritschilo[1], R. Fernandes[2], K. Musunuri[8], M. Shibata[2], A. Villagra[1]; [1]Georgetown University, Washington DC, DC, [2]George Washington University, Washington DC, DC, [3]University of Houston, Downtown, Houston, TX, [4]Beth Israel Deaconess Medical Center, Boston, MA, [5]George Wsahington University, Washington DC, DC, [6]Tampa General Hospital, Tampa, FL, [7]University of Illinois, Chicago, IL, [8]Avstera Therapeutics Inc, Malvern, PA

The interplay between tumor cells and immune cells within the tumor microenvironment (TME) dictates protumor or antitumor immune responses. Tumor-associated macrophages (TAMs) respond to signals of the TME and exhibit a spectrum of phenotypes ranging between M1 (antitumor) and M2 (protumor) macrophages. In most tumor types, including melanoma, the balance between M1 and M2 macrophages is critical with a higher M1/M2 ratio favoring antitumor immunity. Therefore, strategies enhancing the M1/M2 ratio can significantly alter the TME towards antitumor immunity. In this study, we administered luciferase and GFP-expressing M1 macrophages as an adoptive cell therapy (ACT) through intravenous (i.v) and intratumor routes respectively, into mice bearing SM1 murine melanoma tumors to determine the effective treatment modality. We reprogrammed antitumor M1 macrophages ex-vivo with HDAC6 inhibitors to lock into the M1 phenotype and administered intratumorally as ACT in the syngeneic SM1 murine melanoma and humanized NSG-SGM3 melanoma models. We performed histological analysis of tumors for macrophage markers, immune phenotyping of infiltrated immune cells, single-cell secretome analysis of tumor macrophages, and single-cell RNA-seq analysis of CD45+ immune cell populations to demonstrate the benefit of macrophage ACT. Tail vein injected, luciferase-expressing M1 macrophages localized in the lungs and spleen, failed to reach the tumor as visualized by IVIS imaging, suggesting that i.v administration is ineffective for macrophage therapy. On the contrary, intratumor M1 macrophage ACT resulted in diminished tumor growth. Single-cell RNA-seq analysis of the CD45+ sorted tumor-associated immune cell population revealed distinct macrophage subsets and a significant M1/M2 macrophage ratio increase. NicheNet cell-cell interaction analysis indicated that M1-like TAMs activated infiltrating T-cells and monocytes through ligand-receptor interactions. Trajectory analysis of infiltrated monocytes indicated differentiation toward inflammatory macrophages in ACT tumors. Flow cytometry analysis corroborated that ACT increased the M1/M2 macrophage ratio and an increase in CD8 effector T-cells. Furthermore, HDAC6i-treated macrophages increased antigen cross-presentation. Single-cell secretome analysis of F4/80+ TAMs by the Isoplexis platform revealed polyfunctionality of HDAC6-treated M1 macrophages secreting inflammatory cytokine Tnfa and T-cell recruiting chemokine Cxcl10. Histological examination of tumor sections for macrophage phenotypic markers suggested that transplanted macrophages retained the M1 phenotype post-ACT in both SM1 murine and NSG-SGM3 melanoma tumor models. We demonstrated the potential of reprogramming macrophages ex vivo with HDAC6 inhibitors as a feasible macrophage cell therapy to treat solid tumors.

#5248 Novel costimulatory domain improves CAR-monocyte activity against tumors.

Kevin Carbajal, Warren Anderson, **Kilsoo Jeon**, Grace Reynolds, Prasanna Ekambaram, Beatrice Breckheimer, Anastasya Birger, Jessica Pafford, Mathew Esquivel, Adam Pecoraro, Sumiti Jain

Inceptor Bio, LLC, Raleigh, NC

Myeloid cells, unlike other immune cells such as T cells or NK cells, are known residents in the solid tumor microenvironment (TME). In the absence of checkpoints and in proinflammatory conditions, myeloid cells (particularly M1 macrophages) are known to be capable of direct phagocytosis of tumor cells and can present tumor-associated antigens to the host immune system. However, the immunosuppressive conditions within the TME restrict and limit the anti-tumor response of tumor associated macrophages (TAMs), including their ability to recruit and activate other immune cells against the tumor. Engineered CAR-Monocytes can serve a unique function in cell therapy by bridging a key gap in the treatment of solid tumors. We are developing an autologous engineered CAR-M cell therapy product targeting Glypican-3 (GPC3) to treat hepatocellular carcinoma (HCC). The CAR serves a dual purpose as a homing ‘GPS’ signal for trafficking directly to the tumor site, and for directing phagocytosis specifically at targeted tumor cells. We have designed a proprietary CAR molecule (M83 CAR) which contains a macrophage-specific costimulatory domain that significantly increases the phagocytosis function of the CAR-M cells. Furthermore, we have demonstrated that the M83 CAR-M cells are not inhibited by the prevalent CD47 checkpoint (‘do not eat me’ signal expressed on tumor cells), which is known to restrict myeloid function in the TME. Effective phagocytosis of engineered CAR-M cells is central to subsequent mechanisms of actions that can elicit robust anti-tumor immunity against patient-specific neoantigens. However, the first barrier to overcome is effective infiltration of engineered CAR-M into the tumor from the periphery. We have demonstrated that our engineered CAR-Monocyte drug product can successfully home to the targeted tumor specifically, from the periphery. Subsequent in situ differentiation of CAR-monocytes into CAR-macrophages (M1) enables robust tumor cell phagocytosis, the central mechanism that can result in the following series of events: 1) proinflammatory shift in the TME milieu, 2) recruitment of innate and adaptive immune cells, 3) activation of T-cells against tumor neo-antigens. This is a unique outcome of the CAR-M mechanism of action that is not capitulated by CAR-T or CAR-NK cells. Leveraging and further enhancing CAR-M function could lead to the rejection of the tumor and its metastases, particularly in combination with other immune-modulating therapies.

#5249 Macrophages expressing synthetic cytokine receptors reverse IL10-mediated immunosuppression within solid tumors and promote adaptive immunity.

C. Sloas, S. Beghi, Y. Huangfu, R. Qureshi, B. Schott, M. Ball, D. Blumenthal, T. Condamine, M. Klichinsky, Y. Ohtani;
Carisma Therapeutics, Philadelphia, PA

Motivation: In solid tumors, anti-inflammatory cytokines such as IL10 and TGFβ support an immunosuppressive tumor microenvironment (TME) and inhibit anti-tumor immunity. Many therapeutic approaches to overcome immunosuppression have used monoclonal antibodies to block cytokine signaling. Instead of silencing TME-associated cytokines, a more powerful strategy may be to leverage them as disease markers and convert them into anti-tumor signals, using a logic-gated cell-based immunotherapy. Here, we engineered macrophages with synthetic cytokine switch receptors (SR) that convert IL10 or TGFβ into pro-inflammatory signals. Macrophages are homeostatic regulators capable of both infiltrating solid tumors and initiating inflammation, and we harnessed this proficiency using SRs that convert prevalent cytokines in the TME into pro-inflammatory responses for TME modulation. We termed this engineered myeloid cell platform “Engineered Microenvironment Converters” (EM-C) and evaluated its ability to overcome cytokine-mediated immunosuppression in solid tumors.
Methods: EM-C were produced by transducing primary macrophages or monocytes with a SR that converts IL10 into an interferon-based signal. The response of EM-C to IL10 was monitored *in vitro* using phenotypic characterization of surface molecules, measurement of secreted factors, and mRNA profiling. The *in vivo* activity of EM-C was evaluated using a subcutaneous tumor model in immunocompetent mice. Murine EM-C were administered to tumor-bearing mice, and their ability to modulate the TME was monitored via immunophenotyping, secretome analysis, and single cell transcriptomics. To demonstrate modularity of the EM-C platform, additional SR were designed to convert TGFβ into interferon or toll-like receptor signals.
Results: EM-C efficiently sequestered IL10 or TGFβ and upregulated pro-inflammatory markers, cytokines, and pathways in a dose-dependent manner *in vitro*. EM-C administered to tumor-bearing mice remodeled the TME immune compartment by increasing the abundance of CD8 T cells and reducing the presence of immunosuppressive Tregs. EM-C furthermore augmented the cytokine/chemokine profile of the TME in a manner that correlated with anti-tumor response. TME modulation by EM-C improved tumor control, as compared to non-engineered macrophages, and had additive efficacy with checkpoint blockade.
Conclusion: We present a versatile immunotherapy platform that harnesses macrophages as “living converters” to locally augment inflammation in solid tumors. EM-C exhibit a modular ability to locally convert IL10 or TGFβ into pro-inflammatory signals without systemic cytokine antagonism. The EM-C platform enables development of target antigen-agnostic myeloid cell immunotherapies for overcoming immunosuppression in diverse solid tumors.

#5250 Chimeric antigen receptor macrophages (MOTO CARs) driving repolarization of macrophages in solid tumors.

Michael Boyer[1], Michelle Townsend[1], Timothy Phares[1], Adam Blaszczak[1], Rachel Garlick[1], Kenneth Katschke[1], Gaju Shrestha[1], Toni Mortimer[2], Ashlin Cowager[1], McCall Jensen[1], **Abigail Cheever**[2], Kim O'Neill[2]

[1]ThunderBiotech, Provo, UT, [2]Microbiology and Molecular Biology, Brigham Young University, Provo, UT

Introduction: Though chimeric antigen receptor (CAR) T cells have been effective in treating hematological cancers, they have lacked in solid tumors. Due to the nature of solid tumors and how macrophages are localized there, we propose that macrophages are a better cell type for targeting solid tumors. In tumors, most of the macrophages are Tumor Associated Macrophages (TAMs) which are M2 polarized and promote tumor growth, angiogenesis, and metastases. If these macrophages could be repolarized to an anti-tumor, M1 phenotype, they could alter the tumor immune microenvironment and facilitate destruction of the tumor by immune cells.

Methods: We hypothesize that CAR macrophages (MOTO-CARs) could infiltrate solid tumors, and affect the tumor immune microenvironment to repolarize (TAMs) from an M2 to M1 phenotype. Over 150 signaling domains from published sequences were cloned into a CAR constructs, comprised of an anti-mesothelin scFv, CD34 hinge, and transmembrane and activation domains from various immune cells. Functional activation assays were preformed in reporter HEK cells lines. Functional constructs were then transduced into THP-1 cells. The function of these MOTO-CARs were evaluated using a flow cytometry based phagocytosis assay (indication of an M1 phenotype) and RT-qPCR repolarization assay.

Results: Of the constructs tested in HEK reporter cell lines, around one third demonstrated significant activation, that is 20% higher than the background control. The phagocytosis assay performed on the functional constructs showed that around one third of these constructs exhibited higher phagocytosis compared with a control construct with no signaling domain. However, it is noteworthy that this no signaling domain control had significantly higher rates of phagocytosis than untransduced controls. The RT-qPCR demonstrated that M2-like THP-1 cells transduced with the CAR constructs exhibited a significant shift in expression towards M1 characteristic genes when stimulated with mesothelin beads, with the TLR4 construct exhibiting the greatest shift.

Conclusion: Several of the MOTO-CAR constructs, including TLR4, showed significant activation, phagocytosis, and ability to repolarize macrophages from M2 to M1 phenotype. Further analysis hopes to prove the functionality of these MOTO-CAR constructs with primary cells as well as in vivo, making MOTO-CARs a valuable treatment option for patients with solid tumors.

#5251 RNA primed SMAR-T cells against multiple driver mutations, all HLA's designed for first line therapy.

A. E. Slanetz, S. Srivatsa, F. Muzaffar, W. Barry, D. Ryan, S. Metri, M. Slanetz;
Geneius Biotechnology, Inc., Natick, MA

Success of immune checkpoint inhibitors (e.g., anti-PD1 antibodies) have revolutionized cancer immunotherapy by demonstrating that a patient's own T-cells recognize and treat cancer. The efficacy of PD-1 blockade is driven by recruitment of new T-cells from blood rather than via activation of pre-existing tumor infiltrating lymphocytes (Yost K.E., et al. Nat. Med. 2019). However, anti-PD1 therapy is most effective in ~5% of malignancies i.e., cancers with high mutational burden. Hence, the challenge of addressing most lower mutational burden cancers (the ~95%) needs an alternate treatment strategy. We address this challenge by using RNA to prime and expand peripheral T-cells to cancer-specific mutations ex-vivo. Using our proprietary, patented, and robust manufacturing method, we can generate T-cell populations reactive to as low as 8 and as high as 40 cancer-specific mutant proteins. In-vitro, these T-cells have cancer mutation-specific cytotoxicity and do not kill the normal cells. Further, the T-cells express homing receptors enabling them to infiltrate tumors and express high levels of TNFα and IFNγ, which are associated with effective tumor cytotoxicity and pro-inflammatory modification of tumor microenvironment (TME). Additional characterization shows these cells to be predominantly CD4+ and CD8+ T-cells bearing central and effector memory phenotypic with negligible regulatory or exhausted T-cells. We believe our T-cells can be used for cellular therapy in conjunction with, or as an alternative to, immune checkpoint inhibitors to treat lower mutational burden cancers present in most patients.

#5252 Expansion of human T cells and NK cells for chimeric antigen receptor based therapies using human platelet lysate.

V. Alonso-Camino, W. Mirsch;
Mill Creek Life Sciences, Rochester, MN

T cells and NK cells expressing chimeric antigen receptors (CAR) have demonstrated potent clinical efficacy in patients with hematological malignancies. One of the issues to overcome in the treatment of solid tumors using CARs is the lack of a process that generates large amounts of CAR-T cells, reduces cell exhaustion and differentiation, and improves long term survival after infusion into patients.

Previously, Torres Chavez et al. demonstrated in a series of *in vitro* and *in vivo* experiments, performed in both hematologic and solid tumor models, the profound qualitative impact on CAR-T cell performance after using human platelet lysate (hPL) as a cell growth supplement. T cells expanded with their hPL showed a good proliferative capacity and enhanced long-term in vivo persistence compared to Fetal Bovine Serum (FBS) or human AB Serum (ABS), resulting in superior anti-tumor effects. Additionally, this group demonstrated that the transduction of T cells to generate the CAR-T cells was significantly improved by the use of hPL.

Mill Creek's human platelet lysate (hPL) is produced using expired human platelets obtained from accredited blood banks in the United States. These platelets were originally intended for use in patient transfusion. The safety of platelets used in transfusion is managed by the U.S. Food & Drug Administration (FDA), as well as the Association for the Advancement of Blood & Biotherapies (AABB). These organizations set standards, including testing for transmissible diseases. The United States record for blood safety is well established, with extremely low rates of disease transmission, making the platelet units used for hPL manufacture low risk. The Covid-19 pandemic has increased awareness of emerging infectious diseases, even though transmission of Covid-19 via blood transfusion has not been documented. For that reason, we developed a gamma irradiated version of our products, which offers an additional safety measure in the clinic.

Our data from experiments performed using human CD3+ and purified NK cells from donor peripheral blood suggests that our human platelet lysates offer an improved cell phenotype and expansion capacities versus serum derived products, but also versus other platelet lysates on the market. PLTGold® and PLTGold®-GI efficiently promote cell expansion, with higher cell yields and lower cell exhaustion rate. Additionally, our hPLs are suitable for suspension culture, potentially facilitating the large-scale expansion of allogeneic CAR cells.

The use of our platelet lysates has the potential of significantly improving CAR-T and CAR-NK manufacture, but also the outcome of the therapy itself by improving the quality and potency of the end product.

#5253 Epigenetic drugs partially restored anti-cholangiocarcinoma activity of dysfunctional CD3+CD56+ cells.

A. Wongkajornsilp[1], P. Chusorn[2], K. Phongkitkarun[3], K. Htwe[1], S. Duangsa-ard[1], K. Kasetsinsombat[1], N. Sawatpiboon[1];
[1]Mahidol University, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand, [2]Faculty of Liberal Arts and Science, Roi Et Rajabhat University, Roi Et, Thailand, [3]Faculty of Engineering, Mahidol University,, Nakhon Pathom, Thailand

The cholangiocarcinoma cell-exposed cytokine-induced killer (CIK) cells or their most efficacious $CD3^{\pm}CD56^{\pm}$ subset displayed weaken anti-tumor cytotoxicity upon subsequent exposure. RNAseq analysis of the resistant phenotype gave rise to a list of drugs that could potentially counter the activity of genes associated with resistance to the anti-tumor activity of CIK cells. The top-ranking drugs appeared to be epigenetic drugs. Sublethal concentration of these drugs were assayed for their synergistic activity with CIK cell or the $CD3^{\pm}CD56^{\pm}$ subset for cytolysis of resistant CCA cells in tissue culture model. These drugs, although in low concentration, contained anti-tumor activity. The tumor cytolysis was greater after the combination with either CIK cells or the $CD3^{\pm}CD56^{\pm}$ subset. An in vivo model of CCA-implanted mice exhibited the synergistic activity of subtherapeutic dose of these drugs and $CD3^{\pm}CD56^{\pm}$ subset in suppressing tumor growth. It is concluded that epigenetic drugs in subtherapeutic dose could prevent the dysfunction of CCA-exposed CIK cells.

#5254 The “off-the-shelf ”CD19-CAR-Vδ1T cells demonstrated an enhanced therapeutic effect on B-cell malignancy models.

D. Chen[1], F. You[1], C. Chen[1], S. Xiang[1], P. Zhang[1], H. Wu[1], Z. Zheng[1], M. Wang[2], X. Wang[3], H. Meng[1], N. Yang[1], B. Zhang[4], **L. Yang**[5]; [1]PersonGen BioTherapeutics, Suzhou, China, [2]PersonGenAnke Cellular Therapeutics Co., Ltd, Hefei, China, [3]Department of Hematology, The First Affiliated Hospital of USTC , Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, China, [4]PersonGen BioTherapeutics, Suzhou, China;PersonGenAnke Cellular Therapeutics Co., Ltd., Hefei, China, [5]PersonGen BioTherapeutics, Suzhou, China;Cyrus Tang Medical Institute, Soochow University, Suzhou, China

Background: The commercialization of autologous chimeric antigen receptor T cell (CAR-T) is hindered by the expensive and time-consuming manufacturing process, presenting major challenges. The development of allogeneic products is proposed as an alternative strategy to overcome these obstacles. Vδ1T cells, possessing active homing capability, are known to infiltrate tumor tissues and have been linked with favorable patient prognosis due to their direct killing effect via innate immunity and their sensitive T cell receptors that can broadly recognize tumor antigens. Unlike conventional αβ T cells, Vδ1 TCRs are not restricted by major histocompatibility complexes (MHCs), thus preventing the development of graft-versus-host disease (GVHD). Therefore, Vδ1T cells were hypothesized to be a superior candidate for universal CAR-T cells. Nevertheless, the small portion of Vδ1T cells (less than 1%) in peripheral blood posts a significant challenge for CMC and production. Here we present the successful development of CD19-CAR-Vδ1T cells, which demonstrate enhanced therapeutic efficacy on B-cell malignancy models.

Methods: High-purity CD19-CAR-Vδ1T cells were prepared using PersonGen's proprietary platform technology. Multiple CAR structures were tested for cytotoxicity, and the fourth-generation CAR-transduced Vδ1 cells designated as UTAA09 exhibited sustained killing of CD19+ target cells. UTAA09 underwent in-depth research regarding its anti-tumor efficacy and safety.

Results: The Vδ1T cell purity exceeded 95%, while the residual TCRαβ count remained under 1%. The CAR transduction efficiency remained stable across batches, with medium CAR+~30%, and up to 2×10^{11} UTAA09 cells were harvested in compliance with GMP standards. The presence of secreted IL-2 significantly increased the persistence of UTAA09 in vitro, and UTAA09 showed comparable anti-tumor activity and expansion rates to CD19-CAR-αβT cells. Notably, no exhaustion phenotype was detected for UTAA09 after multiple antigen stimulation processes. Moreover, UTAA09 lacked detectable IL-17A, indicating a non-promoting characteristic in tumor growth. In the xenograft model, significant inhibition of tumor growth was observed in all mice, of which 40% achieved long-term disease-free survival ($p<0.01$) . On days 5, 12, and 19 after the administration of UTAA09, Vδ1T cells underwent significant expansion in all 5 mice tested. Subsequent analysis confirmed that the majority of these expanded Vδ1T cells were CAR+ cells, indicating the specific and long-lasting expansion of CD19-CAR+ Vδ1T cells in vivo. Importantly, none of the mice experienced significant weight loss, demonstrating the safety and outstanding in vivo effectiveness of UTAA09.

Conclusion: UTAA09 shows potential as an off-the-shelf allogeneic cellular therapy for the treatment of B-cell malignancies and autoimmune diseases derived from B cells.

#5255 A B7-H3-CAR-modified Vδ1 T cells showed potentanti-solid tumor potential.

L. Jiang[1], C. Qi[2], F. You[1], S. Xiang[1], P. Zhang[3], M. Wang[3], H. Wu[1], K. Yan[1], J. Huang[1], H. Meng[1], N. Yang[1], S. Zhang[4], L. Shen[2], **L. Yang**[5];
[1]PersonGen BioTherapeutics Co., Ltd., Suzhou, China, [2]State Key Laboratory of Holistic Integrative Management of Gastrointestinal Cancers, Beijing Key Laboratory of Carcinogenesis and Translational Research, Peking University Cancer Hospital & Institute, Beijing, China, [3]PersonGenAnke Cellular Therapeutics Co., Ltd., Hefei, China, [4]PersonGen BioTherapeutics Co., Ltd. / PersonGenAnke Cellular Therapeutics Co., Ltd., Suzhou, China, [5]PersonGen BioTherapeutics(Suzhou) Co., Ltd. / Cyrus Tang Medical Institute, Soochow University / PersonGenAnke Cellular Therapeutics Co., Ltd., Suzhou, China

Background: CAR-αβT cells have made limited advancement in treating solid tumors. Vδ1 T cells, a subtype of γδT cells, are rare in human peripheral blood, but they are the main tissue-resident immune cells found in epithelial and mucosal tissues. This suggests that Vδ1 T cells might be a potential modality for treating solid tumors. To explore this possibility, we hypothesized that Vδ1 T cells modified with B7-H3 CAR (B7-H3-CAR-Vδ1 T) could have great potential of anti-solid tumor activity, making them a promising candidate for further development as a universal cellular therapy product.
Methods: A proprietary manufacturing procedure to produce Vδ1 T cells from the leukopak of healthy donors has been established under GMP compliance. The immune checkpoint molecule B7-H3 was selected as the target. The allogeneic B7-H3-CAR-Vδ1 T cells carrying IL-2 (UTAA06), which displayed the most prolonged anti-tumor activity, were chosen for comprehensive functional validation. Single-cell sequencing and mass spectrometry flow cytometry were utilized to characterize the biology of UTAA06. In vivo effectiveness of UTAA06 was confirmed in animal models.
Results: A clinical-grade manufacturing process for Vδ1 T cells is developed. This process results in a purity of over 95% of Vδ1 T cells, with an expansion of more than 20,000-fold, and a CAR lentiviral transduction efficiency of over 50%.žSingle-cell sequencing and mass cytometry analysis both demonstrated that the Vδ1 T cells produced by our approach exhibited high expression levels of natural cytotoxic receptors (including NKG2D, DNAM1, and NKp series receptors), chemokine receptors (such as CXCR3 and CXCR6), anti-tumor related molecules (such as CD27 and CD137), and low expression levels of inhibitory molecules (such as PD1 and LAG3).ž
UTAA06 cells did not produce IL17A, which is a signal protein with pro-tumor activity. Meanwhile, UTAA06 demonstrated significant and specific inhibitory effects on the growth of various solid tumor cell lines.žUTAA06 cells were found to significantly suppress tumor cell growth in solid tumor mouse models. The complete remission (CR) for each tumor model was 83.3% of neuroblastoma (SK-N-AS, N=6), 66.7% of pancreatic cancer (SW1990, N=6), 100% of lung cancer (A549, N=6), and 70% of colorectal cancer (HCT-15, N=10) respectively. In addition, a potent capacity of UTAA06 to penetrate tumor tissues with a favorable safety profile in mice was observed.
Conclusion: UTAA06 exhibited extraordinary anticancer properties both in vitro and in vivo against solid tumors. Additionally, the outstanding manufacturing process of UTAA06 will facilitate the clinical application of this product.

IMMUNOLOGY: Immune Modulating Effects of Chemotherapy and Other Agents
Poster Session

#5259 Mechanistic evaluations of the immunological and cell biological effects that distinguish eribulin from other microtubule-targeted chemotherapeutics.

Z. Hassouneh, N. Wilkinson, L. Takahashi-Ruiz, N. Mukherjee, A. L. Risinger;
UT Health Science Center at San Antonio, San Antonio, TX

Microtubule-targeted agents (MTAs) are some of the most widely used and effective chemotherapeutics and they continue to find utility as the payloads of antibody-drug conjugates and in combination with targeted agents to improve response, including with immune checkpoint inhibitors. While all MTAs have shared antiproliferative effects, over the last decade it has become increasingly clear that individual drugs of this class have distinct effects on microtubule-dependent signaling and trafficking that are critical for their anticancer efficacy. We and others have demonstrated that eribulin is unique from other MTAs in its ability to promote vascular remodeling, reverse epithelial-to-mesenchymal transition (EMT), and increase immune infiltration into tumors both in animal models and in the clinic. However, the mechanism linking eribulin-mediated microtubule destabilization to these phenotypes, which are associated with improved overall survival of eribulin-treated patients, is unclear. We found that acute eribulin treatment at clinically relevant concentrations promotes the production of antitumor cytokines in both immune and cancer cells and synergizes with direct STING agonists to promote enhanced immune infiltration and improved antitumor efficacy in vivo in both breast and bladder cancer models. This effect was shown to involve activation of natural killer cells and is associated with TBK1-mediated IRF3 phosphorylation, which is regulated downstream of the microtubule associated GTPase GEF-H1. Intriguingly, GEF-H1 release from destabilized microtubules has also been shown to enhance the formation of focal adhesions and promote the differentiation of mesenchymal cells to a more epithelial phenotype. We show that eribulin is indeed sufficient to promote the formation and activation of focal adhesion complexes in mesenchymal triple-negative breast cancer cells, which was not observed when cells were subjected to treatment with microtubule stabilizing chemotherapeutics. Both genetic and pharmacological inhibitors of GEF-H1 were utilized to interrogate the relationship between eribulin-mediated microtubule destabilization and TBK1/IRF3-dependent immunological activation as well as the formation of RhoA-dependent focal adhesions and reversal of EMT-associated phenotypes. Together, our data provide a mechanistic rationale for unique effects of eribulin as compared to other classes of MTAs that could inform on the use of these widely used, but mechanistically underappreciated drugs in a more personalized manner and inform on their rational combination with targeted agents, including immunotherapy.

#5260 Combination activity of eribulin liposomal formulation and anti-PD-1 antibody after tumor regrowth during anti-PD-1 antibody treatment in mice.

M. Tamura, Y. Niwa, T. Semba;
Eisai Co., Ltd., Tsukuba, Japan

Eribulin (ERI) has been reported a microtubule dynamics inhibitor with unique tumor microenvironment modulations such as vascular remodeling activity. In the previous meeting (AACR2022, 2023), we reported that ERI and liposomal formulation of ERI (ERI-LF) also have immunomodulatory activity that induces $CD8^{\pm}$ T cells via its vascular remodeling activity and ERI-LF showed more potent immune modulation and combination activities with anti-PD-1 antibody (PD-1 Ab) than ERI in syngeneic mice models and humanized mice models. Although immune-checkpoint inhibitors (ICI) are using as a key drug for various types of cancers in clinical setting, several clinical questions regarding suitable therapies after ICI therapy and efficacy of ICI rechallenge are remaining. In this study, we evaluated anti-tumor activities of combination of ERI-LF and PD-1 Ab in two syngeneic transplantation models using mouse non-small lung cancer cells, P-glycoprotein-knockout (Pgp-KO) KLN205 cells and Pgp-KO LL2 cells. As a result, combination of 1mg/kg ERI-LF (Q7D×2) with PD-1 Ab (200 ug/head, twice a week ×2 weeks) showed significant stronger antitumor activity compared with each monotherapy in only Pgp-KO KLN205 model, in which ERI-LF increased intratumoral microvascular density as a vascular remodeling activity, not in Pgp-KO LL2 model. We next conducted continuous treatment of PD-1 Ab in Pgp-KO KLN205 model to investigate tumor regrowth during treatment of PD-1 Ab. In this model, tumor growth was inhibited by PD-1 Ab until about two weeks after initiation of the treatment and then this inhibitory activity disappeared after two weeks even by continuous treatment of PD-1 Ab. We performed flow cytometry analysis (FCM) for tumor-infiltrating immune cells and RNAseq analysis using regrowing tumors compared with non-treatment tumors. Expressions of mRNA of several immune inhibitory receptors were upregulated in tumors with regrowth, although $CD4^{\pm}$ cells and $CD8^{\pm}$ cells were also increased in FCM using tumor samples. Furthermore, we investigated anti-tumor activity of combination of ERI-LF and PD-1 Ab against tumors which changed from inhibitory phase to regrowth phase during PD-1 Ab treatment in Pgp-KO KLN205 model. The combination of ERI-LF at 1mg/kg (Q7D×3) and PD-1 Ab (200 ug/head, twice a week ×3 weeks) also showed potent anti-tumor activity against tumors with regrowth by prior PD-1 Ab treatment as well as PD-1 Ab-naïve tumor, suggesting that this combination therapy might be effective after prior ICI therapy. Currently, Phase 1b/2 clinical trial of ERI-LF plus nivolumab in patients with selected solid cancers (NCT04078295) is underway. Patients with or without prior ICI therapy were enrolled in a small cell lung cancer cohort of this clinical study. Our preclinical results might provide a scientific rationale for a uniqueness of ERI-LF as a post ICI therapy.

#5261 Immunologic signatures of peripheral blood cells in patients with advanced pancreatic cancer under lenvatinib-pembrolizumab maintenance therapy.

V. Chung, F. Kos, E. Manual, S. Dempsey, D. J. Diamond;
City of Hope, Duarte, CA

Background: The treatment of pancreatic cancer is limited by chemotherapy toxicities which impacts quality of life. This is a phase 2 clinical trial of lenvatinib and pembrolizumab as maintenance therapy in patients with advanced pancreatic cancer. We observed preclinical activity of this combination in pancreatic mouse models. We hypothesize that this combination may address unmet needs to minimize toxicities associated with standard treatments, stimulate anti-tumor T cell immunity, and improve the progression free and overall survival. Exploratory studies aim to characterize immune-related systemic changes in peripheral blood over the course of therapy and to identify global changes in expression of tumor-related genes in needle biopsy samples of liver metastatic lesions.
Methods: Multiplex gene expression analysis of unsorted peripheral blood mononuclear cells (PBMC) was performed using PanCancer Immune Profiling Panel on NanoString nCounter platform. PBMC samples from pre- through week 32 of treatment were assessed for differential expression of 730 immune profiling genes defining T cell functions and associated immune categories.
Results: PBMC immune profiling from 4/5 patients show a distinctive pattern of increased activation of T cells during the first 9 weeks of treatment followed by a sharp inhibition starting at weeks 9-12 after 3-4 cycles of treatment (CD3E, CD247, LCK, TBX1, TCF7, STAT4, IL2RG). Subsequent upregulation of macrophage-derived scavenger, inflammatory, and immunosuppressive gene expression patterns continued for the remainder of treatment (CD14, MSR1, MARCO, CD68, TGFB1, IL10RA). The median PFS of first 10 patients was 21.5 (9-32) weeks.
Conclusions: Immunotherapy resistance may be related to rapidly developing terminal differentiation and unresponsiveness of T cells in parallel with upregulation of macrophage-derived inflammatory and immunosuppressive processes. Studies are on-going to prevent inhibition of the T-cells.

#5262 MBO enhances anti-tumor immunity in pancreatic ductal adenocarcinoma by inducing immunogenic apoptosis.

S. R. Gaikwad, S. K. Srivastava;
Texas Tech University Health Sciences Center, Abilene, TX

Pancreatic ductal adenocarcinoma (PDAC) poses significant therapeutic challenges due to its aggressive nature and limited treatment options. In this study, we explored the anti-cancer potential of MBO, a compound selected through drug repurposing strategy based on its cytotoxic ability and modulation of key survival pathways in PDAC. Our preliminary in vitro experiments demonstrated MBO's potent cytotoxicity against various PDAC cell lines, inhibiting cellular growth and clonogenicity. MBO induced G1 phase cell cycle arrest in a concentration-dependent manner. In the next step, in vivo, studies using xenograft and orthotopic mouse models confirmed MBO's ability to suppress tumor growth and increase CD8+ T cell infiltration. MBO demonstrated a favorable tumor suppressive activity wherein it suppressed tumor growth by approximately 49% and 56% in xenograft and orthotopic models, respectively. A CD8+ T cell depletion experiment revealed partial dependence on CD8+ T cells for MBO's overall anti-tumor efficacy. Further, combining MBO with anti-PD1 therapy exhibited a synergistic effect, enhancing overall T cell infiltration, particularly CD8+ T cells. Our mechanistic studies revealed that MBO induced immunogenic apoptosis, as evidenced by increased expression of immunogenic cell death markers (HSP90 and calreticulin) and apoptotic markers. To further delineate the mechanism, we performed RPPA profiling. RPPA analysis indicated MBO's impact on mitochondrial gene expression and stress response pathways, suggesting its involvement in disrupting cellular survival mechanisms along with stress-induced immunogenic marker expression. Overall, this study demonstrates MBO as a promising anti-cancer agent with the potential to serve as an immune adjuvant. Particularly, in combination with immunotherapies, MBO can serve as a potential option to improve immunotherapeutic response in PDAC tumors providing valuable insights for developing novel therapeutic strategies in PDAC.

#5263 The impact of MRTX1133 on anti-tumor immunity in lung cancer with KRAS^{G12D} mutation.

Kunihiro Shono[1], Satoshi Watanabe[1], Takaaki Masuda[1], Ryo Suzuki[2], Tomoya Wakabayashi[1], Tomoki Sekiya[1], Susumu Tanaka[1], Aya Ohtsubo[1], Tomohiro Tanaka[1], Koichiro Nozaki[1], Rie Kondo[1], Yu Saida[1], Satoshi Hokari[1], Naohiro Yanagimura[1], Masashi Arita[1], Riuko Ohashi[3], Kenjiro Shima[1], Yosuke Kimura[1], Nobumasa Aoki[1], Yasuyoshi Ohshima[1], Toshiyuki Koya[1], Toshiaki Kikuchi[1]

[1]Department of Respiratory Medicine and Infectious Diseases, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan,[2]Sado General Hospital, Sado, Japan,[3]Division of Molecular and Diagnostic Pathology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background: To date, there have been no clinical molecules that are selective for KRAS^{G12D} mutant tumors. Although immune checkpoint inhibitors (ICIs) have improved the survival for patients with lung cancer, inferior efficacy of ICIs has been reported in KRAS^{G12D} mutant NSCLC. MRTX1133 is a selective KRAS^{G12D} inhibitor, which has been investigated in early clinical studies. In this study, we aimed to reveal the immune status using preclinical murine model of KRAS^{G12D} mutated lung cancer. In addition, we investigated whether MRTX1133 effects the anti-tumor immunity in mice bearing lung cancer with KRAS^{G12D}.
Method: CCSP-rtTA/TetO-Cre mice were crossed with LSL-KRAS^{G12D} knock-in mice to obtain CCSP-rtTA/TetO-Cre/LSL-KRAS^{G12D} conditional mutant mice (KRAS^{G12D} mice). These mice were fed an autoclaved rodent diet supplemented with 0.0625% doxycycline when the mice were about 8~12 weeks old. Mice were treated with 10 mg/kg MRTX1133 in vehicle once daily by intraperitoneal injection for 4 or 8 days. After administration of MRTX1133, the lungs and spleens were harvested, and single cell suspensions were labeled with fluorophore-conjugated antibodies for FACS analyses.
Results: More regulatory T cells (Tregs) infiltrated the tumors of lung of mice treated with doxycycline for a longer period of time. The expression of immune checkpoint molecules (ICMs), including PD-L1, PD-1, TIGIT, TIM-3, LAG-3, were also upregulated on CD4^{+} and CD8^{+} T cells in the KRAS^{G12D} mice. Treatment with MRTX1133 strongly inhibited KRAS^{G12D} tumor progression, reduced the percentage of Tregs and downregulated the expression of PD-1 on CD4^{+} and CD8^{+} T cells infiltrating in lung cancers. The expression of the other ICMs remained high after MRTX1133 administration. In addition, MRTX1133 tended to increase the percentage of tumor-specific CD8^{+} effector T cells infiltration in lung tumors. Conclusion: T cells were exhausted in mice with KRAS^{G12D} mutant lung cancer. MRTX1133 demonstrates the therapeutic efficacy in preclinical murine KRAS^{G12D} mutated lung cancer model. This efficacy is more likely to relate not only signal inhibition but also enhances the anti- tumor immune responses. Our findings could aid in developing an alternative immunotherapy strategy in patients with KRAS^{G12D} mutant lung cancer.

#5264 KRAS^{G12C} inhibition synergizes with checkpoint blockade in KRAS^{G12C}-mutated tumor model.

L. Hua, S. Li, C. Nie, C. Zhang, L. Bourre, **J. Wang**;
Crown Bioscience, Inc., San Diego, CA

Introduction: The KRAS^{G12C} mutation is found in 14% of non-small cell lung cancer (NSCLC) and 3% of colorectal cancer (CRC). Sotorasib (AMG510), which covalently binds to the mutated cysteine 12 of KRAS^{G12C} protein, became the first KRAS^{G12C} inhibitors approved by the FDA for KRAS^{G12C}-mutated NSCLC treatment. AMG510 not only increased apoptosis in cancer cells harboring KRAS^{G12C} mutation, but also re-modelled tumor microenvironment. Thus, to evaluate novel therapeutic strategies for treating KRAS^{G12C}-mutated tumors, we established a CT26-KRAS^{G12C} tumor model and explored the combination of AMG510 with anti-PD1 therapy.

Methods: We knocked in KRAS^{G12C} mutation in murine CT26 colorectal cancer cells using CRISPR/Cas9 to generate CT26-KRAS^{G12C} cells. The mutation was confirmed by PCR sequencing. *In vitro*, CT26-KRAS^{G12C} cells were treated with AMG510 for 2h or 72h, and then p-ERK and cell viability were analyzed. *In vivo*, 3×10^5 CT26-KRAS^{G12C} cells were subcutaneously injected into BALB/c mice, and the tumor bearing mice were treated with AMG510 (30 mg/kg or 100 mg/kg, *QD*×21), anti-PD-1 (10 mg/kg, *BIW*×3) and combination of AMG510 and anti-PD-1. On day 5 after randomization, the composition of immune cells, including CD4^{+} T cells, CD8^{+} T cells, dendritic cells (DC), and natural killer (NK) cells in tumors were analyzed by flow cytometry. The mice with complete tumor regression were re-challenged with bilateral tumors of CT26-KRAS^{G12C} (3×10^5) and unrelated mouse breast tumor cells, 4T1 (3×10^5) to evaluate the effect on tumor growth.

Results: Following confirmation of KRAS^{G12C} mutation, AMG510 treatment decreased p-ERK expression by ~50% and impaired the cell growth with IC50 value of 0.1802 μM in CT26-KRAS^{G12C} cells. *In vivo*, single treatment of AMG510 at 30 mg/kg or 100 mg/kg significantly inhibited tumor growth with TGI of 60% or 99% on day 15 after randomization, respectively (both $p<0.001$). Combined treatment of AMG510 (30 mg/kg or 100 mg/kg) and anti-PD-1 also led to significant tumor inhibition with TGI of 64% or 99% on the same day, respectively (both $p<0.001$), although PD-1 blockade didn't show anti-tumor effect alone. Noticeably, combined treatment of AMG510 (100 mg/kg) and anti-PD-1 induced complete tumor regression in 3 of 10 mice, which remained cured 124 days later. Moreover, the combined treatment significantly improved survival compared to the AMG510 treatment alone. Notably, all 4T1 tumors grew, but none of the CT26-KRAS^{G12C} tumors were palpable in the cured mice after the re-challenge. In the control group, all tumors were well established. Additionally, combined treatment of AMG510 (100mg/kg) and anti-PD-1 markedly increased the infiltration of CD4^{+} T cells, DC, and NK cells in the tumors.

Conclusion: The successfully established CT26-KRAS^{G12C} model is a useful tool for investigating therapeutic strategies to combine KRAS^{G12C} inhibitors with immunotherapy.

#5265 Targeting mtDNA dynamics enhances immunogenicity and sensitizes *KRAS* mutant cancers to PD-1 blockade.

K. Tanaka, Y. Adachi, M. Yoshiya, T. Owari, T. Yamamori-Morita, A. Ohashi, S. Kobayashi, S. Koyama, H. Nishikawa;
National Cancer Center, Chiba, Japan

Mitochondrial DNA (mtDNA) can stimulate an innate immune response that potentiates the efficacy of cancer immunotherapy. However, mtDNA-targeting therapy has not been developed to enhance this innate immune system in specific cancer subtypes efficiently. Here we discover that mtDNA is enriched in *KRAS* mutant tumors where the DNA sensor machinery cGAS-STING signaling is primed for innate immune activation. Intriguingly, MEK inhibitor induces cytosolic mtDNA release to potently activate the cGAS-STING signaling, which in turn induces PRKN-mediated mitophagy in response to mitochondrial stress in *KRAS* mutant cancer cells. During the process of mitophagy, PRKN, as an E3 ubiquitin ligase, degrades BAX protein and attenuates mitochondrial pore formation, which is essential for mtDNA efflux upon MEK inhibition. Combined MEK and mitophagy inhibitors efficiently stimulate type I IFNs in both mtDNA- and STING-dependent manners, and this combination enhances the efficacy of PD-1 blockade in *Kras* mutant murine syngeneic tumors. In the clinic, PRKN is associated with a ‘cold tumor’ phenotype among *KRAS* mutant tumors. Together, targeting mtDNA dynamics by co-inhibition of MEK and mitophagy represents a promising strategy to convert ‘cold to hot tumor’ in mtDNA-enriched *KRAS* mutant cancers.

#5266 Deciphering the systemic immune effects of abemaciclib in recurrent metastatic breast cancer: A multicenter, prospective study.

Y. Fukui[1], K. Kawaguchi[1], Y. Maeshima[1], Y. Fujimoto[1], H. Ishiguro[2], K. Yamagami[3], S. Takahara[4], H. Suwa[5], M. Torii[6], S. Nagai[7], Y. Sagara[8], W. Tsuji[9], H. Yamashiro[10], T. Kotake[10], S. Fukuda[11], K. Saito[12], Y. Yamamoto[12], M. Kataoka[1], Y. Himoto[6], A. Yonezawa[1], Y. Nakamura[1], W. Li[1], S. Tanaka[1], S. Morita[1], M. Takada[1], M. Toi[1];

[1]Kyoto University Hospital, Kyoto, Japan, [2]Saitama Medical University International Medical Center, Saitama, Japan, [3]Shinko Hospital, Kobe, Japan, [4]Kitano Hospital, Tazuke Kofukai Medical Research Institute, Oosaka, Japan, [5]Hyogo Prefectural Amagasaki General Medical Center, Amagasaki, Japan, [6]Japanese Red Cross Wakayama Medical Center, Wakayama, Japan, [7]Saitama Prefectural Cancer Center, Kitaadachigun, Japan, [8]Sagara Hospital, Kagoshima, Japan, [9]Shiga General Hospital, Moriyama, Japan, [10]Tenri Hospital, Tenri, Japan, [11]Keio University, Tsuruoka, Japan, [12]Fujita Health University, Toyoake, Japan

Background: Abemaciclib, a CDK4/6 inhibitor, stands as a cornerstone for managing hormone receptor-positive, HER2-negative advanced or metastatic recurrent breast cancer. It is known to modulate the tumor immune microenvironment, enhancing anti-tumor responses. Yet, its systemic immunological impact remains to be elucidated. This investigation aims to delineate the influence of abemaciclib on both the gut microbiota and the systemic immune landscape in patients with breast cancer.

Methods: A multicenter, prospective clinical trial was conducted involving 40 patients with hormone receptor-positive, HER2-negative advanced or metastatic recurrent breast cancer, scheduled for abemaciclib therapy. The trial's primary objectives were to evaluate the duration of treatment efficacy and the severity of gastrointestinal toxicity. Secondary objectives included assessing the interplay between circulating immune profiles, gut microbiota, and clinical outcomes. Patient samples, including peripheral blood mononuclear cells (PBMCs) for single-cell RNA sequencing and stool for 16S rRNA gene analysis, were collected at baseline and after 90 days of treatment initiation.

Results: This interim report presents findings from 39 patients. We examined 75 PBMC samples and 78 stool samples. Preliminary analysis indicated that abemaciclib precipitated an upregulation of cytokines pivotal for anti-tumor immunity, notably IL-7 and IP-10, alongside an activation of circulating innate immune cells such as CD4-positive T cells and dendritic cells. Concurrently, gut microbiota analysis revealed a post-treatment reduction in alpha diversity, with notable shifts in microbial populations implicated in innate immune activation.

Discussion: This study presents novel insights into the systemic immunomodulatory effects of abemaciclib. Our results suggest that abemaciclib's therapeutic efficacy may partially derive from its ability to alter the circulating immune profile and gut microbiota. These findings could pave the way for innovative immunotherapeutic approaches, integrating gut microbiome considerations into the treatment of hormone receptor-positive, HER2-negative breast cancer.

#5268 Targeting DHX9 triggers interferon response and replication stress in small cell lung cancer.

T. Murayama[1], J. Nakayama[2], K. Q. Cai[1], K. Miyata[3], A. Efimov[1], Y. Tan[1], Y. Zhou[1], K. S. Campbell[1], Y. Yang[1], S. Balachandran[1], I. Canadas[1];
[1]Fox Chase Cancer Center, Philadelphia, PA, [2]National Cancer Center Research Institute, Tokyo, Japan, [3]Japanese Foundation for Cancer Research, Tokyo, Japan

Small cell lung cancer (SCLC) is the most lethal type of lung cancer. The uniqueness of this tumor consists of an initial exquisite response to chemotherapy. However, at relapse, which occurs nearly in all patients, the tumor is resistant to all available therapies, causing a premature death of the patient. Despite the addition of immune checkpoint blockade (ICB) therapy to standard chemotherapy, response rates are modest and only a very small fraction of SCLC patients responds to these therapies because of immunologically “cold” microenvironment. Activating innate immunity in cancer cells through cytoplasmic nucleic acid sensing pathways, a phenomenon known as “viral mimicry”, has emerged as an effective strategy to convert immunologically “cold” tumors into “hot”. Here, through a curated CRISPR-based screen of RNA Helicases, we identified DExD/H-box helicase 9 (DHX9) as a potent repressor of double-stranded RNA (dsRNA) in SCLC cells. Depletion of DHX9 induced accumulation of cytoplasmic dsRNA, which mainly derived from repetitive sequences of short interspersed nuclear elements (SINEs) and long interspersed nuclear elements (LINEs), and triggered tumor-intrinsic innate immunity. Intriguingly, ablating DHX9 also induced the aberrant accumulation of R-loops (DNA/RNA hybrids), which resulted in an increase of DNA damage-derived cytoplasmic DNA and replication stress in tumor cells, selectively killing them. In vivo, DHX9 deletion in SCLC tumor cells promoted a decrease in tumor growth while inducing a more immunogenic tumor microenvironment (TME), invigorating responsiveness to immune checkpoint blockade (ICB). These findings suggest that DHX9 is a crucial repressor of tumor-intrinsic innate immunity and replication stress, and represents a promising and unexplored target for SCLC and other “cold” tumor types where replication stress and genomic instability contribute to pathology.

#5269 Evaluation of mitotic spindle inhibitors as cell autonomous inflammatory stimulants in MYC overexpressing breast cancers.

M. Jacobo Jacobo, A. Goga;
UCSF - University of California San Francisco, San Francisco, CA

The oncogenic transcription factor MYC is overexpressed in most cancer types, including difficult to treat human malignancies such as receptor triple-negative breast cancers (TNBC). MYC overexpression induces aneuploidy and suppresses anticancer immunity. Elevated levels of MYC can induce mitotic spindle assembly defects and chromosomal instability (CIN) events, exemplified by an increase in cells with micronuclei. These defects are partially mitigated by concomitant upregulation of various mitotic spindle genes. Micronuclei result in cytosolic DNA which can activate cGAS-STING signaling, activating an interferon regulatory transcriptional program responsible for mounting an inflammatory immune response that potentially enhances immune cell recognition. We hypothesized that pharmacological inhibition of specific MYC deregulated mitotic spindle genes will further exacerbate mitotic defects in MYC high cells resulting in synthetic-lethal cell death and additional CIN to activate robust cGAS-STING activation. Interferon activation can increase surface expression of antigen presentation machinery, such as MHC-I, restoring the immunogenicity of MYC high cells. Here, we used mouse breast tumor cells in which MYC expression is conditionally expressed as well as human breast cancer cell lines with different levels of MYC expression. We assessed the anti-proliferative and cytotoxic effects of 9 mitotic small molecular inhibitors that affect spindle function. cGAS-STING activation in inhibitor treated and untreated samples was measured by immunoblotting for pathway proteins phosphorylated TBK1, total TBK1, and IFIT1. Differences in MHC-I cell surface expression was quantified using flow cytometry. Our findings revealed that inhibition of kinesin-like protein KIFC1 and transforming acidic coiled-coil-containing protein 3 (TACC3) induced greater levels of apoptosis in MYC high models. Moreover, inhibition of KIFC1 robustly triggered cGAS-STING activity in MYC high cells as evidenced by increased protein abundance of phospho-TBK1 and IFIT1 in a dose-dependent manner. In addition, sublethal KIFC1 inhibition resulted in increased levels of MHC-I surface expression in MYC high models. Our findings suggest that inhibition of MYC regulated mitotic spindle genes, specifically KIFC1, can serve to preferentially eliminate MYC overexpressing aggressive cancers. Furthermore, sublethal concentrations of a KIFC1 inhibitor can stimulate a tumor cell-intrinsic inflammatory-pathway. Future studies will determine if targeting KIFC1 can enhance the response of MYC high cancers to immunotherapy.

#5270 Androgen receptor blockade in macrophages primes NLRP3 inflammasome-mediated phagocytosis and tumor clearance in advanced prostate cancer.

K. Chaudagar[1], S. Rameshbabu[1], S. Mei[2], T. Hirz[2], Y.-M. Hu[3], A. Argulian[1], B. Labadie[1], K. Desai[1], S. Grimaldo[1], D. Kahramangil[1], R. Nair[1], S. DSouza[1], D. Zhou[1], R. Chen[1], J. Shafran[1], M. Loyd[1], Z. Xia[3], D. Sykes[2], A. Moran[3], **A. Patnaik**[1];

[1]University of Chicago, Chicago, IL, [2]Center for Regenerative Medicine, Massachusetts General Hospital Cancer Center, Boston, MA, [3]Knight Cancer Institute, Oregon Health and Science University, Portland, OR

Immune-based therapies induce durable remissions in subsets of patients across multiple malignancies. However, there is limited efficacy of immunotherapy in metastatic castrate-resistant prostate cancer (mCRPC), manifested by an enrichment of immunosuppressive (M2) tumor-associated macrophages (TAM) in the tumor immune microenvironment (TME). Therefore, therapeutic strategies to overcome TAM-mediated immunosuppression are critically needed in mCRPC. Our single-cell RNA sequencing analysis in human tumors revealed that NLR family pyrin domain containing 3 (NLRP3), an innate immune sensing protein, is differentially expressed in TAM from metastatic PC patients treated with standard-of-care androgen deprivation therapy (ADT), relative to other tumor types and untreated primary PC. Furthermore, bulk RNA sequencing analysis in human mCRPC samples revealed an inverse relationship between NLRP3 expression and AR activity, with high NLRP3 expression associated with an M1 signature and a favorable clinical response to ICI in mCRPC. Based on these findings, we hypothesized that androgen axis blockade could enhance NLRP3 expression and potentiate innate immune tumor control in advanced PC. Critically, we discovered that blockade of TAM-intrinsic androgen receptor (AR) activity enhanced NLRP3 expression, but not inflammasome activity in the immunosuppressive (M2) TAM. In contrast, anti-tumor (M1) TAM exhibited high de novo NLRP3 expression, regardless of AR activity. The combination of AR blockade and NLRP3 agonism significantly enhanced phagocytosis of cancer cells by M2 TAM, whereas NLRP3 agonist treatment alone was sufficient to induce phagocytosis in M1 TAM. Following AR blockade/NLRP3 agonist combination treatment, all TAM acquired a distinct phenotype with high PD-L1 and CD86 expression, indicative of phagocytic TAM. Critically, NLRP3 agonism in combination with ADT resulted in significant tumor control in an aggressive c-myc driven advanced PC model, with 55% of mice achieving complete tumor clearance, which was abrogated by concurrent clodronate treatment (which systemically depletes phagocytic macrophages), thus demonstrating TAM-mediated phagocytosis enhancement as a major driver of the observed anti-tumor response. Collectively, our results identify NLRP3 as an AR-regulated “macrophage phagocytic checkpoint” that can be inducibly expressed and activated in TAM following ADT and NLRP3 agonist treatment, respectively, the combination resulting in TAM-mediated phagocytosis and tumor control.

#5271 Pseudohypoxia by HIF-PHD inhibitors activates tumor immune response for MSS colorectal cancer.

T. Ohara, Y. Chen, Y. Hamada, S. Nishimura, H. Kawai, K. Noma, H. Tazawa, T. Fujiwara, A. Matsukawa;
Okayama Univ. Graduate School of Med., Okayama, Japan

Purpose: Microsatellite-stable (MSS) colorectal cancer is resistant for immune therapy, necessitating the exploration of novel modalities for its conquest. Recent revelations have revealed the genetic upregulation of HIF-1α as a potential activator of CD8+ T-cells, enhancing an anti-tumor effect. Pseudohypoxia, characterized by normoxic upregulation of Hypoxia-Inducible Factor (HIF-1α), is known to be induced by iron chelators, including HIF-PHD inhibitors. In this study, we aimed to examine whether pseudohypoxia by HIF-PHD inhibitor can enhance immune response and elucidate the underlying mechanism.
Method: Colon 26, SW480 and HT29 were used as murine and human MSS colorectal cancer model. Human and murine CD8+ T-cells were represented by Jurkat cells and isolated splenic CD8+ T-cells, respectively. HIF-PHD inhibitors Roxadustat and Vadadustat were used in the study, and a subcutaneous Colon 26 tumor model was established in BALB/c WT and nude mice. Hypoxic culture conditions were maintained for 48 hours at 2% O_2.
Results: Roxadustat and Vadadustat did not suppress the proliferation of cancer cells under conditions marked by HIF-1α upregulation. Roxadustat and Vadadustat suppress the colon 26 subcutaneous tumor growth in WT mice, the effect was cancelled in the nude mice. The treatment regimen was associated with an augmentation in the total number and effector-like subtypes of CD8+ T-cells (T_{ex}) infiltrating the tumor. Combination therapy involving Roxadustat and PD-1 antibody synergistically inhibited tumor growth and was accompanied by an increase in PD-1^{lo}, Ly108^{-}, TIM-3^{+} CD8+ T-cells within the tumor microenvironment. Immunohistochemistry revealed that Interleukin-2 (IL-2) expression of murine spleen was stronger in Roxadustat than control group. Interestingly, HIF-PHD inhibitors induced the secretion of IL-2 from isolated CD3+ T-cells of murine spleens in ELISA, a phenomenon uniquely observed under pseudo-hypoxic conditions created by HIF-PH inhibitors, rather than actual hypoxia. This result indicates that pseudo-hypoxia may induce more robust hypoxic response than real hypoxia.
Conclusion: The induction of pseudohypoxia by HIF-PHD inhibitors activates the tumor immune response for MSS colorectal cancer via induction of splenic IL-2.

#5272 APL-1202 enhances anti-tumor immune response through induction of cellular stress signaling and immunogenic cell death pathway in cancer cells.

Rakesh BAM[1], Jingmin Guan[2], Neetha Nanoth Vellichirammal[1], Murli Manohar[1], David Mulholland[3], John Sfakianos[3], Qiaoling Sun[2], Zuoan Yi[1], Alice Chen[1]

[1]Asieris Pharmaceuticals, Inc., Palo Alto, CA,[2]Asieris Pharmaceuticals, Shanghai, China,[3]Mount Sinai School of Medicine, New York, NY

Introduction: Treatment approach combining cancer cell targeted therapy and immunotherapy is an effective strategy to trigger robust tumor-specific immune responses. The aim of this study is to determine the impact of APL-1202, a clinical-stage drug candidate (NCT04813107), on cellular stress-driven immunogenic outcomes in bladder cancer cells.

Methods: RNA-seq analysis was performed using bladder cancer and endothelial cell lines (A56, J82, T24, HUVEC) treated with APL-1202. Key determinants of immunogenic cell death pathway were measured by cell-surface translocation of calreticulin (flow cytometry), extracellular ATP release assay (bioluminescence) and HMGB1 secretion (ELISA) in the supernatants of cancer cells after APL-1202 treatment. Effects on the innate immune effector function was measured by flow cytometry-based phagocytosis assay consisting of Far-Red dye-stained, pre-treated bladder cancer cell lines (UMUC3, T24) in coculture with THP1-derived macrophages/immature dendritic cells or human monocyte-derived dendritic cells. *In vivo*, tumor end-point immune cell analysis, tumor weight and mouse survival were compared in chemically induced (BBN: N-butyl-N-(4-hydroxybutyl)-nitrosamine) orthotopic bladder cancer mice treated with APL-1202 and anti-PD1 antibody.

Results: Pathway analysis of RNA-seq data from APL-1202 treated cells suggested upregulation of cellular stress-related gene signatures (oxidative stress, autophagy, P53) and pro-inflammatory responses (IL-6, IL-8, HMGB1 signaling). Conversely, downregulation of cell cycle (E2F targets, G2-M checkpoint) and IL-10 signaling suggested increased genomic stress and inflammatory switching in the treated cancer cells. Acute exposure to APL-1202 increased cell-surface translocation of calreticulin as well as extracellular release of ATP and HMGB1 in the treated T24 and UMUC3 cells. Higher percentages of phagocytic activities were detected in both THP-1-derived macrophages/immature dendritic cells and human monocyte-derived dendritic cells after coculture with APL-1202 treated T24 and UMUC3 cells compared to coculture with DMSO treated control cells. Immune phenotyping in tumors derived from BBN bladder cancer mouse model revealed increased infiltration of NK cells and CD8+ T cells. Furthermore, APL-1202 enhanced the anti-tumor effects of a therapeutic anti-PD1 antibody in mice as reflected by significantly decreased tumor weights and increased survival in a combination group with APL-1202 treatment compared to the anti-PD-1 antibody alone treatment group.

Conclusion: APL-1202 may improve the efficacy of immune-checkpoint blockade therapies in bladder cancer patients by enhancing cancer cell immunogenicity and subsequent anti-tumor effector immune cell processes, particularly in tumors with deficits in antigen-specific immunity.

#5273 A novel immunogenic cell death that exploits the cancer-specific overexpression of Rad51.

Maria Soloveychik, Charly Chahwan

SyntheX, San Francisco, CA

Overexpression of the Homologous Recombination (HR) DNA repair pathway is often correlated with poor prognosis and metastatic disease. SyntheX developed STX100, a small, stabilized peptide that is able to disrupt the function of Rad51 - a crucial component of HR. STX100 exhibits low nanomolar affinity to the target, cell permeability, and proteolytic stability. STX100 has acute mono-agent activity that is selective towards HR-overexpressing cancer cells. Interestingly, STX100-mediated cell killing is independent of canonical cell death mechanisms (apoptosis, necroptosis, pyroptosis, ferroptosis, etc.). Rather, the elevated abundance of Rad51 in cancer cells relative to healthy tissues underlies the selective cytotoxicity resulting from an acute calcium surge upon STX100-mediated target engagement. The mechanism translates to in vivo models, where a single dose can achieve sustained survival when administered locally as a mono-therapy or in combination with an immune checkpoint blockade agent.

#5274 Targeting retinoblastoma protein in tumor-associated macrophages suppresses ovarian cancer progression.

E. N. Tcyganov[1], T. Kwak[1], X. Yang[1], A. N. R. Poli[1], C. Hart[1], A. Bhuniya[1], J. Cassel[1], A. Kossenkov[1], N. Auslander[1], P. Sharma[1], M. G. Cadungog[2], S. Jean[2], S. Chatterjee-Paer[2], D. Weiner[1], L. Donthireddy[1], B. Bristow[2], R. Zhang[3], J. M. Salvino[1], L. J. Montaner[1];

[1]The Wistar Institute, Philadelphia, PA, [2]Christiana Care Health System, Wilmington, DE, [3]University of Texas MD Anderson Cancer Center, Houston, TX

Ovarian cancer is characterized by an immunosuppressive tumor microenvironment (TME) maintained by tumor-associated M2-like macrophages (TAMs) hindering anti-tumor responses and immunotherapy efficacy. An effective approach to target TAMs in ovarian cancer treatment is currently not available, but would be expected to release immunosuppressive pressure, enable a robust T cell response and improve immunotherapy outcomes. Retinoblastoma protein (Rb) is a well-known tumor suppressor and regulator of tumor cell proliferation. Accumulating evidence demonstrates its role in immune cells, in myeloid cells, in particular. However, these mechanisms remain poorly understood.

Based on our previous data on Rb role in myeloid cell viability, we decided to test the effects of Rb modulation in macrophages. We used the small molecule, AP-3-84 compound, and newly developed analogs which bind the LxCxE motif of Rb and disrupt Rb interaction with its binding adaptor proteins. AP-3-84 induced cell death preferentially in macrophages, but not in T cells or tumor cells (without effects on cell proliferation). Gene and protein expression analysis revealed that Rb targeting induced major intracellular stress response programs and p53/mitochondria-related cell death pathways in TAMs. Moreover, we found that M2 type polarized macrophages expressed higher levels of Rb compared to M1 macrophages. In agreement with that, M2 type macrophages were significantly more sensitive to AP-3-84 treatment than M1 polarized cells. Next, we demonstrated that low dose therapeutic use of AP-3-84 in mice bearing ovarian cancer significantly re-shaped the immune composition of the TME by depleting TAMs and inducing remarkable T cell infiltration. Importantly, these AP-3-84 effects were immune-mediated, since identical AP-3-84 treatment in NSG immunodeficient mice had no effect on tumor growth. Similarly, anti-CD4/CD8 depletion also reverted AP-3-84 effects on cancer inhibition. An analysis of activation and differentiation markers in myeloid and T cell subsets in the TME showed a shift of the remaining macrophages towards an M1-like cell type accompanied by activation of T cells. Using ovalbumin-overexpressing ovarian cancer cell line, we documented the accumulation of antigen-specific T cells in the TME associated with a substantial delay of ovarian cancer upon AP-3-84 therapeutic Rb targeting.

Ex vivo, we observed an analogous cell death induction by AP-3-84 treatment in TAMs from post-surgery ascites from ovarian cancer patients. Using available datasets, we further documented that an increase in Rb expression in the TME myeloid cells is associated with poorer prognosis.

Overall, our data supports that therapeutic targeting of the Rb LxCxE motif is a promising approach for ovarian cancer treatment due to depletion of TAMs and re-shaping the ovarian cancer TME.

#5275 Celecoxib and chloroquine enhance the antitumor effect of immune checkpoint blockade therapy, in a syngeneic mouse model for pancreatic cancer.

J. Moore[1], D. Chand[2], D. Levey[2], D. Von Hoff[1], H. Han[1];

[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [2]Agenus Inc., Lexington, MA

Immune checkpoint inhibitors (ICIs) have shown impressive clinical activities in some cancer types, but they have yet to demonstrate any meaningful clinical benefit in patients with pancreatic ductal adenocarcinoma (PDAC) except those with microsatellite instability high (MSI-H) tumors. Several recent studies showed that concomitant use of NSAIDs such as celecoxib by patients with certain cancers could improve the survival benefit of ICI treatment (e.g., Sebastian et al, Clin Lung Cancer, 2023;). Furthermore, autophagy inhibitors such as chloroquine were also reported to sensitize pancreatic tumors to the treatment of ICIs in mouse models for PDAC (Yamamoto, et al, Nature, 2020). We recently reported that the combination of chemotherapy (triple combination of nab-paclitaxel + gemcitabine + cisplatin) and a mouse surrogate of the IFc-enhanced anti-CTLA-4 antibody botensilimab, showed significantly improved antitumor activity in immune competent KPC syngeneic mouse model for PDAC [Tanne, et al, Cancer Res (13_Supplement), 2020]. In this study, we sought to determine whether or not the addition of celecoxib and/or chloroquine further improve the antitumor activity of triple chemotherapy and ICI in the syngeneic KPC model. We first found that celecoxib (30mg/kg P.O. QDx21) significantly enhanced the tumor growth inhibition when added to triple chemotherapy (Gemcitabine 70mg/kg I.P., Cisplatin 4mg/kg I.P., Nab-paclitaxel 25mg/kg I.V. days 1,4 and 7) plus the murine equivalents of botensilimab (100ug I.P. BIW for three weeks) and balstilimab (200ug I.P. BIW for three weeks) ($p=0.004$, N=10). We then performed a pilot study to assess if adding chloroquine could further improve the activity. While adding chloroquine (60mg/kg I.P. QDx21) alone did not significantly affect tumor growth the addition of both chloroquine and celecoxib greatly improve the tumor growth inhibition compared to just the triple chemotherapy and ICIs ($p=0.009$, N=5). Overall, our data showed that celecoxib or the combination of celecoxib and chloroquine could substantially sensitize the mouse pancreatic tumors to the treatment of chemotherapy and ICIs. (This work was supported in part by the Seena Magowitz Foundation and the Purple Pansies)

#5276 Immunomodulatory activity of intermittent low-dose erlotinib plus sulindac: Implications for hereditary and sporadic colorectal cancer.

C. Tripathi[1], **J. E. Tovar Perez**[1], S. Kapoor[1], A. Muhsin[1], W. Dashwood[1], Y. Demirhan[1], M. Demirhan[1], A. Shapiro[1], A. Mohammed[2], S. Sei[2], P. H. Brown[3], M. I. Savage[3], E. Vilar[3], P. Rajendran[1], R. H. Dashwood[1];

[1]Texas A&M University, Houston, TX, [2]National Cancer Institute, Rockville, MD, [3]The University of Texas MD Anderson Cancer Center, Houston, TX

A once-weekly optimized dosing regimen of erlotinib (ERL) in the polyposis in rat colon (Pirc) model [1] was a reliable predictor of antitumor efficacy in familial adenomatous polyposis (FAP) patients [2]. Pirc rats are increasingly used as a translational tool for FAP studies. Based on transcriptomic data from FAP patients receiving ERL plus sulindac (SUL) vs. placebo [3], we determined the timing of changes in interferon-γ signaling in Pirc adenomas, while performing additional dose titration. In rats that were given ERL administered at 5 mg per kilogram of body weight through oral gavage (two times a week) and that received a diet containing 125 parts per million of SUL, a regimen referred to as SUL125+ERL5x2, significant suppression of tumor growth was observed. This combination represented half of the standard of care SUL dose and about one-quarter of the ERL dose in FAP patients. In adenomas collected after one year of treatment from SUL125+ERL5x2 treated rats, the expression of genes related to the major histocompatibility complex (MHC) class I (β2m, Cnx, Psmb8 and Tap1) and MHC class II (RT1-A2, Cd74, RT-1Bb, Cd74, and Ciita) was increased, compared to vehicle controls, excluding a subset of adenomas that remained resistant. Through the use of multiplex mass cytometry (CyTOF), an increase in tumor-infiltrating CD4+ T cells was observed in adenomas from the SUL125+ERL5x2 treatment group. Administration of single or combined agents increased CD68+ cells and reduced the presence of Foxp3+ and Arg1+ cells in Pirc adenomas. The natural history of adenomatous colon polyps indicated an increase in MHC gene expression as tumors increased in size; however, this trend reversed markedly in fully occluding lesions. Additionally, expression of MHC-related factors increased in Pirc colon adenoma and murine colon carcinoma cells treated with ERL±SUL, resulting in enhanced CD8+ T-cell activation and IL-2 secretion. In conclusion, treatment with intermittent low doses of ERL±SUL increased MHC gene expression and induced changes in the immune cell component in the tumor microenvironment of Pirc rat adenomas. A subset of non-responsive adenomas could benefit from additional immunopreventive approaches, with implications for possible clinical applications in both hereditary and sporadic colorectal cancer.

#5277 The ROCK-2 inhibitor belumosudil exerts a direct antimyeloma effect and improves isatuximab-mediated cytotoxicity against multiple myeloma cells.

M. Meloni[1], P. Perrin[1], C. Nouguier[1], S. Poirier[2], M. Bouaboula[2], K. Bisht[2], H. Van de Velde[2], A. Virone-Oddos[1], M. Chiron[1];
[1]Sanofi, Vitry-sur-Seine, France, [2]Sanofi, Cambridge, MA

Multiple myeloma (MM) is a plasma cell malignancy characterized by clonal accumulation of malignant plasma cells in the bone marrow. Isatuximab (Sarclisa®) is a monoclonal antibody used for the treatment of MM. Isatuximab binds to CD38 (highly expressed on MM cells) and induces tumor cell killing via several mechanisms including antibody dependent cellular cytotoxicity (ADCC) and direct apoptosis. Belumosudil (Rezurock™) is a ROCK2 inhibitor that is approved for the treatment of chronic graft versus host disease (cGVHD). Recent reports suggest that inhibition of ROCK2 induces apoptosis and prevents growth of MM cells. Here, we investigated the potential antimyeloma effect of belumosudil alone or in combination with isatuximab with different readouts of viability, apoptosis and cytotoxicity.

The potential cytotoxic effect of belumosudil (as single agent or in combination with isatuximab) against MM cells was assessed *in vitro* by flow cytometry apoptosis assay, CellTiter-Glo® luminescent cell viability assay or long-term cytotoxic assay (Incucyte). The effect of belumosudil on healthy donor-derived NK cells viability was also assessed by flow cytometry.

Belumosudil reduced the number and viability of several MM cell lines without affecting healthy donor NK cell number and viability. Moreover, belumosudil induced apoptosis of MOLP-8 MM cells in a dose-dependent manner and further increased MOLP-8 cell apoptosis when combined with isatuximab after 2, 3 and 4 days of *in vitro* treatment. Belumosudil induced killing of MM cells in a dose-dependent manner over time (up to 4 days), independently of the presence of NK cells, as measured by Incucyte-based cytotoxicity assay. In addition, the combination of belumosudil (3.3 µM) with isatuximab (10 µg/ml) in presence of NK cells enhanced the killing of different MM cell lines over time compared to single agents.Finally, the expression of CD38 on MM cells has been documented to be decreased after treatment with anti-CD38 antibodies. Interestingly, analysis of CD38 expression on MM cells indicated that belumosudil induces an increase of CD38 on the surface of MOLP-8 MM cells and prevents isatuximab-induced decrease of CD38 expression.

These data suggest that belumosudil has a direct antimyeloma effect and increases isatuximab-mediated cytotoxicity against MM cells, without affecting the viability of NK cells. Taken together, this study provides evidence of the therapeutic potential of belumosudil in combination with isatuximab in the setting of MM.

#5278 Immunological control by PARP inhibitors for successful immunotherapy in metastatic ovarian carcinoma.

P. Holicek[1], S. Vosahlikova[1], I. Moserova[1], S. Orsulic[2], R. Mikyskova[3], M. Hensler[1], L. Kasikova[1], T. Lanickova[1], O. Novotny[3], M. Reinis[3], J. Drozenova[4], A. Ryska[5], J. Laco[5], L. Rob[4], M. Halaska[4], D. Cibula[6], R. Spisek[1], J. Fucikova[1];

[1]SOTIO Biotech, Inc., Prague, Czech Republic, [2]University of California, Los Angeles, CA, [3]Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic, [4]3rd Faculty of Medicine and University Hospital Kralovske Vinohrady, Prague, Czech Republic, [5]Charles University, Faculty of Medicine and University Hospital Hradec Kralove, Hradec Kralove, Czech Republic, [6]Gynecologic Oncology Center, Prague, Czech Republic

Epithelial ovarian carcinoma (EOC) is among the top five causes of cancer-related death in women. Most women with EOC achieve indeed complete remission after primary or interval cytoreductive surgery combined with chemotherapy based on a platinum-taxane doublet. Homologous recombination (HR) defects imposed by germline or somatic BRCA1 DNA repair-associated (BRCA1) or BRCA2 mutations are not only key determinants of platinum sensitivity in EOC patients but also provide a strong rationale for maintenance therapy based on poly(ADP-ribose) polymerase (PARP) inhibitors, which is generally associated with improved progression-free survival (PFS). Besides direct cytotoxic and cytostatic properties, PARPi have been shown to mediate multipronged immunostimulatory effects, largely reflecting their ability to inhibit DNA repair in malignant cells and indicating the possibility to synergy with immune-check point inhibitors (ICIs). Here, using multiparametric flow cytometry, multiplex immunostaining, single cells transcriptomics and functional studies in experimental syngeneic BR5$^{Brca1-/-}$ mouse model and EOC tumor samples, we discuss PARPi immunomodulatory activity, with a specific focus on molecular and cellular pathways that can be harnessed to develop superior combinatorial regimens for clinical management. Thus, PARPi might enhance the mutational load of EOCs as consequence of unrepaired DNA damage and DAMPs exposure, favoring T cell infiltration, but also appear to drive robust type I IFN secretion downstream of cyclic GMP-AMP synthase and stimulator of IFN response cGAMP interactor 1 activation. In addition, the combination of PARPi with ICIs positively regulate the balance between adaptive anti-tumor immunity and innate myeloid components and significantly improve the cytotoxic T cell profile as shown in both experimental mice model and HGSOC tumor samples. We surmise that rationally designed combinations of PARPi and immunotherapeutic agents might be critical to unlock immunosuppression in the EOC microenvironment in support of clinical efficacy.

#5279 Sequential treatment with PARPi and WEE1i minimizes T cell DNA damage and enhances its immune response.

X. Jiao[1], J. Liu[1], W. Mu[1], L. Zhu[1], X. Zhao[1], G. B. Mills[2], Q. Gao[1], **Y. Fang**[1];

[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, [2]Oregon Health and Sciences University; Knight Cancer Institute, Portland, OR

Background: DNA damage response (DDR) targeted therapy, like PARP inhibitors (PARPi) and WEE1 inhibitors (WEE1i), have demonstrated potent anti-cancer activity and are pronounced to activate the cytosolic immunity pathway. Our previous work showed that sequential inhibition of PARP and WEE1 could kill tumor cells as effective as their concurrent application, with ameliorated toxicity to normal cells, suggesting high clinical translational potential of this regimen. However, the effect of sequential treatment on T lymphocytes and anti-cancer immunity remains largely unknown.

Methods and results: T cells were treated with 25 μM olaparib, or 250 nM AZD1775, or olaparib combined with AZD1775 (concurrent group) for 48h, or olaparib for 24h followed by AZD1775 for 24h (sequential group) in vitro. AZD1775 and concurrent treatment reduced the T cell viability to 19% and 14.3%, while sequential treatment maintained the viability to 58.6%, closed to olaparib monotherapy (61.6%). And the most potent proliferation capacity accompanied with the lowest apoptosis level were both recorded after sequential treatment, manifested by the increasing of Ki67 and EdU and the decreasing of cleaved caspase-3. Reverse-phase protein arrays (RPPA) analyses identified relieved DNA damage in T cells receiving sequential treatment. Alkaline comet assay and detecting of γH2AX further confirmed that the T cell DNA damage caused by PARPi and WEE1i was obviously alleviated after sequential therapy. Furthermore, sequential treatment activated cGAS-STING pathway effectively and upregulated the production of CCL5, CXCL10 and IFNβ of downstream type I interferon response compared with monotherapy and concurrent treatment in ovarian cancer cell lines (SKOV3, OVCAR8, A2780). We also evaluated an ID8 intraperitoneal syngeneic immunocompetent mouse model. T cells isolated from tumors, ascites, spleen and peripheral blood in sequential group were presented with the highest proliferation potential and the lowest level of DNA damage. And the tumor burden of mice in sequential group was obviously subsided, which was comparable to that in concurrent group.

Conclusions: This study demonstrated that targeting PARP and/or WEE1 impaired the T cell viability and led to DNA damage. However, administrating PARPi and WEE1i sequentially diminished this inhibitory effect on T cells on the premise of ensuring their anti-tumor effect. These data provide strong rational for the further investigation on exploring the clinical significance of sequential treatment with PARPi and WEE1i.

#5280 Minimizes T cells DNA damage induced by PARP inhibitors and enhances its anti-tumor efficacy.

Jiahao Liu[1], Xiaofei Jiao[1], Wei Mu[2], Huayi Li[1], Li Zhu[2], Xuejiao Zhao[1], Gordon B. Mills[3], Qinglei Gao[1], **Yong Fang**[1]

[1]Department of Gynecological Oncology, Cancer Biology Research Center, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[2]Department of Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[3]Department of Cell, Development and Cancer Biology, Oregon Health and Sciences University; Knight Cancer Institute, Portland, OR

Background: Poly (ADP-ribose) polymerase (PARP) inhibitors have emerged as promising targeted therapies for ovarian and breast cancer. The sustained remission induced by PARP inhibitors largely depends on T cell activity. However, the direct effects of PARP inhibitors on T cells, as well as their precise impact on T cell DNA integrity and subsequent anti-tumor immune responses, have not been fully elucidated.
Method & Result: Following treatment with 25 μM olaparib or 15 μM niraparib for 48 hours, T cell viability decreased by 39.20% and 41.89%, respectively. Reduced proliferation and increased cell death were also observed, as indicated by reduced Ki-67 and elevated cleaved Caspase-3 levels. RNA sequencing further revealed a significant enrichment of DNA damage pathways in T cells after olaparib treatment, which was validated by elevated γH2AX levels in T cells using western blots and immunofluorescence. To assess PARP inhibitor-induced DNA damage in clinical settings, paired ovarian cancer samples pre- and post-niraparib monotherapy were obtained from the NANT trial (NCT04507841). Post-treatment tumor samples exhibited a higher number of γH2AX+ T cells compared to their pre-treatment counterparts. To identify the key protein mediating T cell inhibition induced by PARP inhibitors, a whole genomic CRISPR knock-out screening was conducted in human T cells, revealing an enrichment of sgRNAs targeting PARP1 after PARP inhibitor treatment. This outcome was further confirmed by the knockout of PARP1 in human T cells in vitro, leading to the restored viability and reduced levels of DNA damage after olaparib treatment. Importantly, following cytosine base editors (CBEs) of PARP1 in CAR-T cells, improved anticancer activity was observed both in vitro and in two ovarian cancer patient-derived xenografts (PDX) models when combined with PARP inhibitors.
Conclusion: This study observed that PARP inhibitors can cause significant DNA damage in human T cells, resulting in cell death, inhibited proliferation, and impairment of anti-cancer immunity. PARP1 was identified as the target for PARP inhibitor-induced T cell death, and its knockout or point mutation led to improved anticancer efficacy of T cells when used in combination with PARP inhibitors. [JH Liu and XF Jiao contributed equally as co-first authors.]

#5281 5-Fluorouracil decreases MDSC and the development of osteolytic bone metastases from breast cancer in mice.

P. G. Fournier[1], P. Almeida Luna[1], D. Arellano[1], S. Jimenez[1], F. Olvera[2], P. Juarez[1];

[1]Centro de Investigacion Cientifica y de Educacion Superior de Ensenada, Ensenada, Mexico, [2]Instituto de Biotecnologia Universidad Nacional Autonoma de Mexico, Cuernavaca, Mexico

Bone metastases are a highly debilitating complication in more than 70% of patients with advanced breast and prostate cancer. Currently approved treatments fail to cure bone metastases or increase patient survival. Although immunotherapies can cause a durable response in some patients, it seems that their efficacy is limited in bone metastases, which could be due to a cold metastatic microenvironment. Our aim was to identify immunosuppressive factors in bone metastases and target them using a drug-repositioning type approach. We used a syngeneic model in which 4T1 triple-negative breast cancer cells derived from a Balb/C mouse are inoculated in the left cardiac ventricle of Balb/C mice to cause osteolytic bone metastases. Using flow cytometry, we found that the bone marrow of mice with 4T1 bone metastases is enriched in large cells with a high SSC index that could be myeloid-derived suppressor cells. We confirmed that the inoculation of 4T1 cells increased the amount of $CD11b^{+}$ $Ly6G^{+}$ $Ly6C^{lo}$ ROS^{hi} and $CD11b^{+}$ $Ly6G^{-}$ $Ly6C^{hi}$ NO^{hi} cells. Both cell types were isolated from bone metastases and prevented the proliferation of $CD8^{+}$ T cells *ex vivo*, confirming they were polymorphonuclear- (PMN-) and monocytic-MDSCs (M-MDSCs), respectively. In addition, both types could differentiate into osteoclasts that cause bone loss. Reviewing the current literature, we found that FDA-approved sildenafil (a PDE-5 inhibitor), zoledronic acid (a bone resorption inhibitor), and 5-fluorouracil (5-FU, a chemotherapeutic agent) can decrease MDSCs in other cancer models. However, sildenafil (20mg/kg, i.p., every 2 days) and zoledronic acid (25µg/kg, s.c., 3x/week) did not decrease the amount of MDSCs in 4T1 bone metastases. 5-FU (i.p., 4 inoculations) at 50mg/kg prevented the 4T1-induced splenomegaly and the increase of PMN- and M-MDSCs but seemed to decrease the number of T cells in bone metastases. Thus, we tested the efficacy of a lower number of inoculations. A single inoculation of 5-FU was not efficient, while 2 or 3 inoculations of 5-FU (50mg/kg) prevented the splenomegaly and the histological damage due to extramedullary hematopoiesis in the spleen. In 4T1 bone metastases, there was a decrease of PMN-MDSCs and an increase of the number of $CD4^{+}$ and $CD8^{+}$ T cells. On radiographs, 2 or 3 inoculations of 5-FU (50mg/kg) significantly decreased the area of the osteolytic lesions caused by 4T1 cells (-57% and -60%, respectively, compared to placebo, $P<0.005$). In conclusion, our results show that functional PMN- and M-MDSCs can increase and accumulate in the microenvironment of breast cancer bone metastases and that an optimized treatment with 5-FU can prevent this expansion of MDSC, increasing T cell infiltration in bone metastases and decrease the associated bone lesions. Treatment with 5-FU could then contribute to turning bone metastases from a cold to a hot microenvironment and increase the efficacy of immunotherapies in patients.

#5282 Sulindac modulates the response of triple negative breast cancer to anti-PD-L1 immunotherapy.

B. Yi, R. Ma, Y. Xi;
University of Georgia, Athens, GA

Triple-negative breast cancer (TNBC) is a heterogeneous tumor, and there is a lack of effective therapies. Immune checkpoint inhibitors (ICIs) therapy has been widely used to treat a variety of human cancers including TNBC. Despite the FDA's approval of therapies like Atezolizumab (anti-PD-L1) and Pembrolizumab (anti-PD-1) for certain TNBC cases, more than half of all TNBC patients, especially those with low PD-L1 levels and in advanced stages, remain unresponsive. Therefore, there is urgent clinical need to find other innovative combination therapy strategy for these TNBC patients. In this study, we examined the efficacy of sulindac to enhance the response of TNBC to anti-PD-L1 immunotherapy. We utilized a 4T1 syngeneic mouse tumor model to compare the inhibitory effects of PD-L1 antibody, sulindac, and their combination on 4T1 tumor growth. We found that mice treated with combination therapy showed a significant reduction in tumor volume, along with increased infiltration of activated T lymphocytes (Granzyme B+/CD8+ T cells) in the tumor tissues. We also established a PBMC humanized mouse model to further confirmed that combination therapy could significantly reduce the tumor size of TNBC patient-derived xenografts (56S) and the combination group were found to have the most infiltrating activated human T lymphocytes (Granzyme B+/CD8+ T cells) in the tumor tissues. Immunofluorescent staining of organoids also confirmed that organoids from combination group have more CD8+ T cell and the results of organoid cell viability assay *in vitro* indicated that combination of sulindac with PD-L1 antibody together with activated human PBMC significantly reduce 56S organoid cell viability, which is consistent with *in vivo* study. When investigating the mechanism of action, first we found sulindac could downregulate exosomal PD-L1 by decreasing expression of nsMase2 which is a major regulator in production of exosomal PD-L1. Second, we demonstrated that sulindac could downregulate PD-L1 by blocking Stat3 signaling and enhancing the expression of miR-570-3p which can potentially target PD-L1, which in turn led to a further decrease in exosomal PD-L1. Previous study showed that PD-L1 antibody could be bound and consumed by exosomal PD-L1 in the blood circulation. Therefore, in combination therapy, sulindac downregulating exosomal PD-L1 leads to increased availability of PD-L1 Ab, which potentially improves the overall efficacy of anti-PD-L1 therapy. In conclusion, our findings provide unique insights into the mechanism of action and efficacy for sulindac as an immunomodulatory agent in combination with anti-PD-L1 therapy for the treatment of TNBC.

#5283 Polyamine blockade therapy: A strategy to block immunosuppression in pancreatic cancer.

J. A. Goode;
University of Central Florida, Orlando, FL

Pancreatic ductal adenocarcinoma (PDAC) is lethal in 88% of patients and is characterized by a dense tumor microenvironment (TME) which impedes tumor entry of immune cells and delivery of therapeutics. Immunosuppressive myeloid populations of PDAC, including myeloid-derived suppressor cells (MDSCs) and tumor-associated macrophages (TAMs), are known to not only support PDAC development but also impede the anti-tumor immune response elicited by therapeutic agents. To improve prognosis while maintaining tolerability, this study aims to target polyamine metabolism that is upregulated in the immunosuppressive myeloid populations and cancer cells to disrupt their contribution to PDAC progression and the immunosuppressive TME. We previously demonstrated that polyamine blockade therapy (PBT), via blocking biosynthesis with difluoromethylornithine (DFMO) and transport with a novel inhibitor (Trimer44NMe), elicits an anti-tumor response and improves median survival in PDAC engrafted immunocompetent mice. In the current study, PBT was found to lead to a selective reduction of the dominant MDSC subtype in PDAC, polymorphonuclear (PMN) MDSCs. Upon co-culturing of MDSCs with CD8+ T cells, PBT dampened MDSC-mediated suppression of T cell activity. These findings were corroborated by tracking Arginase 1, a driver of MDSC-mediated immunosuppression, which exhibited a significant decrease in response to PBT at both the activity and gene expression level. Ex-vivo generated M2 macrophages and TAMs treated with PBT also demonstrated a shift from the M2 pro-tumor phenotype towards the anti-tumor M1 macrophage phenotype. In summary, these findings support that PBT is effective at reducing myeloid-mediated immunosuppression through subtype specific modulation and supports the use of PBT for treatment of PDAC in combination with other immunomodulatory therapeutics.

#5284 Immune surveillance of chemotherapy-induced mutant subclones in CRC.

P. Vitiello[1], P. Battuello[1], R. Chila[2], V. Battaglieri[2], V. Amodio[2], G. Grasso[1], F. Di Nicolantonio[1], G. Crisafulli[2], G. Germano[1], A. Bardelli[1];
[1]University of Turin, Torino, Italy, [2]IFOM ETS - The AIRC Institute of Molecular Oncology, Milano, Italy

Molecular alterations generated by DNA repair deficiencies and DNA damaging agents can be detected by the host immune system and this can restrict cancer growth. We have previously reported that temozolomide (TMZ) is able to induce MMR defects and hypermutability leading to immunotherapy clinical benefit in the subset of CRCs characterized by inactivation of O6-methylguanine methyltransferase (MGMT). We reasoned that combination of chemotherapeutic agents could similarly impair DNA repair function, increase mutational burden and trigger cancer immunogenicity in the larger group of MMR proficient (MMRp) / MGMT wild type (MGMTwt) CRCs. For this reason, we investigated the impact of treatment with TMZ and cisplatin (CDDP), as well as other commonly used cytotoxic agents in CRC such as 5-fluorouracil, irinotecan and oxaliplatin, on the immunogenomic features of murine CRC cells. We performed a two-step experiment: first, murine CRC models were exposed *in vitro* to chemotherapy agents used alone or in combination in a pulsatile schedule in order to mimic drug exposure in the clinical setting (priming phase); second, the cells were challenged *in vivo* with subcutaneous injection in immune-deficient and -proficient syngeneic mice (editing phase). Whole exome sequencing (WES) was performed at baseline and after both the priming and the editing phases to identify mutational signatures, predict neoantigens and assess immunoediting. We found that combinatorial treatment of MMRp / MGMTwt CRC cells with CDDP and TMZ causes clonal and subclonal hypermutability, eventually leading to tumor rejection in syngeneic mice. By following the fate of chemotherapy-induced mutations and predicted neoantigens in primed tumors grown in immunocompromised or immunocompetent mice we found that the majority of chemo-induced mutant clones were immunologically deleted in the CDDP-TMZ combination arm. The same effect was not observed when CDDP and TMZ were administered as monotherapy or when CRC cells were primed with the 5-fluorouracil-oxaliplatin-irinotecan (FOLFOXIRI) triplet. Mutational signature profiling of the immunologically deleted mutations was consistent with the previous exposure to chemotherapy in the priming phase. Moreover, the extent of the immunoediting was related to the clonality of the chemo-induced mutations, underlining the relevance of clonal abundance of immunogenic mutations in immune recognition and surveillance. These results indicate that rational combinations of commonly used cytotoxic agents can be exploited to promote cancer cell subclonal and clonal hypermutability. This approach can be used to promote cancer immunogenicity with implications for the design of new chemo-immunotherapy strategies in CRC.

#5285 DKK1 blockade inhibits progression of bone metastases via multiple mechanisms and synergize with zoledronate treatment.

T. Shi, K. Liang, Y. Zhang, X. Zhou, B. Liu, J. Wei;
Department of Oncology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China

Background: Despite the important breakthroughs of immune checkpoint blockade (ICB) therapy in multiple primary cancers, responses of ICB therapy in bone metastases remain extremely poor, largely due to the highly immunosuppressive bone metastasis microenvironment. However, the current understanding of bone metastasis microenvironment is still incomplete, and specific treatment targets for patients with bone metastasis are still lacking.
Methods: Transcriptome sequencing data of gastric and breast cancer bone metastasis samples from The TCGA and GEO databases were obtained. The correlation between DKK1 expression and prognosis, intertumoral immune infiltration of bone-metastatic patients was analyzed. Mouse bone metastasis models from gastric, breast and lung cancer were established, and *in vivo* treatment efficacy of DKK1 and/or zoledronic acid was evaluated by micro-computed tomography (CT), micro-magnetic resonance imaging (MRI) and immunohistochemistry (IHC) staining. The changes of immune components wthin bone-tumor microenvironment were explored via flow cytometry, CyTOF and scRNA-seq analysis. The impact of DKK1 on different immune cell types was analyzed via *in vitro* co-culture models.
Results: Serum detection of gastric cancer patients from our center showed that compared with non-metastatic patients, DKK1 concentration in patients with bone metastasis was the significantly increased ($p<0.0001$); and compared with other metastatic sites of breast cancer patients, bone metastases had the highest level of DKK1 mRNA expression ($p<0.05$). Using multiple bone metastasis mouse models, we found that DKK1 blockade significantly controlled the tumor burden of bone metastases. Results of micro-CT and TRAP staining showed that the bone destruction and osteoclast activity within bone lesions were significantly inhibited after DKK1 blockade. In addition, results of flow cytometry and immunofluorescence staining on bone metastasis samples showed that both innate and adaptive anti-immune responses were obviously improved after DKK1 blockade, including increased infiltration of $CD8^{\pm}$ T cells, M1 macrophages and decreased infiltration of M2 macrophages. Mechanistically, DKK1 directly induced inhibition of $CD8^{\pm}$ T cell activation, M2 polarization of macrophages and maturation of osteoclasts, which all contributes to the immune suppression in the bone metastasis microenvironment. Finally, combined therapy of DKK1 blockade and zoledronic acid had synergistic treatment effects in bone metastases.
Conclusion: Our study provides novel insights into the multiple role of DKK1 in the bone metastasis immune microenvironment. DKK1 is a potential immunotherapeutic target for bone metastases, and dual blockade of DKK1 and zoledronic acid is a promising combination immunotherapy strategy for patients with bone metastasis.

#5286 M2 to M1 repolarization of tumor-associated macrophages via the lysosomal effect of itraconazole.

Y. Takimoto, **H. Tsubamoto**, K. Sakata, R. Isono-Taniguchi, T. Ueda, H. Shibahara;
Hyogo Medical University, Nishinomiya, Japan

Objective: Itraconazole (ITZ), an antifungal agent, has been reported to have tumor agnostic anticancer effects. Previous reports have shown prolonged survival in patients with lung and ovarian cancer who received ITZ. The anticancer mechanisms vary depending on the cancer type and stromal cells. Based on our previous studies, we focused on tumor-associated macrophages (TAMs).
Methods: Anti-tumorigenic M1 and pro-tumorigenic M2 macrophages were established from THP-1 cells and their phenotypes were determined based on morphology, cell surface antigens by Western blotting, and secreted proteins by ELISA. Bulk proteomic analysis of cell proteins was conducted using liquid chromatography-tandem mass spectrometry. The viability of CaSki cervical cancer cells was evaluated both in culture with the supernatant and co-culture with M2 macrophages after treatment with ITZ (10^{-5} M). Single-cell RNA sequencing (scRNA-seq) with surface labeling of M2 macrophages with and without the ITZ was performed. Using LoupeBrowser (10x Genomics, Inc.), ITZ-treated M2 macrophages were divided into two groups, one with newly emerged clusters after ITZ treatment (group 1) and the other (group 2). Differentially expressed genes between group 1 and group 2 were identified based on a two-fold and a 0.05 adjusted p value and were subjected to Reactome pathway analysis. Significant pathways were identified based on both p value < 0.05 and FDR <0.3. A triple-labeling immunofluorescence study was conducted to detect cholesterol, IL-1β, and organelles (the endoplasmic reticulum, phagosome, and lysosome).
Results: ITZ changed M2 macrophages to M1-like morphology and protein expression. While co-culture with M2 macrophages promoted cancer cell proliferation, both culture with the supernatant and co-culture with ITZ-treated M2 macrophages significantly inhibited CaSki cell growth. scRNA-seq identified newly emerged clusters (group 1) among M2 macrophages following ITZ treatment. Group 1 had elevated mRNA expression of M1 markers, including IL1β, IL6, CD86, TL4, GAPDH, and RKM, compared to group 2. Group 1 expressed the CD86 and TLR4 surface antigen proteins. Pathway analysis identified 176 significant pathways including lysosome vesicle biogenesis. Immunofluorescence analysis showed that M1-like macrophages in ITZ-treated M2 macrophages had enlarged lysosomes containing cholesterol.
Conclusion: ITZ repolarized THP-1 derived M2 macrophage to an M1-like phenotype. The mechanism of repolarization involves intracellular cholesterol accumulation via lysosomal dysfunction.

#5287 Ex vivo pharmacologic inhibition of STAT3 effectively targets tumor and tumor associated suppressor cells in high-grade glioma 3D spheroids.

K. A. Lassahn, A. K. Elrod, T. M. DesRochers, **K. M. Appleton**;
Kiyatec, Greenville, SC

Gliomas, a type of brain tumor originating from glial cells, comprise a heterogenous group of neoplasms. High-grade gliomas, in particular, present significant therapeutic challenges in the clinic. Unlike other solid tumors, the heterogenous glioma microenvironment is heavily enriched with tumor associated suppressor cells including myeloid-derived suppressor cells (MDSCs) and tumor-associated macrophages (TAMs), which can account for 30-40% of the cellular composition[1]. These pro-tumorigenic myeloid cells are thought to contribute to the resistance of glioma to immunotherapy. Efforts to target the suppressive nature of these dominating cell types are in development to yield more therapeutic options for patients with these devastating diseases. Constitutive activation of STAT3 in gliomas has been associated with increased tumor progression and reduced immune response. We have observed in other cancer models that a phenotypic switch occurs from STAT3 pathway activation in 3D spheroid culture to STAT3 inactivation when cultured in 2D. Therefore, we sought to determine the role of STAT3 activation and its role in the interplay between glioma and their immune suppressive environment using a 3D spheroid model. We modified our commercially available test platform, 3D-Predict™ Glioma, such that it is conducive to monitoring immune cell function. Newly diagnosed treatment naive primary samples from HGG patients were dissociated and cryogenically preserved and banked. Samples were profiled for the abundance of tumor associated suppressive myeloid cells using flow cytometry. We determined that relative proportions of tumor suppressor cells were detectable and varied across HGG primary patient samples with TAMs being the predominate immune cell type identified. Pro-tumorigenic TAM markers including CD163 and CD206 were correlated with temozolomide response and were associated with poor patient prognosis. When we evaluated the role of p-STAT in HGG primary samples, p-STAT was detected at baseline and abundance was related back to the presence of tumor associated immune suppressor cells. The impact of STAT3 signaling blockade by the inhibitor WP1066 was determined *ex vivo*, and efficacy was related back to MGMT promotor methylation status and patient clinical outcome. We detected shifts in cytokine signatures following treatment of HGG 3D spheroid models with WP1066 which are known to target tumor associated suppressor cell functions. This work demonstrates the critical role suppressive immune cells play in HGG clinical response. Given p-STAT can be altered in 2D culture compared to 3D culture, *ex vivo* therapeutic response profiling of HGG samples is necessary using the more physiologically relevant spheroid culture model.

#5288 Soy isoflavone genistein reboosts targeted therapy sensitivity in triple negative breast cancer.

T. Bankole, Z. Li, **Y. Li**;
University of Maryland, College Park, College Park, MD

Triple-negative breast cancer (TNBC) is a very aggressive type of breast cancer that does not expression important proteins called estrogen, progesterone and HER2. This makes TNBC hard to treat because it does not respond to common targeted treatments. However, recent treatments using the immune system to target key immune proteins such as PD-1 and PD-L1 have been successful in many types of cancer. This form of immunotherapy works by blocking PD-1/PD-L1 pathway and leads to stimulating the body's own immune system to recognize and attack cancer cells, thus providing a potential new treatment option for TNBC patients. Nevertheless, only approximately 30% of TNBC patients may respond to these drugs, suggesting the majority of TNBC patients would not benefit from these innovative immunotherapies. It is believed that low levels of immune cells and PD-L1 expression in tumors are the primary reasons for the lack of response or resistance to anti-PD-1/PD-L1 treatments. The use of nontoxic and healthy food and nutrition to increase treatment response is an emerging field of cancer research. Our studies showed that adding genistein (GE), a bioactive dietary component found in soybean products such as soy milk, soy protein and tofu, could significantly enhance the efficacy of anti-PD-1 immunotherapy in a TNBC mouse model that was previously not responsive to the treatment. Our research also found that soybean GE can increase tumor immune response by significantly recruiting active immune cells into the tumor and increasing PD-L1 expression. Our studies will help to establish a novel nutrition-based intervention targeting TNBC patients who might not qualify for this treatment initially. Eventually, we will develop a novel strategy of administering a tailored dietary plan to resensitize these patients to emerging anti-PD-1/PD-L1 immunotherapies.

IMMUNOLOGY: Immune Modulation Employing Agonist or Co-Stimulatory Approaches
Poster Session

#5292 CD28 humanized mouse model for efficacy and safety assessment of CD28-targeting therapies.
F. Sonego, A. Pappalardo, G. Martin, Y. Cherifi, P. Isnard-Petit, K. Thiam;
genOway, Lyon, France

Agonist antibodies targeting CD28 have proven to be effective against cancer, but also faced challenges due to severe adverse events triggered by its activation. Human (hCD28) and mouse CD28 (mCD28) have different signaling responses, with CD28 ligands and superagonists inducing pro-inflammatory cytokines upon stimulation in absence of TCR ligation in humans, but not in mice. Expression of CD28i amplifier isoform, which is thought to enhanced the production of cytokines in humans, could partially explain this difference, as it is not expressed in mice. In addition, evidence suggests that the different signaling between hCD28 and mCD28 relies on one amino acid change in the intracellular domain (ICD)[1]. Herein, we describe a CD28 humanized mouse model for assessment of CD28-targeting agents. To improve translatability, we decided to keep the expression of both canonical and CD28i human isoforms to avoid undermining the biological effects of the testing agents. Although keeping the human ICD could favor the evaluation of cytokine production and therefore the safety of the test agents, we decided to keep the mouse ICD to enable a proper interaction of CD28 with its signaling partners, allowing a physiological stimulation of CD28 in efficacy studies. The hCD28 model expresses a chimeric protein, with the whole human extracellular domain, and mouse intracellular domain. Human CD28 is expressed at physiological levels on T cells, and these cells can be activated and proliferate in response to hCD28 ligands and agonist antibodies. Tumor growth inhibition and complete tumor regressions are achieved in a MC38-TAA colorectal cancer model following prophylactic treatment with CD28-TAA bispecific antibody in combination with anti-PD-1. Extension of this study and re-challenged of the tumor-free surviving animals shows that re-challenged hCD28 mice have enhanced survival compared to naïve hCD28 mice inoculated with MC38-TAA, suggesting tumor immunological memory. Furthermore, TGN1412 administration in CD28 mice induces cytokine release, and a slightly body weight loss, but no major change in body temperature. Although the model does not fully reproduce the ability of human CD28 to produce cytokines upon activation due to the mouse ICD, the expression of the amplifier isoform CD28i might contribute to the response to TGN1412. Altogether, data suggest that hCD28 model enables assessment of efficacy and safety of CD28-targeting agents. The hCD28 model was intercrossed with CD3 humanized models to enable assessment of combination therapies and bispecific antibodies targeting both CD3 and CD28.

#5293 Preclinical development of NI-3201, a PD-L1xCD28 bispecific antibody mediating CD28 costimulation upon PD-L1 blockade.

S. Majocchi[1], N. Anceriz[1], A. Viandier[1], A. Lesnier[1], L. Cons[1], L. Nouveau[1], E. A. Pace[2], B. L. Millard[2], B. Daubeuf[1], V. Moine[1], S. Salgado-Pires[1], J. Saro[1], L. Shang[1], K. Masternak[1], W. G. Ferlin[1];

[1]Light Chain Bioscience - Novimmune SA, Plan-les-Ouated, Geneva, Switzerland, [2]Residual Dynamics, LLC, Camano Island, WA

NI-3201 is a PD-L1xCD28 bispecific antibody generated on the κλ body platform that blocks the PD-L1/PD-1 immune checkpoint pathway and conditionally provides T cell activation “signal 2” when engaging PD-L1+ tumor or immune cells (e.g., antigen-presenting cells). By combining two distinct mechanisms of action into a single molecule, NI-3201 overcomes two major immune suppression mechanisms commonly observed in a variety of solid tumors, namely: [1] suppression of T cell response (induced by PD-L1+ cells engaging PD-1 on T cells) and [2] restricted/limited T cell activation (due to the lack of costimulatory signal associated to the scarcity of CD28 ligands in the TME). Importantly, NI-3201 was designed to require primary T cell stimulation (“signal 1”) to afford its activity: in the absence of TCR engagement, NI-3201 is unable to activate T cells, thus preventing unintended systemic inflammation.

The single agent pharmacological activity of NI-3201 was assessed *in vitro* through a Cytomegalovirus (CMV) recall assay in which CMV+ PBMCs were cocultured with PD-L1+ cancer cell lines ectopically loaded with CMV-specific MHC-I peptides, thus providing “signal 1”. NI-3201 induced the activation and proliferation of CMV-specific T cells which resulted in killing of the target tumor cells. *In vivo*, the single agent activity of NI-3201 was shown in immunocompetent huCD28-transgenic mice engrafted with huPD-L1-expressing murine colon adenocarcinoma MC38 cells, a model in which NI-3201 induced durable anti-tumor immunological memory response. In humanized mouse models where T cell engagers (TCEs) were ineffective, NI-3201 was able to synergize with TCEs to control tumor growth, even inducing tumor regression in one model. The pharmacokinetics (PK) and tolerability of NI-3201 were investigated in non-human primates (NHP) after single and repeated-dosing. NI-3201 demonstrated favorable PK with close to dose-proportional concentrations being achieved. Upon repeated NI-3201 administration, no hypercytokinemia was observed; only a mild and transient IL-6 release and associated increase in C-reactive protein (CRP) levels were seen, with no clinical signs reported. The favorable profile seen in NHP was supported by data generated *in vitro* further de-risking the cytokine release syndrome (CRS) potential. Quantitative systems pharmacology (QSP) modelling integrating both *in vitro* and NHP data predicted a drug concentration required for optimal NI-3201 activity in the TME, and preliminary data suggests optimal patient activity at Q2W-Q3W dosing schedule.

The anti-tumor activity as a single agent or as universal combination partner for TCEs, shown *in vitro* and *in vivo*, together with the favorable safety profile of NI-3201, support its clinical development planned to start in Q1 2025.

#5294 Conditionally active CD28xVISTA bispecific antibodies induce myeloid-driven tumor-specific T-cell co-stimulation for improved cancer immunotherapy.

T. Thisted, Z.-G. Jiang, Z. Biesova, A. Onumajuru, Y. Kleschenko, K. Malhotra, V. Saxena, A. Mukherjee, F. Smith, E. H. van der Horst;
Sensei Biotherapeutics, Rockville, MD

Introduction: Tumor-specific recruitment of co-stimulatory bispecific antibodies (bsAbs) has emerged as a promising therapeutic strategy. Here, we investigated pH-selective CD28xVISTA bsAbs to act selectively within the acidic tumor microenvironment (TME). Our CD28xVISTA bsAbs are designed for tripartite "*trans*-activation" of CD28 in the TME, aiming for enhanced T-cell-mediated cancer cell killing while minimizing systemic T-cell activation and Cytokine Release Syndrome (CRS) risk.

Experimental Procedures: We evaluated various CD28xVISTA bsAbs, focusing on a prototype 1+2 format with monovalent CD28 binding, bivalent VISTA binding and Fc receptor interaction null mutations (BS2). BS2 was tested for T-cell *trans*-activation using Jurkat-IL-2-luciferase reporter cells in the presence of HEK293 cells expressing membrane bound OKT3-scFv and CHO cells expressing human VISTA. BS2's potency was further evaluated in an xCelligence-based human T-cell killing assay that dynamically monitors growth of LNCaP prostate cancer cells co-cultured with VISTA$^{\pm}$ Kasumi-3 cells, alone or in combination with a CD3xPSMA bispecific T-cell engager. T-cell activation and proliferation were also measured using flow cytometry with CD3, CD4, CD8 and CD25 markers. Additionally, we modified BS2 to introduce pH-selective VISTA binding, limiting its activity to the TME, and tested this version in a syngeneic mouse model in combination with anti-murine PD-1 (anti-mPD-1). Finally, cytokine release from human PBMCs, co-cultured with human umbilical vein endothelial cells (HUVECs) and treated with the pH-selective BS2 (or TGN1412 as a positive control), was measured using a bead-based multiplex immune assay.

Results: Our data show that the combination of anti-mPD-1 and our prototype CD28xVISTA bsAb (BS2) with pH-selective VISTA binding significantly inhibited tumor growth *in vivo*. *In vitro*, CD28xVISTA co-stimulation in *trans* by BS2 potentiated the activity of a CD3xPSMA bispecific T-cell engager in our human T-cell killing assay. Cytokine release assessments demonstrated negligible induction of inflammatory cytokines, indicating a favorable safety profile for this antibody.

Conclusion: Our study demonstrates the feasibility of *cis* and *trans* CD28 co-stimulation using a CD28xVISTA bsAb (BS2). This approach, which bypasses the need for tumor-associated antigens (TAAs) required by other CD28xTAA bispecifics in development, suggests a potentially safer alternative for T-cell engagement and stimulation. Moreover, our novel myeloid-directed TME-selective co-stimulation strategy with a CD28xVISTA bsAb may broaden the potential for T-cell engagement approaches in solid tumors by enabling rational combinations with existing CD3xTAA T-cell engagers without competing for the same target.

#5295 Tumor targeted-CD28 bispecific antibody with optimized potency, robust anti-tumoral activity and stringent CD3-dependence.

Xiguang Zhang, Shiqi Cao, Li Li, Shuaixiang Zhou, Yao Xiong, Dian Kang, Feifei Wang, Jie Ren, Keke Fei, Jianglu Wang, Jinchang Lu, **Huizhong Xiong**

Innovent Biologics, Suzhou, China

CD28 is an essential co-stimulatory signal (Signal 2) for optimal T cell function upon TCR/CD3 activation (signal 1). However, clinical development of CD28 agonist antibodies has been confounded by toxicities presumably from CD3-independent and/or tumor non-specific activation. Here we report a rationally screened CD28 agonist antibody with optimized potency, from which a PSMAxCD28 bispecific was made. The bispecific antibody had several unique features: (1) minimal activity in the absence of CD3, even under stringent conditions, (2) superior tumor killing *in vivo* alone and in combination with anti-PD1 antibody, (3) requirement of abundant level of PSMA for activation, sparing $PSMA^{low}$ cells, and (4) extended half-life in human-CD28 KI mice. To summarize, our anti-CD28 bispecific antibody enhances dependence on TCR/CD3 (Signal 1), induces selective killing of PSMA high expressing cancer cells, and elicits robust tumor eradiation *in-vivo* with extended PK. These features may translate to further improvements in efficacy and safety for tumor-targeted CD28 bispecific antibodies.

#5296 Enhancing the strength and durability of vaccine-induced anti-tumor immunity with CD27 agonism of CD4+ T cells.

B.-J. Hwang[1], E. Crosby[1], T. Trotter[1], L.-C. Tsao[1], T. Wang[1], C. Liu[1], X. Yang[1], G. Lei[1], J. Wei[1], X. Ma[1], B. Liu[1], A. Hobeika[1], M. Morse[1], T. Keler[2], L.-Z. He[2], H. K. Lyerly[1], Z. Hartman[1];

[1]Duke University, Durham, NC, [2]Celldex Therapeutics, Hampton, NJ

Despite encouraging early phase clinical trials, decades of research have yet to yield effective cancer vaccine immunotherapies. To determine potential markers for success, we performed a follow-up study of a HER2-pulsed dendritic cell cancer vaccine Phase I trial performed in advanced HER2+ cancer patients. Surprisingly, we found that all treated patients were alive at over 18 years post-treatment. These patients still possessed significant HER2-specific memory T cell responses, typified by CD27 expression. The expansion of HER2-specific CD27+ memory T cells was also observed in patients from a separate clinical trial, who received a HER2-expressing viral vaccine. To validate these clinical responses, we vaccinated human CD27 transgenic mice with a HER2 viral vector again observing HER2-specific CD27+ memory T cells, suggesting the significance of this axis in eliciting and maintaining effective vaccine-specific memory T cell responses. We hypothesized that CD27 expression was not just a marker of memory T cells, but represented a critical activation pathway during memory formation. To determine the potential impact of CD27 agonism in vaccination, we combined HER2 vaccination with an anti-CD27 agonist antibody (Varlilumab). The combination treatment elicited a robust increase in HER2-specific CD4+ memory T cell responses that was maintained for at least 300 days post-vaccination. Using therapeutic HER2 vaccination in combination with anti-CD27 of HER2+ tumor bearing mice, we show significantly increased anti-tumor efficacy and further enhancement in combination with PD1 inhibition. The anti-tumor response was triggered by anti-CD27 antibody during the vaccine priming phase, which enhanced HER2-specific CD4+ T cells. Critically, we found that HER2 specific CD4+ T cell responses allowed for anti-tumor responses that persisted after CD8+ T cell depletion, indicating a direct role for antigen-specific CD4+ T cells independent of CD8+ T cells. Collectively, our results support a central role for antigen-specific CD27+ CD4+ T cells in cancer vaccination. These data support the addition of CD27 agonism to improve the therapeutic index of cancer vaccines and potentially enhance responses to immune checkpoint blockade in refractory cancers.

#5297 CLN-619, a clinical stage MICA/B-specific hIgG1 monoclonal antibody, engages multiple immune effector cells to promote anti-tumor activity.

K. A. Whalen, C. C. Henry, K. Rakhra, K. Meetze, J. S. Michaelson, P. A. Baeuerle;
Cullinan Oncology, Inc., Cambridge, MA

CLN-619 is a humanized IgG1 monoclonal antibody that targets MICA and MICB (MICA/B) and is currently in phase 1 clinical development in cancer patients (NCT05117476). MICA/B serve as activating signals on target cells for recognition by the NKG2D receptor, which is expressed on NK cells and a subset of T cell populations. MICA/B expression is induced in response to stressed conditions, thereby enabling NKG2D-mediated elimination of target cells. On NK cells, NKG2D is one of many receptors in the complex network of activating and inhibitory receptors, whereby NKG2D pathway activation results in cytokine production, enhancement of ADCC and target cell death. On CD8 T cells, the NKG2D axis plays a costimulatory role in lowering the threshold for lysis upon TCR engagement, and may also drive direct CD8-mediated killing following prior TCR activation. MICA/B is expressed broadly on a range of solid and hematological malignancies. However, tumor cells evade NKG2D-mediated elimination by shedding MICA/B ligand from the cell surface via proteases present in the tumor microenvironment (TME). CLN-619 functions by binding to MICA/B and preventing shedding, thereby increasing MICA/B cell surface expression to restore the NKG2D-MICA/B axis to promote tumor cell killing by NK cells and T cells. Additionally, CLN-619 can mediate ADCC and ADCP by NK cells and macrophages. In preclinical xenograft models, doses as low as 0.03 mg/kg inhibited tumor outgrowth. We investigated the effects of CLN-619 on a variety of primary immune cells including NK cells, T cells and macrophages. In the evaluation of NK cells, we measured CLN-619 modulation of cytokine production and cytotoxicity in the presence of MICA/B expressing target cells. In addition, we demonstrated the contribution of Fc-mediated functions of CLN-619. In the context of T cells, we explored the requirement of TCR co-stimulation or prior antigen exposure in the activation of the NKG2D pathway by CLN-619. In the context of macrophages, we measured the ability of CLN-619 to mediate ADCP against MICA/B-expressing target cells. These data highlight the potential of CLN-619 to engage multiple immune cell types within the TME, which may lead to greater and broader efficacy compared to IO therapies targeting a single immune cell type.

#5298 BSI-093, a best-in-class anti-BTN3A monoclonal antibody for cancer immunotherapy by activation of Vg9Vd2 T cells.

W. Dai[1], J. Li[1], J. Liu[1], H. Li[1], X. F. Liu[2], S. Xia[1], Q. Lyu[1], H. M. Davis[2], **M. Chen**[1], Z. Peng[1];
[1]Biosion, Inc., Nanjing, China, [2]Biosion USA, Inc., Newark, DE

Background: Gamma delta T (γδ T) cells are potent anti-cancer effectors with the potential to target tumors broadly, independent of patient-specific neoantigens or human leukocyte antigen background. Among tumor-infiltrating lymphocytes, the presence of γδ T cells is the most favorable prognostic marker for overall survival of patients with various solid and hematologic tumors. Vγ9Vδ2 T cells are the predominant γδ T cells in peripheral circulation. Butyrophilin 3A (BTN3A) members, widely expressed in tumors, have emerged as novel molecules modulating the function of Vγ9Vδ2 T cells. Targeting BTN3A for activation of Vγ9Vδ2 T cells provides an alternative strategy for cancer immunotherapy.

Experimental procedures: BALB/c mice were immunized with recombinant BTN3A1-ECD-Fc. The Biosion proprietary H^3 (High-throughput, High-content and High-efficiency) antibody discovery platform was used to identify an anti-BTN3A monoclonal antibody lead candidate - BSI-093. The target binding specificity, binding activity, and affinity of BSI-093 were evaluated by protein-based ELISA, cell-based FACS and Biacore-based SPR. *Ex vivo* assays were used to evaluate the cellular bioactivity of BSI-093 on activating Vγ9Vδ2 T cells for killing activity of various tumor cells. B-NDG mice bearing Jurkat-GFP-Luc tumors were used to evaluate the tumor inhibitory activity of the anti-BTN3A antibody.

Summary: BSI-093 is a humanized monoclonal antibody with the following critical properties: (1) binds to all BTN3A members (BTN3A1, BTN3A2 and BTN3A3) with high affinity; (2) has potentially longer half-life and silenced Fc-effector function by Fc-engineering; (3) exhibits cross-reactivity to rhesus BTN3A members; (4) demonstrates strong activity on activating Vγ9Vδ2 T cells to kill a variety of natural cancer cells in *ex vivo* assays; and (5) shows significant anti-tumor efficacy in a CDX model.

Conclusion: BSI-093 demonstrates potential best-in-class biophysical properties and functional characteristics, supporting the initiation of development activities including manufacturing and IND-enabling studies.

#5299 A novel anti-4-1BB antibody with no liver toxicity and its application in a bi-specific antibody.

Jen-Kuan Chang, Jie Xue, Chen Dong, An Ju, Toya Baral, Julie Yoo, Yanling Wang, Marco Muda, Qiang Liu, Wenfeng Xu, Weidong Jiang, Lixin Feng

Henlius USA, Milpitas, CA

4-1BB (CD137, TNFRSF9) is a co-stimulatory receptor initially identified on T cells, belonging to the tumor necrosis factor receptor superfamily. Primarily expressed on activated CD8+ T cells, it plays a crucial role in immune activation. Moreover, the intracellular domain of 4-1BB is leveraged to enhance the proliferation and cytotoxicity of Chimeric Antigen Receptor-T (CAR-T) cells. However, the development of 4-1BB agonist antibodies has encountered challenges, with limited clinical efficacy (e.g., utomilumab) or dose-dependent liver toxicity (e.g., urelumab). Consequently, there is a significant demand for the development of next-generation 4-1BB agonist antibodies, leading to numerous ongoing preclinical R&D efforts and clinical trials. Here, we introduce a novel fully humanized anti-4-1BB antibody, HLX25, and discuss the development of HLX34, a bispecific antibody targeting both 4-1BB and Her2. HLX25 boasts a unique binding epitope distinct from first-generation 4-1BB antibodies and demonstrates multiple cross-species reactivities. Additionally, HLX25 incorporates an engineered Fc region to enhance intratumoral clustering while reducing toxicity. In vitro studies reveal that HLX25 exhibits activity similar to natural 4-1BB ligands. In contrast, utolimumab shows inadequate activity, and urelumab displays superior activity, suggesting a correlation between efficacy and safety. As reported previously, (As been profiled in our Lab,) HLX25 exhibits robust dose-dependent anti-tumor activity in the MC38/h4-1BB KI mouse model. Noteworthy is the superior safety profile of HLX25 in the h4-1BB KI model, where both HLX25 and utolimumab induce no significant AST and ALT upregulation, unlike urelumab, which demonstrates such upregulation in vivo. A comparative analysis of HLX25 with other second-generation anti-4-1BB antibodies in clinical trials in vivo reveals that HLX25 provides superior tumor inhibition without observed toxicity within the effective dose range. Furthermore, we've developed HLX34, a Her2x4-1BB bispecific antibody, derived from Trastuzumab and HLX25. Its format underwent optimization using a reporter assay, indicating superior in vitro activity. Validation through a cytokine release assay with primary PBMCs in vitro and confirmed in vivo activity in animal models, without observed toxicity, strongly supports the efficacy and safety of HLX34 in Her2-positive tumors. These results provide evidence that our novel anti-4-1BB antibody activates proper 4-1BB signaling through tumor-enriched FcgRIIB or tumor-associated antigen-mediated clustering, inhibiting tumor growth with good safety in both in vitro and in vivo settings. This underscores HLX34 as a promising alternative therapeutic strategy for next-generation cancer immunotherapy.

#5300 BH3120, PD-L1 X 4-1BB bispecific antibody, plus PD-1 antagonist results in synergistic anti-tumor efficacy with excellent safety profile.

Jun Wang, Jing Wang, Yang Liu, **Jiangcheng Xu**, Jiawang Liu, Kyoungwoo Lee

Beijing Hanmi Pharm. Co. Ltd., Beijing, China

BH3120 is a clinical stage PD-L1 binding dependent 4-1BB agonist with moderate affinity against 4-1BB. In multiple preclinical evaluations, BH3120 decoupled T cell modulation in TME from that in normal tissues, indicating potential decoupling of efficacy from safety concerns.
4-1BB agonism improves T cell functions in TME, combining BH3120 and PD-1 antagonist shows dose dependent and complete control of established tumor burden with bi-directionally synergistic mechanism: Blockade of PD-1 increases the expression and exposure of surface PD-L1, providing BH3120 more chance to form immune clusters in the tumor environment. In the meantime, increased PD-1 induced by BH3120 can be blocked by PD-1 antagonist.
This bi-directional mechanism results in rapid eradication of tumor tissues shortening the time to regression, indicating potentially fast control of tumor burden and associated symptoms. With the characteristics decoupling co-stimulatory activity in TME from that in normal tissues, BH3120 either as a monotherapy or in combination with PD-1 antagonist was not associated with liver toxicity and other concerns in relation to excessive modulation of immune cells systemically.
Safety profile and clinical signs with BH3120 are being investigated in early-stage clinical trials as a monotherapy and in combination with a PD-1 antagonist.

#5301 Tumor-targeted activation of CD137 using *Bicycles*: New insights into mechanism of action and discovery of BT7455, a clinical candidate for the treatment of EphA2-expressing cancers.

J. Lahdenranta[1], K. Hurov[1], H. Cohen[1], L. Luus[1], C. Bray[1], P. Brown[2], A. Devlen[1], C. Campbell[1], M. Gray[2], M. Kelly[2], G. Mudd[2], P. Upadhyaya[1], S. Battula[1], K. Zhang[1], A.-S. Dugast[1], K. McDonnell[1], P. Brandish[1], N. Keen[1];

[1]Bicycle Therapeutics, Cambridge, MA, [2]Bicycle Therapeutics, Cambridge, United Kingdom

Introduction: Clinical studies in cancer patients have validated CD137 agonism as an activator of the immune system to enable tumor rejection. We have demonstrated that small, chemically synthetic bicyclic peptides can drive tumor-localized agonism of CD137 and anti-tumor immunity in mouse models. Here, we report the next stage of our work - delving into the mechanism of action of these novel agents and extending our program to serve patients whose tumors express EphA2. Experimental Procedures: MultiOmyx™ hyperplexed immunofluorescence assay was used to evaluate the expression of CD137 and EphA2 in head and neck squamous cell carcinoma samples. Human PBMC/tumor cell co-culture assays were used to assess CD137 *Bicycle* TICA™ in vitro bioactivity and syngeneic mouse tumor models were used to evaluate CD137 *Bicycle* TICA anti-tumor activity as mono- or combination therapies. Pharmacodynamic activity was evaluated by transcriptional profiling using NanoString assays or single cell RNA sequencing.

Summary of the Data: Studies utilizing a syngeneic mouse model and deep RNA sequencing of tumors from CD137 *Bicycle* TICA-treated mice implicated intratumoral dendritic cells in addition to T cells as early responders to localized CD137 agonism and potential contributors to the anti-tumor response. Furthermore, a mouse efficacy model demonstrated synergy with checkpoint inhibitor therapy. Multiplex imaging revealed that EphA2 and CD137 are co-expressed in human tumors of high unmet medical need and therefore, using our highly modular *Bicycle* platform, we discovered BT7455, a *Bicycle* TICA that engages EphA2 and CD137 with high affinity, resulting in potent EphA2-dependent activity in vitro and robust anti-tumor activity in vivo with intermittent dosing in mouse models. Gene expression profiling of tumors revealed that BT7455 led to increased production of cytokines and chemokines known to drive T cell infiltration, the extent of which differentiated it from both a checkpoint inhibitor and an anti-CD137 monoclonal antibody agonist. BT7455 was well tolerated in preclinical species and liver function tests indicated no evidence of hepatic toxicity.

Statement of Conclusions: In summary, we have identified EphA2 as a promising target to pair with a CD137 agonist. In addition to CD8+ T cells, tumor-resident dendritic cells are a likely contributor to anti-tumor immunity following treatment with *Bicycle*® TICAs, supporting utility for *Bicycle*® tumor-targeted CD137 agonists in solid tumors beyond those that are highly T cell-infiltrated. We have advanced a clinical development candidate, BT7455, to realize this potential for patients with EphA2-expressing cancers.

#5302 CB699: A novel mesothelin-binding Humabody® CD40 and CD137 dual-agonist for enhancing immune cell responses against MSLN+ tumors.

A. J. Pierce, P. M. Brailey, S. Archer, H. Spencer, M. Song, T. Wong, P. D. Bartlett, K. Williams, L. Jasaitis, P. Bland-Ward;
Crescendo Biologics, Cambridge, United Kingdom

INTRODUCTION: CD137 is a TNF receptor superfamily (TNFRSF9) costimulatory receptor expressed by T cells and NK cells. Clustering-mediated CD137 signaling enhances immune cell survival, proliferation, cytokine production and memory formation. CD40 (previously TNFRSF5) is a related superfamily member expressed primarily on B cells and antigen-presenting cells (APCs) which upon clustering is also a key modulator of T cell responses. Mesothelin (MSLN) is highly upregulated on tumor cells in ovarian and pancreatic cancer and select other solid tumour histologies. To avoid systemic toxicity, CB699 is designed to be immunologically active in the presence of any two of its three binding targets, thus enhancing both immune-immune and tumour-immune crosstalk. We present here the preclinical pharmacology of CB699.

EXPERIMENTAL PROCEDURES: Binding of CB699 to CD40, CD137 or MSLN was measured by surface plasmon resonance and by flow cytometry. CD137 and/or CD40 agonism, immune cell activation and cytokine secretion were evaluated *in vitro* using reporter gene assays and primary cell coculture assays in the presence/absence of MSLN-expressing tumor cells. The ability of CB699 to enhance tumor cell killing was characterized in 3D spheroid cocultures. CB699 toxicology and toxicokinetics was assessed in a dose range-finding study in cynomolgus macaques. CB699 was also assessed *in vivo* with a human CD34+ cell engrafted mouse model.

RESULTS: CB699 binds to primary and immortalized cells that express CD40, CD137 or MSLN, with low nanomolar affinity. CB699 also binds to cells from primary disaggregated human solid tumors. CB699 induces CD137 reporter cell activity in cocultures containing cells expressing either CD40 or MSLN. Additionally, CB699 induces CD40 reporter cell activity in cocultures containing cells expressing either CD137 or MSLN. CB699 induces IL-2 secretion and upregulation of CD86 on B cells in primary cocultures containing healthy human PBMCs and MSLN expressing cancer cells. Enhanced tumor cell killing was observed in spheroid cultures containing CB699 and was coupled with immune cell expansion. CB699 showed significant pharmacology *in vivo* with immune cell engrafted mice. Finally, CB699 was well tolerated in a dose range finding non-human primate toxicology study.

CONCLUSIONS: CB699 is a novel MSLN-binding CD137 and CD40 dual agonist that selectively enhances immune cell activity by enhancing both T cell and APC signaling axes. CB699 is positioned to enter clinical development.

#5303 A novel TIGIT and 4-1BB bispecific antibody, ABL112, exhibits potent in vitro and in vivo antitumor activity through dual immune modulation.

W. Son, Y. Lee, Y. Park, J. Won;
ABL Bio, Inc., Sungnamsi, Korea, Republic of

T cell immunoreceptor with Ig and ITIM domains (TIGIT) is an immune checkpoint molecule responsible for delivering inhibitory signals that suppress immune activation. Due to its inhibitory role in the immune response, TIGIT has emerged as a potential therapeutic target for various malignancies, with several clinical trials exploring the use of anti-TIGIT blocking antibodies with anti-PD-(L)1 therapies. Recent reports have indicated elevated expression of 4-1BB within intra-tumoral Tregs. Therefore, we hypothesized that a dual targeting approach involving both TIGIT and 4-1BB could effectively enhance intra-tumoral immunity. ABL112, a First-in-Class bispecific antibody targeting TIGIT and 4-1BB, demonstrated the induction of T cell activation by blocking the TIGIT signaling and TIGIT dependent 4-1BB clustering. By having intact Fc, ABL112 bound to FcγRI and its crosslinking with 4-1BB also induced 4-1BB activation. ABL112 selectively depleted Treg cells but not other T cells *in vitro*, potentially through antibody-dependent cell-mediated cytotoxicity.
ABL112 demonstrated superior efficacy in tumor regression compared to anti-TIGIT monoclonal antibody across various mouse tumor models. Additionally, combining ABL112 with pembrolizumab significantly inhibited tumor growth better than combining anti-TIGIT monoclonal antibody with pembrolizumab. According to immune cell depletion assay, ABL112-mediated tumor suppressive activity was predominantly driven by $CD8^{+}$ T cells, with a partial tumor reduction by $CD4^{+}$ T cell or NK cell depletion. Mice with complete remission (CR) were further protected from the tumor re-challenge after 3 months of cessation of ABL112 treatment, and the proportion of tumor-specific memory T cells in the blood increased, suggesting long-term immunological memory has been established. In conclusion, ABL112 exhibited potent in vitro and in vivo anti-tumor activity through multiple mode of action including TIGIT inhibition and 4-1BB activation. These results strongly suggest that ABL112 is an innovative and promising therapeutic option with the combination of anti-PD-(L)1 therapies for cancer patients.

#5304 ABL407, a LILRB4x4-1BB bispecific antibody with a wild type Fc, exhibits potent antitumor activity by modulating immune system in multiple ways involving T cells, myeloids, and regulatory T cells.

M. Seon, Y. Lee, H. Youn, Y. Park, S. Kim, K. Park, J. Won;
ABL Bio, Inc., Gyeonggi-Do, Korea, Republic of

Tumor-associated myeloid cells such as myeloid-derived suppressor cells (MDSC) accumulate in the tumor microenvironment (TME) and suppress anti-tumor immune responses in a broad range of cancers. LILRB4 (Leukocyte Immunoglobulin-Like Receptor Subfamily B Member 4), an emerging myeloid target, is specifically expressed in tumor-associated myeloid cells and suppresses the immune response, thus promoting cancer progression and metastasis. ABL407 is a First-in-Class bispecific antibody designed to simultaneously target LILRB4 and 4-1BB, enabling LILRB4 expression-dependent 4-1BB activation. By antagonizing LILRB4 signaling, ABL407 inhibited LILRB4 mediated immunosuppression, restoring T cell activity. In addition, ABL407 inhibited fibronectin, a potential LILRB4 ligand, -mediated suppression of myeloid cells. To evaluate the efficacy of ABL407, we established EL4 murine tumor model overexpressing LILRB4 (EL4/LILRB4) in h4-1BB transgenic mice and hLILRB1/4-h4-1BB triple transgenic mice. We observed LILRB4 was overexpressed in M-MDSC in the blood and liver-metastasized tumors. A significant decrease of M-MDSC population and tumor growth inhibition was observed in mice treated with anti-LILRB4 antibody and ABL407. ABL407 treatment resulted in a proportion increment of T cells. However, the percentage of Treg cells and M-MDSC in the liver and blood was reduced by ABL407 treatment in hLILRB1/4-h4-1BB triple transgenic mice. Mice with complete remission (CR) were further protected from the rechallenge of previously exposed tumor after 3 months of cessation of ABL407 treatment, implicating that immunological memory might be generated. In conclusion, our findings suggest that ABL407, LILRB4x4-1BB bispecific antibody, may be a promising strategy for the treatment of cancer. It can be applied as a "LILRB4 antagonist" as well as a "LILRB4-dependent 4-1BB agonist" across a broad spectrum of cancers.

#5305 M9657, a tumor-targeted anti-CD137 agonist, induced significant antitumor immunity in combination with anti-PD-1 antibody.

C. Xu, S. Yalavarthi, H. Zhang, U. Gundra, C. Bourin, L. Helming;
EMD Serono Research & Development Institute, Billerica, MA

Background: M9657, a first-in-class tumor-targeted conditional immune agonist, was developed to boost antitumor immune responses in the tumor microenvironment (TME) by targeting CD137. The immune agonism potency of M9657 was validated through *in vitro* assays and *in vivo* efficacy studies in syngeneic tumor models using the surrogate antibody FS122m. Combining CD137 agonists and antiPD(L)-1 antibodies presents a novel therapeutic strategy to overcome immune checkpoint inhibitor (ICI) resistance and enhance antitumor activity via complementary mechanisms. Anti-PD-(L)-1 antibodies can reverse the suppressive immune signals, and CD137 agonists can boost T cell activation, improving antigen presentation and cytokine release.
Methods: The antitumor immunity of M9657 + pembrolizumab (anti-PD-1 antibody) combination therapy was assessed using in-vitro luciferase and ex-vivo functional assays. In vivo antitumor efficacy was investigated with the M9657 surrogate (FS122m) and anti-mPD-1 in syngeneic tumor models expressing Mesothelin (MSLN).
Results: The combination of M9657 and pembrolizumab displayed dose-dependent immune agonism potency and significantly enhanced tumor cell cytotoxicity and CD8+ T cell cytokine release relative to single agent treatments. In various syngeneic tumor models, the combination of FS122m with antimPD1 significantly increased antitumor efficacy relative to monotherapies, with more mice achieving complete tumor regression and prolonged median survival. Tumor-cured mice after combination treatment exhibited resistance to the primary tumor rechallenge, indicating the generation of tumor antigen-specific antitumor immunity and long-term immune protectivity.
Conclusion: The combination of M9657 with anti-PD-(L)1 could overcome primary ICI therapy resistance and improve the antitumor efficacy of current anti-PD-(L)1 therapy in the clinic. Our findings support a combination strategy to combine M9657 with anti-PD-(L)1 in a clinical setting, potentially leading to enhanced antitumor immunity and improved patient outcomes. Future studies should investigate the safety and efficacy of this combination therapy in human patients.

#5306 PTPN22 targeting partners with 41BB/OX40 costimulation to overcome anti-PD1 resistance in pancreatic ductal adenocarcinoma.

S. Charmsaz[1], N. E. Gross[1], J. W. Lee[1], J. Lin[2], A. G. Hernandez[1], E. M. Coyne[1], S. M. Shin[1], C. Cannon[1], X. Yuan[1], Z.-Y. Zhang[2], E. M. Jaffee[1], W. Ho[1]; [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Purdue University, West Lafeyette, IN

Background: The pancreatic ductal adenocarcinoma (PDAC) tumor microenvironment (TME) is notable for a scarcity of cytotoxic T cells and an overabundance of immunosuppressive myeloid and regulatory T cells. Checkpoint immunotherapies targeting PD/L1 or CTLA4 have shown efficacy in immunogenic cancers but remain ineffective in PDAC, highlighting a need for novel approaches. Abrogating protein tyrosine phosphatase non-receptor type 22 (PTPN22), a phosphatase in the TCR signaling cascade, has been shown to modulate multiple mechanisms of immune resistance. Furthermore, 41BB costimulatory pathway has recently been investigated as a potential strategy to enhance immunotherapy against PDAC. Using immune-resistant murine models of PDAC, we investigated PTPN22 as an immunotherapeutic target in combination with 41BB co-stimulation and PD1 inhibition against PDAC.

Methods: We employed a well-characterized murine PDAC cell line expressing mutant *Kras*^{G12D} and *Trp53*^{R172H} under the *Pdx1*-cre promoter (KPCY 6419c5). This tumor line is resistant to combination immuno- and chemotherapies. To determine treatment efficacy, PTPN22 deficient mice (KO) were inoculated with KPCY6419c5 cells either subcutaneously or orthotopically into the pancreas. To extend the translatability of PTPN22 targeting, we also injected PTPN22 competent mice with the same tumor cells and treated them with our novel PTPN22 inhibitor L1. Harvested tumors were processed for FFPE and mass cytometry (CyTOF) analysis to track changes in the immune compartment.

Results: When PTPN22 was abrogated, treatment with anti-PD1 and 41BB agonism led to a 10-day delay in substantial tumor formation and roughly 75% reduction in tumor volume by 21-days post treatment. These tumors showed elevated levels of OX40 and OX40L primarily in the setting of PTPN22 KO/PD1/41BB therapy. In a subsequent in vivo experiment using an OX40L neutralizing antibody, we found that OX40 signaling is essential for the efficacy of PTPN22 KO/PD1/41BB therapy. Furthermore, combining OX40 agonist with anti-PD1 in PTPN22 KO sufficiently mimicked the efficacy seen with the anti-PD-1 and 41BB combination. CyTOF analysis indicated that OX40 expression is enriched in Tregs and OX40L is enriched in myeloid derived suppressor cells (MDSCs). Moreover, combination therapy efficacy was reproduced using the PTPN22 inhibitor L1.

Conclusions: PTPN22 abrogation enhances the success of PD-1 inhibition given with either OX-40 or 41BB agonist therapies. In addition, PTPN22 abrogation together with PD1 inhibition and 41BB costimulation reduces MDSC and Treg suppression of effector T cells via the OX40L-OX40 axis. Finally, PTPN22 can be blocked by a small molecule inhibitor strengthening its candidacy as a therapeutic target.

#5307 Preclinical evaluation of a potential FIC 4-1BB/CD24 bispecific antibody IBD0333.

X. Jiang, C. Wu, Z. Chen, **L. Yin**;
SUNHO (China) BioPharmaceutical Co.,Ltd., Nanjing, China

Background: This study demonstrates the preclinical evaluation of a novel 4-1BB/CD24 bispecific antibody IBD0333. 4-1BB's activation triggers a signaling cascade that activates both innate and adaptive immune systems. Due to the hepatotoxicity of current anti-4-1BB monoclonal antibodies, tumor-associated antigens (TAA) targeting to specifically activate immune cells in the tumor microenvironment (TME) is expected to enhance its safety profile. CD24 is highly expressed in many cancers, such as ovarian and breast cancer and its high expression is often related to poor prognosis. The signaling pathway of CD24/Siglec-10 triggers a "don't eat me" signal that facilitates immune escape of tumor cells. Therefore, IBD0333 was designed to target CD24 overexpressed tumor cells and activate CD8+ T cells to induce T cell mediated antitumor immunity in TME of the targeted tumor tissue. To further reduce the toxicity risk, the anti-4-1BB moiety is designed to activate the signaling pathway only when IBD0333 binds to the tumor cells that overexpress CD24.
Methods: For CD24 terminus, we applied virus like particle (VLP) as antigen for immunization to obtain functional CD24 antibodies. For 4-1BB terminus, competitive ELISA/FACS analysis as well as amino acid point mutation binding ability analysis based on the receptor crystal structure were performed to characterize the binding epitope. The in vivo mice efficacy and toxicity study, as well as cynomolgus monkey toxicity study were also conducted to describe the anti-tumor activity and safety profile. For IBD0333, we verified binding affinity by FACS to cancer cells and the 4-1BB activity in reporter-gene assay. IL2 and INF-γ secretion assay were performed to evaluate the PBMC activation. C57BL/6J-h4-1BB humanized mice bearing MC38-hCD24 colon cancer cells were used to validate the anti-tumor efficacy of IBD0333. Preclinical PK and toxicity study was also performed in cynomolgus monkeys to describe the safety profile of IBD0333.
Results: IBD0333 showed excellent binding and PBMC stimulation activities. In toxicology studies of IBD0333, no obvious abnormality in mice or cynomolgus monkeys administered with IBD0333 was observed. The MTD was estimated to be greater than 200 mg/kg with no severe side effects observed in the study, showing that IBD0333 has great potential to achieve significantly improved safety profile. As to efficacy, IBD0333 showed excellent tumor inhibition activities in mice model with 99% tumor growth inhibition at 1 mg/kg and 100% at 3 mg/kg.
Conclusion: IBD0333 is a clinical stage, potential first-in-class, 4-1BB/CD24 bsAb that simultaneously stimulates both innate and adaptive immunity to achieve strong synergistic effects with reduced hepatotoxicity. The IND approvals from the FDA and the NMPA have been obtained and the Phase I clinical trial of IBD0333 in locally advanced/metastatic solid tumors or non-Hodgkin's lymphoma is currently on-going.

#5308 Ifngr1 signaling on tumor-specific CD4 T cells is required to mitigate Treg differentiation during CD40 agonist and anti-PD-L1 immunotherapy in pancreatic ductal adenocarcinoma.

E. Cruz-Hinojoza, A. Burrack, Z. Schmiechen, C.-L. Lonetree, E. A. Miller, M. Patterson, J. Williams, T. Dileepan, I. Stromnes;
University of Minnesota, Minneapolis, MN

Pancreatic ductal adenocarcinoma (PDA) is a particularly lethal malignancy that lacks effective therapeutic strategies. A promising therapeutic modality that can elicit transient antitumor responses in a subset of metastatic PDAs is chemotherapy + CD40 agonist +/- anti-PD-1. A deeper understanding of the cellular mechanisms that mediate the initial responses will inform new strategies to enhance the durability of this therapy. Our prior studies demonstrated that tumor-specific CD4 T cells are critical for mitigating tumor growth in a syngeneic KPC orthotopic tumor model of PDA that expresses a model neoantigen, click beetle red luciferase (CBR). CD4 T cells direct tumor antigen recognition by tumor-associated macrophages and host interferon-gamma receptor (Ifngr1) signaling. Here, we demonstrate that CD4 T cells are required for the antitumor effects of anti-CD40 agonist indicating that this therapy fails to compensate for a lack of CD4 T cell help. We sought to test the hypothesis that host Ifngr1 signaling acts in a CD4 T cell intrinsic manner to promote antitumor responses. As such, we develop and validate a novel MHC class II tetramer (CBR54-62:I-Ab) to track the fate of endogenous CD4 T cells during tumor growth. We demonstrate that tumor-specific CD4 T cell abundance and Th1 polarization is decreased in orthotopic tumors, particularly between day 14 and day 21 post tumor implantation. Combination agonistic anti-CD40 + anti-PD-L1 maintained tumor-specific CD4 T cell numbers in the spleen and pancreas-draining lymph nodes of tumor-bearing mice. Intriguingly, Th1 polarized tumor-infiltrating CD4 T cells were decreased by aPD-L1, but were restored by anti-CD40, a finding further corroborated by single-cell RNA sequencing. Further, agonistic anti-CD40 + anti-PD-L1 alone or in combination robustly decreased Treg polarized tumor-specific CD4 T cells. Using a mixed bone marrow chimeric approach, we show immunotherapy's Treg-depletion effect is dependent on Ifngr1 on antigen-specific CD4 T cells. In contrast, Ifngr1 signaling on tumor-specific CD8 T cells appeared inconsequential to CD8 T cell fate following immunotherapy. To our knowledge, this is the first study to interrogate tumor-specific CD4 T cells in PDA and uncover novel interplay between CD4 T cells, CD8 T cells, and myeloid cells that are critical for immunotherapy response.

#5309 ATOR-4066, a Neo-X-Prime™ bispecific antibody targeting CD40 and CEACAM5, induces tumor localized immune cell activation in preclinical *in vivo* tumor model.

Hampus Andersson[1], Ida Uddback[1], Mona Celander[1], Maria Johansson[1], Lill Ljung[1], Anneli Nilsson[1], Amulya Krishna Shetty[1], David Gomez Jimenez[1], Mattias Levin[1], Sara Fritzell[1], Laura von Schantz[1], Malin Lindstedt[2], Karin Hagerbrand[1], Anette Sundstedt[1], Peter Ellmark[1]

[1]Alligator Bioscience AB, Lund, Sweden,[2]Department of Immunotechnology, Lund University, Lund, Sweden

ATOR-4066 is a preclinical stage bispecific antibody targeting CD40 and CEACAM5, based on Alligator's novel Neo-X-Prime™ antibody technology platform. ATOR-4066 induces a neoantigen specific T-cell response by simultaneous binding to CD40 on myeloid cells such as antigen presenting cells (APCs) and to CEACAM5 on tumor cells. CEACAM5 is a tumor-associated antigen highly expressed on several cancer indications such as colorectal and gastric cancer, as well as on tumor-derived material. ATOR-4066 treatment results in (1) CEACAM5-conditional CD40-mediated activation of APCs and (2) enhanced uptake of tumor-derived material, leading to cross-presentation of neoantigen and priming of neoantigen-specific T cells, resulting in enhanced tumor cell killing. We have previously shown evidence of a potent anti-tumor effect of ATOR-4066 *in vivo*, superior to the effects observed with the corresponding CD40 mAb. Moreover, we have demonstrated CEACAM5-dependent activation of CD40-expressing cells *in vitro*, and an ability to mediate co-localization of CEACAM5-expressing tumor debris and CD40 expressing APCs. In addition, ATOR-4066 was shown to induce CEACAM5-conditional activation of tumor-infiltrating CD40-expressing immune cells in dissociated primary human tumor material from colorectal and gastric cancer patients. Here we present data further elucidating the mode of action of ATOR-4066 *in vivo*. Following ATOR-4066 treatment, tumors and lymph nodes were isolated from human CD40 transgenic mice bearing MC38 tumors expressing human CEACAM5. Flow cytometry analysis shows an increased number of tumor-infiltrating immune cells in mice treated with ATOR-4066 compared to treatments with CD40 mAb or vehicle. The study also reveals upregulation of co-stimulatory molecules such as CD86 on DCs and macrophages after treatment with ATOR-4066 compared to groups treated with CD40 mAb or vehicle. The effect was localized to the tumor microenvironment and not observed in tumor draining lymph nodes, confirming previous *in vitro* results demonstrating CEACAM5-conditional immune activation. Moreover, RNA-sequencing of tumor samples displayed distinct transcriptomic alterations following ATOR-4066 treatment vs. CD40 mAb or vehicle treatment *in vivo*. In contrast, RNA-sequencing of peripheral blood in ATOR-4066 treated mice showed only small transcriptomic differences compared to the vehicle treated group, but distinct from mice treated with a CD40 mAb, further demonstrating the CEACAM5 dependent response of ATOR-4066. In summary, these preclinical data demonstrate that ATOR-4066 activates infiltrating myeloid cells resulting in increases in activated tumor infiltrating T cells, thus creating a pro-inflammatory tumor microenvironment, which strongly supports further development and clinical testing of ATOR-4066.

#5310 KK2269, an epithelial cell adhesion molecule-targeted CD40 agonist, demonstrates antitumor effects in combination with standard therapies for NSCLC.

Y. Tezuka, K. Kawasaki, Y. Sumitomo, M. Saito, A. Yao, M. Ando;
Kyowa Kirin Co., Ltd., Tokyo, Japan

CD40 is a key molecule expressed on antigen presenting cells (APCs), whose signaling activates APCs and generates antitumor immune responses. Although CD40 agonists have been investigated in clinical trials, systemic toxicities have limited their full potential in providing adequate antitumor effects. To overcome this limitation, we developed KK2269, a bispecific antibody, using REGULGENT™ technology. KK2269 binds to CD40 and tumor-expressed epithelial cell adhesion molecule (EpCAM) to allow activation of CD40+ APCs only at EpCAM+ tumor sites, thus avoiding systemic toxicity. EpCAM is overexpressed in many types of epithelial cancers, including non-small cell lung cancer (NSCLC). KK2269 exerts synergistic antitumor activity and tumor-specific immune responses in combination with docetaxel, a common chemotherapy for NSCLC, in an EpCAM-expressing tumor mouse model. Hence, we aimed to evaluate KK2269 for the treatment of NSCLC. Docetaxel is used as a combination therapy with ramucirumab, an anti-VEGF receptor 2 (VEGFR2) antibody, for previously treated advanced NSCLC. In addition, many clinical studies are evaluating the add-on effects of PD-1/PD-L1 blockade combined with standard chemotherapies (including docetaxel) in NSCLC, which may become the standard of care for advanced NSCLC in the future. Therefore, we investigated the antitumor effect of KK2269 in combination with docetaxel + anti-mouse VEGFR2 (study 1) and with docetaxel + anti-mouse PD-1 (study 2) using a mouse EpCAM-expressing B16F10 tumor-bearing human CD40 transgenic mouse model. The prolongation of TTP5X (the day on which the tumor volume is observed to be ≥5-fold of that observed on day 0) was evaluated. In study 1, the median TTP5X (95% confidence interval [CI]) with the control, docetaxel + anti-VEGFR2, and triple combination (KK2269, docetaxel, anti-VEGFR2) was 10.0 days (7.0, 10.0), 26.0 days (17.0, 28.0), and 52.0 days (42.0, not calculable), respectively. The TTP5X was significantly prolonged with the triple combination compared with the control ($p=0.000007$, log-rank test) and docetaxel + anti-VEGFR2 ($p=0.000004$, log-rank test). In study 2, the median TTP5X (95% CI) was 7.0 days (not calculable), 9.0 days (6.0, 11.0), 16.0 days (7.0, 18.0), and 26.5 days (7.0, 32.0) with the control, KK2269, docetaxel + anti-PD-1, and triple combination (KK2269, docetaxel, anti-PD-1), respectively. TTP5X was significantly prolonged with the triple combination compared with the control, KK2269, and docetaxel + anti-PD-1 ($p<0.0001$, $p=0.0003$, and $p=0.0023$, respectively, log-rank test). Thus, a significant antitumor effect was demonstrated when KK2269 was added to the standard treatment of NSCLC (docetaxel + anti-VEGFR2 antibody) and to docetaxel + anti-PD-1 antibody. Our findings strongly suggest that KK2269 provides improved treatment options for patients with NSCLC.

#5311 KK2269, an epithelial cell adhesion molecule-targeted CD40 agonist, stimulates anti-tumor immunity resulting in sustained anti-tumor effect against mouse intrahepatic tumor without hepatotoxicity.

Y. Sumitomo, K. Kawasaki, Y. Tezuka, M. Saito, A. Yao, M. Ando;
Kyowa Kirin Co., Ltd., Tokyo, Japan

Several anti-CD40 agonist antibodies have been evaluated in clinical trials based on their preclinical antitumor activity via generation of antitumor innate and adaptive immunity through activation of antigen-presenting cells. However, conventional monospecific anti-CD40 agonist antibodies have faced limitations in terms of safety margins and clinical efficacy. To address this problem, we developed KK2269, a novel bispecific antibody (REGULGENT™ format) that binds to both CD40 and epithelial cell adhesion molecule (EpCAM), which is highly expressed in several types of tumors. KK2269 demonstrated EpCAM-dependent activation of CD40 signals both in vitro and in vivo, confirming that it is a tumor-targeting CD40 agonist. Liver metastasis is common in EpCAM-positive cancers, including colon, stomach, and lung cancers. Intrahepatic tumors can attenuate the efficacy of immune checkpoint inhibitors due to the liver tumor-specific suppressive immune milieu. Although CD40 agonists are expected to overcome the immunosuppressive environment, non-tumor-targeting CD40 agonists cause hepatotoxicity. In the present study, we used a syngeneic intrahepatic tumor model to examine whether KK2269 exhibits antitumor efficacy without causing hepatotoxicity. Firstly, we confirmed that KK2269 administration did not increase aspartate aminotransferase (AST) or cause pathological abnormalities in the liver despite Il12b induction in the EpCAM-positive tumor. Additionally, gene expression analysis of peritumoral normal liver revealed that KK2269 did not induce inflammatory cytokines. In contrast, a conventional anti-CD40 agonist antibody increased AST, caused pathological abnormalities, and upregulated inflammatory cytokines in peritumoral normal liver, as reported in the clinical setting. Secondly, the antitumor effect of KK2269 in combination with docetaxel was evaluated. The combination therapy synergistically reduced intrahepatic tumor volume, and the effect persisted even 21 days after the administration. Gene expression analysis revealed a lower immune infiltration in the intrahepatic tumor versus subcutaneous tumor and that KK2269 in combination with docetaxel increased T-cell infiltration and activation even in the immunosuppressive intrahepatic tumor. In summary, our study demonstrated that KK2269 activated dendritic cells in an EpCAM-positive tumor in the liver but did not affect peritumoral normal liver tissues. In addition, KK2269 in combination with docetaxel showed potent antitumor effect accompanied by T-cell infiltration and activation against the intrahepatic tumor, which has a lower immune infiltration. These results suggest that the combination therapy of KK2269 and docetaxel is promising for metastatic EpCAM-positive tumors.

#5312 Agonist CD40 engineered smart immunosomes induced anti-tumor immunity, reduced associated toxicities and showed tumor free survival in murine glioblastoma model.

V. Gaur[1], W. Tyagi[2], S. Das[2], S. Ganguly[3], J. Bhattacharyya[4];

[1]Indian Institute of Technology Delhi (IIT Delhi), New Delhi, India, [2]National Institute of Immunology, New Delhi, India, [3]Jamia Hamdard University, New Delhi, India, [4]Indian Institute of Technology Delhi, New Delhi, India

CD40 agonist antibodies (αCD40) have proven great potential as an anti-cancer immunotherapeutic by showing promising anti-tumor response in both preclinical and early clinical studies. However, it has been observed that the systemic administration of αCD40, even at low dose, is associated with serious immune- and hepato- toxicities. In addition, αCD40 showed low tumor retention and induced PD-L1 expression which makes tumor microenvironment (TME) immunosuppressive. To overcome these issues, in this study, we have developed an immunosome where αCD40 is conjugated on the surface and VJ23, a small molecule immune-modulator was encapsulated inside it . Immunosome showed higher tumor accumulation till 96 hr of administration and displayed sustained release of αCD40 *in vivo*. Immunosome significantly delayed tumor growth and showed tumor free survival in mice bearing GL-261 glioblastoma tumor by increasing the population of $CD45^{+}CD8^{+}$ T cells, $CD45^{+}CD20^{+}$ B cells, $CD45^{+}CD11c^{+}$ DCs and $F4/80^{+}CD86^{+}$M1 macrophage in TME. In addition, Immunosome significantly reduced the population of T-regulatory cells, M2 macrophage, and MDSCs and lowered the expression of PD-L1 to modulate immunosuppressive TME. Moreover, Immunosomes significantly enhanced the level of pro-inflammatory cytokines (IFN-γ, IL-6, IL-2) and lowered anti-inflammatory cytokines (IL-4 and IL-10) level which supported anti-tumor response. Most interestingly, Immunosomes averted the *in vivo* toxicities associated with free αCD40 by lowering the levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), IL-6, IL-1α and reduced the degree of liver damage. Our results suggested that this novel formulation can be further explored in clinics to improve the *in viv*o anti-tumor efficacy of αCD40 while reducing the associated toxicities.

#5313 CB307: A dual targeting costimulatory Humabody® V_H therapeutic for treating PSMA-positive tumors.

S. Archer[1], P. M. Brailey[1], M. Song[1], P. D. Bartlett[1], I. Figueiredo[2], B. Gurel[2], C. Guo[2], V. Brucklacher-Waldert[1], H. Thompson[1], J. Akinwale[1], S. E. Boyle[1], C. Rossant[1], N. R. Birkett[1], J. Pizzey[1], M. Maginn[1], J. Legg[1], R. Williams[1], C. M. Johnston[1], P. Bland-Ward[1], J. S. de Bono[2], A. J. Pierce[1];
[1]Crescendo Biologics, Cambridge, United Kingdom, [2]Institute of Cancer Research, London, United Kingdom

INTRODUCTION: CD137 is a T and NK cell costimulatory receptor involved in consolidating immunological responses. The potent CD137 agonist urelumab has shown clinical promise as a cancer immunotherapeutic but development has been hampered by on-target off-tumour toxicities. A CD137 agonist targeted to the prostate-specific membrane antigen (PSMA), frequently and highly expressed on castration-resistant metastatic prostate cancer (mCRPC) tumour cells, could bring effective immunotherapy to this immunologically challenging to address disease.
EXPERIMENTAL PROCEDURES: We designed and manufactured CB307, a novel half-life extended bispecific costimulatory Humabody® V_H therapeutic to elicit CD137 agonism exclusively in a PSMA-high tumour microenvironment (TME). The functional activity of CB307 was assessed in cell-based assays and in syngeneic mouse anti-tumour pharmacology studies. Non-clinical toxicology and toxicokinetic properties of CB307 were assessed in a good laboratory practice (GLP) compliant study in cynomolgus macaques.
RESULTS: CB307 provides effective CD137 agonism in a PSMA-dependent manner, with anti-tumour activity both in vitro and in vivo, and additional activity when combined with checkpoint inhibitors. A validated novel PSMA/CD137 immunohistochemistry (IHC) assay demonstrated a higher prevalence of CD137-postive cells in the PSMA-expressing human mCRPC TME with respect to primary lesions. CB307 did not show substantial toxicity in non-human primates and exhibited a plasma half-life supporting weekly clinical administration.
CONCLUSIONS: CB307 is a first-in-class immunotherapeutic that triggers potent PSMA-dependent T cell activation thereby alleviating toxicological concerns against unrestricted CD137 agonism.

#5314 Improved breast cancer tumor control with addition of CD40 agonist and Flt3 ligand to pegylated liposomal doxorubicin is only partially mediated by CD8 T cells.

P. L. Mylabathula, S. Nooka, A. Alkhani, J. Zhu, A. Vu, R. Ali, V. Ramasamy Balasubramanian, I. Chan, **S. M. Reddy**;
UT Southwestern Medical Center, Dallas, TX

Background: There is a need for improved immunotherapy strategies beyond current FDA approved treatments for triple negative breast cancer. Defective antigen presentation has been shown to play a contributory role in deficient anti-tumor immunity in breast cancers. Flt3 ligand (Flt3L) is a growth factor that increases differentiation into DC1 dendritic cells. CD40 agonist (CD40a) activates all 3 classes of antigen presenting cells - DCs, B cells, and macrophages. Synergy with chemotherapy and CD40a has been seen in other cancers but not explored in breast cancers.

Methods: C57BL/6 mice (aged 6-8 weeks) were injected with 150,000 E0771 breast cancer cells within the mammary fat pad. Tumors were allowed to grow to a volume of ~50 mm^3 before randomization into treatment groups. Mice were treated with triplet therapy of pegylated liposomal doxorubicin (PLD) via tail vein followed by Flt3L intraperitoneal (IP) daily for 5 days and CD40a IP 1 week later as well as monotherapy and doublet therapy controls. Tumor growth and survival were monitored throughout the experiment. Tumors were harvested for single cell RNA sequencing (scRNAseq) and immunohistochemistry. To further study subset specific effects on efficacy of the immunotherapy, CD8 and CD4 T-cells were systemically depleted with anti-CD8 and anti-CD4 antibodies administered IP every 4 days starting 2 days before PLD treatment.

Results: Triplet therapy led to improved tumor control compared to no treatment, monotherapy, and doublet controls ($p<0.0001$). Increased tumor infiltration with CD8 T cells was observed with triplet therapy via immunohistochemistry. scRNAseq showed increased cDC1 subset with Flt3L treatment. Contrastingly, CD40a decreased DC subsets likely due to activation and emigration out of the tumor, remodeled macrophage populations, and decreased T regulatory cells. CD8 depletion led to faster tumor growth whereas CD4 depletion reduced tumor growth. Triplet therapy maintained efficacy over PLD with both CD8 and CD4 depletion but showed reduced magnitude of benefit with CD8 T cell depletion suggesting a partial CD8 mediated process. CD4 T cell depletion did not hinder triplet therapy efficacy compared to PLD but depletion further enhanced tumor control in combination with triplet therapy, with 20% (2/10) of animals achieving complete regression.

Conclusion: Triplet therapy with PLD, Flt3L, and CD40a improved tumor control and survival in syngeneic E0771 breast cancer mouse model. Added benefit of immunotherapy to PLD is partially CD8 T cell mediated. CD4 depletion further enhances tumor control in combination with triplet therapy. Experiments to explore the interactive effect of triplet therapy with other pertinent immune subsets are ongoing. A clinical trial with this combination in metastatic triple negative breast cancer patients is open and recruiting (NCT05029999).

#5315 Bispecific antibody discovery platform for IND enabling studies: Case study of HER-2/NKG2D bispecific antibody.

L. Ratcliffe, R. Pooley, K. Carr, H. Janbazacyabar, D. Cobeta Lopez, D. Bruce, S. L. Martin, M. Benson, J. White, B. Quist, S. Vermond, **G. Moiset**, S. Hill, R. Feldman, P. Wan, E. Oswald, F. Verkaar, M. Aspinall-O'Dea, J. Schueler, N. Jayanth;
Charles River Laboratories, Inc., Leiden, Netherlands

There has been a surge in the number of therapeutic antibody modalities primarily attributable to the increasing array of antibody engineering platforms. Among these, the emergent class of bispecific antibodies has exhibited remarkable potential compared to conventional monoclonal antibodies, marked by their targeting precision, expanded therapeutic scope, and personalized medicine prospects. Presently, eight bispecific antibodies are approved, with over 100 in varying clinical trial phases. Using a bispecific targeting HER-2 and NKG2D, we outline a comprehensive end-to-end platform for bispecific antibody discovery and characterization, designed to facilitate the progression of novel bispecific antibodies through the antibody discovery pipeline. To secure the most optimal binders tailored to specific targets, our methodology capitalizes on an extensive repertoire of phage display libraries. This strategy is instrumental in the identification of antibody candidates with exceptional binding affinity, broad cross-species compatibility, and enhanced drug-like properties. From the anti-HER2 chimeric antigen receptor ML39 and anti-NKG2D Fab KYK2.0, we synthesized four distinct bispecific formats by fusing single-chain variable fragments (scFv) to immunoglobulin G (IgG) molecules. These formats varied in terms of valency and scFv positioning, allowing us to assess their impact on antibody expression, binding kinetics, and functional efficacy. Subsequently, the bispecific antibodies underwent comprehensive in vitro efficacy and safety characterization, employing multiple innovative technologies. Utilizing a distinctive label-free approach with the xCELLigence system, we elucidated the kinetics of immune cell-mediated target cell killing upon antigen-antibody complex recognition in specific cancer cells. Safety assessments, with a focus on on-target/off-tumor effects, were conducted using the Retrogenix platform. Furthermore, cytokine profiling was utilized to evaluate potential risks associated with enhanced cytokine levels, reinforcing the specificity and safety profile of the bispecific antibody. Finally, pertinent in vivo models, including peripheral blood mononuclear cells (PBMC) and immune cell transfer models, facilitated the translation of preclinical bispecific antibody evaluations into clinically relevant contexts. This comprehensive platform for bispecific antibody discovery and functional characterization serves as a robust foundation for supporting Investigational New Drug (IND) applications, thus facilitating the transition of novel bispecific antibodies from the pre-clinical to the clinical phase of the drug discovery process.

#5316 SM2256: A bispecific conditional CD40 and 4-1BB dual agonist for enhanced solid tumor immune response.

W. Song, S. Yang, Y. Wei, S. Lu, H. Geng, X. Liu, H. Zhou, S. Xie, X. Zhang, S. Zhou, **Y. Liang**;
Beijing StarMab BioMed Technology, Ltd., Beijing, China

Background: Monoclonal antibodies targeting the co-stimulatory receptors CD137 (4-1BB) and CD40 have displayed encouraging activity against a wide range of solid tumors in preclinical animal models. However, their clinical development as monotherapy has been hindered by dose-related liver toxicity, leading to limited efficacy at safe doses. To address this challenge and bolster tumor-specific immunity by orchestrating the interaction between dendritic cells (DCs) and cytotoxic T cells, we introduce SM2256 - a bispecific conditional CD40 and 4-1BB dual agonist. SM2256 physically bridges DCs and T cells, enhancing T cell priming and reactivation. In preclinical animal studies, SM2256 exhibited both excellent tolerability and potent anti-tumor activity.
Methods: SM2256 was engineered by fusing high-affinity, non-ligand-blocking VHH domains targeting 4-1BB and CD40 to a silenced IgG1 Fc backbone. This fusion resulted in a tetravalent bispecific antibody capable of conditionally activating CD40 and 4-1BB upon mutual receptor binding. We assessed the binding specificity and affinity of SM2256 to human CD40 and 4-1BB using ELISA and flow cytometry. The target-dependent activation of CD40 and 4-1BB was confirmed via reporter assays and co-culture systems using primary DCs and T cells. In vivo safety and anti-tumor efficacy were evaluated in a syngeneic transplantation model using the MC38 cancer cell line in B-h41BB/B-hCD40 double humanized mice.
Results: SM2256 exhibited sub-nanomolar binding affinity to recombinant human and cynomolgus monkey CD40 and 4-1BB, activating 4-1BB-NFκB-luc and CD40-NFκB-luc reporter cell lines at picomolar concentrations in a strictly target-dependent manner. Furthermore, SM2256 physically facilitated the interaction between DCs and T cells, leading to increased expression of DC co-stimulatory ligands and elevated secretion of cytokines by T cells in mixed lymphocyte cultures. In a syngeneic tumor transplantation model, SM2256 significantly restrained the growth of MC38 tumors in B-h41BB/B-hCD40 double humanized mice.
Conclusions: SM2256 is a novel conditional CD40 and 4-1BB dual agonist that demonstrates promising preclinical efficacy against solid tumors while boasting an improved safety profile when compared to existing monoclonal antibodies.

#5318 SM2275, A tetraspecific, dual EGFR and PD-L1-targeting, conditionally activating co-stimulatory CD28 and simultaneously blocking PD-1/PD-L1 signaling to promoting fully activated T cell killing effects on tumor cells.

S. Lu, X. Liu, S. Zhou, W. Song, H. Geng, S. Yang, H. Zhou, S. Xie, Y. Wei, X. Zhang, **Y. Liang**;
Beijing StarMab BioMed Technology, Ltd., Beijing, China

Background: T cells require both signal 1 TCR engagement and signal 2 co-stimulatory signal to achieve complete activation and tumor recognition. CD28 is a signal 2 co-stimulatory receptor and activating CD28 increases T cell sensitivity, cytokine production and T cell survival. PD-1/PD-L1 signaling attenuates the T cells functional activity by inhibiting CD28 co-stimulation in the presence of TCR stimulation. Therefore, we developed SM2275, a tetraspecific VHH antibody against EGFR, PD-L1, CD28 and HSA, for the treatment of EGFR+/PD-L1+ solid tumors. Preclinical study demonstrated promising efficacy and favorable safety profile via a unique mechanism of action.
Methods: SM2275 was developed using StarMab's proprietary Quadbody multifunctional VHH antibody platform. It features two monovalent, low-affinity binding domains for EGFR and PD-L1, along with nanomolar low affinity CD28 binding domains arranged in a tandem format, followed by a half-life extending HSA binding domain. Differential binding affinities of SM2275 to EGFR/PD-L1 single-expressing versus double-expressing cell lines were analyzed by flow cytometry. Avidity-enhanced blockade of PD-1 on EGFR+PD-L1+ double-positive compared to PD-L1+ single-positive cells was analyzed via competitive binding assay and Jurkat PD1 NFAT Luciferase reporter assay. EGFR/PD-L1 dual-target-dependent CD28 activation was confirmed using a primary human T cell IL2 & IFN-γ release assay in the presence of TCR stimulation. In vivo efficacy against EGFR+/PD-L1+ double-positive human tumors were evaluated using a syngeneic tumor transplantation model of MC38-hEGFR/hPDL1 cell line into hPD-L1/hCD28 humanized mice.
Results: SM2275 displays dramatically increased affinity for cancer cells co-expressing EGFR/PD-L1 compared to single-expressing cells. This leads to an avidity-enhanced PD-L1 blockade specifically on the surface of EGFR+PD-L1+ double-positive cancer cells, enabling localized reactivation of tumor-infiltrating T cells without systemic immune toxicity. Simultaneously blocking the PD-L1 signaling unleashed the inhibition of CD28 co-stimulation for the full T cell activation. In the presence of SM2275, EGFR /PD-L1 double-positive cancer cells induce significantly enhanced CD28 activation and cytokine secretion compared to single-antigen-expressing cells. In a syngeneic tumor transplantation model, SM2275 effectively inhibits the growth of MC38-hEGFR/hPDL1 tumors in hPD-L1-hCD28 humanized mice, with no apparent cytokine release and immune toxicity.
Conclusions: SM2275 is a novel dual-EGFR & PD-L1-targeting, conditional CD28 agonistic antibody. It demonstrated promising efficacy and favorable safety profile in preclinical studies via a unique mechanism of action.

IMMUNOLOGY: Inflammation in Tumor Initiation and Progression
Poster Session

#5321 Chronic use of tobacco products promotes breast cancer progression through α7 nAChR/STING pathway activation.
S. Mugisha, S. Baba, S. Labhsetwar, R. Klemke, J. Desgrosellier;
University of California San Diego - UCSD, San Diego, CA

Tobacco-use is associated with an increased risk of developing aggressive breast cancer, however the cause remains unclear. While there is a dose-dependent decrease of patients' overall survival due to tobacco-use, the risk persists even after cessation. Here we show that chronic treatment with of breast cancer cells with low-dose nicotine significantly increases tumorsphere formation, self-renewal and tumor growth, while the acute treatment has little effect. Interestingly, these outcomes were noted even weeks after nicotine treatment was stopped. Mechanistically, this was attributed to α7 nAChR, previously described as an essential regulator of inflammation. In fact, α7 nAChR knock-out prevented activation of the STING antiviral pathway by reducing the nicotine-induced mRNA expression of STING, CCL5, CXCL10 and STAT3. Overall, these findings highlight long-term impact of nicotine on cancer progression through α7 nAChR/STING pathway. This may inform new biomarkers for diagnosis and potential new treatment strategies to combat tobacco-related breast cancers.

#5322 Discovery of CRD1601, a potent and selective HPK1 inhibitor with robust *in vivo* anti-cancer activity.

M. Banerjee[1], R. Shrivastava[1], D. Pryde[2], S. Middya[1], S. Debnath[1], A. Middya[1], D. Yadav[1], N. Rawat[1], R. Ghosh[1], M. Padaliya[1], S. Basu[1], A. Surya[1];
[1]Curadev Pharma, Noida, India, [2]Curadev Pharma, Sandwich, United Kingdom

Background: Haematopoietic Progenitor Kinase (HPK-1, MAP4K1) is a member of the STE20 family of serine/threonine kinases, expressed predominantly in hematopoietic cells. HPK-1 functions as a negative regulator of T-cell and B-cell receptor activation by triggering proteasomal degradation and disrupting signalosome complexes downstream of TCR and BCR. HPK1 inhibition is a novel IO strategy that could combine with existing chemotherapies and immunotherapies.
Methods: Curadev used a pharmacophore based approach to discover novel small molecule HPK-1 inhibitors using in vitro enzymatic and phenotypic cellular screens using primary cells. CRD1601, the clinical candidate was selected based on its ability to enhance human T-cell proliferation through the induction of IL2 and IFNγ. Syngeneic tumor models were used to assess anti-tumor activity of selected compounds as a monotherapy or combination therapy.
Results: CRD1601 is a potent HPK1 inhibitor with a single digit nanomolar IC50 value in enzymatic assay and potent cellular activity in the SLP76 assay. A single dose of CRD1601 in mice treated with an anti-CD3 antibody caused systemic enhancement of pro-inflammatory cytokines such as IL2, IFN gamma and reduced pSLP76 levels in the spleen. Further, CRD1601 reversed the immunosuppressive effect of PGE2 and NECA. CRD1601 demonstrated significant single agent activity in murine tumor models while also synergizing with chemotherapy and immunotherapy.
Conclusions: Inhibition of HPK-1 is a promising therapeutic modality that could augment the effects of existing anti-cancer treatments including immunotherapy. CRD1601 is a potent and selective HPK-1 inhibitor with favorable drug like properties that has been selected from a rich portfolio of active compounds and shows promising in vivo activity in tumor models.

#5323 Inflammation drives lineage plasticity and a club cell-like phenotype in prostate epithelial cells.

M. Hess[1], H. Song[2], J. Hicks[1], L. Mummert[1], A. De Marzo[1], F. W. Huang[2], K. Sfanos[1];
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of California, San Francisco, San Francisco, CA

Background: Club cells are a type of bronchiolar epithelial cell that serve a protective and antimicrobial function in the lung. An epithelial cell population in adult human prostates was recently identified as sharing a similar transcriptomic profile and morphology to lung club cells. Club-like epithelial cells were identified in the prostatic urethra, collecting ducts, and rarely in the peripheral zone of normal organ donor prostates. However, we recently reported that cells expressing club cell markers (*CP, LTF, MMP7, PIGR, SCGB1A1*) are present in the peripheral zone of radical prostatectomy specimens. Here, expression of club cell markers was restricted to luminal epithelial cells in an inflammation-associated lesion termed proliferative inflammatory atrophy (PIA). We also demonstrated that these club-like cells within PIA express the same markers as intermediate cells, a proposed prostate cancer progenitor cell. We now aim to identify exogenous factors that drive the club cell phenotype *in vitro*. Our ultimate goal is to understand how club cell gene expression affects the oncogenic and metastatic potential of prostate epithelial cells.
Methods: We characterized the expression of club cell genes in prostate cell lines (LNCaP, PREC, and PREC-AR-Myc) following exposure to inflammatory stimuli (TNFα, hydrogen peroxide, uropathogenic *Escherichia coli*) *in vitro*. We performed quantitative reverse transcription PCR (RT-qPCR) to measure expression of club cell markers (*LTF, MMP7, PIGR*) and intermediate cell markers (*AR, NKX3.1, SMOX*). Additionally, we used chromogenic RNA *in situ* hybridization (RISH) to visualize *LTF*, *MMP7*, and *PIGR* expression following exposure to inflammatory stimuli.
Results: We report that TNFα exposure *in vitro* increased expression of club cell genes (*LTF, MMP7, PIGR*). Surprisingly, TNFα exposure induced *LTF* expression in LNCaP cells, despite prior findings that *LTF* is silenced by CpG island hypermethylation in prostate cancer and in LNCaP cells. This finding was confirmed by both RT-qPCR and RISH. Additionally, we found that TNFα exposure altered intermediate cell markers (*AR, NKX3.1, SMOX*) expression consistent with the previously reported gene expression pattern of luminal epithelial cells in PIA.
Conclusions: Overall, our results suggest that TNFα-mediated signaling drives the expression of club cell markers associated with lineage plasticity. Our next step will be to analyze inflammation-driven alterations to methylation and chromatin accessibility around loci associated with club cell genes, proton-oncogenes, and tumor suppressor genes.

#5324 Key antiviral response genes mediate the impact of chromosomal instability on breast cancer stemness.

S. A. Baba, S. Mugisha, S. Iabhsetwar, R. klemke, J. Desgrosellier;
University of California San Diego - UCSD, San Diego, CA

Chromosomal instability (CIN) is a recognized hallmark of cancer, pivotal in tumor evolution and metastasis. Our research unveils CIN as a stress during tumor initiation, uniquely tolerated by activated breast cancer stem cells (aCSCs). Elevated CIN, specific to tumors from aCSCs, contrasts with baseline levels akin to non-stem cell types. This transient increase in CIN, observed in low burden aCSC tumors, diminishes in established disease, suggesting a dynamic induction during initiation. Consist wit this we have observed increase in CIN tolerance in stem-like vs basal-like cells suggesting heterogeneity in response. CIN triggers a specific response, activating proinflammatory cancer autonomous immune signaling. We identified several CIN-induced proinflammatory stem cell-specific genes from our overlap studies. Knockdown assays targeting RSAD2 and PLAU showed a significant decrease in tumorsphere properties, emphasizing their functional relevance for cancer progression. AXL did not show any effect on tumorsphere but was important to tolerate CIN induced due to reversine. Mechanistically, AXL expression was induced by c-Jun stress signaling activation in aCSCs. These antiviral CIN-induced proinflammatory markers, emerge as a vital player in breast cancer progression. This study establishes a foundation for investigating antiviral genes as crucial contributors to cancer.

#5325 Cytokine CCL9, new downstream target of oncogene Kras to modulate acinar-to-ductal metaplasia during pancreatic cancer initiation.

Geou-Yarh (Stancy) Liou[1], Justin K. Messex[2], Crystal J. Byrd[3]

[1]Center for Cancer Research & Therapeutic Development; Biological Sciences, Clark Atlanta University, Atlanta, GA,[2]Center for Cancer Research & Therapeutic Development, Clark Atlanta University, Atlanta, GA,[3]Biological Sciences, Clark Atlanta University, Atlanta, GA

Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal types of cancer with a current five-year survival rate at 12% in the US, and is dominated by oncogenic Kras mutations. Accumulating evidence showed that PDAC can be originated from acinar-to-ductal metaplasia (ADM). In this process, pancreatic acini harboring oncogenic Kras mutations are transdifferentiated to a duct-like phenotype that further progresses to become pancreatic intraepithelial neoplasia (PanIN) lesions, giving rise to PDAC. Although ADM formation is commonly observed in $Kras^{G12D}$ transgenic mouse models of PDAC, the exact mechanisms of how oncogenic $Kras^{G12D}$ modulates this process remain unclear. Here, we unveil a new downstream target of oncogenic Kras, cytokine CCL9 during ADM formation. Either exogenously treating primary pancreatic acini with recombinant CCL9 or ectopically expressing CCL9 in primary pancreatic acini resulted in ADM formation in a 3D organoid culture system. Furthermore, knockdown of CCL9 in $Kras^{G12D}$-expressed acini reduced $Kras^{G12D}$-induced ADM. Higher levels of reactive oxygen species (ROS) were detected in the $Kras^{G12D}$-expressed pancreatic acini, and knockdown of CCL9 in these acini decreased ROS levels. Overexpression of CCL9 in primary pancreatic acini elevated cellular ROS of pancreatic acinar cells. Furthermore, depletion of ROS in 3D organoid culture of CCL9-expressed acini reduced CCL9-induced ADM formation. In transgenic mice of $p48^{cre}$;$Kras^{G12D}$, blockade of CCL9 through its specific neutralizing antibody attenuated ADM formation as well as PanIN structures. Altogether, our results indicated oncogenic $Kras^{G12D}$ initiates PDAC through a new downstream target molecule, CCL9, to enhance ROS levels of pancreatic acinar cells.

#5326 Selective deletion of estrogen receptor β in lung epithelium suppresses K-ras mutant lung tumorigenesis.

M. J. Clowers[1], A. L. Thompson[2], C. I. Rodriguez Reyna[1], S. Deng[1], S. Moghaddam[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Mississippi State University, Starkville, MS

Although lung cancer is the most prolific cause of global cancer-related deaths, outcomes by sex have gained traction as a means to stratify patients and tailor therapies accordingly. In recent years, females have begun to shoulder a greater burden of lung cancer diagnoses, specifically within the lung adenocarcinoma (LUAD) subtype; conversely, mortality is worsened for males. However, other sex-dependent effects in lung cancer are harder to predict. For example, hormone replacement therapy for post-menopausal women has been shown to predict better survival in some cohorts while auguring worse outcomes in others. Similar controversy exists regarding menopausal status, gender affirming care, and castration/oophorectomy status. However, there is consensus that these differential effects relate to a patient's sex hormone composition. Estrogen, a sex hormone abounding in females, boasts well-described pro-tumor signaling in breast cancer. Unfortunately, its role in lung cancer remains elusive. Estrogen is reported to exert inflammatory properties in the lung environment, to drive immune function, and to induce proliferation of lung cancer cells. This functional antagonism has led to questions about how these compartment-specific effects are balanced. In the lung, estrogen signaling occurs mainly via estrogen receptor beta (ERβ), a nuclear hormone receptor highly expressed in lung tissue and lung tumors. ERβ is understudied relative to its sibling ERα, a well-known oncogene in breast cancer. While it is tempting to analogize ERα oncogene function to ERβ, the literature lacks consensus on the role of ERβ in lung cancer, with some authors classifying it as an oncogene and others as a tumor suppressor. In LUAD, Kras mutations encompass a quarter of driver mutations, and interaction of Kras with ERβ is understudied. Here, we tested the effects of genetic ablation of ERβ in a murine model of Kras mutant LUAD (KM-LUAD) termed $CCSP^{Cre}$/LSL-$Kras^{G12D}$ (CC-LR). Esr2 floxed mice were crossed with CC-LR mice to create a lung epithelial-specific conditional knockout of ERβ (LR/$Esr2^{\Delta/\Delta}$). LR/$Esr2^{\Delta/\Delta}$ mice show significant decrease in tumor burden and total lung immune infiltration, indicating reduced tumor development and tumor-promoting inflammation. Of note, this effect manifests regardless of sex. RNA and protein-level analysis further suggest that ERβ deletion alters the balance of inflammatory transcription factors, resulting in skewing from STAT3- to NF-κB-driven inflammation and a net anti-tumor response. These data suggest that ERβ offers a promising early target in nascent KM-LUAD tumors with therapeutic intervention possible regardless of sex-specific effects. Acknowledgement: supported by NIH/NCI grant awarded to Seyed Javad Moghaddam (R01 CA225977); Michael J Clowers partly supported by NIH/NCI (F31 CA261121); Annamarie L Thompson supported by CPRIT Research Training Award (RP210028).

#5327 Interleukin-1 upregulates dual oxidase 2 expression and ROS production in human pancreatic cancer cells.

David J. Mallick[1], Yongzhong Wu[2], Mariam M. Konate[1], Becky Diebold[2], Smitha Antony[1], Jennifer L. Meitzler[2], Guojian Jiang[2], Jiamo Lu[2], Krishnendu Roy[1], James H. Doroshow[1]

[1]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD,[2]Developmental Therapeutics Branch, National Cancer Institute, Bethesda, MD

Chronic pancreatitis increases the risk of developing pancreatic ductal adenocarcinoma (PDAC) and is associated with enhanced expression of the NADPH oxidase (NOX) isoform dual oxidase 2 (DUOX2). Interleukin-1 (IL-1) is a major upstream pro-inflammatory cytokine secreted by malignant or microenvironmental cells that supports pancreatic inflammation, tumorigenesis, invasiveness, and tumor heterogeneity. Previously, our laboratory demonstrated that the expression of DUOX2, one of seven NADPH oxidase (NOX) family members, is significantly enhanced by a wide variety of pro-inflammatory cytokines, and that DUOX2-related ROS production may contribute to the development of an oxidative, pro-angiogenic microenvironment in PDAC. In the current studies, we have shown that DUOX2 is upregulated and expressed along with its maturation factor, DUOXA2, in several human pancreatic cancer cell lines following exposure to both IL-1α and IL-1ß, two major agonists of IL-1 signaling. Administration of the anti-inflammatory antibody anakinra (an IL-1R1 antagonist) either in conjunction with or after prolonged treatment with IL-1 *in vitro* ablated induction of DUOX2/DUOXA2 and of IL-8 (CXCL8), a chemokine essential for neutrophil recruitment and a potent promoter of angiogenesis. Increased expression of other NOX family members following IL-1 exposure was not observed. Using CRISPR/Cas9-mediated DUOX2 knockout models, we report that DUOX2 is the major contributor to IL-1-mediated ROS production in PDAC cells. In a panel of PDAC lines, siRNA knockdown of proximal IL-1 signaling nodes, such as MYD88, significantly decreased expression of DUOX2/DUOXA2 and of CXCL8. However, knockdown of IRAK1 or IRAK4, two critical signaling kinases downstream of MYD88, as well as known downstream mediators of IL-1-related transcription (such as NF-κB, STAT1, MEK/ERK), did not affect IL-1-induced DUOX2/DUOXA2 upregulation, suggesting that alternative pathways of IL-1 signaling might be involved in the enhancement of DUOX2 expression by the cytokine. Because IL-1 signaling is known to affect various acetylation/methylation events in epithelial cells, we evaluated the effect of administering the histone acetyltransferase (HAT) inhibitor A-485 with IL-1; we found that A-485 significantly diminished cytokine-induced DUOX2/DUOXA2 upregulation; however, CXCL8 induction was unchanged. These studies suggest that epigenetic modulation of PDAC cells by IL-1 could contribute to DUOX2-induced ROS production and ROS-related inflammatory stress in the PDAC microenvironment.

#5328 Dual role of Kupffer cell secreted CXCL5 in hepatocellular carcinoma.

T. Tu, H. Hong, L. He, M. Alba, T. Qi, C. T. Okamoto, B. L. Stiles;
USC - University of Southern California, Los Angeles, CA

Hepatocellular carcinoma (HCC) is hallmarked by inflammatory cell infiltration. Chemokines secreted during inflammation are crucial at directing immune cell infiltration during cancer development. We screened patient dataset from different etiologies including HBV, HCV, alcohol and non-alcoholic steatohepatitis (NASH) and identified CXCL5 as the only chemokine consistently upregulated in HCC. Immunohistochemistry (IHC) of patient liver tumor tissues further showed the production of CXCL5 by tumor surrounding non parenchymal cells. Using a mouse model ($Pte^{loxP/loxP}$; Alb-$Cre^{\pm}$, *Pten* null) which recapitulates human liver disease progression from non-alcoholic fatty liver disease (NAFLD) to NASH to liver cancer, we found that CXCL5 was expression was gradually increased during disease progression. Further analysis using IHC and flow cytometry analysis showed that CXCL5 is predominantly expressed by Kupffer cells in *Pten* null livers bearing tumors. Furthermore, we found that LPS stimulated the expression and secretion of CXCL5 in Kupffer cells, but not other macrophages including peritoneal macrophage and macrophage cell line Raw264.7 cells. We hypothesized that the Kupffer cell-secreted CXCL5 in response to LPS promotes tumor progression by promoting HCC cell proliferation and regulating HCC associated immune cell infiltration. To investigate whether CXCL5 increases tumor cell proliferation, we treated wild type and *Pten* null hepatocytes with various concentrations of CXCL5. Our results showed that CXCL5 increased hepatocytes viability in a dose dependent manner. BrdU incorporation assay further confirmed that CXCL5 treatments induces HCC cell proliferation through its receptor CXCR2. We further demonstrated that CXCR2 knockdown led to reduced xenograft tumor growth using HepG2 cells. Additionally, we injected *Pten* null mice with CXCR2 inhibitor to block CXCL5 signal and observed partial response. We analyzed the immune cell profile of the responder mice vs. non-responder mice and showed that tumor inhibition is correlated with T cell infiltration. To test whether Kupffer cells regulate T cells through CXCL5, we isolated primary Kupffer cells from murine livers. We performed transwell migration assay using immune cells from murine spleens. Our results indicate that LPS stimulation in Kupffer cells reduced the ratio of migrated CD4+ T cells, while blocking CXCL5 using a CXCL5 antibody significantly increased $CD4^{\pm}$ T cell recruitment to the LPS-stimulated Kupffer cells and moderately decreased neutrophil recruitment. Consistently, we found that recombinant CXCL5 protein reduces $CD4^{\pm}$ T cell migration independent of neutrophils. In summary, our study suggests that Kupffer cell secreted CXCL5 reduces liver $CD4^{\pm}$ T cell recruitment and increases liver cancer cell proliferation.

#5329 Ovarian cancer predisposes neutrophils to form neutrophil extracellular traps(NETs).

G. Yamamoto, M. Kawano, M. Bun, K. Shimura, A. Toda, K. Nakamura, Y. Kinose, M. Kodama, K. Hashimoto, K. Sawada, T. Kimura;
Osaka University, Osaka, Japan

Objective: Neutrophil extracellular trap (NETs) are neutrophil-derived extracellular DNA released in response to inflammation. In contrast to their primary host-defensive role, NETs have been recently reported to promote cancer progression. The aim of this study is to investigate the role of NETs in ovarian cancer progression.
Method: The clinical data of ovarian cancer patients who underwent primary surgery at Osaka University Medical Hospital were retrospectively reviewed (n=340). The relationship between neutrophilia, peritoneal dissemination and prognosis were analyzed. Prior to initial treatment, peripheral blood was obtained from newly diagnosed ovarian cancer patients and examined for CBC and granulocyte-colony stimulating factor (G-CSF) concentration by ELISA. To evaluate NETs formation capacity, isolated neutrophils were stimulated with G-CSF and incubated in vitro to monitor NETs formation. The ascites was collected at the initial surgery and assessed for G-CSF concentration and for neutrophils population using flow cytometry. The omental tissues were pathologically examined for NETs using H&E-staining and immunostaining with anti-Citrullinated Histon3 (CitH3) antibody. To test NETs induction capacity, we treated human peripheral blood neutrophils with the conditioned media from 20 ovarian cancer cell lines and the serum from ovarian cancer patients. Then human ovarian cancer OVCAR8 cells were co-cultured with NETs to evaluate the effect of NETs on cancer cell adhesion.
Results: Neutrophilia (neutrophils>7000/μl) was found in 39 patients (39/340,11.5%). Patients with neutrophilia were associated with advanced disease accompanied by peritoneal dissemination and compromised survival compared to patients without neutrophilia (5-year PFS 40.0 vs 59.9 %, p 0.0027). In these patients, serum G-CSF was upregulated. Neutrophils from ovarian cancer patients formed NETs significantly earlier than those from benign tumor patients. Ovarian cancer patients with neutrophilia showed elevated G-CSF concentration and increased neutrophils proportion in their ascites. Omental tissues from patients with neutrophilia showed NETs foci close to the disseminated lesions. G-CSF strongly induced neutrophils to form NETs in vitro, which was observed in some conditioned media from ovarian cancer cell lines and serum from ovarian cancer patients as well. The adhesion of ovarian cancer cell was increased by co-incubation with NETs.
Conclusion: Neutrophilia is associated with peritoneal dissemination and poor prognosis in ovarian cancer. One of the underlying mechanism of neutrophilia is upregulated G-CSF, which stimulate neutrophils to form NETs. NETs may have a causative effect on ovarian cancer dissemination.

#5330 Intestine-specific homeobox edits macrophage polarization in the disease microenvironment by activating inflammasome activity.

L.-T. Wang[1], S.-H. Hsu[2];

[1]National Taiwan Normal University, Taipei, Taiwan, [2]Kaohsiung Medical University, Kaohsiung, Taiwan

Inflammasome activity has a pivotal role in the innate immune system, highlighting its importance in the development of various inflammatory diseases, including cancers. However, the specific impact of inflammasome-produced cytokines from tumor cells on disease progression remains uncertain. In this study, we show that the expression levels of inflammasome-related genes (NLRP1 and NLRP3), combined with levels of the intestine-specific homeobox (ISX), significantly correlate with factors like lesion count, disease stage, and lymph vascular invasion. Tumor cells enhance the secretion of key cytokines such as IL-1β and IL-18, exacerbating disease progression via the ISX-TWIST1 complex. In terms of mechanism, transcriptomic analysis and molecular evidence reveal that ISX interacts with the basic helix-loop-helix (bHLH) domain of TWIST1 through its homeobox domain. This interaction forms a transcriptional complex that activates inflammasomes by directly binding to the conserved sequence "-GGDWYR-" in promoter regions of several NF-κB and inflammasome-related genes (NFKBs, RELs, NLRP1, NLRP3, NEK7, AIM2, and ASC). Elevated levels of IL-18, induced by active inflammasomes, lead to the shift of M0 macrophages into the M2-like phenotype within the hepatic microenvironment. In mice with liver-specific ISX mutations, inflammasome-related genes and activities were eliminated, stopping disease progression in an acute hepatic disease model. These findings underscore the critical role of the ISX-TWIST1 complex in liver disease and tumor progression on both mechanistic and clinical levels. They also offer new insights for potential preventive and therapeutic targets in liver disease.

#5331 Spatial resolution of immune cell lineages in the tumor microenvironment of plasma cell dyscrasias.

M. A. Dillon[1], L. Arvidson[2], C. G. Phalen[1], J. R. Ishibashi[1], J. B. Johanneson[1], Z. J. Thomson[1], P. A. Zhao[1], J. Malone[1], M. S. Kopp[1], M. Norton[2], G. Spang[2], S. A. Ludmann[1], A. K. Savage[1], C. E. Gustafson[1], M. Glass[1], E. L. Kuan[1], T. Peng[1], L. T. Graybuck[1], X.-j. Li[1], T. R. Torgerson[1], P. J. Skene[1], A. W. Goldrath[1], S. Jensen[2], S. Anover-Sombke[1], **M. L. Angus-Hill**[1];

[1]Allen Institute for Immunology, Seattle, WA, [2]Cell Signaling Technology, Danvers, MA

Plasma cell dyscrasias (PCDs) are diseases of the hematologic system, with Multiple Myeloma as the most common disease. Less common PCDs include primary and secondary extramedullary plasmacytomas (EMP), which occur in soft tissues. EMPs are typically solitary and infrequent, often localized in the upper aerodigestive and gastrointestinal tracts, lung, and lymph nodes among other organs, and can convert to Multiple Myeloma. Secondary extramedullary plasmacytomas are often noted in advanced disease following multiple rounds of therapy and are commonly associated with poor prognosis. Studies aimed at gaining a better understanding of soft tissue EMPs, whether solitary plasmacytomas with undiagnosed multiple myeloma or in the context of recurrent or metastatic EMP disease, are limited. In this study, we employ a comprehensive approach using multiple modalities, including dissociated CITE-seq, spatial transcriptomics, and multiplexed spatial immuno-fluorescence imaging to interrogate the tumor and immune landscape in EMP disease. Importantly, the use of the same biomarker antibodies across these modalities provides a cross-data-framework for a deep contextual understanding of the immune and tumor cell organization and cell-to-cell signaling in EMP. Ultimately, this study provides new insights into patient-to-patient and tumor location variability, tumor and immune cell microenvironment heterogeneity, and possible future therapeutic strategies for EMP.

#5332 ST316, a clinical peptide antagonist of beta-catenin, induces anti-tumor immune responses by multiple mechanisms of action.

C. Scuoppo, K. Mendelson, R. Ramirez, M. Koester, J. Diehl, E. Gallagher, S. Leong, J. Gonzales, Z. Mattes, L. Ghamsari, G. Merutka, B. J. Kappel, A. Vainstein-Haras, J. A. Rotolo;
Sapience Therapeutics, Inc., Tarrytown, NY

Wnt/β-catenin plays several important roles in cancer, including driving oncogenesis via cell proliferation, survival and metabolic reprogramming of cancer cells, and enhancing immune-desertification of the tumor immune microenvironment (TIME). ST316 is a clinical stage cell-penetrating peptide antagonist of the interaction of β-catenin with its co-activator BCL9, selectively impairing a subset of Wnt target genes and demonstrating potent anti-tumor activity against Wnt-driven tumors in vivo. ST316 is currently being evaluated in a Phase 1-2 study (NCT05848739) enrolling patients with selected advanced solid tumors likely to harbor abnormalities of the Wnt/β-catenin signaling pathway. Here we explore the potential of ST316 to activate the TIME and provide data to support combination treatment with anti-PD-1 and anti-TIGIT therapies. Macrophages derived from human peripheral blood mononuclear cells (hPBMCs) were activated by LPS and IFNγ (M1) or IL-4 (M2) in the presence of ST316 or control and were immunophenotyped by expression of CD80 and CD163 to assess M1 and M2 macrophages, respectively. ST316 induced marked repolarization of hPBMC-derived M2 macrophages to the M1 identity in vitro, as shown by increased CD80 and decreased CD163 staining. Increasing concentration of ST316 in co-cultures of M2 cells with CD8+ T cells induced up to a three-fold increase in IFN-γ expressing cells relative to controls. Additionally, ST316 exposure increased CD155/PVR expression on 4T1 Triple Negative Breast Cancer (TNBC) cells, but not MV411 TNBC that are not Wnt-dependent. When combined with anti-TIGIT treatment, ST316 led to increased T cell activation in an ex vivo assay where 4T1 cells were co-incubated with syngeneic splenic CD8+ cells and frequency of IFN-γ producing cells was assessed. In in vivo experiments, Balb/C mice bearing syngeneic 4T1 TNBC orthotopic tumors were treated with vehicle, ST316, anti-PD-1 or combination. Sub-pharmacologic ST316 enhanced anti-PD-1 suppression of 4T1 tumor growth and induced a substantial decrease of the M2 marker CD209 (DC-SIGN) in the Tumor Associated Macrophage (TAMs). These data support two novel mechanisms of action for the β-catenin antagonist peptide ST316. First, ST316 exposure results in macrophage repolarization towards an immune-active M1 program, both in vitro and in vivo, and increases T-cell activation in co-culture assays. Second, ST316 induced CD155/PVR upregulation and T-cell activation in the presence of anti-TIGIT antibody. Collectively these results suggest a novel immune-modulatory role for ST316 in the TIME and provide rational for combination therapy with checkpoint inhibitors.

#5333 NeoMab: A novel platform for fully human therapeutic antibody development.

M. Zhang, C. Ju, S. Li, J. Peng, J. Zhao, X. Gao;
Gempharmatech Co., Ltd., Nanjing, China

Antibodies and antibody containing therapeutics, such as multivalent antibodies, chimeric antigen receptors (CARs), and antibody directed conjugates (ADCs), have been proven to be highly prominent in cancer treatment. However, challenges such as immunogenicity stemming from non-human or unnatural sequences and limitations in preclinical animal study systems still impede the rapid development of antibody drugs.

To overcome these hurdles, GemPharmatech has created a novel antibody gene humanized model, the NeoMab mouse, to develop fully human antibodies. The NeoMab model was established via large genomic fragment knock-in technology, retaining native mouse constant region encoding genes and regulatory elements, while incorporating human variable gene repertoires into the endogenous loci. Developed in the BALB/c background, the NeoMab mouse carries fully functional MHC molecules, potentially enhancing antigen presentation. These mice sustain a competent immune system with a B cell development and maturation pattern, immune cell profile, and serum immunoglobulin levels comparable to those of BALB/c mice.

NeoMab mice exhibit a robust humoral immune response, with a rapid increase in antigen-specific serum titers upon immunization using different antigens, such as recombined protein, plasmids, and overexpressing cell lines. Utilizing human V(D)J genes to encode immunoglobulins at a human-like frequency and diversity, antibodies derived from NeoMab mice demonstrate affinity and functional activity comparable to, or even surpassing, FDA-approved drugs.

In conclusion, the NeoMab mouse model in the BALB/c background has been rigorously validated to elicit a robust response to specific antigen immunization, producing antibodies with high affinity, diversity, and functional activity. GemPharmatech's extensive drug-target gene humanized mouse library (comprising over 800 targets) and diverse disease models in oncology and other fields facilitate a seamless connection between in vitro antibody screening and in vivo animal studies. The integration of NeoMab, target humanization animals, and disease models enables GemPharmatech to provide an integrated solution, reducing time and costs while elevating the quality of antibody discovery in the field.

#5334 Humanization of NOG mice and next-generation NOG strains to induce lineage-specific differentiation of immune cells for assessment of novel immune cell therapies, check point inhibitors, and immune cell engagers for translational immuno-oncology research.

M. Stecklum[1], L. Baskin[2], **J. Hoffmann**[1];
[1]EPO GmbH, Berlin, Germany, [2]Taconic Biosciences, Inc., Rensselaer, NY

Background: The preclinical evaluation of novel immune therapies requires humanized immune system (HIS) mouse models. In previous studies we have demonstrated that either peripheral blood mononuclear cells (PBMC), subsets of PBMCs like T and NK cells or CD34+ hematopoietic stem cells (HSC) can be used to establish a HIS model. With the development of next-generation NOG mice, lineage-specific differentiation of immune cell sub-populations of interest can be supported. Transplantation of cell line-derived (CDX) or patient-derived (PDX) tumor xenografts on HIS mice provides a full model for human tumors for the investigation of checkpoint inhibitors (CPI), as well as novel cell therapies and immune cell engagers.
Methods: HSC-humanized mice were generated by i.v. transplantation of CD34+ stem cells to immunodeficient mice. For humanization, NOG mice and next-generation NOG strains were used: NOG, NOG-EXL, hIL-2 NOG, hIL-6 NOG and FcResolv™ NOG mice were compared to each other for lineage-specific differentiation using single donors or a mixed HSC donor pool. Engraftment of immune cells was monitored by FACS analysis of blood every four weeks. In humanized NOG mice, CDX and PDX from different entities were s.c. transplanted and used to evaluate CPI.
Results: Humanized hIL-2 NOG mice showed significantly decreased survival after HSC transplantation in comparison to the other mouse strains and had to be sacrificed within the first 6-8 weeks after HSC transplantation. In the other mouse strains, transplanted HSCs engrafted and differentiated mainly into B and T cells. NOG-EXL mice displayed the highest engraftment, with up to 80% of human cells in the blood, including a higher portion of myeloid cells. In humanized hIL-6 NOG mice a higher portion of monocytes could be determined. FcResolv™ NOG mice lack murine Fc gamma receptors in order to reduce confounding interactions between residual murine immune cells and antibody-based therapies, and they engraft and differentiate human HSCs similarly to the parent NOG strain. In humanized NOG mice, selected CDX and PDX tumors successfully engrafted without significant differences in tumor growth compared to non-humanized mice. CPI treatments induced tumor growth delay in selected models.
Conclusions: Next-generation NOG mouse strains are characterized by a lineage-specific differentiation of immune cells depending on integrated human cytokines. Furthermore, we established a human tumor-immune-cell model for NOG mice using different entities of CDX or PDX in combination with CPI. Our human tumor-immune cell models allow preclinical translational studies on tumor immune biology as well as evaluation of new therapies, drug combinations and biomarker identification and validation.

#5335 Immune cell population variations in the livers of commonly used mouse strains.

Francisco J. Rodriguez-Matos, Patrick Huang, Rajiv Trehan, Benjamin Ruf, Chi Ma, Tim F. Greten

Thoracic and GI Malignancies Branch, NIH/NCI, Bethesda, MD

Previous studies have shown that the distribution of major immune cell populations differ across mouse strains in peripheral blood and hematopoietic organs at baseline. Additionally, variations in immune responses exist between mouse strains in *Leishmania spp.* and Melanoma models, but these studies in the context of liver diseases including Non Alcoholic Fatty Liver Disease (NAFLD) and Hepatocellular Carcinoma (HCC) have not been carried out. With the effort to state if these variations exist within the liver, we performed comprehensive spectral flow cytometry analysis on the liver and spleens of three female mouse strains commonly used in cancer research (BALB/c, C57BL/6, and FVBN). NAFLD was induced by providing mice with a methionine choline deficient diet. To promote HCC, a single genotype (myc/p53$^{+/-}$) was induced by administering transposon-based vectors to overexpress Myc-Luc and CRISPR/Cas-9 vectors to knock down p53 via hydrodynamic tail-vein injection. To confirm vector integration and monitor tumor growth (luciferase activity), in vivo imaging was performed at different time points. As a result, we confirm throughout this study that differences exist within immune cell populations of the liver and spleen at baseline. Moreover, we depict differences in the shift of immune cell populations across mouse strains in the pathologic states included. In NAFLD, there is an increase of dendritic cells (DCs), macrophages, NK cells, ILC1s, T regulatory cells (Tregs), T_H1, and T_H2, and a decrease of CD4+ T cells, B cells, γδ-T cells, and NKT cells in the liver across all mouse strains, when compared to controls. However, the population of neutrophils in BALB/c decreases, and the population of CD8+ T cells increases in C57BL/6 mice, which differs from the patterns of change seen in the other mouse strains. Moreover, in spleens, NAFLD promotes an increase of T_H1 and NK cells, and a decrease of T_H2 and NKT Cells across the mouse strains included in the study, whereas the patterns of change differ between mouse strains among the remaining immune cell types. When evaluating liver immune cell population shifts on our HCC model, BALB/c mice showed a decrease in macrophages and ILC1s, C57BL/6 mice showed a decrease in γδ-T cells, prominent shifts across Neutrophils, T_H1, and NKT cells, and null changes in T_H2 and CD4+ T cell shifts, and FVBN mice had a less prominent decrease of B cells, which differed from the shifts observed in the mouse strains used for comparison. Immune cell populations in the spleens of our HCC mouse model also presented with differences across the mouse strains studied. In conclusion, we highlight that key differences in immune profiles exist across commonly used mouse strains for cancer research in the presence of liver pathology including HCC, suggesting that mouse strains could be possible confounders in the study of immune oncology of HCC.

#5336 Establishment and characterization of a novel inducible *Apoc2* knockout mouse model to study the roles of Apoc2 in normal hematopoiesis.

X. Zhang, R. Chandwani, M. Pospiech, Y. Meng, K. Dhuri, B. Thakker, A. Ali, S. M. Kadam, Y.-C. Wei, H. Alachkar;
USC - University of Southern California, Los Angeles, CA

Apolipoprotein C2 (Apoc2) is upregulated in acute myeloid leukemia and presents a viable therapeutic target. Whether this gene plays a role in normal hematopoiesis remains unknown. To investigate the impact of targeting *Apoc2* on normal hematopoiesis, we established and characterized an inducible *Apoc2* knockout mouse model. Homozygous floxed *Apoc2* mice (*Apoc2*$^{fl/fl}$) were obtained from the NIH (Dr. Remaley's lab) and were crossed with homozygous R26-CreERT2 mice. After three generations, *Gt(ROSA)26Sor*$^{Cre/Cre}$, *Apoc2*$^{fl/fl}$ mice were generated and confirmed by genotyping. Male (M) and female (F) mice were injected with tamoxifen (TAM: 20mg/mL dissolved in corn oil) intraperitoneally (75mg/kg per day for 5 days) to induce *Apoc2* knockout (*Apoc2*-KO). The control wild type (WT) group included *Gt(ROSA)26Sor*$^{wt/wt}$, *Apoc2*$^{fl/fl}$ mice, and CD45.2^{+} WT mice injected with TAM, or *Gt(ROSA)26Sor*$^{Cre/Cre}$, *Apoc2*$^{fl/fl}$ mice injected with corn oil.No obvious abnormal phenotypes were observed in Apoc2-KO mice. The average increase of body weight 3 weeks post TAM or corn oil injections of 5-week-old *Gt(ROSA)26Sor*$^{Cre/Cre}$, *Apoc2*$^{fl/fl}$ siblings was not statistically significantly different (*Apoc2*-KO (n = 2M + 2F) vs WT (n = 2M + 2F) = 2.450g vs 2.125g, P = 0.63). Analyses of *Apoc2*-KO (n = 5M + 3F) and WT (n = 4M + 2F showed no significant difference in livers and spleens weight when normalized to mice age. The percentage of knockdown in liver (99.96%), spleen (77.32%), bone marrow (BM, 83.56%) and blood (82.02%) was confirmed by qPCR. In-vitro cell expansion was performed in the presence of thrombopoietin and stem cell factor for BM cells and IL-2 and PHA for T cells. *Apoc2*-KO BM cells exhibited similar in vitro expansion to that of control mice (*Apoc2*-KO vs WT: Day 10/ Day 6: 1.22 fold vs 1.57 fold; Day 10/Day 1: 57.26% vs 72.34%; P > 0.05; and Cell Trace assay: mean fluorescence intensity (MFI) of Day 9 normalized to Day1: *Apoc2*-KO vs WT = 0.37 vs 0.39; P > 0.05). Also, the colony forming ability was not significantly different between *Apoc2*-KO and WT BM cells (*Apoc2*-KO vs WT = 79.09 units vs 81.47 units, P = 0.62). In-vitro T cell expansions of splenocytes were not significantly different between *Apoc2*-KO and WT mice (*Apoc2*-KO vs WT: Day 10/ Day 4: 1.73 fold vs 1.83 fold; Cell Trace: mean MFI of Day 9 normalized to Day1: *Apoc2*-KO vs WT = 0.6208 vs 0.7088; P > 0.05). Hematology analysis assessing white blood cell count, red blood cell count, hemoglobin count, neutrophil, lymphocytes, showed no significant difference between the groups.Here we report the first inducible *Apoc2* knockout mouse model and demonstrated that *Apoc2* knockout has limited impact on normal hematopoietic cells in mice. On-going research using this model will assess the impact of *Apoc2* knockout on ageing related phenotypes and leukemia progression.

#5337 Profiling of human CD34+ donors in a myeloid-supportive HIS model provides increased predictability and facilitates study design for evaluation of immuno-oncology therapeutics.

J. R. Richardson[1], M. M. MacBride[1], E. Andino[1], E. Sack[1], N. Smith[1], P. Y. Ho[2], F. Xiao[2], K. A. McEachin[2], D. T. Omstead[2], R. Grgich[2], M. N. Alonso[2], J. A. Kenkel[2], S. E. Ackerman[2];

[1]Taconic Biosciences, Inc., Rensselaer, NY, [2]Bolt Biotherapeutics, Redwood City, CA

Background: Humanized immune system (HIS) mice are critical immuno-oncology tools for *in vivo* evaluation of therapeutic target engagement and efficacy. HIS mice require a human donor source of CD34+ hematopoietic stem cells to provide the human immune cell system. However, variance across donors complicates study design and hypothesis testing. To determine if parameters critical to drug discovery are consistent across batches of HIS mice from the same donor, we evaluated two independent cohorts of human tumor xenograft-bearing mice made using a common set of five different CD34+ cell donors. Our study included evaluation of tumor growth kinetics, human immune reconstitution and phenotype, and the pharmacokinetics and anti-tumor efficacy of a therapeutic monoclonal antibody directed against a human target expressed on tumor-associated macrophages (TAMs).

Method: HIS NOG-EXL (huNOG-EXL) mice were created using CD34+ cells from five donors in two independent cohorts (~12 weeks apart). Baseline immune reconstitution in blood was assessed at 10 weeks post engraftment. MDA-MB-231 cells were inoculated bilaterally and mice were randomized into groups for immune profiling, pharmacokinetics, and efficacy studies. Body weight, clinical observations, endogenous hIgG levels, and tumor growth were measured. For efficacy, tumors grew to ~100 mm^3 and mice were dosed intraperitoneally every five days (6 doses total). Separate cohorts of mice were used for immune phenotyping and the single-dose PK study.

Results: Donor consistency was seen for some of the parameters assessed but not all. The overall health outcomes for a given donor appeared to have an impact on the consistency of important parameters (e.g. efficacy). Donors that had poor health outcomes (body condition scores [BCS] <3) showed less consistency than those that experienced good (BCS=3) outcomes. The health trajectory, peripheral human immune cell engraftment, and PK profiles were similar across experiments for a given donor. Total human immune cell infiltration in tumors was similar across experiments, but there were notable shifts in immune cell composition. Whereas mice in the first cohort showed a dominant TAM phenotype within the tumor (~>50% of all hCD45+ cells), mice across donors in the second cohort had reduced TAMs and corresponding increases in several T cell subsets. Efficacy was consistent in donors with good health outcomes (Donors 1 and 4) and was inconsistent in those with poor outcomes (Donors 3 and 5).

Conclusion: Our study demonstrates that a return-to-donor approach can provide information that is reproducible across cohorts to help build a donor profile. An understanding of this profile should afford greater predictability and facilitate study design for drug discovery applications.

#5338 Evaluation of checkpoint inhibitor efficacy in a humanized immune system mouse model lacking murine Fc gamma receptors.

N. Smith[1], M. Buczek[1], M. MacBride[1], E. Andino[1], E. Sack[1], D. Freer[1], M. Vedder[1], K. Bott[1], L. Baskin[1], D. France[2], F. Bichat[2], C. Mignard[2], J. Richardson[1];
[1]Taconic Biosciences, Inc., Rensselaer, NY, [2]Oncodesign Services, Dijon, France

Humanized immune system (HIS) mice are critical immuno-oncology tools for evaluating antibody-based therapeutic target engagement and efficacy in a human-like context. Most antibody-based therapeutics have an IgG backbone and thus engage Fc gamma receptors. Traditional HIS mice retain murine immune cells such as neutrophils and macrophages which can interact with human IgG-based therapeutics and confound preclinical results. To determine whether knockout of murine Fc gamma receptors (FcγRs) in a super-immunodeficient mouse model would alter anti-PD1 efficacy compared to the parent strain, we studied tumor growth kinetics, human reconstitution, and tumor infiltrating leukocytes (TILs) in each strain engrafted with HCC827 lung adenocarcinoma tumor cells treated with pembrolizumab or vehicle. Methods: HIS NOG (huNOG) or HIS FcγR knockout NOG mice (FcResolv™ huNOG) were created using identical protocols with CD34+ cells from three human donors shared across both strains. Baseline reconstitution was evaluated in naïve animals via flow cytometry. HCC827 cells were inoculated in remaining animals. Animals were randomized on day 7 post-tumor implantation into 12 groups. Body weight, clinical observations, and tumor growth were measured. Mice received treatment from D7, dosed twice weekly for four weeks, and were then euthanized for FACS analysis, collecting blood, spleen, and tumor samples. Results: For a given donor, no significant differences were seen between strains in human immune reconstitution and kinetics. Pembrolizumab treatment showed significant tumor growth inhibition in one donor in FcResolv huNOG, but not in donor-matched huNOG mice. Evaluation of human TILs in pembrolizumab-treated animals showed significant differences between the strains across all donors, with FcResolv huNOG mice showing increased CD8+ T cells and decreased tumor-associated macrophages compared to vehicle-treated mice, and no significant differences in huNOG. Evaluation of murine TILs revealed differences in murine macrophage populations, regardless of treatment, with $Ly6C^{lo}$ dominant in FcResolv huNOG and $Ly6C^{hi}$ dominant in huNOG. In the presence of pembrolizumab, the murine myeloid and granulocyte population within the spleen is significantly decreased in FcResolv huNOG mice whereas no change was seen in huNOG. Conclusions: Our study demonstrates when treated with anti-PD1, FcResolv huNOG mice show expected pharmacodynamic changes and donor-dependent efficacy whereas, despite identical donors and creation protocols, pembrolizumab-treated huNOG mice showed neither. These differences are due to the presence or absence of murine FcγRs and their impact on antibody IgG-based therapeutics.

#5339 Establishment of a humanized IL5/IL5RA mouse model to evaluate modulators of eosinophilic inflammation *in vivo*.

S. Zhao[1], S. Zhang[1], Z. Chen[1], L. Yang[1], **M. Kuraguchi**[2], J. Yuan[1], H. Shen[1];
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China, [2]Biocytogen Boston Corp, Waltham, MA

IL-5/IL-5R signaling plays a key role in the maturation, activation, survival, and recruitment of eosinophils to sites of inflammation. Targeting this pathway is an attractive therapeutic strategy for certain inflammatory diseases, such as asthma. Here, we generated a novel humanized IL5/IL5RA model (B-hIL5/hIL5RA) to examine the utility of human IL-5/IL5R-targeting therapeutic candidates. Specifically, the entire murine *Il5* coding region was replaced by the corresponding human *IL5* sequence, and the human *IL5RA* sequence coding the extracellular domain was inserted to replace the corresponding murine sequence. Successful generation of the model was confirmed by expression of human IL-5 by ELISA and IL5RA by flow cytometry. Furthermore, the proportion of eosinophils in the blood of B-hIL5/hIL5RA mice increased after stimulation with human IL5 recombinant protein, indicating that the humanized IL5RA protein is functional. Next, the ability of the humanized mice to establish asthma-like disease was tested using ovalbumin: following a 14 day sensitization period, mice were challenged with nebulized OVA daily from day 21 until the endpoint; treatment with mepolizumab or benralizumab analog was performed. Flow cytometric analysis of the bronchioalveolar fluid indicates that treatment with mepolizumab or benralizumab analog significantly lowered the number of eosinophils when compared to the isotype control in homozygous B-hIL5/hIL5RA mice. Blood counts and quantification of lung H&E sections also confirm that the treatments lowered the number of eosinophils in circulation and lung tissue, respectively. Taken together, these data indicate that B-hIL5/hIL5RA mice are a suitable preclinical model to test novel modulators of human IL-5/IL-5RA signaling.

#5340 NK-humanized mouse models for the *in vivo* evaluation of NK cell-based therapies in solid tumors.

P. Rettman, S. Benhamouche-Trouillet, M. Pelat, K. Franciszkiewicz, G. Azar, L. Blot, L. Calvet, **S. Sidhu**, C. Nicolazzi;
Sanofi, Vitry-sur-Seine, France

Novel immunotherapeutic strategies targeting Natural Killer (NK) cells using monoclonal or multi-specific antibodies and immune modulator molecules are under development and suitable mouse models are needed to evaluate these therapeutics. We developed and characterized robust *in vivo* models that allow the engraftment and long-term maintenance of fully functional human NK (huNK) cells in immunodeficient transgenic mice for human cytokines (IL15). In efficacy studies, we confirmed that huNK cells are recruitable by NK cell-based therapies including therapeutic antibodies or multi-specific biologics and able to control tumor growth in these models.To establish a more relevant model for better clinical translatability for Fc-competent therapeutics evaluation, we optimized the model by validating a mouse strain with a functional knock-out of murine Fcγ receptors (FcgR-KO) to minimize the confounding impact of mouse immune cells. We characterized huNK cells kinetics and profile by flow cytometry compared to NOG-huIL15 mice. In efficacy studies with the FcgR-KO strain, therapeutic antibodies are inactive in non-NK-humanized mice, whereas in NK-humanized mice huNK cells can be recruited by the therapeutic antibody to control tumor growth by ADCC, in B cell lymphoma or multiple myeloma bearing mice.We also report the development of NK-humanized models for the evaluation of NK-based therapies in solid tumors. We characterized huNK intratumoral infiltration in several subcutaneous tumor xenograft models and evaluated the impact of tumor environment on the expression of functional NK markers (NKp46, NKG2D, Tim3, CD69) by flow cytometry and IHC studies.In summary, we have developed and optimized robust murine models sustaining fully functional huNK cells that can be proficiently recruited *in vivo* by various NK-based therapeutics. These models can also be used to evaluate the efficacy of combination therapies.

#5341 Novel FcγR humanized mouse model enables assessment of PK/PD of therapeutic antibodies.

F. Sonego[1], A. Pappalardo[1], G. Martin[1], R. Courtois[2], S. Augier[2], Y. Cherifi[1], A. Morel[2], P. Isnard-Petit[1], K. Thiam[1];
[1]genOway, Lyon, France, [2]Innate Pharma, Marseille, France

Therapeutic antibodies have revolutionized the way we treat cancer. Enhanced activity of therapeutic IgG can be achieved by the modulation of Fc binding to Fcγ receptors (FcγR), which will consequently modulate the Fc-effector functions triggered upon crosslinking of target and effector cells by these antibodies. Assessment of therapeutic antibodies pharmacodynamic (PD) in preclinical models is challenging, as the FcγR are different from mice to human, as well as their expression pattern. FcRn is involved in the recycling and transport of IgG and is a key determinant of the pharmacokinetics (PK) of IgG. We report here a novel mouse model expressing human FcγR with a human-like expression pattern, in which human FcγRI, FcγRIIA, FcγRIIB, FcγRIIIA, FcγRIIIB are expressed and replace their mouse orthologs. The model was intercrossed with the hSA/hFcRn mouse model (Viuff *et al*., 2016), which has shown to improve translatability of PK assessment of therapeutics with extended half-life via FcRn recycling and/or HSA binding. Investigation of FcγRI, FcγRIIA, FcγRIIB, FcγRIIIA, FcγRIIIB expression on DC, monocytes, granulocytes, NK, T and B cells shows that expression pattern in hFcγR mice is consistent with their expression on human PBMC, with a few exceptions. These receptors are functional, as a human IgG1 targeting mouse CD20 induces approximately 50% of B-cell depletion in blood and liver, after a single iv administration in hFcγR mice. This depletion is Fc-mediated, as it is abrogated when hFcγR mice are treated with an anti-mouse CD20 human IgG1 with a Fc-null mutation. Assessment of antibody-dependent cell cytotoxicity (ADCC) *ex vivo* to investigate FcγR functionality in NK cells shows that Rituximab, an anti-human CD20 chimeric IgG1 with regular Fc, induces higher ADCC efficacy in NK cells from hFcγR than in NK cells from WT mice. Obinutuzumab, an anti-human CD20 featuring an optimized Fc portion to enhance binding to FcγRIII, shows higher tumor cell lysis than Rituximab in NK cells from hFcγR mice, suggesting this model enables ranking of antibodies. Moreover, assessment of activity of Fc-engineered anti-influenza IgG antibodies also shows that anti-Flu antibody with enhanced Fc binding outperforms the WT antibody, improves protective activity, and demonstrates effector function in influenza challenge model, following prophylactic treatment. Conversely, hFcγR mice treated with an Fc-null version of the anti-Flu antibody shows reduced protective activity and survival compared with the WT antibody. Therefore, the model reported here is a novel tool for testing efficacy of Fc-engineered therapeutic antibodies. We are currently investigating the PK profile of therapeutic antibodies in the hFcγR/hSA/hFcRn model. This novel tool is being improved to enable tolerability to human IgG1, biodistribution to the central nervous system, and flexibility of test of therapeutics through expression of human immune checkpoints.

#5342 Evaluation of autologous and allogeneic T cell-based therapies in *ex-vivo* and *in-vivo* xenograft tumor models.

S. Liu, J. Borroel, C. Sunico, E. Eastwood, B. Corcoran, B. Carapia, J. Sperry, J. Nakashima, R. Shrimali;
Certis Oncology Solutions, San Diego, CA

The field of adoptive T cell-based immunotherapy, including tumor-infiltrating lymphocytes (TILs), T cell receptor (TCR) & Chimeric antigen receptor (CAR) - T cells, has undergone unprecedented growth, specifically later in delivering effective and durable clinical response. Notable success with CAR-T cells is limited to hematological malignancies while clinical gains with solid tumors is still a challenge. Solid tumors' heterogenous target expression and loss, T cell status and metabolic fitness, T cell trafficking into the tumor, and the hostile immunosuppressive tumor microenvironment (TME) have hampered T cell efficacy in the patients. There is a lack of clinically relevant solid tumor models for the translation of T cell-based therapies into the clinic.

We report the development of translational *ex-vivo* and *in-vivo* platforms for evaluating cell line-derived and patient-derived xenografts (CDX and PDX) models (BarneyOI™ model), validated with hCD3 T-cells, autologous TILs and/or allogeneic 3rd generation CAR-T cells (scFv(HER2)-CD28-4-1BB-CD3zeta CAR-T). Anti-hPDL1 but not anti-hPD1 significantly enhanced hCD3 T-cell and autologous TIL-mediated killing of tumor cells in an *ex-vivo* co-culture assay using Incucyte-based live cell imaging. Also, a dose-dependent killing of HER-2 expressing CDX (A549 & Colo205) and PDX was observed with HER-2 targeting CAR-T cells in an *ex-vivo* co-culture assay. This was in concordance with the activation, effector function, and differentiation status of the CAR-T cells, immune phenotype by Cytek aurora spectral flow cytometry. Further, to imitate the patient population and the effect of solid TME, HER-2 targeting CAR-T cells were assessed for their *in-vivo* efficacy and immune response differences in the subcutaneous and orthotopically implanted HER-2 expressing PDX in immunodeficient NOG mice. Our findings highlight the importance of testing T cell-based immune therapies in the appropriate translational tumor models with better certainty of clinical outcome.

#5343 Depletion of gut microbiota with broad spectrum antibiotics drives *Pten*-null prostate cancer growth in mice.

Marco A. De Velasco, Yurie Kura, Kazuko Sakai, Mitsuhisa Nishimoto, Yasunori Mori, Kazuhiro Yoshimura, Kazutoshi Fujita, Kazuto Nishio, Hirotsugu Uemura

Kindai University Faculty of Medicine, Osaka-Sayama, Japan

Gut microbes have the potential to be either promoters or inhibitors of cancer. Use of antibiotics during cancer therapy can lead to dysbiosis, which may affect treatment outcomes. Here, we examine the effects of broad-spectrum antibiotics on cancer progression in mice with *Pten*-null castration resistant prostate cancer (CRPC). After five or eight weeks, orchiectomized conditional *Pten*-null knockout (KO) mice aged 50 and 90 weeks were given two biweekly cycles of a broad-spectrum antibody cocktail (BSAbx), respectively. The effects of BSAbx on tumor burden were compared, and molecular and immunological responses were analyzed by quantitative IHC (qIHC) and qRt-PCR at week four after antibiotic treatment. BSAbx treatment resulted in tumor burdens of 1.2 and 2.4-fold higher than in control mice in mice aged 50 and 90 weeks, respectively. qIHC analysis of KI67 showed increased proliferation in stromal and cancer cells. Additionally, androgen receptor (AR) protein and gene expression levels of *Ar* and *Ar* target genes (*Fkbp5*, *Tmprss2*, and *Timp4*) were elevated in tumors of BSAbx-treated mice. Restoring gut microbiota by fecal microbiota transplantation (FMT) from KO mice CRPC after BSAbx restored AR transcriptional activity to basal levels and lessened tumor growth. FMT from non-castrated KO with castration-naïve prostate cancer or heathy wildtype mice further reduced AR Transcriptional activity. Moreover, altering the gut microbiota of CRPC mice with FMT from heathy mice resulted in a tendency for lower tumor burden, 21% reduction versus control mice. Immunologically, BSAbx treatment resulted in decreased CD11b+/GR1+ cells in tumors and were associated with decreased interferon-gamma (IFN-gamma), dendritic cell functions and T cell-mediated cytotoxicity gene signatures. Mice that received FMT form health mice showed enhanced T cell mediated immunity as demonstrated by higher IFN-gamma signatures and tumor abundances of CD8+ T cells expression IFN-gamma, TNF-alpha and the cytotoxic granule granzyme B. Our study shows that broad spectrum antibiotics caused dysbiosis and promoted prostate cancer growth in mice with *Pten*-null prostate cancer. The effects were partly mediated through the upregulation of AR signaling and the impairment of neutrophil and T cell-mediated immune responses in tumors.

#5344 Myeloid populations upregulated in prostate cancer are associated with colitis induced colorectal cancer.

Yurie Kura, **Marco A. De Velasco**, Kazuko Sakai, Mamoru Hashimoto, Syogo Adomi, Takafumi Minami, Kazuhiro Yoshimura, Kazutoshi Fujita, Kazuto Nishio, Hirotsugu Uemura

Kindai University Faculty of Medicine, Osaka-Sayama, Japan

Chronic systemic inflammation caused by diseases like ulcerative colitis (UC) and Crohn's disease (CD) increases the risk of developing colorectal cancer (CRC). Research indicates that patients with UC are more susceptible to prostate cancer (PCa) and individuals with PCa may also be at a higher risk for developing CRC. However, these relationships are not well defined. Here, we explored these relationships using preclinical mouse models of dextran sulfate sodium (DSS)-induced colitis (DSS-UC) and in young and aged healthy wild-type mice and conditional transgenic mice harboring *Pten*-deficient (KO) or *Pten/Trp53-deficient* (DKO) PCa. After a 25-week follow-up, DSS-induced UC caused more severe colitis in prostate tumor-bearing DKO compared to healthy WT mice. None of the DSS WT mice developed tumors, whereas 75% (3/4 mice) of DSS DKO mice did, including two out of four mice that developed multiple tumors. Overall, DKO mice with prostate tumors had increased levels of $CD11b^{\pm}/Gr1^{\pm}$ in peripheral blood, prostate, and colon compared with WT mice. Quantitative immunohistochemical analyses revealed that DKO mice with prostate tumors had a significantly higher 2.8-fold increase in the levels of Gr1+ cells in the colon compared to heathy WT mice. Overall, DSS-induced colitis further increased Gr1+ cells in the colon of WT and DKO mice by 2.5- and 2-fold, respectively. Gr1+ cells comprised 3.0%, 4.7%, and 10.1% of cells in normal colon from control WT mice and inactive and active regions of the colon in DSS-exposed WT mice, respectively. In DKO mice, Gr1+ cells comprised 7.0%, 19.2%, and 23.6% of cells in normal colon from control mice and inactive and active regions of the colon in DSS-exposed mice, respectively. CD68+, which corresponds to M1 polarized macrophages comprised 0.9%, 1.8%, and 20.6% of cells in normal colon from control WT mice and inactive and active regions of the colon in DSS-exposed WT mice, respectively. However, in DKO mice CD68+ cells comprised 3.0%, 2.8% and 1.6% of cells in normal colon from control mice and inactive and active regions of the colon in DSS-exposed mice, respectively. Our study suggests that Gr1 cells that were abundant in PCa-bearing mice were also present in colons and could have contributed to CRC. Moreover, CD68+ macrophages in the colons of healthy mice may have decreased tumor promoting effects of DSS. This study provides preclinical evidence showing that systemic inflammation in the presence of an existing malignancy increases the risk of a second malignancy, in this case linking PCa to colitis-induced-CRC.

#5345 Development and validation of humanized HLA mouse model platforms for preclinical evaluation of novel peptide vaccines.

Zhenlan Niu[1], Xuan Yu[1], Zhiyuan Shen[1], Jing Guo[1], Qingcong Lin[2], **Veronika Chromikova**[2], Hui Xu[1]

[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]Biocytogen Boston Corp, Waltham, MA

The human leukocyte antigen (HLA) class I major histocompatibility complex (MHC) plays an integral role in immune surveillance by presenting intracellular antigen peptides on the cell surface, enabling recognition by cytotoxic T cells and subsequent elimination. Harnessing this intrinsic process for cancer immunotherapy is a promising therapeutic strategy; thus, developing preclinical models to evaluate the efficacy of novel peptide vaccines *in vivo* and *ex vivo* is critical. Previously, we developed a humanized MHC I mouse model (B-HLA-A2.1 mice), in which we successfully demonstrated efficacy of peptide vaccines as assessed by splenocyte IFN-γ production measured via ELISpot. Here, we provide evidence that B-HLA-A2.1 mice can also mount immune responses to NY-ESO-1 and WT1-Db126 peptides using the same assay. Additionally, immunization with WT1-Db126 at 7, 14, and 21 days prior to tumor inoculation with WT1-expressing MC38 colon cancer cells significantly reduced tumor volume. Additionally, we have generated two new humanized HLA models: B-HLA-A11.1 mice and B-HLA-A24.2 mice. Flow cytometric data demonstrate successful expression of the human HLAs on the cell surface of splenocytes isolated from both strains. Compared to wild-type C57BL/6 mice, analysis of leukocyte and lymphocyte subpopulations in the humanized mice indicates that the CD4/CD8 ratio is altered in favor of CD4+ T cells in both strains, similar to what was observed in B-HLA-A2.1 humanized mice. Despite these observed alterations, B-HLA-A24.2 mice were able to mount an immune response to peptide SART2 93-101, which was measured by splenocyte IFN-γ production. In summary, our data indicate that humanized HLA-A mice provide a powerful preclinical model for *in vivo/ex vivo* evaluation of novel peptide vaccines.

#5346 A novel humanized CD16A model to evaluate efficacy of human antibody therapeutics in triggering ADCC.

Xiao Liu[1], Zhenlan Niu[1], Ruili Lv[1], Qingcong Lin[2], **Mari Kuraguchi**[2], Qingqing Xu[1]

[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]Biocytogen Boston Corp, Waltham, MA

Antibody-dependent cellular cytotoxicity (ADCC) is a mechanism by which immune effector cells engage the Fc portion of antibodies bound to antigen on the surface of another cell, thereby targeting that cell for destruction. In mice, the Fcgr4 receptor is primarily responsible for triggering ADCC, while the FCGR3A receptor (CD16A) mediates this function in human NK cells, which are an attractive target cell type for cancer immunotherapy. Given these differences, we sought to generate humanized CD16A preclinical models to evaluate the efficacy of antibodies in triggering human CD16A-mediated ADCC *in vivo*. Previously, we established humanized CD16A mice on immunocompetent backgrounds for evaluating efficacy of novel antibodies in preventing growth of syngeneic tumor models. Here, we introduce a novel humanized CD16A mouse on the CB-17-SCID background, in order to inoculate human tumor cells for therapeutic efficacy testing. We confirmed expression of CD16A in human NK cells and monocytes/macrophages, but not granulocytes in the model; expression of murine Fcgr4 was no longer detectable, indicating successful generation of the model. Assessment of leukocyte populations in the humanized model indicated no significant alterations in the percentages of NK cells, dendritic cells, granulocytes, monocytes and macrophages in the spleen or blood of the humanized mice compared with wild-type CB-17 SCID mice. Subsequently, the ability of these mice to grow human tumor cells was evaluated: B-hHep3B-Luc, HC116, K-562, and NCI-N87 tumors were all successfully established. Finally, efficacy of an anti-human CLDN18.2 antibody was evaluated against B-hCLDN18.2 BxPC-3 tumors in the humanized mice, which showed modest anti-tumor efficacy at 30 mg/kg when compared to isotype control-treated mice. In summary, humanized B-hCD16A mice (CB-17-SCID) provide a suitable model for evaluating the ability of antibody candidates to induce ADCC.

IMMUNOLOGY: Tumor-Induced Immune Suppression 2: Intrinsic Factors

#5350 Decr2 regulates tumor cell ferroptosis and immunotherapy efficacy.
S. Li, J. Shapiro, H. Shah, E. F. Higgs, L. Xie, Y. Zha, J. Trujillo, A. Cabanov, T. A. Jones, B. Flood, K. Hatogai, J. Kline, T. F. Gajewski;
University of Chicago, Chicago, IL

Checkpoint blockade therapies have transformed the landscape of cancer care. Durable clinical responses have been observed in a subset of patients. However, many patients do not respond, and understanding the mechanisms that determine tumor resistant to checkpoint blockade drugs could potentially benefit more patients. Ferroptosis is a relatively newly described form of regulated cell death distinct from apoptosis and necroptosis. Recently, T cell-promoted tumor ferroptosis was shown to be an anti-tumor mechanism and targeting this pathway could be a potential therapeutic approach. To identify genes critical to immunotherapy resistance, B16.SIY cells were transduced with a genome-scale gRNA lentivirus to generate loss of function mutants. *In vitro*-primed $CD8^{\pm}$ T cells isolated from $2C/Rag2^{-/-}$ TCR transgenic mice specific for the SIY antigen were co-cultured with transduced B16.SIY tumor cells. Resistant mutants were identified by deep sequencing of survival clones. The gene encoding Decr2, a peroxisomal 2,4-dienoyl-CoA reductase, was identified. Decr2 mutants were relatively resistant to $CD8^{\pm}$ T cell killing *in vitro*. Consistent with this resistance to $CD8^{\pm}$ T cell killing, Decr2 knock-down tumors showed minimal response to anti-PD-L1 therapy *in vivo*. Tumor microenvironment analysis in Decr2 knockdown B16.SIY tumors showed failed antigen specific $CD8^{\pm}$ T cells' expansion and less IFN-γ production after anti-PD-L1 treatment. Knock-down of Decr2 resulted in diminished ferroptosis, triggered either by pharmacologic inducers or antigen-specific $CD8^{\pm}$ T cells. Mechanistic studies revealed that Decr2 knockdown resulted in diminished induction of polyunsaturated ether phospholipids (PUFA-ePLs), which is due to reduced polyunsaturated ether phospholipids synthesis rate . Analysis of melanoma tumors from human patients revealed that up-regulation of Decr2 was associated with anti-PD-1 efficacy. Our results proved Decr2 knock down suppressed tumor ferroptosis and confer tumors resistance to anti-PD-L1 therapy by reducing the polyunsaturated ether phospholipids (PUFA-ePLs) synthesis.

#5351 Tumor PKC-Delta induces immune exclusion in non-small cell lung cancer.

X. Fan;
Macau University of Science and Technology, Macao, Macao

The recruitment of a sufficient number of immune cells to induce an inflamed tumor microenvironment (TME) is a prerequisite for effective response to cancer immunotherapy. The immunological phenotypes in the TME of EGFR-mutated lung cancer were characterized as non-inflamed, for which immunotherapy is largely ineffective. To orchestrate host immunity against lung tumors, we proposed that PKCδ, a gatekeeper of immune homeostasis with kinase activity, is responsible for the un-inflamed phenotype in EGFR-mutated lung tumors. It promotes tumor progression by stimulating extracellular matrix (ECM) and PD-L1 expression which leads to immune exclusion and assists cancer cell escape from T cell surveillance. Ablation of PKCδ enhances the intratumoral penetration of T cells and suppresses the growth of tumors. Furthermore, blocking PKCδ significantly sensitizes the tumor to immune checkpoint blockade (ICB) therapy (αPD-1) in vitro and in vivo models. These findings revealed that PKCδ is a critical switch to induce inflamed tumors and consequently enhances the efficacy of ICB therapy in EGFR-mutated lung cancer. This opens a new avenue for applying immunotherapy against recalcitrant tumors.
This work was funded by the FDCT project grant to Dr. Xing-Xing Fan (Grant no. 0058/2020/A2).

#5352 SOX9-dependent immune microenvironment remodeling drives KRAS-induced lung adenocarcinoma progression.

Dinoop Ravindran Menon[1], Hua Zhong[2], Shridar Ganesan[2], Hatim Sabaawy[1], Sharon Pine[1]

[1]Division Of Medical Oncology, University of Colorado, Aurora, CO,[2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Interactions between tumor intrinsic factors and tumor microenvironment play a vital role in disease progression and treatment response. SOX9, a transcription factor crucial for tissue development and homeostasis, has been linked to the advancement of tumor growth. However, its specific role as a driver in lung adenocarcinoma (LUAD) is not well-defined. Additionally, the impact of SOX9 on the tumor microenvironment has not been previously explored. We here identify SOX9 transcription factor to play a critical role in defining tumor immune microenvironment and driving disease progression. We employed CRISPR/Cas9 and Cre-LoxP gene knockout methods within the *Kras* G12D-induced mouse model of lung adenocarcinoma (LUAD). Our objective was to investigate the mechanisms through which SOX9 contributes to the development and advancement of lung adenocarcinoma. To substantiate our findings, we conducted immune profiling, gene expression analyses, RT-qPCR, and immunohistochemistry assessments in the *Kras* G12D-driven murine LUAD. These results were subsequently validated by examining bulk and single-cell gene expression profiles, as well as immunohistochemistry, in human lung adenocarcinoma. Our studies indicated that SOX9 played a very important role by enhancing lung tumor development, burden, and progression, leading to lower overall survival. SOX9. SOX9 consistently facilitated the growth of organoids in vitro. However, the promotion of tumor growth by SOX9 was notably reduced in immunocompromised mice compared to syngeneic mice. SOX9 demonstrated a suppressive effect on immune cell infiltration, particularly affecting the functionality of tumor-associated CD8+ T cells, natural killer cells, and dendritic cells. CD8+ T cells in the SOX9 overexpressing tumors showed upregulation of exhaustion markers. SOX9-mediated tumor growth advantage could not be observed in the CD8 knockout mice model, suggesting a CD8+ T cell-dependent role. In addition, SOX9 significantly upregulated collagen-related gene expression, leading to a substantial increase in collagen fibers possibly affecting the migration of immune cells into the tumor microenvironment. Together, our studies indicate that SOX9 plays a very critical role in modulating tumor microenvironment by controlling immune cell infiltration and CD8+ T cell exhaustion driving *Kras* G12D- driven lung tumor progression.

#5354 High-resolution analysis of immune checkpoint activation utilizing a combined PD1/PD-L1 *in situ* proximity ligation assay (isPLA) and multiplex immunofluorescence (mIF) imaging approach.

A. Christians[1], J. Boog[1], C. E. Jackson[2], M. H. Ingalls[2], J. S. Schwarz[2], S. Bodbin[3], A. Z. Wicher[3], S. Basu[3], O. Braubach[2];
[1]Canopy Biosciences-A Bruker Company, Hannover, Germany, [2]Canopy Biosciences-A Bruker Company, Saint Louis, MO, [3]Navinci Diagnostics, Uppsala, Sweden

The immune checkpoint involving PD-1 and PD-L1 generates suppressive signals in T cells, which help to prevent autoimmunity by inducing a state of immune exhaustion. In the context of the tumor microenvironment (TME), however, cancer cells can manipulate these pathways to camouflage themselves from an immune attack. Blocking these checkpoints has thus emerged as a key immunotherapeutic tactic. Nonetheless, the success rate of immune checkpoint inhibitors (ICIs) has been mixed, even for patients who test positive for relevant diagnostic biomarkers. Patient stratification currently depends on immunohistochemical staining for checkpoint proteins like PD-L1, but these tests do not provide adequate stratification. A more comprehensive stratification, one that includes immune profiling of the TME plus an evaluation of immune checkpoint interactions, might provide better patient stratification and ICI responsiveness. Here we describe mIF that is augmented with a PD-1 and PD-L1 protein-protein interaction assay.

Human formalin-fixed, paraffin-embedded (FFPE) tissue sections were subjected to standard histological processing and then incubated with primary antibodies against PD1 and PD-L1. Sections were then treated with oligonucleotide-modified secondary probes suitable for *in situ* Proximity Ligation Assay (isPLA), enabling the detection of PD1 and PD-L1 interactions. The PLA protocol utilized a fluorescent probe complementary to amplified nucleic acid to enhance the visibility of the protein interactions. The sample was then mounted in a closed microfluidic chamber and imaged on the CellScape™ platform for Precise Spatial Multiplexing. After imaging of the isPLA signal, the CellScape cyclic multiplex mIF staining approach was used to iteratively stain immune and structural markers on the tissue sample utilizing the VistaPlex™ Spatial Immune Profiling Assay Kit.

This proof-of-concept study demonstrates that high-plex mIF can be augmented with an isPLA on human FFPE samples. The combined application of both methods allows visualization of PD1/PD-L1 protein-protein interactions and integrates this interaction within the spatial context of the surrounding cell populations. This approach allows for a more comprehensive insight into the interplay of different immune cell and non-immune cell populations during checkpoint activation processes in normal and neoplastic tissues.

#5355 A novel subset of Treg-like MDSCs expressing LAG-3 found in advanced gastric cancer.

T. Iwasawa[1], S. Yamauchi[2], T. Fukunaga[3], H. Orita[3], T. Ito[4], K. Kazunori[1];

[1]Toyo Univ., Bunkyo-ku, Japan, [2]Johns Hopkins Univ., Dept. Surg., MD, [3]Juntendo Univ., Bunkyo-ku, Japan, [4]Juntendo Univ., Nagaoka, Japan

The development and progression of cancers are frequently promoted by immunosuppressive cells, such as Treg and myeloid-derived suppressor cells (MDSCs) mediated by various immune checkpoint molecules. Therefore, MDSCs are potential diagnostic and therapeutic targets in cancer. However, the definitive cell surface markers for defining MDSC and the subset that correlates with cancer progression are not clear. In our previous studies, there was no difference in the amount of total granulocyte MDSCs (G-MDSCs) between early and advanced gastric cancer. We inferred that there is a novel subset of G-MDSCs involved in cancer progression rather than the previous marker-based classification. The purpose of this study is to analyze MDSCs in gastric cancer patients at different stages of progression and to identify subsets of G-MDSCs that are involved in cancer progression. As a result, we identified a subset of novel G-MDSCs that correlate with cancer progression by expressing LAG-3. LAG-3 is a molecule that is expressed in Tregs and causes strong immunosuppression, suggesting that it is involved in the immunosuppressive potential of MDSCs.

#5356 Wild type Kirsten rat sarcoma (Kras) activation drives evasion of interferon-mediated immunity in hepatocellular carcinoma.

M. Lei, T. Lee;
Hong Kong Polytechnic University, Hong Kong, Hong Kong

Background: Immune checkpoint inhibitors (ICIs) exhibit heterogeneous efficacy in patients with advanced hepatocellular carcinoma (HCC). Currently, there are no effective biomarkers to select patients who could benefit the most from ICIs or to predict response outcomes. Increasing evidence indicates that oncogenic pathway activation is associated with the generation of an unfavorable tumor microenvironment, with consequent immunotherapy resistance. Therefore, an understanding of the immune evasive mechanism of HCC is urgently needed.
Methods: Utilizing the antigen-expressing c-Myc^{OE}/Tp53^{KO} HCC mouse model, a critical oncogenic signaling pathway in immune evasion was identified by data-independent acquisition mass spectrometry (DIA-MS) proteomics. Potential downstream pathways were investigated by scRNA-seq, immune profiling, western blot, and multiplexed immunofluorescence staining. We also examined the therapeutic potential of targeting wild-type Kras using the Kras inhibitor MRTX0902 and the MEK inhibitor trametinib to enhance the efficacy of immunotherapy in HCC.
Results: We identified a significant upregulation of wild-type Kras in immune-escaped tumors, with concurrent activation of its ligand-driven EGFR and its downstream MEK/ERK signaling. Likewise, endogenous Kras overexpression in this model resulted in increased tumor burden with reduced survival time in mice, implicating the regulatory role of Kras signaling in immune evasion. Clinically, wild-type Kras showed elevated expression in HCC at both the mRNA and protein levels, and was associated with tumor recurrence and poorer patient survival. Through scRNA-seq analysis, we demonstrated that Kras hindered dendritic cell recruitment, leading to compromised Cd8^{+} T cell activity via the suppression of interferon-mediated Cxcl9. Wild-type Kras activation further impaired HCC recognition by T cells via the downregulation of MHC-I expression. Notably, the combination therapy of MRTX0902, trametinib, and anti-PD-1 effectively enhanced intratumoral Cd8^{+} T cell infiltration and demonstrated a favorable response in survival outcomes.
Conclusion: This study showed that wild-type Kras, via the activation of its downstream MEK/ERK signaling, acts as a crucial immune evasive mechanism in HCC and contributes to resistance to anti-PD-1 therapy. It also provided new insights into the therapeutic potential of targeting wild-type Kras to enhance the efficacy of anti-PD-1 therapy, providing a foundation for further exploration and potential clinical applications in HCC.

#5357 The tumor-intrinsic RNA binding protein HuR is essential for anti-tumor immunity in PDAC.

Y. Guo, J. M. Finan, A. Q. Bartlett, J. R. Brody, R. Eil;
OHSU, Portland, OR

Immunotherapies have shown limited effectiveness in pancreatic ductal adenocarcinoma (PDAC), despite having success in other cancers. The RNA-binding protein HuR is known to play a critical role in the oncogenesis of PDAC by regulating key mRNA transcripts. Our lab has shown that tumor-intrinsic HuR is overexpressed in PDAC and regulates the tumor microenvironment composition, altering multiple tumor cytokines to release. Thus, we hypothesized that HuR plays a role in immune evasion of PDAC. We disrupted the locus encoding HuR (*Elavl1*) using CRISPR Cas9 in Kras-p53 mutant-driven (KPC) murine PDAC to assess its function in tumor immune evasion. Here, we report that HuR, a known pro-survival factor for PDAC, has a role in tumor immune evasion by suppressing T cell infiltration and T cell activation. Specifically, HuR-knockout (KO) KPC tumors grew slower compared to KPC wildtype (WT) tumors in an orthotopically implanted model (p-value < 0.0001), even though human PDAC cell lines with HuR-WT and HuR-KO grew at the same rate in NRG mice (in an immune-compromised environment). Accordingly, HuR-KO tumors had more T cell infiltration and activated T cells compared to HuR-WT tumors (p-value = 0.0047). Importantly, T cell depletion (both CD4+ and CD8+) partially rescued the size of HuR-KO tumors. Next, we rescued the expression of HuR in the HuR-KO cell line, and the re-expression partially rescued the tumor size in vivo. This observation validates a HuR-mediated dependent mechanism. Collectively, these data support the hypothesis that HuR suppresses T cell activation and prevents T cells from infiltrating into the PDAC microenvironment, leading to PDAC immune evasion. Ongoing experiments will transduce KPC cell lines with ovalbumin (OVA) antigen, which will selectively activate CD8+ OT-I T cells through their transgenic TCR, to measure the ability of KPC HuR-WT or HuR-KO OVA cells in directly activating CD8+ OT-I T cells. We will also investigate HuR's impact on immune cells' cytokine release and how that will impact the cytotoxicity of T cells. These findings support the ongoing concept that HuR plays an important pro-survival role in PDAC in vivo, and targeting strategies against HuR being developed (e.g., siHuR nano-therapies and small molecule inhibitors) could potentially enhance PDAC sensitivity to immune-based anti-cancer therapies, such as checkpoint blockade and T cell transfer.

#5358 The influence of extracellular vesicles on immune cells in PDAC.

C. S. Mundry, Y. Huang, P. M. Grandgenett, M. A. Hollingsworth;
University of Nebraska Medical Center, Omaha, NE

Introduction: Pancreatic Ductal Adenocarcinoma (PDAC) is bad. The tumor microenvironment consists of an abundance of immunosuppressive immune cells and anti-inflammatory cytokines that contribute to local and systemic immunosuppression in PDAC. Tumor cells can influence the tumor microenvironment and, with that, the present immune cells through the secretion of cytokines or chemokines or the secretion of extracellular vesicles (EVs). EVs are a media of communication among the tumor cells themselves, but also with other cells of the body, with the goal to promote tumor expansion and metastasis and decrease any anti-tumor-directed forces of the immune system. Our lab has shown that those EVs play a significant role in tumor growth and metastasis in PDAC. We have found MUC1 to be an important marker for tumor-derived EVs (tdEVs), associated with their activity and influence on cell proliferation and tumor growth *in vitro* and *in vivo*. Determining which immune cell populations are most targeted and impacted by tdEVs is essential to improving our understanding of the role of EVs in PDAC.

Methods: TdEVs were isolated from murine pancreatic cancer cell lines through differential ultracentrifugation. EVs were then labeled with a membrane dye, which allows tracking of the EVs in the mouse. We designed an *in vivo* study to investigate the effects that tdEVs have on different immune cell populations, as well as tumor growth and metastasis. This study has two distinct phases: a 3-week “Pre-Education Phase”, with injection of either $MUC1^{\pm}$ or MUC1KO EVs, is followed by orthotopic implantation of tumor cells in the pancreas.

Data: We hypothesized that tdEVs impact effector immune cells in PDAC, leading to phenotypic, transcriptional, and functional changes that result in a decreased anti-tumor immune response. The highest uptake of EVs was found in macrophages and dendritic cells (DCs). Furthermore, most immune cells preferably take up $MUC1^{\pm}$ as compared to MUC1KO EVs. After three weeks of EV education, RNA sequencing of the liver showed differential gene expression in a variety of genes related to processes associated with B cells. Treatment with $MUC1^{\pm}$ EVs downregulated B cell-related processes in the liver, B cell differentiation, proliferation and activity are reduced. Several genes coding for immunoglobulin parts were affected as well. Immune cell profiling of the blood and spleen showed that $MUC1^{\pm}$ EVs reduce NK and macrophage numbers in the spleen as compared to MUC1KO EV treatment after three weeks. Additionally, EV-treatment increased $CD8^{\pm}$ T cell numbers in the blood but decreased $CD8^{\pm}$ T cells in the spleen.

Conclusion: We have shown that tdEVs induce phenotypic and transcriptional changes in immune cell populations and alter immune cell frequencies *in vivo*. Ongoing research in our lab involves analysis of phenotypic and transcriptional changes after tumor implantation as well as functional differences in EV-treated immune cells *in vitro* and *in vivo*.

#5359 Targeted engineering mRNA 3′UTR length enhances immunotherapy response in prostate cancer.

F. Huang[1], F. Yuan[1], Y. Cui[2], L. Li[2], K. Li[1], Z. Cui[1], J. Yan[3], Q. Chen[4], C. Nicchitta[4], W. Ye[2], Y. Zhang[3], W. Hankey[1], J. Everitt[1], M. Chen[1], J. Huang[1], H. Wang[1], X. Lu[5], E. Wagner[6], Y. Dong[3], W. Li[2], Q. Wang[1];

[1]Department of Pathology and Duke Cancer Institute, Duke University School of Medicine, Durham, NC, [2]Division of Computational Biomedicine, Department of Biological Chemistry, School of Medicine, University of California, Irvine, CA, [3]Division of Pharmaceutics & Pharmacology, College of Pharmacy, The Ohio State University, Columbus, OH, [4]Department of Cell Biology, Duke University School of Medicine, Durham, NC, [5]Department of Biological Sciences, Boler-Parseghian Center for Rare and Neglected Diseases, Harper Cancer Research Institute, University of Notre Dame, Notre Dame, IN, [6]Department of Biochemistry & Biophysics, University of Rochester School of Medicine and Dentistry, Rochester, NY

Background: Global mRNA 3′untranslated region (3′UTR) shortening through alternative polyadenylation (APA) has been widely observed in most cancers; however, it has not been demonstrated whether targeted interference of specific oncogenic mRNA 3′UTR lengths can inhibit tumor growth and potentiate immunotherapy response in prostate cancer.

Methods: DaPars algorithm was applied for *de novo* identification of dynamic alternative polyadenylation (APA) during prostate cancer progression to the lethal phase; 3′UTR polyadenylation site (PAS) locations and usages were identified by Poly(A)-ClickSeq (PAC-seq) and 3′RACE; APA transcripts were quantified by RHAPA assay; a 3′UTR CRISPR/dCas13 Engineering System (3′UTRCES) was developed to manipulate the length of desired 3′UTRs; RIP-qPCR and PAR-CLIP-qPCR assays were used to determine the mechanistic basis of 3′UTRCES in APA editing; RNA-seq was utilized to evaluate the off-target effects; TT3 Lipid-like nanoparticles (LLN) were applied for intratumoral delivery of 3′UTRCES RNA molecules for targeted 3′UTR therapy. Quantitative proteomics and immunoprecipitation assays were conducted to investigate how major histocompatibility complex class I (MHC-I) substrates were recognized by SPSB1-containing ubiquitin ligase complex for degradation; Flow cytometry and T cell cytotoxicity assays were performed to evaluate MHC-I level and killing of tumor cells by antigen-stimulated $CD8^{\pm}$ T cells.

Results: 3′UTR globally shortens during prostate cancer progression to castration-resistance. Through blocking the proximal PASs, 3′UTRCES efficiently and specifically reverses the 3′UTR shortening of novel APA-linked, clinically-relevant prostate cancer oncogenic mRNAs, such as *SPSB1*, leading to reduced *SPSB1* mRNA translation and prostate cancer cell proliferation. Intratumoral injection of TT3 LLN encapsulating 3′UTRCES RNA molecules effectively and safely inhibits prostate tumor growth in engrafted and transgenic mouse models. Notably, downregulation of SPSB1 protein by 3′UTRCES disrupts the interactions of SPSB1-containing ubiquitin ligase complex, leading to compromised ubiquitination-mediated MHC-I degradation and increased stability and abundance of MHC-I protein. Consistently, 3′UTRCES enhances MHC-I-regulated antigen presentation and thereby augments $CD8^{\pm}$ T cell-mediated cytotoxicity, which suggest the potentials of 3′UTRCES to sensitize prostate cancer to immune checkpoint therapies. Importantly, 3′UTR shortening of *SPSB1* mRNA is significantly associated with decreased MHC-I expression, reduced cytotoxic T-cell infiltration and activation in castration resistant prostate cancer patients.

Conclusions: Our results establish the concept of “3′UTR targeted therapy” for treatment of prostate cancer with broad applications to other cancers and other 3′UTR-related diseases.

#5360 Relief of chromosomal instability-induced cGAS-STING signaling sensitizes *STK11*-mutant non-small cell lung cancer to immune checkpoint blockade.

L. A. Caprio[1], C. Hong[2], A. D. Amin[1], S. Tagore[1], M. Duran[2], M. Rogava[1], L. Cai[1], L. Ebel[1], J. Melms[1], H. Hibshoosh[1], S. Bakhoum[2], B. Izar[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Non-small cell lung cancers (NSCLCs) harboring deletions or inactivating mutations in *STK11* (encoding LKB1) are associated with poor prognosis and immune evasion, but the underlying mechanisms are poorly understood. Through integrative analyses of >10,000 molecular profiles from public data sources and an additional ~15,000 new patient data profiles, we find identify *STK11*-deficient NSCLC as an archetypical chromosomally unstable tumor. Using high-content imaging, we show that both human and murine *STK11*-mutant models have a higher rate of micronuclei and chromosome mis-segregation events, confirming their high degree of chromosomal instability (CIN). We show that CIN-induced tonic activation of the cGAS-STING pathway results in impaired type I interferon expression, thus, turning the physiological function of this pathway on its head. We show that temporary relief of tonic CIN-induced signaling reprogrammed cancer cells towards production of type I interferons. We achieved this through orthogonal routes, including genetic suppression of CIN by overexpression of mitotic centromere-associated kinesin (MCAK), rescue of wild-type *STK11* (but not its kinase-dead) allele, genetic deletion or pharmacological inhibition of cGAS. Relief through any of these approaches re-sensitized cells to acute STING agonism with its endogenous ligand (cGAMP) or pharmacological stimulation. Using otherwise isogenic, syngeneic *KRAS*-mutant *Stk11*/Lkb1$^{-/-}$ (KL) and *KRAS*-mutant *p53* mutant (KP) murine models, we show that cGAS KO sensitized otherwise highly resistant KL models to immune checkpoint blockade (ICB), while an increase in CIN (through overexpression of dominant-negative MCAK) in KP conferred resistance in this otherwise ICB-sensitive model. In summary, we define *STK11*-mutant as archetypical chromosomally unstable form of NSCLC, provide mechanistic basis that correlates with poor clinical outcomes, and demonstrate how relief of tonic CIN-induced changes may be therapeutically leveraged.

#5361 Aberrant glycosylation in mPDAC is associated with increased epithelial-mesenchymal transition and recruitment of immunosuppressive cells.

S. Brookens[1], D. Degaramo[1], K. Wilson[2], W. Condori Obregon[3], P. Nagarkatti[2], M. Nagarkatti[2], A. Posey Jr.[1];
[1]University of Pennsylvania, Philadelphia, PA, [2]University of South Carolina, Columbia, SC, [3]Gettysburg College, Gettysburg, PA

The tumor-associated glycan Tn antigen (GalNAc-α-O-Ser/Thr) is associated with poor prognosis in various solid tumors. However, the mechanisms that Tn antigen promotes tumorigenesis are incompletely understood. Here, we generated Tn antigen-expressing murine pancreatic ductal adenocarcinoma (mPDAC) tumor cell lines through CRISPR/Cas9-mediated knockout of the *C1galt1c1* gene. Tn antigen expressing mPDAC cell lines exhibited increased *in vitro* proliferation and migration compared to parental controls. RNA sequencing revealed that loss of *C1galt1c1* in mPDAC cells correlated with increased expression of genes associated with epithelial-mesenchymal transition, myeloid recruitment, and extracellular matrix deposition. Consequently, knock-down of elevated genes using CRISPR interference dampened *in vitro* cell proliferation of *C1galt1c1* knockout mPDAC cells to the growth rate of parental controls. Additionally, *C1galt1c1* knockout mPDAC cells implanted into mice led to accelerated tumor growth and increased tumor infiltration of myeloid-derived suppressor cells and neutrophils as determined by flow cytometry and scRNAseq. Interestingly, surface expression of a binding partner of Tn antigen, macrophage galactose-type lectin 2 (Mgl2), was altered in the immune infiltrate of *C1galt1c1* knockout tumors suggesting a role for the Mgl2-Tn interaction in tumor progression. Mgl2-deficient mice exhibit increased T effector cells in the draining lymph nodes of tumors highlighting a potential mechanism for promoting the influx of immune cells in ordinarily cold tumors. Together, our data indicate that truncated O-glycans expressed commonly on tumor cells promotes tumorigenesis through creating an immunosuppressive microenvironment in mPDAC.

#5362 Targeting IRE1α alleviates the immunosuppressive tumor microenvironment in prostate cancer.

B. Unal[1], O. F. Kuzu[1], Y. Jin[1], D. C. O. Hurtado[1], M. L. Kuijjer[1], M. Daugaard[2], H. Z. Oo[2], J. B. Patterson[3], F. Saatcioglu[1];
[1]University of Oslo, Oslo, Norway, [2]Vancouver Prostate Centre, Vancouver, BC, Canada, [3]Orinove Inc, Newbury Park, CA

Unfolded protein response (UPR) is a central stress response pathway in normal cells that is hijacked by tumor cells for their survival. However, how activation of UPR in cancer cells shapes the tumor microenvironment (TME) remain largely unexplored. Here, we investigated the role of IRE1α-XBP1s pathway on modulation of TME dynamics in prostate cancer (PCa). We found that IRE1α is increased in PCa patients and genetic or pharmacological inhibition of IRE1α signaling in the immunocompetent syngeneic mouse PCa model dramatically reduced tumor growth. Multiomics analysis of tumor samples upon IRE1α deletion in cancer cells showed significantly potentiated interferon (IFN) response and activation of immune system related pathways in the TME. Single-cell RNA sequencing (scRNA-seq) analysis revealed that the abundance of immunosuppressive cells, such as tumor-associated macrophages (TAMs) and T regulatory cells were markedly reduced in the IRE1α deficient tumors. Analysis of differentially expressed genes in the annotated cell types in the TME demonstrated that expression signatures associated with IFN responses were significantly enriched in TAMs, cancer cells, and dendritic cells. In addition, a novel scRNA-seq derived TAM gene signature is strongly associated with poor PCa survival. Furthermore, IRE1α inhibition by the small molecule MKC8866 (ORIN1001) that is in clinical trials significantly enhanced anti-PD-1 checkpoint inhibitor therapy in mice. Our findings indicate that IRE1α not only promotes cancer cell growth and survival, but it also strongly inhibits anti-tumor immunity in the PCa TME.

#5363 New targeted therapy on SOCS1-related immune-response in triple-negative breast cancer.

Shigeru Imoto[1], Tomohiro Chiba[2], Hirohito Seki[1], Yoshiharu Ishizaka[1], Ai Tsuchiya[1], Tomoko Kitaoka[1]

[1]Department of Breast Surgery, Kyorin University Hospital, Mitaka city, Japan,[2]Department of Cytology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Triple-negative breast cancer (TNBC) is heterogenous, which includes basal-like, immunomodulatory, mesenchymal, mesenchymal stem cell and luminal androgen receptor subtypes. In addition to chemotherapy, PARP inhibitors and immune checkpoint inhibitors are effective for TNBC with *BRCA*-mutated and PD-L1-positive cases. However, overall survival of TNBC remains unfavorable. To explore new targeted therapy in TNBC, we reported previously that SOCS1 (suppressor of cytokine signaling 1), IL-13 and several genes were predicted as interactive targets of miRNA in TNBC from the microarray expression analysis (Agilent Technologies, Inc.) of small RNA extracted from 11 breast cancer specimens (AACR2020, #1709). Thus, we investigated SOCS1-related immune-response under co-culture of TNBC and monocyte cell lines with or without paclitaxel exposure.
Materials and Methods: MDA-MB-231, MDA-MB-468, RAW264.7 cell lines were used with co-culture system (Falcon® Cell Culture Inserts, Corning, NY, USA). SOCS1-expression vector and siSOCS1 were transfected into TNBC cell lines with polyethylenimine (PEI Max; Polysciences, Inc., Warrington, PA). RAW264.7 was activated with lipopolysaccaride (5ug/ml) and IFNγ (10ng/ml) for 2 days before co-culture. Relative cell viability of TNBC cell lines with vehicle control (DMSO) or paclitaxel exposure was measured with WST-8 (Cell Counting Kit-8; Dojindo, Japan) using TC20 Automated cell counter (Bio-Rad Laboratories, Inc., Japan) after 2 days' co-culture of TNBC and RAW264.7 cells under several conditions of SOCS1 overexpression and /or RAW264.7 activation.
Results: First, paclitaxel inhibited cell growth of MDA-MB-231 and MDA-MB-468 in a dose-dependent manner (at 1nM~100nM). Second, at paclitaxel exposure of 10 nM and 50 nM, relative cell viability of MDA-MB-468 decreased with co-culture of activated RAW264.7. The tendency was enhanced with SOCS1 overexpression in breast cancer cell lines. Similar results were observed in MDA-MB-231 cells.
Discussions: SOCS1 is well known as a negative regulator of JAK-STAT pathway. SOCS1 is also related to suppression of T cell activation and modulation of M1 macrophage. At AACR2020, we reported that SOCS1 gene amplification in cancer tissues after neoadjuvant chemotherapy was relatively lower in 6 cases with pathologically partial or complete response than in 11 cases with no pathological response. In vitro, paclitaxel-toxicity in TNBC cells was augmented by activated monocyte (M1 macrophage) and more sensitized with SOCS1 overexpression in TNBC cells. These results suggest that proinflammatory cytokines from M1 macrophage influence cell viability of TNBC.
Conclusion: SOCS1 is a promising molecular target to modulate immune-response in TNBC.

#5364 Progesterone receptor modulates the antigen processing and presentation machinery decreasing MHC class I expression on tumors.

J. Tinoco[1], L. Werner[1], E. Chowanec[1], H. Saunders[1], S. Xiaopeng[2], J. Gertz[3], J. Balko[4], Z. C. Hartman[5], C. Hagan[1];
[1]University of Kansas Cancer Center, Kansas City, KS, [2]Vanderbilt University, Nashville, TN, [3]University of Utah, Salt Lake, UT, [4]Vanderbilt University Medical Center, Nashville, TN, [5]Duke University School of Medicine, Durham, NC

Hormone receptor (HR) positive breast cancers, which account for approximately 75% of all breast cancers and express both estrogen receptor (ER) and progesterone receptor (PR), have been the subject of much research. As such, successful anti-estrogen/ER-based therapies have been very successful in the treatment of HR+ breast cancer. Despite this success, over 1/3 of patients will eventually progress on current ER/estrogen-targeted therapies, underscoring the need for new targeted therapies in HR+ breast cancer. Unlike ER, the role of PR in breast cancer progression has received far less attention. In a previous study, we found that a mouse mammary tumor cell line E0771, modified to express the mouse progesterone receptor (mPR) and the OVA peptide, demonstrated decreased T cell-mediated cell death when treated with progesterone compared to the control group. Progesterone-mediated protection from T-cell death was only observed in mPR+ cell lines. Flow analysis of the E0771-Ova-mPR cells also revealed a decrease in MHC Class I presentation in progesterone-treated cells compared to a vehicle control. To further explore the role of the machinery required for antigen processing and presentation of MHC Class I molecules, we conducted additional experiments using the E0771 cell line. Our results showed that treatment with progesterone led to a reduction in RNA levels of all the machinery required for antigen processing and presentation (APP). Based on these findings, we hypothesize that activation of the progesterone receptor by progesterone may decrease MHC Class I expression by regulating APP. Our results showed that treatment with progesterone resulted in a reduction in RNA levels of Tap1, Tap2, Tapbp, Nlrc5, B2m, and Psmb8, which are essential for APP. We therefore propose that activation of the progesterone receptor by progesterone may decrease MHC Class I expression by directly modulating the APP pathway. The findings of this study may have significant implications for our understanding of how breast cancer cells evade T-cell mediated cytotoxicity.

#5365 Characterizing signaling in macrophage-GBM cell coculture.

A. D. D'Souza, R. Mukkamala, R. Ahn, F. M. White;
MIT, Cambridge, MA

Macrophages are a type of immune cell that play a crucial role in the tumor microenvironment. In tumors, macrophages can be polarized towards a pro-inflammatory phenotype, referred to as M1, or towards an anti-inflammatory and tumor-promoting phenotype, referred to as M2. M2 macrophages promote tumor growth by secreting cytokines that increase tumor proliferation, angiogenesis, and dampen the immune response from other immune cells such as T cells and dendritic cells. The balance between M1 and M2 macrophages in the tumor microenvironment is critical in determining the outcome of cancer progression and response to therapy. By understanding the pathways that lead to macrophage polarization, we can develop therapeutics that inhibit this process and support an anti-tumor macrophage response. Co-culture is a powerful model to study interactions between different cell types. We created co-cultures with macrophages and glioblastoma multiforme (GBM) cells to understand how these cell-cell interactions can lead to altered cell phenotype. Several studies have looked at the interaction of two populations using a transwell system where one cell population is placed in a well with a permeable membrane and the other population is placed below, allowing for the exchange of soluble factors. However, this does not account for an important mode of cell-cell interaction, which is physical contact. Therefore, we tested how macrophages derived from primary monocytes polarized in the context of conditioned media (supernatant), cell lysate, and direct co-culture. We used U87-MG as a model GBM cell line. We assayed the M2 phenotype by using flow cytometry with CD163 as a marker. Our findings show that direct co-culture is crucial for promoting macrophage M2 polarization. Using our in vitro model for tumor-induced macrophage polarization, we conducted phosphoproteomic analysis to characterize signals associated with this phenotypic change. To study how co-culture induced differential signaling in tumor populations and macrophages, we devised a method to fix cells to preserve cell signaling, followed by separation using flow cytometry and LC-MS/MS analysis of individual cell populations. We created co-cultures of U87-MG tumor cells and macrophage-differentiated THP-1 cells, a monocyte cell line. We then tested whether our method could reliably separate the different populations, whether we could detect altered signals due to co-culture, and showcase how separating cell populations yields information that could not be gathered from bulk analysis of co-cultures. Our data shows that the analysis was highly reproducible and that the signaling from cells separated from co-culture was highly similar to signaling in cells that were grown individually. However, some phosphorylation residues were uniquely upregulated in the co-culture condition, pointing to signaling that may occur in response to tumor interaction.

#5366 ATR promotes extracellular matrix stiffness mediated cytoskeleton remodeling and immunosuppression.

X. Tu, Z. Lou, R. Mutter;
Mayo Clinic, Rochester, MN

The stiffening of the extracellular matrix (ECM), a phenomenon that often promotes metastasis and immunosuppression in many cancers, is a process that is not yet fully understood. Our study reveals that ATR, a molecule primarily recognized for its role in maintaining the genome, plays a crucial role in ECM stiffness-induced immune evasion and metastasis in triple negative breast cancer (TNBC) through DNA repair independent manner. In response to ECM stiffness, ATR activates SUN2, a component of the linker of nucleoskeleton and cytoskeleton (LINC) complex. This activation enhances the interaction of SUN2 with outer nuclear membrane proteins KASH1 and KASH2. The interaction between SUN2 and KASH1/2 facilitates the nuclear localization of β-catenin, which in turn promotes epithelial mesenchymal transition (EMT) and reduces the expression of E-cadherin. E-cadherin is essential for attracting CD103+ immune cells that perform anti-tumor immunity. Interestingly, inhibiting ATR reduces EMT in tumor cells, leading to an increase in CD103+ dendritic cell infiltration while decreasing neutrophil and polymorphonuclear myeloid-derived suppressor cell (PMN-MDSC) infiltration. Further, we found that ATR levels are inversely correlated with immunotherapy response rates in patients. The alteration in immune cell composition sensitizes tumors to immunotherapy, thereby suppressing tumor growth and metastasis. In conclusion, the role of ATR in remodeling the immune environment could be crucial for optimizing the clinical use of ATR inhibitors. This makes ATR a promising target for overcoming immunotherapy resistance. We suggest early or prolonged treatment with an ATR inhibitor to potentially reduce metastasis rates and improve the prognosis of TNBC patients. Furthermore, we suggest using ATR levels as a marker to predict response rates and prognosis in TNBC patients. For patients with higher ATR expression levels, combination treatment with ATR inhibitors and immunotherapy may yield better outcomes. Enhanced anti-tumor immunity could increase the chances for patients to eliminate cancer cells and help end breast cancer. Finally, our research suggests the combined treatment of ATR inhibition and immunotherapy for patients without necessarily applying DNA damage stimulation. This approach could potentially reduce toxicity while still benefiting patients.

#5367 Single cell resolution spatial transcriptomics reveals genetic driver and TME interaction in clear cell renal cell carcinoma.

I. Strunilin, W. Caravan, A. Abedin-Do, A. Houston, Y. Li, Y. Song, S. Cao, C.-K. Mo, S. Chen, R. Pachynski, F. Chen, L. Ding;
Washington University in St. Louis, Saint Louis, MO

BAP1 mutations are associated with increased T cell and tumor-associated macrophage infiltration in clear cell renal cell carcinoma (ccRCC) and are predictive of poor prognosis. BAP1 mutations have also been found to be associated with T-cell infiltration in peritoneal mesothelioma and uveal melanoma. Because BAP1 mutations are known to be associated with aggressive disease and poor survival, we hypothesize that these mutations lead to a more immunosuppressive microenvironment. Using single nucleus RNA sequencing and high-resolution spatial transcriptomics, we confirmed that BAP1 mutant tumors are immune hot with a high fraction of Treg, exhausted CD8+ T cells, CD4+ T cells, and macrophages. At the same time, these tumors have a lower proportion of endothelial cells and pericytes. Evident of pro-tumor microenvironment we have found BAP1 mutations to be associated with the upregulation of SPP1, CD163, and MARCO immunosuppressive genes in tumor-associated macrophages. Here we propose a mechanism by which BAP1-mutant cancer cells induce an immunosuppressive microenvironment: through activation of the complement system and TGF-β signaling to attract macrophages. Taken together, our results suggest that BAP1 mutations contribute to poor ccRCC outcomes not only through cell-intrinsic effects, but also by promoting infiltration of Tregs and tumor-associated macrophages and polarizing infiltrated macrophages towards immunosuppressive phenotype.

#5368 Targeting tumor-intrinsic S100A1 augments antitumour immunity and potentiates anti-PD-1 efficacy.

Y. Guo, **R. Wan**, H. Bai, J. Wang;
National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Immune-checkpoint blockade (ICB) has revolutionized cancer treatment. However, only a minority of patients achieve the long-term, durable response to ICB, and the response rates in most advanced tumors is limited to 10%-25%. The unsatisfactory overall response to ICB and the great variation in response among individuals highlight the necessity for developing predictive biomarkers and overcoming ICB resistance. A potential mode of resistance is tumor-mediated immunosuppression leading to inhibition of T cell-mediated infiltration and immunity. Here, combining single-cell and bulk transcriptomic analysis with liquid biopsy of tumor patients, we showed that S100 calcium binding protein A1 (S100A1) was closely related to ICB response, and that detecting plasma S100A1 level could help predicting the response to ICB, implying that tumor-intrinsic S100A1 may contribute to immunosuppressive tumor microenvironment (TME) and resistance to ICB. Importantly, endogenous *S100a1* knockdown (*S100a1*^{KD}) promoted anti-tumor immunity, conferred tumor regression, and sensitized tumors to anti-PD-1 immunotherapy in multiple syngeneic murine models. By characterizing the immune landscape of *S100a1*^{KD} syngeneic murine tumor models and non-small cell lung cancer (NSCLC) clinical samples, we demonstrated a negative relationship between tumor-intrinsic S100A1 expression and infiltration of M1-like macrophage and CD8^{+} T cells. Single cell and spatial transcriptomic analyses, together with functional studies, have revealed that ablation of tumor-intrinsic S100A1 exerts profound impacts on the M1-like polarization of macrophages and cytotoxicity of CD8^{+} T cells. Moreover, the conditioned medium from *S100a1*^{KD} tumor cells promoted M1 polarization of both bone marrow-derived macrophages (BMDMs) and Raw264.7 cells, which in turn reinvigorated tumor-specific T cell immunity both *in vitro* and *in vivo*. Of note, as a secreted protein, introducing recombinant S100A1 into the medium from *S100a1*^{KD} tumor cells could not reverse the effects on T cells and macrophages, suggesting that these effects were independent of extracelluar S100A1 secretion and that S100A1 may act as an intracellular signaling molecule. Mechanistically, S100A1 affects deubiquitination of NF-κB through interacting with the ubiquitin-like (Ubl) domains of ubiquitin specific protease 7 (USP7), leading to upregulated granulocyte-macrophage colony-stimulating factor (GM-CSF) expression. Collectively, these data identified the S100A1/USP7/p65/GM-CSF inhibitory axis as a critical immune suppressor on M1-like macrophage polarization and T cell immunity for the promotion of tumor progression and resistance to ICB. Our findings demonstrated the potential of plasma S100A1 expression in predicting the response to ICB, and provide a rationale for combining GM-CSF and anti-PD-1 immunotherapy in tumors with high S100A1 expression.

#5369 Mapping a T cell-cold phenotype to the colorectal cancer genome to identify POFUT1 as a driver of CD8+ T cell inhibition.

C. J. Wagner, E. D. Routh, R. Rutledge, L. D. Miller;
Wake Forest University School of Medicine, Winston-Salem, NC

CD8+ T cells are a critical anti-cancer immune subset; however, most colorectal cancer (CRC) patients have inadequate levels of CD8+ T cells in their tumor microenvironment (TME), contributing to poor survival and increased CRC aggression. While current immune checkpoint inhibitors are able to elicit anti-cancer CD8+ T cell responses in some patients, a majority of patients are still nonresponsive, and have minimal levels of tumor-infiltrating CD8+ T cells. This effect is potentially due to still-unrecognized cancer-driven mechanisms of immunosuppression. To identify candidate genes with roles in CD8+ T cell exclusion, we used a T cell gene signature (Tsig) to quantify CD8+ T cell infiltration in tumors profiled by RNA-seq. Partial Spearman correlation adjusted for tumor purity was performed for all annotated genes (N=20501) in the TCGA CRC RNA-seq data set (N=373) to identify genes most inversely correlated with Tsig. A locus at chromosome 20q was identified as the region of the genome most inversely correlated with Tsig - both by copy number analysis and by RNA expression. Interestingly, this region is the most copy number-amplified region in CRC tumors, and the genes at this locus are among the most highly expressed genes in CRC tumors. Within this region, the amplified and overexpressed gene Protein O-Fucosyltransferase 1 (POFUT1) had the strongest inverse correlation to Tsig. POFUT1 function is essential to canonical NOTCH signaling, and CRC-expressed NOTCH is implicated in increased CRC secretion of immunosuppressive factors IL-6, TGF-β and VEGF, and reduced CD8+ T cell secretion of IFN-γ and IL-2. POFUT1 overexpressing (OE) CT26 and MC38 cell lines were generated, and confirmed by Western Blot to have elevated levels of both cleaved NOTCH1 (NICD1), and NOTCH pathway transcriptional target, HES1. Murine CD8+ T cells were stimulated *in vitro* with CD3/CD28 microbeads and IL-2 in conditioned medium (CM) from vector or POFUT1-OE lines. CD8+ T cells cultured in CM from POFUT1-OE lines had significantly lower levels of activation markers (CD45 (p=0.0022), CD8 (p=0.0095), CD25 (p=0.0069, CD69 (p=0.0099)), reduced proliferation (CFSE, p=0.1281), and generated less ATP (Cell-Titer Glo, p=0.0003) than CD8+ T cells cultured in vector CM. In pan-cancer correlational analyses, POFUT1 is in the top 5% of genes most inversely correlated with Tsig in 12/24 solid tumor types annotated in TCGA (SKCM, THCA, COAD, READ, LUSC, CESC, KIRC, STAD, HNSC, KIRP, LIHC, UCEC p<0.0001). POFUT1 is robustly negatively correlated with T cell infiltration in many cancer types. We observed a positive association in CRC between POFUT1 and NOTCH signaling, and observed that POFUT1 expression reduced CD8+ T cell activity, potentially through upregulation of extracellular factors (in progress). Our findings fit a model where POFUT1 amplification in CRC promotes CD8+ T cell dysfunction as a mechanism of immune escape.

#5370 Tumor-intrinsic cGAS-STING activation promotes anti-tumor inflammatory response in osteosarcoma.

E. P. Young, C. Johnson, A. G. Lee, E. A. Sweet-Cordero;
UCSF - University of California San Francisco, San Francisco, CA

A “cold” tumor microenvironment (TME) is often seen in patients with osteosarcoma (OS). Genomic instability, characteristic of OS, can stimulate the cGAS-STING pathway and activate the innate immune system. Tumor-intrinsic STING pathway silencing mechanisms can link genomic instability to immune evasion in OS. We hypothesize that dysregulation of the cGAS-STING pathway suppresses an innate immune response to genomic instability and plays a key role in tumor progression through establishing an immunosuppressive TME in OS. Using a novel panel of 11 OS patient-derived cell lines, we have identified two groups in terms of capacity for tumor-intrinsic STING activation, and we aim to unravel the mechanism of STING repression in a subset of OS tumors. To investigate the effects of tumor-intrinsic STING activation on macrophage polarization we employed tumor conditioned media (TCM) assays with murine-derived macrophages and tumor lines treated with cGAS-STING agonism. Tumor-intrinsic STING activation resulted in a significant increase in pro-inflammatory macrophages in a manner dependent on tumor STING. Lastly, we performed bulk RNA seq of OS PDX cell lines treated with STING agonist, defining for the first time the OS-specific STING activation signature. We then evaluated primary patient samples for evidence of this signature by single sample GSEA and performed survival analysis after stratifying samples as high or low for this signature, which demonstrated a significant protective effect of the STING activation signature on progression-free and overall survival. We have defined two subtypes of OS in terms of responsiveness to STING activation and demonstrated that STING activation has a protective effect in the human disease, which is the foundation of current efforts to identify targetable mechanism to reverse STING unresponsiveness and activate immune surveillance in this cancer.

#5371 Multimodal CRISPR activation screens reveal new mechanisms to sensitize cancer cells to targeted T cell mediated elimination.

R. V. Akana, C. Sun, Y. Kim, Y. Cai, S. Kim, J. Yoe, O. Laveroni, L. Jerby-Arnon;
Stanford University, Palo Alto, CA

Cell autonomous resistance mechanisms can protect cancer cells from targeted T cell elimination, resulting in resistance to a broad range of immunotherapies. High-throughput gene knockout and gene inhibition screens have been instrumental in identifying key drivers of such mechanisms, yet often uncovering gene activity that is essential but not sufficient for response. Here we set out to leverage gene activation as an orthogonal approach to identify novel regulators of the cancer-immune interface. First, we performed CRISPR activation screens in melanoma cells co-cultured with antigen-specific primary CD8+ T cells. Our findings revealed a collection of novel genes that substantially sensitize melanoma cells to targeted T cell-driven elimination when activated, including DNA damage and unfolded protein response genes (e.g., ETS1, TSPYL2), Wnt ligands (e.g., WNT3A, WNT1), and others that are deleterious only in combination with targeting T cells. Among the resistance genes we found regulators of insulin signaling (e.g., HGF, TCF7L2) and numerous glycoproteins (e.g., PDPN, CD44). Second, we validated top novel hits in 2D and in 3D spheroid models, using optical readouts to investigate their impact on cancer cell elimination and cancer-T-cell spatial dynamics. Third, we performed a Perturb-seq screen to stratify dozens of hits into functional groups based on the transcriptional readouts in the cancer cells. Lastly, we developed an in situ Perturb-Seq method, where we combine high-plex spatial transcriptomic readouts at subcellular resolution with in situ detection of genetically modified cells, and applied it to track the impact of the (de)sensitizing perturbations not only on the cancer cells themselves, but also on T cell recruitment and suppression. Taken together, our study provides a catalog of immune evasion mechanisms and an array of novel targets, demonstrating that synthetic gene activation can diminish immune evasion and open novel avenues for development of agonist-based and RNA-based interventions.

#5372 KITENIN leads immunosuppression in the glioblastoma microenvironment via CCL20.

E.-J. Ahn[1], N. Kim[1], S. Kim[1], J.-H. Lee[1], J. Rhee[1], K.-K. Kim[1], H. Kim[2], K.-H. Lee[1], **K.-S. Moon**[1];
[1]Chonnam National University Medical School, Hwasun, Korea, Republic of, [2]Sunchon National University, Sunchon, Korea, Republic of

Background: Glioblastoma (GBM) is characterized by an immunosuppressive tumor microenvironment (TME), limiting the effectiveness of existing treatments. The author investigated the role of KAI1 COOH-terminal interacting tetraspanin (KITENIN) in mediating this immunosuppression, focusing on its effect on cytokine secretion and tumor-infiltrating lymphocyte (TIL) profiles in the TME.
Materials and Methods: Using cytokine array and Luminex multiplex assays, the author evaluated cytokine secretion in KITENIN-modulated GL261 cells. The author further isolated TILs from an orthotopic mouse model implanted with these cells and induced in vitro differentiation of myeloid cells. The effect of neutralizing antibody for target cytokine, was assessed in vivo, and clinical relevance was investigated using GBM patient data from our cohort and TCGA.
Results: Employing cytokine array and Luminex multiplex assays, we found increased level of CC chemokine ligand 20 (CCL20) within KITENIN-overexpressed (KIT-HA) GL261 cell supernatants. Immunohistochemical analyses using GBM samples confirmed that both KITENIN and CCL20 expressions co-directionally increased and this was associated with decreased survival by TCGA analysis. Myeloid-derived suppressor cells (MDSCs), macrophages, and $CD4^{\pm}Foxp3^{\pm}$ regulatory T cells (Tregs) were observed to be higher in brain tumor implanted with KIT-HA GL261. Furthermore, KIT-HA GL261 conditioned medium expanded $CD45^{\pm}CD11b^{\pm}Gr1^{-}Ly6c^{\pm}$ monocytic MDSCs (M-MDSCs), an effect that was abrogated by CCL20 downregulation. In vivo neutralization of CCL20 resulted in reduced tumor volume, prolonged survival, and decreased M-MDSCs, thus affirming the role of CCL20 in mediating immunosuppression.
Conclusion: These findings underscore the KITENIN-CCL20 axis as a promising target for alleviating the immunosuppressive TME in GBM, potentially unlocking new avenues for GBM immunotherapy.

#5373 Decoding the role of intrinsic pancreatic cellular signaling in shaping the immunosuppressive tumor microenvironment.

Bushangqing Liu, Ethan Agritelley, Daniel Nussbaum, Junping Wei, Gangjun Lei, Melissa Gajda, Zachary Hartman

Duke University School of Medicine, Durham, NC

Background: Pancreatic ductal adenocarcinoma (PDAC) has the highest mortality rate among major cancers, with over 50% of patients having liver metastases at diagnosis. Conventional T-cell-based immunotherapies are ineffective against PDAC liver metastases due to the intricate hepatic tumor microenvironment (TME) that hinders effective immune responses. Thus, it is vital to promote the influx of cytotoxic lymphocytes and prime antitumor immunity. PDAC cells exhibit plasticity and intrinsic cellular heterogeneity, leading to varying immune cell infiltrates and immune responses. Concurrently, early metastases to the liver create an immunosuppressive environment. Our study employs multiple PDAC models, originating from a congenic array of distinct PDAC cell clone tumors with varying degrees of T cell infiltration to delineate the signaling pathways that lead to immunosuppression in the pancreas and liver.
Methods: The compendium of congenic PDAC murine cell clones mirrors immune heterogeneity observed in tumors, spanning from low to high T cell infiltration. To overcome a scarcity of tumor-specific neoepitopes in PDAC, we engineered PDAC cell clones expressing chicken ovalbumin (OVA) for antigen-specific T and B cell responses. By subcutaneous and intraportal vein injection of PDAC cell clones into mice, we induce primary pancreatic and metastatic liver tumors to explore immune phenotypes and assess anti-tumor adaptive immune responses, including myeloid and lymphoid cell subsets.
Results: In vivo engraftment of PDAC clones showed varied CD4+/CD8+ T cells and polymorphonuclear myeloid-derived suppressor cells, accentuated with immunogenic OVA antigen expression. While all OVA+ PDAC lines elicited antigen-specific immune responses, only ‘TIL high’ tumors were eradicated, while ‘TIL low’ clones persisted in vivo. Additionally, ‘TIL low’ clones formed liver metastases upon intraportal injection, despite OVA expression. RNAseq unveiled differential expression in IL-1 family cytokines and receptors, chemokine-like factor gene superfamily, parathyroid hormone relevant function and metabolism. Current investigations include altering these pathways to re-program the tumor microenvironment and induce local immune suppression.
Conclusion: Using diverse PDAC models, we created tumors with immune heterogeneity and altered transcriptional profiles. We identified validated differentially expressed immune altering cytokines, such as CXCL1 and CSF3, and potential novel IL-1 family genes and parathyroid signaling genes. The altered TME conferred protection against tumor antigen-specific immunity in certain clones, both in subcutaneous and liver metastasis models. Ongoing studies will assess the impact of these genes in the distinct environments, offering avenues for immunotherapeutic strategies targeting pancreatic cancer liver metastasis.

#5374 Novel mouse models to study the role of the docking protein GAB2 in general and in cancer.

M. Angel[1], V. Klappstein[1], J. Schrimpf[1], M. Langhammer[1], K. Shoumariyeh[1], C. Miething[1], U. Kloz[2], B. Armstrong[2], F. van der Hoeven[2], T. Brummer[1], S. Halbach[1];

[1]Albert-Ludwigs-Universitat Freiburg, Freiburg im Breisgau, Germany, [2]German Cancer Research Center (DKFZ), Heidelberg, Germany

The docking protein GAB2 binds to growth factor, cytokine and antigen receptors via the adaptor GRB2. Thereby, GAB2 amplifies the signaling output of the SHP2/Ras/ERK, PI3K/AKT and STAT5 pathways, leading to survival, proliferation and migration. Beside these physiological functions, GAB2 is often overexpressed or hyperphosphorylated in different types of cancer, in particular melanoma, breast cancer and various leukemia entities. Previous studies demonstrated that mice with constitutive *Gab2* deficiency are protected against breast cancer, acute and chronic myeloid leukemia driven by HER2, BCR::ABL1 and FLT3-ITD, respectively. While these studies support a critical role in tumor initiation, nothing is known about the relevance of GAB2 for tumor maintenance and progression. To this end, we have developed two novel conditional loss- and gain-of-function mouse models to further analyze the role of GAB2 in cancer.
In the first model, the transgenic GAB2 mouse, GAB2 is expressed under the control of the TET-O promotor, allowing the tetracycline dependent expression in tissues expressing a tetracycline trans activator (tTA). We have already started by crossing in the SCLtTA mouse, in which tTA is expressed under the control of the murine stem cell leukemia 3' enhancer. Here we show that the expression of transgenic GAB2 is tightly regulated by tetracycline and restricted to hematopoietic cells. This system is now perfectly suited to analyze the role of GAB2 in hematologic malignancies. By expressing tTA under different promotors, we propose that GAB2 overexpression can be directed to other organs or cell types. Combining this mouse line with cancer mouse models will allow to study the role of GAB2 in different cancer entities.
With the second mouse model, the conditional *Gab2* KO mouse, it is possible to study the therapeutic potential of GAB2 impairment *in vivo*. In this mouse, exon three of the *Gab2* gene is flanked by LoxP sites. This allows for its CRE recombinase mediated deletion, leading to GAB2 deficiency. The combination of this mouse model with inducible and tissue specific CRE strains will allow to analyze the role of GAB2 in various cancer mouse models. To demonstrate the efficient conditional deletion of exon 3, we first crossed in the tamoxifen inducible ROSA26 CreERT2 mouse line. So far, we were able to show the functionality of this system *in vitro* in mouse embryonic fibroblasts (MEFs) generated from the conditional *Gab2* KO mouse. In a next step we will verify the results *in vivo* and will cross this mouse line with a mouse model for Chronic Myeloid Leukemia (CML) to investigate the therapeutic potential of GAB2 in CML.
In summary, we are convinced that these two novel mouse models will help to identify GAB2 as a potential target or biomarker in various cancer entities. In particular, the conditional approach will allow to alter GAB2 expression in already established tumors, thus mimicking pharmacological targeting.

#5376 Quantitative profiling of HLA class I and class II antigens and neoantigens in tissue biopsy and PBMC samples using an optimized mass spectrometry-based workflow.

I. Shapiro, M. Tognetti, T. Temu, O. Bernhardt, **D. Redfern**, Y. Feng, R. Bruderer, L. Reiter;
Biognosys AG, Schlieren, Switzerland

Major histocompatibility complex (MHC) molecules play a central role in orchestrating immune responses by presenting antigenic peptides derived from both self and foreign proteins. In the context of cancer, understanding the repertoire of tumor-associated antigens (TAAs) presented by MHC molecules (or HLA molecules in human) is crucial for deciphering how the immune system recognizes and responds to malignant cells. The identification of neoantigens, unique to individual tumors due to somatic mutations, has become a focal point in immunopeptidomic studies. One significant hurdle in systematic immunopeptidomics analysis is the high input material requirement. Here, we present a semi-automated workflow to robustly identify and quantify immunopeptides from reduced amounts of clinical tissue biopsy and peripheral blood mononuclear cell samples. At the core of immunopeptidomics is the enrichment of HLA-associated peptides, followed by identification using mass spectrometry and bioinformatics tools. We optimized the native lysis and a sequential immunoprecipitation workflow for both class I and class II immunopeptides while ensuring scalability and reproducibility. Leveraging the magnetic properties of the beads, 1,000 samples can be processed within a week by a single operator. For both tissue and PBMC samples, we performed a systematic ramping experiment starting with as little as 2.5mg tissue or 5 million PBMCs. In all experiments, The established sample preparation offers high reproducibility and identifications of good quality: 1) Class-I immunopeptides: >60% of the peptides identified are 9-mers, >80% predicted strong binders, and the expected amino acids are enriched at the anchor positions; 2) Class-II immunopeptides, >50% of the peptides identified are 14-to-16-mers, and >50% are predicted strong binders. Furthermore, the pipeline is highly sensitive as we could still identify over 2,800 class-I immunopeptides when processing 2.5 mg fresh frozen tissue and 2,000 - 3,000 class-I immunopeptides when starting from 5 million PBMCs. Furthermore, the developed immunopeptidomics workflow was deployed to profile a cohort of 12 cancerous and matched healthy lung tissue samples. Their Class-I immunopeptidomes clearly displayed a pattern where matched tissues from each subject cluster together, further underlining the fact that the intricate immune-tumor interface is highly personalized. Overall, we established a robust pipeline for for class-I and II immunopeptidome profiling from clinically relevant sample types. Taking advantage of the nature of mass spectrometry-based methods, customized targeted assays can be developed without the need for affinity reagent, allowing specific and absolute quantification of any immunopeptide of interest.

#5377 Investigating human leukocyte antigen (HLA) class 1 leukemogenic pathways in acute myelogenous leukemia.

P. Sackstein[1], S. Mudra[1], L. Williams[1], G. Diltz[1], R. Zemel[1], S. Teegavarapu[2], M. Mims[2], C. Lai[3], K. Doucette[1], A. Renteria[1], O. Timofeeva[1], G. A. Rivero[1]; [1]Georgetown Univ. School of Medicine, Washington, DC, [2]Baylor College of Medicine, Houston, TX, [3]University of Pennsylvania, Philadelphia, PA

Background: Aging, smoking and germline predisposition are known to accelerate leukemogenesis. However, the the ability for myeloid clonal pathogenic variants (MCPV) to elicit an antigen-driven host antileukemia immune response is not well characterized. A better understanding on how cellular immunity selectively discriminates leukemia-related “neopeptides” could uncover mechanisms supporting tumor genome evolution.

Methods: 122 patients with acute myelogenous leukemia (AML) were included and 111 had available protein coding sequences. A neopeptide library was created using protein FASTA coding extracted for individual myeloid clonal mutations via National Center for Biotechnology Information (NCBI). Patient class 1 HLA typing was obtained through Tempus, and Genomic Testing Cooperative laboratories. Prediction of number and strength of AML neopeptide bindings to MHC class I molecules were obtained via NetMHCPan-1. Analysis was performed with K-means algorithm assigning age at diagnosis, detected MCPV, number of neopeptides binding (as continuous variable), overall survival (OS) and event-free survival (EFS) as variables. Unsupervised data input allowed 3 cluster partitions for differential survivals allowing HLA class 1 peptide binding aggregation with potential roles in leukemogenesis and patient outcome. Descriptive statistics were performed with SAS.

Results: Sixty-six different MCPV were detected. Of 111 patients, 70 (63%) with available MCPV produced at least 1 MHC I neopeptide binding. Frequently observed variants were *P53* (13%), *FLT3* (9.2%), *WT1* (7%), *DNMT3A* (6.5%), *RAS* (5%), *ASXL1* (4.3%), *RUNX1* (4.2%), *NPM1* (4.2%) and *IDH1/2* (2.6%). Cluster 2 demonstrated a lack of favorable and higher proportion of adverse ELN 2022 subgroups. Cluster 3 exhibited a higher of *P53* [p=0.03] and MDS-related mutations. OS was 79, 239, and 1551 days for cluster 2,1 and 3, respectively [p=0.0001]. EFS was 134, 363 and 451 days for cluster 2,1 and 3, respectively [p=0.0001]. Interestingly, Cluster 2 and 3 assembled the highest probability for peptide binding [1 v 2 v 3 = 1.76% v 36.6% v 62%, p=0.01]. Lastly, albeit in low frequencies, higher diversity of DNA repairing enzymes was seen in cluster 2.

Conclusions: Different MCPV arising in AML genome are variably immunogenic and leukemia-related neopeptide binding’s ability is differentially expressed in our 3 clusters. Frequent neopeptide bindings in clusters 2 and 3 may reflect higher AML immunogenicity resulting in genomic instability. It is possible that less “edited” genomes in cluster 1 preserve higher chemosensitivity resulting in better OS, while highly edited genomes in cluster 2 and 3 are less chemo-sensitive and circumvent host immunosurveillance. Further expansion of cluster 2 is necessary to better understand the role of DNA repairing enzymes in younger patients’ outcomes, especially when genomic instability is observed.

#5378 Spatially resolved human leukocyte antigen (HLA) expression correlates with motif neoepitope expression and durable response to immune checkpoint blockade (ICB) in non-small cell lung cancer (NSCLC).

Lucas Goldman, Sarah Gorbatov, Collin Shen, Alexa Berezowitz, Edward Garon, **Amy Lauren Cummings**

UCLA - University of California Los Angeles, Los Angeles, CA

Background: We previously showed electrostatic interactions enhance binding between “motif” neoepitopes and HLA and predict advanced NSCLC ICB benefit, suggesting optimal neoantigen presentation drives effective anti-tumor immune response (Cummings 2020). However, not all cases with motif neoepitopes exhibit favorable ICB outcomes.

Methods: As proof-of-concept, participants from our published NSCLC ICB cohort with available pre-treatment archival tissue were selected based on HLA supertype B44, predicted motif neoepitopes, and best response of progressive disease (PD) vs partial/complete response (PR/CR). Whole exome sequencing, HLA typing and neoepitope prediction were previously performed (Cummings 2020). GeoMx slides were prepared, hybridized with RNA probes and stained with antibodies to cytokeratin (CK), nuclear material and CD45 per manufacture instructions (Geiss 2008). Antibody to CD8 (Novus) was optimized at 1:50 dilution. Twelve regions of interest (ROI) were selected per sample including the following compartments: CK+CD8+, CK+CD8-, CK-CD8+ and CK-CD8- (negative control). Each ROI included ~150 nuclei selected using GeoMx Digital Spatial Profiler. Sequencing was performed on Illumina Novaseq 6000 (50bpx2) demultiplexed using Illumina Bcl2fastq v2.19.1.403. Raw reads were normalized and compared using paired student’s T-tests with Tukey’s correction via R v4.1. Neoepitope (non/motif) comparisons used matched numbers per sample selected by highest expression.

Results: Seven participants (3 PD, 3 PR, 1 CR) were included, each exhibiting 1-7 motif neoepitopes without HLA loss of heterozygosity. 84 ROI included 24 CK+CD8+, 24 CK+CD8-, 24 CK-CD8+ and 12 CK-CD8- with at least one ROI per category per participant. PD samples had fewer CD8+ ROI (12 vs 36) and lower CXCL9 ($p=0.011$) and CD274 ($p=0.014$). HLA-A/B/C expression followed a gradient with highest expression in CK+CD8+ ROI with limited detection in CK-CD8- ROI. Among HLA, HLA-B had highest median expression (A: 226, B: 650, C: 202; $p<0.001$). In CK+ ROI, motif neoepitope expression was detectable for all participants but not statistically different from non-motif expression ($p=0.23$). HLA-A/B/C all exhibited lower expression in PD CK+ ROI ($p<0.001$).

Conclusion: HLA expression may modify prediction of clinically meaningful neoepitopes and response to ICB. Validation in a larger, prospective cohort is planned.

#5379 Inhibition of ULK1/2-mediated autophagy augments antigen processing and presentation in STK11 mutant NSCLC.

S. C. Schwager, E. Park, A. Van Abbema, Y. Guan, C. Rosen, S. Cho, M. Black, I. Kurilyak, J. Jeffrey, J. Fung, S. L. Paprcka, E. Fernandez-Salas; Arcus Biosciences, Inc., Hayward, CA

BACKGROUND: Inactivating mutations and deletions in STK11 are present in 9-20% of NSCLC and result in immunologically cold tumors that respond poorly to therapy, despite having a high tumor mutational burden and neoantigen load. STK11 mutations in NSCLC are associated with higher levels of ULK1/2-mediated macroautophagy, resulting in localization of MHC-I to autophagosomes and lysosomes leading to its degradation and decreased antigen presentation. Knockdown of ULK1/2 can restore surface MHC-I in highly autophagic cell lines. Here, we show that inhibition of ULK1/2 decreases macroautophagy, resulting in increased antigen processing and presentation (APP) and MHC-I levels in cancer cells, supporting the hypothesis that inhibition of ULK1/2 will restore antigen presentation in NSCLC STK11mut tumors.

METHODS: TCGA datasets were analyzed to determine transcriptional differences in autophagy and APP between STK11 WT and mutant NSCLC tumors. CRISPR was used to stably knockout STK11 in multiple human NSCLC cell lines to generate isogenic pairs. mRNA and protein levels of APP machinery in NSCLC cell lines were assessed using qPCR, western blots, and flow cytometry. CRISPR was additionally used to knockout ULK1 and ULK2 in human STK11 mutant A549 cells. ULK1/2 tool compounds were synthesized based on existing patent literature. Effects of the combination of ULK1/2 inhibition with low levels of IFNγ on surface MHC-I levels were evaluated in several NSCLC cell lines by flow cytometry.

RESULTS: NSCLC tumors with loss of function mutations or deletion of STK11 display increased transcription of genes in the ULK complex and reduced transcription of genes necessary for APP. STK11mut and KO NSCLC cell lines also display lower levels of APP at the mRNA and protein levels. Double knockout of ULK1 and ULK2 in A549 cells is not cytotoxic and results in decreased autophagy as well as increased immunoproteasome components and cell surface MHC-I. ULK inhibition reduces autophagy and restores APP at the protein level, but not at the transcriptional level, in all NSCLC cell lines evaluated. Combination of very low concentrations of IFNγ with ULK inhibition demonstrates additive increases in MHC-I greater than either single-agent treatment alone.

CONCLUSIONS: STK11mut/del is associated with poor prognosis in NSCLC and leads to increased ULK-induced autophagy and decreased APP. ULK inhibition increases APP and surface MHC-I levels in STK11mut cell lines. In the presence of low concentrations of IFNγ, ULK1/2 inhibition restores APP in NSCLC STK11mut cell lines to the levels seen in NSCLC STK11 WT cell lines. The data presented here provides a rationale for targeting ULK1/2 to amplify immune recognition in immunologically cold tumors with high autophagy to increase responses to immunotherapies.

TUMOR BIOLOGY: Angiogenesis in Cancer
Poster Session

#5384 The hypoxia-alleviating agent ITPP restores vascular function in zebrafish xenografts of pancreatic cancer.

R. Abou Khouzam[1], F. Amorim[2], A. Rifath[1], H. Nawafleh[1], V. Povoa[2], R. F. Zaarour[1], J. M. Lehn[3], R. Fior[2], P. Limani[4], S. Chouaib[5];
[1]Gulf Medical University, Ajman, United Arab Emirates, [2]Champalimaud Foundation, Lisbon, Portugal, [3]University of Strasbourg, Strasbourg, France, [4]University Hospital Zurich, Zurich, Switzerland, [5]Gustave Roussy, Villejuif, France

Pancreatic cancer mostly manifests as pancreatic ductal adenocarcinoma (PDAC) and is characterized by a highly hypoxic microenvironment that is associated with worse patient survival and resistance to therapy. Hypoxia induces angiogenesis and the resulting leaky and unstructured vessels fail to reoxygenate the tumor mass, thus exacerbating hypoxia and its downstream impact on tumorigenesis. Myo-inositol trispyrophosphate (ITPP) is a non-toxic allosteric effector of hemoglobin shown to reduce tumor growth and enhance survival in mice and rat models of different tumor types. Herein the aim is to assess for the first time the ability of ITPP to effectively treat PDAC tumors *in vivo* in zebrafish xenografts and to investigate its impact on vascular normalization. To that aim, four PDAC cell lines, AsPC1, Capan1, MIA PaCa2, and PANC1 were included, as well as the angiogenic breast cancer cell line, Hs578t. Cells were grown in appropriate conditions and on injection day, labeling was done with deep red. Labeled cells were then injected in the perivitelline space of anesthetized larvae. The following transgenic larvae were used: those having labeled blood vessels only (*Tg(kdrl:DsRed)*), labeled blood and lymphatic vessels (*Tg(fli1:eGFP)*), and double transgenics with labeled gata+ erythrocytes (*Tg(fli1:eGFP;gata:dsRed)*). One day post injection (dpi) xenografts were sorted based on size and treated by immersion for three consecutive days with control medium or ITPP at a concentration selected based on the maximum tolerated dose assay. Treatment was refreshed daily, and at 4dpi live confocal imaging was conducted on select *Tg(fli1:eGFP;gata:dsRed)* xenografts. All xenografts were then fixed and subjected to whole mount immunofluorescence. Nuclei were stained with DAPI and anti-Caspase3^{Asp175} was used as a marker for apoptosis. Imaging was performed using the Zeiss LSM confocal microscope and tumor size, apoptosis and mitotic figures were quantified with ImageJ. Vascular function was defined as the presence of gata+ cells within tumor-related vasculature, while vessel density and infiltration were determined in ImageJ by calculating the percentage of GFP area in the tumor. Thus far results from AsPC1-derived xenografts demonstrate that ITPP leads to a significant decrease in mitotic figures ($p=0.0132$) and an increase in apoptosis ($p=0.0025$), with no change in tumor size. Preliminary data reveal a trend of increased functional vasculature in both the AsPC1- and Hs578t- derived xenografts upon ITPP treatment. A trend of decreased vasculature infiltration could also be observed in the ITPP-treated Hs578t-derived xenografts. Based on these results, the zebrafish model could be an appropriate alternative for assessing the anti-tumorigenic activity of ITPP in PDAC in a short turnaround time and could potentially enable the visualization of ITPP's impact on angiogenesis at single cell resolution.

#5385 Synthetic disulfide derivative of vitamin B1, fursultiamine, prevents VEGF-induced angiogenesis.

S. Tran, Z. Frost, K. Ramana;
Noorda College of Osteopathic Medicine, LLC, Provo, UT

Angiogenesis is a process in which new blood vessels are formed from the existing blood vessels required to supply nutrients and oxygen to various tissues. Angiogenesis plays a significant role in the growth and spread of many cancers, and several anti-angiogenic agents act as chemotherapeutic agents. Recent studies have shown that fursultiamine (thiamine tetrahydrofurfuryl disulfide), a lipid-soluble synthetic disulfide derivative of thiamine, possesses viable antineoplastic and antiviral effects. However, its role in preventing angiogenesis is not known. We hypothesize that fursultiamine, with its potent antioxidative actions, prevents VEGF-induced angiogenesis in vitro and in vivo. Human umbilical vein endothelial cells (HUVECs) were treated with VEGF in the absence and presence of fursultiamine (0-100 uM) in a time and dose-dependent manner. Cell viability was determined by MTT assay and in vitro angiogenesis by tube formation assays. The expression of various pro-angiogenic, anti-angiogenic and inflammatory markers will be determined by specific antibody arrays. Our results indicate that fursultiamine prevents VEGF-induced endothelial cell growth in a dose-dependent manner. Further, fursultiamine prevents the in vitro tube formation as determined tube formation assays. Further, fursultiamine also regulated the VEGF-induced expression of various angiogenic markers such as VEGF, PDGF, EGF, Ang1, Ang2, angiogenin, and FGF, inflammatory markers such IL-1b, GM-CSF, TGF-b, MMPs, and others such as TIMPs, PTX3 and CF-III. Based on our in vitro data, we suggest that fursultiamine could prevent VEGF-induced angiogenesis, and this compound as a potent anti-angiogenic agent that could prevent cancer growth and metastasis.

#5386 Increased sprouting angiogenesis in a microphysiological model of cisplatin-resistant recurrent lung cancers.

E. Olsen, G. Kpeli, O. Ahmad, M. Mondrinos;
Tulane University, New Orleans, LA

Non-small cell lung cancer (NSCLC) constitutes 85% of total lung cancer cases and first-line therapies still often employ the platinum-based agents. Cisplatin therapy for NSCLC often leads to relapse of aggressive tumors with high metastatic potential after a period of dormancy. We hypothesize that cisplatin-resistant tumor cell phenotypes will increase features of aggressivity including sprouting angiogenesis in microphysiological models of NSCLC. First, we engineered various TME configurations using A549 cell spheroids and cancer associated fibroblasts (CAF) to establish a baseline of tumor cell proliferation, ECM deposition, and expression of proangiogenic and proinflammatory genes. Next, we generated cisplatin-resistant (Cis-R) A549 sub-lines to test the hypothesis that 3D tumor models engineered using these drug-resistant cells will capture hallmarks of highly aggressive recurrent tumors such as increased expression of progression-associated genes, increased induction of local stromal reactions and more profound angiogenesis. We treated parent A549 with 25 μM cisplatin for 96 hours followed by at least 14 days of recovery to generate Cis-R A549 cells. Interestingly, Cis-R spheroids exhibited significantly lower rates of proliferation ($P<0.01$) relative to parent A549 spheroids as measured by Ki67 index. Cis-R cells and spheroids exhibit increased genetic expression for genes involved in inflammation, EMT, proliferation and chemoresistance. Furthermore, Cis-R cells in 2D displayed a mesenchymal-like morphology and further exhibited dysmorphic spheroid morphology in 3D. We then developed a membrane free microphysiological system (MPS) comprised of two adjacent and contiguous tissue layers to investigate cancer mediated angiogenesis. We seeded one layer with lung fibroblasts and endothelial cells, which formed a vascularized network, while the other lane was cultured with no cells (control), parent A549 spheroids, or Cis-R A549 spheroids. Media void of VEGF was used throughout the duration of the experiment to isolate the effect of TME-derived factors. We measured increased angiogenetic sprouting induced by Cis-R tissues relative to parent using the following metrics: sprout density (Cis-R = 49.86 ± 10.93 $\mu m/\mu m^2$, parent = 13.73 ± 4.12 $\mu m/\mu m^2$, blank = 14.76 ± 4.22 $\mu m/\mu m^2$), sprout length (Cis-R = 15006 ± 5507 μm, parent = 2466 ± 639.1 μm, blank = 4749 ± 1547 μm), and sprout area fraction (Cis-R = 0.10 ± 0.028, parent = 0.041 ± 0.010, blank = 0.032 ± 0.0095). Thus, the creation of drug resistant tumor cell sub lines enables the construction of more aggressive engineered tumor microenvironments. Future iterations of our MPS model will be used to investigate angiogenesis in the context of additional cancers, including breast and colon, while transitioning to the use of patient-derived organoids.

#5387 Host-derived CCL2 drives prostate cancer bone metastasis *via* CCND2/STAT3 pathway.

J. Meng[1], M. Chang[2], S. Qin[2], X. Huang[2], W. Liang[2], H. Tong[3], **J. Zhang**[2];

[1]Liuzhou Worker's Hospital, Liuzhou, Guangxi , China, Liuzhou, China, [2]Southern University of Science and Technology, China, Shenzhen, China, [3]University of Macau, Taipa, Macao SAR, China

Overexpression of tumor-derived CCL2 has been shown to partially promote prostate cancer (PCa) bone metastasis, but the function of host-derived CCL2 is not fully understood. We first developed a mouse model using intracardiac injection and obtained highly metastatic PCa cell subclones through *in vivo* selection. The highly metastatic tumor cells were injected intracardially into CCL2 knockout (CCL2 KO) mice and wild-type (WT) controls, and the tumor cell growth and metastasis were monitored weekly by bioluminescence imaging. The osteolytic lesions were evaluated by radiography, micro-computed tomography (microCT) and immunohistochemistry (IHC) staining. The cells in the bone microenvironment were analyzed by flow cytometry. Also, RNA sequencing (RNA-seq) analysis was performed on the cells either from CCL2 KO mice or WT controls. We found that a loss of host-derived CCL2 significantly retarded tumor growth in bone and prolonged mouse survival. In addition, bone density analysis revealed a decrease in osteolytic lesion in CCL2 KO mice, compared to WT controls. Systemically, CCL2 deficiency reduced the proportion of granulocyte-myeloid-derived suppressor cell (G-MDSC) populations with immunosuppressive function and decreased the PCa conditioned medium (CM)-induced osteoclast formation. The enrichment analysis revealed that the dysregulated genes in bone metastatic cells from CCL2 KO mice were significantly enriched in several biological processes, including vitamin metabolism, monoatomic anion homeostasis, immune response, and bone growth. Additionally, we also confirmed that the CCND2/STAT3 pathway is apparently suppressed in the cells from CCL2 KO mice. This study demonstrated that targeting the host-derived CCL2 might be a novel potential anti-metastatic approach. Supported by the NSFC projects (81972766, 81972420, 82173336), as well as grants from the Science and Technology Project of Shenzhen (JCYJ20190809161811237, JCYJ20210324104214040).
Key words Host-derived CCL2; Prostate cancer; Bone metastasis; osteoclast; CCND2

#5388 FOSL1 promotes glioma tumorigenesis and stemness through NF-κB and STAT3 pathways.

M. Liu[1], V. Ramar[1], A. Khedri[1], B. Hudson[1], S. Guo[2];
[1]Morehouse School of Medicine, Atlanta, GA, [2]Xavier University, New Orleans, LA

Background: Glioblastoma multiforme (GBM) is the most common and malignant primary brain tumor, GBM's inevitable recurrence suggests that glioblastoma stem cells (GSC) render these tumors persistent. Our previous work showed that FOSL1, which is transactivated by the STAT3 gene, functions as a tumorigenic gene in glioma pathogenesis and is a diagnostic marker and potential drug target for glioma patients. Accumulating evidence shows that STAT3 and NF-κB cooperate to promote the development and progression of various cancers. The link between STAT3 and NF-κB suggests that NF-κB can also transcriptionally regulate FOSL1 and contribute to gliomagenesis.
Methods: 1). To investigate downstream molecules of FOSL1, we analyzed the transcriptome after overexpression of FOSL1 in a PDX-L14 line, characterized by very low FOSL1 expression 2). We conducted immunohistochemical staining for FOSL1 and p65 using rabbit polyclonal anti-FOSL1 and p65 in glioma tissue microarrays (TMA) derived from 76 glioma patients and 10 normal individuals. 3). Mutants of the human FOSL1 promoter, featuring mutations in essential binding sites for NF-κB and STAT3, were generated using a Q5 site-directed mutagenesis kit. Subsequently, we examined luciferase activity in glioma cells and compared it to the wild-type FOSL1 promoter. 4). We explore the mutual regulation between NF-κB signaling and FOSL1 by modulating the expression of NF-κB or FOSL1. Subsequently, we assessed the activity of FOSL1 and NF-κB. 5) To understand the role of FOSL1 in cell growth and stemness, we conducted a CCK-8 assay, cell cycle analysis, assessing apoptosis and GSC markers, ALDH1 and CD133 under varying FOSL1 expression conditions.
Results: 1) Transcriptome analyses of downstream molecules of FOSL1 show that NF-κB signaling pathways are regulated by FOSL1. 2) p65 protein expression correlates to the expression of FOSL1 in glioma patients. 3) NF-κB is a crucial transcription factor activating the FOSL1 promoter in glioma cells. 4) Mutual regulation between NF-κB and FOSL1 contributes to glioma tumorigenesis and stemness through promoting G1/S transition and inhibition of apoptosis.
Conclusion: The FOSL1 molecular pathway is functionally connected to NF-κB and STAT3 activation, enhances stemness, and FOSL1 is a novel GBM drug target.

#5389 Development of T-cell exclusion in melanoma.

Ha-Ram Park, Hee Won Yang, Minah Kim

Columbia University Irving Medical Center, New York, NY

Immune checkpoint inhibitors (ICIs), which prevent immune cell exhaustion and boost an antitumor response, have shown remarkable treatment efficacy in patients with advanced melanoma. However, its efficacy is limited by the emergence of resistance associated with an immunosuppressive tumor microenvironment (TME). The contribution of abnormal tumor vasculature to limited immune cell infiltration into the tumor core has been reported but the mechanisms of its development are still elusive. We analyzed how tumor angiogenesis affects the immune cell exclusion at different time points of primary melanoma using syngeneic murine melanomas. The spatial distribution of various immune cell populations and vascular integrity were analyzed in whole tumor cross-sections via multiplex immunofluorescence staining. We found that the exclusion pattern of CD8+ T cells was less evident with a balanced distribution across the whole tumor regions at the early stage. However, as the tumor grows, there is a pronounced accumulation of CD8+ T cells at the tumor periphery with a conspicuous absence in the core. Tumor blood vessels were structurally uniform and functionally stable in the early developmental tumor but became unstable and leaky as the tumor progressed, which was associated with the development of CD8+ T-cell exclusion. To understand the mechanism underlying vascular regulation of immune exclusion during tumor progression, we will investigate the expression of genes related to tumor angiogenesis using spatial transcriptomic analysis and RNA sequencing of endothelial cells (CD45+CD31-) sorted from the murine melanomas. These results highlight the contribution of spatial tumor vascular destabilization to the T-cell exclusion development, implying the potential of targeting tumor vasculature to enhance immune activation and the therapeutic efficacy of ICI in melanoma.

#5390 Exploring signaling pathways of tumor-nerve interactions in prostate and breast cancer.

B.-J. Hwang[1], G. J. Edwards[2], C. Knoblich[3], K. Rezvani[2], V. Odero-Marah[1];
[1]Morgan State Univ., Baltimore, MD, [2]Claflin University, Orangeburg, SC, [3]Sanford School of Medicine, Vermillion, SD

A significant portion of prostate cancer (PCa) and breast cancer (BCa) patients develop bone metastatic disease. In some cases, cancer spreads through the nervous system, a process known as perineural invasion (PNI). Neurite outgrowth is believed to be a precursor to PNI. Snail is an important gene which regulates the epithelial-mesenchymal transition (EMT) process in which tumor cells at the invasive front undergo this transition to promote invasion, migration, and subsequent metastasis. We recently published that Snail promotes neurite outgrowth in PCa cells. We hypothesize that Snail expression will stimulate neurite outgrowth in both PCa and BCa cells through extracellular vesicles from cancer cells interacting with neurons. To test this hypothesis, we first collected conditioned media from PCa and BCa cells expressing Snail and isolated exosomes. Exosomal markers were detected using western blot to confirm the isolated exosomes. Additionally, we used Transmission Electron Microscopy (TEM) to observe the secretion of exosomes. Proteomics was performed to analyze proteins expressed within exosomes of LNCaP Snail overexpressing or C4-2 Snail knockdown PCa cells. Our results showed that Snail-expressing cells secrete exosomes containing Talin1, specifically, the proteolyzed C-terminal rod domain, while full-length Talin1 is found in whole cell lysates from Snail-expressing cells. Talin1 has previously been associated with neurite outgrowth. Neurite outgrowth assays were then performed using conditioned medium collected from C4-2 PCa cells with Snail knockdown and MCF-7 BCa cells with Snail overexpression. Increased neurite outgrowth is observed in PC-12 cells and NPC (Induced Pluripotent Stem Cells differentiated neuronal progenitor cells) when cultured with conditioned medium collected from PCa and BCa cells expressing high levels of Snail. AKT activation was observed in the neuronal cells in response to conditioned media from Snail-expressing cells. Furthermore, we found that mH_4, a proprietary small molecule inhibitor of Talin1, reduces Snail-mediated neurite outgrowth and AKT activation (p-AKT Thr308 and Ser473). Overall, we have uncovered a pathway whereby Snail transcription factor promotes secretion of exosomes containing Talin1 which promotes AKT signaling in neuronal cells and neurite outgrowth. Talin1 small molecule inhibitor shows promise for therapeutic targeting of tumor-nerve interactions.

#5392 Plasma levels of Matrix metalloproteinases 9, an angiogenic promoting protein, are persistently elevated three weeks after minimally invasive colorectal resection (MICR) for cancer which may support residual tumor metastasis.

Chandana S. K. Herath Mudiyanselage, Anuj R. Sharma, Neil Mitra, Aashutosh Sah, Xiaohong Yan, Pablo Palacios, Vesna Cekic, Richard L. Whelan

Department of Surgery, Lenox Hill Hospital, New York, NY

Introduction: The Matrix metalloproteinases (MMPs) family are a collection of zinc and calcium-dependent endopeptidases. MMP-9 is instrumental in modifying the extracellular matrix (ECM) and generating bioactive molecules which influence a range of physiological functions. Cellular TNF-a, IL-8, VEGF, and FGF-2 can stimulate the production of MMP-9 in endothelial cells (EC), a process that controls healthy and disease-related angiogenesis. MMP-9 facilitates tumor metastasis and also is involved with wound healing. MMP-9 is generated by white blood cells, ECs, and several other cells. There's a significant increase in plasma MMP-9 levels in patients suffering from colorectal cancer (CRC). The aim of this study was to assess plasma MMP-9 levels before and during the first month following MICR for CRC.

Method: CRC patients enrolled in an IRB approved data/plasma bank who had undergone MICR for whom plasma samples were available from the following time points were deemed eligible for this study; preoperatively (PreOp) and on Postoperative Day (POD) 1, POD 3 and at least 1 later postop timepoint (POD 7-41). The demographic, clinical operative and pathology reports were reviewed. Blood specimens were collected, processed, and frozen. MMP-9 levels were measured in duplicate via ELISA. The Wilcoxon paired t-test was used for analysis and significance set at $p<0.05$.

Results: 86 CRC MICR patients (69% colon,31% rectal; laparoscopic 69%, hand-assisted 31%; 47 males, 39 females; mean age 63.9± 14.3 years), met the entry criteria. The mean hospital stay was 6.5±3.0 days. The cancer stages were distributed as follows: stage I; (n=26), II; (n=25), III; (n=30), and IV; (n=4). Compared to the mean preop MMP-9 plasma levels (155.3±132.1,n=86; ng/ml), there was a significant increase on postoperative day (POD) 1 (292.6± 213.0; n=86, $p<0.001$), POD3 (232.1±205.9,n=78, $p<0.01$), POD7-13 (217.8±171.2, n=63, $p<0.01$), POD14-20 (228.7± 109.1,n=24,p=03). No difference was found at the POD 21-41 time points vs preop results. Non-significant increases in plasma MMP-9 levels were noted in the hand-assisted surgery group during the POD 3-27 period compared to the laparoscopic group.

Conclusion: Postop plasma MMP-9 levels were significantly elevated (20% - 88%) vs preop levels for 3 weeks after MICR for CRC. The increased MMP-9 levels in the early postoperative period may be due to the acute inflammatory response, including increases in IL-1 and TNF mediated activation of neutrophils and macrophages. However, the spike during weeks 2-3 may be related to wound healing given MMP-9's role in angiogenesis. This persistent elevation for 3 weeks after surgery may also enhance angiogenesis in residual cancer deposits postoperatively. Further studies are needed.

#5393 Characterization of small ubiquitin-like modifier (SUMO) protein complex expression in human cancer cells to identify novel therapeutic targets.

M. A. Salih, R. Williamson, S. Kantamneni;
University of Bradford, Bradford, United Kingdom

SUMOylation is a post-translational modification where a number of small ubiquitin-like modifier proteins (SUMO) are conjugated to lysine residues of the target proteins and contribute to various cellular functions essential for cancer cell survival and proliferation. The unique behaviors, phenotypic and molecular adaptations found in the naked-mole rat (NMR) suggest a high stability and effective functioning of the molecular machinery that counteracts damage accumulation in its genome. NMR can reach 32 years, shows no signs of ageing, and possesses a very efficient mechanism of resistance to cancer. This study aims to investigate the regulation of SUMOylation machinery between NMR tissues in comparison to human cancer cells, to find novel targets for cancer therapy. Gene expression of SUMO isoforms between NMR and humans, were investigated through qRT-PCR. The data suggests a significant low expression level for most SUMO machinery (except PIAS4) in NMR brain and intestine tissues compared to MCF-7, DLD-1, SH-SY5Y, and MCF-10A cells. Western blotting analysis also revealed high protein expression of PIAS4 in NMR compared to SENP1 and Ubc9. Also, SUMO machinery expression levels from NMR are recapitulated in cancer cells either silencing (hUBE2I: shRNA, hSENP1: shRNA) or overexpression (Myc/hPIAS4: Exp). Further, cytotoxicity assay was analyzed in relevance to Doxorubicin in MCF-7, 5-Fluorouracil in DLD-1 and Methotrexate in SH-SY5. The functional assays such as clonogenic and invasion assays were performed including apoptotic mechanisms (Bcl-2, and BID). In conclusion, the data revealed important differences in SUMOylation machinery between NMR and human cancer cells, which provides a future therapeutic path for cancer treatment.

#5394 Nicotine-induced exosomal miR-3157-3p from prostate cancer cells promotes angiogenesis.

S. Singh, M. Khan, S. Anand, S. Saranyutanon, S. Srivastava, S. Singh, A. P. Singh, K. Vikramdeo;
Mitchell Cancer Institute, University of South Alabama, Mobile, AL

Nicotine is a psychoactive component of cigarette smoke responsible for addictive properties of tobacco and is shown to promote cancer pathogenesis. We earlier reported that exosomes released from nicotine-treated prostate cancer cells played a key role in tumor angiogenesis, a process necessary to maintain the supply of nutrients and oxygen to the fast proliferating cancer cells. Here, we examined the molecular mechanisms underlying the exosome-mediated effect of nicotine on angiogenesis. For this, we screened the expression of angiogenesis-related miRNAs in the exosomes derived from LNCaP and C4-2 cells treated with vehicle or nicotine (400 nM). Highest and most differential abundance of miR-3157-3p was found in exosomes derived from nicotine-treated prostate cancer cells. Furthermore, the expression of TIMP-2 and KLF-2, established targets of miR-3157-3p, was also downregulated in endothelial cells transfected with exosomes derived from nicotine-treated prostate cancer cells or miR-3157-3p mimics. Studies are currently underway to establish direct targeting of TIMP-2 and KLF-2 by miR-3157-3p and confirm that their suppression is indeed associated with observed changes in endothelial cell growth, migration and capillary-forming ability.

#5395 The influence of hyperthermia on epigenetic signaling in dysbiotic tumor vasculature.

H. Kristian, S. Jenkins, R. Griffin, **R. P. Dings**;
UAMS Winthrop P. Rockefeller Cancer Institute, Little Rock, AR

The overall use of antibiotics has increased significantly in recent years. Although they resolve infections, oral antibiotics (ABX) severely alter the gut microbiota, disrupting commensal bacteria crucial for maintenance of various homeostatic processes. ABX-induced microbial imbalance, or dysbiosis, has systemic and long-lasting deleterious effects on the host. For example, we and others have shown that distal, non-GI tract solid tumors show accelerated progression during dysbiosis due to vascular immune suppression. Localized hyperthermia has been increasingly recognized to elicit various cellular responses, yet the epigenetic effects of hyperthermia on the tumor vasculature during ABX-induced dysbiosis are unknown. The balance of histone acetylation and deacetylation plays a critical role in the regulation of gene expression and thereby cellular processes. Therefore, we assessed which histone deacetylases (HDACs) are expressed and their abundance in endothelial cells of various sources with or without dysbiotic stress and/or hyperthermia to understand the utility of thermal medicine to promote normal functioning of the vasculature in dysbiotic patients. We found that HDAC expression levels differed among endothelial origins and that hyperthermia (60 min of either 41.5 °C or 43 °C) influenced the HDAC levels differentially. Especially HDAC 2, 3 and 8 were inhibited by hyperthermia. Additionally, we found that the vasculature receptors for endogenous HDAC inhibitors, GPR41, GPR43, and GPR109a are less abundant intrinsically on dysbiotic than orthobiotic tumor endothelial cells and that hyperthermia increased this expression. Although further studies are warranted, these results demonstrate that hyperthermia exerts epigenetic effects and is capable of overcoming the dysbiosis-induced phenotype. Since anti-cancer treatment with HDAC inhibitors has shown promise in the clinic but is hindered by systemic toxicities, localized hyperthermia may become a viable alternative in the future.

#5396 Vascularized gastric cancer 3D co-culture model using a microphysiological system as an oncolytic virus testing platform.

Y. Kim[1], Y. Song[2], Y. Choi[2], J. Jang[2], S. Kim[2], T.-L. Liu[2], K. Baek[2], K. Oh[3], S. Ma[4], T. Kim[5], W. Kwon[5], S. Yoo[2], J. Kim[1], S. Rha[6];
[1]Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Qureator, San Diego, CA, [3]Research Center, SillaJen Inc., Seongnam-si, Korea, Republic of, [4]SillaJen Bio., San Francisco, CA, CA, [5]Song-dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [6]Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: Angiogenesis is a critical aspect of cancer growth and metastasis. Consequently, inhibiting angiogenesis has garnered substantial attention in oncology research. JX-594 (pexastimogene devacirpvec; Pexa-Vec®), engineered from the Wyeth vaccine strain, has emerged as an attractive oncolytic virotherapy and demonstrated oncolytic, immunotherapeutic, and tumor vasculature-disrupting capacities. In our previous study, we found that JX-594 reduced the amount of vasculature in gastric tumors using a xenograft mouse model. In the present study, we investigate the effect of JX-594 on tumor vasculature using an *in vitro* human cell 3D co-culture model of vascularized gastric cancer, to determine if this tool provides improved accuracy in evaluating the mechanism of action and biological activity of JX-594 as compared to traditional animal models.
Methods: The Curio-Spheroid chip is a Microphysiological System (MPS) that can grow tumor organoids or spheroids in 3D using physiologically relevant hydrogels and culturing them with other human cell types such as fibroblasts, endothelial cells, and immune cells. We evaluated nine human gastric cancer cell lines (YCC-18, YCC-19, YCC-22, YCC-30, YCC-32, YCC-38, Hs746T, NUGC-3, SNU-620) for their ability to form spheroids and induce angiogenesis inside Curio-Spheroid chips. We selected YCC-32 for the oncolytic virus testing. Serial increases of M.O.I (multiplicity of infection) of JX-594 disrupted the tumor-induced angiogenesis in a dose-dependent manner.
Results: JX-594 treatment of the YCC-32 spheroid resulted in decreased levels of Ki-67 and cytopathic effects in a dose-dependent manner inside the Curio-Spheroid MPS system. Angiogenesis was observed surrounding the spheroid when co-cultured with endothelial cells and fibroblasts. JX-594 decreased YCC-32 spheroid-induced angiogenesis in a dose-dependent manner in the vascularized gastric cancer 3D co-culture model.
Conclusion: JX-594 had an inhibitory effect on tumor-induced angiogenesis in our vascularized gastric cancer *in vitro* 3D human cell co-culture model, demonstrating the utility of the platform as a tool to interrogate the effects of an oncolytic virus on both tumor cell killing and tumor-induced angiogenesis.

#5397 Characteristics of cancer associated fibroblasts isolated from refractory colorectal cancer using RNA sequence.

H. Kasashima, Y. Fukui, K. Yonemitsu, K. Kitayama, Y. Miki, M. Yoshii, T. Fukuoka, T. Tamura, M. Shibutani, T. Toyokawa, S. Ree, M. Yashiro, K. Maeda; Osaka Metropolitan University, Osaka, Japan

Primary tumor location of colorectal cancers (CRCs) is emerging as an important prognostic factor owing to distinct biological features. In fact, the patients with right-side CRCs (R-CRCs), in which primary tumors were resected in our department and followed by systemic chemotherapy, have a poorer prognosis in 2-year overall survival and progression-free survival than those with left-side CRCs (L-CRCs). Furthermore, cancer-associated fibroblasts (CAFs) promote tumor malignancy, but the precise transcriptional mechanisms regulating the acquisition of the CAF phenotype are not well understood. Here, we isolated the CAFs and normal counterparts from 10 CRCs which were performed radical resection, including 5 L-CRCs and 5 R-CRCs, and analyzed transcriptomic profile of CAFs by RNA-sequencing. Gene Set Enrichment Analysis (GSEA) was performed and inflammatory signatures, such as "HALLMARK IL2 STAT5 SIGNALING"(NOM p-value<0.001, FDR q-value=0.146), "HALLMARK IL6 JAK STAT3 SIGNALING"(NOM p-value=0.014, FDR q-value=0.162), "HALLMARK INTERFERON GAMMA RESPONSE"(NOM p-value=0.032, FDR q-value=0.1726), were enriched in the CAFs isolated from R-CRCs (R-CAFs). In addition to sidedness of CRCs, based on gene expression profiles from bulk tumors, CRCs were classified into four consensus molecular subtypes (CMS1-4). Among them, The fibrotic CMS4 subtype portends poor relapse-free survival. We identified 4 CMS4-CRCs, which have the characteristics of stromal activation and the worst prognosis among other CRCs. GSEA showed that the signature of "HALLMARK TNFA_SIGNALING_VIA_NFKB" (NOM p-value=0.023 FDR q-value=0.207), "HALLMARK GLYCOLYSIS" (NOM p-value=0.036 FDR q-value=0.239) were upregulated in the CAFs isolated from CMS4-CRCs. These results indicated that CAFs isolated from refractory CRCs have unique phenotypes and the elucidation of these mechanisms might lead to a promising treatment for refractory CRCs.

#5398 Single-cell transcriptomic analysis of partial endothelial-to-mesenchymal transition in sprouting angiogenesis.

K. Thapa[1], C. J. Hatch[2], C. Hughes[2], J. S. Fang[1];

[1]Tulane University, New Orleans, LA, [2]University of California, Irvine, CA

Endothelial-to-mesenchymal transition (EndoMT) is a process of morphological, functional, and molecular shift of endothelial cells (EC) towards a mesenchymal identity. This process is critical for embryonic development, and knockout animals lacking copies of the individual master EndoMT transcription factors – including Slug, Snail, and Twist – exhibit significant cardiovascular defects. We previously showed that while Slug knockout animals have a modest developmental vascular phenotype, there is a striking loss of tumor angiogenesis in these animals. Based on these and other data, we hypothesize that sprouting angiogenesis involves transient acquisition of an intermediate state of the EndoMT program –i.e., partial EndoMT (pEndoMT). To test this hypothesis, we used single cell RNA sequencing at day 2 and day 6 following TGF-β activation to map the transcriptomic changes associated with complete endothelial-to-mesenchymal transition. In parallel, we sequenced EC activated to undergo sprouting angiogenesis *in vitro* at the same timepoints. We show that angiogenic EC transiently acquire a transcriptomic profile of the pEndoMT state, but then later reacquire the transcriptomic profile of committed EC rather than transition completely into mesenchymal cells. We further use this dataset to identify several candidate genes that appear to be regulated by Slug and associated with the pEndoMT state. Future work will use *in vitro* and *in vivo* angiogenesis models to identify how pEndoMT is regulated in angiogenesis, and how this regulation may differ in the presence of tumor stroma.

#5400 CD160 regulates angiogenesis in activated human endothelial cells.

A.-i. AZIZ;
Mohammed VI Polytechnic University, Ben Guerir, Morocco

Angiogenesis, the process of forming new blood vessels from pre-existing ones, plays a pivotal role in various physiological and pathological conditions. CD160, a cell surface receptor known for its modulatory function in the immune response, has recently garnered attention as a surface marker for activated endothelial cells. In this study, we investigate the anti-angiogenic effects of a novel anti-CD160 antibody. Using the tube formation assay, we evaluated the novel anti-CD160 antibody's ability to inhibit neovascularization potential in activated Human umbilical vein endothelial cells (HUVEC) *in vitro*. Our results revealed a significant reduction in total tube length, the number of branches, and closed networks, indicating the antibody's efficacy in impeding neovascularization. In addition, we explored the molecular mechanisms underlying CD160's anti-angiogenic properties, showing its ability to selectively decrease fibroblast growth factor-2-induced angiogenesis. Furthermore, we assessed the safety profile of our new anti-CD160 antibody by examining its impact on endothelial cell apoptosis. Encouragingly, our findings demonstrated no induction of apoptosis, suggesting the antibody's selective targeting of angiogenic processes without compromising endothelial cell viability, thus supporting CD160's vascular normalization properties. In conclusion, our research provides compelling evidence for the anti-angiogenic effects of the CD160 antibody, as evidenced by its inhibition of tube formation without inducing apoptosis in activated endothelial cells. These findings hold promising therapeutic implications for targeting angiogenesis in various pathological conditions, warranting further exploration for potential clinical applications.

Keywords: CD160, Angiogenesis, Endothelial cells. HUVECs.

#5401 Vasculogenic mimicry: A three-step progress to form lumen-containing and fluid-conducting tubular structures *in vitro*.

G. I. Owen[1], N. Santander[1], G. Mingo[1], P. Gonzalez[1], V. George[1], N. Babbitt[1], A. Espinioza[1], I. Vega[1], C. Canales[1], C. Ibanez[1], R. Gejman[1], J. Roa[1], F. Nualart[2], A. Ravasio[1], C. Bertocchi[1];

[1]Pontificia Universidad Catolica de Chile, Santiago, Chile, [2]Universidad de Concepcion, Concepcion, Chile

Introduction: Vasculogenic mimicry (VM) is a clinical phenomenon by which cancer cells can form vessel-like structures in an endothelial-free (CD31-) fashion. VM presence in tumors correlates to poor patient prognosis. In our laboratory we have established an *in vitro* model where cancer cells from either cell lines or primary culture form lumen-lined and fluid-conducting tubular structures when grown on laminin-rich Matrigel over a four-day period. Given the duration of formation and the complexity of these structures, we hypothesize that VM *in vitro* is a multistep process, where each stage requires spatio-temporal organization of adhesive proteins, stemness and EMT (suggesting the need for epithelial to mesenchymal transition) signaling.

Methods: Using our *in vitro* models, we analyzed by siRNA, immunostaining and live cell imaging with Airyscan the distinct phases and the corresponding spatio-temporal organization of selected proteins.

Results: We show that VM *in vitro* has three distinct phases that are characterized by (1) alignment and migration, (2) contraction, proliferation and bridge formation, and (3) tubular structure closure and lumen formation. These steps require spatio-temporal distribution of ZEB1 and E-cadherin (suggesting gain and loss of epithelial to mesenchymal transition), the presence of Integrin β1 and laminin 111, and the distinct localization of Laminin and CD44.

Conclusion: A better characterization of VM may lead to the identification of a clinically useful marker to predict poor patient prognosis and shed light on a druggable pathway to treat this subgroup of aggressive cancer.

#5402 Understanding the role of exercise in lymphatic vessel regulation in melanoma.

P. Tirumala[1], J. Lee[2], K. L. Schadler[2];
[1]Rice University, Houston, TX, [2]University of Texas MD Anderson Cancer Center, Houston, TX

Exercise has been demonstrated to be an effective method to remodel tumor blood vessels and to improve immune cell infiltration in multiple tumor models in mice. However, it is unclear whether aerobic exercise alters lymphatic vasculature in tumors. The lymphatic system plays an important role in tumor growth and metastasis because it regulates interstitial fluid pressure via lymph flow and immune cell trafficking, in conjunction with blood vessels. Lymphatic vessels are particularly important during metastasis because tumor cells frequently escape the primary tumor through lymphatic vasculature to establish the first site of metastasis in the lymph nodes. Here, we evaluated the effect of aerobic exercise on lymphatic vessels and lymphatic endothelial cell junctions in melanoma in male C57BL/6J mice. BP melanoma cells derived from transgenic mice with *Braf*$^{V600E/+}$ and *Pten*$^{-/-}$ mutations were injected subcutaneously. Mice were assigned to no exercise and exercise groups when tumors reached ~30 mm^3. The exercise group completed treadmill running at 12 meters/minute for 45 minutes for 5 consecutive days with 2 days of rest per week for 2 weeks before tumor harvest. Tumor lymphatic endothelial cells were identified by LYVE-1, endothelial tight junctions by ZO-1, and nuclei were identified by DAPI using immunofluorescence staining on frozen tumors. The number of total lymphatic vessels, elongated vessels(>100 µm), open lumens, and co-localization of ZO-1 with LYVE-1 was quantified on 6 random images per tumor using NIH Image J software. ANOVA and t-test were used to conduct statistical analysis ($p < 0.05$). Tumors from exercised mice had higher lymphatic vessel density ($p=0.002$) and more open lumens ($p=0.001$). Surprisingly, tumors from exercised mice had fewer ZO-1 positive vessels ($p=0.015$) and lower co-localization of ZO-1 and LYVE-1 ($p = 0.0185$) than tumors from non-exercised mice, suggesting fewer stable endothelial cell junctions in lymphatic vessels. The higher lymphatic vessel density and higher number of open lumens present in tumors from exercised mice may contribute to an exercise-induced improved anti-tumor immune response, which has been previously reported. However, the lower ZO-1 expression on lymphatic endothelial cells in tumors from exercised mice may indicate lymphatic vasculature dysfunction and/or hyper-permeability. Further work is needed to assess the functional changes in tumor lymphatic vasculature by exercise, and how these changes impact the anti-tumor immune response and metastasis.

#5403 Meeting the Physical Activity Guidelines is associated with increased CD8+ T-cell density in the tumor microenvironment of breast cancer patients.

R. Cannioto[1], A. Omilian[1], E. Davis[1], L. Mendicino[1], S. Abrams[1], B. Qin[2], C.-C. Hong[1], E. Bandera[2], S. Yao[1], C. Ambrosone[1];
[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Background: Our current understanding of how physical activity (PA) is associated with immunity in breast cancer (BC) patients is based on pre-clinical evidence gleaned from mouse models or immune cells in the circulating blood, which may not be reflective of the tumor immune microenvironment (TIME). Whether self-reported PA is associated with immune cell infiltration in the breast TIME, the most relevant site for prognosis, remains a fundamental gap in knowledge. Herein, we examined the association of self-reported PA in the year before BC diagnosis with CD8+ T-cell density in the breast TIME. As prior evidence from healthy adults suggests the relationship between exercise and immunity is not linear, we hypothesized that patients reporting the highest PA level would not have the highest $CD8^{\pm}$ T-cell density in their tumor.

Methods: We leveraged data and tumor samples from 685 women with BC (548 self-identified Black and 137 self-identified White) enrolled in the Women's Circle of Health Study and the Women's Circle of Health Follow-Up Study. $CD8^{\pm}$ T-cell density per square millimeter of tumor tissue was derived from IHC staining of tissue microarrays. Weekly PA in the year before diagnosis was categorized as inactive; low active (<7.5 MET hours/week); moderately active [7.5-14.9 MET hours/week, the equivalent of meeting the minimum PA Guidelines (PAG)]; or high active (≥15.0 MET-hours/week, exceeding the minimum PAG). Log transformed mean $CD8^{\pm}$ T-cell densities were compared by PA level using t-tests and multivariable linear regression with adjustment for age, race, estrogen receptor status, and tumor grade.

Results: Meeting the minimum PA Guidelines was associated with significantly higher $CD8^{\pm}$ T-cell density in the breast TIME [120.4 (353.6)] in comparison to inactivity [62.0 (154.5), p=0.02]. Although there were also distinct differences in T-cell density between moderate and low-active patients [120.4 (353.6) versus 69.5 (172.6), p=0.10] and moderate and high-active patients [120.4 (353.6) versus 80.7 (223.3), p=0.051], associations were shy of significance. Multivariable linear regression analyses confirmed that moderately active patients had significantly higher $CD8^{\pm}$ T-cell density in comparison to inactive patients, overall (p=0.029), and among Black patients (p=0.021).

Conclusions: In comparison to inactivity, BC patients meeting the PAG (moderate activity) had significantly increased $CD8^{\pm}$ T-cell density in their tumor, which is associated with better survival outcomes. This new translational knowledge suggests exercise-induced immunomodulation may be an important molecular mechanism underlying the association of PA with improved BC survival. As the immune system is a key player in treatment response and efficacy, further study of the role that PA ancillary to therapy may play in improving treatment and survival outcomes is warranted.

TUMOR BIOLOGY: Invasion and Motility
Poster Session

#5407 Temozolomide promotes matrix metalloproteinase 9 expression through p38 MAPK and JNK pathways in glioblastoma cells.
C. Jung, H. D. Thanh, S. Lee, K.-S. Moon;
Chonnam National University Medical School, Hwasun-gun, Korea, Republic of

Glioblastoma multiforme (GBM) is a highly aggressive and deadly brain cancer. Temozolomide (TMZ) is the standard chemotherapeutic agent for GBM, but many patients experience recurrence and invasion of tumor cells. We investigated whether TMZ treatment of GBM cells regulates matrix metalloproteinases (MMPs), which have main function to promote tumor cell invasion. TMZ effectively killed GL261, U343, and U87MG cells at a concentration of 500 μM, and surviving cells upregulated MMP9 expression and its activity but not those of MMP2. TMZ also elevated levels of *MMP9* mRNA and *MMP9* promoter activity. Subcutaneous graft tumors survived from TMZ treatment also exhibited increased expression of MMP9 and enhanced gelatinolytic activity. TMZ- mediated-MMP9 upregulation was specifically mediated through the phosphorylation of p38 and JNK. This then stimulates AP-1 activity through the upregulation of c-Fos and c-Jun. Inhibition of the p38, JNK, or both pathways counteracted the TMZ-induced upregulation of MMP9 and AP-1. This study proposes a potential adverse effect of TMZ treatment for GBM: upregulation of MMP9 expression associated with increased invasion and poor prognosis. This study also provides valuable insights into the molecular mechanisms by which TMZ treatment leads to increased MMP9 expression in GBM cells.

#5408 SERPINB3 impact on cervical cancer cell mobility and migration.

M. L. Campos Guerrero, L.-Y. Chen, S. Markovina;
Washington University In St. Louis, St. Louis, MO

Cervical cancer is the fourth most common cancer in women, with 311,000 deaths worldwide in 2018. About two thirds of patients with cervical cancer exhibit elevated serum levels of squamous cell carcinoma antigen (SCCA), also known as SERPINB3. SERPINB3 is associated with advanced stage and lymph node metastasis and we have previously shown it has a protective role against radiation treatment and chemotherapy induced cell death. We have also shown that SERPINB3 promotes tumor growth in both immunocompromised and immune competent murine models, yet the molecular mechanism is unknown. We have recently shown that SERPINB3 expression results in activation of signal transducer of transcription 3 (STAT3) and extracellular signal regulated kinase (ERK) in cervical cancer cells. These signaling cascades promote cell proliferation, survival, invasion, and metastasis. Proximity labeling using biotin-ligase fused to SERPINB3 revealed STAT3 and ERK as potential interacting partners. We aim to identify the molecular mechanism by which SERPINB3 promotes tumor progression, and determine if SERPINB3 drives invasion and metastasis in-vivo. We hypothesized that SERPINB3 directly interacts with and activates STAT3 and ERK leading to downstream signaling promoting invasion and metastasis. To test this hypothesis, we used cervical tumor cell lines engineered with SERPINB3 or empty vector control and determined migration by wound healing assay and downstream activation of STAT3 and ERK. Co-immunoprecipitation (co-IP) with western blot was performed to determine an interaction between SERPINB3 and STAT3 and ERK. E6/E7-expressing TC-1, and Lewis Lung Carcinoma cells, LL2, to develop a method for injecting the cervix of immunocompetent c57BL/6 albino mice (no available murine cervical carcinoma line). Wound healing assays revealed that knocking out SERPINB3 shows a decrease in wound closure in both SW756 and HT3 cervical cancer cells compared to control cells, respectively. Co-IP of STAT3 in HT3 cells revealed the presence of SERPINB3, providing further evidence for an interaction between STAT3 and SERPINB3. We were able to grow tumors in the cervix of the C57/BL6 mice and identified potential metastatic deposits in the lung. Moving forward, we plan to identify the minimal functional domain of the interaction between SERPINB3 and STAT3/ERK using a step-wise genetic approach for protein domain deletion. To determine the role of SERPINB3 on metastasis in vivo, we will use, LL2 and TC-1 engineered with the mouse orthologue mSERPINB3a to determine effect of SERPINB3 on invasion and metastasis. Conducting this study will provide insights as to how SERPINB3 may function in a pro-tumor role in cervical cancer and allow the development of SERPINB3-targeted drugs.

#5409 Phosphorylated focal adhesion kinase by mild reduction of cell surface proteins inhibits integrin α5β1-dependent patient- derived cancer cell migration and invasion.

J. Kim[1], L. D. Anggradita[1], S. Hur[1], J. Park[2], S.-H. Kim[3], M. Ban[2], Y. Hwang[1];

[1]Soonchunhyang Institute of Medi-bio Science, Cheonan-si, Korea, Republic of, [2]Soonchunhyang University Cheonan Hospital, Cheonan-si, Korea, Republic of, [3]Korea Institute of Science and Technology, Seoul, Korea, Republic of

Although head and neck squamous cell carcinomas (HNSCCs), including tongue, vocal cord, and buccal cancers, are one of the most common cancers worldwide with a mortality rate of more than 40%, there have been no solid standard biomarkers for effectively diagnosing HNSCCs at early stages and no effective protocols available to support in vitro expansion of HNSCC cells. To establish a cell culture method to support in vitro self-renewal of HNSCC cells, patient-derived tumor was enzymatically digested, and the tongue cancer epithelial cells were seeded onto feeder cells with the Rho kinase inhibitor (Y-27632). Additionally, to test our hypothesis that free thiol groups in the cells, generated by a mild reduction of cell surface proteins using the reducing agent tris(2-carboxyethyl) phosphine hydrochloride (TCEP), would modulate cancer cell adhesion and migration, we assessed the expression levels of integrins, focal adhesion kinase (FAK), and phosphorylated FAK (pFAK) of tongue cancer epithelial cells cultured on both soft and rigid polyacrylamide (PAAm) hydrogel-based cell culture substrates. Patient-derived tongue cancer epithelial cells exhibited self-renewal ability and maintained cancerous phenotypes, with high expressions of P53, Ki67, E-cadherin, CD44, and AHDH1A1. Treatment with the reducing agent (TCEP) increased the degree of cell adhesion through the significantly upregulated integrin α5β1-mediated phosphorylation of FAK, resulting in inhibited single-cell and collective cell migration as well as invasion. Additionally, when these cells were cultured on stiff PAAm hydrogels mimicking the tumor microenvironment, the cells exhibited accelerated cell migration behaviors, compared to cells on soft hydrogels. These results highlight the synergetic contributions of feeder cells and Rho kinase inhibitor to support long-term self-renewal of tongue cancer patient-derived epithelial cells.

#5410 Unveiling PAI-1 as a new player in chemoresistant melanoma in aged human skin reconstructed in vitro.

R. Oliveira da Silva[1], L. A. C. Carvalho[2], D. E. M. Camarena[1], J. R. Silva[1], I. H. Y. Noma[1], M. O. Moraes, Jr.[1], P. C. Pennacchi[3], S. S. Maria Engler[1];
[1]University of Sao Paulo, Sao Paulo, Brazil, [2]Moffitt, Tampa, FL, [3]Vivia Biotech,, Madrid, Spain

The impact of advanced glycation end products (AGEs) accumulation is associated with the development and exacerbation of many degenerative processes and disorders, including aging and cancer. AGEs accumulation in the skin leads to stiffness and loss of elasticity by building up in the connective tissue during aging process. This process has implications of the extracellular matrix, affecting the adhesion, migration, and invasiveness potential of melanoma cells. Furthermore, tumor invasiveness is correlated with mechanical stiffness, contributing to the high metastatic capacity of melanoma. To address this research gap, our study aimed to evaluate the invasive potential of chemoresistant melanoma using an in vitro model of reconstructed aged human skin modified by glycation. Glycated skin exhibited distinct features indicative of aging, including positive pentosidine fluorescence and elevated CML labeling and expression, well-established biomarkers of aging. Furthermore, glycated skin with resistant melanoma demonstrated reduced expression of differentiated keratinocytes (CK-10) and increased expression of undifferentiated keratinocytes (CK-14). Overall, in glycated skin with resistant melanoma, decreased proliferation and increased tumor invasion were observed, associated with changes in the expression of key markers, such as reduced MITF and SOX-10 and increased AXL. Downregulation of MITF in skin with resistant melanoma resulted in decreased Melan-A expression, implying altered pigmentation of melanoma cells. Additionally, resistant melanoma in glycated skin showed enhanced inflammation, as indicated by higher levels of IL-8 and IL-1α. Gene screening showed upregulation of the PAI-1, ABL-1, COL1A1, SPARC genes. Among these genes, PAI-1 (Plasminogen activator inhibitor-1) was upregulated in resistant melanoma compared to naïve melanoma both in glycated skin. PAI-1 may play a critical role in the development of aging-associated pathological changes. In addition, PAI-1 is recognized as a marker of senescence and a key member of a group of proteins collectively known as the senescence-messaging secretome. It also performs protumorigenic functions, such as promoting vasculature, increasing growth, motility and protecting tumor cell apoptosis. Overall, this work demonstrated that skin aged by glycation when associated with i-Braf resistant melanoma exhibited a more invasive and less proliferative profile (low MITF and SOX10, elevated AXL), more inflammatory (elevated IL-8 and IL-1α) and with a greater number of immature keratinocytes (elevated ck-14). PAI-1 overexpression may be a promising target to expand studies caused by oncogenes in the model of aged skin by glycation with resistant melanoma.

#5411 Effect of different fatty acids on ccRCC behavior and metabolism.

I. Ramos de Andrade, D. Wang, S. Welford;
University of Miami Miller School of Medicine, Miami, FL

Introduction: Clear Cell Renal Cell Carcinoma (ccRCC) is the most common type of kidney cancer, presenting with defining characteristics of increased lipid droplets formation, loss of the VHL tumor suppressor, and low levels of fatty acid oxidation (FAO). Obesity is associated with an increase in ccRCC incidence, although obese patients respond better to different therapies, a phenomenon called as obesity paradox. The consumption of diets rich in lipids and leading to obesity has been increasing, but how the dietary composition affects ccRCC progression, or could be modulated in combination with other therapies for better responses is still unclear. In the present study, we aimed to evaluate how different fatty acids (FAs) affect ccRCC behavior and metabolism.
Methods: We used 786-O and 769-P ccRCC cell lines. Palmitic acid (PA), oleic acid (OA), and linoleic acid (LA), which are saturated, monounsaturated, and polyunsaturated fatty acids, respectively were used as stimuli for the cells at 50 or 200μM. All stimuli were diluted in culture media with 5% FBS. Lipid droplets were evaluated by Oil Red O staining; viability was assessed by MTT; protein expression was tested by Western Blotting; Oxygen Consumption rate (OCR) by Seahorse; survival was quantified by clonogenic assay; and mRNA was measured by RT-qPCR.
Results: All FAs increased the amount of lipid droplets compared to the control, but OA was the most potent. PA impaired the growth rate for cells compared to control, and other FAs in both cell lines, and did not increase the expression of cleaved caspase-3. PA, even in a lower concentration [50μM], impaired the formation of colonies for both cell lines compared to control and other FAs. LA impaired colony formation only in the higher concentration [200μM], while OA only induced a difference for 769-P cells at the smaller concentration, increasing the number of colonies. OA, and mainly PA, decreased 769-P cells migration, at the time of 6 and 12 h, while only PA decreased migration for 786-O cells, at the time of 12 h. LA, and mainly PA, increased CPT1a mRNA levels in 786-O cells but did not induce a significant difference to 769-P, and all FAs decreased FASN in both cell lines.
Conclusion: It was demonstrated that OA was a potent inducer of lipid droplet formation, which can be protective in avoiding lipid peroxidation. On the other hand, PA and LA induced fewer lipid droplets probably because they are going to FAO, as we observed increased mRNA CPT1a levels, which is the rate-limiting enzyme in FAO. PA impaired potentially the formation of colonies and growth rate, and it is important to highlight that it was without inducing caspase 3-dependent programmed cell death. Taken together our data suggest that PA could be a target therapy for ccRCC, but it is still necessary for more studies in vitro and in vivo to evaluate how PA and enriched lipid diet can impact a better outcome for patients.

#5412 In vitro plasticity profiling of metastatic cancer cells with an imaging-based pipeline.

Saba Sameri[1], Durdam Das[2], Stefanie Michaelis[3], Joachim Wegener[3], Hedayatollah Hosseini[1], Martin Hoffmann[2]

[1]Experimental Medicine and Therapy Research, University of Regensburg, Regensburg, Germany,[2]Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Regensburg, Germany,[3]Fraunhofer Institute for Electronic Microsystems and Solid State Technologies EMFT, Regensburg, Germany

Different types of cancer cells exhibit varying levels of invasiveness, migration behavior and ability to resume growth at distant sites. In order to classify cell lines for these fundamentally important traits of metastasis, we sought to generate an image-based *in vitro* assay that quantifies morphological and functional features of cancer cell plasticity. We developed an Imaging-Based Pipeline as an R Package for *in vitro* cell monitoring using the breast cancer cell lines MDA-MB-231 and MCF-7 that represent high-metastatic and low-metastatic cells *in vivo*, respectively, to identify relevant feature variables. Live cell imaging via the zenCELL owl system captured images for labeling and segmentation. Pre-trained neural network models from Cellpose, combined with user-calibrations, accurately segmented cells for tracking. The tracking pipeline calculated similarity coefficients, Jaccard index, between consecutive frames for cell trajectory analysis. Geometric and morphological features, speed, and distance measurements were derived for assessing structural motility and proliferation-associated changes. The analysis of two cell line models revealed significant variations in morphological changes, with MDA-MB-231 showing more rapid changes between round and elongated shape compared to MCF-7 cells. Moreover, the analysis of cell motility, consistent with the morphological changes, revealed that TGF-beta1 induced migration in MDA-MB-231 cells much stronger than in MCF-7 cells. Likewise, differences in proliferation induction upon addition of growth factor was monitored, showing that MCF-7 cells are more responsive to the growth stimulation than MDA-MB-231 cells. Consequently, the morphological plasticity of cancer cells, closely linked to the epithelial-to-mesenchymal transition (EMT) state, emerges as a defining factor for the *in vitro* plasticity of these cells. Quantified proliferation rate and migration speed of the cells was then used to establish an *in vitro* "plasticity index" that captures a cell line's ability to switch between migration and proliferation. This index will undergo validation using cell lines with well-established metastatic propensities.
In conclusion, we developed an Imaging-Based Pipeline that can effectively explore cancer cell plasticity in vitro and monitor the impact of genetic or pharmacologic perturbations on this critical characteristic of aggressive cancer cells.

#5413 *In vitro* modeling of the migration ability of lung adenocarcinoma cell lines under hypoxic conditions.

S. E. Surguta[1], M. Baranyi[2], L. Svajda[1], I. Ranđelović[1], M. Cserepes[1], J. Tovari[1];
[1]National Institute of Oncology, Budapest, Hungary, [2]KINETO Lab Ltd., Budapest, Hungary

Hypoxia is a common condition in the tumor microenvironment that contributes to tumor cell migration, invasion, and metastasis, partly through inducing epithelial-mesenchymal transition (EMT). One of the key proteins in this process is hypoxia-inducible factor 1 (HIF-1), which regulates the expression of various genes as transcription factor and is vital for the cellular response in tissue hypoxia. Several studies have investigated the causation between hypoxic conditions and increased *in vitro* tumor cell motility and the role of potential regulatory signaling pathways. Understanding the precise molecular mechanisms underlying hypoxia-induced responses is crucial for better targeting tumor progression. However, establishing sound and predictive models is urgently needed to achieve this.In this study, we investigated the migration ability of four non-small cell lung cancer cell lines carrying different mutations of the growth factor pathway (H1975: EGFR T790M, PF901: BRAF V600E, PF139: KRAS G12C mutant, and H838: triple WT) under normoxic, hypoxic, and hypoxia-mimicking $CoCl_2$-treated conditions. The motility of the cells was investigated by 48 h video microscopy (single cell random migration) and 72 h scratch assay. We analyzed the expression of crucial genes and proteins, including HIF-1α, as well as molecules associated with epithelial-mesenchymal transition (*vimentin, n-cadherin*, and *e-cadherin*), proliferation (PCNA), and apoptosis (PARP), using Western blot and qPCR techniques. Our work showed no change in cellular motility between any of the cell lines following treatment with $CoCl_2$ compared to normoxic conditions. However, PF139 and PF901 cell lines showed a significant decrease in single-cell motility upon hypoxia. Interestingly, immunoblot analysis revealed stabilization of HIF-1α in response to both $CoCl_2$ and hypoxia in the meantime. Additionally, we observed cell line-dependent changes in EMT marker expression upon $CoCl_2$ treatment and hypoxia. Our work complements previous results published by our group and others on the tumor-promoting role of hypoxia, demonstrating that short-term exposure to hypoxia may act as an acute stressor for tumor cell lines. Our work suggests that the tumor progression-promoting effects are tissue-specific and should be investigated using long-term hypoxia models.
Acknowledgments: This work was supported by the Hungarian Thematic Excellence Program (TKP2021-EGA-44) and the National Laboratories Program - National Laboratory for Tumor Biology (NLP-17). Sára Eszter Surguta is a grantee of the ITM-NKFIA funded Cooperative Doctoral Program (1018567).

#5414 BDNF/TrKB signaling may lead to higher incidence of perineural invasion in men with prostate cancer.

G. J. Edwards[1], V. Odero-Marah[2];
[1]Claflin University, Orangeburg, SC, [2]Morgan State University, Baltimore, MD

Perineural invasion (PNI) is a crucial mechanism facilitating prostate cancer metastasis. PNI encompasses perineural, circumferential, and intraneural invasion, with cancer cells closely interacting with nerves. Evidence suggests that cancer cells utilize the nervous system for metastasis through signaling pathways. PNI is associated with poor prognoses in various cancers, but its role in prostate cancer remains unclear. PCa primarily metastasizes through systemic routes, such as lymphatic and circulatory systems. Metastasizing cancer cells undergo epithelial-mesenchymal transition (EMT), enhancing their motility. SNAIL1, a transcriptional repressor, induces EMT and promotes cancer cell migration, including towards nerves, termed neurite outgrowth. Neurite outgrowth involves intricate signaling between tumor cells and nerves, possibly facilitating cancer cell infiltration into nerve sheaths and PNI. Our lab has shown SNAIL1 in interactions with neurotrophic factors like Brain-Derived Neurotrophic Factor (BDNF) and Tyrosine Kinase Receptor Beta (TrkB), modulating cancer cell behavior. TrkB is overexpressed in various cancers, while BDNF signaling contributes to EMT via the Twist-Snail axis. BDNF may also play a role in PNI pathogenesis. **Our hypothesis posits the BDNF-TrkB axis drives aggressive prostate cancer and PNI.** This study employed prostate cancer cell lines for comprehensive analysis. We assessed BDNF expression in different cell lines, particularly those with high Snail levels, and analyzed BDNF transcript levels via real-time quantitative PCR following RNA extraction and reverse transcription. We explored whether BDNF overexpression enhanced cancer cell migration towards nerves, employing migration assays. Our findings indicated heightened migration in BDNF-high cell lines, C42, PC3, and MDA-2b, compared to BDNF knockdown cells. Additionally, a TrkB inhibitor, K252a, attenuated migration due to BDNF-induced TrkB phosphorylation. Our study establishes that BDNF/TrkB signaling promotes prostate cancer cell migration towards nerves, a phenomenon reversible with K252a, offering a potential strategy to impede prostate cancer progression and metastasis.

#5415 Fibroblast mediated head and neck tumor cell invasion in 3D culture is independent of partial epithelial to mesenchymal transition.

P. Park, M. M. Alexander, J. M. Curry, A. J. Luginbuhl, A. P. South;
Thomas Jefferson University, Philadelphia, PA

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide, with a five-year-survival of 61-64%. Recent studies have demonstrated tumor keratinocytes with features of a partial transition from epithelial to a mesenchymal phenotype, also known as partial-EMT (pEMT), at the edge of invading tumor islands associates with metastatic disease. As such, pEMT likely results from direct interactions between tumor cells and their surrounding microenvironment. To test if specific secreted factors or cell interactions drive the acquisition of pEMT, we first analyzed a series of primary and established HNSCC cell populations to determine TGF-β1 responsiveness since TGF-β1 is a known driver of pEMT. Of the eight populations tested, six displayed an increased level of pSMAD3 upon incubation with 5 ng/mL of TGF-β1 ($p < 0.0001$). To determine if this TGF-β1 response leads to an increase in pEMT phenotype, a pEMT-score (derived from mRNA expression of 9 pEMT markers) for each HNSCC population was determined following TGF-β1 treatment. As expected, the two non-responsive HNSCC populations showed no increase in pEMT-score, whilst five of the six TGF-β1-responsive HNSCC populations demonstrated a significant increase in pEMT-score ($p = 0.006$). To assess if TGF-β induced pEMT phenotype correlates with increased invasive potential, we produced 3D skin equivalent models using the eight HNSCC keratinocyte populations, in the presence or absence of primary fibroblasts and/ or TGF-β1 treatment. TGF-β1 treatment alone caused a significant increase in invasion of all five TGF-β1-induced pEMT HNSCC populations ($r^2 = 0.449$, $p = 0.0045$), whilst the three populations previously shown to be pEMT unresponsive to TGF-β1 treatment showed no increase. Interestingly, addition of primary fibroblasts without TGF-β1 treatment caused a universal dramatic increase in invasion in 3D organ culture ($p = 0.0064$, 34-fold increase), regardless of the previously determined TGF-β1-induced pEMT status. Unexpectedly, TGF-β1 treatment in the presence of fibroblasts caused no significant increase in invasion in 3D cultures ($r^2 = 0.00001$, $p = 0.9906$). We next compared levels of pEMT markers in 3D cultures using immunofluorescence and observed a significant increase in PDPN in six of the eight HNSCC populations ($p = 0.0136$) with the addition of fibroblasts suggesting that factors independent of TGF-β1 contributes to pEMT marker expression and invasion in 3D culture. Overall, these data demonstrate fibroblasts induce HNSCC keratinocyte invasion regardless of the population's ability to respond to TGF-β1-induced pEMT and that pEMT may be driven by factors independent of TGF-β1 in 3D culture.

#5416 Purinergic P2Y6 receptor antagonists as potential anti tumor agents.

K. Ghimeray, S. Sharma, R. S. Akundi;
South Asian University, New Delhi, India

Introduction: Cancer places a tremendous strain on society in both developed and economically less developed nations. It remains the most recurring and deadliest disease despite rapid advances in treatment modalities. The major contributors are the prevalence of known risk factors, urbanization, population growth and ageing. Cancer resurgence depends on the organ in which the tumor first appears, immune response, patient's characteristics, disease stage and tumor microenvironment (TME). Among the several inflammatory molecules found within the TMEs, the levels of adenosine triphosphate (ATP) has been found to be high. In healthy tissue, the concentration of ATP in the extracellular space (eATP) is negligible and does not accumulate significantly due to the activity of ectonucleotidases. However, tissue injury, cellular stress and chemotherapy mediated cell death can increase the levels of ATP in the TME. The eATP exerts its effect mainly through purinergic P2 receptors expressed by most malignant cells. We have previously shown that eATP promoted migration and invasion of cancer cells in vitro through increased expression of the enzyme cyclooxygenase 2 (COX-2) (Sharma et al., 2021). We showed that eATP mediated COX-2 expression is through P2 receptors (Akter et al., 2021). Accordingly, we hypothesized that blocking the P2 receptors would abolish the COX-2-mediated migration of tumor cells and tested the same in an animal model.

Methodology: Tumors were generated in 8-15-week-old male C57BL/6 mice (20-25 g weight) through subcutaneous injection of syngeneic EL4 lymphoma cells in the left flank of the mice. When tumors were palpable around day 10, saline or P2 receptor, antagonists were directly injected into the center of the tumor and mice were divided into three groups: saline (vehicle control), suramin (broad-spectrum P2 receptor antagonist), and MRS 2578 (P2Y6 receptor-specific antagonist). Drugs were chosen based on prior in vitro research and a vernier caliper was used to assess the growth of the tumor every day. Behavioral tests were performed on day 8 (prior to P2 receptor injections) and days 11, 14 and 17 post-tumor injection. Mice were continuously monitored for their health and were sacrificed on day 18 with deep CO_2 anesthesia and cervical dislocation.

Results: We found that suramin-injected tumors had a substantial reduction in tumor volume when compared to saline-injected ones. Intra-tumoral injections of P2 receptor antagonists such as MRS-2578 also resulted in similar outcomes as suramin. In tumors treated with P2 receptor antagonists, the expression of COX-2, cell cycle proteins and epithelial-to-mesenchymal (EMT) markers, which aid in metastasis, were significantly downregulated, indicating a suppressive effect. Therefore, we propose that P2 receptor-dependent anti-inflammatory drugs (PBAIDs) could be considered a potential alternative therapeutic option for preventing cancer recurrence.

#5417 PHGDH expression level impacts tumorigenesis and metastasis in human breast cancer.

J. Baik[1], J. Kim[2], S. Lee[1], A. Park[3], K. Shin[4], S. Kwon[4], H. Lee[5], W. Han[3];

[1]Integrated Major in Innovative Medical Science, Seoul National University Graduate School, Seoul, Korea, Republic of, [2]Biomedical Research Institute, Seoul National University, Seoul, Korea, Republic of, [3]Interdisciplinary Programs in Cancer Biology Major, Seoul National University Graduate School, Seoul, Korea, Republic of, [4]Department of Electrical and Computer Engineering, Seoul National University, Seoul, Korea, Republic of, [5]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Phosphoglycerate dehydrogenase (PHGDH) is a metabolic enzyme, which is associated with the first step of serine synthesis. The gene encoding this enzyme is often elevated in some types of human cancer, including breast cancer. There are some researches that High-PHGDH expression promotes cancer cell proliferation and tumorigenesis. However, latest study showed that although breast tumors with high expression levels of PHGDH had more possibility to undergo primary-tumor growth, were less likely to metastasize than tumors with low expression of PHGDH by using mouse cell derived mouse models and PDX models. Nevertheless, the applicability of these outcomes to human breast cancer cell lines remains uncertain.
Methods: The survival analysis according to PHGDH mRNA expression was analyzed in METABRIC datasets of breast cancer and the whole-transcriptome sequencing data of 120 breast cancer patients. To investigate the effect of PHGDH in human TNBC cell lines, PHGDH overexpressing MDA-MB-231 cell lines and PHGDH knockdown MDA-MB-468 cell lines were established. Subsequent functional experiments were performed to explore the influence of PHGDH on breast cancer tumorigenesis and metastasis.
Results: In the analysis using METABRIC datasets, overall survival and disease-free survival were reduced in patients with high PHGDH expression and basal type breast cancer showed the highest mRNA level of PHGDH. Using whole-transcriptome sequencing data of 120 breast cancer patients, we also found PHGDH expression level was higher in cancer tissue(n=120) than normal tissue(n=90). In particular, triple-negative breast cancer indicated higher PHGDH level than luminal type breast cancer. We also used this data to perform analysis of overall survival, disease-free survival, metastasis free survival of non-TNBC patient and it resulted in reducing survival rate when patient showed high-PHGDH expression. However, TNBC patients demonstrated diametrical results in the identical analysis. We examined the impact of PHGDH overexpression in MDA-MB-231 cells and PHGDH knockdown in MDA-MB-468 cells, observing increased proliferation and decreased migration in breast cancer cells with elevated PHGDH levels. Conversely, PHGDH knockdown exhibited opposing effects. Subsequently analysis of markers associated with epithelial-mesenchymal transition revealed a correlation with PHGDH expression.
Conclusions: Our data suggest that a potential role for PHGDH in breast cancer as a marker of reduced survival in triple-negative breast cancer, and as a regulator of cancer cell proliferation and metastasis.

#5418 Lamellipodial protrusions induced by hypoxia depend upon kindlin-2 in prostate cancer cells.

C. Nelson[1], D. Hernandez-Cortes[2], K. D. Marr[1], J. M. Gard[1], A. I. Paxson[1], W. L. Harryman[1], N. K. Seppanen[1], J. M. Ryniawec[1], A. E. Cress[1];
[1]University of Arizona, Tucson, AZ, [2]University of California San Fransico, San Fransico, CA

Hypoxia is a physiologically relevant feature of the prostate microenvironment that promotes migration and invasion resulting in extracapsular extension, the first step toward metastatic progression. Prostate cancer invasion depends on integrins as mechanosensing membrane receptors during creation of membrane lamellipodial protrusions and focal adhesions (FAs). The objective of this study was to determine the molecular events that promote membrane protrusions under hypoxia and whether this was dependent upon kindlin-2, an essential integrin adapter that marks activated β1 integrin heterodimers. DU145 cells depleted of one copy of FERMT2$^{+/-}$ (50% kindlin-2 expression) by CRISPR/Cas9 or DU145 FERMT2^{wt} (normal kindlin-2 expression) were grown under acute exposure to hypoxia (1% O_2) and compared to cells grown under normal tissue culture conditions. Immunofluorescence microscopy experiments were performed to analyze the spatial temporal expression of kindlin-2 complexes. Kindlin-2 complexes were confirmed by immunoprecipitation using an anti-kindlin-2 3A3-antibody from Sigma-Aldrich. Colocalization was determined by obtaining 2D immunofluorescence microscopy images analyzed using ImageJ 2.1.0/1.53c and Nikon NIS-Elements 5.30.04. Under hypoxic conditions, analysis over four time points (4h, 8h, 12h & 16h) increased the number and area of FAs (marked by paxillin (PXN)) containing kindlin-2 in a time-dependent manner by 2-fold and 1.5-fold, respectively, but not in DU145 FERMT2$^{+/-}$ cells. Additionally, hypoxia increased membrane area, perimeter, and the plasma membrane intensity of kindlin-2 exclusive of FAs in DU145 FERMT2^{wt} cells which was maximal after 8 hours of hypoxia. Interestingly, limiting the kindlin-2 expression in FERMT2$^{+/-}$ cells resulted in a loss of hypoxia-induced lamellipodial protrusions (marked by lamellipodin (RAPH1)) containing kindlin-2 while hypoxia-induced kindlin-2 FA changes were preserved. The current working hypothesis is that lamellipodial protrusions are dependent upon kindlin-2 expression whereas the established FAs are stable under conditions of reduced kindlin-2 expression in hypoxia. This data suggests that an early stage of migration, lamellipodial extensions are sensitive to kindlin-2 availability. Further studies are required to determine the dynamic interplay between protrusive events and focal adhesions in relation to kindlin-2 for prostate cancer cells to migrate and invade.

#5419 Claudin-7 mediates Rab25-induced suppression of colon cancer cell invasion.

S. Cho[1], B. Jeong[2], S.-H. Yoon[1], C. Park[1], H. Lee[1];
[1]Konyang Univ. College of Medicine, Daejeon, Korea, Republic of, [2]Oregon Health Science University, Portland, OR

Ras-related protein 25 (Rab25) is a member of small GTPase, and growing evidence demonstrates the context-dependent roles of Rab25 in cancer progression. While Rab25 aggravates cancer cell invasion in ER-positive breast, ovarian, and gastric cancers, Rab25 is under-expressed and suppresses colon and triple-negative breast cancer progression. Claudins are major components of tight junctions, and disruption of claudins is implicated in tumorigenesis. Among 27 known members of the claudin family, claudin-7 is suggested to suppress colon cancer progression. Previously, we identified that Rab25 induces endothelial-mesenchymal transition (EMT) and invasiveness of several types of cancer cells through activating the β1 integrin/epidermal growth factor receptor (EGFR)/Snail signaling cascades. However, little is known about the underlying mechanism of Rab25-induced tumor suppression. In the present study, we identify the critical role of claudin-7 in Rab25-induced suppression of colon cancer invasion. 3D Matrigel and modified Boden chamber were used to assess the invasiveness of colon cancer cells. Wound-healing assay was used to analyze colon cancer cell migration. 3D Matrigel was used to analyze tumor growth. Immunoblotting was used to assess the protein expression. Rab25 induced claudin-7 expression in colon cancer cells through protein stabilization. In addition, the enforced expression of claudin-7 not only reduced the EGFR/ Ras signaling activity and Snail expression but also attenuated colon cancer cell invasion. However, silencing of claudin-7 expression rescued the tumor suppressive role of Rab25, thereby increasing colon cancer cell invasiveness. Collectively, our data demonstrate for the first time that Rab25 reduces the EGFR/ Ras/ Snail signaling activity and inhibits colon cancer cell invasion by upregulating claudin-7 expression.

#5420 NLRX1 involves in prostate cancer cell growth, survival and migration.

W.-W. Lin, V. Rathore;
National Taiwan University College of Medicine, Taipei, Taiwan

Prostate cancer (PCa) is one of the most common male cancer and is the second leading cause of death in men. The basic working components about its cause and progression are not surely known in the research as well as the practitioner community. The current curing therapies such as surgery, radiation therapy, cryotherapy, and hormone therapy are not very encouraging. Subsequently, there is a need to investigate new potential targets for focused treatment. NLRX1 (NOD9 or NLR family member X1) is one member among the NLRs and is a non-inflammasome forming NLR sub-group localized in mitochondria. Previous studies showed that NLRX1 is involved as a tumor suppressor in colorectal cancer and hepatocellular carcinoma. However, NLRX1 serves as tumor promoter in breast cancer and head and neck cancer sarcoma. The present study focuses on the role of NLRX1 in prostate cancer cells under stress conditions including serum-free and hydrogen peroxide (H_2O_2) to understand cell regulation and functions of NLRX1. We used human prostate cancer PC3 and LNCaP cell lines as the models and the following methods, including Annexin V/PI staining for cell viability, BrdU incorporation for cell proliferation, mitoSOX staining for mitochondrial ROS, wound healing assay for cell migration and Boyden chamber for cell invasion. First, we assessed the TCGA database via UCSC Xena and found that prostate cancer tumors have high NLRX1 expression than normal tissues. Next, we knock down the NLRX1 through lentivirus transduction. We found that silencing NLRX1 expression can decrease cell proliferation in PC3 cells. Furthermore, silencing NLRX1 can significantly decrease cell viability under H_2O_2 in PC3 cells and serum-free condition in both cancer cell lines. In addition, we found that H_2O_2-induced cell death is reversed by necroptosis inhibitor Nec-1. Moreover, NLRX1 silencing reduces cell migration in both PC3 and LNCaP cells and can inhibit cell invasion in both cell lines at 24 h. These results suggest that NLRX1 is a positive regulator of cell growth, migration and invasion in prostate cancer cells, and NLRX1 provides a cell-protective role in response to H_2O_2 and serum-free stress. Thus, this study will provide a potential target for the development of a therapeutic strategy for prostate cancer.

#5421 Characterizing functional cell migration states with highly multiplexed immunofluorescence imaging.

W. D. Leineweber, A. Finkelstein, E. Lundberg;
Stanford University, Stanford, CA

Cancer cell migration is a necessary step in the metastatic cascade, but there are heterogeneous cellular mechanisms to achieve this behavior. This study leveraged live-cell tracking and end-point spatial proteomics to better characterize what underlying molecular states drive migration heterogeneity. U2OS osteosarcoma stably expressing the FUCCI cell cycle reporter system were tracked for 20 hours on a Leica DMI8 widefield microscope. Immediately after, cells were fixed and prepared for highly-multiplexed immunofluorescence imaging on a Canopy CellScape instrument. Initial results from these experiments demonstrate that transferring the sample between these two systems is feasible and results in minimal loss of cells despite the multiple staining cycles. Unlike standard marker panels intended to differentiate between cell types, the initial panel used in this study includes markers that differentiate between migration modes. Even within one cell line, unsupervised clustering identified cell clusters for vimentin high/ E-cadherin low and E-cadherin high/ vimentin low, indicated an epithelial to mesenchymal transition (EMT) axis in the dataset. Furthermore, the spatial relationships between the cell neighborhoods show largely heterogeneous distributions of cell states, with clusters of more homogeneous cell states arising in more densely-packed regions of the coverslip. Further analysis of how single cell trajectories correlate to these cell states, as well as how cell cycle dynamics impact both migration and molecular cell states are in progress. Results from these analyses will shed new light on the “go vs. grow” hypothesis by directly testing how cell speed, persistence, and overall invasion correspond to cell cycle stage and progression. Furthermore, the high-resolution detail from the multiplexed imaging will allow for subcellular profiling of dynamic proteins, such as beta catenin, and directly link it to a larger protein and migration state. Overall, this experimental approach represents an important bridging between functional measurements and end-point omics technologies that will be crucial to gain actional insights amid the boom in multiomics.

#5422 Identification of ZEB1-regulated circular RNAs in lung cancer cells.

S. Cho, J.-A. Choi, Y.-H. Ahn;
Ewha Womans University, Seoul, Korea, Republic of

ZEB1 is a master transcription factor playing a crucial role in promoting epithelial-mesenchymal transition (EMT), as well as the progression and metastasis of lung cancer. The progression of lung cancer is regulated by non-coding RNAs, including microRNAs, long non-coding RNAs, and circular RNAs (circRNAs). In this study, we aimed to identify circRNAs under the regulation of ZEB1 and elucidate their functions within lung cancer cells. Through RNA sequencing and subsequent CIRI-full analysis in ZEB1-overexpressing lung cancer cells, we identified 25 circRNAs displaying differential expression compared to control cells. Among these circRNAs, we targeted circDennd1b, which showed down-regulation in ZEB1-overexpressing cells. We used siRNAs to target the back-splicing junction of circDennd1b, resulting in its knockdown and consequently promoting the invasion of lung cancer cells. Now, we are studying how circDennd1b affects the progression and metastasis of lung cancer. In summary, the circRNAs modulated by ZEB1 are anticipated to play a key role in the invasion, progression, and metastasis of lung cancer.

#5423 Selective inhibition of glucose transporter 3 (GLUT3) suppresses triple-negative breast cancer cell migration by modulating actin cytoskeleton and cell mechanics.

T.-H. Kim[1], A. Qadir Bhat[1], C. V. Iancu[2], J.-Y. Choe[2];
[1]University of New Mexico Health Sciences Center, Albuquerque, NM, [2]University of New Mexico, Albuquerque, NM

Studies have reported clear clinical observations indicating that obesity and diabetes, which often accompany hyperglycemia, are linked to a poor prognosis across various types of cancer. Specifically, multiple clinical studies involving breast cancer patients have demonstrated that hyperglycemia (>7 mM) is associated with an unfavorable prognosis. Despite the evident correlation between elevated glucose levels and cancer metastasis, the causality remains unclear, and the underlying molecular mechanisms are largely unknown.

In both normal and diseased physiology, a broad range of tissue glucose levels has been documented, ranging from normal blood circulation (5.5 mM) to normal tissues (1 - 3 mM) and to tumor tissues (<0.5 mM). Consequently, during the early stages of metastasis, cancer cells undergo a significant increase in extracellular glucose levels.

The capacity of cancer cells to deform and exert contractile force, collectively known as cell mechanics, plays a crucial role in various stages of metastasis. In our previous work, we demonstrated that elevated extracellular glucose levels boost glycolysis and activate the RhoA signaling pathway. This leads to heightened cell stiffness and increased contractility in human triple-negative breast cancer (TNBC) cells. Furthermore, the modified cell mechanics are associated with enhanced cell migration and invasion.

In this study, we present findings indicating that the inhibition of glucose transporter 3 (GLUT3) significantly diminishes the motility of human TNBC cells, including MDA-MB-231 and its highly metastatic variant, MDA-MB-231/HM cells. Mechanistic investigations reveal that GLUT3 inhibition, facilitated by a well-characterized potent GLUT3-selective inhibitor (G3iA), results in reduced glucose uptake and glycolysis. The diminished glycolysis, induced by GLUT3 inhibition, activates 5' AMP-activated protein kinase (AMPK) and enhances the phosphorylation of Yes-associated protein (YAP). Moreover, GLUT3 inhibition leads to a decrease in non-muscle myosin II activity and induces alterations in F-actin rearrangement by influencing actin-binding proteins such as VASP and cofilin. These changes are associated with a reduction in cell migration.

In summary, our results suggest that inhibiting GLUT3 modifies the mechanics of TNBC cells, leading to a decrease in cell motility. Given that GLUT3 is notably elevated in TNBC and is linked to metastatic progression and a poor prognosis in breast cancer patients, our findings underscore the need for further in vivo studies to validate G3iA as a potential anti-metastatic drug in hyperglycemic TNBC animal models.

#5424 Respiratory function linked to *in vivo* metastatic lung cancer progression.

P. Bisoyi, Y. Sei, N. Bennett, K. Nakamura, J. L. Nakamura;
UCSF - University of California San Francisco, San Francisco, CA

Metastases are a major cause of morbidity and mortality in patients with cancer. How metastatic tumors employ metabolic programs to successfully colonize diverse microenvironment is poorly understood. Using an orthotopic xenograft mouse model of lung cancer that develops metastases and recapitulates metastatic lung cancer spread, we injected GFP-LUC-expressing human H1975 lung tumor cells into the left lungs of mice. In vivo bioluminescence imaging was used to visualize tumor growth and metastatic spread for 30 days. Animals were then euthanized and primary and metastatic tumors were collected from different anatomical sites of the body (left lung, right lung, mediastinum, abdominal metastases). Tumor samples were analysed by RNA sequencing analysis. The transcriptomes of lung metastases demonstrated a significant reduction in the expression of genes encoding respiratory pathway protein as compared to the primary lung tumors, suggesting metabolic reprogramming of their respiratory metabolism. CRISPRi-mediated silencing of genes encoding components of respiratory function in human lung cancer cells was associated with significantly increased metastatic spread *in vivo*. These studies suggest the functional importance of respiratory metabolism on modulating *in vivo* disease spread.

#5425 MITF/TFE regulatory programs in neural crest migration are co-opted in melanoma metastasis.

J. Chang[1], K. Campbell[1], R. Moore[1], R. Cornell[2], C. Kenny[1];

[1]University of Iowa Hospitals & Clinics, Iowa City, IA, [2]University of Washington, Seattle, WA

Introduction: Microphthalmia-associated transcription factor (MITF) is a critical regulator of melanocyte differentiation and melanoma oncogenesis. Melanoma expression profiling has revealed a strong trend between low MITF expression levels and invasive behavior. However, it is unclear how low levels of MITF are connected to invasive behavior. Preliminary data from our lab has identified transcription factor E3 (TFE3), a MITF paralog, as a transcriptional regulator in MITF-low melanoma states. We hypothesize that in melanoma cells with low MITF levels, TFE3 promotes invasion. To assess the possibility that the antagonistic regulatory interaction between MITF and a paralog was coopted from the embryo, we examine migratory behavior of neural crest cells in zebrafish embryos that are wild-type, *mitfa* loss-of-function (LOF) mutants, *tfec* (TF3 ortholog) LOF mutants, or *mitfa/tfec* double LOF embryos.
Methods: We evaluated TFE3 levels by Western blot in a panel of melanoma cell lines known to express a range of MITF expression levels. We mutated *TFE3* exon 4, which encodes the DNA binding domain, using a single guide RNA, and assessed cellular invasive potential using an *in vitro* transwell invasion assay. CUT&RUN sequencing was used to profile TFE3 genomic binding. Zebrafish embryos were generated in which the *mitfa* promoter drove expression of RNA encoding green fluorescent protein (GFP), and of the genotypes mentioned above. From transgenic wild-type and *mitfa* LOF mutant embryos we isolated GFP-expressing cells and conducted single cell-RNA sequencing. We assessed migration of GFP-labeled cells by fluorescent microscopy in 20-48 hour post fertilization zebrafish embryos of all genotypes mentioned above.
Results: We found that melanoma cell lines with high levels of *MITF* (SKMEL3 and SKMEL28) had low levels of TFE3 protein, and those with low levels of *MITF* (A375 and RPMI 7952) had high levels of TFE3 protein. The TFE3-high cell lines were more invasive *in vitro* than the TFE3-low cell lines. TFE3-high cell lines depleted of TFE3 were less in invasive *in vitro* than parental cells. CUT&RUN profiling of TFE3 demonstrates that TFE3 binds mesenchymal-like enhancers in MITF-low cell lines. Single cell RNA sequencing revealed that in a melanocyte precursor cluster present in both wild types and in *mitfa* mutants, expression of *tfec* was higher in the latter. Finally, migration of GFP-expressing cells was higher in *mitfa* LOF mutant embryos than in *mitfa/tfec* double LOF mutant embryos.
Conclusion: These data indicate that reduction of MITF expression up-regulates TFE3 expression in melanoma and *tfec* in zebrafish melanocytes, although the mechanism of this regulation is unclear. They also show that TFE3 and Tfec promote migration of metastatic melanoma and melanocyte precursors, respectively. Because regulatory mechanisms in cancer are often coopted from embryonic cells, studying the embryo may illuminate cancer pathogenesis.

#5426 SMC2 orchestrates non-small cell lung cancer proliferation, invasion, and metastasis by modulating the ERK/AKT/NF-κB pathways.

Y. He[1], Z. Luo[2], Y. Wang[2], S. Xiong[2], **R. Wan**[1], X. Zhang[1], H. Bai[1], J. Wang[1];

[1]CAMS Key Laboratory of Translational Research on Lung Cancer, State Key Laboratory of Molecular Oncology, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical , Beijing, China, [2]Southwest Medical University, Luzhou, China

Chromatin instability has been associated with the expression of structural maintenance of chromosomes (SMC) family members and is a common feature in many tumors. SMC family members have been associated with poor outcomes in several cancer types. However, little is known about their functions and mechanisms in promoting cancer progression, particularly in non-small cell lung cancer (NSCLC). Here, we evaluated the expression of SMC family members in the tumor microenvironment of NSCLC specimens using single-cell RNA sequencing analyses. After a survival analysis, it was found that the sole factor associated with a poor prognosis for NSCLC was member SMC2 expression. Immunohistochemistry was used with data from the Human Protein Atlas, the Cancer Genome Atlas, and the Gene Expression Omnibus databases to confirm the overexpression of SMC2 in NSCLC. We demonstrated that SMC2 regulates not only the fluctuations in the critical states of tumor cells, which are defined by different transcriptome and metabolic properties but also coordinates the immunological components and cell-to-cell communications of the immune milieu, potentially through the pleiotrophin and the Galectin pathways. In vitro and in vivo evidence support the pro-metastatic role of SMC2 in NSCLC. Subsequent investigations showed that SMC2 increases NSCLC progression and metastasis via modulating the ERK/AKT/NF-κB pathway and the epithelial-mesenchymal transition process. Our research clarifies the role and potential mechanisms of SMC2 in NSCLC, providing new treatment options and valuable insights for the management of NSCLC.

TUMOR BIOLOGY: Mechanisms of Cancer Cell Stemness and Resistance
Poster Session

#5430 Discovery of CYP26A1 as a link between WNT and retinoic acid signaling pathways that modulates retinoid-induced differentiation of *APC*-mutant colorectal cancer cells.

C. O. B. Facey, V. O. Hunsu, C. Zhang, B. T. Osmond, L. M. Opdenaker, B. M. Boman;
Helen F. Graham Cancer Center & Research Institute, Newark, DE

APC mutation is the main driver mechanism of CRC development and leads to constitutively activated WNT signaling, overpopulation of ALDH+ stem cells (SCs), and incomplete differentiation. We previously reported that retinoic acid (RA) receptors are selectively expressed in ALDH+ SCs, which provides a way to target cancer SCs with retinoids to induce differentiation. We hypothesize that a functional link exists between WNT and RA pathways, and *APC* mutation generates a WNT:RA imbalance that decreases retinoid-induced differentiation and increases ALDH+ SCs. Accordingly, to restore parity in WNT:RA signaling, we induced *wt-APC* expression in *APC*-mutant CRC cells and assessed the ability of all-trans-retinoic acid (ATRA) to induce differentiation. Notably, ATRA substantially increased expression of the WNT-target gene, *CYP26A1*, and inducing *wt-APC* reduced this expression by 50%. Thus, RA and WNT pathways crosstalk to modulate *CYP26A1* metabolism of retinoids and retinoid agents. We found that inducing *wt-APC* augments ATRA-induced cell differentiation by: *i*) decreasing cell proliferation; *ii*) suppressing ALDH1A1 expression; *iii*) decreasing ALDH+ SCs; and *iv*) increasing neuroendocrine cell differentiation. NanoString profiling and bioinformatics also identified a novel *CYP26A1*-based network that links WNT and RA signaling. Moreover, in an effort to translate manipulation of the WNT/RA imbalance as a therapeutic approach *in vitro*, we treated HT29, SW480, and HCT116 CRC cells with inhibitors against CYP26A1 enzyme activity and WNT signaling. We found that CYP26A1 inhibitors sensitized CRC cells to the anti-proliferative effect of drugs that downregulate WNT signaling. Furthermore, decreased CYP26A1 expression in tumor vs normal tissue was determined to be a predictor of patient survival in patients who have *wt-APC*. Thus, by inducing *wt-APC* expression and exogenously activating RA signaling, we found a way to increase differentiation of SCs along the NEC (and other) lineage(s). Translating this strategy *in vivo* might lead to new, more effective treatments involving retinoids for CRC patients.

#5431 Identification of serine/threonine kinase 39 (STK39) as a driver for multidrug resistance in hepatocellular carcinoma.

C. Leung, **T.-W. Lee**;
Hong Kong Polytechnic University, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) is a common type of cancer globally and is associated with a poor prognosis due to its high recurrence rate and resistance to treatment. Solid evidence showed the existence of cancer stem cells (CSCs) that are crucial for therapeutic resistance. However, there are only a few kinase inhibitors that have been found to specifically target liver T-ICs for the HCC treatment. To understand the regulatory mechanism of liver CSCs, we employed RNA-Seq analysis to compare the gene expression profiles, with a particular focus on protein kinases, between (1) sorted CD133$^{\pm}$ liver CSCs and CD133- differentiated cells extracted from two HCC cell lines (Huh7 and PLC8024), as well as cultured hepatospheres and adherent differentiated cells of HCC cell line PLC/PRF/5. Our analysis identified Serine/Threonine kinase 39 (STK39) as a commonly up-regulated protein kinase in both CD133$^{\pm}$ liver CSCs and CSC-enriched hepatospheres. Based on our analysis of the TCGA data, a positive correlation has consistently been observed between STK39 mRNA expression and the expression of liver CSC markers, including CD24, CD133, and CD47. Utilizing publicly available transcriptome datasets from the NCBI Gene Expression Omnibus (GEO), including GSE14520 and GSE25097, we found that overexpression of STK39 is detected in HCC tumor tissues ($p<0.001$) and is significantly associated with poorer overall survival and disease-free survival. Through the use of lentiviral based overexpression and knockdown approaches, we have demonstrated the role of STK39 in regulating liver CSC properties, including self-renewal, tumorigenicity, cell invasiveness, and the expression of liver CSC markers. STK39 expression was found to be significantly elevated in in HCC cells that were resistant to both sorafenib and lenvatinib, and its inhibition resulted in increased sensitivity of HCC cells to these treatments. To identify the downstream target of STK39 for regulation of cancer stemness, tandem affinity purification coupled with mass spectrometry was employed. The analysis led to the identification of PARP1 as a novel protein binding partner of STK39. Upon suppression of STK39 in HCC cells, it was observed that the phosphorylation of PARP1 at Threonine 368 (T368) was significantly inhibited, indicating its role as a downstream effector of STK39-mediated liver CSC functions. Interestingly, STK39-mediated PARP1 phosphorylation led to development of resistance to PARP1 inhibitor, rucaparib. Additionally, STK39 plays a critical role in regulating PARP1-mediated chromatin decondensation, which enables it to open chromatin structure at the promoter regions of SOX2/OCT4. In summary, treatment of molecular targeted drugs including rucaparib and lenvatinib with STK39 inhibitor may be a potential therapeutic strategy for treatment of this deadly disease.

#5432 The role of nuclear factorκB-inducing kinase in ovarian cancer stem cells, chemoresistance, and relapse.

Cassidy C. Lucht, Mikella Robinson, Samuel F. Gilbert, Omar Lujano Olazaba, Carrie D. House

San Diego State University, San Diego, CA

Ovarian cancer is the most lethal gynecological cancer in the United States, largely due to its high relapse rates. Research suggests these high relapse rates are due to cancer stem-like cells (CSCs), a subpopulation of tumor cells that are resistant to chemotherapy and have enhanced tumor-initiation capacity. Post-treatment, CSCs self-renew to re-establish new tumors, leading to recurrent disease that is now resistant to chemotherapy. Given that over-expression of NF-κB has been linked to CSCs, cancer progression, and chemoresistance in various tumors, including ovarian, studies uncovering the mechanisms of this pathway are needed to develop novel therapeutics for ovarian cancer treatment. The upstream activator of the alternative NF-κB pathway, Nuclear Factor κB-inducing Kinase (NIK), could be an enticing target for eliminating CSCs, however its function in these cells is not established. In our current studies, we show that HGSOC cells grown as CSC-enriching 3D spheroids have increased NIK expression and activity relative to monolayer cultured cells. Moreover, cells expressing CSC markers (CD117+/CD133+), have increased NIK gene expression, further supporting an association between NIK and CSC maintenance. Upon treatment with chemotherapies carboplatin and paclitaxel, NIK gene expression increased in the surviving population, indicating a role in chemoresistance. Knockdown of NIK using siRNA led to changes in alternative NF-kB transcriptional activity and higher sensitivity to carboplatin and paclitaxel relative to vehicle controls. Current studies are evaluating the role of NIK in tumor-initiation capacity, asymmetric division, proliferation, and changes in expression of stemness genes. Lastly, an *in vivo* relapse model will test the feasibility of using a NIK inhibitor following chemotherapy to prevent relapse and prolong survival. Findings from this work will further define the role of NF-kB pathway components in facilitating CSCs survival and re-establishment of tumors and identify a new potential target for eliminating CSCs in ovarian cancer.

#5433 Functional involvement of ribosomal protein L9 to colorectal cancer stemness.

E.-H. Jeon[1], K. Park[1], H.-M. Ryoo[2], I. Hwang[1], Y.-H. Lee[1];

[1]Keimyung University Dongsan Medical Center, Daegu, Korea, Republic of, [2]Daegu Catholic University, Daegu, Korea, Republic of

We have previously demonstrated that targeting of ribosomal protein L9 (RPL9) suppresses the growth of colorectal cancer (CRC) via the inactivation of Id-1/NF-κB signaling axis which is known to augment tumor stemness. Thus we aimed in this study to investigate whether the function of RPL9 was associated with CRC stemness properties. It was initially evidenced that inhibition of RPL9 expression reduces the migration and invasion abilities of HT29 parental cell population. We have then sorted out $CD133^{\pm}$ cancer stem cells (CSCs) from HT-29 parental cell culture and treated RPL9-specific siRNAs to the isolated CSCs to observe the effect of RPL9 targeting on stemness. As results, knockdown of RPL9 significantly suppressed the proliferation potential and sphere forming capacity of $CD133^{\pm}$ HT29 CSCs accompanying with the reduction in CD133 and Id-1 levels. Reflecting these molecular alterations, targeting RPL9 also inhibited the abilities of migration and invasion in $CD133^{\pm}$ HT29 CSCs population. Taken together, these findings suggest that RPL9 could be a therapeutic target for both primary CRC treatment and the prevention of metastasis and/or recurrence.

#5434 A novel combination therapy for lung squamous cell carcinoma.

D. Alqasrawi[1], R. Argo[1], C. Ratliff Rang[1], P. Pandya[1], S. Klinge[1], J. Lindemann[2], N. Searl[3], A. Fields[1], V. Justilien[1];
[1]Mayo Clinic Florida, Jacksonville, FL, [2]University of North Florida, Jacksonville, FL, [3]Stanton College Preparatory School, Jacksonville, FL

Lung cancer is the leading cause of cancer deaths in the US. Non-small cell lung cancer (NSCLC) accounts for ~80% of lung cancer cases and is further classified into adenocarcinoma (LUAD), squamous cell carcinoma (LUSC), and large cell carcinoma. New approaches targeting pathways in NSCLC have emerged, resulting in encouraging new treatments that benefit LUAD patients, but very few advances have been made in the treatment options for LUSC which accounts for ~30% of lung cancer cases. NSCLCs, including LUSCs, contain a sub-population of cells that exhibit properties of cancer stem cells (CSCs) and are responsible for tumor initiation, maintenance, therapeutic resistance, and relapse. Therefore, CSCs must be effectively targeted to elicit long lasting therapeutic results in LUSC patients. Our studies have shown that: *1)* PKCι is an oncogene and prognostic marker in LUSC; *2)* copy number gains (CNGs) of the PKCι gene (*PRKCI*) drives overexpression of PKCι in 90% of LUSCs; *3)* PKCι phosphorylates SOX2, and controls SOX2-mediated transcriptional activation of Hedgehog Acyl Transferase, resulting in Hedgehog (Hh) pathway activation that drives a CSC phenotype in LUSC cells; and *4)* the FDA approved compound Auranofin (ANF) is a potent inhibitor of oncogenic PKCι. In this study, we assessed the effect of ANF in combination with the Hh pathway inhibitor, LDE225, on LUSC CSCs and tumor growth. Cell viability, sphere formation and soft agar assays were used to assess the effects of ANF and LDE225 alone or in combination on the growth of LUSC CSCs with *PRKCI* CNGs or LUAD and LUSC CSCs without *PRKCI* CNG to determine if *PRKCI* CNG can be used to predict response to ANF and LDE225 and test the selectivity of response for LUSC. The effects of ANF and LDE225 on the levels of PKCι-Hh signaling components was assessed by qPCR and western blotting. Finally, the efficacy of ANF and LDE225 in combination was evaluated in human primary LUSC patient-derived xenograft (PDX) models that harbor *PRKCI* CNGs and the ability of PKCι-Hh signaling intermediates to serve as biomarkers of PKCι-Hh pathway inhibition was validated *in vivo*. We observed a dose-dependent decrease in cell proliferation, clonal expansion and transformed growth in CSCs treated with ANF and LDE225 alone. ANF and LDE225 combined treatment of LUSC CSCs with *PRKCI* CNGs (but not LUAD or LUSC CSCs without *PRKCI* CNG) synergistically inhibited CSC phenotypes based on results of combination index analysis. Furthermore, treatment of LUSC PDX models with ANF and LDE225 in combination had a synergistic effect on tumor growth inhibition. Lastly, ANF and LDE225 treatment led to inhibition of PKCι-Hh signaling intermediates demonstrating the on-target effects of treatment. Our data indicate that a PKCι-Hh vertical blockade strategy of combined ANF and LDE225 effectively targets LUSC CSCs and blocks tumor growth *in vivo* and provides compelling rationale to develop this novel combination strategy further in clinical trials.

#5435 CUEDC2 involved in the inhibitory effect of dandelion on triple-negative breast cancer stem cells.

X. Deng, Y. Jiao, H. Hao, Z. Guo, D. Xue, **S. Han**;
Peking University Cancer Hospital, Beijing, China

Background: Cancer stem cells (CSCs) exert a substantial influence on the initiation, progression, and metastasis of triple-negative breast cancer (TNBC). Dandelion has exhibited encouraging outcomes in impeding the proliferation of TNBC cells. Nevertheless, the extent of investigation regarding the efficacy of dandelion in targeting CSCs remains restricted.
Purpose: The aim of this study was to investigate the impact of dandelion extract (DE) on CSCs properties.
Methods: *In vitro* experiments were conducted using TNBC cell lines. Mice bearing TNBC tumors were established for *in vivo* investigations. Biochemical analysis and cell biological assay were carried to evaluate the effect of dandelion and the underlying mechanisms.
Results: DE treatment significantly decreased the proportion of ALDH+ cells, mammosphere formation ability, and CSCs-related markers. CUEDC2 is highly expressed in ALDH+ TNBC cells, and its overexpression increased the expression of markers related to CSCs. Conversely, the tumor growth was impeded in CUEDC2 KO mice and the markers related to CSCs also were also reduced. CUEDC2 overexpression reversed the inhibitory effect of DE on TNBC CSCs properties. Mechanistically, CUEDC2 related pathway involved in the inhibitory effect of DE on TNBC CSCs properties.
Conclusion: CUEDC2 played a crucial role in maintaining the stem cell properties of TNBC. DE inhibit the self-renewal of TNBC stem cells by regulating the CUEDC2 related signaling pathway.
Keywords: Dandelion; CUEDC2; Triple-negative breast cancer; Cancer stem cell.

#5436 A therapeutically targetable dysadherin/YAP axis promotes cancer stem features and tumor aggressiveness in hepatocellular carcinoma.

S.-E. Jeon, T.-Y. Jang, C.-J. Lee, H.-J. Yun, Y.-H. Cho, D.-Y. Lim, J.-S. Nam;
Gwangju Institute of Science & Technology, Gwangju, Korea, Republic of

Hepatocellular carcinoma (HCC) remains one of the most challenging tumors to treat. Cancer stem-like cells (CSCs) are believed to be important in HCC development, immune evasion, and treatment resistance. Dysadherin is a cell membrane glycoprotein linked to cancer progression by endowing HCC with CSC features. However, the underlying mechanism of increasing CSC characteristics in refractory advanced HCC is not entirely understood. A comprehensive bioinformatics study revealed that dysadherin-expressing HCC cells were associated with cancer stemness and the YAP signaling activation. Dysadherin knockdown or overexpression in liver cancer cell lines attenuated or increased cancer stemness and aggressiveness via YAP signaling, respectively. Correspondingly, dysadherin deficiency lowered cancer stemness and aggressiveness in the HCC mouse model by blocking the YAP pathway. Mechanistically, dysadherin promoted YAP nuclear localization, which activated stem cell transcription factors such as OCT4, KLF4, and MYC. Of note, our comprehensive gain and loss of function studies in CSCs demonstrated that targeting the dysadherin/YAP axis could boost sorafenib's therapeutic effect and suppress PD-L1 expression, which helps tumor cells escape from immune surveillance. Thus, our results highlight that the dysadherin/YAP axis drives the aggressive phenotype of HCC, providing a potential therapeutic strategy for HCC.

#5437 Chemoproteomics-enabled discovery of covalent inhibitors targeted at AGPAT4: Unravelling tumor lineage plasticity to overcome drug resistance in hepatocellular carcinoma.

K.-Y. Ng[1], T.-Y. Koo[1], T.-L. Fong[1], Y. Gao[1], T.-L. Wong[1], Y. Gao[2], J.-P. Yun[3], X.-Y. Guan[1], M. Liu[4], C. Y. Chung[1], **S. Ma**[1];
[1]The University of Hong Kong, Hong Kong, Hong Kong, [2]Fourth Military Medical University, Xian, China, [3]Sun Yat-Sen University Cancer Centre, Guangzhou, China, [4]Guangzhou Medical University, Guangzhou, China

The liver is a unique organ that is responsible for many metabolic functions. During hepatocellular carcinoma (HCC) development, these metabolic machineries are extensively reprogrammed to support the insatiable nutrient requirements of HCC. Tumor lineage plasticity, a recognized hallmark of cancer, is a phenomenon in which tumor cells co-opt developmental pathways to attain cellular plasticity, enabling them to evade targeted therapeutic interventions. Cancer cells can reprogram their metabolic pathways to match their increased metabolic needs for cancer cell survival under adverse conditions. Identifying novel metabolic targets related to stemness can offer promising strategies for targeting cancer stemness roots and hence to kill and control their growth. Through pathway enrichment analysis of genes that linked metabolism and stemness, we identified an aberrant glycerophospholipid metabolism signature, with AGPAT4 ranking as the top-hit. AGPAT4 upregulation in HCC is strongly correlated with aggressive clinical features, including survival, metastasis, and stemness signatures. AGPAT4 expression peaked during early liver progenitor development, decreased during hepatocyte maturation and progressively increased from well-differentiated to poorly differentiated HCCs. Enrichment of AGPAT4 in HCC is mediated by promoter binding of SOX9 to drive AGPAT4 transcriptional activity. AGPAT4 inhibition can mitigate tumor initiation, self-renewal, metastasis, and sorafenib resistance. Mechanistic studies revealed an AGPAT4-mediated phosphatidic acid production axis that promotes HCC through the regulation of mTOR signaling. Inhibition of Agpat4 by AAV8 shRNA reduced tumorigenicity and stemness, and sensitized HCC tumors to sorafenib. AGPAT4 overexpression can predict sorafenib response in clinical settings. Through chemoproteomics screening of a cysteine-reacting compound library using activity-based protein profiling, a cysteine-reacting compound with high binding affinity and selectivity towards AGPAT4 was identified and found to work synergistically with sorafenib to suppress HCC, as demonstrated in HCC patient-derived tumor xenograft (PDTX) models. Toxicity analysis through histological examination of organs, body weight measurements, and biochemical tests revealed minimal toxicity associated with the covalent inhibitor. In conclusion, AGPAT4 is a novel metabolic driver of oncogenic stemness, dedifferentiation, and metastasis in HCC. AGPAT4-induced tumor lineage plasticity may represent an Achilles heel for HCC treatment, and inhibition of AGPAT4 may widen the therapeutic window for sorafenib treatment in the clinic.

#5438 Circulating tumor cells exhibit a tumor stemness defense phenotype in Head and Neck cancer subjects undergoing cisplatin based chemotherapy.

L. Pathak[1], B. Pal[2], J. Talukdar[1], P. J. Saikia[1], S. Sandhya[1], W. Tasabehji[3], H. Li[3], J. Phukan[4], A. Bhuyan[5], S. Patra[6], B. Das[1];
[1]KaviKrishna Laboratory, Indian Institute of Technology Research Park, Guwahati, India, [2]Thoreau Laboratory for Global Health, UMass, Lowell, MA, USA, Lowell, MA, [3]Forsyth Institute, Cambridge, MA, USA, Cambridge, MA, [4]Guwahati Medical College, Guwahati, India, Guwahati, India, [5]KaviKrishna Telemedicine Care, Sualkuchi, Assam, India, Guwahati, India, [6]Indian Institute of Technology, Guwahati, Guwahati, India

Introduction: We have proposed that tumor has its own defense mechanism similar to an organism having its own defense at the population level. We also proposed that the center of this tumor defense is the hypoxic niche of cancer stem cells (CSCs). Our lab has previously characterized the hypoxic niche of CSCs, and demonstrated that these CSCs reprogram to a highly inflammatory, aggressive and embryonic stemness phenotype during oxidative stress (1). These reprogrammed CSCs, the tumor stemness defense (TSD) phenotype is transient, and exert altruistic defense against bacterial invasion in SCC-25 cell line (2). Further, VEGF/VEGFR1 autocrine signaling was found in cisplatin induced TSD phenotype (4) and Myc/Hif2alpha stemness pathway was found in TSD phenotype of a leukemia stem cell model (3). We hypothesize that the platinum-induced stress may also activate TSD phenotype in the dormant CSC fraction of head and neck squamous cell carcinoma (HNSCC), which may mobilize to the distant tissue via circulation as circulating tumor cells (CTCs).
Methods: To test the hypothesis, we isolated EpCAM+/ABCG2+ CTCs (blood, n=14) and EpCAM+/ABCG2+ CSCs (tumor tissue, n=6/14) of HNSCC subjects under cisplatin treatment. CTCs were collected from peripheral blood mononuclear cells (PBMNC) by the immunomagnetic sorting of EpCAM+ cells, and then cells were expanded in a defined serum free media that we used to maintain the hypoxic CSCs (1). We evaluated the EpCAM+/ABCG2+ CTCs and EpCAM+/ABCG2+ CSCs for TSD phenotype by performing qPCR gene expression, Boyden chamber assay of invasion, clonogenic assay and serial transplantation assay in NOD/SCID mice. Data was compared with the EpCAM+/ABCG2- cell population. We also developed a pre-clinical model of cisplatin-induced reprogramming of HNSCC derived CSCs to understand the molecular mechanisms.
Results: In 8/14 patient derived EpCAM+/ABCG2+ CTCs and EpCAM+/ABCG2+ CSCs showed TSD phenotype associated gene expression, high migration/invasion, self sufficiency (ability to form spheroid when grown in serum free media without growth factors), enhanced secretion of protumorigenic growth factors; VEGF, SDF-1, PIGF, and HMGB1. These CTCs and CSCs have shown tumor formation with significant CSC frequency, when injected to NOD/SCID mice. Finally, using a SCC-25 cell line derived pre-clinical model, we demonstrated that cisplatin therapy reprogram CSCs to TSD phenotype.
Conclusion: Our work indicates that CTCs with TSD phenotype may indicate the interaction between cisplatin and CSC niche defense. Using the pre-clinical model, the TSD phenotype based CSC niche defense mechanism may be further explored to develop markers for therapy response, metastasis or recurrence in HNSCC.

#5439 Metastasis-enhancing protein KITENIN confers temozolomide resistance in glioblastoma with unmethylated MGMT via upregulation of cancer stem cell makers.

E.-J. Ahn[1], Y. Kim[1], T.-Y. Jung[1], J.-H. Lee[1], J. Rhee[1], K.-K. Kim[1], S. Kim[1], N. Kim[1], H. Kim[2], K.-S. Moon[1], **K.-H. Lee**[1];
[1]Chonnam National University Medical School, Jeollanam-do, Korea, Republic of, [2]Sunchon National University, Sunchon, Korea, Republic of

Background: Elevated expression of cancer stem cell (CSC) markers is linked with progression, poor survival, and treatment resistance in glioblastoma (GBM). Our prior work identified KAI1 COOH-terminal interacting tetraspanin (KITENIN) as key to GBM progression. We investigated its influence on temozolomide (TMZ) resistance in GBM through modulation of CSC markers.
Methods: We examined KITENIN and CSC markers in TMZ-resistant GBM cells and patient-derived GBM cells, and assessed therapeutic responses to TMZ in mice implanted with KITENIN-modulated GBM cells. The correlation of these markers with clinical outcomes was analyzed using our cohort and The Cancer Genome Atlas (TCGA) data.
Results: High KITENIN expression correlated positively with elevated CSC marker levels in human GBM samples and KITENIN-modulated GBM cells. Inhibition of KITENIN using usnic acid reduced tumor progression by decreasing CSC marker expression. Our data and TCGA analyses linked co-directional increase of these factors with tumor recurrence and shorter survival in GBM patients with unmethylated MGMT. This increase was also observed in TMZ-resistant cell lines with unmethylated MGMT. Implantation of KITENIN-overexpressing cells led to TMZ resistance in our mouse model, associated with co-directionally increased CD44 and ALDH1A1 expression. The link between KITENIN and CD44/ALDH1A1 could be inhibited by DKC2511, a novel KITENIN inhibitor, and T5244, a c-Fos/AP-1 inhibitor.
Conclusion: KITENIN might contribute to TMZ resistance in GBM patients with unmethylated MGMT, potentially through AP-1 activation and subsequent upregulation of CSC markers. Hence, targeting KITENIN could provide a novel strategy to overcome TMZ resistance in GBM patients with unmethylated MGMT.

#5440 TM4SF1 maintains cancer stemness in cholangiocarcinoma.

X. Zhu[1], J. Golino[1], X. Wang[2], C. Xie[3];
[1]NIH/NCI, Bethesda, MD, [2]Albert Einstein College of Medicine, New York City, NY, [3]NIH/NCI/CCR, Bethesda, MD

Cholangiocarcinoma (CCA) is an aggressive liver malignancy with increased incidence globally but poor prognosis. Cancer stemness plays critical roles on tumor initiation, recurrence, and resistance to therapy. However, the mechanism of stemness maintenance in CCA has been less explored. Previously, we have reported TM4SF1 is associated with poor survival in CCA and high expression of TM4SF1 tends to promote tumorigenesis. In this study, we found that the expression of TM4SF1 gene is upregulated in tumor tissues compared to adjacent normal tissues in CCA based on bulk RNA sequencing dataset from The Cancer Genome Atlas (TGCA) CCA cohort. There is a positive correlation between the expression of TM4SF1 and stemness genes, ITGB3, SOX9, ALDH1A3, and ITGB1. Interestingly, knockdown of TM4SF1 with siRNA in CCA cell line HuCCT-1 cells demonstrated a decrease in expression of cancer stem cell surface markers, CD24 and Prom1. Furthermore, with a CRISPR-based lentivirus construct to knockdown TM4SF1 gene in HuCCT-1 cells *in vitro*, we found that spheroid formation in TM4SF1 knockdown was attenuated in comparison to TM4SF1 wild type. In addition, the results from flow cytometry and RT-PCR showed a corresponding decrease in CD24 and CD133 expression with TM4SF1 knockdown when comparing to TM4SF1 wild type. In conclusion, TM4SF1 is associated with the stemness of CCA and could be a therapeutic target for CCA therapy to overcome therapy resistance in future.

#5441 Down regulation of cysteine glutamate antiporter in ALDH1A1 expressing oral and breast cancer stem cells induced oxidative stress triggered ferroptosis.

R. Bellala;
Gitam University, Visakhapatnam, India

Background: Sulfasalazine, an xCT inhibitor, is being used as a repurposed antineoplastic drug to induce ferroptosis. Ferroptosis is a regulated necrotic cell death pathway that is dependent on iron reserves. Interestingly, cancer stem cells (CSCs) that are regarded as major drivers of resistance to conventional therapies accompanied with tumor relapse and recurrence have bulk amount of iron reserves in the form of ferritin. This suggests that inducing ferroptosis might disrupt stemness and drug resistant mechanisms in cancer stem cells, thereby reducing the risk of drug resistance, cancer recurrence, and relapse.
Materials & Methods**:** In the present study, ALDH1A1 expressing oral (OCSCs) and breast (BCSCs) cancer stem cells were sorted and used to investigate the role of sulfasalazine to induce ferroptosis. To check the self-renewability of CSCs spheroid formation assay was performed and the resultant CSCs were treated with sulfasalazine (SAS) and subjected to gene expression analysis RT PCR and flow cytometry. FACS was performed to check stem cell marker expression, cell cycle arrest, and apoptosis.
Results**:** Our results suggest that the cells showed a gradual increase in sphere formation till S3 in the case of OCSCs and S2 in the case of BCSCs, with a gradual decrease in sphere forming efficiency from the respective generations. When treated with 0.6mM SAS, these cells induced ferroptosis by downregulating stem cell markers like ALDH1A1, SLC7A11, ferritin, and GPx 4 with a concomitant increase in transferrin and STEAP 3. Flow cytometry studies revealed that the cells have undergone mitochondrial dysfunction characterized by loss of membrane potential and the cell cycle progression was halted in the G2/M phase.
Conclusion**:** In the present study, we demonstrate that SAS potentially induced ferroptosis accompanied with oxidative stress in both OCSCs as well as BCSCs by lowering GPx 4 activity, a key enzyme that scavenges the products produced as a result of oxidative stress.

#5442 Tert^{high}cells: key players in salivary gland homeostasis and regeneration after radiation therapy in adult mice.

L. Guan[1], V. Viswanathan[1], S. V[1], H. Cao[1], Y. Jiang[1], J. Zhao[2], D. R. C. Colburg[1], P. T. Neuhoefer[1], Y. Xu[1], E. E. Laseinde[1], S. Artandi[1], Q.-T. Le[1]; [1]Stanford University, Stanford, CA, [2]Columbia University, New York, NY

Salivary gland homeostasis and regeneration post-radiotherapy depend significantly on stem/progenitor cells. However, the lineage of SMG progenitor cells is not as well defined as in other normal organs, and better understanding of this population would be important for their future clinical application for tissue regeneration. Using a mouse strain expressing regulated CreERT2 recombinase from the endogenous Tert locus, we identify a distinct Tert^{high} cell population that are located in the ductal region throughout the submandibular gland (SMG), express ASCL3 (another progenitor cell marker) and can give rise to ductal cells during homeostasis. In contrast, Tert^{high} cells are found to repopulate both ductal and acinar cells at one year of tracing after radiotherapy. Tert^{high} cells from adult SMG retain self-renewal capacity when subjected *in vitro* culture, are resistant to radiation cell kill, and display enhanced proliferative activity post-radiation. Similarly, primary human SMG cells with high Tert expression display enhanced cell survival after radiotherapy. RNA sequencing reveals upregulation of the cell cycling and oxidative stress response pathways these cells after radiation. Mechanistically, Tert appears to modulate cell survival and ROS level in SMG spheres following radiation damage. Collectively, these data suggest that Tert^{high} cells constitute a novel subset of SMG progenitor cells located throughout the ductal region of the gland that can help to repopulate both ductal and acinar cells after RT damage.

#5443 Identifying key regulators of glioblastoma cancer stem cells.

T. Wang, X. Xie, L. F. Parada;
Memorial Sloan Kettering Cancer Center, New York, NY

Glioblastoma multiforme (GBM) has a dire prognosis that has had little progress over the past three decades. The existence of a unique population of stem-like gene signature baring quiescent cells (GSCs) within GBM are important for GBM tumorigenesis, therapy-resistance and recurrence. Our lab has developed one of the most faithful genetically engineered mouse models, encompassing a *Nestin* promoter-enhancer driven CreER^{T2}-H2BeGFP-hDTR cassette (hereafter as *CGD*), that allows us to accurately capture and isolate GSCs in mouse GBM. The next logical step is to leverage these tools to uncover therapeutic vulnerabilities of GSCs and make a meaningful impact on GBM patient outcomes. To our knowledge, very few studies have explored the functional regulators of GSCs using a CRISPR/Cas9 screening approach. Our GSC signature provides a strong foundation for performing targeted *in vitro* or *in vivo* screens. In this study, to identify functionally important genes that may regulate GSC self-renewal and tumorigenic properties, an *in vitro* CRISPR knockout screens using a gene library derived from the GSC signature. The viral library was applied to low passage primary cultures of FACS sorted CGD_GFP+ and CGD_GFP- GBM cells developed from *CGD; Nf1*$^{f/+}$*;Trp53*$^{f/f}$*;Pten*$^{f/+}$ mice, respectively. The result of our *in vitro* CRISPR knock-out screen demonstrated guide depletion of *Atp1b2*-sgRNA in CGD_GFP+ but not in CGD_GFP- cells. The main objective of this study is to utilize *in vitro* and *in vivo* functional assays to test the difference between *Atp1b2* WT and *Atp1b2* KO GSCs and *Atp1b2* WT vs KO GSC-derived tumors. Having a targeted candidate gene list is also particularly helpful for designing an *in vivo* CRISPR knockout screen, which is more physiological relevant. Therefore, I propose to use the candidate gene list derived from the *in vitro* screen as a starting point. The in vivo screen can provide valuable insights for the selection of the most optimal candidates for anti-GSC therapies.

#5444 EGFR missense mutation(s) induce OLIG2 expression to regulate glioma stem cells maintenance and therapeutic resistance.

S. Weaver[1], A. Miller[1], M. Blomquist[1], J. McNamara[2], K. Orndorff[2], C. Sereduk[1], J. Kloss[1], J. Loftus[1], S. Mehta[2], N. L. Tran[1];
[1]Mayo Clinic Arizona, Scottsdale, AZ, [2]Barrow Neurological Institute, Phoenix, AZ

Glioblastoma (GBM) tumors contain a subpopulation of glioma stem cells (GSC) which can escape therapeutic effects through self-renewal and invasion. Epidermal growth factor receptor (EGFR) mutations are the most common alteration in GBM (50%). One example includes extracellular domain missense mutations like G598V, A289V, and R108K (10-15%). These extracellular domain missense mutations increase ligand binding affinity, inducing a highly active receptor. Earlier reports have shown these EGFR missense mutations exhibit therapeutic resistance; however, the molecular mechanism of these missense mutations in GBM remains unknown. In this study, we show high oligodendrocyte transcription factor 2 (OLIG2) expression in GSCs with EGFR-G598V and EGFR-A289V missense mutations. OLIG2 is universally expressed in glioma and essential for reprogramming GBM cells into stem-like tumor cells. Here, we report GSCs with these point mutations display increased self-renewal, growth, invasion, and therapeutic resistance. In addition, EGFR-G598V and EGFR-A289V trigger distinct downstream signaling pathways in GSCs to regulate OLIG2 function. These missense mutation(s) also represent different pathway-based GBM subclassifications, where A289V induces a Neuronal subtype and G598V induces a Glycolytic/Plurimetabolic subtype. We hypothesize that GBM tumors harboring EGFR missense mutations (G598V, A289V) influence stem cell properties *via* multiple pathways to evade therapeutic effects and inhibiting these different signaling pathways will decrease therapeutic resistance in GBM. Understanding the mechanism of these EGFR mutations may lead to improved therapeutic strategies for GBM patients.

#5445 Unravelling the molecular mechanisms of stemness in small cell lung cancer using an iPSC-based approach.

S. Gara[1], H. Wang[1], A. Singh[1], T. Tolunay[1], V. Shukla[2], R. Wang[1], M. Zhang[1], S. Shiffka[1], D. S. Schrump[1];
[1]National Cancer Institute, Bethesda, MD, [2]FDA, White Oak, MD

Introduction: The cancer stem cell hypothesis explains the heterogeneity, drug resistance, and metastatic potential of Small Cell Lung Cancer (SCLC). To address limited surgical tissue availability, we developed an induced pluripotent stem cell (iPSC) model for investigating SCLC stemness mechanisms and potential novel therapies. Cigarette smoke condensates (CSC) have previously been linked to stem cell activation in lung epithelial cells. We aimed to transform normal lung iPSCs (Lu-iPSC) through prolonged CSC exposure to identify candidate genes in the transition to cancer stem cells.
Methods: Four Lu-iPSC clones derived from normal human small airway epithelial cells (SAEC) of two healthy donors were exposed to CSC at different concentrations for short- (7 days) and long-term (6 months) periods. RNA-seq was performed to identify differentially expressed genes (DEGs) relative to respective SAEC. Gene expression data of 23 SCLC cell lines and 38 NSCLC from the public databases was extracted and analyzed relative to SAEC. In vitro tri-lineage differentiation studies, drug sensitivity assays, and phenotypic characterization by flow cytometry was performed in this study.
Results: Gene expression profiles of Lu-iPSCs closely resembled those of SCLC rather than NSCLC. Short-term CSC exposure reduced Lu-iPSC proliferation while increasing the expression of key stemness markers such as SALL1 in a dose-dependent manner. Concurrently, CSC exposure downregulated the expression of nodal and its inhibitors, LEFTY1 and LEFTY2, which can be considered as the earliest signs of differentiation events in Lu-iPSC. Long term CSC exposure induced expression of epithelial mesenchymal transition markers including ZEB1 and ZEB2. In-vitro trilineage differentiation studies revealed that CSC particularly decreased expression of endodermal lineage specific markers (GATA4, SOX17, and FOXA2) without affecting mesodermal and ectodermal markers. Importantly, CSC induced the phenotypic expression of several lung cancer stem cell markers (CD44, CD133, and CD338) along with resistance to cisplatin and topotecan. RNA seq analysis of long-term CSC exposed Lu-iPSCs identified 92 common DEGs (53 up and 39 down) relative to their controls. Gene set enrichment analysis on DEGs indicated upregulation of Notch signaling, IGFBPs, TGF beta receptor signaling, and NCAM1 interactions while GABA receptor activation and GPCR signaling were downregulated. Comprehensive RNA seq analysis of CSC exposed and unexposed Lu-iPSCs relative to SCLC and NSCLC, identified potential candidate genes associated with SCLC stemness.
Conclusion: Our findings suggest that this iPSC model shows promise for investigating mechanisms mediating stemness in SCLC and identifying candidate genes and their associated pathways as potential targets for preclinical development of novel treatment regimens for these highly lethal neoplasms.

#5446 The role of snoRNAs in GBM cells, GSCs, neuronal precursor cells (NPCs), astrocytes, and normal brain tissues.

S. Chatterjee[1], S. Kuersten[1], C. Middle[1], M. Roos[1], P. A. F. Galante[2], G. Guardia[2], L. Penalva[3];
[1]Illumina, Inc., San Diego, CA, [2]Instituto Sirio-Libanes de Ensino e Pesquisa, Sao Paulo, Brazil, [3]UT Health San Antonio, San Antonio, TX

rRNA modification are a crucial step in ribosome assembly and function. Small nucleolar RNAs select which nucleotides in rRNAs get modified. Typically, C/D box snoRNAs are implicated in 2'-O-ribose methylation (2'Omet) while H/ACA box snoRNAs are responsible for pseudo-uridylations. Alterations in snoRNA expression have been described in multiple tumor types while distinct snoRNAs have been linked to cancer-relevant phenotypes. Our initial study on snoRNA expression using a dedicated Ampliseq platform revealed a specific glioma stem cell (GSC) signature. We propose this snoRNA signature creates a unique rRNA modification pattern that shapes the ribosome, favoring the translation of genes in pathways critical for GSC growth and survival. We will expand our study and characterize the expression profile of snoRNAs and 2'Omethylation in a large panel of GBM cells, GSCs, neuronal precursor cells (NPCs), astrocytes, and normal brain tissues. Next, we will select snoRNAs displaying differential expression in GSCs and determine if changes in their levels affect proliferation, viability, response to temozolomide and radiation, and translation. We and others have observed that the integrity of protein complexes that regulate ribosomal biogenesis depends on PolyADP-ribosylation (PARylation)and PAR-binding. In agreement, genomic screenings determined that multiple genes regulating ribosome biogenesis confer sensitivity to PARP inhibitors. These findings offer a therapeutic opportunity. We will investigate the functional impact of PARylation on rRNA modification by determining the effect of PARP inhibitors on snoRNP assembly and 2'Omethylation. Finally, we will test the hypothesis that PARP and ribosome biogenesis inhibitor combinations would be more effective than PARP inhibition alone in treating GBM.

#5447 Microtubule-associated protein MAP2 promotes drug resistance and cancer stemness in hepatocellular carcinoma through integrin dysregulation.

Ut Kei Lou[1], Ka-Hei Lam[1], Huajian Yu[1], Jia Jian Loh[1], Ki-Fong Man[1], Lei Zhou[2], Yuan Gao[3], Tin-Lok Wong[1], Cheng-Han Yu[1], Stephanie Ma[1]

[1]School of Biomedical Sciences, Li Ka Shing Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong,[2]Precision Medicine Institute, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China,[3]State Key Laboratory of Cancer Biology, Biotechnology Center, School of Pharmacy, Fourth Military Medical University, Xi'an, China

Integrins are adhesion molecules that mediate mechanical and chemical signal transduction pathways to support cell survival and proliferation. Dysregulated integrin signaling empowers tumor cells to drive oncogenic stemness functions, including tumor initiation, epithelial plasticity, metastatic reactivation, and resistance to therapies. However, the interplay between cancer stemness and integrin signaling in hepatocellular carcinoma (HCC) remains poorly understood. HCC cells marked by CD133 represent an important functional subset of HCC tumors, displaying a dedifferentiated status with stem cell traits. In this study, transcriptome profiling reveals specific downregulation of integrin α family genes and integrin signaling in 'HCC' CD133^{+} cells isolated from NRAS+AKT-driven HCC, but not epithelial-specific 'normal' CD133^{+} cells isolated from regenerating liver. Of note, one of the most differentially upregulated genes identified in CD133^{+} HCC cell profiling, microtubule-associated protein MAP2, demonstrates the ability to suppress integrin expression. MAP2 overexpression is frequently observed in HCC and correlates with aggressive clinical and stemness features, including survival, tumor stage, and stemness signatures. Epigenetic modifications by H3K27Ac contribute to MAP2 upregulation. Functionally, MAP2 promotes cancer stemness and cell invasion, and confers resistance to the targeted therapy sorafenib. Mechanistically, the inhibition of collagen-binding integrin α subunits by MAP2 subsequently ablates integrin β1-mediated cell adhesion and FAK signaling. Estramustine Phosphate (EMP), previously reported to inhibit the interaction of MAP2 with actin filaments, attains a synergistic effect in suppressing tumor initiation and growth of HCC cell lines, HCC patient-derived organoids and NRAS+AKT HCC mouse model when used in combination with sorafenib. In summary, MAP2 inhibition may represent a potential novel therapy for HCC by targeting its cancer stemness roots and altering integrin signaling. Ongoing work is focused on the study of MAP2 regulation of integrin signaling and cell behaviours in the maintenance of a more stemness state in HCC.

#5448 Malignant RNA editing by inflammation-responsive RNA editase ADAR1 drives T-cell leukemia relapse via attenuating dsRNA sensing.

M. D. Rivera[1], H. Zhang[1], Q. Zhou[1], J. Pham[1], J. Isquith[1], R. Sasik[1], A. Mark[1], S. Enlund[2], F. Holm[2], M. Wenxue[1], K. Fisch[1], D. Kuo[1], C. Jamieson[1], Q. Jiang[1];

[1]UC San Diego, San Diego, CA, [2]Karolinska Institutet, Stockholm, Sweden

Leukemia-initiating cells (LICs) play a crucial role in leukemia research and treatment, being considered the source of relapse and resistance, posing a substantial challenge for successful management of the disease. It's crucial to identify the key factors that drive LIC self-renewal to develop targeted methods for eliminating LICs and preventing relapse. In this study, we demonstrate that the RNA editing enzyme ADAR1 plays a vital role as a determinant of stemness, promoting LIC self-renewal by reducing the detection of abnormal double-stranded RNA (dsRNA). As a result, ADAR1-knockdown significantly impairs the ability of LICs to self-renew and extends survival in T-ALL PDX models. We performed RNA-seq studies on enriched T-ALL LICs (CD34+Lin-). The lentivirus-to-cell ratio was optimized to achieve a 50% reduction in ADAR1, resulting in differential expression of 661 genes, with downregulation of critical self-renewal genes in ADAR1-deficient leukemia-initiating cells. Importantly, additional data indicated that ADAR1 likely influences self-renewal gene expression independently of A-to-I RNA editing, revealing novel regulatory mechanisms in leukemia. Knockdown of MDA5 and ADAR1 in patient-derived xenograft (PDX) T-ALL leukemia-initiating cells (LICs) revealed diverse rescue effects on self-renewal in different PDX models. The differential response was associated with variations in gene expression patterns in Rig-I-Like signaling and cytosolic sensing pathways, suggesting intrinsic differences in IFN signaling properties among patients. Moreover, the study proposes a patient-specific reliance on the ADAR1 p150-MDA5 axis for promoting self-renewal, as evidenced by differential rescue effects and varying expression levels of ADAR1 isoforms and MDA5 in T-ALL patient samples and cell lines. ADAR1, beyond its role in RNA editing, acts as a dsRNA binding protein, exerting RNA editing-independent functions to suppress aberrant IFN signaling and promote cancer progression. Using Jurkat cells with high intrinsic MDA5 levels, an ADAR1 knockout (KO) was generated, revealing that ADAR1 is upregulated by IFN treatment, predominantly the p150 isoform. We explored the dual roles of ADAR1—RNA editing-dependent and -independent—in suppressing IFN-induced apoptosis, demonstrating the necessity of both for optimal function. Additionally, ADAR1 was found to suppress cytoplasmic dsRNA sensing pathways, such as RIG-I and PKR, and its RNA editing-independent activity contributes significantly to the suppression of interferon-stimulated gene (ISG) expression in T-ALL. In summary, our findings reveal that ADAR1 acts as a factor that promotes self-renewal while limiting the recognition of naturally occurring dsRNA. Therefore, targeting ADAR1 emerges as a safe and effective therapeutic approach for eradicating LICs in T-ALL.

#5449 Exploring signaling pathways essential for stemness and metastasis of colorectal cancer cells.

T. Fujishita[1], M. M. Taketo[2], **M. Aoki**[1];
[1]Aichi Cancer Center Research Institute, Nagoya, Japan, [2]Kyoto University Hospital-iACT, Kyoto, Japan

The prognosis of colorectal cancer (CRC) patients with distant metastasis remains poor, requiring elucidation of molecular mechanisms and identification of therapeutic targets. While cancer stem cells have been implicated in metastasis, recurrence, and drug resistance, our understanding of the regulatory mechanisms governing the stemness of CRC stem cells remains largely incomplete. In this study, we utilized an innovative autochthonous metastatic mouse model of CRCs generated by the introduction of sporadic mutations in *Ctnnb1*, *Kras*, *Trp53*, and *Smad4* genes (CKPS mice) and CRC cell lines derived from the mice (CKPS cells). Our investigation revealed that the cAMP/PKA/CREB and TGFβ/SMAD4 pathways play a positive and negative role, respectively, in the sphere-forming and metastasis-initiating ability of CRC cells. Treatment with the CREB inhibitor 666-15 or the genetic knockout of CREB significantly reduced the spheroid-forming and metastasis-initiating potentials of CKPS cells. Intriguingly, we observed that the irinotecan treatment induced CREB phosphorylation in liver metastases, and co-treatment of 666-15 greatly potentiated the inhibitory effect of irinotecan on liver metastasis. Furthermore, we found that the transition from 2D to 3D spheroid culture of CKPS cells led to the induction of RhoC expression. Notably, RhoC knockout in CKPS cells effectively suppressed spheroid formation *in vitro* and inhibited metastasis formation in an intrasplenic injection liver metastasis assay. Potential therapeutic implications of these findings will be discussed.

#5451 FOXC2 influences EMT-induced stem cell properties through regulation of FABP4 in breast cancer.

B. R. Demestichas[1], V. Shivakumar[2], E. Ramirez-Pena[2], J. Taube[3], P. den Hollander[1], S. A. Mani[1];
[1]Brown University, Providence, RI, [2]MD Anderson Cancer Center, Houston, TX, [3]Baylor University, Waco, TX

Cancer stem cells (CSCs) pose a significant clinical challenge due to their inherent resistance to therapies and prevalence in cancer recurrence. CSCs have the ability for self-renewal and to adapt to different microenvironments during dissemination and seeding into distal organs, and these properties are critical in metastasis. We and others have shown that epithelial to mesenchymal transition (EMT) drives the acquisition of stem cell properties, particularly via the forkhead box protein C2 (FOXC2) transcription factor. FOXC2 is a master regulator of EMT and is necessary for the induction and maintenance of CSC properties. Importantly, FOXC2 is not expressed in most adult tissues except adipocytes, in which it dictates several aspects of lipid metabolism. Additionally, metabolic changes during EMT can equip cancer cells with enhanced survival mechanisms during tumor progression and metastasis. We hypothesized that FOXC2 regulates metabolism in EMT-induced cells, facilitating stem cell properties and metastatic competence.

To determine the downstream metabolic genes regulated by FOXC2 and that enhance stemness properties in cancer cells, we performed gene expression profiling and identified fatty acid binding protein 4 (FABP4), which is known to be involved in lipid metabolism, especially in adipocytes and macrophages. We demonstrate that inhibition of FOXC2 expression using shRNA in EMT-induced cells markedly reduces FABP4 expression. In agreement with this, we found that the overexpression of FOXC2 expression rescues the expression of FABP4. In addition, FOXC2 binds to the FABP4 promoter and regulates its expression suggesting that FABP4 is a direct target of FOXC2. We demonstrate that both lipid uptake and CSC formation is inhibited in a dose-dependent manner using a FABP4-specific small molecule inhibitor. Additional experiments are underway to assess the role of FABP4 in CSC formation in vivo and in contributions to metastasis, using our small molecule inhibitor in mouse models of metastatic breast cancer.

Overall, our data indicate that FABP4 is a key regulator of stemness in breast cancer cells and targeting the FOXC2—FABP4 axis may provide therapeutic benefits for breast cancer. This work also provides insights into the metabolic shifts that occur during EMT and CSC formation, which warrants further investigation into these mechanisms.

#5452 AXIN2 differentially modulates stem cell subpopulations providing a potential therapeutic opportunity for targeting colorectal cancer stem cells.

C. Zhang, C. O. B. Facey, L. M. Opdenaker, B. M. Boman;
Helen F. Graham Cancer Center & Research Institute, Newark, DE

Constitutively activated WNT-signaling promotes stem cell (SC) overpopulation which drives most colorectal cancer (CRC) development. It is not known, however, how WNT-signaling activity regulates different SC sub-populations. We previously reported that SC population size decreases as AXIN2 is knocked down, and increases when AXIN2 is overexpressed. Changes in cell cycle and apoptotic rate were also observed. Here, we present our recent results on changes between different SC subpopulations (ALDH+ *vs.* LGR5+) that occur due to AXIN2 modulation. We *hypothesize* that modulation of AXIN2 promotes differential expansion between different CRC SC subpopulations (ALDH+ and LGR5+). We observed that AXIN2 not only increases LGR5+ SC population size, but also expands the ALDH+ SC population to a greater extent as shown by an increased ALDH+-to-LGR5+ SCs ratio. This indicates that AXIN2, via WNT signaling, regulates SC population size, particularly ALDH+ SCs. Since the ALDH SC marker is also a key component in the retinoic acid (RA) signaling pathway, we surmised that increased AXIN2 would not only lead to elevated ALDH levels, but also upregulate the RA-signaling pathway components in CRC cells. To this end, we conducted NanoString mRNA profiling to study the effects of *AXIN2* knockdown and overexpression in HT29 and SW480 CRC cells. The results showed that increased AXIN2 significantly up-regulated several key components of the RA-signaling pathway. Taken together, our results indicate that AXIN2 drives a shift in SC subpopulation sizes favoring the ALDH+ SCs. It also promotes the RA-signaling component expression - a pathway known to regulate SC differentiation. As a potential treatment strategy for CRC, therapeutically inducing high levels of AXIN2 could shift the balance between SC populations towards ALDH+ SCs, which may provide a way to target cancer SCs with retinoids to induce their differentiation.

TUMOR BIOLOGY: Pediatric Cancer Microenviroment, Tumor Heterogeneity, and Targeted Therapeutics
Poster Session

#5456 Identifying the role of tissue factor in osteosarcoma metastasis.
C. C. Treinen, A. Gross, M. Cam, B. Kerlin, R. Roberts;
Nationwide Children's Hospital, Columbus, OH

Patients with osteosarcoma who develop metastasis face very poor prognoses. Even when treated with the most effective medical and surgical interventions available, about forty percent of osteosarcoma patients will eventually succumb to lung metastasis. Despite the relevance of metastasis to clinical outcomes, we understand little about the mechanisms that drive these tumor cells into the lung and facilitate their metastatic growth. Consequently, there are no approved antimetastatic agents for osteosarcoma and outcomes have not improved in more than 40 years. Tissue factor is a tightly regulated physiologic initiator of coagulation with functions in inflammation, cytokinesis, angiogenesis, apoptosis, and growth factor secretion. These functions are divided between two separate pathways: initiation of the coagulation cascade via activation of factors VII and X, and propagation of cell signaling pathways via PAR activation. It is aberrantly expressed in many cancers and has been associated with metastatic behavior and inferior outcomes by affecting metastatic vascularity, growth, and migration. Osteosarcoma has been shown to also aberrantly express tissue factor, with descriptive studies suggesting similar effects on metastatic behavior. We hypothesized that tissue factor expressed on the surface of disseminated osteosarcoma cells activates procoagulant pathways and PAR signaling, and that both facilitate pulmonary metastasis. To test this, we first established and quantified expression of tissue factor across six osteosarcoma cell lines using Western blot, flow cytometry, and confocal microscopy in both monoculture and in coculture with human bronchial epithelial cells. PAR1 and PAR2 were also discovered to be expressed in osteosarcoma cells. RNA sequencing performed suggests that both tissue factor and PAR1 expression in osteosarcoma increase over the metastatic period, as does FVII expression by alveolar macrophages; this implies that tissue factor activation during metastasis is dynamic and dependent on host interactions. Ongoing work includes functional assays of osteosarcoma tissue factor and PARs activity as well as preclinical testing of tissue factor inhibition in a murine xenograft model of osteosarcoma. To define how tissue factor propagates metastasis, we are separately inhibiting its coagulant and cell signaling pathways after murine tail vein injection using apixaban or pathway-specific antibodies. We will also use an inducible F3 knockout to alter tumor expression of tissue factor. If we find that manipulation of tissue factor expression changes metastatic behavior across cell lines, this will suggest that tissue factor plays a crucial, mechanistic role in osteosarcoma metastasis. Varying effectiveness of coagulation or signaling pathway inhibition on metastasis will implicate tissue factor's mechanism of metastatic propagation.

#5457 Inflammatory paracrine loops established between metastasis-initiating cells and alveolar epithelium drive interactions between tumor cell subtypes that are essential for osteosarcoma lung colonization.

Amy C. Gross[1], James B. Reinecke[1], Amanda Saraf[2], John Hinckley[3], Maren Cam[1], Matthew V. Cannon[1], Sophia Vatelle[1], Ryan D. Roberts[1]

[1]Nationwide Children's Hospital, Columbus, OH,[2]Riley Children's Health, Indianapolis, IN,[3]Battelle, Columbus, OH

Introduction: The development of lung metastasis drives the poor outcomes experienced by children and young adults with osteosarcoma. The mechanisms that facilitate metastatic colonization remain poorly understood. We previously determined that IL6 and CXCL8 are two osteosarcoma derived cytokines that are required for metastasis, though roles played by these cytokines have not been identified.
Methods: To explore the interactions that drive cytokine expression, the role these factors play in tumor cell trafficking, and the mechanisms that facilitate metastatic niche development, we utilized transwell and co-culture systems together with a panel of metastatic osteosarcoma mouse models that allowed tumor cell manipulation via lentiviruses, CRISPR-based gene editing, and pre-clinical therapeutic evaluation approaches.
Results: While metastatic osteosarcoma cells produced small amounts of IL6 and CXCL8 at baseline, lung epithelial cells markedly upregulated IL6/CXCL8 production. Ligand-receptor analysis utilizing single-cell transcriptomic data identified IL1 as an epithelial derived ligand that drives tumor IL6/CXCL8 production. Interestingly, IL6/CXCL8 production was limited to a small subset of hypo-proliferative osteosarcoma cells that have metastasis-initiating capacity. Utilizing CRISPR-mediated ablation of IL1R1 signaling within osteosarcoma cells and pharmacological inhibition with recombinant IL1R antagonist (anakinra), we elucidated that formation of pulmonary lesions in multiple mouse models of metastatic osteosarcoma required IL1 signaling. Recent work from our lab has demonstrated that osteosarcoma metastases are defined by marked phenotypic heterogeneity, though the mechanisms by which metastatic heterogeneity occurred were unclear. We hypothesized that hypo-proliferative metastasis-initiating cells may recruit circulating cells with higher proliferative capacity to establish phenotypic heterogeneity. Transwell migration assays showed that tumor cells induced the chemotactic recruitment of other tumor cells in an IL6/CXCL8-dependent manner. To test this hypothesis *in vivo*, we injected mice with GFP-tagged osteosarcoma cells, then injected the same mice 14 days later with RFP-labeled tumor cells from the same culture. Lungs harvested 14 days later exhibited RFP-dominant lesions surrounding a small core of GFP-labeled cells.
Conclusions: Collectively, these data suggest that cytokines expressed by a subgroup of hypo-proliferative tumor cells upon interaction with lung epithelium drive the trafficking of highly proliferative circulating tumor cells into developing metastatic lesions and that disrupting these signaling networks can prevent metastatic colonization.

#5458 Plasticity of CAF-like states in Ewing sarcoma is mediated by TGF-beta.

E. Wrenn[1], A. A. Apfelbaum[2], K. Braun[1], E. R. Rudzinski[3], X. Deng[3], A. Miyaki[1], T. Lipson[4], N. M. Garcia[1], V. J. Hoglund[1], E. R. Lawlor[1];
[1]Seattle Children's Research Institute, Seattle, WA, [2]Dana Farber Cancer Institute, Boston, MA, [3]Seattle Children's Hospital, Seattle, WA, [4]University of Washington, Seattle, WA

Transcriptional plasticity of cancer cells promotes tumor progression and treatment resistance via generation of phenotypically distinct cell states. We previously showed that Ewing sarcoma (EwS) cells exhibit inter- and intra-tumoral transcriptional heterogeneity and that they undergo state changes in response to cues from the tumor microenvironment (TME). More recently, we identified phenotypically distinct EwS tumor cell subpopulations in vivo that deposit pro-tumorigenic extracellular matrix (ECM) proteins, adopting similar functions to cancer-associated fibroblasts (CAFs). Here, we sought to identify the upstream regulators of these CAF-like EwS cells with the goal of defining molecular mechanisms that control EwS plasticity and creation of ECM-remodeling states. Integration of single cell proteogenomic sequencing (CITE-seq) with immunofluorescence and digital spatial profiling of cell line xenografts and patient tumors validated the cell-surface protein CD73 (*NT5E*) as a biomarker of ECM-secreting EwS cell subpopulations in vitro and in vivo. The transcriptomes of CD73+ CAF-like cells were compared to isogenic CD73- cells (n=9 cell lines) and highly significant enrichment of gene ontology terms related to TGF-beta signaling (p.adj = $<4.4x10^{-14}$) was noted. EwS cells were previously reported to be non-responsive to TGF-beta due to profound transcriptional repression of the TGF-beta type 2 receptor (*TGFBR2*) by EWS::FLI1. In support of this, *TGFBR2* expression was low in bulk measurements of EwS cells. However, *TGFBR2* mRNA and surface protein expression were significantly increased in CD73+ subpopulations. Exposure of EwS cells to TGF-beta ligands (TGFB1 or TGFB2) strongly induced the CAF-like gene signature, including ECM genes *BGN, COL1A1, SPARC,* and *TNC* (p. adj < $8.5x10^{-5}$), and this was augmented in CD73+ cell populations. Transduction of EwS cells with dominant negative-TGFBR2 inhibited both basal and TGF-beta-induced expression of CAF-like signature genes and blocked SMAD2 phosphorylation. To test the functional significance of the TGF-beta response, unsorted EwS cells were plated in 2D or as tumor spheroids in collagen I-rich 3D cultures and exposed to TGFB1 or SB-505124, a TGF-beta inhibitor. TGFB1 treatment had no effect on cell viability or proliferation in 2D but increased invasion into collagen in 3D. Inhibition of TGF-beta reduced CAF-like gene expression in 2D cultures and diminished both viability and invasion in 3D. Finally, our studies revealed that *NT5E* (CD73) is a TGF-beta induced target in EwS cells and that CD73+ cells upregulate expression of *TGFB2.* Thus, an autocrine signaling circuit is created in which TGF-beta activity in CAF-like tumor cell subpopulations is sustained by CD73+ tumor cell-derived ligand. Together these studies demonstrate that TGF-beta is a key determinant of cell plasticity and ECM remodeling in EwS.

#5459 Inflammatory gene-based subtyping of osteosarcoma patients reveals the association of inflammation in tumor microenvironment with better survival.

L. Yang[1], Y. Sheng[1], S. Qiao[1], D. Hu[2], D. Chowdhury[1], H. Yip[1], Z. Chen[1], Y. He[1], A. Lu[1], F. Li[1];
[1]Hong Kong Baptist Univ. School of Chinese Med., Hong Kong, China, [2]Huazhong University of Science and Technology, Wuhan, China

Introduction: Inflammation has a significant impact on the tumor microenvironment (TME) of osteosarcoma (OS). Nevertheless, due to the high heterogenecity and variable inflammatory characteristics among OS patients, it is still unclear which inflammatory factors or immune/stroma cell types are crucially associated with OS prognosis. Therefore, it is essential to explore the immune infiltration pattern and the related core inflammatory genes in OS. **Method:**We combined bulk RNA-seq data of 88 osteosarcoma (OS) patients from the TARGET database and single cell RNA-seq data in GSE152048 from the NCBI Gene Expression Omnibus. Firstly, we calculated the inflammatory gene expression matrix of bulk RNA-seq data by combining 80 inflammatory gene sets (3427 genes in total) from the MSigDB using the gene set variation analysis (GSVA). Secondly, consensus clustering was executed to evaluate the stability of clustering for the above matrix. Furthermore, the overall survival and differential expression analyses were used to screen for core inflammatory genes. Immune infiltration patterns among groups were profiled with CIBERSORT. Finally, we employed the scRNA-seq series to evaluate cell-level information to identify the survival-associated cell subpopulations using the Seurat package. The t-SNE was used for dimensionality reduction and cluster identification. **Results:**88 osteosarcoma (OS) patients were clustered into two distinct groups according to the consensus clustering of our formed GSVA inflammatory gene expression matrix. Group 1 (43 patients) exhibited evident inflammation features, while Group 2 (45 patients) displayed limited inflammation features. Patients from Group 1 had significantly better overall survival than those from Group 2. The difference in immune infiltration pattern of two groups were examined using bulk RNA-seq data. Group 1 showed a higher population of macrophages and CD8+ T cells compared to Group 2, implying high inflammatory features might lead to a better immune activation of TME in patients. To explore the factors and cell types that contributes to restricted immune infiltration and activation in OS TME, scRNA-seq data of 11 OS patient tissues were analyzed. Consistently with bulk RNA seq analysis, the 338 up-regulated genes from Group 1 were mainly expressed in immune cells including macrophages and myeloid cells. Interestingly, the 64 up-regulated genes from Group 2 were found nearly uniformly expressed in two type of non-immune cells: myoblasts and chondroblastic cells. **Conclusion:**Inflammatory gene-based subtyping of osteosarcoma (OS) patients reveals that the inflammation in TME led by myeloid-derived immune cells including macrophage is associated with better prognosis. Furthermore, myoblasts and chondroblastic cells might contribute to the limited inflammation response in OS TME.

#5460 Discovery and validation of effective combination therapies targeting cell state-specific master regulator vulnerabilities by network-based protein activity inference in diffuse midline glioma.

E. Calvo Fernandez[1], L. Tomassoni[1], X. Zhang[1], A. Obradovic[1], P. Laise[1], A. T. Griffin[1], L. Vlahos[1], J. Wang[2], H. E. Minns[1], D. V. Morales[1], C. Simmons[1], M. Gallito[1], H.-J. Wei[1], Z. Zhang[1], R. Gartrell[1], L. Szalontay[1], S. Zacharoulis[1], C.-C. Wu[1], A. Califano[1], J. Pavisic[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]University of California LA, Los Angeles, CA

Diffuse Midline Glioma (DMG) are fatal pediatric brain tumors with no effective systemic therapies. We leveraged network-based methodologies to dissect tumor heterogeneity, discover Master Regulators (MR) representing pharmacologically accessible vulnerabilities of distinct DMG cell states, and validated candidate MR-reversing drugs predicted by the NYS CLIA-certified OncoTarget and OncoTreat algorithms (Cancer Discov 2023) *in vivo*.

We first interrogated single cell DMG regulatory networks generated by ARACNe (Nat Genet 2005) with publicly available gene expression signatures from 3,039 tumor cells across 6 patients using VIPER (Nat Genet 2016) to infer single cell regulatory protein activity. Clustering of cells by protein activity defined 7 patient-independent cell states with distinct MR profiles reflecting known glial lineage markers (OPC-like-S1, OPC-like-S2, OC-like-S1, OC-like-S2, Cycling, AC-like, and AC/OPC-like). We then generated drug-induced differential protein activity from RNAseq profiles following perturbation with 372 oncology drugs in two DMG cell lines that together recapitulate the MR signatures of the cell states and used this to identify drugs that invert tumor MR activity profiles using OncoTreat. Candidate drugs predicted by OncoTarget (inhibitors of individual MRs) and OncoTreat were distinct across the cell states, and we selected five drugs targeting the OPC/cycling-like cells (Trametinib, Dinaciclib, Avapritinib, Mocetinostat, and Etoposide), and four drugs targeting the AC-like cells (Ruxolitinib, Venetoclax, Napabucasin, Larotrectonib) for further validation as these states comprised most tumor cells across patients.

We generated single-cell RNAseq for 95,687 cells after 5 days of treatment with either vehicle control (n = 4) or candidate drug (n = 2-3/drug) in subcutaneous SU-DIPG-17 mouse models. We show this model recapitulates cell states seen in patients and confirm reduction in tumor growth and significant depletion of either OPC/cycling-like cells or AC-like cells in line with our drug predictions for 8/9 candidate drugs. We then treated a syngeneic (DIPG4423) orthotopic DMG model with each drug and demonstrate significant differences in survival with Avapritinib, Dinaciclib, and Trametinib. Notably, the combination of drugs targeting OPC/cycling-like and AC-like cells (*i.e.* Trametinib+Ruxolitinib and Avapritinib+Venetoclax) showed significantly lower tumor volumes after 2 weeks of treatment as compared to vehicles or each drug alone, and significant survival differences for some combinations. This work provides a precision medicine platform to nominate much-needed novel drug combinations addressing DMG tumor heterogeneity for further study to improve outcomes in this devastating disease.

#5461 Antecedent STING agonist therapy improves tumor response to chemotherapy in murine models of osteosarcoma.

E. E. Resch, E. Kulp, M. Doucet, A. Recho, B. H. Ladle;
Johns Hopkins University, School of Medicine, Baltimore, MD

Little improvement has been made in outcomes for pediatric patients with osteosarcoma in decades. Cytotoxic chemotherapy alone is insufficient for cure and upfront complete surgical resection is usually required to achieve long-term survival. Better systemic therapies are needed. Osteosarcoma is characterized by a high degree of genomic instability that would suggest these tumors have sufficient neoantigen burden to be immunogenic and responsive to immunotherapy, but trials of immune checkpoint inhibitors in osteosarcoma have shown poor effectiveness. Although immunotherapy drugs targeting the adaptive immune system have worked poorly, we hypothesize that an innate immune adjuvant - stimulator of interferon response cGAMP interactor 1 (STING) agonist - in combination with cytotoxic chemotherapy would improve chemotherapy effectiveness and immune-mediated tumor clearance, particularly given the abundance of innate immune cells in the microenvironment of these tumors. Using two different immune-competent *in vivo* murine models of osteosarcoma (K7M2 in BALB/c mice and F420 in C57BL/6 mice), we challenged mice with tumor cells via subcutaneous or intratibial injection. In all experimental replicates, we observed improved tumor regression in mice treated with intratumoral STING agonist followed by intraperitoneal treatment with carboplatin. Responses included complete tumor response in up to 40% of treated mice. Treatment with STING agonist alone or carboplatin alone only delayed tumor growth compared to untreated controls. Additionally, mice treated first with carboplatin and then with STING agonist demonstrated an initial modest response to treatment, but ultimately exhibited tumor progression, suggesting an importance to the sequence of STING agonist administration. *In vitro* treatment of K7M2 and F420 cells with STING agonist showed a tumor-intrinsic transient increase in expression of pro-inflammatory mediators Cxcl10, Ccl5, and Ifnb 4 hours after STING exposure. Flow cytometry analysis of K7M2 tumors demonstrated increased infiltration of STING/carboplatin-treated tumors with $CD8^{+}$/$IFN\gamma^{+}$ lymphocytes and $CD11b^{+}$/$MHCII^{+}$/$F480^{+}$ tumor-associated macrophages. Interestingly, these tumors also demonstrated an increased quantity of $CD11b^{+}$/MHCII^{-}/F480^{-}/$Ly6G^{lo}$/$Ly6C^{+}$ myeloid-derived suppressor cells despite their favorable clinical response. Our findings suggest that intratumoral STING agonist therapy stimulates tumor-intrinsic and tumor-extrinsic pro-inflammatory mediators that improve the tumor response to treatment with carboplatin. Ongoing studies are further investigating the tumor-intrinsic and extrinsic mediators that are driving this improved response to therapy.

#5462 Single-cell spatial proteomic analysis to explore the spatial heterogeneity of desmoplastic small round cell tumors.

D. Truong, S. Krishnan, C. Agyemang, D. Ingram, R. Lascano, A. Basi, J. Gomez, J. Burks, A. Lazar, J. Ludwig;
UT MD Anderson Cancer Center, Houston, TX

Desmoplastic small round cell tumor (DSRCT) is a rare and usually incurable aggressive sarcoma subtype. All malignant cells harbor a pathognomonic EWSR1::WT1 fusion protein (FP). However, FP-targeted agents are nonexistent; less than 20% of patients survive beyond five years. The spatial organization of DSRCT, consisting of tumor nests surrounded by desmoplastic stroma, is a hallmark of this disease. Given this context, we seek to understand the spatial heterogeneity within DSRCT and the tumor-stroma interactions to reveal potential therapeutic vulnerabilities. We generated a 20-panel marker developed to interrogate the cellular constituents of the tumor microenvironment (TME) and to characterize the multilineage expression DSRCT, including androgen receptor (AR) and neuroendocrine signatures (NE). The following markers were used: DSRCT (ST6GALNAC, pan-Cytokeratin), Fibroblasts (Collagen, α-smooth muscle actin), Endothelial Cells (CD31, α-smooth muscle actin), T-cells (CD45, CD4, CD8), Macrophages (CD45, CD68, CD163, CD11c), AR/NE markers (AR, neural-specific enolase, synaptophysin). We explored the expression of these markers in a nine-patient cohort from 9 x 9 mm^2 tissue sections imaged by the Lunaphore COMET. We used a deep learning model in Visiopharm to extract high-quality areas and segment cells based on their nucleus. The spatial image data was converted into matrix data, which could be further analyzed in R. We confirmed that the tumor nests are surrounded by dense desmoplasia by collagen expression. We identified tumor cells, fibroblasts, immune cells, and endothelial cells by thresholding for classical cell markers. ST6GALNAC, a sialyltransferase that was found to be highly expressed in DSRCT based on RNA-seq data, marked the tumor nests. Previous data from single-nucleus RNA-sequencing (snRNA-seq) showed that DSRCT exhibited three possible subtypes: AR+/NE-, AR-/NE+, and Hybrid AR+/NE+. We found concordance between the prior transcriptomic signatures and the proteomic markers. In tumor nests that were positive for AR, we found AR localized to the nucleus, suggesting downstream activation of this pathway. High AR expression was also correlated with positive expression of pan-cytokeratin in the tumor nests. Future work will focus on quantifying spatial relationships and patterns. This includes characterizing the spatial distribution of all cell types found in DSRCT, including fibroblasts, endothelial cells, and immune cells. We will also address whether tumor nest characteristics are associated with cell phenotype or DSRCT subtype.

#5463 Germline *DICER1* loss promotes rhabdomyosarcoma via innate immune system.

R. Larsen IV, J. Hanna, K. Reed, H. Jin, W. Kimbrough, K. Vuong, M. Evans, C. Langdon, C. Drummond, M. Garcia, D. Finkelstein, P. Schreiner, J. Rehg, M. Hatley;
St. Jude Children's Research Hospital, Memphis, TN

DICER1 syndrome is a cancer predisposition syndrome where affected patients have increased risk of neoplasms including pleuropulmonary blastoma, Sertoli-Leydig cell tumor, and fusion-negative rhabdomyosarcoma (FN-RMS). This syndrome is defined by germline heterozygous loss of function mutations in the gene *DICER1*, but it remains unclear exactly how these mutations predispose children to develop cancer. One would expect the germline loss of one allele to provide a sensitized background in the tumor cell to acquire a second hit mutation. To gain insight into the role of *Dicer1* loss in FN-RMS, we deleted the *Dicer1* gene both globally in the germline and conditionally in the tumor cell in our previously established mouse model of FN-RMS. Surprisingly, we observed faster tumor onset and increased penetrance in mice with germline heterozygous *Dicer1* loss (*Dicer1*$^{+/-}$) but not in mice where *Dicer1* loss was restricted to the tumor cells, demonstrating that *Dicer1* functions as a non-cell autonomous haploinsufficient tumor suppressor. Single cell RNA sequencing (scRNA-Seq) revealed massive expansion of immature neutrophils in *Dicer1*$^{+/-}$ tumors, which were enriched for proteases associated with neutrophil extracellular traps (NETs). NETs are webs of chromatin and proteases released when neutrophils undergo NETosis in response to inflammatory stimuli. These NETs are known to cause significant damage to the local extracellular matrix (ECM) and have been implicated in tumor promotion. In addition to the neutrophil enriched immunophenotype, we found that *Dicer1*$^{+/-}$ tumors show significant ECM remodeling and are enriched for C5a, the potent neutrophil chemoattractant and NET-priming factor. Taken together, these results suggest NETosis is upregulated in *Dicer1*$^{+/-}$ FN-RMS tumors. Performing iTALK ligand-receptor pair analysis on the scRNA-Seq data revealed a putative interaction between a NET-derived ligand and EGFR and IGF1R on tumor cells, suggesting direct tumor promoting signaling from NET-to-tumor. We validated this novel FN-RMS promotion mechanism in vitro using human FN-RMS cell lines and observed that this NET-derived ligand promoted FN-RMS growth in a dose-dependent manner and could function through both EGFR and IGF1R signaling. Finally, we incorporated a *Padi4*$^{-/-}$ allele into our tumor model to genetically block NETosis and observed complete rescue of the accelerated tumor onset and increased penetrance observed in *Dicer1*$^{+/-}$ mice, demonstrating that NETosis promotes the growth of *Dicer1*$^{+/-}$ FN-RMS tumors. Importantly, these findings may be applicable to many *DICER1* syndrome-associated cancers, as neutrophils which get converted to tumor promoters by heterozygous *DICER1* loss are present in *DICER1* syndrome patients regardless of tumor type.

#5464 Galectin-3 expression in Ewing sarcoma: Modulation of the immune microenvironment in an immunocompetent model.

Y. Maharjan, S. Dey, E. Mukherjee, J. Daley, K. M. Bailey;
University of Pittsburgh School of Medicine, Pittsburgh, PA

Objective: Ewing sarcoma is an aggressive cancer of adolescents. Patients with metastatic Ewing sarcoma often receive radiation as part of their treatment protocol. We have demonstrated that both Ewing tumor cells and T cells infiltrating Ewing tumors express Galectin-3 (*Gal3*), an immunosuppressive protein in the tumor microenvironment. Here, we utilize an immunocompetent, humanized mouse model of Ewing sarcoma to investigate the role of Galectin-3 in the Ewing tumor immune microenvironment both at baseline and following radiation. Specifically, we sought to determine the influence of Galectin-3 on post-radiation inflammation in Ewing sarcoma.

Methods: Human Ewing cells -/+ *Gal3* expression were generated using CRISPR/Cas 9 technology. Cells -/+ *Gal3* were orthotopically injected into humanized mice and allowed to established tumors over ~3 weeks. Tumors were then treated with radiation (or no radiation controls). To also address immune cell expression of Gal3, galectin inhibitors were utilized. Tumors were analyzed by bulk RNA sequencing and flow cytometry analysis (Cytek Aurora) for human CD45, CD3, CD4, CD20, CD8, CD56, CD14, CD16, etc. Peripheral blood controls were also collected and analyzed to ensure consistent baseline immune reconstitution.

Results: CHLA10 and TC32 Ewing sarcoma cell lines both demonstrate Gal3 expression at baseline by western blot. CRISPR/Cas 9 knock-out of *Gal3* in both cell lines showed successful knock down. Impact on growth and sensitivity to radiation *in vitro* was assessed by live cell Incucyte assays. Tumors in humanized mice were established utilizing these cells (or *Gal3* expressing non-targeting controls) and changes in the post-radiation transcriptional profiles were assessed. Immune cells infiltrating these tumors were also quantified. Ongoing work focuses on additional characterization of these tumor infiltrating immune cell populations following radiation therapy and the impact of broader galectin inhibition on this effect.

Conclusion: This work contributes to the understanding of radiation-induced tumor inflammatory responses in Ewing sarcoma by defining the role of tumor and T cell galectin-3 expression inn Ewing immunobiology. Next steps will explore translational opportunities based on these findings.

#5466 *In vivo* characterization of neuroblastoma intratumoral heterogeneity.

W. R. Squires, A. Weiss, S. Cohen-Gogo, A. Shlien, D. Kaplan, M. S. Irwin, M. N. Hayes;
The Hospital for Sick Children, Toronto, ON, Canada

Background: Neuroblastoma is a pediatric solid tumor that arises from neural crest-derived progenitor cells of the peripheral sympathetic nervous system (PSNS). Neuroblastoma patients display a significant level of genetic and phenotypic heterogeneity, with amplification of the *MYCN* oncogene associated with poor clinical outcomes. To better understand underlying genetic mechanisms associated with aggressive neuroblastoma, our group incorporated patient-relevant loss-of-function mutations into the established MYCN-driven zebrafish model of neuroblastoma (Tg(*dbh*:EGFP-MYCN)), which resulted in increased tumor penetrance and a highly metastatic phenotype.
Aims & Methods: We aimed to investigate metastases-associated intratumoral heterogeneity *in vivo* using our patient-relevant metastatic zebrafish models, with functional validations performed using human neuroblastoma cell lines.
Results: Single-cell RNA sequencing of metastatic zebrafish neuroblastoma tumors revealed intra-tumor cell heterogeneity, with a subset of cells highly expressing markers of more differentiated adrenergic-like cell fates (*th*, *dbh*, *phox2a*) while others enriched for markers of less differentiated mesenchymal-like progenitor cells (*prrx1a*, *vim*, *fn1a*). Differential cell labeling in zebrafish neuroblastoma suggests distinct tumor cell populations for follow-up validation and characterization throughout metastatic progression.
Conclusion: Single-cell RNA sequencing of zebrafish metastatic neuroblastoma showed evidence of intratumoral heterogeneity that warrants further investigation. We are characterizing neuroblastoma intratumoral heterogeneity in our *in vivo* metastatic zebrafish models to examine the association between neuroblastoma tumor composition and metastatic potential. Altogether, this work aims to improve our understanding of the evolution of tumor cell heterogeneity associated with neuroblastoma metastasis and uncover novel therapeutic opportunities to improve patient outcomes.

#5467 Identification of possible new treatment options for rare pediatric CNS tumors using a panel of validated and characterized PDX models.

E. Oswald[1], D. Lenhard[1], K. Lashuk[1], O. Delattre[2], D. Surdez[2], J. Gojo[3], D. Lotsch-Gojo[3], W. Berger[3], S. Pfister[4], **J. B. Schueler**[1];
[1]Charles River Laboratories, Inc., Freiburg, Germany, [2]Institut Curie, Paris, France, [3]Medical University, Vienna, Austria, [4]DKFZ, Heidelberg, Germany

Central nervous system (CNS) malignancies are the most frequent group of childhood solid tumors. While pediatric mortality due to CNS tumors has decreased over the past 40 years, however, there has been no significant change in brain and other CNS tumor mortality in children and adolescents since 2007*. Advances in research and innovative therapies are crucial to improving outcomes and reducing mortality. Collaborative efforts between researchers, healthcare professionals, and the pharmaceutical industry play a pivotal role in developing more effective treatments for these indications. One important piece in this endeavor is the availability of well characterized preclinical models for rigorous preclinical testing. In the framework of the ITCCP4 consortium (www.ITCCP4.eu) our group determined the pharmacological profile of ten orthotopically implanted pediatric brain tumor PDX models. The panel comprises amongst others four CNS-BCOR models, one ZFTA::RELA ependymoma model and two models of PFA ependymoma. We tested the models in a single mouse trial format with 16 arms covering standard of care therapy including radiation as well as targeted agents. All tumors were intracranially implanted into immune-compromised NSG mice. Tumor load was determined using a fluorescence based *in vivo* imaging technology based on the lentiviral transient transduction of PDX cells with iRFP713 prior to implantation into the brain. In addition, body weight and neurological scoring were monitored to determine the overall condition of the animals. At the end of the study brain tissue was harvested and tumor load confirmed by immunohistochemistry. Vismodegib, a first in class inhibitor of the hedgehog signaling pathway, was the most efficacious treatment with a significantly extended overall survival (Log Rank, $p< 0.001$) and a reduced tumor load compared to untreated control arms. The effect was most prominent in the subclass of CNS-BCOR models leading to growth delay or stable disease. Several targeted agents such as Ipatasertib (AKT inhibitor), Idasanutlin (MDM2-antagonist) and standard of care such as Carboplatin and Radiotherapy induced stable disease as well but had no significant effect on overall survival. The positive results for Vismodegib, Ipatasertib as well as Idasanutlin will be validated in a smaller subset of models in a conventional set-up to confirm the current dataset. In summary, the single mouse trial format using intracranially implanted PDX models proved to be a feasible tool to identify most promising drug candidates for pediatric ependymoma. *Ostrom QT, Price M, Ryan K, Edelson J, Neff C, Cioffi G, et al.. CBTRUS statistical report: pediatric brain tumor foundation childhood and adolescent primary brain and other central nervous system tumors diagnosed in the United States in 2014-2018. Neuro-Oncology (2022) 24(Supplement_3):iii1-38.

#5468 Pediatric Preclinical In Vivo Testing (PIVOT) data portal enables access to 15 years of retrospective treatment study data in support of prospective study design.

S. E. Acevedo[1], T. M. Stearns[2], P. Webster[1], V. Philip[2], M. W. Lloyd[2], A. Srivastava[3], S. Neuhauser[2], D. Begley[2], D. M. Krupke[2], E. L. Jocoy[4], C. J. Bult[2], J. H. Chuang[3], D. A. Dean II[1];

[1]Velsera, Charlestown, MA, [2]The Jackson Laboratory, Bar Harbor, ME, [3]The Jackson Laboratory, Farmington, CT, [4]The Jackson Laboratory, Sacramento, CA

The PIVOT program (https://preclinicalpivot.org) is a National Cancer Institute (NCI) funded initiative in support of the RACE Act that funds collaborations between academic centers and industry partners to test the efficacy of targeted cancer treatments developed for adult oncology for potential application in diverse pediatric cancers, including cancers of the central nervous system, leukemia, osteosarcoma, sarcoma, and neuroblastoma. In support of the PIVOT program, we have harmonized more than 15 years of data collected during two previous preclinical pediatric testing programs. To disseminate the data and results of these programs broadly we designed and implemented the PIVOT Data Portal.

The PIVOT Data Portal is an R Shiny App that makes treatment efficacy data from PIVOT accessible on the web. The data are harmonized which supports comparison of treatment results across different cancer types. The data from the portal are freely available and downloadable. The portal includes study summaries within and across cancer models, statistical reports, tables, and tools for the visualization of treatment results. Data summary tables include entries for objective response measures (ORM), mean outcome, number of tumor studies, and p-value as appropriate. Visualizations include relative tumor volume plots for solid tumors; CD45 plots for leukemia; and survival curves to compare survival time across treatment groups. Treatment study visualizations and data summaries with their related metadata can be generated and downloaded within the Shiny App, allowing researchers to perform further downstream analysis.

The portal collectively contains data for 52 agents, 45 drug targets, 34 drug classes (including ADCs, small molecular inhibitors, protein degraders, BiTEs, etc.), and 167 models, with a total of 245,926 data points. Currently, 44% of agents have been tested on 2 or more cancer types. Among the solid tumor models tested, 10 had at least one treatment that resulted in an ORM of maintained complete response (MCR), while 29 leukemia models had an ORM of MCR. Similarly, 48% of agents tested had an ORM of MCR for at least one cancer type.

The PIVOT Data Portal makes pediatric cancer model treatment data available without restriction to support retrospective analyses and design of prospective studies. We are working to link cancer model data within the portal to molecular data. Merging outcome data with genomics data will facilitate computational approaches for molecular target identification, personalized treatment, and treatment optimization.

#5469 ITCC-P4, a preclinical proof-of-concept drug testing platform as a tool for pharmacological screening in pediatric tumor models.

Cancer remains the main cause of disease-related death in childhood. Pediatric tumors are characterized by a low mutational burden and high intertumoral heterogeneity, with multiple subtypes compared to their adult counterparts. The lack of access to many innovative therapies remains one of the main challenges in the pediatric oncology, especially for the 25% of patients who experience relapses. In this context, the need for the development of a well characterized collection of pediatric models, to provide large scale preclinical testing, is capital for the subsequent identification and prioritization of promising novel therapeutic options. The EU funded “Innovative Therapies for Children with Cancer-Pediatric Preclinical Proof-of-Concept Platform” (ITCC-P4) consortium is a unique public-private collaborative project consisting of academic and industrial partners that aimed at establishing a collection of >400 patient-derived xenograft (PDX) models representing the most common high-risk pediatric cancers. The project involved various aspects of model development including the thorough molecular and pharmacological characterization. XenTech’s participation was focused on the development and preclinical in vivo drug testing of Ewing sarcoma (n=17), hepatoblastoma (n=10), rhabdoid tumors (n=6), synovial sarcoma (n=2), rhabdomyosarcoma (n=2) and other tumors (n=6), as part of overall cohort. PDXs were obtained by transplantation of post-surgery tumor specimens, either by grafting tumor fragments into the interscapular region or subcutaneously in the right flank of nude, NOD-Scid or NOD-Scid gamma mice. Tumor xenografts were amplified by serial transplantation, and tissue samples were retained at early passages for molecular characterization. Fragments from established PDX models where frozen to generate a revivable ITCC-P4 PDX collection. Then, proof-of-concept drug testing was conducted, in a single mouse trial format: each tumor type (n=X PDX models) was treated with a dedicated panel of Standard-of-Care (SoC;n=3) and novel targeted therapies (n=6), or combinations of 2 or 3 novel targeted therapies; for each PDX model n=1 mouse being included per treatment. All molecular and drug-testing data obtained by the different partners are being centralized in the R2 repository (https://r2.amc.nl), providing a powerful tool for data integration, visualization and interpretation of the results. A unique collection of well characterized pediatric PDX models derived from the most relevant pediatric tumor types was enabled by a strong public-private collaborative project. This large cohort is now available for preclinical testing of novel therapeutic agents within a non-for-profit spinoff company, ITCC-P4 gGmbH (www.itccp4.com), offering new perspectives to the identification of promising treatment options for children with cancer.

#5470 ONC206 inhibits tumour growth and is a potential novel therapeutic strategy for refractory medulloblastoma.

T. Tzaridis[1], J. Liu[2], V. Prabhu[3], R. Wechsler-Reya[4], T. MacDonald[2];
[1]Sanford Burnham Prebys Med. Discovery Inst., La Jolla / San Diego, CA, [2]Department of Pediatric Oncology, Emory University School of Medicine, Children's Healthcare of Atlanta, Atlanta, GA, [3]Chimerix, Durham, NC, [4]Department of Neurology and Herbert Irving Comprehensive Cancer Center, Columbia University Medical Center, New York, NY

Medulloblastoma is the most common malignant pediatric brain tumor with a for certain molecular subgroups very low overall survival and therefore an urgent need for novel treatment approaches. Dordaviprone (ONC201) and its chemical derivative with nanomolar potency ONC206 are inhibitors of the dopamine receptor 2 (DRD2) and more importantly induce apoptosis of cancer cells by activation of the mitochondrial caseinolytic protease P (ClpP). ONC201 has shown objective responses in patients with diffuse midline gliomas and is currently being evaluated in the Phase 3 ACTION study. ONC206 is currently in Phase I clinical trials for pediatric and adult patients with primary brain tumors. In this study, we evaluated the preclinical therapeutic effects of ONC206 in medulloblastoma *in vitro* and *in vivo* and investigated the molecular mode of action for this imipridone. We found evidence for high expression of ClpP at both the RNA and protein level in medulloblastoma tumours, compared to very low expression in normal brain and normal cerebellum. In addition, we saw a pronounced reduction in cell viability of human Group 3 and Group 4 and murine medulloblastoma cells treated with ONC206 with extremely low IC-50s (range: 14nM - 2µM).After treatment with ONC206, we observed a significant downregulation of mitochondrial electron transport chain complexes I and III and mitochondrial hyperpolarization, as well as an induction of the ATF4 pathway, thereby implying that ONC206 induces an integrated stress response and mitochondrial damage. In order to test the efficacy of ONC206 *in vivo,* we used murine models of SHH-driven and Group 3 medulloblastoma as well as Group 3 patient-derived xenografts (PDXs). ONC206 led to a significant prolongation of survival in both murine models, with the SHH mice demonstrating a remarkable survival benefit. Mice from both Group 3 PDXs also responded to ONC206, with 25% of ONC206 treated animals exhibiting long-term tumor-free survival. Our results highlight ONC206 as a novel attractive therapeutic option for patients with relapsed medulloblastoma and importantly pave the way for a clinical trial testing the efficacy of ONC206 in the treatment of these patients.

#5471 Ribosome heterogeneity and RNA poll inhibition in osteosarcoma heterogeneity.

Marc Baud'huin[1], Elvina Colleville[2], Rose Anne Thepault[2], Emilien Orgebin[2], Francois Lamoureux[2], Benjamin Ory[2]

[1]CRCI2NA / INSERM UMR 1307 / CNRS UMR 6075 / Nantes Universite /CHU de Nantes, Nantes, France,[2]CRCI2NA / INSERM UMR 1307 / CNRS UMR 6075 / Nantes Universite, Nantes, France

Osteosarcoma is the most common primary bone tumour in adolescents and young adults, with an incidence rate of 3.8 per million. These tumors affect the long bones of the body such as femur. Current standard therapy includes tumour resection associated with multi-drug chemotherapy. The 5-year survival rate can reach 65% but is significantly reduced to 30% when pulmonary metastases are detected at the time of diagnosis. As this rate has not improved in the last 50 years, it is necessary to identify new therapeutic strategies. Inhibition of ribosomal biogenesis is one of the strategies developed in many cancer studies. This can be obtained by inhibition of RNA pol I, and in particular by BMH-21. The objective of this study was to analyze the complexity and heterogeneity of osteosarcomas through the ribosomal spectrum. The effect of BMH-1 on survival was also studied in osteosarcoma cell lines. The data obtained showed that there was no difference in ribosome protein composition in the “core” ribosome in different osteosarcoma cell lines. In addition, BMH-21 decreased cell viability in all osteosarcoma and chemoresistant cell lines. However, any activation of the apoptotic pathway by caspases was detected, nor any impact on the formation of new colonies after treatment with BMH-21. These results suggest a rather cytostatic mechanism. Moreover, a G0/G1 arrest in cell cycle was shown for U2OS cells. Finally, BMH-21 does not appear to have any impact on migration in HOS and U2OS cells. The different molecular mechanisms involved in the regulation of proliferation need to be further investigated.

#5472 Direct cytotoxicity of hu14.18K.322A in high-risk neuroblastoma.

M. Gnanamony, M. Thomas, T. Nguyen, A. M. D'Souza, P. de Alarcon;
University of Illinois College of Medicine (Peoria), Peoria, IL

Background: Neuroblastoma is a childhood cancer of the sympathetic nervous system and is associated with disialoganglioside GD2 overexpression. The main goal of this study is to investigate the involvement of GD2 targeting humanized antidisialoganglioside monoclonal antibody hu14.18K.322A (hu14) in high-risk neuroblastoma direct cell cytotoxicity, assess for synergy with induction chemotherapy agents, and delineate the mechanisms involved in cell death.
Methods: For this study, we used a panel of GD2 expressing cell lines [SK-N-BE (2), SK-N-BE (1), LAN5, CHLA15] and a GD2 non-expressing cell line LAN6. We measured surface expression of GD2 and performed cell cycle analysis using flow cytometry. The role of hu14 in neuroblastoma cell death was assessed using cell viability assays, proliferation assays, real time PCR and western blot analysis. We measured synergy between hu14 and induction phase chemotherapy drugs. Further, we employed next generation sequencing (NGS) to analyze the transcriptomic changes in human neuroblastoma cell lines in response to hu14 treatment to understand the pathways involved and the molecular mechanisms of hu14-mediated cellular response.
Results: Using a cell viability assay, we found that CHLA15 and SK-N-BE (1) cell lines were sensitive to hu14 treatment whereas SK-N-BE (2), LAN5, LAN6 were resistant. Hu14 treatment resulted in a dose dependent reduction in cell proliferation in these cell lines. We also found that hu14 treatment resulted in increased expression of apoptotic and autophagy pathway proteins, but not ferroptosis or necroptosis pathways proteins. Hu14 induced cell death was partially inhibited by a pan-caspase inhibitor, confirming that caspase-dependent pathways are involved. Western blot analysis also showed decreased levels of p53 phosphorylation in both sensitive cell lines upon hu14 treatment suggesting an important control mechanism centered on the p53 pathway. Hu14 treatment reduced the surface expression of GD2 in the sensitive cells suggesting direct inhibition of the GD2 synthesis pathway. However, PCR analysis of GD2 synthesis genes did not show any significant difference upon treatment suggesting posttranscriptional control of these genes. Furthermore, NGS analysis revealed alterations in several pathways, but these changes were distinct between the cell lines reconfirming the complexity of therapy response in high-risk Neuroblastoma.
Conclusion: Taken together, our findings suggest that hu14.18K322A induces direct cell cytotoxicity in a subset of high-risk Neuroblastoma and synergizes well with standard chemotherapy drugs. Furthermore, our research highlights the complex nature of signaling pathways involved in hu14-mediated cytotoxicity that can be harnessed towards targeted therapy.

#5473 Combined inhibition of MDM2 and PARP lead to a synergistic anti-tumoral response in p53 wild-type rhabdomyosarcoma.

G. Pons[1], G. Gallo-Oller[1], L. Garcia-Gilabert[1], P. Zarzosa[1], J. Sansa-Girona[1], N. Navarro[1], P. Cabre-Fernandez[1], M. Segura[1], J. Sanchez de Toledo[2], S. Gallego[2], L. Moreno[2], J. Roma[1];

[1]Vall d'Hebron Research Institute (VHIR), Barcelona, Spain, [2]Hospital Universitari Vall d'Hebron, Barcelona, Spain

Targeting MDM2-p53 interaction to enhance p53 activity represents an attractive antitumoral strategy for p53 wild-type tumors. However, early-phase clinical trials in hematological and solid cancers have shown limited efficacy of MDM2 inhibitors highlighting the necessity for exploring more effective combinations with additional agents. In this study, we provide results from a 22-drug combination screening demonstrating the therapeutic potential of combining Siremadlin (MDM2 inhibitor) and Olaparib (PARP inhibitor) for treating p53 wild-type rhabdomyosarcoma (RMS). Cell survival, cell death and apoptosis analysis revealed synergistic effects when combining Siremadlin and Olaparib *in vitro*. Combination of both drugs resulted in a significant increase of p53 activity as evidenced by p53 accumulation and K382 acetylation along with an increased expression of p53 targets. Finally, combination of both drugs resulted in significant reduction of tumor growth and increased overall survival outperforming individual treatments and control groups. In summary, our study demonstrates, for the first time, the synergistic effect of the combination between Siremadlin and Olaparib in the inhibition of p53 wild-type RMS tumor growth *in vitro* and *in vivo*. These findings advocate for the exploration of this drug combination in clinical trials and underscore the need for further investigation in tumors sharing similar molecular features.

#5474 Biorepository yields potential for personalized medicine approach in pediatric brain cancer patients.

A. Pronina, E. Nasajpour, C. Tran, T. Schouten, E. Gibson, J. Nirschl, L. M. Prolo, K. Mahaney, H. Vogel, C. K. Petritsch;
Stanford University, Palo Alto, CA

Childhood brain cancer, with a 12% mortality rate, stands as the most lethal cancer among children. Out of the annual 4,000 diagnoses, 30% involve low-grade gliomas, with a troubling 10% progressing to lethal high-grade gliomas within 2 years. While surgery can often cure the remaining 90%, 50% necessitate adjuvant therapies like chemotherapy and molecular targeting, with radiation sparingly used. Alarmingly, 66% of survivors grapple with long-term health, mental, and cognitive issues due to treatment toxicity, emphasizing the urgent need for innovative biological therapies in pediatric glioma treatment.Our proposed strategy involves the acute analysis of freshly discarded tissue from brain cancer craniotomies, departing from the use of FFPE-preserved tissue, which may exhibit suboptimal quality. All patients provided informed consent, and by prospectively preserving viable tissue, we enable its utilization in ten or more subsequent analyses. These encompass cell-culture-based assays, viability assays, bulk, single cell, and single nucleus RNA sequencing, DNA sequencing, single-cell proteome analyses, flow cytometry, and immunofluorescence.Our findings highlight a direct correlation between surgical sample size and analysis feasibility. Bulk RNA sequencing proves valuable in acutely isolated surgical tissue and cryostored or flash-frozen tissue for identifying novel therapeutic targets in individual patients. Viable cells retrieved from cryopreserved tissue of the same patient allow ex vivo functional validation of therapeutic targets, eliminating the need for establishing patient-derived cell lines and xenografts, particularly challenging for low-grade gliomas. These findings establish the feasibility of a personalized bedside-to-bench approach, contingent on an adequate supply of surgical material.Expanding this approach to encompass all childhood brain cancer types, we plan to investigate using our comprehensive biorepository, housing viable tissue and single-cell suspensions from 122 childhood brain cancer patients. Among these, 51 cases yielded tissue for single-cell RNA-seq and viable cryoprotection. The most common tumor histology identified was low-grade glioma (32), primarily pilocytic astrocytoma (19), followed by embryonal (12) and ependymal tumors (4).In summary, we developed a standard operating procedure for analyzing fresh and cryopreserved surgical discards, identifying novel targets in childhood brain cancer tissue, and functionally validating them in patient-matched samples. This personalized medicine approach holds promise in circumventing the tedious development of patient-derived models.

#5475 Development of high-throughput 3D bioprinted pediatric models for precision medicine.

V. Poltavets[1], M. Jung[1], J. Skhinas[1], K. Kimpton[1], A. Kamili[1], G. Tax[1], J. Mao[1], L. Cui[1], M. Wong[1], M. J. Cowley[1], L. Lau[1], E. M. M. Dolman[1], J. J. Gooding[2], M. Kavallaris[1];

[1]Children's Cancer Institute, Randwick, Australia, [2]University of New South Wales, Sydney, Australia

Childhood cancer patients with high-risk disease have poor prognosis. Therapies given to treat these patients are often highly toxic and determined empirically, exposing children to damaging and ineffective therapies. Precision medicine is a promising strategy for these patients. However, tumor biopsies often lack sufficient sample for phenotypic drug screening, requiring cell expansion via primary cell culture or development of patient-derived xenograft models - a slow process with variable success rates. There is an unmet need for sensitive, predictive, and timely drug testing models. Dynamic interactions between cells and the extracellular matrix (ECM) impact cellular signaling and response to cancer therapy. The development of patient-derived tumor models that are reflective of the patient sample and achieved in a clinically relevant timeframe will be game changing. In-silico analysis of 265 ECM gene expression from a high-risk neuroblastoma and sarcoma patient cohort (n=145) identified collagens and fibronectin to be the most abundantly expressed ECM genes in the tumor samples. To reflect this environment, we developed tuneable tissue ECM-like bioinks where cells are embedded within the bioink that mimics growth constraints within a tumor [1]. Specifically, we functionalized the bioinks with peptides of collagen I, fibronectin, and laminin to mimic the ECM environment and combined this with HTP 3D bioprinting technology to create patient-derived tumoroids. In this proof-of-concept study, we identified conditions that enable the growth and expansion of the neuroblastoma and sarcoma cells in a 3D ECM-like environment. The tumor samples proliferate in the bioinks and HTP drug screening was used to determine drug sensitivity. Importantly, the bioprinted cells reflect the genetic and phenotypic characteristics of the original patient tumors and retained their tumorigenic capacity in vivo. Collectively, we have successfully generated preclinical models that reflect patient tumors and are directly compatible with preclinical drug testing. Importantly, our 3D bioprinting platform has the potential to advance cancer precision medicine in a clinically relevant timeframe. These findings have broader applications for a range of cancer types for preclinical testing, drug discovery and cancer biology.1. Utama, RH, et al. *Macromolecular Bioscience*, 2021. 21(9):e2100125

TUMOR BIOLOGY: Spatial Resolution of the Tumor Microenvironment
Poster Session

#5479 Spatially resolved molecular features in the tumor-immune microenvironment of germline BRCA1/2 mutated versus BRCA wild type high grade serous ovarian cancers.

J. Qian[1], L. D. Roman[1], R. Bassiouni[2], S. Rajpara[1], M. Neuman[1], V. Khetan[1], D. W. Craig[2], J. W. Carlson[1], J. D. Carpten[2];
[1]Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]City of Hope, Duarte, CA

High-grade serous ovarian cancer (HGSC) is the most common and aggressive subtype of epithelial ovarian cancer. Importantly, germline mutations in BRCA1/2 give rise to HGSC. Because most HGSC are diagnosed at stage III/IV, outcomes are poor and more effective therapies are needed. Although immune checkpoint inhibitors show promise for a number of cancer types, efficacy has been variable in HGSC. To help provide new clues to the molecular features of HGSC, we set out to elucidate the tumor microenvironment of HGSC using spatial transcriptomics approaches. Specifically, we applied 10x Genomics Visium Spatial Transcriptomics (ST) technology to 48 samples representing primary HGSC tumors from 24 patients, including 15 BRCA1/2 mutated cases and 9 BRCA non-mutated cases. In addition to individual sample analysis, we normalized data from 64,784 total features across all sections and performed an integrated cluster analysis to get an overall picture of the cellular architecture of HGSC, but to also directly investigate differences in the tumor microenvironment based on BRCA mutation status. The resulting 17 integrated clusters were subjected to molecular annotation using GSEA, ESTIMATE, and CIBERSORTx, which revealed feature clusters representing important cell types defined by marker genes. Analysis of the entire dataset identified a primary tumor cluster defined by the expression of known ovarian cancer genes including *WFDC2* and “don’t eat me” marker genes *CD24* and *CD47*. However, the predominant tumor cell population in BRCA mutated cases was marked by the expression of *MUC1, EPCAM, CLDN3*, and *CD24*, while BRCA non-mutated tumor cell cluster was marked by *EFNA1, ID1, LSR*, and *CD9*. Importantly, both groups revealed the presence of a specialized monocyte derived macrophage cluster defined by the expression of *LYZ* and genes involved in cholesterol metabolism including *APOE* and *APOC1*. These lipid-associated macrophages are M2 polarized and shown to be associated with poor outcome. Additional analyses are underway to determine spatial dependencies of various tumor and immunological cell compartments. These data provide novel insights into the HGSC tumor microenvironment that may influence HGSC’s vulnerability to immunological therapies.

#5480 Single cell and spatial transcriptomic profile of appendiceal tumour peritoneal disease.

M. C. Strach[1], N. Yeung[2], E. Apostolov[2], T. Wang[2], H.-M. Lin[2], N. Ansari[3], C. Koh[1], J.-S. Shin[3], J. Kench[3], A. Swarbrick[4], L. Horvath[5], **K. L. Mahon**[5]; [1]University of Sydney, Camperdown, Australia, [2]Garvan Institute of Medical Research, Darlinghurst, Australia, [3]Royal Prince Alfred Hospital, Camperdown, Australia, [4]Garvan Institute of Medical Research, Camperdown, Australia, [5]Chris O'Brien Lifehouse, Camperdown, Australia

Introduction: Appendiceal tumors (AT) are rare and often develop peritoneal disease (PD), with 5 year survival of 15-63% for high grade adenocarcinomas (HG) and 46-96% for low grade mucinous neoplasms (LG). While the mainstay of treatment is cytoreductive surgery and heated intraperitoneal chemotherapy (CRS/HIPEC), the role of systemic chemotherapy is less clear with limited biological characterization of AT and its tumor microenvironment (TME). The purpose of this study was to evaluate the TME of AT PD. Here we present an atlas of AT PD cells alongside a spatially resolved transcriptomic profile comparing HG and LG.

Methods: We collected tissue from 29 patients with AT PD during CRS prior to HIPEC (18 LG, nine HG and two no tumor control). We performed comprehensive single-cell RNA sequencing (38224 cells) on fresh tissue specimens from nine patients (four HG, five LG), and whole transcriptome spatial analysis (>18000 genes) using the GeoMx Digital Spatial Profiler on formalin-fixed paraffin-embedded tissue from 22 patients (five HG, 13 LG). In the spatial profiling, we used anti-CK20, anti-CD45 and SYTO 83 as morphology markers to select areas of interest (AOIs): tumor (CK20), immune (CD45) and stroma (non-CK20/CD45). Analyses were performed with R and a false discovery rate threshold of 0.05.

Results: Single-cell RNA sequencing showed that both LG and HG have a preponderance of T-lineage cells including CD8, CD4 and NK T-cells. Both LG and HG tumors display association of mesothelial cells with cancer-associated fibroblasts (CAF), and CAF subsets expressing genes of epithelial-mesenchymal transition (EMT). LG and HG tumors display different patterns of mucin gene expression - epithelial cells of HG express the secreted mucin *MUC20* in addition to *MUC2* and *MUC5B* also expressed in LG; a subset of mesothelial cells in LG but not HG express the transmembrane mucin genes *MUC1, MUC3A, MUC12* and *MUC16*. Spatial analysis of tumor AOIs revealed HG compared to LG had increased expression of genes associated with MYC targets, oxidative phosphorylation, anti-tumor immune pathways (IFNα/γ response, intestinal immune network for IGA production), cell cycle pathways (E2F targets, G2M checkpoint) and EMT. LG compared to HG had increased expression of genes associated with inflammation-mediated disease (TNFα signaling via NFKB, inflammatory response), regulation of tumor growth (P53), hypoxia and early cell cycle (estrogen response) and glycosylation pathways. Immune and stromal AOIs did not have significant transcriptomic differences between LG and HG.

Conclusion: This study provides novel insights into the biological profile of AT PD by describing TME cell types, immune function, tumor growth and cell cycle pathways. These findings may be used to identify clinically relevant biomarkers and new therapeutic targets.

#5481 Spatial multiplex proteins profiling of tumor microenvironment to decipher d*e novo* metastasis in nasopharyngeal carcinoma.

Larry Ka-Yue Chow, Ying Wang, Lanqi Gong, Siqi Xu, Zhaozheng Hou, Xinyuan Guan, Dora Lai-Wan Kwong, Victor Ho-Fun Lee, Wai Tong Ng, Anne Wing-Mui Lee, Zhonghua Liu, Yunfei Xia, **Wei Dai**

The University of Hong Kong, Hong Kong, Hong Kong

Background: Nasopharyngeal carcinoma (NPC) has a high incidence rate in Southeast Asia, where more than 90% of NPC cases are associated with Epstein-Barr virus (EBV). Although NPC patients are generally sensitive to radiotherapy and chemotherapy, about 20-30% of patients have treatment failure due to the development of distant metastasis, i.e. *de novo* metastasis. In this study, we utilized GeoMx Digital Spatial Profiler (DSP), a multiplex and high-throughput sequencing platform designed for spatially- and morphologically resolved protein expression profiling to investigate the intra-tumoral and inter-tumoral heterogeneity of tumor microenvironment (TME) and identify the mechanisms underlying distant failure in NPC.
Methods: We utilized GeoMx Protein Assays consisting of 147 proteins from 15 functional modules to compare the difference between NPC cases developing distant failure (DF) (n=21) and stage-, age-, gender- and treatment-matched NPC cases without developing distant failure (noDF) (n=15) within five years of treatment. Two fluorescent morphological markers including PanCK and CD45, were used for delineating the structural architecture of the tissues, identifying cell types, and selecting regions of interest (ROIs), followed by sequencing for protein expression quantification. NanoString GeoMx DSP Analysis Suite was used for quality control and data normalization. The NPC TME heterogeneity was further investigated by the 10X Visum platform for spatial transcriptome. The public single-cell RNA sequencing (scRNA-Seq) and bulk RNA sequencing datasets were obtained for the downstream analyses.
Results: By analyzing protein expression profiles, the study revealed the intratumoral and intertumoral heterogeneity associated with EBV latent infection in the TME of NPC. Regions with high EBV latent gene expression exhibited a noticeable reduction in T cell infiltration, indicating an "immune cold" phenotype, whereas regions with low EBV latent gene expression displayed heavy T cell infiltration, indicating an "immune hot" phenotype. Moreover, the study identified a panel of autophagic and anti-apoptotic proteins that were significantly upregulated in the cancer cells of NPC cases developing distant failure after treatment. This observation, supported by the single-cell RNA sequencing datasets, further implicated EBV latent infection for the upregulation of autophagic and anti-apoptotic genes. Notably, the study also demonstrated that the genes upregulated in the immune cells in NPC cases with distant failure were associated with poor progression-free survival in an independent NPC cohort.
Conclusions: These findings shed light on the crucial role of EBV latent infection in TME heterogeneity and highlight the potential involvement of autophagy and anti-apoptosis in *de novo* metastasis in NPC.

#5482 Spatial and multi-omic interrogation of the primary and recurrent glioblastoma microenvironment.

J. R. Clemenceau, P. Suarez-Meade, A. Quinones-Hinojosa, T. Hwang;
Mayo Clinic Florida, Jacksonville, FL

Glioblastoma remains as one of the deadliest malignancies with most cases likely to recur. Recent work has focused on characterizing not only glioma cells, but the tumor microenvironment via single-cell and spatial transcriptomic technologies. This has improved our understanding of the high heterogeneity of this disease and described potential tumor domains. However, there is still a need to further understand the changes that occur between the primary and the recurrent lesion. We propose that a spatial, multi-omic characterization of matched primary and recurrent glioblastoma can yield insights into recurrence mechanisms occurring throughout the tumor microenvironment. We collected 22 IDH-WT glioblastoma samples from 12 patients (11 primary, 11 recurrent, 10 matched pairs) from the Mayo Clinic Neuroscience Biobank. We performed single-nucleus RNA sequencing (15 samples, 10 patients, 5 matched pairs) and proteomics (16 samples, 6 matched pairs) from fresh-frozen tissue, as well as spatial transcriptomics with 10x Visium (14 samples, 8 patients, 6 matched pairs) and 10x Xenium in-situ molecular imaging (6 samples, 2 matched pairs). Using spatial transcriptomics data, we identified regional subsets present in different proportions and distributions between primary and recurrent glioblastoma. These clusters were characterized with gene set and gene ontology analysis, identifying regions enriched with known glioma subtypes and cellular activity. Spatial-based cluster genes were consistent with significantly differentially expressed proteins. We used single-nucleus RNAseq and in-situ molecular imaging data from matched tissue samples to further interrogate relevant cell populations and location in the tumor micro-environment. We identified regions with enriched extra cellular matrix interaction and remodeling signatures to be highly expressed in recurrent glioblastoma. Primary glioblastoma was enriched with oligodendrocyte-like regions with high cell communication and extracellular vesicle signatures. This study will further our understanding of the changes in the mechanisms at play in the complex ecosystem of glioblastoma as it recurs.

#5483 Macrospatial ecotype heterogeneity in early-stage breast cancer identified by spatial nucleus barcoding.

K. Wang*[1], **Z. Xiao***[1], Y. Lin[1], R. Wei[1], S. Bai[1], J. Ye[1], R. Ye[1], M. Hu[1], A. Thennavan[1], E. Sei[1], A. Thompson[2], S. Krishnamurthy[1], N. Navin[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Ductal carcinoma *in situ* (DCIS), the predominant form of early-stage breast cancer and a precursor to invasive breast cancer, remains inadequately understood in terms of spatial microenvironment reprogramming. In this study, we developed a Spatial Nucleus Barcoding (SNuBar) approach for single-nucleus RNA sequencing (SNuBar-RNA) that utilizes a single oligonucleotide adaptor to preserve spatial information. The accuracy and scalability of SNuBar was validated using cell line mixture experiments. We then applied SNuBar-RNA to investigate the macrospatial ecotype heterogeneity in early-stage breast cancer. By analyzing single cells from different macrodissected spatial regions in normal breast tissues, matched normal and DCIS tissues, we identified 13 major cell types and 43 distinct cell states, co-localizing in diverse combinations across four primary topographic areas (adipose-enriched, normal epithelial, activated stroma and tumor). Spatial analysis revealed the reprogramming of vascular and myoepithelial cells in localized zones near premalignant cells, while fibroblasts, T-cells, and myeloid cells exhibited reprogramming across broader fields. Validation using the MERSCOPE assay confirmed stromal heterogeneity between tumor and normal areas. Collectively, our data shows that many diverse cell types are reprogrammed in spatially-defined areas in the early-stage breast cancer microenvironment, relative to the normal breast tissue regions.

#5484 Spatial transcriptomic profiling reveals characteristic gene expression patterns of cancer-associated fibroblasts in lung adenocarcinoma with interstitial pneumonia.

C. Inoue[1], Y. Miki[1], Y. Aoyama[1], S. Shibata[2], Y. Okada[2], T. Suzuki[1];
[1]Tohoku University Graduate School of Medicine, Sendai, Japan, [2]Institute of Development, Aging and Cancer, Tohoku University, Sendai, Japan

Background: Interstitial pneumonia (IP) is a risk factor for lung cancer (LC). LC, a significant contributor to mortality, shows improved prognosis with molecular targeted drugs. However, LC combined with IP (LC with IP) has a poor prognosis because of acute exacerbations. Therefore, developing effective drugs for LC with IP is necessary. Cancer-associated fibroblasts (CAFs), influencing cancer progression through interactions with the microenvironment are anticipated as a new therapeutic target. Therefore, we hypothesized that CAFs in LC with IP, having undergone repeated destruction and regeneration, exhibit distinct characteristics from those in LC without IP and exert varied influences on carcinogenesis and cancer progression.
Methods: Six cases of lung adenocarcinoma, the predominant type of LC, were enrolled in this study. Spatial profiling was performed on FFPE specimens from three LC with IP and three LC without IP cases, using GeoMx whole-transcriptome atlas assay. Immunostaining for α-SMA, a major CAFs-marker, and pan-cytokeratin (CK), an epithelial marker, were employed to identify regions of interest (ROIs). In LC with IP, two ROIs were designated for cancerous and non-cancerous areas, respectively, whereas in LC without IP, two ROIs were selected for cancerous areas. Each ROI was segmented for epithelium and cancer (CK+/α-SMA -) and α-SMA-positive stroma (CK-/α-SMA +) areas of illumination. NGS data were analyzed using the edgeR to compare mRNA expressions in cancerous (LC-IP) and non-cancerous (NC) areas of LC with IP. Additionally, comparisons were made between LC-IP and cancerous areas of LC without IP (LC-nonIP) for mRNA expression.
Results: Analysis of α-SMA-positive stroma revealed 86 differentially expressed genes (DEGs) in LC-IP vs. NC. Notably, COTL1 and NFKB2 increased, whereas TNC and MMP7 were decreased in LC-IP α-SMA-positive stroma. Pathway Enrichment analysis indicated activation of the response to cytokines. Between LC-IP and LC-nonIP, 151 DEGs were detected. CXCL8 and NFKB2 were elevated, whereas ACAN and ELN decreased in LC-IP α-SMA-positive stroma. KEGG pathway analysis demonstrated inactivated ECM-receptor interactions. Analysis of CK-positive regions showed 710 DEGs in LC-IP vs. NC, and KEGG pathway analysis indicated inactivated ECM-receptor interaction. In LC-IP vs. LC-nonIP, 321 DEGs were detected, with KEGG pathway analysis suggesting inactivation of ECM-receptor interaction and activation of a chemokine signaling pathway and cytokine-cytokine receptor interaction.
Conclusion: These findings suggest that inflammatory factors may play a more critical role than extracellular matrix in the interaction between α-SMA-positive stroma and CK-positive cancer cells in LC with IP. Future plans include conducting *in vitro* experiments, as well as immunohistological studies.

#5485 Spatial characterization of the immunosuppressive tumor microenvironment in estrogen receptor positive breast cancer at single cell level.

J. Tessier[1], S. Curras-Alonso[2], J. Lee[1], F. Delahaye[2], H. Ma[1], K. Malley[1], D. Bangari[1], D. Jackson[1], A. Hadjipanayis[1];
[1]Sanofi, Cambridge, MA, [2]Sanofi, Vitry-sur-Seine, France

We characterized immune cell exclusion in estrogen receptor positive (ER+) breast cancer through the study of spatial relationships among various subsets of cancer-associated fibroblasts (CAFs), tumor-associated macrophages (TAMs), and other immune cells using a novel in-situ spatial transcriptomic technology. ER+ breast cancer is the most common breast cancer subtype. While endocrine therapy and immune checkpoint inhibitors have considerably reduced relapse and mortality for breast cancer patients, tumor resistance to treatment remains a major challenge. The tumor microenvironment (TME) plays an important role in this mechanism of resistance. Our previous spatial proteomic analysis of ER+ breast FFPE samples demonstrated the intricate relationship between tumor and immunosuppressive cells such as CAFs and TAMs via the CXCR4-CXCL12 axis associated with the exclusion of CD8 T cells from the TME. However, the limited number of antibodies in the panel made it challenging to investigate the diversity of those CAF and TAM populations and better understand their contribution to T cell exclusion. For this purpose, we further characterized the TME of 4 human ER+ breast cancer FFPE cores using the Xenium in-situ transcriptomic platform with a breast cancer-focused panel of 280 genes from 10x Genomics plus 100 additional genes selected from literature and publicly available single cell datasets to delineate CAF and TAM sub-populations. Image analysis enabled the quantification and spatial mapping of the target genes within each cell boundary. Cells were manually annotated through unsupervised clustering of over 1 million cells. The cell phenotyping analysis allowed us to annotate major cell types including tumor cells, macrophages, T cells and fibroblasts. With our curated panel, we further characterized CAF and TAM sub-populations by identifying myofibroblastic CAFs (myCAFs), inflammatory CAFs (iCAFs), and antigen-presenting CAFs (apCAFs) in addition to M1 and M2-like macrophages as reported in the literature. We then performed spatial neighborhood analysis based on the similarity of the cell type composition in the vicinity of each cell. The results showed that myCAFs and M2-like macrophages are found in proximity to tumor cells and may play a role in T-cell exclusion. In addition, iCAFs mainly express CXCL12, a chemokine known to attract immunosuppressive cells such as regulatory T cells and M2-like macrophages as well as repel cytotoxic T cells from infiltrating the tumor via the CXCR4-CXCL12 axis. Overall, our work shows the potential of spatial transcriptomics to elucidate the spatial distribution of cells and their contribution to the immunosuppressive TME, which may enable researchers to improve understanding of tumor biology and drug target discovery efforts.

#5486 Spatial profiling reveals unique immune-transcriptomic features of tertiary lymphoid structures in melanoma.

[1]Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX,[3]Sarcoma Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[5]Epidemiology, UT MD Anderson Cancer Center, Houston, TX,[6]Colon and Rectal Surgery, UT MD Anderson Cancer Center, Houston, TX,[7]University of Virginia School of Medicine, Charlottesville, VA,[8]Epigenetics and Molecular Carcinogenesis, UT MD Anderson Cancer Center, Houston, TX,[9]Cordeliers Research Centre, Paris, France,[10]Immunology, UT MD Anderson Cancer Center, Houston, TX,[11]Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[12]Thoaric Head and Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: Previous studies have shown that intratumoral immune aggregates called tertiary lymphoid structures (TLS) are associated with exceptional response to immune checkpoint blockade (ICB) in several cancer types. However, the specific mechanisms through which TLS contribute to ICB-response remain poorly characterized in part due to technical limitations with isolating TLS. Here, we use the NanoString GeoMx digital spatial profiler to interrogate TLS with deep spatial and transcriptional resolution and identify cellular and molecular features of response-associated TLS in melanoma.
Methods: Twelve neoadjuvant ICB-treated high-risk resectable melanoma patients [NCT02519322] with formalin-fixed paraffin embedded (FFPE) surgical resections were included in this study. Major pathologic response (MPR) defined as <10% viable tumor at time of surgery was used to evaluate response (R – responder; NR – non-responder). TLS were sampled (via H&E) using 1mm core punches and assembled into a tissue microarray (TMA). The TLS TMA was probed using the human whole transcriptome atlas (huWTA) and the human T-cell receptor (huTCR) atlas. Melanoma (S100B) and immune markers (CD45 and CD20) were used to guide region-of-interest (ROI) selection of classical TLS. Differential gene expression was calculated using a linear mixed model and corrected with Benjamini-Hochberg. Immune deconvolution was performed using CIBERSORTx with FDR cutoff of < 0.25.
Results: Fifty percent (6/12) of patients included in this study demonstrated MPR following treatment with neoadjuvant ICB. Principal component analysis of huWTA probes revealed distinct transcriptional states of R TLS vs NR TLS, with PC1 strongly correlating with response status ($r=0.88$, $p<0.0001$). Differential immune analysis showed that R TLS harbored more CD8+ T-cells ($p<0.001$), NK cells ($p=0.004$), γδ T-cells ($p=0.017$) and memory B-cells ($p=0.026$) and preferentially upregulated inflammatory genes such as pattern recognition receptors (TLR8 and KLRC2) and immune-stimulatory markers (CD27 and CD103). Immune-repertoire analysis revealed a trend towards increased TCR diversity in R TLS ($p = 0.3$) and distinct TCR signatures in R TLS underscored by elevated expression of TRDJ4 ($p<0.001$), TRGJ1/2($p<0.001$), TRGV4($p<0.001$) and TRAV1-2($p=0.018$) genes amongst others.
Conclusions: These findings demonstrate that, although melanomas from both R and NR patients contain TLS, the immune-phenotype of R TLS is more cytotoxic and characterized by a more diverse TLS-resident T-cell population. These findings present new insights into the therapeutic underpinnings of TLS in cancer and will inform future investigations evaluating their formation/function in solid tumors.

#5487 Improved spatial biology analysis of the tumor microenvironment with the next generation of the MultiOmyx™ platform.

M. Lazare, H. Nunns, F. Jelvhei Moghaddam, X. Jin, C. Todorov, E. Leones, M. Thio, F. Sahafi, E. Parnell, Q. Au;
NeoGenomics, Aliso Viejo, CA

Multiplexed Immunofluorescence is a powerful tool for spatially characterizing and phenotyping cells within the tumor microenvironment. MultiOmyx has been one of the leading platforms for generating multiplexed immunofluorescence data to support translational and clinical research for more than 10 years. However, MultiOmyx and other similar platforms are often hampered by a limited imaging area due to either restricted staining areas or being cost prohibitive due to excessive imaging times. Here, we demonstrate the capabilities of an improved MultiOmyx platform which can be used to generate whole-tissue data from the iterative MultiOmyx multiplexing process using the CyteFinder® II microscope and a customized software package developed by RareCyte, Inc. The new NeoLYTX image analysis pipeline in conjunction with the whole-tissue image output allows for improved interaction with pathologists, better histological context, and unbiased spatial analysis. In this study we utilized a 16-marker panel consisting of CD3, CD4, CD8, FoxP3, CD20, CD68, CD163, HLA-DR, PD-1, PD-L1, CTLA-4, CD34, Vimentin, SOX10, Ki67, and PanCK to generate immune profiles for colorectal carcinoma, prostate carcinoma, non-Small cell lung cancer, and triple negative breast cancer samples. We showed concordance with the current MultiOmyx imager - the IN Cell 2200 - for each of the markers in the panel. Additionally, we demonstrated that the updates made to the proprietary NeoLYTX image analysis pipeline are able to facilitate the significantly larger data sets that will be generated with the new MultiOmyx platform. This study successfully demonstrates the capability of the improved MultiOmyx system to characterize the distribution of T-cell and myeloid phenotypes in the tumor microenvironment using the proven MultiOmyx workflow, now enhanced by whole slide images and analysis.

#5488 AI-enhanced spatial proteomics reveals B-cells & FoxP3+ cells interactions in HPV(+) oropharyngeal squamous cell carcinoma Progression.

S. Nakkireddy[1], R. David[2], K. Bartemes[2], D. Ma[2], T. Hwang[1], K. Van Abel[2], C. Nimeh Abdel-Halim[2];
[1]Mayo Clinic Florida, Jacksonville, FL, [2]Mayo Clinic, Rochester, MN

Background: Analyzing interactions and the microanatomical distribution of the tumor immune microenvironment (TIME) is essential for a comprehensive understanding of tumor progression. Imaging Mass Cytometry (IMC) is a high-dimensional tissue imaging system that enables the deeper and multiparametric *in situ* exploration of tumor microenvironments at a single-cell level. This study describes a pipeline for analyzing 39-plex IMC images of human HPV(+) oropharyngeal squamous cell carcinoma (OPSCC) tumor sections, elucidating immune cells' nature, functions, and interactions with tumor cells. The IMC data analysis provides valuable information for clinical studies that could be used for the identification of prognostic biomarkers and mechanisms of resistance to current immunotherapies.

Methods: A retrospective study was conducted on (N=20) patients (10 progressors and 10 non-progressors) with HPV(+) OPSCC. The dataset comprises paired hematoxylin and eosin (H&E) images with IMC data from multiple Regions of Interest (ROIs) (N=82), enabling the in-situ profiling of 39 proteins in primary tumor tissue. Cell segmentation was followed by employing original images and their segmentation masks for cell phenotype identification using a probabilistic neural network method to spatially profile cancer cells, macrophages, NK-M cells, B-cells, and distinct T-cell populations. We identified protein expression at single-cell resolution and investigated the impact of multicellular spatial organization on the disease progression. The spatial neighborhood interaction score of tumor cells with various other cells was computed for all the ROIs across the two groups.

Results: The markers showed varying expression levels of intensity distribution, likely due to differences in tissue sample composition. Specifically, CD3, CD4, CD8, CD19, CD20, and CD68 showed significantly higher intensity in non-progressors. Interestingly, FoxP3 also had a significantly higher intensity level in non-progressors. Cell phenotyping emphasized that non-progressors generally have increased levels of NK-M cell markers. Spatial analysis revealed a significant increase in interaction between CD3 cells and tumor cells in non-progressors (p-value=0.07, Mann-Whitney U test). Furthermore, a significant rise in the interaction between B-cells and FoxP3+ cells was observed in non-progressors (p-value<0.05, Mann-Whitney U test) suggesting a coordinated suppression of tumor growth.

Conclusion: We developed a deep learning-based pipeline to analyze spatial relationships in the TIME of IMC data, demonstrating its clinical relevance in predicting disease progression. Our findings emphasize the importance of spatial relationships in the TME for response and suggest that proximity between either CD3+ T-cells to cancer cells or B-cells to FoxP3+ cells are candidate biomarkers.

#5489 The spatial landscape of early-stage lung adenocarcinoma.

Junbum Kim, Hiranmayi Ravichandran, Liron Yoffe, Bhavneet Binder, Timothy McGraw, Nasser K. Altorki, Vivek Mittel, Olivier Elemento

Weill Cornell Medicine, New York, NY

Cellular and molecular basis of ground-glass opacities (GGO), which has been used as a screening indicator for lung cancer, remains a gray area. Our aim was to investigate the tumor-immune microenvironment (TIME) in a cohort of early-stage lung adenocarcinomas (LUAD) through imaging mass cytometry, enabling us to examine the TME spatial composition of nodules at single-cell resolution. We collected 354 imaging mass cytometry (IMC) regions of interest (ROI) from 135 early-stage lung adenocarcinoma patients to investigate the spatial and molecular profiles of early stage LUAD. Specifically, we gathered 27 solid (S), 39 part-solid (PS), 74 pure non-solid (PNS) patients and 89 matched adjacent-normal cases to profile the phenotype of 2.24 million cells across the two IMC panels to characterize the cellular and molecular composition of GGO nodules. Comparing progression from adjacent normal, pure non-solid, part-solid, to solid, we observed consistent reduction in RAGE+ AT1 cells ($p^*<1.6E-7$) and a reciprocal increase in SFTPC+ AT2 cells ($p^*<1.3E-8$) and PanCK+Ki67+ proliferative epithelial cells ($p^*<2.8E-7$). We also report fibrogenesis and an increase in immune cell populations such as regulatory ($p^*<1.4E-5$), CD4 ($p^*<0.0024$), CD8 T ($p^*<0.017$) cells, B ($p^*<5.5E-9$) cells, and macrophages. Spatially, we quantify an upregulation of tumor-tumor and tumor-fibroblast interaction, and a downregulation of tumor-immune interaction. We believe this evidence suggests the role of fibroblasts as liner for tumors, barricading immune infiltration and harvesting uninterrupted tumorigenesis. In summary, we performed a highly multiplexed IMC data to analyze the TIME spatial profiles of GGO nodules in early-stage LUAD at a single-cell level. Spatial analysis of this integrated multidimensional omics dataset provides insight into the pivotal role of fibroblasts in early-stage LUAD in immune suppression, evasion, tumorigenesis, and potentially metastasis.

#5490 Spatial profiling of inflamed tumor microenvironment of clear cell renal cell carcinoma.

T. Pellinen[1], L. Luomala[1], K. Mattila[2], J. Saila[1], A. Hemmes[1], K. Valimaki[1], O. Bruck[1], L. Paavolainen[1], H. Nisen[1], P. Jarvinen[1], O. Kallioniemi[1], P. Vainio[2], P. Jaakkola[2], T. Mirtti[1],

[1]University of Helsinki, Helsinki, Finland, [2]University of Turku, Turku, Finland

Clear cell renal cell carcinoma (ccRCC) presents a distinctive tumor microenvironment (TME) characterized by extensive vascularization and immune infiltration. This unique TME makes ccRCC an attractive target for anti-angiogenesis and immune checkpoint blockade (ICB). To better understand the complexity of ccRCC and the associated cell types and states involved in disease progression, we conducted high-throughput single-cell immunofluorescence imaging on tissue sections from 437 localized tumors that were surgically resected. These samples included regions from the tumor center, tumor edge, and adjacent benign areas (TMA cores, n=1859). Our primary focus was on tumors with elevated immune cell enrichment ($CD45^{high}$), as these tumors are known to be aggressive and may respond well to immunotherapy. Our study reveals the intricate interactions between tumor, vascular, stromal, and immune cells within ccRCC. We find that $CD45^{high}$ tumors, upon losing epithelial marker expression, acquire tumor cell PD-L1 and mesenchymal markers such as Fibroblast activation protein (FAP). This shift is indicative of the epithelial-mesenchymal transition (EMT) process. These $CD45^{high}$ and EMT^{high} tumors are enriched with changes in TME, including elevated FAP+ cancer-associated fibroblasts (CAFs) and subsets of immune suppressive T cells and macrophages. We report that ccRCC patients with high tumor PD-L1 expression or abundant FAP+ CAFs are associated with earlier metastasis and, in sunitinib-treated patients, shorter progression-free survival. This study illuminates the intricate connection between immune cell infiltration, stromal biology, and EMT in ccRCC, offering a deeper understanding of the disease's complex biology and potentially guiding future therapeutic approaches and strategies.

#5491 Mapping ovarian cancer spatial organization uncovers immune evasion drivers at the genetic, cellular, and tissue level.

K. Aguirre, C. Yiwen-Yeh, O. Laveroni;
Stanford University School of Medicine, Stanford, CA

Immune exclusion and evasion are central barriers to the success of immunotherapies and cell therapies in solid tumors. Here we applied single cell spatial and perturbational transcriptomics alongside clinical,histological, and genomic profiling to elucidate immune exclusion and evasion in high-grade serous tubo-ovarian cancer (HGSC). Using high-plex spatial transcriptomics we profiled more than 1.3 million cells from 95 tumors and 60 patients, revealing generalizable principles in HGSC tumor tissue organization.Our data demonstrates that effector T cells resist stroma-mediated trapping and sequestration. However, upon infiltration into the tumor, T cells, as well as Natural Killer (NK) cells, preferentially co-localize only with a subset of malignant cells that manifest a distinct transcriptional cell state. The latter consists of dozens of co-regulated genes and is repressed under various copy number alterations. Performing CRISPR Perturb-seq screens in ovarian cancer cells, we identified functionally diverse genetic perturbations - including knockout of the insulin sensing repressor PTPN1 and the epigenetic regulator ACTR8 - that de-repress the proposed immunogenic malignant cell state identified in patients and indeed sensitize ovarian cancer cells to T cell and NK cell cytotoxicity. Taken together, our study uncovered a profound connection between somatic genetic aberrations, malignant cell transcriptional dysregulation, and immune evasion at the cellular and tissue level, allowing us to identify targets that reprogram malignant cell states as an avenue to unleash anti-tumor immune responses.

#5492 Spatial organization and cellular composition of immunity hubs in human colorectal cancer.

Mukta G. Palshikar[1], Maxwell Spurrell[2], Jack Demaray[3], Han Chen[3], Scott Engels[3], Roopa Madhu[4], Milan Parikh[5], Izabella Zamora[6], Arnav Mehta[6], Nicolas Fernandez[7], Colles Price[7], Jiang He[7], Sonia Cohen[6], Karin Pelka[3], Nir Hacohen[5], Jonathan Chen[6], Ilya Korsunsky[1]

[1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[2]Massachusetts General Hospital (MGH) Krantz Family Center for Cancer Research, Boston, MA,[3]Gladstone-UCSF Institute of Genomic Immunology, Gladstone Institutes, San Francisco, CA,[4]Immunology, Harvard Medical School, Boston, MA,[5]Broad Institute of Massachusetts Institute of Technology (MIT) and Harvard, Cambridge, MA, USA, Cambridge, MA,[6]Broad Institute of Massachusetts Institute of Technology (MIT) and Harvard, Cambridge, MA,[7]Vizgen, Inc, Cambridge, MA

Background: Among colorectal cancer (CRC) tumors, mismatch repair deficient (MMRd) tumors have more immunogenic neo-antigens, hence more cytotoxic T-cell mediated anti-tumor immunity than mismatch repair proficient (MMRp) tumors. Previously[1], we transcriptionally profiled over 300,000 cells from 62 MMRd and MMRp CRC tumors and found an MMRd-unique network of immunologically active transcriptional states enriched in interferon-stimulated genes (ISGs). With 4-color imaging, we showed that this program arises from spatially organized hubs of at least 3 cell types: IFNã-secreting T and interferon-responsive CXCL9/10/11+ myeloid and tumor cells. To characterize the breadth of cells involved in tumor immunity hubs, we must simultaneously measure the expression of 100s of genes *in situ*.

Methods: To describe the cellular composition, structural organization and intercellular spatial interactions of these immunity hubs, we profiled primary untreated resection specimens from 17 CRC donors (n=12 MMRd, 5 MMRp) using multiplexed error-robust FISH (MERFISH) mRNA microscopy. Efforts were made to sample both the tumor body and the invasive border of the tumor. We designed a panel of 479 genes to capture key transcriptional programs from our single-cell atlas[1]. We wrote analytical pipelines to segment transcripts into cells, select high-quality cells, and organize cells into distinct zones in tissue. To leverage the rich information in the scRNA-seq atlas[1], we designed a robust label transfer analysis to assign cell state labels to MERFISH cells by comparison to scRNAseq cells.

Results: We profiled 7.5 million high quality MERFISH cells across 21 CRC tissue sections and labeled the cells into 7 major lineages: 63.19% epithelial, 22.52% stromal, 7.75% myeloid, 3.72% T/NK/ILCs, 1.45% plasma, 1.2% B, and 0.17% mast cells. We visualized the spatial location of these cell types. T cells aggregated into 3 distinct regions of tissue: tertiary lymphoid structures (TLS) outside the tumor, and smaller clusters near the invasive border and in the tumor center. We identified immunity hubs defined by colocalized *CXCL9/10/11* expressing cells and T cells near the invasive border and in the center of MMRd tumors. As expected, we found enrichment of *CXCL13*, *IFNG*, and ISGs such as *CD74* and *MHCII* genes at these locations. In contrast, we found evidence of *CCL17+CCL19+LAMP3+* activated dendritic cells and B cells enriched in the TLS. These results support a distinct composition and localization of immunity hubs in tumors, in contrast to TLS outside tumors.

Conclusions: Our study defines the composition, spatial organization, and intercellular interactions of immunity hubs, shedding light on the anti-tumor immune response in CRC.

Ethics Approval: Approved by the DF/HCC Institutional Review Board (protocol #02-240).(1) Pelka, K. et al. Spatially organized multicellular immune hubs in human colorectal cancer. Cell 184, 4734-4752.e20 (2021)

#5493 Digital spatial profiling of MC38 colon carcinoma following checkpoint inhibition.

P. Singh, D. Saims, **S. Barnes**, D. Draper;
Labcorp Drug Development Inc., Ann Arbor, MI

Immunotherapy aims to bolster the immune response within the tumor microenvironment (TME). However, checkpoint inhibitors utilized in the treatment of colon carcinoma have demonstrated efficacy only in certain patients. To develop more effective therapeutics, strategies that navigate the heterogeneous nature of the TME must be employed. The MC38 tumor model, known for its immunologically active characteristics and responsiveness to certain immunotherapies, is widely used for preclinical drug development. Furthermore, elevated levels of pan-cytokeratin (PanCK) expression in tumors have shown an association with diminished survival rates among colon carcinoma patients. In this study, we used the GeoMx® DSP platform (NanoString Technologies) to investigate the spatial expression profile of PanCK in MC38 tumors and analyze the impact that PanCK expression exerts on anti-PD-1 induced gene expression in tumor and immune cells. To this end, C57BL/6J female mice were implanted with MC38 cells, enrolled into groups, and treated with anti-PD-1 antibody. Tumor growth was monitored by caliper measurements and anti-PD-1 produced minimal responses with a Day 22 median % Delta T/C value of 88%. For DSP analysis, tumors were collected 10 days post-treatment, formalin fixed for paraffin embedding, and then sectioned for PanCK and CD45 protein visualization. Regions of interest were drawn to create a matrix analysis that defined regions with high or low PanCK expression, that were proximal or distal to CD45+ immune rich regions of the tumor. A segmentation algorithm was applied to examine gene expression within each region using the GeoMx Mouse Whole Transcriptome Atlas. Cluster analysis revealed an enrichment of apoptosis and autophagy gene sets in tumor cells that were proximal to immune rich regions. In the CD45+ segment, immune cells adjacent to high PanCK-expressing cells contained 318 genes with significantly increased expression levels when compared to low PanCK-expressing cells, and only 11 genes with decreased expression levels. The upregulated genes were enriched for numerous biomarkers of T cell recruitment and activation, including cd3, cd8, cxcr3, ccl5, cxcl9, icos, and cd27. Next, we conducted a linear mixed model analysis to examine the impact of PanCK expression on anti-PD-1 induced gene regulation. Notably, an enrichment of genes that code for T cell exhaustion biomarkers was observed in immune cells near PanCK high expressing cells, including ctla4, slamf7, tigit, and lag3. In summary, the most pronounced transcriptomic changes occurred within immune cells situated near tumor cells displaying high PanCK expression and suggest that PanCK expression correlates directly with T cell recruitment and activation but also exhaustion. Furthermore, these data emphasize the significance of spatial analysis as a valuable component of preclinical research, as demonstrated in MC38 tumor model.

#5494 Spatial organization between claudin and the tumor microenvironment in head and neck squamous cell carcinomas.

K. Maclean, L. Chandramohan, M. Rohafza, H. Nunns, E. Parnell, Q. Au, A. Juncker-Jensen;
NeoGenomics, Aliso Viejo, CA

Background: Head and neck squamous cell carcinoma (HNSCC) is the sixth leading form of cancer worldwide and one of the most difficult and challenging malignancies, with a high level of heterogeneity and a wide range of treatment responses. Oral squamous cell carcinoma (OSCC) is the most common head and neck cancer and accounts for over 90% of cancers that develop within the mucosal epithelium of the oral cavity. Additional carcinogenic risk factors, including tobacco, alcohol and HPV infection are also associated with the pathogenesis of oral carcinogenesis. Unfortunately, today the failure of standard treatment modalities, such as surgery, radiotherapy, and chemotherapy underscore the need to identify better biomarkers of this disease. Advances, especially in spatial technology have created unprecedented opportunities to identify cell types and biomarkers of disease processes, revealing important relationships within the tumor microenvironment (TME) that allow a detailed characterization of specific cell phenotypes defined by co- or lack of expression of multiple markers that may help in predicting clinical responses and mechanisms of resistance to therapy. Recent findings indicate that abnormal expression of claudins (CLDNs) is closely related to the occurrence, progression and prognosis of many solid tumors. Specifically, CLDN6 is expressed in numerous tumors but rarely found in adult normal tissues making it a potential therapeutic target in head and neck tumor types. To investigate this further, expression of CLDN6 and the its relationship with changes within the TME of cohort OSCC tumors was determined using a proprietary comprehensive spatial workflow and gene expression analysis.

Methods: A retrospective analysis was performed on biopsied Formalin-Fixed Paraffin-Embedded (FFPE) samples from OSCC patients with and without a history of smoking and treated +/- chemotherapy. Patient samples representing matched normal tissue to serve as controls were compared to samples derived from OSCC tumors. In order to perform a comprehensive expression profiling of the TME from OSCC tumors we used the spatial MultiOmyx™ immunofluorescence (IF) multiplexing assay with transcriptomic information from bulk mRNA gene expression acquired using the NanoString nCounter® PanCancer IO 360™ panel that includes the Tumor Inflammation Signature (TIS), as well as targets that characterize immune hot, desert, and cold regions in the stroma and tumor epithelium.

Results: We characterized the expression of CLDN6 across the different cohorts of OSCC samples and further investigated the relationship within the tumor immune microenvironment coupled to genes related to the prognosis of OSCC. A better understanding of the TME and gene expression profiling of OSCC tumors and the effect of smoking will allow us to tailor the treatment of patients to continue to improve outcomes.

#5495 Multiplexed analysis across cancers of diverse origins to unravel spatial interactions within the tumor microenvironment.

V. Agrawal[1], L. Arvidson[2], M. J. Smith[1], K. O. White[1], R. A. Heil-Chapdelaine[1], S. Jensen[2], **A. BOSE**[1];
[1]Leica Microsystems, Waltham, MA, [2]Cell Signaling Technology, Danvers, MA

The tumor microenvironment (TME) is heterogeneous and is primarily composed of fibroblasts, extracellular matrix, immune cells, and blood vessels. Importantly, the tumor immune microenvironment (TIME) is a major source of cancer heterogeneity and influences both disease progression and response to therapeutic interventions. Malignant cells typically recruit various cell types such as vascular endothelial cells, cancer-associated fibroblasts (CAFs), and tumor-associated macrophages (TAMs) to promote tumor growth. Therefore, studying such a complex interplay among tumor, stromal cells, and immune cells within the TME necessitates a multiplexed analytical approach to investigate cancerous tissues from diverse origins, to ultimately predict clinical outcomes and design novel therapies. While numerous studies have been focused on investigating the expression patterns of immune-oncology markers within specific tissues, the extent to which such marker expression patterns are shared across tumors originating from various tissues is not adequately understood. In this study, we analyzed a large panel of Cell Signaling Technology (CST®) antibodies that are targeting immune, stromal, epithelial, and vascular markers in cancer tissues derived from various origins including lung, colon, and pancreas. Using multiplexed Cell DIVE imaging, key spatial interactions in the tumor microenvironment that are (1) tissue-specific, and (2) shared across tumors irrespective of origin were determined. Specifically, cluster analysis of a common panel of markers across tissues of different origins uncovered molecular signatures that are common to all cancer tissue types as well as those that are unique to specific tissue types to advance our understanding of the disease, and its progression, shedding light on the intricate interactions within the TME.

#5496 Multi-omic spatial analysis of the tumor microenvironment in gliomas.

D. Klymyshyn[1], V. Jain[2], L. Whaley[2], E. Hocke[2], B. Ben Cheikh[1], A. Smith[2], K. Abramson[2], N. Nelson[3], D. Satterfield[4], E. Thomas[4], G. Lopez[4], S. Hariharan[4], M. Brown[4], N. Jhaveri[1], R. McLendon[5], D. Ashley[4], M. Waitkus[4], S. Gregory[4];

[1]Akoya Biosciences, Menlo Park, CA, [2]Duke Molecular Genomics Core, Duke Molecular Physiology Institute, Durham, NC, [3]Abcam, Cambridge, United Kingdom, [4]The Preston Robert Tisch Brain Tumor Center at Duke, Brain Tumor Center, Durham, NC, [5]Duke Cancer Center Brain Tumor Clinic, Durham, NC

Introduction: The diverse tumor environment of high-grade glioma, which remains refractory to treatment, demands new innovative, multi-omic approaches to characterize tumor heterogeneity and expression profiles associated with progression and therapeutic response.

Approach: We have applied an integrated, multi-omic approach using paired spatial *in situ* sequencing (Xenium) and protein profiling (PhenoCycler® Fusion) of glioma tissue to identify distinct glioma cellular phenotypes, activation states and metabolic pathways at true single cell resolution. Our multi-omic approach used hundreds of phenotypic RNA target probes and >50 antibodies in an unbiased single-cell analysis of primary, recurrent, and IDH1 mutant/wild type tumors with a range of heterogeneity.

Summary: We were able to distinguish differentially regulated genes and pathways between aggregated primary and recurrent GBM, including cell cycle pathways being upregulated in primary vs recurrent GBM glial cell clusters and a down regulation of ERBB4 signaling in vascular cell clusters in primary GBMs. Our data also suggests that SOX11, known to be involved in tumorigenesis, is >2-fold upregulated in annotated tumor cells in primary compared to recurrent tumors. We were also able to quantitatively localize the expression of Epidermal Growth Factor Receptor, variant III (EGFRvIII) to specific tumor-cell sub-types, which is important given its association with therapeutic resistance. Further, we have been able to establish the cellular neighborhoods and cell-cell and receptor-ligand relationships within the tumors. Our spatial protein analysis identified distinct tumor and immune phenotypes with varying abundance of myeloid and lymphoid populations in IDH1 wt and mt tumors. Moreover, spatial proximity analyses and cellular neighborhood analyses revealed differences in higher order organizational landscapes that may contribute to the differential outcomes across wt and mt tumor subtypes.

Conclusion: Multiomic spatial analysis enables deeper characterization of the glioma cellular and functional landscape to broaden our understanding of the key TME features that contribute to disease pathogenesis and prognoses. Our study provides an analytical framework to combine RNA and protein-based spatial data for a holistic investigation into a variety of glioma subtypes and aid in the identification of novel biomarkers, spatial neighborhoods, and functional states that drive glioma progression.

#5497 Towards a drag and drop spatial biology workflow: Introducing sample reinterrogation as a conduit for the progressive development and on-line analysis of high parameter spatial biology data.

M. H. Ingalls[1], X. Meshik[1], C. E. Jackson[1], K. E. Cashion[1], A. Christians[2], A. Brix[2], M. Boettcher[3], J. S. Schwarz[1], O. Braubach[1];
[1]Canopy Biosciences-A Bruker Company, St. Louis, MO, [2]Canopy Biosciences-A Bruker Company, Hannover, Germany, [3]Canopy Biosciences-A Bruker Company, Leipzig, Germany

The potential for spatial biology in cancer research is understood and edified. With it we can understand the tumor microenvironment, unravel responsiveness to drug treatments and cell therapies, and ultimately stratify patients for targeted treatment and clinical trial enrollment. Yet, researchers exploring spatial biology may be discouraged by what can be a resource intensive exercise, and most importantly, a commitment of high value patient samples. Furthermore, the design of reagent panels used to study samples is not trivial, and a specimen's unique biomarker expression profile may require adjustments. Here we present a novel solution that permits sample re-interrogation and in-flight adjustments of reagent panels in our spatial biology workflow.

The CellScape™ platform for Precise Spatial Multiplexing paired with VistaPlex™ Assay Kits provide a ready-to-use cyclic multiplex immunofluorescence (IF) solution to interrogate fresh frozen and FFPE tissue samples. Tissues are mounted in enclosed fluidic chambers, while staining and imaging are conducted on the CellScape instrument. The experiment requires no additional autostainer equipment and is divided into separate staining and imaging rounds. The end user may therefore pause between rounds and conduct *inter-round* analyses, which can then guide decisions of whether and how to continue the experiment. To illustrate the benefit of this approach, we present a use case in which we applied VistaPlex antibody panels to reveal the spatial distribution of major immune cell populations. *Inter-round* analysis and conclusions were then drawn from this preliminary phenotype map before successive rounds of rationally planned staining were conducted to further deepen the depth and breadth of spatial phenotyping.

The CellScape sample reinterrogation feature is a pragmatic spatial biology solution that optimizes the use of precious resources, whilst allowing researchers to generate informed decisions about antibody panel designs almost in real time. This enhanced utility may reduce the resistance to spatial biology among researchers working with samples that are limited or irreplaceable.

#5498 Multi-modal examination of spatial heterogeneity in the astrocytoma microenvironment.

J. Moffet, J. Kriel, T. Lu, L. Freytag, J. Whittle, S. Best, **S. Freytag**;
The Walter & Eliza Hall Institute of Medical Research, Parkville, Australia

Astrocytoma is a diffuse tumor that infiltrates the brain. Despite post-operative therapy including radiation and chemotherapy, 52% of patients' tumors recur within five-years of surgery. These tumors are characterized by mutations in the IDH1 or IDH2 gene that confer metabolic alterations, most notably the production of the onco-metabolite 2-hydroxyglutarate. To reveal the metabolic alterations and their upstream regulation across the tumor microenvironment, we applied spatial metabolomics and spatial transcriptomics to sequential sections from resected tumor samples of patients with low grade astrocytoma. This necessitated extensive optimization of atmospheric-pressure MALDI-TOF, including the establishment of a custom automated computational pipeline with abilities to identify metabolic niches. Additionally, using sequential sections of the same tumor, we also compared all commercially available imaging-based spatial transcriptomic technologies (10x Genomics Xenium, Nanostring CosMx, Vizgen MERSCOPE) to evaluate their suitability with regards to building a multi-modal model of metabolic activity and regulation across the tumor microenvironment. We found that 10x Genomics Xenium was most suited for this task as image registration across sequential sections was comparatively straight-forward. Combining spatial transcriptomics generated with 10x Genomics Xenium and spatial metabolomics across 8 matched sequential slices of the same tumor, we identified metabolic niches associated with distinct cell type composition and transcriptional regulation.

#5499 Spatially-resolved transcriptomics analyses of liver cancer.

Liang Wu

University of Chinese Academy of Sciences/BGI-Shenzhen, Shenzhen, China

Dissecting and understanding the cancer ecosystem, especially that around the tumor margins, which have strong implications for tumor cell infiltration and invasion, are essential for exploring the mechanisms of tumor metastasis and developing effective new treatments. Using a novel tumor border scanning and digitization model enabled by nanoscale resolution-SpaTial Enhanced REsolution Omics-sequencing (Stereo-seq), we identified a 500 μm-wide zone centered around the tumor border in patients with liver cancer, referred to as “the invasive zone”. We detected strong immunosuppression, metabolic reprogramming, and severely damaged hepatocytes in this zone. We also identified a subpopulation of damaged hepatocytes with increased expression of serum amyloid A1 and A2 (referred to collectively as SAAs) located close to the border on the paratumor side. Overexpression of CXCL6 in adjacent malignant cells could induce activation of the JAK-STAT3 pathway in nearby hepatocytes, which subsequently caused SAAs’ overexpression in these hepatocytes. Furthermore, overexpression and secretion of SAAs by hepatocytes in the invasive zone could lead to the recruitment of macrophages and M2 polarization, further promoting local immunosuppression, potentially resulting in tumor progression. Clinical association analysis in additional five independent cohorts of patients with primary and secondary liver cancer (n = 423) showed that patients with overexpression of SAAs in the invasive zone had a worse prognosis. Further in vivo experiments using mouse liver tumor models in situ confirmed that the knockdown of genes encoding SAAs in hepatocytes decreased macrophage accumulation around the tumor border and delayed tumor growth. The identification and characterization of a novel invasive zone in human cancer patients not only add an important layer of understanding regarding the mechanisms of tumor invasion and metastasis, but may also pave the way for developing novel therapeutic strategies for advanced liver cancer and other solid tumors.

#5500 Single cell sequencing reveals cancer associated fibroblast heterogeneity at the core of the tumor microenvironment in brain metastasis.

T. Simon[1], D. N. Buckley[1], B. Y. Tew[1], M. Salomon[1], Z. Yang[1], G. C. Gooden[1], S. A. Toms[2], G. Zada[1], B. Salhia[1];
[1]University of Southern California, Los Angeles, CA, [2]The Warren Alpert Medical School of Brown University, Providence, RI

Introduction: Brain metastasis (BM) remains incurable with a dismal 2-year survival of less than 2%. BM are surrounded by a complex tumor microenvironment (TME) comprised of a meshwork of extracellular matrix (ECM) proteins and an assemblage of cell types including cancer-associated fibroblasts (CAFs), the most prominent cell type within the TME. We have previously shown that patient-derived BM CAFs can either support or inhibit tumor growth *in vivo*, suggesting that BM CAFs are heterogenous. Yet, there remains a dearth of data on the functional and mechanistic underpinnings of CAFs in the BM TME.
Methods: To explore both the molecular profiles of CAFs and their heterogeneity in the BM TME, we performed a single cell Multiome (RNA and Assay for Transposase-Accessible Chromatin (ATAC)) sequencing (scMultiome-seq) analysis of 9 human BM tissue samples and 4 BM patient-derived CAF cell lines, from both lung and breast primary cancers. Next, we investigated the tumor supportive or inhibitory capabilities of BM CAF cell lines on the growth of BM tumor cells *in vitro*.
Results: ScMultiome-seq analysis of BM tissue samples identified 4 distinct CAF subpopulations, that we termed desmoplastic, immune, contractile, and neural CAFs, in the BM TME. These CAF subpopulations are respectively involved in either regulating the ECM organization, orchestrating the neuroimmune response, triggering tissue contraction or regulating neural components upon BM growth. CellPhoneDB analysis revealed that CAFs had more cell-cell interactions with other cells than any other cell types in the BM TME. Pseudotime analysis demonstrated the potential cell of origin of each BM CAF subpopulation and the cell state transition they undergo. We observed that the end cell state of the desmoplastic CAFs expressed high levels of immunoglobulin superfamily containing leucine rich repeat (ISLR). ISLR was also observed to be highly expressed in a BM patient-derived CAF cell line which was previously reported by our lab to restrain tumor growth *in vivo*, suggesting that desmoplastic CAFs with high ISLR expression (ISLR-CAFs) might be tumor inhibitory. ScMultiome-seq analysis of BM CAF cell lines validated that tumor inhibitory CAF cell lines were primarily of the desmoplastic ISLR-CAF subpopulation. Conditioned media obtained from ISLR-CAFs containing high levels of ISLR inhibited tumor cell viability *in vitro* compared to controls.
Conclusion: Our study is the first to describe the heterogeneity of CAFs and their potential central roles in the BM TME. We also identify that CAF subpopulations are dynamic and can transition to tumor inhibitory cell states, such as ISLR-CAFs. These data have potential to help design therapeutic strategies that selectively target tumor supportive CAFs whilst protecting tumor inhibitory ones.

#5501 Novel whole slide imaging modes for imaging mass cytometry unveil extensive cellular heterogeneity in human gliomas.

N. Zabinyakov, Q. Raza, **T. D. Pfister**, N. Parsotam, D. Howell, L. Lim, C. Loh;
Standard BioTools, Markham, ON, Canada

Gliomas present a complex form of cancer that is challenging to diagnose and treat, with a median survival of just over one year after diagnosis for primary glioblastoma (GBM). GBM can occur as multi-lesion, remote, or diffuse tumors, and often contains a tumor microenvironment (TME) that is devoid of peripheral immune cells. Additional hallmark features of GBM include necrosis, hemorrhage, and pseudo palisades, making it a highly heterogeneous disease requiring further investigation. Identification of the cellular and spatial level composition of the TME is vital for interpretation of GBM disease origin, progression, prediction, and treatment.

A 40-plus-marker neuro-oncology Imaging Mass Cytometry™ (IMC™) antibody panel was used to determine the cellular and structural landscape of the brain TME. We applied the panel on a tissue microarray (TMA) containing dozens of human glioma cores and uncovered the spatial distribution of over 40 distinct molecular markers. We performed imaging using two new features of the Hyperion XTi™ Imaging System that provide whole slide scanning capabilities. Ultrafast preview mode was applied to rapidly screen tumor cores for expression signatures associated with tumor immuno-oncology processes. This enabled biomarker-guided selection of areas in tumor tissue that were imaged at higher resolution and analyzed using single-cell analysis. In parallel, a high-throughput tissue mode was applied to perform a detailed scan of the brain tumor TMA followed by pixel-based analysis to unravel the spatial composition of the TME. Using tissue mode imaging, we successfully mapped the spatial location of cell populations making up human gliomas, such as neurons, astrocytes, microglia, and oligodendrocytes, across the entire TMA. Various tumor cell phenotypes, resident and infiltrating cells, and resting and activated microglia were detected across all TMA cores. Subsequent single-cell analysis of select regions of interest provided a quantitative assessment of the cellular composition of the brain TME. We classified the distinct states of neurons and quantified myeloid and lymphoid immune cell infiltration across normal, astrocytoma, and GBM tissues. Striking cellular and protein heterogeneity was observed between acquired cores, indicating the complexity of each case that is impossible to capture with low-plex visualization techniques. Therefore, IMC is a highly relevant tool capable of quantitative spatial evaluation of the high-plex protein composition in the brain TME without the complications of autofluorescence, tissue degradation, and spectral overlap. Empowered by the neuro-oncology panel and new whole slide imaging modes, IMC accelerates neurological research and provides insights into the spatial complexity of gliomas and other tumors.

For research purpose only. Not for use in diagnostic procedures.

#5502 Multiplex data utilizing a single-step staining and imaging workflow for the investigation of multiple sample types.

S. Larkin, T. George, E. Kaldjian;
RareCyte, Inc., Seattle, WA

Background: Tissue consists of heterogenous cell types, each with diverse functions and functional states, where spatial organization can impact patient health status. Resolving this complexity at the subcellular level has historically been challenged by image resolution, the number of targets that can be simultaneously assessed, and throughput. Such barriers can be broken using high plex and whole slide biomarker imaging data, in one single cycle thus also mitigating issues that arise with multiple cyclic rounds.
Methods: A range of whole slide healthy and diseased tissue types were stained with 15 to 18-plex validated biomarker panels. The tissues' inherent autofluorescence was isolated into discrete fluorescence channels for enhanced information about each tissue's morphology. Whole slide spatial staining and imaging was conducted on the Orion™ spatial biology platform, and H&E staining was performed after immunofluorescence (IF) imaging on the same section and imaged by brightfield microscopy. The full protocol is fairly quick and simple, using standard histology tools: - Mount sections on glass slides- De-paraffinize and perform antigen retrieval- Quench autofluorescence- Stain slides with a panel of ArgoFluor™ conjugated antibodies- Coverslip with ArgoFluor Mounting Medium and cure overnight- Image whole slides at 20X magnification using the Orion instrument- Process to ome.TIFF and analyze- De-coverslip in aqueous solution- Perform H&E staining and scanning on same section.
Results: Imaging data within each tissue type presented here reveals important biological insights which can then be used for quantitative analysis. The little to no tissue degradation due to the one round staining and imaging process also enables H&E capabilities after IF, further enhancing biomarker quantitation. The combination of speed and resolution proved effective for comprehensive phenotypic profiling and characterization of tissue architecture, tumor heterogeneity, and the immune response.
Conclusions: There is a need to show tissue biology in a high quality, high resolution, subcellular fashion as it provides a more in-depth understanding of each biological sample and thus can lead to improved spatial research of various human diseases. The single-stain and scan method described here improves the acquisition of subcellular spatial context and greatly reduces/removes errors in multiplex image data compared to cyclic methods. A single stain and image cycle across a 12-18 plex sample provides accurate downstream biomarker quantitation, offering better prediction of patient outcomes.

#5503 Ultrahigh-plex spatial phenotyping of head and neck cancer tissue uncovers multiomic signatures of immunotherapy response.

A. Pratapa[1], L. Hernandez[1], B. Ben Cheikh[1], N. Jhaveri[1], A. Kulasinghe[2];
[1]Akoya Biosciences, Marlborough, MA, [2]The University of Queensland, Brisbane, Australia

Background Targeted immune checkpoint inhibitors (ICI) with anti-PD-1/PD-L1 therapy offer durable treatment of mucosal head and neck squamous cell cancer (HNSCC), in both human papillomavirus-positive (HPV+) and negative (HPV-) patients. However, currently available biomarker signatures for targeted ICI therapies have limited predictive value. Our recent ultrahigh-plex profiling of HNSCC tissue with 100+ cancer hallmarks of tumor and immunobiology uncovered distinct spatial domains that serve as defining factors for clinical response and resistance.
Methods Our unbiased analysis of whole-slide metastatic HNSCC tumors is from a clinical cohort of patients treated with Pembrolizumab/Nivolumab. The cohort consisted of patients with a range of outcomes from complete vs partial vs progressive disease responses to ICI therapy. We first characterized the tumor microenvironment using our ultrahigh-plex protein panel with 100+ antibodies on the PhenoCycler®-Fusion platform. To expand upon our biomarker discovery, we included multiomic cancer hallmarks with a multimodal protein/RNA detection panel. Targeted spatial RNA detection was performed to complement and augment the microenvironment characterization achieved by our protein panel. To further consolidate the multiomic data, we leveraged MaxFuse, a state-of-the art computational framework that integrates multimodal spatial and single-cell expression data.
Results Our multiomic spatial phenotyping uncovered diverse tumor regions, each with distinct biomarker expression that is reflected across modalities including protein, RNA, and metabolic activity, indicating regions likely associated with resistance to immunotherapy. Our multiomic data integration also revealed spatial signatures associated with different tissue compartments, such as the tumor and non-tumor associated tertiary lymphoid structures.
Conclusions We demonstrate a multi-pronged approach that incorporated both novel experimental and computational techniques for elucidating tumor microenvironment in HNSCC tissue prior to ICI-based immunotherapy. Our multiomic approach provides deeper characterization of the HNSCC at the transcriptomic and proteomic level incorporating depth across the entire transcriptome and single-cell spatial resolution of key protein determinants for predicting and furthering our understanding of immunotherapy response to ICI therapy.

#5504 Integrating ultrahigh-plex spatial phenotyping: From discovery to clinical applications.

A. Pratapa, N. Ma, N. Jhaveri;
Akoya Biosciences, Marlborough, MA

Background The journey from discovering predictive spatial biomarkers (known as spatial signatures) for immunotherapy responses to their clinical application necessitates a cohesive approach bridging ultrahigh-plex discovery experiments with high-throughput translational studies. This study focuses on integrating Akoya Biosciences spatial multiplexed imaging technologies with advanced data analysis techniques for comprehensive spatial phenotyping across the discovery-to-clinical continuum.
Methods Human formalin-fixed, paraffin-embedded (FFPE) cancer tissues were profiled using ultrahigh-plex PhenoCode™ Discovery panels to examine cell lineage, immune activation, and checkpoint markers via the PhenoCycler®-Fusion spatial biology platform. The subsequent use of PhenoCode™ Signature panels targeted specific biomarkers of immune profile, immune contexture, tumor-infiltrating lymphocytes (TIL), macrophage polarization, and T cell status via the PhenoImager® HT platform. Open-source whole slide image analysis software QuPath was employed for precise image analysis, including ROI segmentation, cell detection, classification, exploration of spatial interactions, and identification of distinct spatial signatures.
Results Our analysis revealed distinct spatial relationships within various tumor types, quantifying immune cell distributions and their interactions. The ultrahigh-plex data correlated with high-throughput signature panel analyses, thus paving a new simplified way for targeted identification and development of predictive spatial signatures for immunotherapy outcomes.
Conclusions The combined use of ultrahigh-plex discovery panels, high-throughput signature panels, and deep-learning image analysis provides a comprehensive understanding of cellular interactions in the tumor microenvironment. This integrated approach, utilizing Akoya's end-to-end workflows, accelerates the identification of predictive spatial biomarker signatures across various human tissue samples.

#5505 Automating a spatial profiling workflow to explore the effects of hypoxia in the tumor microenvironment in head and neck cancer.

D. Mason[1], K. Teplitz[2], **J. R. Mansfield**[1], K. Hunter[3], J. Campos[3], J. Brooks[4];
[1]Visiopharm, Horsholm, Denmark, [2]NanoString Technologies, Seattle, WA, [3]Propath UK, Hereford, United Kingdom, [4]University of Birmingham, Birmingham, United Kingdom

Head and neck cancer (HNC) is a heterogeneous group of malignancies that arise from the mucosal surfaces of the upper aerodigestive tract. The tumor microenvironment (TME) of HNC is characterized by the presence of immune cells, stromal cells, and extracellular matrix components. A key feature of the TME is hypoxia, which promotes tumor growth, invasion, and metastasis by altering the expression of genes involved in angiogenesis, cell survival, and metabolism. Understanding the complex interplay between hypoxia and immune infiltrates in the TME of HNC is crucial for the development of novel therapeutic strategies for the treatment of this disease. Whole transcriptome analysis by digital spatial profiling is an excellent method of probing the TME, but assessing large cohorts can be time consuming. Automating a profiling workflow to reduce hands-on time and region of interest (ROI) selection bias will enable exploration of large cohorts to identify mechanisms of action, potential drug targets, and biomarkers.

We developed an optimized spatial multi-omic workflow to enable high-throughput spatial analysis on GeoMx® Digital Spatial Profiler (DSP) using the Whole Transcriptome Atlas (WTA) and immuno-fluorescent morphology markers: SYTO82 (nuclei), CAIX (hypoxia), pan-cytokeratin (epithelium), CD3 (T-cells). A.I.-based analysis (Oncotopix® Discovery) of serial section H&E images and GeoMx IF images was developed to identify ROIs for GeoMx collection. Immune hot and cold selection used leukocyte density; tumor/stromal interface selection used epithelial areas. Areas of illumination (AOI) were chosen using concentric CAIX expression gradients. Integrated analysis of digital images using Oncotopix Discovery and the whole transcriptome was done to assess the above TME compartments.

Automated ROI placement based on tumor/stroma, hypoxia and immune infiltration and AI /Deep Learning based AOI segmentation reduced AOI selection time and improved accuracy of tissue compartment enrichment, especially between samples and tissue types. Automated development of hypoxia gradient-based AOI enabled a selection strategy not possible in the standard DSP software. Cell phenotyping using IF morphology scan was used to supervise cell deconvolution. DSP results correlated well with patient outcomes.

This work shows that ROI-based spatial analyses can be used to explore the effects of hypoxia levels on immune infiltration in HNC. Automated AI-based ROI selection provides a means of sampling relevant tumor subtypes based on hypoxia and immune infiltrate criteria in an unbiased, reproducible manner, and can provide a standardized, automated method for selecting ROIs and segmenting AOIs across a cohort of mixed tissue types and pathological subtype, improving throughput.

#5506 HOST-Factor: A comprehensive platform for single-cell highplex immunofluorescence staining, digital imaging, spatial mapping, and quantitative analysis of the tumor microenvironment.

J. Franco-Barraza[1], F. Schneider[2], R. Norre-Sorensen[2], R. Ahrenkiel-Lyngby[2], C. Brown[1], D. Winkowski[2], **J. R. Mansfield**[2], E. Cukierman[1];
[1]Fox Chase Cancer Center/Lewis Katz School of Medicine, Philadelphia, PA, [2]Visiopharm, Horsholm, Denmark

Solid tumor complexity extends beyond the genetic and functional landscapes of heterogenous cancer cells, encompassing the tumor microenvironment (TME). Elucidating the TME's complexity requires a comprehensive assessment of its cellular composition, functional states, and spatial distributions. We developed the Harmonic Output of Stromal Traits (HOST) to identify TME cells, and the HOST-Factor to quantify their functional states. The HOST-Factor is a numerical value that reflects the relative contribution of cancer-associated fibroblasts (CAFs) to tumor-suppressive or tumor-promoting functions.
Our workflow combines automated cycling highplex immunofluorescent microscopy with artificial intelligence (AI)-guided image analysis. This generates HOST-Factor values for each identified TME cell within selected regions of interest, providing spatial distribution data. The TME signature encompasses 15 immune cells and 14 CAF antibody-detected biomarkers.
We applied our workflow to ten human pancreatic cancer specimens, generating OME-TIFF output images. This cancer model was used due to its significant TME makeup. The 29 highplex AI-based digital image analysis was conducted using the Phenoplex™ workflow from Visiopharm. The workflow included deep-learning-based tissue morphologic and cellular segmentations, cellular phenotyping, and integration of spatial/location data. Biomarker subsets were visualized, and a user-trained algorithm was used for tissue segmentation. Nuclear segmentation was done using a pre-trained algorithm on a DAPI-labeled DNA channel. Cellular phenotyping was performed using thresholds based on visual assessment and confirmation of positivity. Spatial neighborhood plots and metrics, heatmaps and partitioned t-SNE plots were generated for the dataset for downstream analysis. Importantly, the workflow's visualization templates, pre-trained nuclear/cytoplasm segmentation tools, and neighborhood plots and metrics, are reusable and fully customizable for new datasets.
Using HOST-Factor values, we successfully classified cancer and TME cells, along with their functional states, and spatial distributions.
This AI-based computational approach and user-friendly workflow provides a simple and effective way to obtain single-cell information from multiplex immunofluorescence images, making spatial phenotyping of several cell populations in tissues more accessible to researchers, providing a fully amendable means for future clinical translation.

#5507 High-resolution spatial atlas reveals insight into spatial landscape of lung cancer and chronic lung diseases.

R. Nandigama[1], B. Cheikh[2], J. Nabhanizadeh[1], F. Grimminger[1], W. Seeger[1], N. Jhaveri[2], S. Savai Pullamsetti[1], **R. Savai**[1];
[1]Justus Liebig University, Giessen, Giessen, Germany, [2]Akoya Biosciences, Massachusetts, MA

Background: Patients with lung cancer often have a high prevalence of severe comorbidities, primarily due to the significant correlation with cigarette smoking and the aging process. Dysregulations of the immune response are the cause of chronic inflammatory diseases such as chronic obstructive pulmonary disease (COPD), pulmonary arterial hypertension (PAH), pulmonary fibrosis (PF) and lung cancer. In addition, the lung microenvironment in these chronic inflammatory diseases has not yet been sufficiently investigated. Therefore, we aimed to investigate the spatio-temporal localization and cellular distribution in the lung microenvironment and to compare lung cancer with the concomitant diseases of lung cancer.
Methods: FFPE lung sections, each 3µm in thickness, were collected from patients with diagnoses of lung cancer, COPD, PAH, PF, and from healthy donors, with three samples taken for each category. These sections were subsequently imaged using the PhenoCycler®-Fusion system, utilizing a comprehensive panel of 45 antibodies, including immune, epithelial, vascular, proliferation and apoptosis markers. The first step of the analysis workflow consists of cell segmentation using a fine-tuned deep learning model leading to a total of 5.2 million cells across the whole dataset. Protein expressions were then calculated from the segmented cells, and unsupervised clustering was performed based on the normalized expression values. The resulting clusters were manually annotated into 16 cell phenotypes based on their protein expression patterns as displayed on a hierarchical clustering heatmap. The percentages of cell phenotypes were then calculated for each sample and compared between disease groups. Furthermore, the spatial proximity and cellular neighborhood analyses were performed to study the spatial organization of the different cell phenotypes in the tissues.
Results: Quantitative assessment revealed unique characteristics specific to each disease, identified by the varying abundance of different immune cell subtypes. Additionally, when comparing lungs from healthy donors with those affected by lung diseases, notable differences were observed in the spatial arrangement of immune cells and their proximity to lung blood vessels.
Conclusions: This study presents the first architectural map of lung cancer, COPD, PAH, and PF linking various immune cell types to their spatial location within the tissue. Such in-depth spatial analyses will aid in comprehending the spatial and temporal interplay within the lung's microenvironment in diverse lung conditions, as well as in developing targeted therapies for specific cell types.

#5508 Single-cell spatial landscape of the mutation-specific human lung tumor immune microenvironment.

R. Nandigama[1], B. Cheikh[2], N. Ma[2], J. Wilhelm[3], L. Klotz[4], F. Eichhorn[4], M. Kriegsmann[4], M. Bartkuhn[1], J. Nabhanizadeh[1], S. Seidel[1], T. Stiewe[5], A. Stenzinger[6], A. Weigert[7], M. Looso[8], F. Grimminger[1], W. Seeger[1], S. Savai Pullamsetti[1], N. Jhaveri[9], H. Winter[4], **R. Savai**[1];
[1]Justus Liebig University, Giessen, Giessen, Germany, [2]Akoya Biosciences, Massachusetts, MA, [3]Justus Liebig University Giessen, Giessen, Germany, [4]Thoraxklinik at the University Hospital, Heidelberg, Germany, [5]Philipps-Universitat, Marburg, Marburg, Germany, [6]Universitatsklinikum, Heidelberg, Heidelberg, Germany, [7]Goethe-University, Frankfurt, Frankfurt, Germany, [8]Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany, [9]Akoya Biosciences, Massachusetts, Germany

Background: Therapies targeting immune checkpoint have significantly transformed the treatment of several cancers, including lung cancer. However, only 20% of lung cancer patients show a response to immunotherapies. KRAS and EGFR mutations are significant factors in the development and progression of lung cancer and its response to immunotherapy. Hence, it's vital to understand intra-tumoral heterogeneity, the makeup of the Tumor Microenvironment (TME), and the cellular interactions in tumors with KRAS and EGFR mutations to uncover new insights.
Methods: Lung cancer tissues from 200 patients were collected, focusing on KRAS and EGFR mutation statuses, specifically KRAS+/EGFR-, KRAS-/EGFR+, and KRAS-/EGFR-. For each patient, two samples were taken, resulting in a total of 400 tissue microarray (TMA) cores. These samples were imaged at single-cell resolution using the PhenoCycler®-Fusion system, which employed a 42-plex antibody panel targeting immune, tumor, proliferation, and apoptosis markers. The first step in the analysis was cell segmentation, performed using a fine-tuned deep learning model. This process successfully segmented a total of 2.16 million cells across the entire collection of samples. Following this, the protein expressions for each cell were calculated, and unsupervised clustering was performed, resulting in 36 distinct clusters, that were manually annotated into 14 cell phenotypes. The proportions of these cell phenotypes were then quantified for each of the 400 TMA cores and compared across the three mutation groups. The analysis also included the spatial proximity and cellular neighborhoods in relation to these mutation groups.
Results: Quantitative analysis focusing on the relative abundance of cell types revealed that the ratio of tumor cells to immune cells was significantly lower in KRAS-/EGFR- tumors compared to those with KRAS+/EGFR- and KRAS-/EGFR+ mutations. Furthermore, the percentages of Regulatory T cells (Tregs) and M1 Macrophages were significantly higher in the KRAS+/EGFR- group compared to the KRAS-/EGFR+ group. Spatial proximity analysis indicated that in the KRAS-/EGFR+ group, M2 Macrophages were significantly closer to Cytotoxic T cells and Helper T cells compared to the distances observed in the other two groups. Moreover, neighborhood analysis identified 20 distinct cellular neighborhoods, each defined by specific cell-cell interactions. COX hazard analysis based on these cellular neighborhoods demonstrated notable variations among the three mutation groups, which are linked to differences in patient outcomes.
Conclusions: Through single-cell spatial phenotyping, this work has shown that the spatial immune landscape of lung tumors is influenced by KRAS and EGFR mutation statuses. This presents a novel opportunity to enhance our understanding of the spatial structure of lung cancer and to identify more effective therapeutic targets.

TUMOR BIOLOGY: Tumor Microenvironment of Metastasis
Poster Session

#5512 Cerebral endothelial FAK paradoxically inhibits brain metastasis *in vivo*.

S. Noda-Narita, A. Aiba;
The University of Tokyo, Tokyo, Japan

Introduction: In cancer metastasis in the trunk, the secreted proteins from tumors, such as VEGFs and TNF-α, activate focal adhesion kinase (FAK) in vascular endothelial cells (VECs). The activated FAK promotes VE-cadherin phosphorylation and the expression of cell adhesion molecules, and it facilitates the extravasation of cancer cells. In the cerebral blood vessels, the VECs maintain very strong cell adhesion supported by the surrounding pericytes and astrocytes. The strong barrier of cerebral VECs is called the blood-brain barrier (BBB) and is regulated differently from trunk VECs. Although the role of FAK in trunk metastasis is shown in many studies, its importance in brain metastasis is not verified. In this study, we focused on the role of the cerebral endothelial FAK and compared the role of FAK in brain metastasis with that in trunk metastasis.

Methods: We generated tamoxifen-inducible VEC-specific FAK knockout (FAK-cKO) mice (*VEcad-Cre*^{ERT2}*; Ptk2-flox/flox*) and brain metastatic (BrM) cell lines of Ex3LL (murine lung cancer cell line). We intracardially injected BrM cells of Ex3LL into the FAK-cKO mice and analyzed the tumor development using *in vivo* bioluminescence imaging and a CUBIC tissue clearing system. We also analyzed the intracranially injected mice of the parental and BrM cell lines to evaluate the tumor angiogenesis, which is reported to be promoted by the endothelial FAK.

Results: Although FAK-cKO in VECs has been reported to inhibit lung metastasis, brain metastasis was accelerated in FAK-cKO mice compared with control mice. The number of brain metastatic sites increased in FAK-cKO mice, but there was no difference in the individual tumor size. It suggests that the brain metastasis was promoted by FAK-cKO, but that the proliferation of brain metastasis was not promoted by FAK-cKO. Blood vessel density was decreased with irregular shape in the brain tumors of FAK-cKO mice, suggesting that the angiogenesis was inhibited by FAK-cKO. It indicates that the angiogenic function of endothelial FAK in the brain vasculature was not different from that in the trunk.

Conclusion: FAK-cKO in VECs exacerbated the brain metastasis of the BrM cells although it has been reported to inhibit the metastasis in the trunk. FAK-cKO in VECs decreased tumor angiogenesis both in the brain and the trunk. It suggests that the regulatory mechanism of cell adhesion and the FAK function in the brain vasculature is partly different from that in the other organs in the body trunk. We need further investigation to elucidate the function of endothelial FAK in brain metastasis.

#5513 Sexual differences in the aged melanoma tumor microenvironment dictates metastasis and therapeutic responses.

Y. Chhabra[1], M. Fane[2], S. Pramod[1], L. Hueser[1], D. Zabransky[3], V. Wang[1], E. Kumah[1], A. Carey[1], E. Harper[1], M. Ramos Rocha[1], A. Weeraratna[1];
[1]Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD, [2]FoxChase Cancer Center, Philadelphia, PA, [3]Johns Hopkins University, Baltimore, MD

There is documented sex disparity in cutaneous melanoma incidence and mortality, increasing disproportionately with age and in the male sex. However, the underlying mechanisms remain unclear; while biological sex differences and inherent immune response variability have been assessed in tumor cells, the role of the microenvironment surrounding the tumor, contextually in aging, has been overlooked. We find that skin fibroblasts undergo age-mediated changes in their proliferation, senescence, ROS levels and stress response that vary with sex. We find that aged male fibroblasts selectively drive an invasive and slow-cycling phenotype in melanoma cells in vitro by increasing AXL expression. This is also evident in syngeneic mouse models where metastasis is increased in aged male mice. Mechanistically, intrinsic aging in male fibroblasts coupled with elevated ROS promotes EZH2 decline thereby increasing BMP2 secretion, which in turn drives the slower-cycling, highly invasive, and therapy-resistant melanoma cell phenotype, characteristic of the aged male TME. Inhibition of BMP2 activity blocks the emergence of the invasive phenotype and sensitizes melanoma cells to BRAF/MEK inhibition. Our data provides an integrated view of how age and sex of the host contributes to melanoma progression and therapy responses. Bridging this knowledge gap will improve patient stratification and assist in tailoring the therapy to the individual.

#5514 Crosstalk between prostatic epithelial cells and the tumor microenvironment drives cancer progression and metastasis.

D. Yanushko[1], B. German Falcon[2], C. Keime[1], T. Ye[1], C. Thibault-Carpentier[1], D. Metzger[1], G. Laverny[1];
[1]IGBMC - Univ. of Strasbourg, Illkirch, France, [2]Center of Prostate Disease Research, Bethesda, MD

Prostate cancer is a heterogeneous disease with a slow progression and a highly variable clinical outcome. Recent advances in the clinical handling of localized prostate cancers resulted in an almost 100% 10-year survival, but no curative treatment is currently available for metastatic disease. Thus, understanding the molecular mechanisms of progression of primary tumors to metastasis is crucial to develop new therapeutic strategies. While tumorigenesis initiates in prostatic epithelial cells, various cell types, including cancer associated fibroblasts (CAFs), immune and endothelial cells produce extra-cellular matrix and secrete signaling molecules that might contribute to tumor progression. However, the complex communication network driving tumor progression is poorly characterized. As the tumor suppressors *PTEN* and *TP53* are among the most frequently altered genes in prostate cancer, we generated genetically engineered mice with *Pten and Trp53* selective inactivation in prostatic epithelial cells at adulthood. Their analysis revealed that they develop precancerous lesions that progress to invasive and metastatic tumors. Spatial transcriptomic and single-cell analyses of *Pten*- and *Trp53*-deficient prostatic tumors identified the presence of a cancer cell population exhibiting cell plasticity driven by Jak/Stat3 signaling and induced by CAF-produced IL6. In addition, these tumors exhibit a hypoxic core and an immune infiltrate dominated by neutrophils. Inhibition of the hypoxic signaling reduced immune infiltration in primary tumors and their metastatic potential, but did not induce apoptosis of *Pten*- and *Trp53*- deficient epithelial cells, in contrast to those of *Pten*-deficient tumors. These results underline the importance of the tumor genomic background for therapeutic intervention. Taken together, our work highlights the key role of the tumor microenvironment in driving prostate cancer progression and uncovers new vulnerabilities of this disease.

#5515 Low body mass index (BMI) induces neuronal NPY and promotes brain metastasis of lung cancer.

A. Tyagi, S.-Y. Wu, R. Deshpande, K. Wu, L. Liu, K. Watabe;
Wake Forest Baptist Comprehensive Cancer Ctr., Winston-Salem, NC

Brain metastases (BrMs) are a common occurrence in lung cancer with a dismal outcome. To develop a more effective therapeutic strategy, it is crucial to understand the underlying pathological mechanism of brain metastasis. Recent clinical data has unveiled a significant association between low body mass index (BMI) and an increased risk of brain metastasis in lung cancer patients, leading to reduced survival rates compared to other primary tumors. However, the molecular mechanism underlying this paradoxical relationship, often referred to as the "obesity paradox," in the context of lung cancer mortality presents a complex and intriguing puzzle and warrants in-depth investigation. Here, we examined biological mechanism of how low BMI promotes lung cancer brain metastasis. In this study, we conducted a retrospective pan-analysis of 5,516 patient cohorts with brain metastasis originating from lung, breast, melanoma, and renal cancers with their BMI status. We found that lung cancer patients with low BMI have significantly higher brain metastatic incidence compared to the high BMI patients, in contrast to breast, melanoma, and renal cancers. Furthermore, we found that low BMI plays a pivotal role in mediating neuron activation within the brain and that the secretion of neuronal neuropeptide Y (NPY), a protein involved in appetite and energy homeostasis via GHSR-receptor manner, promotes metabolic switching through NPY/NPY5R axis in the tumor cells in the brain thereby enabling metastasis. Elevated levels of neuronal NPY in the brains of cancer-free subjects with low BMI suggest its potential utility as a promising prognostic biomarker for identifying the increased risk of metastatic disease in lung cancer patients with low BMI. We also demonstrated that reversing low BMI or blocking the NPY/Y5R interactions effectively abrogated brain metastasis in our animal model. Our findings suggest a novel pro-metastatic role of low BMI-induced NPY in the progression of brain metastasis. We emphasize the importance of elucidating the clinical implications of this relationship to develop an updated intervention strategy for the clinical care of patients with lung cancer and low BMI.

#5516 Aberrant activation and perpetuation of lung wound response facilitates osteosarcoma metastasis.

J. B. Reinecke, A. C. Gross, M. Cam, L. Jimenez Garcia, M. V. Cannon, R. D. Roberts;
Nationwide Children's Hospital, Columbus, OH

Introduction: The mechanisms that allow tumor cells to integrate with unfamiliar parenchymal cells within hostile distant tissues during metastatic colonization remain poorly defined. Nowhere are these mechanisms more important than in osteosarcoma-a pediatric bone tumor where metastases cause nearly all osteosarcoma related deaths and occur almost exclusively in the lung. The purpose of this study was to define the cellular and molecular events that facilitate osteosarcoma lung colonization to devise novel therapeutic strategies that prevent and treat metastasis.
Experimental Approach: We generated experimental lung metastases using a panel of immunocompetent murine and human xenograft osteosarcoma models. A combination of immunohistochemistry, single cell RNA sequencing, and spatial transcriptomics were used to define the metastatic niche. Relevant findings were validated in human primary tumor, lung metastasis, and normal lung tissue specimens.
Results: Disseminated osteosarcoma cells physically associate with alveolar epithelial cells and trigger changes in surrounding epithelial cells that are characteristic of the aberrant, non-resolving wound response seen in non-malignant lung diseases such as idiopathic pulmonary fibrosis (IPF). This process drives the accumulation of fibrotic epithelial cells and scar-associated macrophages confined within a dense fibronectin-based matrix. Anti-fibrotic tyrosine kinase inhibitors used to treat patients with IPF (nintedanib) prevent the observed fibrogenic changes and inhibit metastatic colonization. Epithelial-osteosarcoma paracrine signaling is dominated by an inflammatory cytokine milieu that facilitates this transition towards fibrosis. Blocking one of the dominant paracrine signals with a recombinant IL1 receptor antagonist (anakinra) has similar effects on both fibrosis and metastatic colonization.
Conclusions: Our study demonstrates that tumor interactions with host stromal cells are critical for metastasis. Metastatic colonization requires transformation of the local lung microenvironment into a fibrotic, non-resolving, cytokine-rich, wound-like state that is both provoked and sustained by tumor-epithelial interactions. These insights have identified several potential therapeutic approaches to prevent metastatic colonization and treat established metastases.

#5517 Chronic stress causes metastasis via neutrophil-mediated changes to the microenvironment.

X.-Y. He[1], Y. Gao[2], D. Ng[2], E. Michalopoulou[2], S. George[2], J. M. Adrover[2], L. Sun[2], J. Albrengues[2], J. Da?ler-Plenker[2], X. Han[2], L. Wan[2], X. S. Wu[2], L. S. Shui[2], Y.-H. Huang[2], B. Liu[2], C. Su[3], D. L. Spector[2], C. R. Vakoc[2], L. VanAelst[2], M. Egeblad[4];

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, [3]Weill Cornell Medicine, New York, NY, [4]Johns Hopkins University School of Medicine, Baltimore, MD

Chronic stress is associated with increased risk of metastasis and poor survival in cancer patients, yet the reasons are unclear. We show that chronic stress increased lung metastasis from disseminated cancer cells 2- to 4-fold in mice. Chronic stress significantly altered the lung microenvironment, with fibronectin accumulation, reduced T cell infiltration, and increased neutrophil infiltration. Depleting neutrophils abolished stress-induced metastasis, indicating their critical role. Chronic stress shifted neutrophils' normal circadian rhythm, and, via glucocorticoid release, caused increased neutrophil extracellular trap (NET) formation. Importantly, in mice with neutrophil-specific glucocorticoid receptor deletion, chronic stress failed to increase NETs and metastasis. Furthermore, digesting NETs with deoxyribonuclease (DNase) I prevented chronic stress-induced metastasis. Together, our data show that glucocorticoids released during chronic stress cause NET formation and establish a metastasis-promoting microenvironment. Therefore, NETs could be targets for preventing metastatic recurrence in cancer patients, many of whom will experience chronic stress due to their disease.

#5518 Tumor immune microenvironment of bone marrow metastasis in patients with solid tumor.

A. Saijo[1], K. Kinowaki[1], K. Yamamoto[1], S. Watanabe[1], K. Takemura[1], T. Yamaguchi[1], Y. Tanabe[1], K. Suyama[1], H. Yano[2], Y. Komohara[2], Y. Miura[1];
[1]Toranomon Hospital, Tokyo, Japan, [2]Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan

Background: The tumor immune microenvironment plays a crucial role in tumor progression and treatment outcomes, both at the primary tumor site and metastatic sites. Metastatic growth within the bone marrow (BM) is relatively infrequent. Despite its unique immunological characteristics, there is a paucity of research on tumor immune microenvironment in the context of BM metastasis, particularly in patients with solid cancer. This study aims to elucidate the dominant immune cell populations within the BM of patients with solid cancer BM metastasis.
Materials and Methods: Patients with solid tumors, who underwent BM examinations (aspiration and/or biopsy) for suspected BM metastasis at our institution between 2016 and 2023 were extracted from the database of pathology. To evaluate BM immune microenvironment in patients with BM metastasis originating from solid tumor, we performed flow cytometry analysis of myeloid and lymphoid subsets using bone marrow aspiration. Myeloid-derived suppressor cells (MDSCs) were defined as $CD33^{+}CD14^{+}HLA\text{-}DR^{-/low}$. Additionally, a control group was established, consisting of patients in whom BM metastasis were pathologically ruled out.
Results: The study involved the BM examinations in 39 patients, 22 of whom were pathologically diagnosed with BM metastasis. No substantial difference in age or gender were observed between patients with or without BM metastasis. However, the incidence of bone metastasis was significantly higher in the BM metastasis group compared to the non-BM metastasis group (90.9 vs. 47.1%, P=0.004). The median duration from the initial diagnosis of metastatic state to the occurrence of BM metastasis was 14.5 days (range 0 - 2194 days) for patients with BM metastasis, whereas it was 170 days (range 0 - 1304 days) for those without BM metastasis. Among the patients who underwent BM examinations, flow cytometry analysis was available in 13 patients with BM metastasis and 11 patients without BM metastasis. Our analysis revealed that a substantial increase in the mean percentage of MDSCs ($CD14^{+}HLA\text{-}DR^{-/low}$) in $CD14^{+}$ monocytes of BM aspirates from patients with BM metastasis compared to those without (28.06 vs. 8.09%, P=0.0005). Additionally, while not statistically significant, the mean percentage of $CD3^{+}$ T cells in the total live cell population appeared to be higher in patients with BM metastasis compared to those without (10.26 vs. 6.67%, P=0.0622). In terms of lymphoid subsets, CD4/8 ratio was significantly elevated in patients with BM metastasis as opposed to those without BM metastasis (1.57 vs. 0.76%, P=0.0472).
Conclusion: The tumor immune microenvironment in BM metastasis was skewed toward immunosuppressive state. Further investigations are warranted to understand the involvement of other immune cells that also suppress immune system, such as regulatory T cells and M2 macrophages.

#5519 Enlarged metastasis-free tumor-draining lymph node is a marker of tumor invasion in local tissues with an active NK cell-mediated immunity.

Z. Wan, **H. Yu**;
The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Colorectal cancer (CRC) is the third most common cancer worldwide, accounting for about 10% of all new cancer cases. The tumor-draining lymph node (TDLN) is a key site for the development of anti-tumor immunity that has been reported to be involved in both CD8+ T and NK cells. As a major role of innate immunity, NK cells can produce IFN-γ, perforin and granzyme to eliminate tumor cells in the early stages of cancer development. This study aimed to investigate the difference of clinicopathological and immunological profiles in local tissues between CRC patients with enlarged and non-enlarged metastasis-free TDLNs.
Methods: The patient cohort was obtained from the NEPDC cohort (No. 2015CB554000). A total of 45 patients with pathologically confirmed stage I-II colorectal cancer were included in this study. Based on the MRI, these patients were divided into enlarged and non-enlarged TDLN groups (lymph nodes >/= 5mm and lymph nodes < 5mm). We collected the tumor tissue and tumor-adjacent normal tissue that was 2 cm away from the tumor lesion. The genomic DNA of the tumor and tumor-adjacent normal tissues was treated with bisulfite and analyzed with the EPIC methylation array. The MeTMEC algorithm based on the methylation profile estimated subsequent cell abundance in these patient tissues.
Results: The study sample was comprised of 22 enlarged TDLN and 23 non-enlarged TDLN patients. There were 4 T1-T2 and 18 T3-T4 patients in the enlarged TDLN group, with 12 T1-T2 and 11 T3-T4 patients in the non-enlarged TDLN group. The proportion of T3-T4 patients in the enlarged TDLN group was higher than that in the non-enlarged TDLN group (p=0.017, Chi-squared test), suggesting an advanced invasion in the local tissue of patients with enlarged TDLN. Then, the abundance of monocytes, dendritic cells, macrophages, neutrophils, eosinophils, Treg cells, naive T cells, memory T cells, CD8+ T cells, NK cells, and B cells in the tumor and tumor-adjacent normal tissues were inferred with the MeTMEC algorithm by using DNA methylation profile. In the T1-T2 subset, we found that the infiltration of NK cells in the tumor-adjacent normal tissues was significantly more abundant in the enlarged TDLN group compared with the non-enlarged TDLN group (p=0.021, t-test), suggesting an active immune response of NK cells for potential local tumor control. No significant difference in other immune cells was observed between the two groups.
Conclusion: Enlarged TDLN indicates an advanced invasion of tumors in local tissues with an active NK cell-mediated immunity. Our findings suggest that enlarged metastasis-free TDLN might be a promising marker for NK cell-based cancer immunotherapy.

#5520 β2 adrenergic receptor signaling promotes colorectal cancer liver metastasis.

Y. Zhang, J. Chen, T. Chan, H. Wang, J. Lu, J. Li, J. Zhou;
The Chinese University of Hong Kong, Hong Kong, Hong Kong

Liver is the most common site for cancer metastases, which may be attributed to the hepatic immunosuppressive microenvironment. Recent studies have highlighted the immunomodulatory and tumor-supportive roles of neurotransmitter-receptor signals in various cancers. Given that various neurotransmitter receptors are expressed in the liver, we aimed to investigate their possible involvement in the metastatic-prone liver microenvironment. Single-cell RNA sequencing analysis identified *ADRB2*, which encodes β2-adrenergic receptor (β2-AR), as the top-upregulated neurotransmitter receptor gene in colorectal cancer (CRC) and liver metastasis in patients with CRC liver metastasis (CRLM). Co-immunofluorescence (co-IF) staining confirmed the colocalization of β2-AR with myeloid cell marker CD11b instead of T cell marker CD3 and NK cell marker CD56 in patients with CRLM. Consistently, we observed the upregulation of CD11b/β2-AR double-positive cells in the liver tissues from mice bearing CRC or CRLM compared to naïve mice through co-IF staining. High-dimensional flow cytometry analysis further revealed that β2-AR was mainly expressed in macrophages and myeloid-derived suppressor cells (MDSCs). Treatment of CRC-tumor bearing mice with pan β-AR inhibitor propranolol and β2-AR specific inhibitor showed a potential to reduce liver metastatic incidence without suppressing primary CRC. Mechanistically, β2-AR activation may upregulate the expression of *S100a8/9* to enhance the immunosuppressive activity of macrophages and MDSCs, thereby promoting CRC liver metastasis. Taken together, our findings reveal the potential of targeting β2-AR signaling for the prevention and treatment of liver metastasis.

This project is supported by the Hong Kong University Grants Committee through the General Research Fund (14104820, 14107622, 24110323) and the Strategic Seed Funding for Collaborative Research Scheme (SSFCRS) from the Chinese University of Hong Kong.

#5521 Nicotine promotes perineural brain metastasis of lung cancer by activating GABAergic neurons.

S.-Y. Wu[1], A. Tyagi[1], R. P. Deshpande[1], K. Wu[2], E. C. Smith[1], K. Watabe[1];
[1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]University of North Carolina Greensboro, Greensboro, NC

Tobacco smoking significantly increases the incidence of brain metastasis. However, the pathological mechanism by which smoking promotes brain metastasis through modulating brain microenvironment is yet poorly understood. We previously showed that the incidence of brain metastasis is associated with nicotine intake. Nicotine enhanced polarization of M2 pro-tumor microglia, which promoted brain metastasis. In addition to the immune surveillance role, microglial cells also control neuronal synapse formation. Microglial cells promote neuron synapse formation in the developing brain, whereas microglia depletion suppresses synapse density. Furthermore, microglia-secreted microRNAs (miRNAs) have been shown to promote synaptic formation by targeting synapse-related genes of the DKK-Wnt family. Neurons are one of the most abundant cell types in the brain, and they are highly specialized for cell-to-cell signal activation. However, little is known about the roles of neurons in brain metastasis of lung cancer. We hypothesize that nicotine stimulates microglia to secrete exosomal miR-32-3p, which promotes brain metastasis by augmenting GABAergic synaptic formation and hence releasing GABA that serves as a metabolic substrate to fuel tumor cell growth. We also hypothesize that inhibiting the GABA transporter of tumor cells suppresses brain metastasis by blocking the GABA shunt. We found that lung cancer patients with a smoking history had significantly higher synaptic formation and the expression of GABA transporter in brain metastasis. To investigate the effect of smoking and nicotine intake on brain metastasis *in vivo*, mice were intracardially transplanted with lung cancer brain metastasis cells (H2030BrM and PC9BrM) followed by administration of nicotine or cigarette smoke exposure in a smoking chamber. We found that smoking and nicotine increased M2 microglia polarization, synaptic formation, and the expression of GABA in mouse brain metastasis. Furthermore, nicotine increased the secretion of miR-32-3p from nicotine-pretreated microglia, which promoted GABA release from GABAergic neurons. Treating H2030BrM and PC9BrM cells with conditioned medium (CM) obtained from neurons exposed to CM derived from nicotine-treated microglia exosomes resulted in increased tumor growth through the activation of the GABA shunt pathway. Blocking GABA transporter 1 (GAT1) by CRISPR/Cas9 or a small molecule of GAT1 inhibitor suppressed the GABAergic neuron-induced tumor progression. Our results indicate that nicotine-activated microglia enhanced GABA release from neurons followed by the promotion of GABA shunt in tumor cells and that a GAT inhibitor serves as a promising therapeutic tool for the treatment of lung cancer patients with brain metastasis.

#5522 Elucidating the role of P-selectin/P-selectin ligand-1 axis in lung cancer brain metastasis.

K. Salomon[1], E. Yeini[1], N. Frommer[1], I. Kamer[2], J. Bar[2], I. Barshack[2], R. Satchi-Fainaro[1];
[1]Sackler Faculty of Medicine Tel Aviv Univ., Tel-Aviv, Israel, [2]Sheba Medical Center, Tel-Aviv, Israel

Lung cancer (LC) stands as a prominent cause of cancer-related mortality. Brain metastasis (BM) is a common occurrence in LC, constituting nearly 50% of all BM cases with the brain emerging as the preferred site for LC metastasis. Unfortunately, current LCBM treatment options yield limited success, as reflected in the median survival of BM patients at 7.8 months. Consequently, there is an imperative need for novel and more efficacious therapeutic approaches targeting LCBM. Evidence suggests that brain microenvironment cells, particularly microglia and tumor-associated macrophages (TAMs), play a pivotal role in facilitating the colonization and growth of LCBM. Previous investigations from our lab have identified the involvement of the P-selectin/P-selectin glycoprotein ligand-1 (SELP/PSGL-1) axis in microglia/TAMs immunophenotypes, promoting pro-tumorigenic activity. This led us to explore the role of the SELP/PSGL-1 axis in the interactions between LCBM cells and the brain microenvironment[1]. Thus, we conducted Immunostaining on human tissue samples, revealing increased expression of SELP, PSGL-1, PD-1, PD-L1, IBA-1, and CD68 in LCBM tissues. Simultaneously, we employed advanced 3D models to investigate the intricate interactions between cancer cells and microglia/TAMs. Actively inhibiting the SELP/PSGL-1 axis with pharmacological agents led to a significant decrease in migration and invasion when LC cells were co-cultured with microglia and TAMs. Moreover, SELP inhibition prompted a shift in microglia/TAMs state towards an M1-like phenotype, enhancing the ability of CD4/CD8 cells to target cancer cells in our unique 3D LCBM models. This effect was further enhanced when co-treated with a PD-1 inhibitor, demonstrating a potential synergistic impact in targeting both pathways for therapeutic intervention. Our results suggest that combining SELP inhibition with other immunomodulators, including a small molecule PD-L1 inhibitor developed in our lab[2], could synergistically enhance both innate and adaptive anti-tumor immune responses. Taken together, this study may enhance our understanding of LCBM immunogenicity and contribute to the development of novel immunotherapeutic approaches that can improve patient outcomes.1.Yeini, E., *et al.* P-selectin axis plays a key role in microglia immunophenotype and glioblastoma progression. *Nat Commun* 12, 1912 (2021). 2. #5523 granulocyte-colony stimulating factor secreted from cancer associated fibroblasts initiates tumorigenesis and metastasis in triple negative breast cancer.

N. Gotoh[1], Y. Tacheuchi[1], T. Murayama[1], R. Kashimura[1], K. Ikeda[2], K. Horie[2], S. Inoue[2], K. Okamoto[3];
[1]Kanazawa University Cancer Research Institute, Kanazawa, Japan, [2]Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan, [3]Teikyo University Advanced Comprehensive Research Organization, Itabashi-ku, Japan

Although cancer stem-like cells (CSCs) interact with cancer-associated fibroblasts (CAFs), it remains obscure how it occurs and what are the functional roles of this interaction. When patient-derived breast cancer cells (BCCs) were co-cultured with CAFs, significantly more spheroids were formed compared to those cells cultured alone. This suggests that CAFs produce soluble factors that increase the tumor-initiating ability of CSCs. Transcriptome analysis revealed that the expression of granulocyte colony stimulating factor (G-CSF) was highly upregulated in the conditioned medium of CAFs co-cultured with BCCs. Tumor-initiating ability was increased in the presence of G-CSF. Furthermore, G-CSF neutralizing antibody treatment suppressed tumorigenesis and bone metastasis in the patient-derived xenograft (PDX) model. These findings indicate that G-CSF secreted by CAFs induces CSCs to initiate tumors and metastasis. Inhibition of G-CSF would be a novel therapeutic target for breast cancer.

#5524 Identification of PAEP as an immune activity modulator to mediate the immune resistance in tumor metastasis.

Rand Gabriel M. Buenaventura[1], Weiping Chen[2], Shuling Zhang[1], Beverly Mock[1], Glenn Merlino[1], Yanlin Yu[1]

[1]Laboratory of Cancer Biology and Genetics, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD, [2]The National Institute of Diabetes and Digestive Kidney Diseases, National Institutes of Health, Bethesda, MD

Most cancer-related deaths are associated with the complex phenotypic behavior of metastasis, a process in which tumor cells spread from their initial site to distant sites. To successfully metastasize, the tumor cell will be required to make numerous adjustments and survive a series of stages involving intravasation, circulation in the blood or lymph system, extravasation, and growth at distant organs, and overcome the challenges of immunosurveillance. The tumor microenvironment is the ecosystem that surrounds and feeds the tumor. The molecular mechanism by which the metastatic tumors survive and escape from immune attack in the tumor microenvironment remains unclear. To study the molecular mechanism of interaction between metastatic tumors and the immune system in metastasis, we established immune-resistant metastatic models. We identified that PAEP, a progestogen-associated endometrial protein, is significantly upregulated in immune-resistant metastatic tumors compared with non-immune-resistant tumors. PAEP is a glycoprotein that inhibits cell immune function and plays an essential role in the pregnancy process. To examine the function of PAEP in tumor metastasis, we first introduced PAEP into non-immune resistant and poorly metastatic melanoma and rhabdomyosarcoma (RMS) cells. We found that overexpression of PAEP significantly promotes tumor metastatic potential of both melanoma and RMS cells in immunocompetent mice. Interestingly, there was no difference in metastasis between the control and overexpression groups in immunodeficient mice. These data suggest that PAEP may mediate tumor metastasis relating to host immunity. To further confirm the function of PAEP in tumor metastasis, we use CRISPR/Cas9 technology to knockout endogenous PAEP and will test the metastatic potential in different hosts. We will also investigate the molecular mechanisms using RNA sequencing and Digital Spatial Profiling (DSP) to analyze the metastatic samples. Our study will uncover a new mechanism for how tumors survive in the microenvironment and identify a novel target for the treatment of metastatic diseases.

#5525 Tissue-resident cytotoxic T cell infiltration predicts metachronous colorectal cancer metastasis.

R. Cohen[1], T. Lee-Pullen[1], T. Miller[1], S. Pirasteh[2], C. Platell[1], K. Meehan[1], K. Fuller[1], M. McCoy[1];
[1]University of Western Australia, Perth, Australia, [2]Western Diagnostic Pathology, Perth, Australia

Background: Identifying patients at high risk for metachronous colorectal cancer metastasis is essential for improving prognosis. The balance between host immune regulation and tumor immune evasion ultimately permits or prevents cancer progression. Lymphocytic infiltration in colorectal cancer can predict long-term clinical outcomes. However, these lymphocytes' origin, subtype and function have yet to be adequately explored. We investigated the association between the development of metastasis and $CD8^{\pm}$T cells expressing the integrin protein CD103, a marker of tissue-resident memory T cells.

Methods: In this retrospective, case-control matched study, we conducted multiplex immunofluorescence staining of tumor samples from 124 patients with colorectal cancer. Tissue microarrays containing representative cores of the central tumor, invasive margin, and adjacent normal tissue were immunostained for CD3, CD8, CD103, pSMAD3, and cytokeratin, using tyramide signal amplification. Cells were quantified using StrataQuest digital image analysis software, with intratumoral and stromal regions analyzed separately. Kruskal-Wallis one-way analysis of variance with subsequent Dunn's test for pair-wise comparisons was performed using the Bonferroni method of multiple-comparison correction.

Results: Central tumor and invasive margin $CD3^{\pm}$ densities were associated with synchronous metastasis. Compared to non-metastatic patients, those who went on to develop metachronous metastasis (n=42) had a low proportion of intra-epithelial $CD8^{\pm}CD103^{\pm}$ T cells at the central tumor (non-metastatic: 32.8%, IQR 15.0-42.7%; metachronous metastasis: 12.9%, IQR 2.08-28.4%; P = 0.013). Similarly, patients with metachronous metastasis had a low proportion of stromal $CD8^{\pm}CD103^{\pm}$ T cells at the invasive margin (non-metastatic: 3.51%, IQR 1.83-6.55%; metachronous metastasis: 1.75%, IQR 0.62-3.72%; P = 0.019). On multivariate Cox regression of histological features, amongst patients with metastasis, significant overall survival prognostic markers included a low proportional $CD8^{\pm}CD103^{\pm}$ T cell infiltration (HR 2.41, 95%CI 1.16-5.01, P = 0.019), mucinous features (HR 4.28, 95%CI 1.98-9.24, P < 0.001), and the presence of perineural invasion (HR 2.75, 95%CI 1.28-5.89, P < 0.001).

Conclusion: $CD8^{\pm}CD103^{\pm}$ lymphocytes may protect from the development of colorectal metastasis. Proportional $CD8^{\pm}CD103^{\pm}$ T cell infiltration is a promising prognostic marker in colorectal adenocarcinoma for the development of metachronous metastasis, and, amongst patients with metastasis, it is a prognostic marker of overall survival.

#5526 Activation of platelet-activating factor (PAF) in high-risk melanoma patients with nodal metastasis.

A. McMasters, J. Chariker, J. Y. Hwang, X. Yin, X. Ma, R. Xu, X. Zhang, J. W. Park, K. M. McMasters, **H. Hao**;
University of Louisville, Louisville, KY

Background: Platelet-activating factor (PAF) is one of the lipid mediators in ultraviolet-induced immunosuppression signaling. Sentinel lymph nodes (SLNs) are the first organs to receive lymphatic drainage via afferent lymphatic channels leading directly from the primary melanoma. In patients with nodal metastasis, it has been shown that the SLN has a profoundly immunotolerant microenvironment. We sought to determine whether lymphatic fluid signals, including PAF, may be involved in modulating the SLN immune microenvironment to favor melanoma metastasis.
Hypothesis: Upregulation of PAF can bind to its receptor on monocytes and activate downstream immunosuppressive chemokines, resulting in an immunosuppressed environment in SLNs that permits nodal metastasis and melanoma progression.
Methods: Lymphatic fluids, plasma samples, and SLN samples were collected from patients undergoing surgical excision of melanoma with SLN biopsy under an IRB-approved protocol. Metabolic analyses were performed on lymphatic fluids from high- versus low-risk patients by two-dimensional liquid chromatography system coupled with mass spectrometry (2D LC-MS). Single cell sequencing was done on single cell suspensions from SLN samples. Protein array was used to compare the cytokine and chemokine levels in plasma samples from high- versus low-risk melanoma patients. We compared two groups: low-risk (no SLN metastasis) and high-risk (with SLN metastasis).
Results: Lymphatic fluid PAF levels were 3-fold greater in high-risk melanoma patients compared with low-risk patients (p=0.0039). Macrophages were identified as the cell type with greatest PTAFR (platelet-activating factor receptor) expression by single cell sequencing. CCL17 levels in plasma samples from high-risk patients were significantly lower than in low-risk patients (p<0.05). These results suggest that increased PAF in lymphatic fluid may bind to PTAFR in SLN macrophages, inhibit chemokines (such as CCL17), and result in an immunosuppressive SLN environment to favor nodal metastasis and melanoma progression.
Conclusion: Lymphatic fluid PAF signaling may contribute to an immunotolerant microenvironment in the SLN that allows nodal metastasis and melanoma progression through downregulation of CCL17. Further studies will investigate whether this pathway can be exploited to therapeutic advantage.

#5527 Spatiotemporal analysis of growth factor regulation of osteosarcoma AKT and ERK signaling dynamics in an *ex vivo* lung metastasis model.

R. Makkawi[1], R. D. Roberts[2], J. Copperman[1], A. E. Davies[1];

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH

In the present study, we investigated the relationships between spatiotemporal distribution of growth factors in the lung microenvironment, metastatic osteosarcoma cell signaling, and intratumoral gene expression heterogeneity. Osteosarcoma is an aggressive bone malignancy that commonly metastasizes to the lungs, resulting in significant patient mortality. During metastasis, disseminated cancer cells are exposed to microenvironment-derived growth factors that result in signaling pathway activation. Two such pathways are MAPK/ERK and PI3K/AKT, which regulate complex transcriptional programs underlying cell proliferation and survival decisions. In this study, we utilized precision cut lung slices (PCLS) obtained from mice with established osteosarcoma metastases to ex vivo model associations between the spatiotemporal distributions of growth factors in the lung, osteosarcoma signaling dynamics, and intratumoral gene expression heterogeneity, with single cell precision. To accomplish this, we engineered osteosarcoma cells that co-expressed genetically-encoded ERK and AKT sensors, engrafted them into PCLS tissues, then recorded sensor dynamics via live-cell microscopy. These tissues were subsequently fixed and immuno-stained for measurement of growth factor expression in resident lung cells and spatial correlation with observed tumor cell ERK-AKT signaling dynamics. Using this approach, we found that growth factor expression was diffusely increased within areas bordering osteosarcoma metastases. FGF2 and IGF1, which we have previously demonstrated to potently induce ERK signaling in osteosarcoma cells, were both significantly upregulated in these regions. However, despite relatively uniform overexpression of growth factors adjacent to tumors, individual osteosarcoma cells displayed stochastics patterns of ERK and AKT signaling, and downstream gene targets. These findings revealed that upregulation of lung growth factors, and the inherent systems-level properties of osteosarcoma signaling networks, can converge to promote intratumoral signaling and gene expression heterogeneity. Together, our results, using a novel PCLS and live-cell biosensor imaging approach, provide new insight into how spatial and temporal changes in microenvironmental signaling composition are integrated by metastatic osteosarcoma cells to promote heterogeneity.

#5528 Adaptive immune cells in colorectal cancer between normal mucosa, primary tumor and liver metastasis.

A. Trailin, W. Ye, E. Ali, S. Pavlov, L. Cervenkova, F. Ambrozkiewicz, O. Vycital, O. Daum, V. Liska, K. Hemminki;
Charles University in Prague, Medical faculty in Pilsen, Pilsen, Czech Republic

Introduction: We aimed to assess the role of local adaptive immunity in the metastatic process by comparing densities of adaptive immune cells between normal colorectal mucosa (NM), primary colorectal cancer (pCRC) and liver metastases (LM) in patients with synchronous and metachronous disease.
Patients and Methods: We enrolled patients, who underwent resection of pCRC and LM in Pilsen University Hospital between 1999 and 2022. 56 patients presented with LM (stage IV, synchronous) and 43 patients (stage II/III) developed LM later (metachronous). After immunohistochemical staining and whole slide scanning densities of CD3+ and CD8+ T cells and CD20+ B cells were quantified in NM, pCRC and LM using QuPath software. In pCRC and LM cell densities were measured in tumor center (TC), inner margin (IM), outer margin (OM) and peritumor (PT) region. IM and OM were defined as 500 µm on each side of the invasive tumor border.
Results: For all examined cells in both groups we found smaller densities in TC of pCRC and LM compared to NM (Table). In pCRC of synchronous group compared to LM densities of all cells were smaller in IM and OM and densities of CD3+ and CD8+ cells were smaller in PT region. In pCRC of metachronous group compared to LM densities of all cells were greater in TC, densities of CD3+ were smaller in OM and PT region, whereas densities of CD20+ cells were smaller only in OM. Compared to metachronous group patients with synchronous metastases had smaller densities of CD3+ T cells in IM and CD8+ T cells in TC and IM of pCRC.
Conclusion: Development of pCRC is accompanied by decreased densities of T and B cells in TC compared to NM, which further decrease in metachronous LM. Lower densities of T and B cells in IM and OM and T cells in PT region of pCRC compared to LM is a hallmark of synchronous group. TC of pCRC harbors larger numbers of T and B cells compared to LM in metachronous group. Low numbers of CD3+ and CD8+ T cells in IM and CD8+ T cells in TC of primary CRC may contribute to development of synchronous metastases.

Densities of CD3+, CD8+ and CD20+ cells per mm2 of the tissue (median)

	Patients witn liver metastases					
	Synchronous			Metachronous

#5529 Mimicking CAFs, pial cells support leptomeningeal metastasis.

J. Snyder, J. Remsik, A. Boire;
Memorial Sloan Kettering Cancer Center, New York, NY

Leptomeningeal metastasis (LM), the spread of cancer into cerebrospinal fluid (CSF)-filled coverings of the brain and spinal cord, is a dismal complication of cancer leading to rapid neurologic disability and death. While a diverse array of primary tumors may result in LM, recent work from our laboratory (Chi Y et al 2020 Science) demonstrates a conserved transcriptional signature, independent of primary tumor, suggesting that tumor-microenvironmental interactions play a dominant role in this pathology. We have proteomically interrogated CSF collected from breast (n = 45), lung (n = 30), and melanoma (n = 27) patients with and without LM. We detect robust expression of inflammatory cytokines in all LM+ samples, 15 of these cytokines including IL8, IL6, and CXCL1 are conserved across tumor types in the presence of LM. Because cancer cells in the CSF do not express mRNA associated with these cytokines, we hypothesized that these inflammatory cytokines may originate from the microenvironment. Within the leptomeninges, LM cells adhere to and interact with the innermost layer of the meninges, the pia mater, which contains fibroblast-like cells. Co-culture of cancer cells with pial cells induced changes in the pial cell transcriptome and secretome, leading to increased IL8, IL6, and CXCL1 production. This communication between cancer cells and pial cells is preserved in the absence of direct cell-cell contact. These pial cells support cancer cell growth *in vivo*, as measured by co-implantation experiments. In addition, bulk RNA sequencing of mouse pial cells shows an inflammatory signature upregulated in the presence of LM. Taken together, these observations support a cancer-associated-fibroblast like role for pial cells in the setting of LM. Our work extends the CAF phenotype beyond classical fibroblasts to include pial cells, suggesting novel therapeutic opportunities within CNS malignancies.

#5530 Metastasis founder cells activate immunsuppression early in human metastatic colonization.

[1]University of Regensburg, Regensburg, Germany, [2]University Medical Center Regensburg, Regensburg, Germany, [3]Fraunhofer-Institute for Toxicology and Experimental Medicine, Regensburg, Germany, [4]Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Hannover, Germany, [5]Leibniz Institute for Immunotherapy, Regensburg, Germany, [6]University of Tubingen, Tubingen, Germany

Metastatic dissemination occurs very early in melanoma, often before diagnosis, rendering prevention of metastasis formation an important therapeutic goal. However, the earliest steps of lethal metastasis in patients are incompletely understood. Therefore, in this study we searched for the earliest detectable disseminated cancer cells (DCC) in sentinel lymph node biopsies of 492 stage I-III melanoma patients. We used micromanipulator-assisted isolation and single-cell transcriptome analysis of these extremely rare DCC and identified melanoma -associated chondroitin sulfate proteoglycan (MCSP) expressing melanoma cells as strong candidates for metastasis founder cells in lymph nodes. Based on a median follow-up time of 6 years, their detection was the strongest predictor of systemic metastasis and death upon multivariable analysis. Single-cell transcriptome analysis revealed that melanoma DCC were exposed to CD8 T cell attack during the transition from single cells to metastasis-initiating clusters, activated the extracellular vesicular exosomal pathway, and expressed the immunomodulatory proteins CD155 and CD276, but rarely PD-L1. CD155- and CD276-positive extracellular vesicles from patient-derived DCC models showed an immunosuppressive activity on CD8 T cells. In conclusion, our data suggest that either direct targeting of metastasis-founder cell with MCSP or their immune escape mechanisms may be key to curing early-stage melanoma.

#5531 Loss of csf2(gm-csf) with cisplatin treatment decreases metastasis and improves survival in a hpv positive head and neck cancer murine model.

P. Ghosh, C. Welbon, W. C. Spanos;
Sanford Research, Sioux Falls, SD

Granulocyte macrophages colony stimulating factor (GM-CSF) also known as CSF2 is a popular cytokine responsible for homeostasis. According to TCGA databank CSF2 expression upregulated in human HPV+ (Human Papilloma Virus) Head and Neck Small Cell Carcinoma (HNSCC) compared to normal tissue. The mechanism of CSF2 in tumor progression and chemo resistance has not been well studied. Previously, our lab generated a murine model of HPV+ HNSCC that is partially responsive to cisplatin and radiation (like human disease). The role of our study is to evaluate the importance of Csf2 with cisplatin treatment (CT) in HPV + HNSCC in the murine model. Using CRISPR-Cas9 technology we knocked out the expression of the Csf2 ligand in our parental mEERL (murine E6 E7 Ras Luciferase) tumor cell line and implanted both the parental mEERL tumor and the Csf2 KO mEERL tumor in the oral cavity of C57BL6/J mice. When tumors reached a palpable size, we administered Cisplatin (20mg/m^2, 3 doses total). We observed slow tumor growth in absence of Csf2 without treatment. On the other hand, we observed tumor regression in both tumor models with cisplatin treatment. Post treatment, mice with Csf2 KO tumors had a significantly prolonged rate of survival. To evaluate the role of Csf2 in the Tumor Microenvironment (TME), we collected the tumors 96 hours post CT and characterized the TME using multicolored flow cytometry. The results showed that post treatment mice with Csf2 KO tumors increased the number of the Natural Killer cell population and a surge of M-MDSC (Ly6Chi) population. The synergistic effect of knocking out Csf2 and cisplatin treatment in our tumor model appears to be driven by chemokine and cytokine changes in the TME. Simultaneously, we observed significantly lower levels of lung metastasis in Csf2 KO tumor bearing mice compared to those with parental mEERL tumors. Whereas we have seen increased metastasis in ipsilateral lymph node of Csf2 KO mice. This metastasis data mimics human disease where many patients have regional lymph node involvement, but few develop distant metastasis. These results indicate that GM-CSF (CSF2) in the TME could be an excellent target that would cause less metastasis and improved overall survival. Further investigations are needed to understand the underlying mechanism of immune response in the absence of CSF2 in the TME.

#5532 Differences in immune contexture across metastatic sites and tissue compartments in ovarian cancer.

B. Tate[1], E. Pavlatos[1], T. Kim[2], K. Wilson[1], E. Cid[1], J. Rao[2], G. Konecny[2], J. Pucilowska[1];
[1]Oregon Health & Science University, Portland, OR, [2]University of California, Los Angeles, Los Angeles, CA

Introduction: Characterizing the immune contexture within the tumor microenvironment (TME) can provide valuable biological insights that may impact treatment regimens and improve clinical outcomes. The advent of neoadjuvant chemotherapy has provided a unique opportunity to study matched, pre- and post-treatment sample pairs, but these samples are often obtained from different metastatic sites. Innate differences in the immune profiles across metastatic sites could therefore be a confounding factor when attempting to determine treatment-related effects. Furthermore, immune contexture can also vary by region within the TME, so results could vary depending on the regions of interest (ROIs) selected for analysis.

Methods: 36 matched, advanced primary ovarian cancer samples were obtained pre- and post- treatment with neoadjuvant chemotherapy aimed at reducing tumor burden. The first biopsy was taken at the time of initial diagnosis, whereas the second biopsy was collected after 3-4 rounds of carboplatin paclitaxel chemotherapy. Each slide was processed using a 26-plex multiplex immunohistochemistry (mIHC) assay, which interrogates immune cell densities and functional states for a broad range of immune cell populations, including CD8+ T cells, Tregs, TH1s, B cells, dendritic cells (DCs), granulocytes, macrophages, and monocytes. Tumor and stroma ROIs were selected by a board-certified pathologist using H&E slides immediately adjacent to the mIHC samples, and cell densities were calculated separately for each of the two tissue compartments.

Results: When comparing pre-treatment samples from the omentum (n = 8) with post-treatment samples from the omentum (n = 14), all of the statistically significant changes were found within the tumor compartment, with higher densities in the post-treatment samples for CD8+ T cells ($p = 0.009$), Tregs ($p = 0.012$), DCs ($p = 0.04$), and monocytes ($p = 0.027$). In contrast, when comparing post-treatment samples from the omentum (n = 14) and the ovary (n = 14), all of the significant differences were found within the stroma compartment, with higher densities in the omentum for CD8+ T cells ($p = 0.002$), Tregs ($p = 0.043$), TH1s ($p = 0.003$), and macrophages ($p = 0.048$).

Conclusions: These results demonstrate that the site of metastasis can be a significant confounding factor when making statistical comparisons between variables such as timepoint and that differences in immune cell density before and after treatment may be more apparent in the tumor, while differences between tissue types may be more apparent in the stroma. Further research into the immune profiles of different metastatic sites is warranted, but our findings demonstrate the importance of considering both tissue type and ROI selection strategy when designing a study with the intent to detect differences between longitudinal patient samples.

#5533 The difference of immune microenvironment between*de novo*metastatic and non-metastatic microsatellite instability-high colorectal cancer.

K.-H. Chen[1], C.-L. Hs[2], Y.-L. Su[3], C.-T. Yuan[1], J.-H. Tsai[2], Y.-H. Liang[2], A.-L. Cheng[1], K.-H. Yeh[2];
[1]National Taiwan University Cancer Center, Taipei, Taiwan, [2]National Taiwan University Hospital, Taipei, Taiwan, [3]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan

Introduction: Microsatellite instability-high (MSI-H) colorectal cancer (CRC) consists of 15% of all CRC but only 2-4% of metastatic CRC. The favorable prognosis of non-metastatic (early-stage) MSI-H CRC may be related to vigorous immune reaction in tumor microenvironment. However, the mechanisms of immune evasion in metastatic (late stage) MSI-H CRC are largely unknown.
Materials and Methods: We retrospectively collected patients with MSI-H CRC from National Taiwan University Hospital and Kaohsiung Chang Gung Memorial Hospital. The archival tumor specimens were used for immune cells analysis by Nanostring PanCancer Immune Panel, and spatial immune characterization by multiplex immunofluorescence stains. Only surgical resected primary tumors and metastatic tumors were included. Gene expression and immune cells composition were compared between non-metastatic and *de novo* metastatic tumors.
Results: We enrolled 59 and 27 patients with early-stage and late-stage MSI-H CRC, respectively. Twelve metastatic site tumors were also collected. The clinicopathologic characteristics between patients who have early- and late-stage MSI-H CRC were not significantly different. There are heterogeneous immune cell compositions in these 98 MSI-H tumors. Compared to early-stage MSI-H tumors, there are significantly fewer cytotoxic (difference -0.497, p = 0.001) and dendritic cells (difference -0.528, p = 0.021) in late-stage MSI-H tumors. Gene set enrichment analysis disclosed significantly decrease in the expression of *JAK-STAT-IFN-γ-* and antigen processing-related pathways in late-stage MSI-H tumors. The top 5 genes with significantly differential expression between late-stage and early-stage tumors are *C7, TNFRSF12A, MFGE8*(up-regulated) and *CXCL5, IFNL1, GZMH, HMGB1* and *CXCR1* (down-regulated).
Conclusions: There are significantly fewer cytotoxic and dendritic cells in late-stage MSI-H CRC, compared to early-stage MSI-H CRC, which is associated with decrease expression in *JAK-STAT-IFN-γ-* and antigen processing-related pathways.

#5534 Needle biopsy induces pro-metastatic progression and systemic dissemination of estrogen receptor-positive breast cancer cells through the COX-2/PGE_2 cascade.

H. Kameyama[1], M. Leslie[1], R. Simmons[1], Y. Sun[2], M. Yi[3], P. Dondapati[1], J. F. Langenheim[3], K.-M. Fung[1], I. Chervoneva[3], H. Rui[3], T. Tanaka[1]; [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Thomas Jefferson University, Philadelphia, PA

Breast cancer is the most commonly diagnosed malignancy in the U.S. and over two-thirds of invasive breast cancer cases are diagnosed early stage. However, 15-year survival rates for early-stage breast cancer remain in the range of 70-77%. Mounting evidence showed an increased risk of disease progression and mortality among early-stage breast cancer patients whose surgery was delayed over 60 days after the diagnostic biopsy. Yet, the mechanism(s) underlying the rapidly increased mortality due to delay of surgery after diagnosis remains unknown.

Our cohort analyses of early-stage breast cancer patients reveal the emergence of a significantly rising mortality risk when the biopsy-to-surgery interval was extended beyond 53 days. Additionally, histology of post-biopsy tumors shows prolonged retention of a metastasis-permissive wound stroma dominated by M2-like macrophages capable of promoting cancer cell epithelial-to-mesenchymal transition and angiogenesis by secretion of transforming growth factor beta 1 (TGF-β1) and vascular endothelial growth factor (VEGF). We show that needle biopsy promotes systemic dissemination of cancer cells through a mechanism of sustained activation of the cyclooxygenase-2 (COX-2)/prostaglandin E2 (PGE_2) cascade, which favors M2-polarization and its associated pro-metastatic changes, but are abrogated by oral treatment with COX-2 inhibitors in estrogen receptor-positive (ER+) syngeneic mouse tumor models.

Therefore, we conclude that needle biopsy of ER+ breast cancer provokes progressive pro-metastatic changes, which may explain the mortality risk posed by surgery delay after diagnosis. Also, our data may provide a rationale for a pharmacologic strategy to inhibit the COX-2/PGE_2 cascade in cases when delay of surgery is unavoidable.

#5535 Intracellular negative regulators of RTK-Ras-ERK signaling alter breast cancer perception of metastatic niche-derived growth factors.

V. Murthy[1], C. Erdem[2], J. Copperman[1], M. Birtwistle[2], A. Davies[1];
[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]Clemson University, Clemson, SC

Triple negative breast cancer (TNBC) is an aggressive breast cancer subtype that commonly metastasizes to distant organs, such as the lung, resulting in the poor clinical outcomes. TNBC cells commonly overexpress epidermal growth factor receptor (EGFR), a receptor tyrosine kinase (RTK) which when bound by microenvironmental growth factors, results in the activation of downstream effector kinases ERK-AKT and initiates transcriptional programs that control cell fate. Tumor cells, however, simultaneously receive many growth factor inputs from their respective microenvironments, many of which stimulate RTKs other than EGFR, that converge at ERK and AKT resulting in different transcriptional and cell fate outputs. This raises questions as to how tumor cells perceive, decode, and respond to a complex set of microenvironmental signals and what the relevance of this process may be for disease pathogenesis and treatment. To this end, our study aimed to determine how disseminated breast cancer cells perceive and respond to a complex growth factor milieu upon seeding and engraftment in the lung. Using live-cell microscopy techniques and TNBC cells carrying biosensors for ERK and Akt signaling pathways, we monitored the dynamic signaling behaviors of single tumor cells, in real-time, as they adapted to the environment in living human lung tissue. Strikingly, we found that individual disseminated tumor cells are *less* responsive to growth factors once seeded in the lung, as compared to outside this tissue, despite the presence of RTK stimulating ligands. We showed that partial activation of EGFR is necessary for complete activation of ERK signaling by other growth factor-RTK pairs, and expression of downstream ERK target genes, whereas AKT signaling was unaffected. Using quantitative modeling and experimentation, we showed that reshaping of ERK signaling response dynamics occurred via dysregulation of negative regulators that are dominantly controlled by EGFR signaling. Together, these results provide novel insight into how tumor cells perceive and respond to complex microenvironmental signals, which has important implications for drug targeting strategies.

#5536 The role of p38 MAPK in the tumor-induced immune suppressive microenvironment in metastatic breast cancer.

P. Rajan, R. Zollo, M. Lieberman, Y. Guo, M. Alruwaili, M. Alqarni, B. Morreale, S. Olejniczak, J. Barbi, S. Abrams, A. Bakin;
Roswell Park Comprehensive Cancer Center, Buffalo, NY

The tumor microenvironment (TME) in Metastatic Breast Cancer (MBC) is a major factor contributing to therapy resistance and suppression of antitumor immune response. Tumors promote expansion and recruitment of immune suppressive cells such as myeloid-derived suppressor cells (MDSCs) contributing to tumor invasion and suppressing anti-tumor T cells. Our prior work suggested a critical role of p38 MAPK in tumor-induced expansion and mobilization of myeloid cell populations thereby facilitating metastasis. The current study examined the role of p38 MAPK in tumor-induced changes in immune landscape and explored the mechanisms by which p38 mediates tumor-immune interactions. First, the contribution of T cells to anti-metastatic activity of p38 inhibitor (p38i) was addressed by depletion of CD8 T cells. Depletion of $CD8^+$ T cells negated the effects of p38i on tumor growth and metastasis in the syngeneic 4T1 model. Next, we examined whether p38i exhibits a direct effect on T cells *in vitro* or *in vivo*. The *in vitro* assays showed that p38 blockade increased levels of $CD44^+$ $CD62L^+$ $CD8^+$ T cells indicating enhancement of T cell differentiation. To determine the effects of p38 blockade on the immune landscape *in vivo*, single-cell RNA-seq and flow cytometry studies were performed in the 4T1 model with p38i or p38-deficient cells in which p38α/Mapk14 was inactivated by CRISPR/Cas9 (p38KO). The scRNA-seq data showed that p38 blockade increased the expression of T cell differentiation markers in the TME. Furthermore, p38 blockade significant decreased IL-6 signaling in myeloid cells, an important mediator of MDSC function. Assessment of myeloid cell populations showed a decreased expression of the immune suppressive signature. This observation was further validated in MDSCs isolated from the spleens of 4T1 tumor-bearing mice treated with p38i and in p38KO cohorts. Our prior work showed that p38i does not affect the generation of MDSCs *in vitro*. Therefore, we examined whether blockade of p38 affects the chemotactic capacity of conditioned media from MBC cells using mouse monocytes. The chemotaxis assays showed that p38i and p38KO largely reduced the ability of conditioned media to stimulate transwell migration of mouse monocytes. Notably, p38i and p38KO largely reduced expression of chemotactic cytokines in MBC cell models. Furthermore, p38i and p38KO reduced production and chemotactic ability of exosomes isolated from tumor cells. Together, these observations suggest that tumor p38 MAPK signaling promotes immune-suppressive TME and metastasis by facilitating expansion and mobilization of myeloid cell populations through the mechanisms involving production of exosomes and pro-myeloid chemokines/cytokines. This work highlights that p38 blockade can be utilized in combination with immune therapy or chemotherapy to enhance clinical benefits of immune therapy and reduce promyeloid effects of chemotherapy.

#5537 How aging promotes immune mediated reactivation from metastatic melanoma dormancy.

P. Datt[1], J. Passamonte[1], C. Price[1], D. Zabransky[2], Y. Chhabra[1], A. Weeraratna[3], **M. E. Fane**[1];
[1]Fox Chase Cancer Center, Philadelphia, PA, [2]Johns Hopkins School of Medicine, Baltimore, MD, [3]Johns Hopkins School of Public Health, Baltimore, MD

Disseminated cancer cells that escape the primary tumor can seed distal tissues but may take several years to grow into clinically detectable metastases, a phenomenon termed tumor dormancy. Despite its importance in metastasis and residual disease, few studies have been able to successfully model melanoma dormancy. We have previously shown that while tumors grow more slowly in aged mouse skin, they form more lung metastases in aged mice compared to young mice. We queried whether the lung microenvironment undergoes age-related changes that establish a permissive niche for metastatic outgrowth. We identified that Wnt5A and AXL are not only required for efficient dissemination away from the primary tumor but also activate dormancy of melanoma cells within the lung. The young lung microenvironment maintains melanoma cells in a dormant state; however, age-associated reprograming of lung fibroblasts increases secretion of the soluble Wnt antagonist sFRP1, which inhibits both Wnt5A and AXL to enable reactivation from dormancy and the formation of larger metastatic colonies in the aged lung. We found that downregulation of AXL in melanoma cells leads to an increase in the related TAM family receptor MERTK, which promotes a proliferative melanoma phenotype and enables reactivation from dormancy. We have now found that both the aged-pre and post metastatic niche regulate immune cells in the lung to create a permissive niche for reactivation of metastatic melanoma. NK cells are significantly decreased in the healthy lungs of aged mice, are significantly less active, and have increased exhaustion markers. NK cell infiltration remains low in early and late-stage metastasis in aged mice. Depletion of NK cells in young mice is sufficient to induce reactivation from dormancy. Further, MERTK induced reactivation of melanoma cells results in paracrine secretion of its own ligand PROS1 to facilitate a growth permissive lung microenvironment. Melanoma-secreted PROS1 increases infiltration of PMN-MDSCs and decreases macrophage infiltration to maintain an immunosuppressive lung niche for efficient outgrowth. Selective inhibition of PMN-MDSCs using a TRIAL-R2 agonistic antibody significantly decreases metastatic outgrowth and promotes smaller, non-proliferative dormant colonies. Our findings indicate a significant role that aging plays in altering NK-cell infiltration and function to create a growth permissive pre-metastatic niche and how reactivation from dormancy can further contribute to create an immunosuppressive microenvironment for efficient outgrowth via PROS1 induced infiltration of PMN-MDSCs. Importantly, the clear differences found in our young and aged mouse modelling systems for outgrowth in metastatic tissues necessitates the need for age-appropriate pre-clinical modelling for better patient and disease representation.

#5538 Efferocytosis-induced HIF-1α enhances tumor vascularization and promotes osteoblastic bone remodeling in metastatic prostate cancer.

G. G. Kleer, M. Molina Sanchez, V. Mendoza-Reinoso, A. J. Koh, J. Rubin, L. K. McCauley, H. Roca;
University of Michigan, Ann Arbor, MI

Metastatic prostate cancer (PCA) exhibits a predilection for bone metastasis, initiating a complex interplay with bone cells, leading to dysregulated remodeling and mixed-pathological bone alterations. Human PCA primarily yields osteoblastic bone lesions, linked to bone pain and an adverse prognosis. In this study, we explored the activation of HIF-1α in myeloid phagocytic cells by apoptotic cancer cells in the context of bone metastatic PCA. Our previous findings demonstrated HIF-1α stabilization in bone macrophages engulfing apoptotic PCA cells in vitro. This study extends our understanding to an in vivo setting using mouse prostate cancer cells designed to express inducible caspase 9, triggering apoptosis (and subsequent efferocytosis) when exposed to the dimerizer molecule AP20187 (AP). Our assessment of PCA tumor growth in bone utilized a syngeneic mouse model, introducing a loss-of-function Hif1a mutation into myeloid lineage cells using LysM-Cre mice crossed with Hif1a-floxed mice ($Hif1a^{mut}$ ($LysM\text{-}Cre^{+/-}$ $Hif1a^{flox}$)), compared with the $LysM\text{-}Cre^{-/-}$ $Hif1a^{flox}$ (WT). In the first model, cancer cells were inoculated into the tibiae of these mice and apoptosis was induced with AP on days 3 and 5 post-inoculation (AP model). Results were compared to a model where apoptosis was not induced after inoculation (No-AP). In the AP model, fractional bone volume (BV/TV) in the medullae was significantly higher in tumor-inoculated tibiae than in non-inoculated (No-tumor) contralateral bone, highlighting the predominance of osteoblastic lesions. Conversely, in the No-AP model, increased BV/TV significance was achieved in WT mice (tumor vs. No-tumor), but not in mutant mice. Trabecular thickness (Tb.Th) was increased in both models in the presence of tumor, regardless of the Hif1a phenotype. Importantly, significant differences in BV/TV and Tb.Th between WT and $Hif1a^{mut}$ tumor tibiae were exclusively noted in the context of induced apoptosis. Histological differences between tumors in the AP model were observed by immunofluorescence (IF) staining, which revealed a reduced fractional $F4/80^{\pm}$ area in $Hif1a^{mut}$ vs. WT tumors, with no differences in $TRAP^{\pm}$ (osteoclasts) lining bone surfaces. RNAseq analysis of $HIF1a^{mut}$ vs. WT macrophages efferocytosing apoptotic cancer cells showed downregulated processes related to vasculature development and blood vessel morphogenesis ($p< 10^{-5}$). In correlation, IF analysis with endomucin (EMCN) demonstrated a reduction in stained area ($EMCN^{\pm}$) relative to tumor area in $Hif1a^{mut}$ tibiae vs. WT, suggesting a role of efferocytosis-induced HIF-1α in tumor vascularization. This study unveils intricacies of metastatic tumor growth in bone and proposes a connection between efferocytosis-induced HIF-1α in myeloid phagocytic cells and the promotion of tumor vascularization, alongside the enhancement of osteoblastic bone remodeling.

#5539 PRDM16 is an intrinsic regulator of dormancy in bone disseminated prostate cancer cells.

M. M. Nasr, T. Li, R. T. Bishop, J. S. Frieling, C. C. Lynch;
H.Lee Moffitt Cancer Center, Tampa, FL

Metastatic prostate cancer (PCa) frequently occurs in the bone and can remain inactive for extended periods after primary tumor treatment. Understanding the intricate molecular mechanisms that govern this phenomenon could open the door to novel therapies, potentially reducing mortality rates. To address this, we developed a novel protocol to induce cellular dormancy in PCa cell lines (RM1, 22Rv1, LAPC4) *in vitro*. We noted that dormant cells exhibited distinctive clustering and could be reactivated when exposed to serum even after 21 days of stasis. The dormancy program was validated by multiple assays including cell cycle analysis, membrane dye retention, and $Edu^{\pm}$ incorporation. RNASeq analysis showed significant transcriptional changes during dormancy induction, with 8 genes commonly upregulated across multiple human and mouse PCa cell lines, of which the transcription factor, PRDM16. We focused on PRDM16 since, 1) it is a known regulator of hematopoietic stem cell quiescence, 2) our emerging data points to bone morphogenetic protein-7 (BMP7), a well-known exogenous mediator of dormancy as an inducer of PRDM16 expression and 3) clinically, PRDM16 is suppressed in primary PCa and active metastases. First, we validated the upregulation of PRDM16 during dormancy *in vitro*. Silencing PRDM16 led to impaired dormancy phenotype and cell death, while its overexpression significantly mitigated proliferation rates and promoted survival. *In vivo,* we employed an intra-iliac immunocompetent model (RM1 & C57BL6J) and demonstrated that overexpressing PRDM16 in active RM1 cells resulted in significant reduction of metastasis formation and Ki67 expression concurrent with extended survival when injected *in vivo* compared to control cells. Prostate cancer cells with PRDM16 over-expression were detected in bone sections as solitary or small clusters (<20 cells) demonstrating an inverse relationship between PRDM16 expression and metastatic outbreak. In defining the targets via which PRDM16 controls dormancy entry, we focused on RAR related orphan receptor C (RORC) based on bioinformatic analysis and publicly available PRDM16 ChIP-Seq. Our data demonstrate that pharmacological inhibition of RORC using GSK805 promoted the apoptosis of dormant PCa cells specifically when compared to their actively growing counterparts. In conclusion, our studies have revealed the critical role of PRDM16 in promoting PCa cell dormancy, in part via upregulating RORC. Translationally, clinically approved RORC inhibitors for non-cancerous conditions (psoriasis) have been developed. We expect, based on our results, that these inhibitors could be repurposed for the eradication of dormant PCa cells in patients with advanced disease.

#5540 Single cell multiomic analysis of human brain metastasis reveals conserved dormancy population.

R. Klotz[1], **Y. Wang**[1], A. Sunkara[1], F. Attenelo[2], M. Yu[1];
[1]University of Maryland, Baltimore, Baltimore, MD, [2]University of Southern California, Los Angeles, CA

This study explores the complex realm of brain metastasis, pivotal in crafting effective anti-tumor strategies. Leveraging single-cell multi-omics sequencing, we profiled the transcriptomes and chromatin accessibility landscapes of tumor cells and their surrounding microenvironment in human brain metastases that originated from across a spectrum of primary cancers. Our investigations have identified distinct, yet uniformly present, tumor cell subpopulations, each defined by unique gene expression patterns, chromatin accessibility, and the interactions between tumor and stromal cells. Notably, one such subpopulation exhibits a dormancy signature, characterized by enhanced interferon response, oxidative phosphorylation, and upregulated HLA class molecules, alongside alterations in circadian rhythms. Our trajectory analysis charts a course from these dormant cells to rapidly proliferating ones, with notable shifts in circadian rhythm genes, underscoring their potential role in brain metastasis. This aligns with recent findings that disruptions in circadian rhythms can modify stem cell characteristics in glioblastomas. This insight led us to focus on a specific circadian rhythm gene, highly active in the dormant cells and located on the HER2 amplicon—an area linked to high brain metastasis relapse rates in patients. We've developed inducible models for both overexpression and knockdown to scrutinize this gene's impact in her2 positive breast cancer cell lines, examining gene expression and proliferation in vitro. Complementing this, we are conducting spatial transcriptomic analysis to evaluate the microenvironmental regulation of tumor dormancy in human brain metastases. This multi-omics approach reveals a nuanced regulatory landscape of brain metastasis, highlighting a novel and often overlooked factor in metastasis progression and brain tumor relapse: the interplay between circadian rhythms and tumor dormancy. This discovery not only deepens our understanding of brain metastases but also opens potential new avenues for therapeutic interventions.

#5541 The unique metabolite landscape of the aged microenvironment dictates melanoma migratory and invasive capacity.

G. M. Alicea, P. Patel, M. Wei, V. Rebecca, D. Wirtz;
Johns Hopkins, Baltimore, MD

Metastatic burden and organ failure are the root causes of mortality in patients with advanced melanoma; however, little is known of the metabolic drivers that enable organ colonization and the formation of overt metastases. Recent studies have drawn attention to the importance of metabolism in the survival and colonization of cancer cells. In melanoma, there have been studies focusing on the invasive capabilities of cells; however, not much is known regarding metabolic plasticity in melanoma migratory, invasive and ultimately metastatic capabilities.We have previously shown changes in the lipid landscape of the aged microenvironment promotes melanoma resistance to targeted therapy. Here, we find a distinct metabolite landscape in the aged microenvironment elevates melanoma metastatic capacity. We utilized a panel of well characterized melanoma models and tested their invasiveness and motility under different metabolite levels modeled after the aged microenvironment. Transcriptomic and proteomic analysis identifies distinct signatures that explain the migratory and invasive differences in cells cultured in varying metabolic environments. We hypothesize that different nutrient availabilities melanoma cells are exposed to during the metastatic phase affect the migratory and invasive capacity of the cell. We tested this by performing 3D migration assays, organoids and transwell assays of cells grown in media with varying nutrient levels. Further analysis is currently underway to better understand the mechanisms in which these metabolic differences facilitate cell migration, invasion and eventually colonization. This work has important implications for our understanding of the metabolic determinants of melanoma migration and metastatic colonization, and we hypothesize restraining tumor metabolic plasticity is vital to prevent and treat metastases in melanoma.

TUMOR BIOLOGY: Tumor-Immune System Cross-Talk
Poster Session

#5545 FADD activation renders hepatocellular carcinoma sensitive to immune checkpoint blockade by turning cold tumors hot.
J. Zhou, J. Lu;
Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong

The heterogenicity of hepatocellular carcinoma (HCC) remains a key obstacle in turning the majority of 'immune-cold' tumors 'hot' for effective immune checkpoint blockade (ICB) therapy. Through studying the naturally-existed 'hot' HCC variant lymphoepithelioma-like (LEL)-HCC by RNA and whole exome sequencing analysis, we identified fas-associated death domain (FADD) as one of the top differentially expressed genes that associated with high tumoral $CD8^{\pm}$T cell abundance. Of note, FADD upregulation was also observed in HCC patients with better ICB responsiveness. As FADD was mainly expressed in tumor cells from HCC by scRNAseq analysis, we constructed *Fadd* knockout stable cells using murine HCC cell lines. Interestingly, CRISPR knockout of tumoral *Fadd* led to increased tumor weights in immunocompetent but not immunodeficient mice, accompanied with decreased tumoral $CD8^{\pm}$T cells. Mechanistically, FADD phosphorylation promoted NF-κB transcriptional activity to increase CCL5 secretion from HCC cells via interacting with its nuclear binding partners Src-associated-substrate-during-mitosis-of-68kDa/KH domain containing, RNA binding, signal transduction associated 1 (Sam68/KHDRBS1) and lysine (K)-specific methyltransferase 2D (KMT2D), thus directing $CD8^{\pm}$T cell tumor infiltration. In addition, anti-PD1 triggered FADD phosphorylation via IFN-γ and TNF-α release from $CD8^{\pm}$T cells in ICB-sensitive but not resistant tumors. Most importantly, sequential FADD activation via genetic and pharmacologic approaches could re-sensitize the therapeutic efficacy of anti-programmed death 1 (PD1) antibody in ICB-resistant orthotopic and spontaneous HCC models by turning cold tumors hot. Taken together, our findings reveal a key molecular feature of ICB-responsive hot tumors that may guide the development of sequential combinatory immunotherapies for the majority of HCC patients with low responsiveness to ICB monotherapy. This project is supported by the University Grants Committee through General Research Fund (24110323, 14107622, 14104820) and the Health and Medical Research Fund (07180556).

#5546 CRISPR-based kinome screen identifies *Ikbkb* as a regulator of phagocytic evasion in hepatocellular carcinoma.

S. Chan, T. Lee;
The Hong Kong Polytechnic University, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) is one of the most lethal and prevalent malignancies worldwide and is associated with poor prognosis. Recently, immune checkpoint inhibitors (ICIs) have revolutionized the oncology landscape by targeting genes critical for immune checkpoint pathways, leading to the immune evasion of cancer cells. Phagocytosis checkpoints have emerged as essential checkpoints for cancer immunotherapy by functioning as “don’t eat me” signal to suppress immune response. Given the druggable properties of protein kinases, together with recent reports showing the antitumor immunity of kinase inhibitors, we aimed to identify protein kinases critical for phagocytic evasion in HCC by transducing a lentiviral sgRNA expression plasmid containing 2,852 unique single-guide RNAs (sgRNAs) targeting the 713 mouse kinase gene in mouse HCC cells, RIL-175, and subsequently co-incubated with RAW 264.7 macrophages. Based on the deep sequencing analysis comparing the sgRNA distribution in RIL-175 with or without co-incubation, we identified the *Ikbkb* gene as top-sensitizing hit on this screen, with at least two-fold sgRNA reduction upon incubation with macrophages.

To verify the phagocytic evasive role of *Ikbkb* in HCC, we have employed CRISPR/Cas9 knockout approach to delete *Ikbkb in mouse HCC cell line,* RIL-175 cells. The results showed that upon co-incubation with RAW 264.7 cells, the *Ikbkb* knockout cells exhibited increased phagocytosis, as confirmed by both flow cytometry analysis and microscopy observation. The analysis of the TCGA-LIHC cohort revealed that the expression level of *Ikbkb* was elevated and associated with unfavorable clinical outcomes. Notably, Ikbkb expression was found to be significantly correlated with established anti-phagocytic markers, including CD24, CD47, and CD274, further supporting their roles in the anti-phagocytic activities of HCC cells.

In summary, we have uncovered IKBKB as a cancer-intrinsic regulator of phagocytosis, which has the potential to target IKBKB as a novel therapeutic strategy to enhance the efficacy of current ICI treatments for HCC patients.

#5547 Non-invasive monitoring of tumor biomechanics and implications for immunotherapy in HCC.

A. C. Cortes, K. Minamiguchi,, H. Kostan, M. S. Stenkamp, S. Anfossi, N. Fowlkes, R. Avritcsher;
The University of Texas MD Anderson Cancer Center, Houston, TX

Shear-wave elastography (SWE) is a novel non-invasive technique used to quantify tissue stiffness. This approach can be used to longitudinally monitor tumor biomechanics and holds promise for guiding informed clinical decision-making. This study aims to explore the impact of tumor stiffness, as evaluated by SWE, on the proliferative potential of endothelial, tumor, and immune cells in a preclinical model of hepatocellular carcinoma. Tumor tissue sections from a Buffalo-McA-RH7777 rat HCC tumor model, utilizing a rat hepatoma cell line stably expressing green fluorescent protein genes (fluc/GFP) were selected based on the degree of tumor stiffness assessed by SWE. Nodules were separated based on mean shear wave values (3.05 versus 2.26 m/s) and categorized as stiff or soft, respectively. A 6-color panel was used to assess the percentages of different tumor, immune, and endothelial phenotypes in different areas of the tumor including immune cells (CD45+), endothelial cells (CD34+), green fluorescent protein (GFP), Ki67 (cell proliferation), and class-III intermediate filaments - vimentin. Our findings demonstrated increased expression of vimentin on immune cells (CD45+) within the tumor margin interphase. Stiffer tumors exhibited a higher percentage of CD45 cells co-expressing vimentin compared to softer tumors (P=0.01), whereas softer tumors showed an increased prevalence of CD34+ cells concurrently expressing Ki67 (P=0.01). Same pattern persisted in the tumor margin interphase regarding the proliferation of tumor cells identified by the expression of GFP co-expressing Ki67 (P<0.01). These findings highlight a significant association between tumor mechanical properties and the proliferative activity of endothelial and tumor cells, suggesting a link between tissue stiffness and the regulatory mechanisms associated with cellular proliferation and aggressiveness in HCC. Additionally, the presence of vimentin in immune cells may suggest that stiffer tumors may require enhanced migratory and invasive properties to compensate for changes in tumor mechanics thus potentially influencing immune function.

#5548 Cannabidiol enhances efficacy of atezolizumab via upregulation of PD-L1 expression by cGAS-STING pathway in triple negative breast cancer cells.

Bu Gyeom Kim[1], Bo Ram Kim[1], Dae Yeong Kim[1], Hyemi Yun[2], Dayoung Kim[2], Woo Young Kim[3], Sanghee Kang[3], Sun Il Lee[3], Sang Cheul Oh[1]

[1]Oncology, Korea University College of Medicine, Seoul, Korea, Republic of,[2]Biomedical Sciences, Korea University College of Medicine, Seoul, Korea, Republic of,[3]Surgery, Korea University Guro Hospital, Seoul, Korea, Republic of

The current treatment for patients with triple negative breast cancer (TNBC) relies on cytotoxic therapy. Currently, atezolizumab and chemotherapy can be combined in patients with TNBC, but this approach is not effective for all patients with low reactivity to atezolizumab. As there is a lack of alternative treatment options, new anti-cancer drugs are urgently needed to enhance atezolizumab reactivity against TNBC. Recent strategies have focused on regulating the expression of programmed death-ligand 1 (PD-L1) or enhancing immune response activation by combining anti-cancer drugs with immune checkpoint inhibitors (ICIs). Cannabidiol (CBD), a cannabinoid component derived from the cannabis plant, has been reported to have anti-cancer therapeutic potential because of its capacity to induce apoptotic cell death in tumor cells while avoiding cytotoxicity in normal cells. Previous studies have demonstrated the effects of CBD on apoptosis in various types of cancer cells. However, the potential role of CBD as an immune modulator in the regulation of PD-L1 expression and the anti-cancer immune response remains to be explored. In this study, we found that CBD stimulated PD-L1 expression in TNBC cells, which significantly induced CBD-mediated cGAS-STING pathway activation. Taken together, we demonstrated that the combination of CBD and anti-PD-L1 antibody enhances the anti-cancer immune response *in vitro* and *in vivo* experiments. Our findings identified the mechanism of PD-L1 regulation by CBD in TNBC cells and suggested that CBD could be a potential candidate for the development of new combinatorial strategies with ICIs in TNBC patients.

#5549 Multicellular spheroid structural and metabolic characterization through radial line profiling.

S. N. Bess, M. J. Igoe, G. K. Smart, T. J. Muldoon;
University of Arkansas, Fayetteville, AR

Three-dimensional multicellular tumor spheroids have emerged as a step between *in vitro* and *in vivo* models that can offer biological insight in fields such as tumor biology. Spheroids closely resemble *in vivo* solid tumors regarding their heterogeneous architecture and gradients of nutrients and oxygenation. These characteristics give the spheroid model great potential for studying basic tumor biology. However, traditional characterization methods investigate changes in the discrete regions within the spheroid, limiting the amount of spatial information regarding cellular metabolism. In this study, multicellular spheroids were created through a combination of hanging drops and gentle agitation using murine RAW 264.7 macrophages and colorectal adenocarcinoma CT26 cells. Hanging drops were maintained for three days then transferred to 6-well plates and placed on an orbital shaker set to 70 RPM for seven days. Prior to metabolic imaging, spheroids were moved to a microincubator with controllable temperature and humidified gas delivery (5% CO_2). A custom inverted multiphoton imaging system (Bruker) equipped with an Ultrafast Ti:Sapphire via a 60x/1.2NA water immersion objective (Olympus) and four close-proximity, high-efficiency GaAsP detectors. NADH fluorescence was captured with a 460 (± 20) nm band pass filter at 755 nm excitation and FAD fluorescence with a 525 (± 25) nm band pass filter at 855 nm excitation. NADH and FAD fluorescence were normalized by PMT gain and laser power. An integrated fluorescence lifetime imaging microscopy (FLIM) module was used to measure mitochondrial function regarding the different components contributing to NADH autofluorescence. Immunofluorescence was used to characterize macrophage populations (M1 vs M2) and cellular proliferation (Ki67) and apoptosis (CC3). CD206, a M2 marker, showed a lower normalized fluorescent intensity at the spheroid core (0.429) compared to the proliferative edge (0.570). Similar trends are also observed for CD80, a M1 marker and Ki67. CC3 showed a higher normalized fluorescent intensity at the spheroid core (0.823) compared to the proliferative edge (0.004). The optical redox ratio displays a slightly lower value at the core (0.429) compared to the proliferative edge (0.570). Overall, these results indicate that the proliferative edge shows higher numbers of immune cells and more oxidative metabolism compared to the core. Future work includes exposing this spheroid model to low levels of oxygen to investigate how environmental changes in oxygen can affect spheroid structure and metabolism.

#5550 Crosstalk of estrogen receptor B with tumor microenvironment signaling explains tumor suppressor actions in TNBC.

Kristina Diana A. Zambo[1], Harika Nagandla[1], Kim Cuong Cap[1], Aireana Phillips[1], Fotis Nikolos[2], Wei Qian[1], Jianying Zhou[1], Jenny Chang[1], Christoforos Thomas[1]

[1]Cancer Center, Houston Methodist, Houston, TX,[2]Urology, Houston Methodist, Houston, TX

Triple Negative Breast Cancer (TNBC) is a subtype of breast cancer lacking molecular targets, possessing one of the poorest prognoses of all breast cancers. Recent studies using breast tumor samples show an association between the expression of estrogen receptor β (ERβ) and improved survival of patients with TNBC. ERβ - whose function largely opposes that of oncogenic ERα - is involved in the regulation of many tumor repressive pathways and has lately been observed to partake in immune modulation, thus presenting a promising target for TNBC. Discovering selective ERβ agonists is critical to understanding the potential of activating the receptor as a therapy approach for TNBC. It enables us to elicit estrogen signaling response specific to the tumor suppressive function of the β receptor subtype. We have set out a screening process to test and identify ligands that display the greatest activation and specificity for ERβ as determined by reporter assays and changes in downstream target gene expression. We selected to study *in vitro* and *in vivo* the compounds with optimal biological activity to delineate tumor-intrinsic and -extrinsic effects and validate the mechanism of action employing human and mouse cell models that reflect the heterogeneity of the disease. We propose that activation of ERβ decreases the proliferative and metastatic ability of breast cancer cells by altering cellular pathways and crosstalk with immune cells. The results of these studies help lay the groundwork for further research on the clinical potential of ERβ especially in the realm of immunotherapy and treatment of TNBC.

#5551 Targeted nanoparticles co-delivering PARP inhibitor and other immune modulators overcome the immunosuppressive tumor microenvironment.

R. Khoury[1], R. Kleiner[1], E. Yeini[1], D. Rodriguez Ajamil[1], S. Israeli Dangoor[1], T. Sanalla[2], I. Barshack[2], R. Satchi-Fainaro[1];
[1]Tel Aviv University, Tel Aviv, Israel, [2]Sheba Medical Center, Ramat Gan, Israel

Several mutations have been identified that are associated with an increased risk of triple-negative breast cancer (TNBC), including those that are deleterious in the BRCA gene. TNBC is associated with the worst prognosis and the highest incidence of brain metastasis (30%) among all subtypes of BC. Despite objective responses to poly (ADP-ribose) polymerase (PARP) inhibition and improvements in progression-free survival (PFS) compared to standard chemotherapy in patients with BRCA-mutated TNBC, benefits are transitory. Furthermore, our understanding of the effect of PARP inhibitors (PARPi) in treating breast cancer brain metastasis (BCBM) and modulating its tumor microenvironment (TME) is still lacking. To this end, we analyzed the brain TME of BRCA-mutated BCBM in the absence or presence of treatment with PARPi. Interestingly, we found that the immune TME of the brain hinder the antitumor activity of PARPi by upregulating multiple immunosuppressive molecules, including PD-L1. Furthermore, we found that BCBM overexpress P-selectin through its interaction with the tumor-associated microglia, bone marrow-derived macrophages and endothelial cells in the TME. Thus, we designed a novel nanoparticle (NP) targeting P-selectin to serve as a brain-penetrant delivery system for the treatment of BCBM. In order to target BRCA-mutated BCBM, we harnessed our novel P-selectin-targeted NPs to entrap PARPi and other immune modulators that we found to exert synergistic activity when combined. To evaluate the antitumor activity of our P-selectin-targeted NPs, we established 3-dimensional (3D) *ex vivo* and *in vivo* BRCA-mutated BCBM models. Importantly, we saw favorable effects of the P-selectin-targeted NPs in comparison to the combination of the free drugs, suggesting that out targeted-NPs overcome the TME-mediated resistance to PARPi through the modulation of the immunosuppressive microenvironment of the brain.

#5552 Uncovering clinically significant tumor microenvironment interaction programs across diverse cancers.

Ido Nofech-Mozes, Vivian Wang, Philip Awadalla, Sagi Abelson

Ontario Institute for Cancer Research, Toronto, ON, Canada

Background: Cell-cell interactions (CCI) within the tumor microenvironment (TME) play pivotal roles in various tumor behaviors, including cancer growth, metastasis, immune evasion, and resistance to therapy. Compared to front-line treatments, targeting specific CCIs marks a paradigm shift in cancer therapy, aiming for enhanced response rates with reduced side effects. Although current approaches targeting immune regulation pathways exhibit effective anti-tumor responses, substantial variability in response rates across patients and cancer types persists. Consequently, a critical imperative emerges to discover novel interaction programs (IPs) across diverse TMEs, demonstrating clear clinical impact across a broad spectrum of patients.
Methods: *Characterization of pan cancer IPs.* We compiled a pan cancer single-cell RNA-seq (scRNA-seq) atlas, including 4 million cells from 890 tumors across 14 cancer types. In each sample, CCIs were inferred using a ligand-receptor (LR) analysis framework, generating ranked CCI scores based on consensus from various LR inference methods. To find IPs enriched across TMEs, we applied an unsupervised factorization approach. The outcome represents CCIs as factors, where sample loading indicates factors' strength, and feature loading highlights the cells and LR pairs constituting each IP.
Evaluating IPs in clinical RNA-seq cohorts. Given the more immediate translational potential of bulk cancer sequencing for patient stratification, we devised an approach to predict IPs' strengths in bulk RNA-seq. Random Forest regression models using pseudo-bulk expression of cancer genes were trained to predict the loading (strength) of factors (IPs) in each sample in the scRNA-seq pan-cancer atlas. These models were subsequently applied to cancer samples in The Cancer Genome Atlas (TCGA) cohort to assess the clinical impact of various IPs on patient mortality.
Results: We assessed the impact of IPs on 5-year overall survival using Cox proportional hazard models. We identified multiple factors significantly associated with survival in at least 4 cancer types. Notably, a robust prognostic factor linked to the inclusion of anti-tumor natural killer cell interactions and exclusion of pro-tumor macrophage interactions was found in MESO, LGG, ACC, and UVM (HR 1.6-6.6, $p < 0.05$). The validation of IPs using spatial transcriptomics and evaluation of IP prediction's utility in targeted treatment cohorts are currently underway.
Conclusion: We highlight a potent method for detecting clinically significant IPs involving cells in TME communicating through LR pairs. The ability to assess these scRNA-seq-derived IPs in clinical bulk RNA-seq cohorts signifies a valuable advancement. Our approach holds promise for expanding the repertoire of cell therapies, identifying new treatment targets, and improving our predictive capabilities for responses to existing therapies.

#5553 Glycan CA19-9 mediated immune modulation in the pancreatic tumor microenvironment.

J. Hsu, T. Oh, K. L. Peck, A. E. Rock, G. Bishop, S. R. Okhovat, S. M. Kaech, D. D. Engle;
Salk Institute, La Jolla, CA

Pancreatic ductal adenocarcinoma (PDA) is an intractable common malignancy with a pro-tumorigenic and immunosuppressive microenvironment (ME) that often limits treatment efficacy. Only 10-15% of patients are eligible for surgical resection, which is the only cure for PDA. The glycan CA19-9 is used to follow treatment response in PDA patients, but its functional role in PDA remained unknown until recently because rodents lack the ability to produce this carbohydrate. CA19-9 elevation in a KRAS-mutant background results in increased tumor proliferation and ME remodeling in mice. The tumor ME is encompassed by hypovascularized stroma consisting of cancer associated fibroblasts (CAFs) and tumor associated macrophages (TAMs) that contribute to desmoplasia and immunosuppression. All prior work investigating the tumor ME in PDA mouse models was performed in CA19-9 negative context, potentially missing a key element of PDA biology. Elevation of CA19-9 in mice caused expansion of both antigen-presenting (ap)CAFs and TAMs. CA19-9 induction in KRAS-mutant organoids increased gene expression of M-CSF, IL1a, and TGFb and led to increased apCAF and TAM differentiation. This project aims to uncover the mediators of CA19-9-mediated ME remodeling. CA19-9-modified macrophage colony-stimulating factor (M-CSF) was identified via immunoprecipitation and mass spectrometry from KRAS-mutant CA19-9-inducible pancreatic organoids. CA19-9-M-CSF induced increased immunosuppressive TAM differentiation *in vivo* and *in vitro* using a novel Macrophage, Organoid, and Fibroblast (MOrF) co-culture platform. This project will identify the mechanisms by which CA19-9 directly contributes to PDA ME immune modulation and unveil essential molecular underpinnings of PDA biology that will inform effective therapies in the future.

#5554 Breast cancer with different chemosensitivity has distinct influence on the immune microenvironment.

E. Skourti, K. Seip, E. V. Egeland, S. Jabeen, N. Mensali, I. Oynebraten, S. Juell, E. M. Inderberg, O. Engebraten, A. B. Corthay, G. M. Malandsmo, L. Prasmickaite;
Oslo University Hospital, Oslo, Norway

Triple Negative Breast Cancer (TNBC) is a BC subgroup with the least favorable outcome and limited therapeutic options. Chemotherapy has long been the standard treatment, but resistance often develops. In recent years, various immunotherapy approaches have diversified, including combinations of chemo and immunotherapies. Increased understanding on how the difference in chemosensitivity affects the immune cells is of importance for further development of chemo-immunotherapies for TNBC. In this project we investigate how TNBC with distinct chemosensitivity modulate the immune microenvironment. Specifically, we explore the influence of the secretome, derived from the chemoresistant versus the sensitive BC cells, on macrophages (MØs) and T-cells. We have disclosed the chemosensitivity-dependent differences in the secretome, which were associated with diverse effects on MØ recruitment, polarization, and activation. Currently we investigate the secretome influence on interferon (IFN)-activated MØ. IFN stimuli is known to trigger tumoricidal activities in MØ, and we are setting up a co-culture assay, where such MØ functions could be explored in vitro. To study the secretome influence on T-cells, we employ T cell receptor (TCR)-engineered T cells that become activated in the presence of target cells. The preliminary results indicate that activation of the TCR T-cells was reduced in the presence of the “chemoresistant” secretome, suggesting its immunosuppressive influence. Work is in progress to validate this observation using other TCR T cells and functional markers of active T cells.

#5555 Lung squamous cancer cell mTORC2 signaling suppresses antitumor immunity by up-regulation of PSGL-1, a ligand of VISTA/ PD-1H checkpoint receptor.

V. M. Ngwa, Y. Hwang, D. N. Edwards, W. Song, J. Chen;
Vanderbilt University Medical Center, Nashville, TN

Lung squamous cell carcinoma (LUSC) represents 30% of non-small cell lung cancer (NSCLC) cases and has a high mortality rate with limited targeted therapies. Unlike lung adenocarcinoma (LUAD), which has seen advancements in targeted therapies, LUSC has not benefited from similar breakthroughs despite having similar genetic abnormalities. While immune checkpoint inhibitor therapies have shown promise in some LUSC patients, a significant portion does not respond effectively, leaving limited treatment options. In this study, we investigated vulnerabilities in NSCLC and found that a substantial number of LUSC patients have genetic alterations in the PI3K-mTORC2-AKT signaling pathway. By using CRISPR/CAS-9, we showed that disrupting mTORC2 function in LUSC cells reduced glycolysis and lactate secretion, which in turn reduced tumor growth in vivo. Remarkably, the loss of mTORC2 also enhanced the activity of CD4+ and CD8+ T cells within the tumors. To further understand the metabolic and immune changes associated with mTORC2 loss of function, we performed RNA sequencing comparing wild-type (WT) and mTORC2-deficient cells. Our results confirmed a link between mTORC2 and HIF-2α, while regulating PSGL-1, a ligand of the VISTA/PD-1H checkpoint receptor. Furthermore, introducing a stable, non-degradable form of HIF-2α in mTORC2-deficient tumor cells restored PSGL-1 expression in vitro and in vivo. These results suggest that the interaction between PSGL-1 and VISTA plays a role in suppressing the anti-tumor immune response in LUSC tumors. Indeed, anti-VISTA treatment inhibited the growth of LUSC WT tumors in vivo, suggesting that mTORC2 plays a role in regulating PSGL-1 expression in the tumor microenvironment. Together, these data demonstrate that targeting mTORC2 or inhibiting VISTA checkpoint receptor may serve as a potential therapeutic strategy for improving immunotherapy in LUSC.

#5556 An vascularized melanoma model for with unidirectional perfusion of circulating immune cells for advancing immune-oncology research.

M. C. Torregrosa, S. de Ruiter, T. Burton, K. Queiroz, **W. Allen**, J. Komen, S. Trietsch, L. van den Broek;
MIMETAS, Oegstgeest, Netherlands

Understanding the interactions between the tumor the vascular systems and circulating immune cells is crucial for elucidating mechanisms of immune cell recruitment in cancer and in exploring potential immunotherapeutic approaches. However, current in vitro models often lack the fidelity to replicate these intricate dynamics observed in vivo. The OrganoPlate Graft has been developed for perfusion of peripheral blood mononuclear cells (PBMCs) through a vascular bed with a melanoma monolayer (A375) to study aspects such as immune cell adhesion, extravasation and interaction with the tumor. The OrganoPlate Graft comprises 48 chips per plate, each designed to simulate the conditions of vascular beds. The device achieves flow through passive leveling, utilizing gravity to induce a pressure drop and unidirectional flow across the vascular bed in both positive and negative inclines. This approach avoids the complications and potential artifacts introduced by external pump, reduces complexity, and increases the throughput with up to 16 plates (768 chips) served by each OrganoFlow rocker. In experimental settings, formation of the vascular bed was seen to be consistent in plates and the introduction of the chemokine CXCL-12 led to the establishment of a gradient. Subsequently, PBMCs were observed to localize in clusters as a result of extravasation towards this gradient and the A375 monolayer. This behavior is consistent with known chemotactic responses in more complex in vivo environments. A notable observation was the sustained activity of PBMCs within the system. Cells continued to perfuse through the vascular bed for up to three days after seeding. In summary, the OrganoPlate Graft provides a platform for studying immune interactions in an immunocompetent vascular bed model. Its design and functionality allow for the exploration of immune cell behaviors in proximity to tumor cells, offering potential insights for immune-oncology research. The system's ability to mimic immune cell migration and extravasation in a controlled environment, and future potential to observe tumour killing makes it a valuable tool for advancing our understanding of immune-tumor interactions and may contribute to the development of novel immune-oncology therapeutic strategies.

#5557 Stem-like T cells maintain latent anticancer activity and underly therapy resistance.

F. Tao, S. McElroy, J. Nemechek, I. Pushel, J. Szarejko, S. Khanal, T. Bradley, D. Myers, J. M. Perry;
Children's Mercy Research Institute, Kansas City, MO

Pre-cancerous cells are normally recognized and eliminated by immune cells. Cancer progresses only when this immunosurveillance system fails. Although immunotherapy has driven the most significant and exciting advances in cancer treatment in modern times, current approaches are running into barriers. An emerging area of interest includes evidence for rare but highly potent stem cell-like T cells. Stem-like T cells combine long-term persistence and high potency with immunological memory. Our recent findings reveal insights into the nature and regulation of stem-like T cells and their potential anticancer activity. Minimal residual disease (MRD) underlies therapeutic resistance, dictates treatment escalation, and predicts patient outcomes. We have shown that the Wnt and PI3K pathways promote the transformation of hematopoietic stem cells (HSCs) into chemoresistant leukemia stem cells (LSCs), which form the root of leukemia initiation and post-treatment recurrence. High-throughput screening revealed that LSCs could be targeted by low dose anthracycline treatment. Mechanistically, low dose, but not high dose anthracyclines indirectly target LSCs by inhibiting their unique properties of immune escape, allowing for their elimination by CD8+ T cells. We employed single-cell genomic and proteomic analysis to investigate immunological changes during development of HSCs, LSCs, and their progeny in response to low dose anthracycline treatment. While leukemia progression results in exhaustion of differentiated CD8+ T cells, stem-like T cells accumulate. However, low dose anthracycline treatment reverses this imbalance. Comparing MRD+ and MRD- patient samples, we found that differential proportions of stem-like T cells persist in the bone marrow of leukemia patients. While T cells of MRD- patients recover following chemotherapy induction, T cell recovery is severely attenuated in MRD+ patients. Furthermore, failure of immunological recovery is driven at least partially by a lack of stem-like T cells in MRD+ leukemia patients. Overall, our studies have revealed that low dose anthracyclines, in contrast to high dose, induce opposing, dichotomous effects on LSCs vs. HSCs and stem-like vs. differentiated T cells.

#5558 Whole-slide multiplexed tissue imaging of prostate adenocarcinoma reveals distinct immune niches in high- versus low-grade tumors.

J. Wala[1], J.-R. Lin[2], B. Labadie[3], D. Peiffer[4], A. Gagne[1], K. Chaudagar[4], Y.-A. Chen[2], E. Van Allen[1], P. Sorger[2], **A. Patnaik**[4];
[1]Dana-Farber Cancer Institute, Boston, MA, [2]Harvard Medical School, Boston, MA, [3]Columbia University Medical Center, New York, NY, [4]University of Chicago, Chicago, IL

Objectives
Tumor-immune interactions are a critical determinant of tumor evolution and are increasingly targeted by novel therapeutics (e.g. immune checkpoint blockade). However, their significance in treatment-naive localized prostate cancer remains largely unknown. Here, we employ multiplexed tissue imaging on radical prostatectomy specimens across Gleason grades to create a single-cell spatial atlas of primary prostate tumors and characterize their innate and adaptive immune landscape.

Methods
Whole-slide radical prostatectomy (RP) specimens were obtained from 28 patients: 14 with Gleason Grade Group ≤ 3 (Low-grade; LG) and 14 with Gleason Grade Group ≥ 4 (High-grade; HG). Tumors were imaged with our cyclic immunofluorescence (CyCIF) platform using a 27-marker panel encompassing epithelial, T-cell, innate immune and stromal markers. Tumor and stromal compartments were manually annotated by a pathologist. Cell densities were compared between tumor and stromal compartments of LG and HG tumors.

Results
Across the 28 RP specimens, we identified and spatially resolved over 27 million individual cells. Overall, higher Gleason grade was associated with a significantly increased innate and adaptive immune reaction. CD8+ cytotoxic T-cell density was significantly higher in HG vs LG ($p = 0.003$) specimens, although this effect was largely due to enrichment in adjacent stroma rather than direct tumor infiltration. By contrast, FOXP3+ T-cells were significantly increased throughout the tumor and stromal compartments of HG compared with LG tumors ($p = 0.001$). Tertiary lymphoid structures (TLS) and CD163+ myeloid cells were also significantly enriched in HG tumors relative to LG tumors ($p = 0.029$ and 0.039, respectively). PD-1+ cells were specifically enriched in TLS structures in HG tumors ($p < 0.001$). There were no significant differences in CD11c+ and CD103+ cell densities between LG and HG tumors.

Conclusions
This spatially resolved single-cell atlas of localized prostate cancer reveals that high-grade tumors exhibit significant inflammation, particularly of TLSs and stromal CD8+, and are enriched in markers of T-cell anergy and myeloid-derived suppression. These findings raise the hypothesis that immunotherapy may have activity in treatment-naïve high-grade prostate cancer, despite the failure of immune checkpoint blockade in mCRPC.

#5559 The anti-tumor efficacy and immune effects of combining of ceralasertib, an oral ATR kinase inhibitor, with imipridones, in prostate cancer treatment *in vitro* and *in vivo*.

Y. Xia[1], L. Zhang[2], M. Ghandali[1], M. P. Schwermann[1], W. El-Deiry[1];
[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]Brown University, Providence, RI

Prostate cancer is the most common cancer and the second leading cause of cancer death among men in the United States. There is an estimated 10% to 50% of cases progress to metastatic castration resistant prostate cancer (mCRPC) state within 3 years of diagnosis. mCPRC remains lethal despite therapeutic advances. There is approximately 20% of mCRPC patients present somatic DNA damage repair (DDR) gene mutations. Ceralasertib, formerly known as AZD6738, is a potent and selective orally bioavailable inhibitor of the ataxia tenlangiectasia and Rad3-related (ATR) kinase, which is involved in DNA repair in response to DNA damage and replication stress. Preclinical studies have demonstrated ATRi sensitizing alterations in DNA damage response (DDR) genes. Ceralasertib's antitumor activity as a monotherapy in treating prostate cancer is moderate. Thus, we combined ceralasertib with imipridones (ONC201 and ONC206), which target mitochondrial caseinolytic protease P (ClpP) and the integrated stress response, resulting in enhanced antitumor efficacy in vitro. Prior data have demonstrated sensitivity of 4 prostate cancer lines to ceralasertib and imipridones monotherapies, synergistic activities with the combination treatments, and immune enhancement effects with the combination treatments when co-cultured with NK92MI cell line. We proceeded to a short term in-vivo study validating the combination treatment efficacy. Preliminary results include cytokine profiling using the Luminex 200 technology to understand treatment induced changes in the tumor microenvironment (TME) from both in vitro and in vivo studies. Our results guide novel clinical trials for effective clinical responses in mCPRC patients.

#5560 Role of SPARC and collagen in immunogenicity of cancer: A theoretical approach.

R. P. Are, A. Babu;
National Inst. of Technology Rourkela, Rourkela, India

Secreted protein acidic and rich in cysteine (SPARC), is a multifunction protein that interacts with extracellular matrix (ECM), cell surface receptors, and signaling molecules. These interactions in cancer cells result in less susceptible of cells to the immune system, leading to poor prognosis. SPARC plays a crucial role in transporting collagen, a significant component of the ECM, from the site of synthesis to the basement membrane of the cells. Collagen mediated rigidity enhancement of cell microenvironment promotes cancer cell growth, proliferation, and angiogenesis. Collagen remodeling plays a complex and multifaceted role in cancer immunomodulation. Our current research focuses on exploring the cancer treatment mechanism by immunomodulation based on SPARC and collagen through theoretical and computational approaches. Our previous investigations identified SPARC and collagen as potential biomarkers for targeting cancer cells. Our current theoretical research identifies the role of SPARC and collagen in tuning the tumor microenvironment and altering the immune system cell surface receptors. This theoretical investigation is followed by computational study to formulate the pathway from secretions of both SPARC and collagen to reprogramming of tumor microenvironment. SPARC and collagen's effects on the cell immune system are analyzed by performing molecular interaction and molecular dynamics studies for SPARC and collagen with the cell surface receptors. From our study, we identify the cellular mechanisms involved either actively or passively in the progression and prognosis of the cancer. Our study will provide insight into a novel pathway for targeting the cancer microenvironment, which will be helpful in the formation of low-dosage cancer drugs, resulting in the decreased adverse effects of drugs and increased patient quality of life.

#5561 Whole slide Imaging Mass Cytometry allows the rapid profiling of the immune landscape of histopathologically aggressive prostate tumors.

J. L. Gorman[1], L. Y. Liu[2], J. P. Hartig[3], N. Parsotam[4], A. Khoo[2], V. Ignatchenko[2], S. Asbury[1], S. Afiuni[1], R. Gonzalez[1], M. J. Geuenich[1], C. F. Harrigan[1], Y. Lee[1], J. Chen[5], L. Lim[4], Q. Raza[4], P. M. Angel[3], K. Campbell[1], S. K. Liu[5], M. R. Downes[6], R. R. Drake[3], T. Kislinger[2], D. King[4], H. W. Jackson[1];
[1]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada, [2]Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Medical University of South Carolina, Charleston, SC, [4]Standard BioTools Canada Inc., Markham, ON, Canada, [5]Sunnybrook Research Institute, Toronto, ON, Canada, [6]Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Patients with Gleason pattern 4 or 5 prostate tumors have a high risk of biochemical recurrence and worse survival. Affected by their local environment, dynamic immune cell phenotypes can both hinder or drive cancer progression. To understand the proteomic environments that facilitate specific immune cell responses and interactions in advanced prostate cancer, we have spatially resolved the immune cell content and metabolic features of Gleason pattern 4 and 5 and subpatterns of prostate tumors. To scale quantitative multiplexed histopathology measurements to human disease, we have applied a new high-throughput whole slide modality of high-plex Imaging Mass Cytometry™ to simultaneously quantify immune cells, metabolic states, prostate specific pathways, and biomarkers in 125 whole slide sections from 42 patients over 100 cm^2 of tissue. It is essential to image whole slide sections in order to fully evaluate the complete heterogeneity of these cancer samples. In parallel, multi-region macrodissection shotgun proteomics and both glycan and extracellular matrix MALDI imaging mass spectrometry have quantified the proteome associated with specific immune cell environments. Together, we identify localized proteomic microenvironments associated with specific tumor supportive or inhibitory immune cell content in human tumors that may help differentiate which high-risk patients will have a rapid biochemical recurrence following radical prostatectomy.

#5562 Altered tumor microenvironment in animal model of concomitant GBM and Alzheimer's pathology.

D. Nascari, R. Eghlimi, A. Beniwal, D. Alton, J. Fryer, N. L. Tran;
Mayo Clinic Arizona, Scottsdale, AZ

Glioblastoma (GBM) and Alzheimer's disease (AD) are two devastating central nervous system diagnoses with no known cure. Both diseases are associated with advanced age. The majority of GBM tumors form in the frontal and temporal lobes, two of the brain regions most impacted by amyloid and tau pathology in AD. Females have a higher risk of AD, while males have a higher risk of GBM. Several large case series have established epidemiological evidence that the two diseases are inversely correlated. Nevertheless, it remains unknown whether presence of subclinical amyloid or tau pathology antagonizes the establishment or progression of GBM. The present study sought to characterize GBM growth, progression, and immune response in the setting of concomitant AD pathology using the syngeneic murine GL261 tumor model. To further understand the tumor cell changes that occur in the presence or absence of AD pathology, we engineered GL261 with a dual-tagged vector consisting of RiboTag (to allow for full-length mRNA profiling) and TurboID (to allow for proteomic profiling). GL261 cells were injected intracranially into $APP^{NL\text{-}G\text{-}F/NL\text{-}G\text{-}F}$ - $MAPT^{human/human}$, $APP^{NL\text{-}G\text{-}F/+}$ - $MAPT^{human/+}$, and wildtype C57BL/6J mice. Tumors in both wildtype and AD conditions contained ~50% intratumoral myeloid cells (Iba+, P2RY12-). Differential activation of intratumoral myeloid cells will be assessed with immunohistochemistry. Microgliosis (IBA1, P2RY12) and astrogliosis (GFAP) around the tumor in the setting of Alzheimer's pathology versus normal conditions will be compared. Invasiveness, proliferation, DNA damage (pH2AX), and apoptosis (cleaved PARP, cleaved Caspase 3) will be compared. Tumor cell-specific changes unique to tumors in the AD microenvironment will be assessed transcriptionally with RiboTag profiling as well as proteomically with TurboID purifications. Our preliminary data suggests that the presence of concomitant AD pathology affects GBM growth and progression as well as the immune response to the tumor, and warrants further investigation.

#5563 Novel approaches to measuring tumor-mutational burden provide insights into tumor-immune interaction in primary melanoma.

E. R. Shteinman[1], N. Maher[1], J. W. Conway[1], G. H. Attrill[1], F. Newell[2], N. Waddell[2], N. Hayward[2], J. V. Pearson[2], G. V. Long[1], R. A. Scolyer[1], J. S. Wilmott[1], I. A. Vergara[1];

[1]Melanoma Institute Australia, The University of Sydney, Sydney, NSW, Australia, [2]Cancer Program, QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia

Background: Tumor mutation burden (TMB) has been widely explored in metastatic melanoma as a proxy of neoantigenic load. In contrast, the role of TMB on the biology of primary melanoma disease progression is less understood. In this study, we explored the associations between the immune context of melanoma subtypes and TMB as measured by several standard and novel criteria.

Methods: Whole-genome-sequencing and multiplex immunohistochemistry (mIHC) were used to characterize the genomic and immune landscape of a cohort of 116 primary melanomas, including cutaneous non-acral (n=59), acral (n=39) and mucosal (n=18) subtypes, as well as 5 mucosal metastases. mIHC was used to identify intratumoral CD8+ T-cells, memory T-cells, macrophages, dendritic cells, B-cells and PD-L1 expression. Standard measures of TMB -total mutational burden (tTMB) and non-synonymous (ns) mutational burden (nsTMB)- as well as novel measures that incorporate multiplicity and clonality -ns persistent mutation burden (ns-pTMB), and ns mutation dosage (ns-dosTMB) were calculated, and their association with immune profiles and clinical-pathological factors established.

Results: In cutaneous non-acral melanomas, ns-pTMB and ns-dosTMB were positively associated with CD8+ T cell proportions (p=0.02 for both comparisons). Clonal, but not subclonal ns-pTMB from mutations present in single-copy regions of the genome were positively associated with higher tumor-resident CD103+CD8 T-cell (p=0.01) and B-cell proportions (p=0.02). Higher single-copy ns-pTMB was also associated with tumors presenting early/intermediate regression compared to late regression. In mucosal melanomas, clonal ns-dosTMB had the strongest positive association with the presence of macrophages (CD68, p=0.005). Additionally, macrophages (p=0.01), tissue resident memory T-cells (p=0.02), PDL1+ cells (p=0.03) and B-cells (p=0.048) were found to be positively associated with clonal ns-pTMB from mutations present in multiple copies, which was also positively associated with the presence of lymphatic invasion (p=0.03). Mucosal patients who recurred had lower levels of single-copy ns-pTMB (p=0.03). In acral melanomas, all measures of TMB were positively associated with the presence of dendritic cells (CD11c), with no particular role for clonality observed. In both cutaneous non-acral (p=0.046) and acral melanomas (p=0.03), but not mucosal (p=0.4), clonal ns-dosTMB was found positively associated with tumor mitotic rate.

Conclusion: Novel TMB measures reveal associations between tumor and immune context that are not captured by standard TMB measures alone in primary melanomas. Different TMB measures are linked to distinct immune populations across melanoma subtypes that harbor unique genomic and immune landscapes. Clonal mutations play a dominant role in the associations of TMB with immune cell populations.

#5564 The regulation of PD-L1 in glioblastoma cells involves Pyk2 signaling.

T. Porter, L. Kucheryavykh;
Universidad Central del Caribe, Bayamon, PR

Glioblastoma (GBM), the most aggressive brain cancer which is usually fatal within a year after diagnosis, poses a significant therapeutic challenge with conventional treatments providing limited success. Despite advancements in immune checkpoint blockade, PD-L1 inhibitors exhibit suboptimal efficacy in recurrent GBMs with recent clinical trials demonstrating only 8% objective responses in patients. Utilizing the R2 Genomic Analysis Visualization Platform, we identified a positive 8-18% correlation between Pyk2 and PD-L1 gene expression in human GBM specimens. We hypothesize that Pyk2 signaling is involved in the regulation of PD-L1 expression in GBM cells. In this study, primary human glioblastoma cell lines and GL261 mouse glioma cells were assessed employing CRISPR/Cas9 Pyk2 knockout (Pyk2KO) combined with pharmacological Pyk2 inhibition. Flow cytometric analysis revealed a 35% decrease in PD-L1 expression in Pyk2KO GL261 cells compared to wild-type cells. SiRNA knockdown against Pyk2 in primary human GBM cells demonstrated a similar response, with a 50% decrease in PD-L1 expression compared to MOCK control cells. Additionally, the application of the Pyk2/FAK inhibitor defactinib at a concentration of 0.2 μM reduced PD-L1 expression by 32% in both GL261 and primary human GBM cells. These findings highlight Pyk2 as a potential therapeutic target for modulating the immunosuppressive microenvironment in GBM and enhancing the effectiveness of immune checkpoint blockade therapies.
This study was supported by: NIH Grant 1SC1GM122691 and PRSTRT2022.

#5565 Multiomic characterization of colorectal cancer using MICS technology reveals interaction of antigen presenting cancer associated fibroblasts and T cells.

Emily Neil[1], Rebecca C. Hennessey[1], David Agorku[2], Dongju Park[1], Julia Femel[2], Michael DiBuono[1], Hanna Lafayette[1], Erica Lloyd[1], Hsinyi Lo[1], Alex Makrigiorgos[1], Shaina Lu[1], John Lee[1], Sameh Soliman[1], Dominic Mangiardi[1], Paurush Praveen[2], Philip Strobel[3], Silvia Ruberg[2], Fabian Staubach[2], Ryan Hindman[1], Thomas Rothmann[2], Olaf Hardt[2], Hansueli Meyer[1], Tanya Wantenaar[2], Jinling Wang[1], Werner Muller[2], Robert Pinard[1], Andreas Bosio[2]

[1]Miltenyi Biotec, Waltham, MA,[2]Miltenyi Biotec, Bergisch Gladbach, Germany,[3]University Medical Center Gottingen, Gottingen, Germany

In solid tumors, the tumor microenvironment (TME) is composed of diverse cell types including cancer cells, immune cells, stromal cells, and other tissue specific cell types. The complex intercellular interactions that occur between these various cell populations determine cancer development and progression. Cancer-associated fibroblasts (CAFs) have been identified as key players in the TME, capable of promoting tumor cell growth and invasion, as well as manipulating immune responses. To better resolve potential subpopulations, spatial relationships, and signaling occurring between cell types within the TME, we performed same-section multiomic profiling of colorectal cancer (CRC) using the MACSima™ Imaging Cyclic Staining (MICS) technology. We combined a custom 40plex RNA panel with a panel of antibodies to characterize the drivers of tumorigenesis and the activation state of immune cells. FFPE CRC specimens were reviewed by a pathologist for clinical assessment and region of interest selection. Then, gene expression profiles were generated using RNAsky™ technology with each gene being detected via cyclic rounds of detection probe hybridization, image acquisition, and signal erasure. Subsequently, fluorescently labeled antibodies were applied to the same section following an equivalent acquisition process. Finally, multiomic clustering and cell population analyses were performed using MACS® iQ View software. The analysis revealed spatially separated subpopulations of CAFs. Functional characterization of cellular neighborhoods and the cell-to-cell interactions occurring within the TME showed that one of the CAF populations potentially promoted cancer cell growth while another subpopulation, resembling antigen-presenting CAFs (apCAFs), closely interacted with T cells in the TME. These findings will deepen our understanding of tumor progression in colorectal cancer and potentially other solid tumors.

#5566 Streamlining tissue sample preparation: A comparative study on the efficiency and reproducibility of the Omni-Stainer™ dewaxing and HIER protocol.

N. Samusik[1], Y. Goltsev[1], **N. Kedei**[2];
[1]Parhelia Biosciences, Austin, TX, [2]National Cancer Institute, Bethesda, MD

The evolution of life sciences research has entailed a shift toward understanding cellular functions within tissue microenvironments, with an emphasis on cell- and tissue-specific relationships. A key challenge in these endeavors is the need for accurate data acquisition, which can be impeded by variability in the multistep manual assay preparations. In the quest for developing reliable and efficient tissue sample preparation workflows, two protocols using multiple dewaxing agents have been compared: the Omni-Stainer™ Dewaxing and HIER antigen retrieval protocol from Parhelia Biosciences, Inc. and the analogous one on Leica BOND Rx. The objective of this research was to assess the efficiency and reproducibility of these methods in the context of a four-color morphology immunostaining used for GeoMx DSP RNA and protein detection assays (Nanostring). We examined the efficiency of automated dewaxing using various non-toxic xylene alternatives, including C12-15 alkyl Benzoate, diethylene glycol, methyl octanoate or methyl decanoate, and compared them to the proprietary Leica Bond Dewaxing solution. Then, we compared the quality of post-HIER immunostaining using two different four-antibody panels on human jejunum samples. After several rounds of optimization, we found that the V4 of the open-source Omni-Stainer™ dewax-HIER protocol resulted in identical quality of morphology immunostaining compared to proprietary Leica Bond protocol. This study validates the Omni-Stainer™ Dewaxing and HIER protocol as a viable and efficient approach for automation of sample prep for GeoMx DSP studies.

#5567 Breast cancer cell alteration of immune cell transcriptome through indirect communication.

J. Kennard, K. Norek, K. Fuh, R. D. Shepherd, K. D. Rinker, **O. A. Kharenko**;
Syantra Inc, Calgary, AB, Canada

Crosstalk between tumor and non-tumor cells plays an important role in cancer progression and metastasis often leading to a modification of non-malignant cells into pro-oncogenic phenotypes. Understanding this process is important for diagnostic and therapeutic advances. We previously reported clinical validation results for a new way to detect early-stage breast cancer using a panel of RNA biomarkers from whole blood and a machine learning software-powered testing system. Recently, we showed that immune cells undergo transcriptomic and functional changes upon direct contact with breast cancer cells. Here, we report results from investigation of indirect communication between breast cancer and immune cells leading to cancer-driven immune cell transformation and activation of multiple oncogenic pathways. To characterize these modifications, we performed RNAseq and pathway analysis on a human monocytic cell line, THP1, exposed to media from triple negative breast cancer (TNBC) cells (MDA-MB-231) in culture. Our results demonstrate that 24 hours of THP1 cell exposure to soluble factors secreted by tumor cells leads to significant gene modulation, with over 1,100 differentially expressed genes (|Fold Change|>2; $p<0.05$). KEGG and Reactome enrichment analysis revealed overlap of multiple pathways between THP1 cells exposed to direct and indirect cancer cell contact conditions, such as cytokine-cytokine receptor interaction, JAK-STAT signaling pathways and others. TNF, NMP1, STING1 and TGM2 were identified as key upstream regulators potentially driving this transformation in both direct and indirect contact conditions. The S100 pathway, which we previously found to be activated by fluid shear stress in MDA-MB-231 cells was also activated in THP1 cells upon both direct and indirect contact. The observed gene expression changes in THP1 cells exposed to media from MDA-MB-231 suggests that indirect intercellular communication alone can transmit an oncogenic signal. These results support a role for secreted factors from breast cancer cells in transforming immune cells and modulating the gene expression markers detected by our blood test, expanding the potential for leveraging this type of tumor education response in advancing cancer detection and treatment.

#5568 Understanding the role of immune exclusion in mammary tumor growth.

P. Mitra, J. Azpurua, H.-C. Chiang, R. Li;
The George Washington University, Washington, DC

Multiple solid tumor types, including triple-negative breast cancer (TNBC), respond poorly to immunotherapy due to low infiltration of CD8+ T cells into the tumor core. The extracellular matrix (ECM) and its components such as collagen have been found to contribute to immune cell exclusion. Discoidin domain receptor 1 (DDR1) is a collagen receptor known to be aberrantly expressed in TNBC among multiple solid tumor types. We have uncovered a previously unappreciated function of DDR1 in immune exclusion through shaping a collagen fiber-based tumor defense against anti-tumor immunity (Sun et al, ***Nature*** 599, 673-678 (2021)). Our study showed that deletion of DDR1 in mouse mammary carcinoma cell lines such as E0771 and M-Wnt (syngeneic with C57BL/6 strain background) promotes infiltration of CD8+ T cells and reduces tumor growth in an immunocompetent mouse model. Extending the published study to other immunocompetent mouse strain backgrounds, we observed that deletion of DDR1 in EMT6 cells, another immune excluded TNBC mouse model in the BALB/c strain, increased the infiltration of CD8+ T cells to the tumor core and reduced tumor growth. Data concerning the DDR1-dependent spatial architecture of the mammary tumor microenvironment will be presented. Identifying specific immune and stromal cell populations and proteins spatially modified in the presence or absence of DDR1 may aid in development of new stand-alone or combination anti-cancer treatments with anti DDR1 antibody.

#5569 Mechano-chemical control of secretory cues regulating immune tolerance, survival and invasion in oral squamous cell carcinomas.

B. R. Bareham, M. Dibble, L. Mouhib, A. Bermejo Arteagabeitia, S. Mukhopadhyay, M. Parsons;
King's College London, London, United Kingdom

Tissue fibrosis and extracellular matrix (ECM) stiffening have been shown to promote tumor cell proliferation, metastasis, and chemoresistance in a range of cancers. Stiffness of the ECM can lead to changes in cancer cell behavior, including enhanced proliferation, activation of mechano-sensitive signaling pathways, and potential genomic damage, with implications for cancer progression and immune responses. Recent research suggests stiff matrix may also induce the release of tumor-derived small extracellular vesicles (sEVs) that promote tumor growth. Tumor-derived sEVs carry bioactive cargo, such as micro-RNAs (miRNAs) and DNA fragments, and function as a unique form of intracellular communication promoting cell survival, growth, and metastasis. Understanding these mechano-sensing mechanisms is essential for identifying potential targets in precision medicine for solid tumor treatment. However, the influence of tumor stiffness on secretory cues, and their subsequent role in immunomodulation and/or chemo-resistance has not been extensively studied.
This project aims to explore how tumor stiffness can alter cell responses to genotoxic stress and how these responses can perpetuate feedback to the immune system through the release of secretory cues such as sEVs. Here, we outline the isolation and characterization of tumor-derived sEVs obtained from culture media of oral squamous cell carcinoma (OSCC) spheroids, cultured at varying stiffness (0.2kPa-1.5kPa). In this project, we use OSCC lines that are either sensitive or resistant to cisplatin (HSC-3 and HN-5, respectively). To explore the immunomodulatory effects of these tumor-derived sEVs, we first established a consistent supply of $CD206^{+ve}$ macrophages differentiated from human induced pluripotent stem cells (iMacs), following the established protocol of Douthwaite et al (2021). iMacs were then treated with sEVs with their resulting immunophenotype, and activation assessed. These preliminary experiments provide a step towards understanding how the biophysical environment influences tumor cell resistance to therapy and how sEVs can modulate the relationship between cancer cells and macrophages.

#5571 Collagen stabilization directs immune suppression in the head and neck squamous cell carcinoma hypoxic subtype.

S. Srivastava, J. Powers, R. Chaudhary, S. Marzban, R. J. C. Slebos, J. West, X. Song, J. A. Guevara-Patino, C. H. Chung, A. L. Amelio;
H. Lee Moffitt Cancer Center, Tampa, FL

Head & neck squamous cell carcinoma (HNSCC) show limited clinical benefit to immune checkpoint inhibitors (ICI). Interactions between extracellular matrix (ECM), tumor, and immune cells underly the mechanisms leading to immunosuppression and resistance to ICIs. Collagen matrix remodeling within tumor stroma can influence accessibility and function of immune cells. Specifically, telopeptidyl lysine residues in fibrillar collagen can be hydroxylated by Lysyl hydroxylase 2 (LH2) prior to cross-linking which leads to stiffened, stable collagen. We previously showed that this LH2-modified tumor microenvironment (TME) drives HNSCC invasion and metastasis. Here, we elucidate the interplay between LH2-modified collagen and the immune landscape within TME of hypoxic and immunosuppressive HNSCC.

Bioinformatics analyses of RNAseq datasets were performed to assess pathways regulating collagen deposition and stabilization. Tissue microarray having 81 primary, 28 recurrent primary, and 3 lymph node metastases tumor cores was analyzed. Cores were classified according to our published Hypoxia-Immune signature (Chaudhary R. et al. 2023, *Can Res Comm*). We performed Second Harmonic Generation imaging of H&E stained TMA section to analyze the orientation and length of collagen fibrils. Picrosirius red (PSR) staining allowed quantification of total collagen and collagen maturation was assessed by polarized light imaging of birefringence. Further, we performed multiplex immunofluorescence staining for CD3+ (T-cell); CD14+ (Monocyte & Macrophage); CD11c+ (Dendritic); Pax5+ (B-cell); Pan-Cytokeratin+ (tumor), and LH2.

Low (0-1) LH2 expression was seen in 29.5% of analyzed cores whereas 70.5% of cores scored high (2-3) for LH2 expression. Cores classified under the hypoxia subtype exhibit high LH2 and enrichment of collagen stability signature. Late-stage tumors have highly oriented collagen fibers compared to normal tissue or early-stage tumors which have randomly distributed fibers. CT-Fire-based measurements revealed that $LH2^{hi}$ cores have significantly increased fiber length and lower coefficient of variance for fiber angles. The area of collagen measured by PSR staining had no correlation with tumor stage or subtype indicating that collagen deposition is similarly high in HNSCCs. However, birefringence measurements showed that a higher fraction of mature fibrillar collagen is associated with late-stage $LH2^{hi}$ tumors. Interestingly, LH2 expression positively correlated with increased CD3+ T cells in stroma suggesting that anti-tumor T cells are physically obstructed by the presence of LH2-stabilized and stiffened collagen fibers.

LH2 expression influences the quality of collagen but not the quantity. Understanding the effect of LH2-mediated collagen modifications on the TIME may have implications for therapeutic strategies to enhance anti-tumor immune response in HNSCC.

#5572 Microneedle-guided lymphatic delivery of a natural immune modulator toxin for enhanced cancer immunotherapy.

S. Lim, B. Kim, P. LIU, J. Shin, J. Jeong;
Sungkyunkwan University School of Pharmacy, Suwon-si, Korea, Republic of

Cancer immunotherapy has demonstrated significant potential as a cancer treatment by enhancing the immune system's ability to recognize and eliminate cancer cells. However, its efficacy can be limited by factors such as tumor heterogeneity, immunosuppressive tumor microenvironments, and systemic toxicities. Recent advances in drug delivery systems have facilitated the development of more targeted and personalized cancer therapies. Microneedles have emerged as a promising platform for non-invasive and highly localized drug delivery, directly administering drugs, vaccines, and other therapeutic agents to the skin. In this study, we designed dissolving microneedles (dMN) based on a biocompatible amphiphilic tri-block copolymer, which enables the self-assembly of nano-micelles containing hydrophobic drugs when applied to the skin. We used the dMN technology to formulate SKKU-06, a hydrophobic natural immune modulator toxin derived from fungi, which exhibits anti-cancer and immunomodulatory properties in melanoma (SKKU-06@dMN). After intratumoral application of SSKU-06@dMN to skin tumors, the drug-loaded nano-micelles can migrate to tumor-draining lymph nodes (TDLN). The dMN-guided delivery of SKKU-06 to skin tumors and TDLN induced immunogenic cell death and stimulated the activation and maturation of antigen-presenting cells (APCs), promoting the development of humoral and cellular anti-tumor immunity. Furthermore, the immunomodulatory effects of SSKU-06@dMN were enhanced when combined with anti-PD-1 treatment, impacting the tumor microenvironment through increased intratumoral $CD8^{+}$ T cell infiltration and reduced T_{reg} populations. This resulted in efficient growth inhibition of established skin cancer and metastatic cancer, as well as prolonged survival. The dMN-guided lymphatic delivery of SKKU-06 demonstrates the potential for treating metastatic solid tumors and improving cancer immunotherapy efficacy by modulating the tumor microenvironment.

#5573 Loss of glutathione S-transferase omega 2 promotes immunosuppressive tumor microenvironment by the induction of PD-L1 expression in lung adenocarcinoma.

R. Sumiya[1], H. Hatano[2], T. Hagiwara[2], S. Nagasaka[2], K. Yamada[2], N. Kokudo[2], H. Suzuki[3], Y. I. Kawamura[2];
[1]Juntendo Univ. School of Medicine, Tokyo, Japan, [2]National Center for Global Health and Medicine, Tokyo, Japan, [3]Sapporo Medical University School of Medicine, Hokkaido, Japan

Glutathione S-transferase omega 2 (GSTO2) is known as one of important regulators for the glutathione redox balance. We recently reported that GSTO2 is exclusively expressed in airway basal cells, Clara cells, and type II alveolar cells, which have self-renewal capacity in the lungs; however, its expression was completely lost in lung squamous cell carcinoma (LSCC) (*Cancer Science*, 2022). In this study, we examined the expression of GSTO2 in lung adenocarcinoma (LAC), another type of lung cancer, and analyzed the relationship between GSTO2 expression and clinicopathological features. We enrolled 139 patients who were diagnosed with LAC and underwent surgery, and immunohistochemically evaluated the expression of GSTO2 using formalin-fixed, paraffin-embedded sections of surgical specimens. Fifty eight of 139 lung adenocarcinoma samples exhibited GSTO2 expression, while remaining 81 cases did not. The expression of GSTO2 in LAC samples was significantly associated with never or light (Brinkman Index < 400) smoking history (P=0.0027) and histological subtypes (lepidic 77%; acinar 44%; papillary 22%; micropapillary 16.7%; solid 9.6%; P<0.0001). There were no significant differences between the groups with respect to pN, pM, EGFR mutation, ALK fusion, and ROS-1 fusion. However, GSTO2 expression in LAC significantly associated with pT1 (P<0.0001), early stage (P<0.0001), and absence of PD-L1 expression (P=0.0027). Moreover, patients with GSTO2-negative LAC had a significantly lower disease-free survival rate than those with GSTO2-positve LAC (P=0.028). To examine whether GSTO2 expression affects PD-L1 expression, we prepared GSTO2-transfected and mock-transfected lung adenocarcinoma cell lines (A549 and PC-9). In both cell lines, mRNA level of PD-L1 was significantly reduced in GSTO2-transfectants. Because Jang RH et al reported that vimentin, reflecting to acquire mesenchymal traits in epithelial-mesenchymal transition (EMT), regulates the PD-L1 expression, we next examined whether GSTO2 overexpression affects the expression of EMT related molecules. There was no difference in a mRNA level of E-cadherin, while the mRNA expression of vimentin and SLUG, a transcriptional inducer of EMT, were significantly suppressed in GSTO2-transfected PC-9. In both cell lines, protein expression of vimentin was also significantly reduced in GSTO2-transfectants. The present study shed light on a novel function of GSTO2 as a PD-L1 regulator, which may contribute to prevention of tumor immune escape.

#5574 Degradation of PIP4K2C by novel bivalent functional degrader LRK-A induces tumor regression in CRC.

E. Corse, K. Goodman, M. O'Shea, G. Ye, M. Chow, J. Arnold, V. Giacalone, S. Hayes, E. Dube, S. Alnemy, O. Akinrinmade Adigun, K. Brown, **E. d'Hennezel**, C. Sabatos-Peyton;
Larkspur Biosciences, Inc., Watertown, MA

Phosphatidylinositol 5-phosphate 4-kinase, type II, gamma (PIP4K2C) is a lipid kinase with critical roles in vesicular trafficking, autophagy-dependent catabolism, and modulation of the immune system. Family members PIP4K2A and PIP4K2B are implicated in regulation of autophagy, cancer cell proliferation, and response to insulin, whereas PIP4K2C has a unique function in the immune response to cancer. Beyond the ability to convert PI5P to PI45P2, PIP4K2 kinases regulate membrane localization and clustering of PI45P2 and thus govern multiple aspects of membrane trafficking. These activities are likely to be independent of catalytic function[1]. The involvement of PIP4K2C in membrane lipid dynamics has the potential to broadly impact pro-tumor and immune-suppressive biology in cancer, including uptake of cancer cells by immune cells, and subsequently increase antigen processing, presentation, and T cell activation. Mice deficient in PIP4K2C develop immune cell infiltrates in tissues and increased proinflammatory cytokines in plasma[2], suggesting that modulation of PIP4K2C could enhance anti-tumor immunity in cancer patients.

Achieving potent targeting of PIP4K2C while sparing other family members or other lipid kinases has so far precluded the exploration of its potential as a therapeutic target. Here, we report the discovery of the highly potent and specific PIP4K2C bifunctional degrader LRK-A, which shows rapid and exclusive degradation of PIP4K2C. We show that LRK-A can rapidly and deeply degrade PIP4K2C in primary human PBMCs and cancer cells in vitro, and with broad species cross-reactivity. The specificity of LRK-A for PIP4K2C was established using whole-cell proteomic analyses, without co-degradation of off-target proteins including SALL4 and GSPT1. In mice treated with LRK-A, we observed a dose-dependent, profound, and sustained degradation of PIP4K2C. We further demonstrate that dosing of LRK-A as a single agent significantly reduced tumor growth, including full regressions, at low doses in a mouse syngeneic model of colorectal cancer.

Collectively, our results show that PIP4K2C can be specifically and effectively targeted in vivo using a bifunctional degrader. The reduced tumor growth we observed upon targeting PIP4K2C alone suggests that PIP4K2C is a highly promising target for therapeutic intervention. Further explorations are ongoing to enable the development of PIP4K2C-targeted therapeutic strategies.

#5577 TRPM8 mediated Ca2+ signaling as a therapeutic target in prostate cancer.

S. Asuthkar[1], K. Velpula[1], V. D. Griend[2];
[1]University of Illinois College of Medicine (Peoria), Peoria, IL, [2]University of Illinois College of Medicine (Peoria), Chicago, IL

Prostate cancer (PC) is a prevalent and deadly malignancy, necessitating the development of innovative therapeutic strategies. Transient receptor potential melastatin 8 (TRPM8), an ion channel highly expressed in prostate epithelium, has emerged as a potential target. Our preliminary studies demonstrate that TRPM8 plays a crucial role in PC progression. We observed an initial increase in TRPM8 mRNA expression during early-stage PC, followed by a decline in advanced and androgen-independent prostate cancer (AIPC) stages. Additionally, TRPM8 knockout mice exhibited elevated serum testosterone levels, heightened androgen receptor (AR) activity, and increased cell cycle, invasion, and adhesion-related effects. In xenograft models, TRPM8 demonstrated potent antitumor properties in both AR+ and AR- contexts. Our research suggests that TRPM8 activation on the plasma membrane promotes calcium influx and induces apoptosis in PC cells. Conversely, TRPM8 internalization correlates with PC pathogenesis. By exploring the effects of TRPM8 on PTEN-mediated cellular signaling, we aim to uncover novel insights into the molecular mechanisms underlying TRPM8's role in PC. This abstract underscores the potential of targeting TRPM8-mediated Ca2+ signaling as a promising therapeutic approach to combat PC progression, offering hope for improved patient outcomes.

#5578 Multi-omics approach reveals a SMAD4-deficiency signature, translational reprogramming and synthetic lethality in esophageal adenocarcinoma.

J. V. Milne, K. Fujihara, E. Kusnadi, M. Pechlivanis, N. Thio, C. Cabalag, T. Gulati, J. Gotovac, K. Simpson, C. Duong, L. Furic, W. Phillips, N. Clemons; Peter MacCallum Cancer Centre, Melbourne, Australia

Esophageal adenocarcinoma (EAC) is a cancer of high mutation burden with negligible recurrent and druggable driver genes and, therefore, a paucity of options for targeted therapy. Mutation or loss of the tumor suppressor gene *SMAD4* occurs in up to 20% of EAC cases, and we have previously shown that loss of SMAD4 is sufficient to promote EAC tumorigenesis in an *in vivo* xenograft model. The present study aimed to delineate the role of SMAD4 in EAC tumorigenesis and identify synthetic lethal interactions in SMAD4-deficient cancers as a novel approach for treating EAC.

Our multi-omics methodology integrated RNA-sequencing, proteomics, polysome-sequencing, reverse-phase protein arrays, and genome-wide CRISPR-Cas9 screening to unveil a SMAD4-deficiency signature and new therapeutic avenues for EAC. These data reveal a complex interplay between SMAD4 loss and regulation of mTOR signaling, with specific downstream effects to reprogram translation. SMAD4-deficient cells express decreased levels of 4E-BP1, the inhibitory binding partner of EIF4E, which is the rate-limiting component of the cap-dependent translation initiation complex. This was accompanied by increased mTOR activity, including phosphorylation and inactivation of 4E-BP1. We found that SMAD4-deficient cells exhibit vastly different polysome traces compared to their wildtype counterparts and preferentially upregulate cap-dependent translation, acquiring an addiction to translation of oncogenic mRNAs. Furthermore, perturbation of additional negative regulators of mTOR signaling in combination with *SMAD4* knockout exacerbated these effects and accelerated tumorigenesis *in vivo* and growth of patient-derived organoids *in vitro.*

This work advances our knowledge of EAC tumorigenesis, provides new mechanistic insights into SMAD4-driven transformation as well as novel potential therapeutic avenues for SMAD4-deficient EAC.

#5579 *MGA*loss-of-function regulates mitochondrial oxidative metabolism-induced cancer stem cell phenotype during lymphomagenesis with therapeutic potential.

J. Xiong, W.-F. Wang, W.-L. Zhao;
Shanghai Institute of Hematology, Shanghai, China

As an antagonist of *MYC* oncogene, *Max* gene associated (*MGA*) gene are implicated in multiple cancers, proposing the potential role of tumor suppressor. Using multi-omics data of The Cancer Genome Atlas (TCGA, n=10,295) and lymphoma datasets from our group (n=702), we defined genetic features associated with *MGA* and its related MYC/MAX/MXD network members across 36 cancers. Pan-cancer, *MGA* mutation, predominant as nonsense or frameshift, was observed in 4.39% of all samples. *MGA* expression was significantly downregulated in mutated samples than that of wild type samples. Moreover, *MGA* mutation was positively associated with inferior clinical outcomes in diffuse large B-cell lymphoma (P=0.001 and P<0.001 in 2 independent datasets), peripheral T-cell lymphoma (P=0.044) and natural killer/T-cell lymphoma (P=0.012), encouraging in-depth study on the important role of *MGA* in lymphomagenesis. Conditional knockout of *MGA* in hematopoietic system using Vav-iCre (*Mga*$^{fl/fl}$*, Vav-iCre* mice) led to reduction in the numbers of peripheral blood lymphocyte due to blockade differentiation and enhanced stemness as evidenced by flowcytometry and RNA-sequencing (RNA-seq). To investigate the molecular mechanism, we performed pulldown assay in NK-92 cells molecular silencing of *MGA* or scramble control, and subsequently subjected for mass spectrum analysis. A total of 97 proteins were identified to interaction with MGA and mainly enriched to nucleosome (26), cytosolic ribosome (16), immune response (13), and glycolysis (6). Molecular silencing of *MGA*, localizing in the nucleolus, interfered with ribosomal RNA processing, enhanced “onco-ribosome” biogenesis, and contributed to aberrant translational program characterized by mitochondrial oxidative metabolism. Changes in mitochondrial respiration and membrane potential are key to maintaining stemness in cancer cells. Considering that stemness is important for tumorigenesis, recurrence, metastasis, and drug resistance, we exploited high-throughput drug screening platform and found that targeted inhibition of Exportin 1 (XPO1) significantly suppressed the viability of tumor cells molecular silencing *MGA*, which were resistant to chemotherapeutic agents such as gemcitabine, etoposide, etc. Mechanically, molecular silencing *MGA* induced abnormalities of nucleocytoplasmic localization in 739 proteins involving in mitochondrial respiratory chain complex I assembly, oxidative phosphorylation, and mitochondrial translation, 50% (332/739) of which were rescued by treatment with XPO1 inhibitor Selinexor. In summary, MGA initiated lymphoma cell stemness via onco-ribosome mediated activation of mitochondrial oxidative metabolism. Selinexor targeted the aberrant nucleocytoplasmic localization and served as a promising therapeutic agent.

#5581 The DACH1 gene, frequently co-deleted with BRCA2 in prostate cancer, governs PARP inhibitor resistance.

Z. Li[1], X. Jiao[1], T. Khan[1], D. Li[1], S. Zha[2], L. Phoon[3], L. Lan[3], A. Robertson[4], A. W. Ashton[5], K. A. Iczkowski[6], A. D. Borowsky[6], A. Ashworth[7], **R. G. Pestell**[1]; [1]Baruch S. Blumberg Institute, Doylestown, PA, [2]Columbia University, New York, NY, [3]Duke University, Durham, NC, [4]Dxige Research Inc., Courtenay, BC, Canada, [5]Lankenau Institute for Medical Research, Wynnewood, PA, [6]UC Davis Health, Sacramento, CA, [7]University of California San Francisco, San Francisco, CA

Background: Prostate cancer (PCa), the second leading cause of death in American men, includes distinct genetic subtypes with distinct therapeutic vulnerabilities (1,2). The *DACH1* gene, in the 13q21.31-q21.33 region, encodes a winged helix/Forkhead DNA-binding protein that governs cell-fate determination that is deleted in ~ 18% of human PCa, where it is associated with poor prognosis (3). Prostate-specific deletion of the *Dach1* gene enhanced prostatic intraepithelial neoplasia (PIN).

Methods: Analysis of *DACH1* gene deletion and expression was conducted from public data bases and human prostate cancer samples. Cells derived from *Dach1* gene deletion mice and human prostate cancer cell lines with DACH1 overexpression were analyzed for PARP inhibitor responses and mechanisms of PARPi resistance. Transgenic prostate Oncomice were generated in which the *Dach1* gene was deleted in the prostate.

Results: Herein, *DACH1* was shown to be co-deleted with *BRCA2* in each of 8 separate cohorts (N=2,186 patients), in ~3-12% of patients. *Dach1* gene deletion or knockdown conferred PARP inhibitor resistance (talazoparib > niraparib > olaparib > rucaparib > veliparib). DACH1 enhanced PARP sensitivity through several mechanisms affecting replication stress, PARP1 binding, inhibiting G9a (reducing H3K9me2), inhibiting $CHK1^{p}$ and $CDK1^{p}$ and inducing expression of snoRNA, specifically the snoRNA known to bind PARP. PARP1 has a BRCT (BRCA1 C-terminus 1) homology domain governing PARP1 dimerization and binding to intact DNA in a complex within a nucleosome. DACH1 binding to PARP1 requires the BRCT domain.

Conclusions: There is a correlation between *DACH1a*$^{-/-}$ and PARPi resistance, correlating with PARPi trapping ability. As reduced *Dach1a* expression may define a subclass of PCa that warrants specific therapies, testing for DACH1a may be warranted.

#5582 Discovery and preclinical characterization of ISM8001, a covalent and selective FGFR2/FGFR3 dual inhibitor with strong monotherapy anti-tumor activity against advanced solid tumors.

Y. Zhang[1], Y. Wang[1], X. Cai[1], J. Liu[1], H. Cui[1], J. Qiao[1], X. Lin[1], X. Ding[1], S. Bavadekar[1], **S. Rao**[2], M. Zhang[1], F. Ren[1], A. Zhavoronkov[1];
[1]Insilico Medicine, Pu Dong Xin Qu, China, [2]Insilico Medicine, New York, NY

Oncogenic alterations in fibroblast growth factor receptors 2 and 3 (FGFR2 and FGFR3) are key drivers in intrahepatic cholangiocarcinoma, urothelial carcinoma and multiple other solid tumors. Currently approved pan-FGFR inhibitor therapy is limited by off-isoform toxicity (FGFR1-mediated hyperphosphatemia and FGFR4-mediated diarrhea) and acquired FGFR2 or FGFR3 kinase domain resistance mutations. The second generation of FGFR inhibitors currently undergoing clinical evaluation such as RLY-4008 and LOXO-435 are primarily focused on achieving selectivity against either the FGFR2 or FGFR3 isoform, which may narrow their clinical potential. To overcome this limitation and to allow a favorable toxicity profile, we designed and evaluated the anti-cancer effects of a novel and selective FGFR2/FGFR3 dual inhibitor, ISM8001. Biochemically, ISM8001 showed superior inhibition against FGFR2 and FGFR3 with >90-fold and >800-fold selectivity of FGFR2 over FGFR1 and FGFR4, respectively. As an irreversible inhibitor, ISM8001 displayed strong affinity and high efficiency of covalent bond formation with FGFR2/3. Additionally, ISM8001 showed broad inhibition against multiple FGFR2/3 mutant isoforms, especially gatekeeper mutation (FGFR2-V564F and FGFR3-V555M). ISM8001 inhibited cell proliferation of multiple human cancer cell lines with FGFR2/3 aberration with IC_{50} <10 nM while IC_{50} >1 μM was observed in cell lines without FGFR2/3 alterations. Furthermore, ISM8001 demonstrated robust *in vivo* anti-tumor efficacy in multiple cell line-derived xenograft mouse models including the SNU-16 gastric cancer model (FGFR2-amplification), the AN3CA endometrial cancer model (FGFR2 N549K mutation) and the RT4 bladder cancer model (FGFR3-fusion), with tumor growth inhibition varying from 80%~120% while no significant serum phosphate increase or body weight loss. ISM8001 also displayed strong anti-tumor effects in xenograft models of Ba/F3-FGFR2/3 engineered cell lines with different gatekeeper mutations. ISM8001 is classified as a BCS II compound with favorable DMPK properties and druggability, high permeability, low efflux ratio and low DDI risk. *In vivo* PK profiles showed moderate to low clearance and high oral bioavailability across preclinical species. In addition, ISM8001 showed a promising *in vitro* safety profile with favorable selectivity in 468-kinase and Cerep-44 panel studies, and no hERG concerns. Results of 28-day non-clinical toxicology studies in rat and dog showed a safety window of approximately 2-5 fold based on efficacious exposure in different models. Taken together, these data support the clinical development of ISM8001 as a novel, selective FGFR2/FGFR3 dual inhibitor for the potential tissue-agnostic therapy of advanced solid tumors with FGFR2/3 aberrations.

#5583 *Helicobacter pylori* induces the wee1, promoting immune suppressive in human gastric adenocarcinoma.

Md Obaidul Islam, Krishnapriya Thangaretnam, Heng Lu, Dunfa Peng, Nadeem Sidiq Bhat, Mohammed Soutto, Wael El-Rifai, Zheng Chen

University of Miami Miller School of Medicine, Miami, FL

Background: Gastric cancer (GC) is the fourth most common cause of cancer-related death worldwide. GC has a dismal 5-year survival rate of about 32%. *Helicobacter pylori* (*H. pylori*) infection is the strongest risk factor for gastric carcinogenesis. 75-90% of gastric cancer patients exhibit positive *H. pylori* serology. WEE1 is a nuclear kinase that regulates cell cycle progression by inhibiting cyclin-dependent kinases.

Methods & Results: Analysis of non-cancer normal stomach tissue (n=360) and human GC samples (n=1221) identified that WEE1 mRNA was significantly overexpressed in GC. Using immunohistochemistry (IHC) staining in 41 normal and 44 GC human samples, the data indicated that WEE1 protein was significantly overexpressed in GC. Western blot and immunofluorescence (IF) staining confirmed that *H. pylori* infection induces WEE1 overexpression in GC cells with an unexpected cytosolic localization of WEE1 in GC cells. *Tff1* knockout GC mouse model (*Tff1*$^{-/-}$) was infected with mouse-adapted *H. pylori* strain PMSS1. Western blot and immunohistochemistry data demonstrated that *H. pylori* infection induced WEE1 expression in *Tff1* $^{-/-}$ HGD/cancer mouse gastric tissues compared to control *Tff1* $^{-/-}$ mouse stomach. To study how *H. pylori* infection induces WEE1 in GC, analysis from miRTAR, Target Scan, and miRDB demonstrated that WEE1 is predicted to be targeted by miR-497-5p. Using qRT-PCR analysis, we assessed 30 normal and 30 GC human tissue samples, revealing a pronounced downregulation of miR-497-5p in GC specimens. Western blot analysis confirmed that the restoration of miR-497-5p in GC cells markedly reduced WEE1 protein expression. Interestingly, *H. pylori* infection further decreased miR-497-5p levels in GC cells, upregulating WEE1 protein expression. Since the miR-497-5P host gene promoter region contains CpG islands, we confirmed that treatment with 5 Azacytidine (demethylating agent) or DNMT1 knockdown induced expression of miR-497-5p with decreased WEE1 level in GC cells. Furthermore, our preliminary results indicate that aberrant WEE1 overexpression in GC demonstrates a significant positive correlation with immune-suppression gene signatures, underscoring its predictive value for unfavorable patient survival outcomes in GC. Using the *TFF1* knockout mouse GC model, we found that WEE1 inhibition notably decreases the number and activation of CD4+ and CD8+ T cells in neoplastic gastric tissues. These findings also indicate a crucial relationship between WEE1 and the immunosuppressive microenvironment in GC, establishing WEE1 as a promising therapeutic target to enhance therapeutic efficacy and overcome immunotherapy resistance in GC.

Conclusions: Our findings demonstrated a novel mechanism in which *H. pylori* activates the WEE1 in GC, promoting an immune suppressive microenvironment. WEE1 inhibition with immunotherapy could be a promising therapeutic method for GC patients.

#5584 Experimental 'loss-of function' annotation of STK11 mutations with prognostic and therapeutic implications (TNG260mutationfinder.com).

Leanne G. Ahronian, Preksha Shahagadkar, Lauren Flynn, Lauren Grove, Shangtao Liu, Samuel R. Meier, Binzheng Shen, Hannah Stowe, Hsin-Jung Wu, Yi Yu, Andre Mignault, Iga Sienczylo, Heather DiBenedetto, **Silvia Fenoglio**, Teng Teng

Tango Therapeutics, Boston, MA

Loss of function mutations in Serine Threonine Kinase 11 (STK11) occur in 15% of lung adenocarcinoma and have been shown to drive resistance to immune checkpoint blockade clinically, as well as in preclinical models. Though STK11 is commonly inactivated in human cancer with strong implications for treatment outcomes, few STK11 mutations identified from tumor samples have been functionally characterized.

TNG260 is an inhibitor of CoREST that is currently being investigated in combination with pembrolizumab for the treatment of STK11-mutant cancer (NCT05887492). Patients are eligible for enrollment in the TNG260 phase 1/2 trial if their tumor contains a deleterious STK11 mutation. To begin classifying non-annotated variants, over 2,000 distinct mutations in the STK11 gene were identified from STK11 literature or public repositories of tumor sequencing data such as AACR Project GENIE and ClinVar. Where possible, loss-of-function annotations were captured from literature or predictive tools such as PolyPhen-2. However, many STK11 variants, particularly missense mutations, have never been functionally characterized.

We developed a functional screening approach to characterize STK11 alterations using the lung adenocarcinoma cell line A549. A549 cells contain homozygous loss of STK11 via a truncation mutation at Q37, and re-expression of wild-type STK11 in these cells strongly impairs their growth in vitro and in vivo. We created a library of STK11 variant cDNAs, each containing a unique barcode. This library was expressed in A549, and cells were maintained in vitro or in vivo to allow for positive selection of STK11 loss-of-function variants and depletion of variants that behave like wild-type STK11. At the end of the screen, variants were quantified by NGS using each mutant cDNA's unique barcode and compared to well-annotated controls.

These data were assembled to generate TNG260mutationfinder.com -- the first website to curate STK11 variants with functional annotations.

#5585 Genetic variants of IDH and EGFR as diagnostic and prognostic biomarkers in glioblastoma multiforme: A case-control study in the Jordanian Arab population.

A. N. Al-Bzour, S. M. Al-Khatib, **M. N. Almajali**, T. A. Jarrad;
Jordan University of Science & Technology, Irbid, Jordan

Background: Glioblastoma multiforme (GBM) represents a highly aggressive primary brain tumor with poor prognosis. Mutation in the Isocitrate dehydrogenase (IDH1) gene and epidermal growth factor (EGFR) amplification are key diagnostic markers for GBM. However, the prognostic role of genetic variants of these genes remains unclear. Therefore, we aimed to investigate the association between specific single nucleotide polymorphisms (SNPs) for IDH and EGFR genes, and their impact on the risk and prognosis of GBM patients within the Jordanian Arab population.
Methods: We carried out a case-control study involving 63 GBM patients and 226 healthy controls at King Abdullah University Hospital in Jordan. Genomic DNA was extracted from formalin-fixed and paraffin-embedded tissue for GBM patients and blood samples for controls. IDH1 (rs121913500C>T), IDH2 (rs11540478G>A), EGFR (rs231677G>A), and EGFR (rs1468727C>T) SNPs were genotyped and analyzed using the Sequenom iPLEX assay sequencing technique. Overall survival (OS) was analyzed between SNPs using the univariable Cox proportional hazard model. The Cancer Genome Atlas (TCGA-GBM) cohort of 585 patients were analyzed for IDH1, IDH2, and EGFR alterations with OS, disease-free survival (DFS), and progression-free survival (PFS). Single-cell RNA analysis was performed on the following scRNA datasets from the Gene Expression Omnibus (GEO): GSE163108 (n=25,013 cells), and GSE102130 (n=3,321 cells) .
Results: Our study revealed a significant difference in genotype frequency between GBM cases and controls for IDH1 rs121913500C>T, and EGFR rs1468727C>T SNPs. Univariable Cox model showed that the G/G genotype of rs231677G>A (EGFR) SNP was associated with better OS in the codominant model (HR: 0.24, 95% CI: 0.08-0.73, p-value=0.012), and rs11540478G>A (IDH2) SNP (HR: 0.02, 95% CI: 0.0-0.29, p-value=0.005) showing significantly better prognosis compared to the A/G genotype. In the TCGA validation cohort, the altered group of IDH1 were significantly associated with better OS (HR: 0.35, 95% CI: 0.24-0.50, p-value<0.001), DFS (HR: 0.34, 95% CI: 0.23-0.50, p-value<0.001) , and PFS (HR: 0.43, 95% CI: 0.30-0.62, p-value<0.001). The scRNA analysis showed predominant expression of IDH1, IDH2, and EGFR by malignant cells, oligodendrocyte precursor cells, and macrophages.
Conclusion: Our investigation into the genetic landscape of GBM within the Jordanian population suggest that specific genetic variants, particularly in IDH1 genes and EGFR, may serve as diagnostic and prognostic biomarkers for GBM. Additionally, IDH1 alterations were associated with better prognostic outcomes. Single-cell RNA analysis further illuminates the predominant expression of IDH1, IDH2, and EGFR by malignant cells which can be used as potential avenues for targeted therapies based on genetic profiles.

#5586 Hijacking mutant E3 ligase for targeted protein degradation: Discovery of cancer-specific PROTACs for the treatment of FBXW7 R465C driven cancers.

H. Zhang;
Blueray Biopharma, Shanghai, Shanghai, China

Many cancers carry LOF mutations of tumor suppressor genes and drug discovery against these cancers are challenging. Fbxw7 is a major tumor suppressor E3 ligase and is frequently mutated (LOF) in cancer. Fbxw7 R465C mutation correlates with worse survival and resistance to both chemo- and targeted therapies. Blueray have discovered Fbxw7 R465C-selective ligands and developed PROTAC molecules selectively targeting cancers carrying Fbxw7 R465C mutation. The Fbxw7 R465C-based PROTACs show superior degradation activity for several target proteins and inhibit proliferation of cancer cells carrying Fbxw7 R465C mutations. These PROTACs show tumor growth inhibition in Fbxw7 R465C mutant cell derived xenograft models with clear PK/PD correlations. Development of bi-functional molecules such as PROTACs bring new options to target cancers with LOF mutations.

#5587 Regulator of chromosome condensation 1 (RCC1) as a novel therapeutic target in pancreatic ductal adenocarcinoma.

S. F. Bannoura[1], H. Y. Khan[1], A. Aboukameel[1], M. Uddin[1], R. Nimri[2], E. Beal[1], S. Kim[1], M. Al Hallak[1], B. El-Rayes[3], P. A. Philip[2], B. Pasche[1], R. Mohammad[1], A. S. Azmi[1];

[1]Wayne State University School of Medicine, Detroit, MI, [2]Henry Ford Cancer Institute, Henry Ford Health, Detroit, MI, [3]O'Neal Comprehensive Cancer Center, University of Alabama, Birmingham, AL

Background and Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal disease with limited treatment options. There is an urgent need for the identification of novel therapeutic targets for PDAC. The transport of molecular cargo between the nucleus and cytoplasm, facilitated by Ran-GTPase, is a critical process that dividing cells rely on to maintain their growth. Elevated nuclear Ran-GTP levels are produced by the activity of the Ran guanine nucleotide exchange factor (GEF) known as Regulator of Chromosome Condensation 1 (RCC1), which is found in the nucleus bound to chromatin. This creates a Ran-GTP gradient across the nuclear membrane, which maintains proper directional transport of proteins and RNA. To sustain proliferative signaling, cancer cells become reliant on high rates of nucleocytoplasmic transport through dysregulation of transport machinery.

Methods: We examined the role of RCC1 in the biology of PDAC. The impact of RCC1 modulation on PDAC growth was evaluated using RNA interference and CRISPR-Cas9 *in vitro* and *in vivo* using PDAC cell lines and LSL-$Kras^{G12D/+}$; LSL-$Trp53^{R172H/+}$; Pdx1-Cre (KPC) tumor-derived cells. The broader impact of RCC1 silencing on PDAC-sustaining signaling was evaluated through RNA-sequencing and proteomics.

Results: Transcriptomic sequencing of PDAC tissue (n=5,071) as well as analysis of publicly available data from the TCGA, CPTAC and GTEx revealed that RCC1 expression is higher in PDAC tissues compared to normal pancreas. Moreover, PDAC patients with higher RCC1 expression were more likely to have poorer outcomes. RCC1 silencing by RNAi and CRISPR-Cas9 resulted in reduced proliferation in 2D and 3D cultures and attenuated tumor growth *in vivo*. RCC1 KD decreased migration and colony formation, enhanced apoptosis, and altered the cell cycle in human and KPC mouse PDAC cells. Subcutaneous RCC1 KO cell line-derived xenografts show arrested growth. Subcellular Ran distribution was disrupted upon RCC1 KO, suggesting that nuclear Ran concentration is important for PDAC proliferation. Nuclear and cytosolic proteomic analysis revealed altered subcellular proteome in RCC1 KD KPC tumor-derived cells. Altered cytoplasmic protein pathways include several metabolic pathways, PI3K-AKT, and Hedgehog signaling. Nuclear enriched pathways include cell cycle, mitosis, metabolic processes, and RNA processing. RNA-seq of RCC1 KO cells showed widespread transcriptional alterations. Upstream of RCC1, c-MYC activates the RCC1-RAN axis, and RCC1 KO cells show differential sensitivity to c-MYC inhibitors. Finally, RCC1 KD resulted in the sensitization of PDAC cells to Gemcitabine. Molecular characterization of conditional $Rcc1^{fl/fl}$ KO transgenic model to study the role of RCC1 in PDAC *in vivo* is ongoing.

Conclusions: Overall, our results show that RCC1 is involved in the regulation of PDAC growth and is a potential target for therapy.

#5588 Protein Arginine Methyltransferase 2 is involved in the control of inflammatory processes in acute myeloid leukemia.

C. Sauter[1], T. Morin[1], F. Guidez[1], J. Simonet[1], C. Fournier[1], C. Row[2], D. Masnikov[1], B. Pernon[1], A. Largeot[3], A. Aznague[1], Y. Herault[4], G. Sauvageau[5], M. Maynadie[1], M. Callanan[1], J.-N. Bastie[1], R. Aucagne[1], **L. Levadny Delva**[1];

[1]Inserm U1231, Dijon, France, [2]Inserm U1231, Dijon Hospital, Dijon, France, [3]Luxembourg Institute of Health, Dijon, Luxembourg, [4]IGBMC, Illkirch, France, [5]IRIC, Montreal, QC, Canada

A direct link between chronic inflammation and development of Acute Myeloid Leukemia (AML) has been highlighted in the past few years, demonstrating an interconnection between marked inflammatory phenotype and aberrant myeloproliferation in AML patients. Treating AML patients exhibiting a higher inflammatory signature with anti-inflammatory molecules resulted in significant increase of overall survival. Protein Arginine Methyltransferases (PRMTs) are epigenetic factors known to regulate gene expression through methylation of histone tails. It has been previously reported that PRMT1, 4, and 5 inhibition exhibit anti-proliferative effects on AML models. In this study, we investigated the role of another PRMT, called PRMT2, in the development of AML through its regulatory roles in inflammatory pathways. We first determined from an AML cohort (The Leucegene project, IRIC, Montréal, QC, Canada) that patients with a low PRMT2 expression display an enrichment of proinflammatory pathways compared to patients with a high PRMT2 expression. Therefore, we hypothesized that PRMT2 could be a key regulator of inflammatory processes in AML. We thus used a PRMT2 knockout mouse model (Prmt2 KO) and a PRMT2 knockout human AML cell line to validate our hypothesis. Although we demonstrated no difference in the bone marrow progenitors or mature cell populations of Prmt2 KO mice compared to control, we observed that Prmt2 KO Bone-Marrow Derived Macrophages (BMDMs) are more sensitive to LPS stimulation and express higher levels of pro-inflammatory cytokines, supporting our previous findings for a role of PRMT2 in the negative regulation of inflammatory processes. PRMT2 depleted human AML cells displayed an increased pro-inflammatory signature due to overactivation of STAT3, which is caused by an enhanced activation of the NFkB signaling pathway, leading to an overproduction of IL6. Together, these findings demonstrate that PRMT2 is a key regulator of the control of inflammation in AML. Recognition of PRMT2 as a biomarker of inflammation in AML would help to adapt treatment possibly through the synergistic use of anti-inflammatory molecules with other cytotoxic drugs.

#5589 *CBFB::MYH11* expression activates *Trp53* in myeloid cells, which inhibits cell growth and sensitizes cells to cytarabine.

R. B. Day, J. A. Hickman, C. D. S. Katerndahl, S. Mukund Ramakrishnan, C. A. Miller, T. J. Ley;
Washington University In St. Louis, St. Louis, MO

CBFB::MYH11 acute myeloid leukemia (AML) is a subset of Core Binding Factor AML initiated by an oncofusion in which Core Binding Factor Beta (CBFB) is fused to the C-terminus of smooth muscle myosin heavy chain 11 (MYH11). *CBFB::MYH11* AML has a high cure rate with conventional anthracycline/cytarabine induction and high-dose cytarabine consolidation in patients under the age of 60, and remains chemosensitive after multiple relapses; the mechanisms underlying chemosensitivity are unknown. *TP53* is a key regulator of DNA damage response and apoptosis, and *TP53*-mutated AML is often chemoresistant. Large sequencing studies have revealed only rare co-occurrence of *TP53* mutations with *CBFB::MYH11*. We initially used *CBFB::MYH11* as a negative control for an unrelated study of *TP53* function and unexpectedly found striking synergy. While expression of *CBFB::MYH11* in WT murine hematopoietic stem and progenitor cells (HSPCs) induced a low-penetrance (~20%), long latency (~6 months) myelomonocytic AML, expression of *CBFB::MYH11* in *Trp53*$^{-/-}$ HSPCs induced AML with 100% penetrance and a median latency of 8 weeks. *CBFB::MYH11*-induced AMLs arising in *Trp53*$^{-/-}$ cells were similar by morphology and flow cytometry phenotype. We validated these findings in a second model, using a conditional *Trp53*$^{flox/flox}$ *x Vav1-Cre* model in which *Trp53* is inactivated in HSPCs, with nearly identical results. *Trp53*$^{-/-}$ cells transduced with Empty Vector did not develop AML, but did develop T cell lymphoma with a median latency of 16 weeks, similar to prior studies. *Trp53* deficiency also cooperated with *RUNX1::RUNX1T1*, the other Core Binding Factor oncofusion, to induce a high-penetrance (100%) and short latency AML (median latency 10 weeks); consistent with prior data, *RUNX1::RUNX1T1* expression alone in *Trp53* WT cells was insufficient to induce AML.

To determine whether *Trp53* influences the chemosensitivity of *CBFB::MYH11* expressing cells, we performed cytarabine dose-response experiments. While *CBFB::MYH11*-transduced WT HSPCs were very sensitive to cytarabine (relative to EV), sensitivity was reduced in *CBFB::MYH11*-transduced *Trp53*$^{-/-}$ cells, suggesting that *CBFB::MYH11*-induced chemosensitivity is, at least in part, mediated by the TP53 pathway. To determine whether *CBFB::MYH11* expression results in upregulation of key TP53 pathway genes, we transduced WT HSPCs with EV or *CBFB::MYH11*, transplanted cells into WT mice, harvested bone marrow at 3 months, and performed RNA-Seq. Key TP53 pathway genes were upregulated, including *Bbc3/Puma*, *Bax*, *Cdkn1a/p21*, and *Trp53* (all 2.6-4.6-fold, $p \leq 0.05$). These data suggest that the chemosensitivity and the favorable prognosis of *CBFB::MYH11* AML may be due to the direct activation of the TP53 pathway by *CBFB::MYH11*. Similar studies are underway with *RUNX1::RUNX1T1*-transduced cells to determine whether TP53 is relevant for the chemosensitivity of that CBF AML as well.

#5590 Engineered destabilized 3'UTR of TEAD1 therapeutically inhibits and degrades TEAD1 mRNA and YAP1 interactors across multiple cancers.

C. U. Awah;
UTR Therapeutics Inc, New York, NY

The hippo pathway mediated by TEAD1 is overexpressed and oncogenic in multiple cancers. We report here the development of engineered destabilized 3'UTR of TEAD1 which overwrote and degraded oncogenic TEAD1 in ethnically diverse breast cancers, prostate cancers, ovarian cancers, and pancreatic cancer. We validated the destabilization and degradation of TEAD1 on the transcript and protein levels. This led to the loss of cancer cell size causing severe shrinkage as hippo pathway controls cells size , impaired cancer cell migration abilities and loss of cancer cell viability. These properties are titratable and specific demonstrating the specific engagement of the engineered destabilized 3'UTR of TEAD1 with oncogenic TEAD1 mRNA in destabilizing and degrading it. In a dose dependent titration analysis, we determined the IC50 of the engineered destabilized 3'UTR of TEAD1 across many cancers. IC50 dose dependent titration comparison with the engineered destabilized 3'UTR of TEAD1 constructs and chemotherapies (DNA damaging agents, microtubules inhibiting drugs, alkylating agents) as well as immune checkpoint inhibitor. We found evidence that suggests that the engineered destabilized 3'UTR of TEAD1 is superior. Mechanistically, the loss of TEAD1 led to the loss of TEAD2,3 and YAP1 and FOSL1 , JUN and c-MYC.

#5591 ARID domain containing BAF subunits exhibit neomorphism: Have we identified the new Achilles heel in cancer?.

S. Sarkar, **M. D. Bashyam**;
Ctr. for DNA Fingerprinting & Diagnostics (CDFD), Hyderabad, India

The SWI/SNF chromatin remodeler utilizes energy of ATP hydrolysis to slide or evict nucleosomes or histones, respectively, thus enabling nuclear processes by driving an 'open' chromatin architecture. The mammalian SWI/SNF, also termed the BrG1/Brm associated factor (BAF) complex, is the major chromatin remodeler in ontogeny and adult life. Three major BAF complexes namely canonical (cBAF), polybromo (pBAF), and non-canonical (ncBAF) have been studied. BAF components, classified as a tumor suppressors, exhibit frequent mutations in cancers. Though, studies have evaluated functional roles of BAF subunits, very few attempted to study BAF mutations identified across cancer types. In our previous studies, we identified tumor specific mutations in the gene encoding 'A-T rich interaction domain containing 1B' (ARID1B), within its nuclear localization signal (NLS). NLS-inactivated ARID1B exhibited cytoplasmic localization and promoted tumorigenesis by activating the ERK and Wnt/β-catenin pathways. More recently, we detected inactivating mutations in the gene encoding ARID2, a component of the pBAF complex and an ARID1B paralogue. We now present detailed characterization of tumor-specific ARID2 truncations that were presumed to be inactivating in nature. One such truncation mutation viz. p.Ser989fsArg21*, identified in our previous study, is expected to yield an ARID2 protein truncating at amino acid position 1010 (as against the full length of 1835 amino acids). Scrutiny of The Cancer Genome Atlas cBioPortal and Cancer Cell Line Encyclopedia mutation data bases revealed several ARID2 mutations expected to truncate the protein around the 1010 position. Surprisingly, ectopic expression of truncated ARID2 forms promoted oncogenic function in both ARID2 proficient and deficient backgrounds, thus validating a neomorphic gain of function for the truncated protein. Fluorescence based intracellular localization assays revealed a surprising cytoplasmic localization of truncated ARID2. Further, we mapped the ARID2 NLS by *in silico* analysis followed by evaluation of several deletion constructs, to be located at 1488-1518 position; thus, explaining the cytoplasmic localization of ARID2 forms truncating around 1010 position. Further, truncated ARID2 was unable to bind other pBAF components and did not sequester other pBAF components to the cytoplasm, in both ARID2 proficient and deficient cells. Tandem Affinity Purification Mass-spectrometry revealed putative interaction partners for truncated ARID2; analysis is currently underway to reveal the mechanism of tumorigenic induction exhibited by truncated ARID2. Immunohistochemistry on colorectal and breast cancer tissue microarrays revealed ARID2 cytoplasmic localization in a significant fraction of samples. We have discovered a novel YIN-YANG function of BAF components expected to yield efficient therapeutic options in cancer.

#5592 HMGA1 modulates chromatin state and transcriptional networks involved in plasticity in refractory myeloid leukemia.

B. E. West[1], J.-H. Kim[1], A.-A. Supreme[1], I. Herrera[1], Z. Thompson[1], L. Z. Luo[1], F. Shaik[1], J. Kim[1], H. Woo[1], S. Meshinchi[2], R. E. Ries[2], L. M. S. Resar[1]; [1]Johns Hopkins University, Baltimore, MD, [2]Fred Hutchinson Cancer Research Center, Seattle, WA

Although High Mobility Group A1 (HMGA1) chromatin regulators are overexpressed in refractory acute myeloid leukemia (AML) and diverse solid tumors, targetable mechanisms underlying HMGA1 remain elusive. *HMGA1* is highly expressed in stem cells and poorly differentiated cancers where it modulates chromatin structure to activate developmental gene networks. In AML arising from *JAK2*^{V617F} myeloproliferative neoplasms (MPN), HMGA1 is required for leukemogenesis by inducing transcriptional networks that drive aberrant proliferation and cell fate. Like MPN AML, KMT2A-rearranged (KMT2A-r) AML is refractory to therapy and highly lethal. KMT2A-r AML is caused by rearrangements of the *KMT2A* gene, which encode abnormal fusion proteins that induce pro-leukemogenic genes, including *HOX* genes. While prior work identified KMT2A fusion partners and protein complexes, this has not led to better therapies for most patients. We therefore sought to examine HMGA1 function in KMT2A-r AML. We hypothesized that: 1) HMGA1 drives plasticity in KMT2A-r AML by altering chromatin state and transcriptional networks, and, 2) Targeting HMGA1 will enhance sensitivity to therapy. In two KMT2A-r AML patient cohorts, *HMGA1* is highly overexpressed compared to CD34^{+} stem and progenitors from healthy controls, suggesting it drives leukemogenesis. To define HMGA1 function, we silenced *HMGA1* using CRISPR or short hairpin RNA in KMT2A-r cell lines (MOLM-14, THP-1, MV4-11). Strikingly, silencing *HMGA1* disrupts proliferation and clonogenicity *in vitro*, while prolonging survival in immunosuppressed mice transplanted with KMT2A-r AML cells. Intriguingly, leukemic cells that engraft in the bone marrow from the pool of cells with *HMGA1* silencing express higher levels of *HMGA1*, suggesting that escape from gene silencing and a specific level of HMGA1 is required for leukemic engraftment and expansion. *HMGA1* also increases in KMT2A-r AML cells that become resistant to cytarabine (AraC), suggesting that HMGA1 endows AML cells with the capacity to survive and expand after AraC. Because repression of tumor suppressors was recently defined as a mechanism of therapy resistance in AML, we also examined tumor suppressor pathways in both *JAK2*^{V617F} and KMT2A-r AML. Intriguingly, HMGA1 occupies the promoter region of the *CDKN1A* locus by chromatin immunoprecipitation and represses its expression in KMT2A-r and *JAK2*^{V617F} AML cells. To define additional mechanisms underlying HMGA1 in KMT2A-r AML, multi-omics studies are underway. In preliminary work thus far, we also found that HMGA1 induces *HOX* genes. Together, these findings implicate HMGA1 as a promising therapeutic target and novel epigenetic regulator in KMT2A-r AML by altering chromatin state and downstream gene expression.

#5593 METTL3-NUP93 axis as a novel therapeutic target in castration-resistant prostate cancer (CRPC).

J. Lee, Z. Zhang, J. Hong, K. Xu;
UT Health Science Center at San Antonio, San Antonio, TX

Androgens and androgen receptor (AR) are the key factors driving the development and progression of prostate cancer. Extensive studies confirm both androgens and AR are required for normal growth and development of the prostate gland, and also in prostate cancer pathogenesis and androgen-independent cancer progression. Therefore, androgen deprivation therapies or targeting AR function have always been the mainstay of therapeutic strategy against advanced prostate cancers. However, the current therapeutic strategies are temporally effective in suppressing prostate tumors, and eventually develop metastatic disease. Nuclear pore complex (NPC) is a large complex composed of approximately 30 different proteins termed nucleoporins (NUPs), which serve as the structural and functional units for macromolecules shuttling including proteins and messenger RNAs (mRNAs) between nucleus and cytoplasm. Abnormal expression or genetic alterations of NUP genes has been indicated to involve in the progression of prostate cancer, but the underlying molecular mechanisms are poorly understood. We recently found that the m^6A methyltransferase METTL3 directly interacts with nucleoporin 93 (NUP93), one of the NPC components in multiple prostate cancer cells, which seems to be more robust in the castration-resistant prostate cancer (CRPC) cell lines. Disruption of METTL3-NUP93 axis abrogated proliferation and oncogenic phenotypes of CRPC cells, suggesting that the METTL3-NUP93 axis may play an important role in prostate cancer progression to castration resistance. Most importantly, a subgroup of mRNAs regulated through METTL3-NUP93 axis encode cholesterol biosynthesis enzymes that trigger the activation of persistent AR signaling in CRPC. Therefore, Our current findings suggest that inhibition of METTL3-NUP93 axis may represent a promising therapeutic strategy for CRPC, the lethal form of the disease.

#5594 Exploring genetic determinants: A comprehensive analysis of SERPINB family variants and prognosis in Jordanian glioblastoma multiforme patients.

S. Al-Khatib, **M. N. Almajali**, A. Al-Bzour, J. Al-Ramadneh, L. Sa'd, N. Othman;
Jordan University of Science & Technology, Irbid, Jordan

Background: Glioblastoma multiforme (GBM) is a major concern with high fatality rate. In Jordan, the incidence of GBM has notably increased, emphasizing the urgency for population-specific research. Serpins are serine proteinase inhibitors, with several Serpins being overexpressed in cancer cells however the exact mechanism by which they affect GBM progression remains unclear. Thus, we aim to analyze the single-nucleotide polymorphism (SNP) of SERPINB11 and its association with GBM survival.

Methods: A cohort of 63 GBM patients recruited from King Abdullah University Hospital (KAUH) in Jordan, underwent genomic DNA extraction, polymorphism analysis, and overall survival (OS) assessments. The Serpin B family were validated using The Cancer Genome Atlas (TCGA-GBM) cohort of 160 patients. We constructed a risk-score using the principal component analysis for the following Serpin genes: Serpinb3, Serpinb5, Serpinb6, Serpinb11, and Serpinb12, and patients were grouped into high- vs. low-risk based on median cutoff. Univariable Cox models were used to study the survival outcomes, differential expression analysis between the high- and low-risk groups was carried out to identify the differentially expressed genes (DEGs), gene ontology (GO and tumor microenvironment analyses were carried out.

Results: In our primary cohort, we identified a significant association between rs4940595 (*SERPINB11*) SNP and survival, with the G/T- genotype showing worse prognosis compared to the G/G-T/T genotype in the over dominant model (HR: 2.75, 95% CI: 1.29-5.88, p-value=0.009). In the TCGA validation-cohort, alterations in the *SERPINB3*gene showed significantly worse OS (Median: 9.53 vs. 14.3, p-value=0.044) compared to the no alteration group. Univariable Cox showed worse PFS outcomes with higher SERPINB5 (HR: 1.67, 95% CI: 1.15-2.43, p-value=0.007) and SERPINB6 expression (HR: 1.44, 95% CI: 1.06-1.96, p-value=0.021). A Serpin B 5-gene risk score was constructed revealing significant association with IDH mutation status and a trend towards worse PFS in the high-risk group. Upregulated DEGs showed GO enrichment in cytokine regulation and production, positive regulation of leukocyte activation and MAPK cascade. While the downregulated DEGs were enriched in forebrain development, and negative regulation of neuron differentiation. The high-risk group showed a significantly higher infiltration of M2 macrophages and activated mast cells.

Conclusion: Our findings showed a significant role of the Serpin B family with GBM survival in the Jordanian population. Molecular analyses showed potential mechanisms underlying these associations. Our exploration of SERPINB family and associated SNPs provides valuable insights into the molecular landscape of GBM, paving the way for potential targeted interventions and personalized treatment strategies.

#5595 Multifaceted role Cornulin in head and neck squamous cell carcinoma: From tumor suppressor pathophysiology to prognosticating biomarker.

R. Kaur, A. Chauhan, S. Ghoshal, J. Bakshi, R. Srinivasan, **A. Pal**;
Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India

Background: In our previous study, based on LC-MS/MS analysis, the salivary Cornulin, a relatively less explored protein, was found to be ~10-fold downregulated in Head and Neck Squamous Cell Carcinoma (HNSCC) patients. However, the exact role of Cornulin in the pathophysiology of HNSCC is not reported. Here, we investigated its role in the pathophysiology of HNSCC and elucidated its potential as a prognostic marker as well as its antitumour effect.
Methods: Sandwich ELISA and immunohistochemistry were performed to estimate the salivary and tissue levels of Cornulin, respectively, in HNSCC patients, along with an analysis of the effects of Cornulin levels on disease outcome. To investigate the antitumor effects ,its levels were upregulated through lentiviral transduction in low expressing Cal27, FaDu cell lines. Subsequently, various assays were conducted to examine the antitumor effects of Cornulin upregulation. The molecular signalling pathway was elucidated by analysing transcriptome. Additionally, the effects of increased Cornulin expression were also evaluated in an *in vivo* nude mice model.
Results: The pre-treatment salivary Cornulin levels were significantly low ($p=0.0001$) in HNSCC patients (n=128,146.4±5.589pg/mL) and in oral premalignant disease patients (n=25, 174.6 + 9.924 pg/mL) with respect to healthy controls (n=84,185.2±7.170pg/mL). Also, the tumor tissue expression of Cornulin (n=113,H-score=12.70±2.396) was significantly downregulated ($p<0.0001$) compared to the tumor-free margin (n=72,H-score=139.6±10.34). The patients showing complete clinical response regained normal salivary levels within 6 months of completion of treatment ($p<0.0001$). More importantly, low salivary Cornulin level at diagnosis was associated with poor overall survival ($p=0.0282$), indicating it to be a potential prognostic marker. On upregulation of Cornulin in low-expressing HNSCC cell lines (Cal27 and FaDu), the cellular viability, migration, and invasion showed a significant decrease. These indicate its potential as a tumor suppressor. RNAseq data of Cornulin overexpressed cell lines and further Gene set enrichment analysis, the G2/M checkpoint pathway was found to be positively enriched. Cornulin overexpression also arrests the G1/S phase of the cell cycle. GSEA and in vitro experiments revealed Cornulin to be involved in the PI3K/Akt/mTOR signalling pathway. In the nude mice xenograft model, decreased tumor progression, and tumor volume, was documented after Cornulin overexpression. There was an increase in differentiation in the xenograft tumors formed by Cornulin overexpressed cells.
Conclusion: Here, we report for the first time that intrinsic Cornulin has a role as a potent antitumor and has potential as a prognostic marker. However the exact molecular mechanism needs to be further evaluated.

#5596 Exploring BRCA1-Y1853ter and potential therapeutic targets in BRCA1-BRCT mutated cancers.

J. Chen;
The University of Kansas Medical Center, Kansas City, KS

The breast cancer gene BRCA1 plays a pivotal role as a tumor suppressor gene. Despite the use of poly (ADP-ribose) polymerase inhibitors (PARPi) in treating BRCA1 mutation carriers, the lack of response or the development of acquired drug resistance underscores the pressing need for new therapeutic targets. One intriguing BRCA1 mutation, BRCA1-Y1853ter, characterized by a minimal truncation, has been identified in multiple individuals with Hereditary Breast and Ovarian Cancer (HBOC) syndrome. We have developed a Halo Tag and adenovirus-based system where wild-type BRCA1 (WT BRCA1) and mutant BRCA1 protein complexes can be studied in multiple cell types. Here, we used this system to affinity purify BRCA1 wild-type and mutant complexes, followed by label-free quantitative proteomics to investigate the dynamic interactome variations between WT BRCA1 and BRCA1 mutant. Contrary to the assumed loss of function, our preliminary findings suggest a potential gain of function, as a significant number of candidate proteins exhibit enhanced binding affinity with the mutant BRCA1. We are currently exploring whether these distinct binding characteristics are shared among various BRCA1-BRCT mutants, which may hint at a common tumorigenesis mechanism. Our overarching hypothesis is that identifying a specific binding partner, shared among various BRCA-BRCT mutants, could unveil a novel therapeutic target with broader applicability in treating BRCA1-related malignancies.

#5597 Clinical significance of RNA polymerase I inhibitor in pancreatic cancer therapy.

M. Ahmad;
University of Texas Rio Grande Valley, McAllen, TX

Pancreatic cancer (PanCa) is the third leading cause of cancer-related deaths in the United States with limited therapeutic options available. Gemcitabine (GEM), a deoxycytidine nucleoside analog is currently considered the most effective therapy for PanCa. However, it shows only a marginal survival benefit of six months. Aberrant ribosome biogenesis occurs in most tumor types. We observed that PanCa cells are addicted to ribosome biogenesis (RiBi), which supports their highly aggressive metastatic phenotypes. Thus, strategically targeting RiBi process could be one of the ideal strategies for the prevention and treatment of PanCa. In this study, we elucidated the molecular mechanisms of POLR1A (RPA194) overexpression and how its targeting along with p53 status impacts RNA polymerase I inhibitor therapy against PanCa. The expression level of RPA194 was significantly elevated in pancreatic tumor tissues when compared with adjacent normal pancreatic tissues. BMH-21 is a potent pharmacological inhibitor of RNA Pol I, which is known to degrade RPA194 protein. Our results demonstrated that BMH-21 can selectively induce apoptosis in various PanCa cells but not in HPNE cells. We also found that the cytotoxic effect of BMH-21 was dependent on the expression pattern of RPA-194 and p53 status. We further examined the therapeutic efficacy of BMH-21 in orthotopic xenograft mouse models by using two different PanCa cells, AsPC1 which contains non-functional p53 and MIA PaCa-2 which contains functional mutant p53. We observed that BMH-21 significantly inhibited the growth of tumors derived from both cancer cell lines. Interestingly, BMH-21-mediated inhibition of tumor growth was more significant in tumors derived from MIA PaCa-2 cells compared to AsPC1 cells. Further examination revealed that the inhibition of tumor growth was correlated with RPA194 degradation followed by inhibition of cell proliferation. Overall, our results strongly suggest that BMH-21 is a promising non-toxic agent for the treatment of advanced PanCa and its therapeutic potential depends on RPA194 expression and p53 status in PanCa cells.

#5598 Combined loss of the chromosome 7 genes *CUX1* and *EZH2* promotes chemotherapy resistance.

M. R. M. Jotte, A. Stoddart, T. C. Martinez, Y. Xue, M. K. Imgruet, M. E. McNerney;
University of Chicago, Chicago, IL

Monosomy 7 (-7) or del(7q) are recurrent in high-risk myeloid neoplasms, including up to 50% of myeloid neoplasms arising after prior exposure to chemotherapy and/or radiation. Although putative chromosome 7 tumor suppressor genes have been identified, the effects of combinatorial 7q gene loss remain unclear. A barrier to understanding the pathogenesis of -7/del(7q) is the challenge of modeling aneuploidy in animal models. To address this knowledge gap, we established an *in vivo* model of del(7q) clonal hematopoiesis and drug resistance using multiplex CRISPR-Cas9 to simultaneously target four 7q genes (*Cux1, Ezh2, Kmt2c,* and *Kmt2e*) in murine hematopoietic stem cells. After chemotherapy exposure, we observe significant myeloid expansion of clones edited for both *Cux1* and *Ezh2*. Compared to the transcriptomes of control or single gene edited cells, *Cux1;Ezh2*-deficient cells fail to induce DNA damage response pathways after genotoxic stress. *Cux1*;*Ezh2*-deficient cells also display reduced deposition of γH2AX after DNA damage, as well as persistent, unrepaired DNA breaks, indicating perturbations to DNA damage recognition and repair. Collectively, our data support the concept of 7q as a contiguous gene syndrome region, in which combined loss of multiple genes drives drug resistance and disease development. This work reveals a genetic interaction between *CUX1* and *EZH2*, and sheds light on how -7/del(7q) contributes to the development and inherent drug resistance characteristic of high-risk myeloid disease. Further, our CRISPR-based approach may serve as a framework for interrogating other recurrent aneuploid events in cancer.

#5599 Role of HOX gene expression in differentiation of colon cancer stem cells.

B. T. Osmond[1], C. O. B. Facey[2], L. O. Opdenaker[2], C. Zhang[1], B. M. Boman[1];
[1]University of Delaware, Newark, DE, [2]Christiana Care Christiana Hospital, Newark, DE

HOX genes encode a highly conserved set of transcription factors critical for stem cell (SC) function and embryonic development. Several HOX genes have also been implicated in a myriad of cancers, including colorectal cancer (CRC). However, how HOX genes play a role in SC regulation and contributes to cancer development is unclear. HOX expression is regulated by WNT, FGF, and retinoic acid (RA) signaling - pathways which also become dysregulated in cancer. *Goal*: To determine how regulation of HOX genes specifies differentiation of colonic SCs into specialized cell lineages and how dysregulation of HOX genes contributes to CRC development. *Hypotheses*: *i*) Each of the different cell types within human colonic epithelium has a distinct HOX gene expression signature; *ii*) All-trans retinoic acid (ATRA) induced differentiation of CRC cells changes HOX expression that correlates with specific HOX expression signatures in normal colon and CRC cells. *Results*: Immunostaining shows that specific HOX proteins (e.g., HOXA9 & HOXC9) are selectively expressed in ALDH-positive SCs and expression of these HOX genes is increased in CRC tissues compared to normal epithelium. Bioinformatics analysis predicted that these HOX genes (plus HOXA4, HOXA10, HOXC8) are regulated by RA signaling. Accordingly, we studied how ATRA influences HOX expression in CRC cells (HT29 & SW480). We found ATRA treatment: 1) Decreases proliferation and increases neuroendocrine cell (NEC) differentiation; and 2). Leads to specific changes in HOX gene expression patterns. Using NanoString profiling, we also discovered that LGR5+ SCs, ALDH+ SCs and GLP2R+ NECs have unique HOX signatures. By defining how these HOX gene expression changes in response to ATRA treatment in comparison to the HOX gene signatures of different colonic cell lineages will help us understand the role that HOX genes play in SC differentiation and how dysregulation of HOX gene expression contributes to CRC development.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: DNA Damage and Repair 2
Poster Session

#5603 Defining the functions of the BRCA2 BRC repeats in modulating RAD51 binding and activity.
J. R. Jensen, R. B. Jensen;
Yale University, New Haven, CT

The BRCA2 (Breast Cancer Susceptibility 2) gene is critical for preserving genome integrity by regulating homology-directed repair (HDR) of DNA double-strand breaks (DSBs). Germline mutations in BRCA2 predispose individuals to a high risk for ovarian, breast, prostate, and pancreatic cancer. BRCA2 contains eight BRC repeats that mediate binding to RAD51. It remains unclear how exactly the different BRC repeats regulate RAD51 functions. In our study, we explore the importance of each BRC repeat, their interconnections, and their impact on RAD51 binding and filament stability. We engineered amino acid substitutions into the BRC FxTAS motif required for specific contacts within a hydrophobic binding pocket of RAD51 to disrupt BRC binding to RAD51. We further created mutations in RAD51 (F86E/A89E) that either prevent self-association but retain binding to the BRC repeats or a mutation (K133R) that results in a hyper-stable RAD51 nucleoprotein filament. Using both cell-based models and biochemical analyses, we have begun studies to parse out the specific functions of each BRC repeat. Our ultimate goal is to incorporate single amino acid changes into each BRC repeat within the context of the full-length BRCA2 protein to comprehensively characterize the contribution of each BRC repeat to HDR and response to chemotherapeutics such as PARP inhibitors.

#5604 Modulating DNA repair through endo-exonuclease inhibition: a new therapeutic paradigm in oncology.

T. Chow, J. Duan, P. Colin, C. Bier;
Montdorex Inc., Montreal, QC, Canada

DNA damage repair (DDR) mechanisms are crucial for the maintenance of genomic stability and are emerging as potential therapeutic targets for cancer. Endo-exonuclease (EE)[1] plays a key role in this process and increase EE expression has been observed in the cancer cells examined. In this context, we identified a dicationic diarylfuran, pentamidine, which is an antiparasitic drug that has been used clinically to treat opportunistic infections such as *Pneumocystis carinii*. Pentamidine is an inhibitor of the endo-exonuclease as determined by enzyme kinetic assay and is known to be active on cancer cells. In a proof of concept study[2], tumor with increased EE expression (determined by IHC) showed the best response to this drug.

We have now identified novel mono- and di-amidine analogs of pentamidine that are more effective than the parent drug in both *in vitro* and *in vivo* studies. Furthermore, pre-clinical animal studies of our lead candidate, MTDX203, showed an increased anti-cancer activity with a higher safety index than pentamidine. Based on a predictive PK/PD model, a human iv infusion dose administered twice weekly at ~0.4 mpk (i.e. 28 mg/day, ~10% of pentamidine effective iv dose) is expected to be clinically effective. Our work establishes the EE as a therapeutic target for cancer and identifies a new First in Class of novel anti-cancer agents.

[1]Chow et al. (2004) MCT 3:911-918[2] NCT01378143: Pentamidine (OCZ103-OS) in Patients With Unresectable and Locally Recurrent or Metastatic Colorectal Cancer Undergoing Standard Chemotherap

#5605 *Cutibacterium acnes* invades prostate epithelial cells to induce BRCAness as a possible pathogen of prostate cancer.

S. Ashida[1], C. Kawada[1], H. Tanaka[2], A. Kurabayashi[1], K.-i. Yagyu[1], S. Sakamoto[1], K. Maejima[3], S. Miyano[2], M. Daibata[1], H. Nakagawa[3], K. Inoue[1];
[1]Kochi Medical School, Nankoku, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan, [3]RIKEN Center for Integrative Medical Sciences, Yokohama, Japan

Abundant evidence suggests that chronic inflammation is linked to prostate cancer and that infection is a possible cause of prostate cancer. However, pathogen of prostate cancer remains to be found. To identify microbiota or pathogens associated with prostate cancer, we investigated the transcriptomes of 20 human prostate cancer tissues. We performed *de novo* assembly of non-human sequences from RNA-seq data and identified four bacteria as candidate microbiota in the prostate, including *Moraxella osloensis*, *Uncultured chroococcidiopsis*, *Cutibacterium acnes*, and *Micrococcus luteus*. Among these, *C. acnes* was detected in 19 of 20 prostate cancer tissue samples by immunohistochemistry. We then analyzed the gene expression profiles of prostate epithelial cells infected *in vitro* with *C. acnes* and found significant alterations in homologous recombination (HR) and Fanconi anemia pathway. Notably, electron microscopy showed that *C. acnes* invaded prostate epithelial cells and localized in perinuclear vesicles, whereas analysis of γH2AX foci and HR assay demonstrated impaired HR repair. In particular, *BRCA2* was significantly down-regulated in *C. acnes*-infected cells. These findings suggest that *C. acnes* infection in the prostate could lead to HR deficiency and BRCAness which promotes DNA double-strand breaks, thereby increasing the risk of cancer development.

#5606 The role of KMT2C in the homologous recombination repair in epithelial ovarian cancer.

M. C. Ma, **Z. Lin**, E. S. Ratner;
Yale University School of Medicine, New Haven, CT

Background: Epithelial ovarian cancer (EOC) with homologous recombination (HR) deficiency is susceptible to PARP inhibitor therapy due to synthetic lethality. Identification of the patient population for PARP inhibitor therapy is imperative to reduce recurrence of EOC and improve the survival outcomes of patients. Current biomarkers for PARP inhibitor therapy consist of an array of genes involved in the HR repair pathway in EOC, including BRCA1, BRCA2 and PALB2. Through TCGA analysis, we found that the lysine (K)-specific methyltransferase 2C (KMT2C) gene is mutated in 10.3% of all EOC patients and considerably enriched in BRCA1 mutated EOC patients. However, the role of KMT2C in HR repair and PARP inhibitor sensitivity of EOC remains largely undefined.
Methods: BRCA2-mutated PEO1 and BRCA2-wild type PEO1-NR cells were transfected with KMT2C siRNA and assayed for KMT2C protein expression by western blotting. DR-GFP (HR) and EJ5-GFP (NHEJ)-SKOV3 cell lines were co-transfected with the ISceI-expressing plasmid pCBA-ISceI and KMT2C siRNA. GFP-positive cells were analyzed by flow cytometry. SKOV3 cells were transfected with KMT2C siRNA and the expression of BRCA2 and Rad51 mRNA was determined using quantitative RT-PCR analysis.
Results: siRNA-mediated knockdown of KMT2C resulted in marked down-regulation of KMT2C protein in PEO1 and PEO1-NR cells. KMT2C knockdown caused a significant decrease in ISceI-induced HR activity in DR-GFP-SKOV3 cells ($p < 0.05$). In contrast, KMT2C knockdown had no effects on ISceI-induced NHEJ activity in EJ5-GFP-SKOV3 cells. As a control, Rad51 knockdown caused complete suppression of HR activity and had no effects on NHEJ activity. Furthermore, quantitative RT-PCR analysis of key HR genes showed that KMT2C knockdown resulted in a moderate but significant down-regulation of BRCA2 ($p < 0.05$) and Rad51 ($p < 0.01$) expression in SKOV3 cells.
Conclusion: Our results suggest that KMT2C partakes in the HR repair pathway in EOC. However, the contribution of KMT2C to HR activity is not rate-limiting. Based on the known function of KMT2C in histone modification, we speculate that KMT2C serves to positively regulate the transcription of HR genes and therefore promote HR activity. Future investigation into the exact roles of KMT2C in HR repair, etiology of EOC, and diagnostic biomarkers for the PARP inhibitor sensitivity of EOC is warranted.

#5607 A highly efficient donor system for CRISPR knock-in editing.

L. Wu, D. Yin, H. Su, J. Fellows, M. Fu, J. Heller, B. Park, A. Juminaga;
OriGene Technologies, Inc., Rockville, MD

CRISPR is a potent tool widely used for genome editing. While CRISPR knock-out, achieved through in-del mutations via cellular repair mechanisms, has proven remarkably effective, the knock-in system for exogenous fragment insertion encounters challenges due to limited specificity and efficiency. Two primary methods for exogenous fragment insertion, namely NHEJ (Non-Homologous End Joining) and HR (Homologous Recombination), exist. HR allows for the construction of DNA insertions with precise junctions but is comparatively less efficient than NHEJ. To address these limitations, our system focuses on enhancing the efficiency of HR-based genome editing. Primarily, we have optimized the Lenti All-in-one CRISPR system to augment the delivery and targeting efficiency of the Cas9-gRNA complex. The system has been successfully employed to knock out Glutamine Synthetase (GLUL) in HEK293T cells, exhibiting superior efficiency compared to commercially available tools. Secondly, we have implemented a pseudo-lenti system to amplify the entry capacity of donor DNA with homology arms into target cells. This technique has shown an improved HR effect in the experiment to tag a GFP at the C terminals of CDC25A. Lastly, we leverage proximity effects by fusing Cas9 with a capture protein that can grasp a bait sequence attached to the donor DNA, thereby facilitating its transfer to the target sites. Our system has demonstrated exceptional efficacy as a CRISPR knock-out platform and a powerful tool for DNA tagging functionality on target genes.

#5608 The BRCA1-associated role of CDK9 in response to DNA damage is independent of its canonical role in transcription.

T. C. Nepomuceno[1], M. A. Carvalho[2], A. N. Monteiro[1];
[1]Moffitt Cancer Center, Tampa, FL, [2]Instituto Federal do Rio de Janeiro, Rio de Janeiro, Brazil

The understanding of the biological role of BRCA1 in maintaining genomic integrity through homologous recombination (HR) repair has driven the development of targeted treatments with PARP inhibitors (PARPi) in *BRCA1*-linked tumors with promising results. Recently, cyclin-dependent kinase 9 (CDK9) inhibitors have emerged as therapeutic options to treat cancer. We have previously implicated CDK9 in genome integrity maintenance through HR repair by modulating BRCA1 recruitment to double-stranded break sites. CDK9 is a component of the positive transcription elongation (PTEF-b) complex and more recently was proposed by the hereditary breast case-control (BEACCON) study as a putative breast cancer (BC) predisposition gene in non-*BRCA* families. Differently from *BRCA1*-linked BCs, loss-of-function mutations in *CDK9* were significantly correlated with ER-positive and Lobular BCs. CDK9 expression is also elevated in metastatic and recurrent ovarian cancer (OC) tissue and correlates with poor prognosis in OC patients. Here we characterize the BRCA1/BARD1/CDK9 complex using protein-protein interaction assays. Our data indicate that the CDK9/BARD1 interaction occurs indirectly through BRCA1. We also generated a separation-of-function mutation in CDK9 (mutCDK9) that disrupts its interaction with BRCA1 but retains its kinase activity and preserves its role in transcription. We rescued the mutCDK9/BRCA1 interaction using a complementary mutation in BRCA1 (cmutBRCA1), that retains BRCA1 role in cell viability. Further, we employed CRISPR-based genome editing to generate genetically defined haploid HAP1 cell lines that express mutCDK9 in various *TP53BP1* and *BRCA1* backgrounds. The mutCDK9 cells preserve global RNA transcription and the phosphorylation status of the RNA polymerase II. We observed that mutCDK9 cells are more sensitive to the PARPi, rucaparib when compared to wild-type cells in proficient and deficient *TP53BP1* backgrounds. However, mutCDK9 expression did not affect the sensitivity of HAP1 cells expressing cmutBRCA1. Collectively, our data suggest that CDK9 acts in genome integrity maintenance by HR through its interaction with BRCA1 independently of its canonical role in transcription.

#5609 A WRN screening cascade to facilitate novel drug discovery.

Aicheng Wang, Kejun Mao, Tao Li, Lizhao Guan, Yuhong Chen, Haiting Dai, Xian Wu, Jiabao Lv, Xu Wang, Cong Huang, **Tiejun Bing**

ICE Bioscience, Inc., Beijing, China

Human RecQ deconjugating enzyme WRN is involved in DNA replication, DNA repair, recombination, transcription and telomere stabilization[1]. It plays a key role in nucleic acid metabolism as well. WRN defects lead to premature aging, type II diabetes, osteoporosis, atherosclerosis and cancer[2]. Hence it is of great interest of both pharmaceutical and academic field to develop the WRN inhibitors. Here we constructed an integrated experimental cascade, which contains both in vitro and in vivo assays, to conduct the high throughput hit-to-lead compound screen. WRN proteins of different length have been successfully purified and utilized to develop multiple biochemical assays such as unwinding assay and ATPase assay. We have also validated different cellular assays, including proliferation and immunofluorescence, to assess the cytotoxicity and the influence of downstream biomarkers of WRN inhibitors. A WRN knock-out cell line has been generated to better appreciate the inhibition mechanism. In addition, we have generated a WRN-HiBiT knock-in cell line to evaluate WRN degraders or target-compound interactions. Lastly, multiple CDX models utilizing different MSI or MSS cell lines have been validated to help determine the efficacy of WRN inhibitors thus shed light on the drug indications. Together our WRN screening cascade can provide comprehensive compound evaluation across in vitro and in vivo platforms, thus serve as an efficient screening platform for new drug discovery.

#5610 Investigating the role of *BRCA2* in the development of pediatric rhabdomyosarcoma.

P. Weinstein[1], R. Zabriskie[1], C. Ozdemir[2], K. M. Miller[2], O. Medina-Martinez[1], J. D. Heaney[1], A. Sabo[1], P. J. Lupo[1], S. E. Plon[1];
[1]Baylor College of Medicine, Houston, TX, [2]The University of Texas at Austin, Austin, TX

Introduction: In a large-scale exome sequencing study of pediatric rhabdomyosarcoma (RMS) patients, we identified a statistical enrichment of patients with germline variants in *BRCA2* (Li, et al. *JNCI*, 2020), which prompted this study to assess the role of heterozygous *BRCA2* variants in the development of pediatric RMS in both precursor cell and mouse models. **Methods:** We engineered *BRCA2* loss of function (LoF) variants in lines of immortalized mesenchymal stem cells, a potential precursor cell to RMS, using CRISPR and Prime Editing (PE). CRISPR was used to induce frameshift alleles in Exons 10 and 11 and with PE, we created two RMS patient specific LOF variants in Exons 5 and 17. We generated a genetically engineered mouse model (GEMM) with heterozygous excision of Exon 11 of *Brca2*. This allele is now being crossed into two different previously established GEMMs of RMS: a myoblast-specific (MyoD1-Cre) conditional loss of *p53,* and a gain-of-function mutant *p53,* LSL-p53^{R172H} (Nakahata, et al. *Dis. Model. Mech.,* 2022), to assess changes in the pace of tumorigenesis and metastatic potential. Through an X01 agreement with the Gabriella Miller Kids First Program, we have submitted paired tumor-normal samples for additional whole-genome sequencing and RNA sequencing (tumor only) on >500 patients with RMS, including those with germline variants in *BRCA2*. **Results:** Using CRISPR, we generated cell lines heterozygous for the frameshift variants c.1345dup, c.5680del, and c.5680dup. With Prime Editing, we created heterozygous lines mimicking two specific variants detected in the RMS cohort, c.462_463del and c.7857G>A. Generation of a C57BL6 GEMM with a heterozygous removal of Exon 11 in *Brca2* has been successful. No homozygous mice were obtained following 7 heterozygous crosses (50 pups), a departure from Mendelian ratios (p=0.0001) consistent with embryonic lethality. Heterozygous *Brca2* mice derived from crosses into two RMS models are being monitored for tumor development. We have completed tumor-normal whole-genome and tumor RNA sequencing for 609 RMS patients, including 228 subjects not previously analyzed. We will directly assess whether there is evidence for mutation or loss of expression of the remaining *BRCA2* allele in tumors and whether these tumor genomes exhibit signatures of DNA repair deficiency. **Conclusions:** The goal of this project is to determine the molecular basis for the enrichment in germline *BRCA2* LOF variants in pediatric malignancies, including RMS. Ongoing experiments using the engineered heterozygous *BRCA2 in vitro* cell line models will assess genomic stability, homologous recombination proficiency, and DNA replication fork stability. Assessment of the effect of heterozygous *Brca2* variants in GEMMs of RMS, and subsequent analysis of additional sequencing data, will further elucidate what role this gene may play in increasing risk or progression of pediatric cancers.

#5611 Unraveling the role of F-actin in resistant GBM: Insights into DNA repair, GSC phenotype, and therapeutic implications.

Y. T. Magalhaes, F. L. Forti;
IQ USP, Sao Paulo, Brazil

Glioblastoma (GBM), a highly aggressive brain cancer, poses a formidable challenge marked by its resistance to conventional therapies. F-actin, a crucial cytoskeletal protein, influences DNA repair and impacts genomic stability. F-actin dynamics also shape the glioma stem cell (GSC) phenotype, affecting self-renewal and migration. Altered F-actin organization contributes to GBM resistance to conventional therapies. Understanding F-actin's multifaceted role is vital for developing targeted strategies to overcome treatment resistance and enhance outcomes for GBM patients. This study goes deeper into the intricate interplay between the F-actin cytoskeleton and the acquisition of resistance in GBM cells. Our primary goal was to explore the effects of pharmacological or genetic F-actin depolymerization on the reversal of acquired resistance to ionizing radiation (IR) and temozolomide (TMZ) in GBM cells, particularly focusing on the underlying mechanisms involving DNA repair, the glioma stem cell (GSC) phenotype, and therapeutic implications. To establish resistant sublines, GBM U87-MG cells underwent cycles of IR and TMZ exposure, revealing a significant increase in IC_{50} values for TMZ and ID_{50} values for IR through viability assays. Subsequent characterization of these sublines growth was in both adherent and spheroid cultures uncovering a distinct sphere-forming capacity. Notably, alterations in DNA repair and the Rho GTPase pathway were observed, with evident disorganized F-actin polymerization in resistant cells, especially at the periphery of spheroids. Elevated expression of stemness markers (Nestin, CD133, and CD44) highlighted a GSC-like profile in the resistant cells, a characteristic further accentuated in spheroid cultures. To assess the relevance of the actin cytoskeleton in maintaining the resistant phenotype, cells were treated with Rho-GTPase inhibitor (C3) or actin polymerization inhibitor (Cytochalasin D). Both treatments resulted in reduced TMZ IC_{50} and IR ID_{50} values, partially attributed to the negative modulation of DNA repair capacity - observed by alkaline comet and host-cell reactivation assays. Additionally, F-actin disassembly was found to impact the expression of stemness markers, further reinforcing the connection between cytoskeletal dynamics and the GSC phenotype. Overall, our data strongly suggest that F-actin cytoskeleton dynamics plays a pivotal role in the development and maintenance of resistance in GBM. Targeting these cytoskeletal components sees a promising pharmacological strategy for resensitizing recurrent and resistant GBM tumors, not only by diminishing DNA repair capabilities but also by influencing the GSC-like phenotype, thus opening new avenues for therapeutic interventions.

#5612 MRE11 function in DNA damage response is regulated by SIRT2 deacetylation.

M. Essien, F. Sesay, H. Zhang, A. Jung, D. Yu;
Emory University, Atlanta, GA

MRE11 is known to play a role in DNA damage repair through the MRE11-RAD50-NBS1 (MRN) complex and homologous recombination. However, the upstream signaling mechanisms regulating MRE11 in DNA repair are unclear. Here, we aimed to determine the extent to which MRE11 is regulated by deacetylation by the SIRT2 sirtuin deacetylase and tumor suppressor protein. We overexpressed MRE11 in HEK293T cells, induced DNA damage through radiation treatment, and performed a series of co-immunoprecipitation (co-IP) studies with and without ionizing radiation (IR). Additionally, we evaluated the acetylation of MRE11 with and without the presence of SIRT2. In a series of functional experiments, immunofluorescence staining assays were performed in U2OS-265 Fok1 cells with SIRT2 knockdown to determine the effect of on MRE11 recruitment to DNA damage sites. Co-IP studies and in vitro DNA pulldown assays were performed to determine the role of SIRT2 in impacting MRE11 interaction with RAD50 and NBS1 and binding to DNA damage. We also examined for IR-induced RPA70 foci formation and downstream ATM-dependent signaling. We found that SIRT2 interacts with and deacetylates MRE11. Furthermore, SIRT2 deacetylation facilitated MRE11 binding to DNA but not interaction with RAD50 and NBS1. Finally, SIRT2 deacetylation facilitated DNA end resection and ATM-dependent phosphorylation of KAP1. In conclusion, our results define a role for SIRT2 in directing MRE11 localization and binding to DNA to promote DNA end resection and ATM-dependent signaling through deacetylation.

#5613 Study of long non-coding RNA TUG1 kinetics under replication stress conditions in cancer cell.

T. Fujita[1], M. Suzuki[1], O. Masui[2], K. Shinjo[1], Y. Kondo[1];

[1]Nagoya University, Nagoya, Japan, [2]RIKEN Center for Integrative Medical Sciences, Yokohama, Japan

Long non-coding RNAs (lncRNAs) are transcripts longer than 200 nucleotides that are not translated into proteins. In contrast to protein-coding mRNAs, certain lncRNAs carry out their functions within the nucleus. A detailed elucidation of the kinetics of lncRNAs contributes to a comprehensive understanding of their bona fide biological characteristics. Consequently, advancements in the in vivo visualization of lncRNAs have continued. Currently, various techniques, including RNA imaging technologies, have been employed to facilitate real-time tracking and visualization of RNA molecules within living cells. Taurine upregulated gene 1 (TUG1) is an oncogenic lncRNA, playing a pivotal role in cancer cells by resolving R-loops formed at stalled replication forks, particularly under replication stress conditions such as Hydroxyurea (HU) treatment. Despite its significance, the dynamic regulation of TUG1 under replication stress conditions remains largely unknown. In this study, we developed a stem loop-based live imaging system enabling real-time visualization of TUG1, providing insights into its subcellular localization and dynamic roles in physiological contexts. Upon treatment with HU, a chemical that interferes with replication, TUG1 expression was rapidly upregulated in the nucleus within 20 minutes. Additionally, we observed TUG1 molecules relocating close to the nuclear membrane. Considering the reported relocation of collapsed forks to the nuclear pore complex, this suggests that TUG1 may be involved in this relocation structure. These data indicate that TUG1 is associated with the fork restore mechanism occurring at the relocated collapsed forks, and the current live-cell imaging system holds potential for further uncovering the critical roles of TUG1 in cancer cells. Our stem loop-based imaging may contribute to a more precise understanding of RNA dynamics in live cells.

#5614 Mechanical regulation of cisplatin-DNA adduct repair in mesenchymal stem cells.

A. G. Zavala, N. Nikitina, C. Cantu, D. DeLaCruz, G. Uzer;
Boise State University, Boise, ID

This study examined whether loss of mechanotransduction in pluripotent mesenchymal stem cells (MSCs) disrupted repair of bulky DNA adducts, such as those induced by ultraviolet light or cisplatin. MSCs are important for the maintenance and responsiveness of skeletal tissues to environmental mechanical challenges. Beyond regulating proliferative and differentiative capacity of MSCs, emerging evidence suggests that physical activity is associated with improved recovery from DNA damage caused by environmental genotoxic stressors associated with stress and aging. Highlighting the possible crosstalk between DNA repair and bone health, defects in nucleotide excision repair (NER), which removes bulky DNA adducts, are associated with myelosuppression and progeroid aging phenotypes that result in bone defects and lipidodystrophies in mice. Cancer, early aging syndromes, and certain musculoskeletal diseases are associated with disruption of the Linker of Nucleoskeleton and Cytoskeleton (LINC) complex that transduces environmental mechanical signals from the extracellular matrix into the nucleus of a cell. Loss of LINC complex elements is associated with breast cancer progression and poorer prognosis. We hypothesize that LINC-mediated mechanical stimulation into the nucleus is critical for repair of bulky DNA adducts. Our pilot project showed that mechanical stimulation applied in the form of low intensity vibration (LIV) improved NER of cisplatin-induced DNA adducts in cultured MSCs. Our findings show a 20% increase in repair of cisplatin-induced DNA adducts in LIV treated samples compared to non-vibrated samples at 24 hours ($P<0.005$). We also quantified the effect of LINC complex disruption on cisplatin-induced DNA damage removal. Intact MSCs showed significant adduct removal after 24 hours, while LINC disruption significantly reduced DNA repair ($P<0.001$). Furthermore, initial experiments suggest that LINC disrupted cells do not arrest at DNA repair checkpoints, therefore, loss of LINC complex may reduce entry into senescence increasing DNA mutagenesis. In conclusion, these findings suggest a novel interaction between mechanical stimulation, the DNA damage response, and LINC complex in DNA repair in multipotent mesenchymal stem cells. Furthermore, we suggest that LINC-mediated mechanical changes associated with LIV treatment may lead to novel therapeutic approaches to combat deleterious musculoskeletal conditions associated with anti-cancer treatments.

#5615 Functional analysis of variants of uncertain significance in the *MSH6* mismatch repair gene.

E. Szabo, E. Blackburn, A. Radecki, A. Rath, C. Heinen;
University of Connecticut Health Center, Farmington, CT

Lynch syndrome (LS) is a hereditary condition that increases patients' lifetime risk of cancer, primarily colorectal cancer. LS is caused by germline mutations in mismatch repair (MMR) genes, *MLH1, MSH2, MSH6*, and *PMS2*. Identification and classification of these mutations is important in LS diagnosis for guiding treatment plans and preventative care for patients' and their families. However, the consequences of some variants in these genes are not immediately obvious, granting them classification as variants of uncertain significance (VUS). Laboratory functional analysis to determine whether these variants disrupt MMR function in human cells can provide important evidence for understanding the pathogenicity of VUS and reclassifying them. Half of known variants in the MMR gene *MSH6* are VUS and, thus, the goal of my project is to provide evidence for a subset of these variants to help provide evidence for reclassification for these variants. We are calibrating and validating functional assays for *MSH6* variants, using known *MSH6* pathogenic and benign controls. We will then test *MSH6* VUS identified in patients as reported in the InSiGHT database, ClinVar database, and current literature. We are using CRISPR gene editing to recreate these variants in the endogenous *MSH6* loci in human embryonic stem cells (hESC). Using these edited hESC lines we are examining the impact of the variants on RNA and protein stability, repair of DNA microsatellites, which is a hallmark of normal MMR function, and induction of the MMR-dependent DNA damage response. With this compilation of data, we will convert the results into a quantitative Odds of Pathogenicity value. This Odds of Pathogenicity score can be used by expert variant interpretation committees to help readily reclassify these variants and provide a clearer diagnosis for these suspected Lynch syndrome patients.

#5616 Targeting the DNA damage response sensor replication protein A for first in class cancer therapy.

K. Pawelczak[1], P. VanderVere-Carozza[2], M. Jordan[2], J. Turchi[2];

[1]NERx Biosciences, Inc., Indianapolis, IN, [2]Indiana University School of Medicine, Indianapolis, IN

The DNA Damage Response (DDR) is an integrated network of DNA repair and cell signaling pathways that are critical towards maintaining genomic stability. The most successful DDR targeted therapies inhibit the DNA damage sensor, PARP, a protein that recognizes single strand DNA (ssDNA) breaks as well as other DNA secondary structures induced by single strand gaps that can initiate chromosome instability and cell death. Building on the initial clinical success of PARP inhibitors, development of DDR targeted therapeutics has become increasingly popular, however, the clinical outcomes with these therapeutics have not met expectations and thus a new approach to targeting the DDR pathway is needed. NERx Biosciences has developed a novel strategy of targeting the DDR by intervening upstream of the DDR kinases and targeting specific DDR sensors. The human ssDNA binding protein, replication protein A (RPA), is a critical sensor for the DDR, serving to sense the ssDNA at replication forks that arise from replication stress (RS) and is a novel target for cancer therapy. We have discovered, developed, and characterized a novel small molecule RPA inhibitor (RPAi) NERx-329 that blocks the RPA-DNA interaction and elicits a state of chemical RPA exhaustion that results in *in vivo* anticancer activity. Extensive chemical optimization enabled in vitro and in vivo analyses to elucidate mechanism of action, cellular engagement, and therapeutic activity of RPA-targeted agents. Biochemical reconstitution of the ATR signaling pathway shows that NERx-329 disrupts ATR kinase activity, further suggesting a novel mechanism of action driven by RPA inhibition induced replication catastrophe. In vivo analysis reveals activity in a series of lung and ovarian patient derived xenograft models of human cancer. Single agent activity results in a tumor growth delay, which can be enhanced in combination therapy with DDR inhibitors as well as traditional DNA damaging cancer therapeutics. Data demonstrate that tumor growth observed in vivo is a function of NERx329 bioavailability and not development of a specific resistance mechanism. In an effort to identify formulations effective in enhancing oral bioavailability, we have pursued the development of Spray-dried dispersions (SDD). PK analysis reveal a dose-dependent substantial increase in C_{MAX} and AUC, allowing for optimal dosing regimens for efficacy and safety studies. In addition, specific genetic predictors of RPAi sensitivity have been identified and results demonstrate specific genetic alterations increase RPAi activity in vitro and in vivo. NERx-329 represents the first clinically viable agent to target the DDR pathway by disrupting the RPA-DNA interaction and holds the potential for significant impact in cancer treatment.

#5617 Combined inhibition of ATR and ATM with tuvusertib and lartesertib (M4076) impacts the tumor microenvironment.

K. Laaber[1], A. Turchick[2], J. Jabs[1], B. Elenbaas[2], L. T. Vassilev[2], A. Zimmermann[1];
[1]The Healthcare Business of Merck KGaA, Darmstadt, Germany, [2]EMD Serono, Billerica, MA

Ataxia telangiectasia and Rad3-related protein (ATR) and ataxia telangiectasia mutated (ATM) are two of the main kinases of the DNA damage response (DDR). Recent work has demonstrated that the addition of ATM inhibitors enhances the cytotoxicity and *in vivo* anti-tumor efficacy of ATR inhibitors by abrogating the ATR inhibitor mediated G_1 cell cycle arrest and enhancing chromosomal damage.[1] Prior to causing cell death, damaged chromosome fragments can end up in the cytosol where they are detected by cytosolic nucleic acid sensors such as cGAS, resulting in the induction of inflammatory signaling pathways and an anti-tumor immune response. This suggests that the mode of action of DDR inhibitors may involve the tumor microenvironment (TME). We therefore aimed to assess the influence of combined pharmacological ATR and ATM inhibition on the TME to better understand how this could be exploited therapeutically.

In line with published results in human tumor models, the treatment of murine colon cancer MC-38 cells *in vitro* with a combination of ATR inhibitor tuvusertib and ATM inhibitor lartesertib led to cell death. Further analysis revealed an activation of the cGAS-STING signaling pathway, an upregulation of PD-L1 and the release of inflammatory cytokines. These results confirmed the activation of immune signaling pathways upon combined inhibition of ATR and ATM.

To analyze the stimulation of an anti-tumor immune response upon tuvusertib + lartesertib treatment *in vivo*, MC-38 cells were transplanted into immunocompetent C57BL/6J mice. Immunoprofiling by flow cytometry and immunohistochemistry staining confirmed that treatment with tuvusertib + lartesertib indeed altered the TME in this setting. In line with the *in vitro* findings, a significant upregulation of PD-L1 on immune and tumor cells could be observed after 24, 48, and 72 h of treatment even though MC-38 cells expressed high levels of PD-L1 already. Immunoprofiling did not reveal any changes in the TME immune cell content at these early time points. Interestingly, PD-L1 expression as well as tumor immune population changed after prolonged (23 days) treatment. PD-L1 was still expressed on tumor cells but to a significantly lesser extent and a depletion of CD8+ T-cells was observed. However, a significant increase in NK cells could be detected.

In summary, we show that inhibition of the DDR through a combination of ATR and ATM inhibitors influences the TME in the MC-38 tumor model. These findings suggest an additional mode of action beyond direct cancer cell cytotoxicity. Further studies on how this may be leveraged therapeutically, for example through a combination with immune checkpoint inhibitors, are warranted.

1. Turchick A, Zimmermann A, et al. *Mol Cancer Ther* 2023;22(7):859-872.

#5618 Evaluating the combination of datopotamab deruxtecan (Dato-DXd) with AZD5305, a highly potent, PARP1-selective inhibitor, -in preclinical models.

G. Patel, J. Owusu, C. Rane, A. Rosen, M. Griffin, M. Sung;
AstraZeneca US, Waltham, MA

Background: Dato-DXd is a TROP2-directed antibody drug conjugate comprised of a topoisomerase I inhibitor (an exatecan derivative, DXd) conjugated to datopotamab, a humanized anti-TROP2 IgG1 antibody, via a cleavable plasma-stable tetrapeptide-based linker. Topoisomerase I inhibitors stabilize DNA-topoisomerase cleavage complexes (Topo1cc) that lead to double-strand breaks and activation of DNA damage response (DDR). Poly(ADP-ribose) polymerase 1 (PARP1) mediates signal transduction in the DDR as an important regulator. AZD5305 is a highly potent and selective inhibitor of PARP1. Since PARP1 is a key component driving the repair of trapped Topo1cc, we aimed to investigate if combinations of Dato-DXd with AZ5305 lead to synergistic anti-tumor effects in preclinical models.

Methods: We evaluated the cytotoxic effect of the combination of Dato-DXd with AZD5305 in a panel of six non-small cell lung cancer (NSCLC) and five triple negative breast cancer (TNBC) cell lines in a 7-day viability assay. We evaluated PARylation inhibition and gH2AX response by Western blotting. Topo1cc accumulation in response to combination treatment was evaluated by immunofluorescence. This combination was evaluated *in vivo* in TROP2+, HRD-negative gastric cancer (GC) N87 cell line xenograft at varying concentrations of AZD5305 and in a TROP2+, PARPi-resistant Ovarian cancer patient derived xenograft (PDX) model (CTG-3718).

Results: The *in vitro* combination screen demonstrated enhanced cell killing by the Dato-DXd and AZD5305 combination over either single agent in both NSCLC and TNBC cell lines. Combination benefit was observed at all doses regardless of homologous recombination deficiency (HRD) status. We observed dose-dependent increase in PARylation inhibition and enhanced induction of gH2AX in the combination treatment. In a N87 tumor model, while Dato-DXd and AZD5305 provided 84% and 31% tumor growth inhibition (TGI) as monotherapies respectively, the addition of AZD5305 to Dato-DXd resulted in 95% TGI. This effect was observed with multiple dose levels of AZD5305. In a TROP2+, ovarian cancer PDX model, AZD5305 demonstrated limited monotherapy activity (<10% TGI) and Dato-DXd demonstrated robust monotherapy activity with 72% TGI. Additional anti-tumor activity was observed for the combination treatment compared to either monotherapy with 88% TGI. All treatment groups were well tolerated *in vivo.*

Conclusion: Dato-DXd combination with AZD5305 increased cytotoxic activity and pharmacodynamic response *in vitro*. This combination led to superior tumor growth inhibition in a GC xenograft model and a PARP1i-resistant Ovarian PDX model *in vivo.* These pre-clinical findings support the ongoing clinical evaluation of Dato-DXd as a monotherapy and in combination with AZD5305 in patients with various advanced solid tumor types (NCT05489211, NCT04644068).

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Gene Regulation and Transcriptional Profiles
Poster Session

#5622 Uncovering the transcriptional regulation of TPPP3.
J. W. Lord, D. Leshchiner, S. Horibata;
Michigan State University, East Lansing, MI

Tubulin Polymerization Promoting Protein 3 (TPPP3) is a protein coding gene primarily associated with microtubule bundling. However more recent research is beginning to reveal more diverse roles it may play in the cell, including B-catenin signaling and endothelial injury. TPPP3 has also been associated with increased cancer growth and proliferation as well epithelial to mesenchymal transition. However, it is unknown how TPPP3 is regulated. We used high grade serous ovarian cancer (HGSOC) as a model to uncover the regulation of TPPP3 as it is highly expressed in many HGSOC cases. To start, we downloaded ~500 HGSOC RNA-seq datasets from The Cancer Genome Atlas (TCGA) and, using python, created a co-expression network to identify a subset of genes exhibiting expression patterns correlated with TPPP3 across all datasets, resulting in the identification of 222 genes. Dynein arm assembly, cilia movement and assembly, and microtubule movement and structure were among the top GO-terms after gene ontology analysis. The genes associated with these processes are typically upregulated in the fallopian tube tissue which aligns with the fact that a majority of HGSOCs originate in the fallopian tube. Fork-head box J1 (FOXJ1) is a transcription factor associated with ciliogenesis and was among the top 222 genes from the co-expression network. It has not been confirmed to transcriptionally regulate TPPP3, but their expression patterns line up across many tissue types. In addition, the TPPP3 promoter contains an RFX2 binding site. RFX2 is DNA binding protein that FOXJ1 uses as a scaffold to bind to proximal promoters due to it binding at to DNA at a distal location. As a result of this evidence, we hypothesize that FOXJ1 transcriptionally regulates TPPP3 via RFX2. To test this hypothesis, we inhibited FOXJ1 and identified TPPP3 downregulation. We are further investigating the regulatory function of how TPPP3 is regulated.

#5624 Dec2, a circadian rhythm gene facilitates pancreatic cancer dormancy through evasion of antitumor immunity.

L. Wang, C. Harris, O. Prela, W. C. Narrow, D. R. Carpizo;
University of Rochester Medical Center, Rochester, NY

Metastatic recurrence following curative intent oncologic surgery is a major clinical problem in patients with pancreatic ductal adenocarcinoma (PDAC). These recurrences are from disseminated tumor cells (DTCs) and can sometimes occur years after surgery indicating that DTCs undergo a period of dormancy. The mechanisms that drive cancer dormancy and its awakening are poorly understood in part due to a lack of animal models that recapitulate dormant tumor cell biology. We created a novel model of PDAC dormancy where mice undergo surgery to remove the primary tumor and are followed for evidence of metastatic recurrence. Dormant DTCs can be isolated from mice without clinical evidence of recurrence for molecular studies. Single cell RNAseq of dormant DTCs detected that the circadian rhythm gene, Dec2 is upregulated. We knocked out (KO) Dec2 from murine pancreatic cancer cells and when implanted into the model we found almost no mice developed metastatic recurrence. When immunodeficient or immunocompetent mice depleted of CD4 and CD8 T cells were used as hosts, we observed no difference in survival in mice engrafted with Dec WT vs. KO cells indicating the survival benefit in the Dec KO group was due to an immune mediated mechanism. We performed a differential expression analysis on bulk RNAseq data comparing the Dec2 WT vs. KO cells and found antigen presentation a top upregulated pathway. We then observed that surface MHC-I was significantly upregulated in Dec2 KO cells as compared to wild type cells. Further mechanistic studies revealed that proteosome activity was significantly higher in Dec2 KO cells and treatment with proteosome inhibitors decreased surface MHCI levels in Dec2 KO cells. Cut and tag experiments revealed that Dec2 binds the promoter of a number of genes that regulate the proteosome. In conclusion, Dec2 promotes cancer dormancy by down regulating cell surface MHCI which facilitates immune evasion.

#5625 Targeting the nonsense mediated mRNA decay pathway to prevent the degradation of highly immunogenic frameshift mutated transcripts.

S. Fernandez Patel[1], R. Vendramin[1], D. Qian[1], Y. Zhao[1], L. Ligammari[1], K. Thakkar[1], J. Murai[1], E. Gronroos[2], J. Carlton[3], K. Litchfield[1];
[1]University College London, London, United Kingdom, [2]The Francis Crick Institute, London, United Kingdom, [3]King's College London, London, United Kingdom

Introduction: Frameshift insertions/deletions (fs-indels) can lead to the generation of immunogenic non-self-peptides which contribute to anti-tumor immune responses. However, fs-indels often generate premature termination codons (PTCs), leading to mRNA degradation by the nonsense mediated mRNA decay (NMD) pathway. Importantly, some PTC-containing transcripts naturally escape NMD degradation and produce highly immunogenic neoantigens. Therefore, we hypothesize that NMD inhibition could be used to increase the cellular pool of fs-indels derived neoantigens in cancer cells, and enhance anti-tumor immunogenicity. NMD also regulates other cellular processes by degrading a subset of non-PTC-containing self-transcripts. Therefore, by focusing NMD inhibition towards the degradation of PTC-transcripts only, toxicity may be limited in a clinical setting. We investigate how targeting different NMD proteins affects the degradation of fs-transcripts across several cancers types. To assess the clinical relevance of NMD inhibition, we study how it specifically affects p53 fs-transcripts, since p53 is the most mutated gene in cancer and fs-mutant p53 has been shown to be highly immunogenic.
Methods: Core NMD proteins were depleted across a panel of cell lines from different cancer types and transcriptomics, flow cytometry, qPCR and western blot were used to evaluate changes in the expression of NMD-targeted transcripts and NMD members. Proteomics and immunopeptidomics were used to study protein expression and HLA-peptide presentation arising from fs-transcripts. A Translating RNA Imaging by Coat protein Knock-off (TRICK) assay was developed to study the translation of NMD-targeted p53 mutants upon NMD inhibition. This assay can precisely quantify the translation of p53 mutant RNA upon different treatments and cellular stresses at single-molecule resolution.
Results: We found an increase in expression of PTC-transcripts upon silencing of multiple NMD members. Our data suggests that some NMD members are better targets for inhibition of NMD PTC-surveillance, whilst others are more appropriate for inhibition of NMD-mediated gene expression regulation. These data support the recently proposed hypothesis that NMD is a branched pathway, where each branch targets specific subsets of transcripts depending on the cell type. These results are clinically relevant as the method by which NMD is inhibited could help optimize the generation of immunogenic neoantigens whilst minimizing toxicity. The TRICK assay has shown that inhibiting NMD surveillance reduces the degradation of p53 fs-transcripts and increases their protein expression.
Conclusion: We have identified NMD pathway members that can be targeted to efficiently inhibit the surveillance role of NMD and prevent the degradation of fs-transcripts that could generate highly immunogenic neoantigens.

#5626 Essential role of Slug during the evolution of drug-tolerance in lung adenocarcinoma.

J. Ostendorp[1], H. Tumbrink[1], P. Hunold[1], M. Hoehne[1], P. Jurmeister[2], A. Dekker[1], F. Heisel[1], J. Bragelmann[1], F. Klauschen[2], R. Haensel-Hertsch[1], M. Sos[3]; [1]Faculty of Medicine and University Hospital Cologne, Cologne, Germany, [2]Ludwig-Maximilians-University Munchen, Munich, Germany, [3]German Cancer Research Center (DKFZ), The German Consortium for Translational Cancer Research (DKTK), Ludwig-Maximilians Univeristy Munchen, Munich, Germany

A major obstacle in the efficacy of targeted therapies of oncogene-driven tumors are drug-tolerant persister cells (DTPs) that build the basis for the outgrowth of drug-resistant clones and ultimately limit patient survival. During treatment, DTPs enter a reversible senescent state to survive therapy while cell death is induced in non-DTPs. Here, using RNA-Seq and proteomic analyses, we identified drug-induced TGFβ2 secretion in DTPs derived from different oncogene-driven lung cancer cell lines. As expected, TGFβ2 induces epithelial-to-mesenchymal transition (EMT) that over time promotes the ability of cells to survive targeted therapy. Using CRISPR/Cas9-mediated loss-of-function and reconstitution experiments we show that downstream of TGFβ2, expression of the transcription factor *SNAI2* (SLUG) is essential for the outgrowth of DTPs during targeted treatment. Unsupervised RNA-Seq data analyses in combination with Cut&Tag profiling revealed that EMT signaling is in part a SLUG regulated process but that is also independent of direct SLUG binding at the transcription start sites (TSS) of EMT signature genes. In contrast, we observed high occupancy of SLUG at TSS of genes involved in the regulation of cell cycle, being repressed in DTPs and at TSS of genes that regulate sphingolipid metabolism and MAPK signaling, being induced in DTPs. In line with our previous findings, a motif-based analysis of the Cut&Tag data (TOBIAS) furthermore uncovered a tight connection between DTP outgrowth and inflammatory signaling induced through IRF7, IRF4 or STAT1 activation. *In vivo, EGFR*-mutant SLUG deficient cells showed a significantly prolonged tumor onset and a higher response rate to osimertinib treatment. Overall, we uncover a major role of TGFβ2/SLUG-mediated EMT signaling that may be induced indirectly through SLUG-dependent reprogramming of cell cycle directed and metabolic processes in drug tolerant cells. These insights may offer unique therapeutic opportunities to limit the outgrowth of drug resistant tumors in cancer patients.

#5627 PPARG-high circulating monocytes exhibit an immunosuppressive phenotype in urothelial cancer patients treated with anti-PD1.

P. A. Nguyen, G. Zhang, B. Kakrecha, R. Marable, S. Kirov, M. Bowden, E. Gjini;
Flare Therapeutics, Cambridge, MA

Background:
PPARG is expressed in a variety of immune cells such as monocytes, macrophages, and lymphocytes, where it plays a role in their maturation and function. PPARG has been implicated in immune mediated resistance but to date, a comprehensive analysis of PPARG expression in peripheral blood mononuclear cells (PBMCs) in urothelial cancer (UC) patients is lacking. In this study, we identified the immunophenotypes associated with PPARG expression in UC patients treated with anti-PD1 therapy.

Methods:
We performed single-cell RNA sequencing of PBMCs from 5 UC patients and 3 normal healthy volunteers (NHV). Real-world samples (Discovery Life Sciences) were collected from patients who received prior Pembrolizumab. Time post-treatment to collection ranged from 46 to 307 days. An average of 9,500 cells were recovered per donor reflecting an ~80% QC pass rate. Count matrices were generated using 10x Genomics Cell Ranger pipeline (v7.0.0; GRCh38 reference). Downstream data processing, analysis and visualization were done on Cellenics software.

Results:
We evaluated 75,725 cells and identified 9 distinct cell populations. The proportion of T-cells was significantly decreased in UC samples compared to NHVs (40% vs 60%, p=0.03). Highest PPARG expression was observed on Classical Monocytes (CMs) cell population. PPARG expression was higher on CMs in UC compared to NHV samples (1.74 vs 0.11 logcounts; padj<0.001). Unsupervised clustering of all monocytes revealed two distinct CM clusters. In cluster A, 95% of the cells originated from UC samples, while most cells in cluster B (81%) originated from NHV samples. PPARG was the top differentially expressed gene upregulated in cluster A (PPARG-high) vs cluster B (PPARG-low) (1.89 vs 0.23 logcounts; padj<0.001). PPARG-high CMs are characterized by a gene signature inclusive of GPRIN3, RGCC, MAFB and IRF2BP, which have been shown to be upregulated in M2 polarized macrophages [1]. Moreover, pathway analysis using GSEA highlighted that PPARG-high CMs are enriched for TREM1 signaling genes (padj<0.001), whose high expression has been associated with immunosuppressive phenotypes in myeloid cells [2] and shorter survival of patients across other cancers [3].

Conclusion:
PPARG-high circulating CMs in UC patients exhibit a transcriptomic profile associated with immunosuppression and M2 macrophage polarization. FX-909, a first-in-class PPARG inverse agonist, is being evaluated in the clinic and the study includes an exploratory biomarker approach to assess the potential effect of PPARG inhibition on the CM immune-profile of advanced UC patients enrolled in the Ph1 study [4].

#5628 Aberrant 3'UTR processing regulates a tumor suppressor network in AML..

E. Wang[1], C. Han[1], A. Calderon[1], A. Lawal[1], S. H. Rajendran[1], S. Karma[1], N. Hariramani[1], I. Aifantis[2], A. Tsirigos[2];
[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT, [2]NYU School of Medicine, New York, NY

Differentiation blockade is a hallmark of acute myeloid leukemia (AML). While inactivating mutations in tumor suppressor genes (TSGs) have been well-studied, non-genetic mechanisms that impair TSGs to promote myeloid differentiation and influence drug response remain poorly understood. In this study, we performed genome-wide *loss-of-function* CRISPR/Cas9 screens to identify suppressors of myeloid differentiation. These screens converged on the zinc finger transcriptional repressor, ZBTB7A whose ablation restricted myeloid maturation and promoted a dysregulated inflammatory state to protect leukemic cells from undergoing differentiation. Moreover, genetic deletion of ZBTB7A or its paralog, ZBTB7B impeded leukemia differentiation and conferred resistance to differentiation-inducing agents. Mechanistically, we found that leukemia cells hijack 3'UTR processes to reduce mRNA expression of the tumor suppressor gene paralogs *ZBTB7A* and *ZBTB7B*. These findings provide a molecular framework of altered 3'UTR regulation that orchestrate a tumor suppressive function and promote resistance to AML differentiation-based therapies.

#5629 MEF2D regulates T cell function via the CD70-CD27 signaling axis and promotes immune escape in hepatocellular carcinomas.

F. Kong[1], L. Wang[2], Q. Ye[3], Y. Xiong[1], **W. W. Hancock[4]**;

[1]Zhongnan Hospital of Wuhan University, Hubei, China, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Zhongnan Hospital of Wuhan University and The 3rd Xiangya Hospital of Central South University, Hubei and Changsha, China, [4]University of Pennsylvania, Philadelphia, PA

Background: Immune escape remains a challenge in the treatment of hepatocellular carcinoma (HCC), one of the most common and deadly cancers in the world. The transcription factor, myocyte enhancer factor 2D (MEF2D), is important in the regulation of differentiation and adaptive responses in many cancers, such that we tested its role in HCC.

Methods: We knocked down MEF2D in HCC cell lines and analyzed HCC tissues and cell lines by RNA sequencing, Western blot and immunohistochemistry. MEF2D protein acetylation and proteins that interact with MEF2D were identified by coimmunoprecipitation assay. Chromatin immunoprecipitation was used to analyze the regulation of CD70 transcription by MEF2D. H22 cells, with MEF2D knockout or without (controls), were injected into the livers of syngeneic BALB/c mice. Flow cytometry was used to analyze the function of T cells in tumors, spleens, and lymph nodes.

Results: Through database searches, we noted that MEF2D and CD70 were upregulated in HCC and associated with shorter patient survival times. Compared to WT tumors, injection of MEF2D-knockdown HCC cells into immunocompetent mice led to smaller tumors with increased T cell infiltration, activation, and impaired T-regulatory (Treg) cell suppressive function. Mechanistically, we found that MEF2D binds to the promoter region of CD70 gene and activates its transcription. Moreover, acetylation of MEF2D enhances the binding of MEF2D to the CD70 promoter and further promotes its transcription. CD70 blocking antibody inhibited activation of the CD70-CD27 signaling axis in murine HCC tumors, leading to impaired immunosuppressive function of Tregs and enhanced T cell-mediated anti-tumor immune responses. Thus, regulation of the CD70-CD27 signaling axis by MEF2D affects the numbers and functions of Treg cells and thereby controls T cell infiltration.

Conclusions: MEF2D in HCC cells increases the expression of CD70 and blocks T cell-mediated anti-tumor immunity via the CD70-CD27 signaling axis. Strategies to manipulate this pathway might increase the efficacy of immune therapies for HCC.

#5630 Targeting the LSD1/ADNP axis as an effective pro-differentiating strategy against acute myeloid leukemia AML.

M. Lone, M. Sayeed, A. Habieb, P. Kumar, M. E. Engel;
University of Virginia, Charlottesville, VA

Acute Myeloid Leukemia (AML) represents a diverse category of blood cancers marked by the clonal proliferation of atypical myeloid precursor cells within the bone marrow. Lysine Specific Demethylase 1 (LSD1), an epigenetic regulator, exhibits elevated expression in AML. Consequently, inhibiting LSD1 has emerged as a promising therapeutic approach for addressing blood and bone marrow cancers. While initial emphasis centered on LSD1's enzymatic inhibition, compelling evidence highlights its pivotal role as a scaffolding protein, orchestrating transcriptional and chromatin remodeling complexes that control cellular differentiation and proliferation. However, our understanding of the precise mechanisms governing these complexes remains limited, necessitating further investigation. The K562 erythroleukemia cell line has served as a prominent model for investigating the molecular factors influencing cell fate determination. In response to specific cues, these cells exhibit a bi-potential capacity, mirroring the behavior of normal hematopoietic megakaryocyte/erythrocyte progenitors (MEP). Notably, when LSD1 is either depleted or inhibited, the erythroid differentiation of K562 cells is hindered, even when exposed to various pro-differentiating triggers, including the BCR-ABL inhibitor Imatinib. In order to gain deeper insights and identify potential new protein partners involved in the K562 differentiation process that interact with LSD1, we employed the erythroleukemic K562 cell model. Using unbiased, proteome-wide proximity labeling we discovered that LSD1 serves as a scaffold for recruitment of the ChAHP complex, comprised of ADNP, CBX3, and CHD4. The ChAHP complex serves fundamental roles in chromatin remodeling, RNA splicing, and transcriptional control. We confirmed these proximity relationships by immunoblotting biotinylated proteins generated in situ by the promiscuous biotin ligase, (BirA*) when anchored to LSD1. We show that depleting ADNP induces spontaneous erythroid differentiation in K562 erythroleukemia cells, which is augmented by BCR-ABL inhibitor Imatinib treatment. ADNP-deficient K562 cells exhibited accelerated erythroid differentiation, as evidenced by a four-fold increase in the surface expression of erythroid markers (CD71, CD235a) and a significant upregulation of beta-globin gene cluster markers. These findings collectively suggest an antagonistic functional relationship between ADNP and LSD1, potentially counterbalancing LSD1's role in lineage allocation. Furthermore, we demonstrate that the loss of the key ChAHP component, ADNP, substantially hampers proliferation and increases apoptosis in K562 cells. These results underscore the potential of ADNP/ChAHP as an appealing target to modulate the choice between erythroid and megakaryocytic fates and offer promise as a target for pro-differentiation therapies in AML

#5631 YAP1 is a critical factor for FUS::DDIT3/BAF/c-Jun complex assembly in myxoid liposarcoma.

R. Berthold[1], I. Isfort[1], L. Heinst[1], E. Wardelmann[1], P. Aman[2], C. Scholl[3], M. Trautmann[1], S. Frohling[4], W. Hartmann[1];

[1]Gerhard-Domagk-Institute of Pathology, Munster University Hospital, Munster, Germany, [2]Sahlgrenska Center for Cancer Research, Institute of Biomedicine, Department of Laboratory Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [3]Division of Applied Functional Genomics, German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT) Heidelberg, Heidelberg, Germany, [4]Division of Translational Medical Oncology, National Center for Tumor Diseases (NCT) Heidelberg and German Cancer Research Center (DKFZ), German Cancer Consortium (DKTK), Heidelberg, Germany

Introduction: FUS::DDIT3 is the dominant fusion protein in myxoid liposarcoma (MLS), resulting from a disease-defining chromosomal translocation. Acting as an aberrant transcription factor, FUS::DDIT3 disturbs gene regulatory networks interfering with adipogenic differentiation, while driving oncogenic gene expression and proliferation. Functionally, FUS::DDIT3 has been shown to cooperate with the transcriptional coregulator YAP1 and to interact with the BAF chromatin remodeling complex. However, mechanistic details on FUS::DDIT3's function in transcriptional dysregulation leading to proliferative effects and the required interactome are incompletely understood. This study was performed to investigate transcriptional and epigenetic players recruited by FUS::DDIT3 to drive MLS proliferation and tumorigenesis.

Experimental Procedures: To study protein-protein interactions between FUS::DDIT3 and its interacting partners, co-immunoprecipitation experiments of nuclear extracts and proximity ligation assays were performed using human MLS cell lines. To further investigate dependencies of nuclear complex assembly, combined RNA interference (RNAi) experiments were conducted. MLS cell viability and proliferation were assessed using MTT assays and xCELLigence real-time analysis, respectively. RT-qPCRs were performed to analyze the expression of FUS::DDIT3 target genes. The expression of FUS::DDIT3's interacting proteins was evaluated by immunohistochemistry in primary human MLS specimens.

Results: Co-immunoprecipitation and proximity ligation assays demonstrated nuclear interactions between FUS::DDIT3, YAP1, and the canonical BAF (cBAF) complex in MLS cell lines. In addition, a novel interaction of FUS::DDIT3 with the AP-1 transcription factor c-Jun was identified. Knockdown of the cBAF-specific subunits ARID1A and ARID1B resulted in reduced MLS cell viability and proliferation. Similarly, RNAi-mediated silencing of c-Jun impaired MLS cell viability and led to decreased expression of FUS::DDIT3 target genes. Strikingly, RNAi-mediated silencing of YAP1 resulted in decreased interaction of FUS::DDIT3 with cBAF components and c-Jun in MLS cells.

Conclusions: Our results identify YAP1 as a key factor mediating the nuclear interaction of FUS::DDIT3 with the cBAF complex and the AP-1 transcription factor c-Jun, both shown to be essential for MLS cell proliferation.

#5632 Advancing transcriptome insights during RNA-Seq library construction of FFPE samples in a novel workflow.

C. Jiang, E. Jordan Dreskin, A. Olcott, L. Lingelbach, S. Perike;
Bio-Rad Laboratories, HERCULES, CA

Formalin-fixed, paraffin-embedded (FFPE) tumor tissue has significant clinical benefits in oncology research and is considered vital for studying tumor gene expression through RNA sequencing (RNA-Seq). However, RNA extracted from FFPE samples tends to be severely degraded, making it suboptimal for constructing high-quality RNA-Seq libraries. The RNA-Seq workflow can further impair data quality, as traditional library preparation and pre-library ribodepletion workflows may result in the loss of valuable information due to rare transcripts being not captured or washed away. Moreover, small, degraded fragments are a challenging template for ligases, and the resulting adapter addition may be inadequate. Here we assessed a novel workflow employing a proprietary enzyme to overcome the limitations and biases of cDNA synthesis using reverse transcriptase (RT) and ligases. This innovative RNA-Seq library preparation approach, coupled with a post-library ribodepletion strategy, aims to capture a more complete transcriptome profile from RNA extracted from FFPE breast cancer samples, and can also be used for evaluation of gene regulation through intronic and intergenic bases. The study also compared two commercially available kits, RecoverAll and PureLink, for FFPE RNA extraction, evaluating quality metrics such as RNA integrity number (RIN), DV200, recovery of small RNAs during NGS library construction, and transcriptome coverage. A parallel fresh frozen RNA sample, extracted using a phenol-based reagent, served as a benchmark. Our findings demonstrate that the novel workflow yields a richer dataset, encompassing a wider range of transcriptomic elements, including both small and long RNAs from FFPE samples. Performing ribodepletion after the library preparation procedure led to increased detection of small RNAs compared to pre-library ribodepletion. The robust analytical performance of this streamlined library preparation protocol enables its suitability for RNA-Seq analysis of archived FFPE specimens, offering substantial utility for oncology research.

#5633 Unravelling the pleiotropic role of HNF4α in invasive mucinous adenocarcinoma of the lung (IMA).

H. Essel Dadzie, G. Fort, K. Gillis, P. Fang, W. Orellana, E. L. Snyder;
University of Utah Huntsman Cancer Institute, Salt Lake City, UT

IMA is a distinct subtype of lung adenocarcinoma (LUAD), marked by a cellular identity shift from a pulmonary to a gastric lineage with the loss of the pulmonary lineage specifier NKX2-1. This distinctive transformation underscores the complexity of lung cancer heterogeneity and highlights the critical role of lineage-specifying transcription factors in dictating tumor behavior. Notably, both human and murine models of IMA overexpress HNF4α, a known lineage specifier for gastric differentiation in the adult mouse mucosa. Also, concomitant deletion of *Hnf4a* and *Nkx2-1* at tumor initiation impairs tumor growth and the extent of HNF4α in regulating IMA tumor growth, cellular identity and drug response remains unknown at large. Here, we utilized genetically engineered mouse models (GEMM) that relies on a sequential recombination strategy to delete *Hnf4a* in established tumors. We induce tumor formation through intratracheal delivery of Flp-O virus, activating the expression of mutant $KRAS^{G12D}$ and Cre in lung epithelial cells. Tamoxifen administration recombines either *Nkx2-1* alone (KN) or in combination with *Hnf4a* (KNH). We have extensively studied the phenotypic role of HNF4α in GEMM and organoids and identified gene sets regulated by HNF4α in IMA at the bulk level. To complement our findings, we profiled both the tumor and stromal compartments via scRNAseq analysis on our GEMM to gain insights into the cellular diversity within the tumor microenvironment (TME) and the role HNF4α plays. Additionally, we performed ChIPSeq in organoids to elucidate the genome occupancy of HNF4α and determine the mechanisms of gene regulation in IMA. We find that deletion of *Hnf4a* impairs tumor growth in GEMM and this is phenocopied in organoids. We identified numerous differentially expressed genes (DEGs) in KNH compared to KN and validated several DEGs in vivo. GSEA analysis reveals a significant involvement in regulating cellular identity and suggests a potential impact on anti-tumor immune responses. To this, our scRNAseq data revealed an enrichment of N2-TAN (tumor associated neutrophils) associated genes in KNH compared to KN, suggesting a nuanced interplay between HNF4α and the TME. Additionally, HNF4α exhibited dual functionality, acting as an activator and indirectly as a repressor by modulating the activity of other transcription factors like FOXA1. FOXA1 was found to bind de novo target genes following the loss of HNF4α. These findings so far collectively illuminate the multifaceted role of HNF4α in IMA, primarily driving tumorigenesis in a cell autonomous manner and secondarily skewing the TME towards a protumor via N2-TAN following loss of HNF4α in tumors.

#5634 Tristetraprolin induces an antitumorigenic phenotype in triple negative breast cancer via a novel non-canonical mechanism.

J. L. Rutherford, M. B. Stemberger, R. Mahmud, C. R. Ross, E. J. F. White, G. M. Wilson;
University of Maryland, Baltimore, Baltimore, MD

The ultimate cause of death for most triple negative breast cancer (TNBC) patients is metastatic disease, which has a five-year survival rate of 12.8%. This low survival rate is partly due to the lack of targeted treatments for metastatic TNBC, resulting from the heterogeneity of the disease. As such, further research is needed to identify novel molecular mechanisms that can be targeted to suppress TNBC malignancy. Tristetraprolin (TTP) is an RNA-binding protein that binds to AU-rich elements (AREs) in the 3' UTRs of select mRNAs, including many that encode proteins involved in cancer-related processes, and targets these mRNAs for degradation. Loss of TTP in tumors correlates with increased disease severity and decreased survival, suggesting a role as a tumor suppressor in multiple cancers, including breast cancer. While previous research has shown that TTP can suppress proliferation in breast cancer, the mechanism remains weakly defined. To elucidate how TTP impacts tumorigenic phenotypes in advanced breast cancer, we stably transfected a FLAG-TTP-expressing construct into three aggressive and metastatic TNBC cell lines. We analyzed TTP-induced changes in gene expression patterns among these cell lines using RNA-sequencing and observed that TTP alters the expression levels of many genes. Gene Set Enrichment Analysis (GSEA) of our datasets revealed that TTP affects multiple pathways, including significant suppression of pathways that promote cell growth, various metabolic processes contributing to tumor growth, and the response to hypoxia. As these pathways highly associated with tumorigenesis, we hypothesized that TTP would attenuate multiple tumor phenotypes. Our subsequent functional analyses revealed that TTP potently suppressed four tumor phenotypes in these cell models: cell proliferation, stem cell frequency, migration, and invasiveness. We hypothesized that inhibition of proliferation was mediated by cell cycle alterations, however, flow cytometry analysis revealed no substantial cell cycle perturbations between TTP-expressing cells and controls. Further analysis of cell cycle regulators revealed minimal changes in expression of proteins encoded by known or suspected TTP target mRNAs. Actinomycin D assays surprisingly revealed that TTP had no effect on the decay kinetics of several known TTP targets, suggesting that TTP's antitumorigenic properties observed in TNBC cells are independent of its RNA-destabilizing function. To confirm this finding, we constructed cell models expressing an RNA-binding defective mutant of TTP, C147R, which recapitulated suppression of the four tumorigenic phenotypes seen with the wild-type protein. Collectively, these findings reveal that expression of TTP can potently suppress several oncogenic phenotypes in TNBC cells via a mechanism independent of its canonical RNA-binding/destabilizing functions.

#5635 TPM4 overexpression promotes colon epithelial cell tumorigenesis *in vitro* and correlates with human colon tumor progression *in vivo*.

G. Ferrero[1], B. Pardini[2], A. Naccarati[2], **M. Papetti**[3];
[1]University of Turin, Turin, Italy, [2]Italian Institute for Genomic Medicine, Turin, Italy, [3]Touro University, New York, NY

Because colon cancer still exerts a heavy burden on human health, we are interested in identifying very early events in colon epithelial cell tumorigenesis in order to develop strategies to treat and possibly prevent colon carcinogenesis. We hypothesize that aberrant expression of genes involved in crypt-luminal colon epithelial cell migration, needed for proliferative, undifferentiated stem cells at the crypt bottom to mature into growth arrested, mature effector cells near the lumen, may disrupt normal differentiation and initiate events that can trigger the transition from a normal to premalignant state in colon epithelial cells. Forced upregulation of tropomyosin 4 (TPM4), an actin-binding protein that exerts many effects on contractility and migration, prevents certain aspects of Caco2 maturation induced by contact inhibition of growth, including increased expression of the digestive enzyme sucrose isomaltase and glutathione S-transferase alpha 1. Furthermore, TPM4.2-overexpressing cells exhibit numerous morphological abnormalities. Compared to untransfected Caco2 cells and empty-vector stable transfectant controls, TPM4.2-overexpressing Caco2 cell clones elaborate aberrant thin membrane protrusions and expanded membrane ruffles. Particularly striking are defective maintenance of dome structures at middle (day 14) and late (day 21) time points of induced differentiation in TPM4.2-overeexpressing clones. We further hypothesize that TPM4 is overexpressed in human colon tumors, particularly at early stages of tumorigenesis. In order to test this hypothesis, we examined TPM4 RNA expression in datasets obtained from human colon tissue at premalignant as well as tumorigenic stages. TPM4 trends toward overexpression in premalignant, relative to normal, human colon tissue (uninvolved mucosa from patients with familial adenomatous polyposis, or FAP) and is significantly overexpressed in adenocarcinoma tissue relative to normal controls. Interestingly, TPM4 overexpression may be more pronounced at earlier, rather than later, stages of adenocarcinoma. Our results suggest that aberrant TPM4 overexpression in colon epithelial cells can promote adoption of a tumorigenic state. Certain aspects of Caco2 cell maturation are disrupted by forced TPM4 overexpression during induced differentiation, and TPM4 overexpression correlates with early stages of colon tumorigenesis. Misregulation of TPM4 gene expression may therefore represent a critical molecular event that can block normal differentiation and induce early events in colon epithelial cell tumorigenesis. TPM4 expression level may therefore prove to be a useful biomarker that can, along with other diagnostics, help to determine tumorigenic progression in human colon tissue and to develop novel strategies to prevent colon cancer and treat it at early stages.

#5636 CUX1 transcriptionally regulates intestinal epithelial homeostasis.

K. Zawieracz, N. An, M. McNerney;
The University of Chicago, Chicago, IL

The small intestine digests and absorbs nutrients, a role made possible by specialized secretory and absorptive cells that constantly replenish from the intestinal stem cell niche. Disruption in intestinal epithelium homeostasis has been linked to pathologies including inflammatory bowel disease (IBD) and cancer. However, the processes regulating differentiation in healthy and disease setting are incompletely understood. CUX1 is a highly conserved homeodomain-containing transcription factor that is expressed in small intestinal crypts and has been previously shown to be essential in mice and *Drosophila*. CUX1 is upregulated upon inflammatory stress conditions, including intestinal damage and in IBD. In addition, CUX1 is predicted to be protective against IBD from genome-wide association studies. The aim of the current work is to determine the mechanistic role of CUX1 in secretory intestinal cells differentiation and epithelial homeostasis. To this end, we have generated transgenic mouse models that modulate CUX1 levels in an inducible manner. Mice with near-null CUX1 levels exhibit rapid weight loss requiring euthanasia while mice with ~50% residual CUX1 halt normal weight gain. Histologic examination of tissues from mice with CUX1 knock-down reveals a lack of mature secretory cells, including goblet and Paneth cells, the latter playing a supportive role to intestinal stem cells. Moreover, mouse intestinal tissues from our knock-down models demonstrated decreased proliferation with increased apoptosis. In transcriptome profiling, we observed downregulation of proliferation, intestinal stem cell, and digestive system developmental gene signatures and decreased levels of key secretory cell regulators, pointing towards a role for CUX1 in stem cell maintenance and differentiation. Indeed, reducing CUX1 levels decreased β-catenin protein levels, while Wnt/β-catenin signaling is required for the organization of the crypt-villus axis. Finally, CUX1 knock-down compromises the ability to form budding organoids, demonstrating the cell intrinsic role for CUX1 in stem cell differentiation. In ongoing studies, we are identifying CUX1 genome-wide binding targets and the epigenetic impact of CUX1 in intestinal epithelium cells. Our findings indicate that CUX1 is a critical regulator of intestinal epithelium homeostasis that has a role in differentiation and potential role in injury-induced de-differentiation in healthy as well as IBD patients. We propose that CUX1 regulates stem cell maintenance and crypt composition by regulating Wnt/β-catenin signaling and inducing fetal-like transcriptomic repair program shown to be coopted by colon cancers. Resolving an intricate network of transcriptional regulation of differentiation in the intestinal crypt holds the potential to successfully target inflammation-related damage in human intestines.

#5638 The BAF complex mediates intertwined activity of YAP1 and β-catenin in synovial sarcoma.

I. Isfort, R. Berthold, L. Heinst, A. Kuntze, E. Wardelmann, M. Trautmann, W. Hartmann;
Gerhard-Domagk-Institute of Pathology, Munster University Hospital, Munster, Germany

Introduction: Synovial sarcoma (SySa) is a rare malignant soft tissue tumor characterized by a specific reciprocal translocation t(X;18). The resulting chimeric SS18::SSX fusion protein drives SySa tumorigenesis by integrating into BAF chromatin remodeling complexes, changing their composition and dysregulating gene transcription. The role of BAF complexes in cancer steadily increases with ~20% of all malignancies having alterations in BAF complex subunits. BAF complexes are multiprotein complexes with several interaction partners determining their localization and functionality. Since previous analyses revealed an induced activation of the transcriptional coregulators YAP1 and β-catenin in SySa, the aim of this study was to analyze if nuclear YAP1 and β-catenin are interacting with BAF complexes and if this has an impact on their transcriptional activity.
Experimental procedures: Co-immunoprecipitation experiments on nuclear protein extracts and proximity ligation assays were performed to investigate interactions between YAP1, β-catenin, and BAF complex subunits in SySa cells. Knockdown of common and specific BAF complex subunits was conducted employing RNA interference. To assess changes in YAP1 and β-catenin transcriptional activities, TEAD and TOPFlash luciferase reporter assays were performed, respectively, and protein expression levels were detected by immunoblotting.
Results: In SySa, protein-protein interaction experiments revealed nuclear interactions between β-catenin, YAP1, the SS18::SSX fusion protein and various BAF subunits. YAP1 and β-catenin's transcriptional activities were found to be interdependent as they mutually enhanced each other's activation. Knockdown of SS18::SSX as well as specific BAF complex subunits was associated with diminished transcriptional activities of these coregulators and, interestingly, substantially affected their mutual activation. This indicates that SS18::SSX-containing BAF complex assembly is crucial for interdependent YAP1 and β-catenin activation in SySa cells.
Conclusions: This study reveals a significant role of the SySa-specific fusion protein and BAF chromatin remodeling complexes in mediating intertwined activation of YAP1 and β-catenin.

#5639 TIP60-independent mechanism of BRD8 is involved in colorectal tumorigenesis.

K. Yamaguchi[1], S. Nakagawa[1], R. Yamaguchi[2], P. Sheridan[1], K. Takane[1], T. Ikenoue[1], S. Nagatoishi[1], H. Kozuka-Hata[1], M. Oyama[1], S. Aikou[1], Y. Ahiko[1], D. Shida[1], K. Tsumoto[1], S. Miyano[1], S. Imoto[1], Y. Furukawa[1];

[1]University of Tokyo, Tokyo, Japan, [2]Aichi Cancer Center Research Institute, Nagoya, Japan

Modifications of histone tails control chromatin structure, and the acetylation is generally associated with euchromatin and transcriptional activation. Acetylated lysine residues are recognized by bromodomains, which serve as acetyl-lysine binding modules and participate in transcriptional regulation. Bromodomain-containing protein 8 (BRD8) is a subunit of the NuA4/TIP60-histone acetyltransferase complex. Although BRD8 has been considered to act as a co-activator of the complex, its biological role remains to be unclear. In this study, we revealed that BRD8 accumulates in colorectal cancer cells through the inhibition of ubiquitin-dependent protein degradation by the interaction with MRG domain binding protein (MRGBP). RNA-seq analysis coupled with genome-wide mapping of BRD8-binding sites disclosed that BRD8 transactivates a set of genes independently of TIP60, a catalytic subunit of NuA4 complex, and that BRD8 regulates the expression of multiple subunits of the pre-replicative complex (pre-RC) in concert with the activator protein-1 (AP-1) transcription factor. Depletion of BRD8 induced cell-cycle arrest at the G1 phase and suppressed proliferation of colorectal cancer cells. We have also shown that the bromodomain of BRD8 is indispensable for not only the interaction with histone H4 or transcriptional regulation but also its own protein stability. These findings provide a new insight into the roles played by BRD8 in human colorectal carcinogenesis and will contribute to the development of new chemotherapeutic agents targeting the bromodomain of BRD8.

#5640 Unlocking the therapeutic potential of SF3B1 inhibitors for bladder cancer treatment.

R. Columbres, A. Chakraborty, A. Apolo, R. Banday;
NIH-NCI, Bethesda, MD

RNA splicing dysregulation is a hallmark of cancer, occurring in multiple solid and hematological malignancies. Splicing factor 3 subunit B1 (SF3B1), a key component of the U2 small nuclear ribonucleoprotein (snRNP) complex that regulates RNA splicing, is frequently altered in a variety of cancer types, including non-muscle-invasive and muscle-invasive bladder cancer, where the E902K mutation is common. In this study, we investigated the therapeutic potential of the SF3B1 inhibitor, pladienolide B, in bladder cancer using *in vitro* models. We used a recombinant plasmid containing the SF3B1^{E902K} mutation and established an UMUC3^{E902K} mutant urothelial cell line. Both UMUC3^{WT} and UMUC3^{E902K} cells were treated with pladienolide B alone or in combination with cisplatin to evaluate differences in cell viability. Flow cytometry using annexin V staining and propidium iodide exclusion was utilized to assess the cell death mechanism. RNAseq was performed after RNA extraction from UMUC3^{WT}, UMUC3^{E902K}, RT4, and HT1376 bladder cancer cell lines were treated with pladienolide alone or combined with cisplatin. We determined that the IC50 for pladienolide B is 5nM for UMUC3 cells observed 72 hours post-treatment. Treatment with pladienolide B halted the cell cycle and caused cell death by apoptosis for both UMUC3^{WT} and UMUC3^{E902K} cell lines. We also observed that UMUC3^{E902K} cells were significantly more sensitive to pladienolide B compared to UMUC3^{WT} cells ($p \leq 0.05$). Furthermore, there was a synergistic effect observed after co-treatment with low-dose pladienolide B (2 nM) and cisplatin (3 µM) for both UMUC3^{WT} and UMUC3^{E902K} cell lines, with UMUC3^{E902K} cells showing greater sensitivity to combination treatment. Our results provide insights into the potential use of splicing inhibitors, alone or in combination with chemotherapy, for treating bladder cancer, specifically for tumors that bear driver mutations in splicing factors. Currently, we are evaluating the mechanism by which SF3B1 mutations make cells sensitive to pladienolide B *in vitro* and *in vivo,* with the goal of identifying specific mRNA splicing vulnerabilities that can be targeted by anti-sense or splice-switching oligonucleotides to achieve anti-tumor outcomes. Additional differential splicing patterns and preliminary *in vivo* results will be presented.

#5641 Transcriptional regulation by nuclear deformation.

A. Cook[1], R. Stephens[1], N. Fursova[2], C. C. Chow[1], D. Larson[2], Y. Miroshnikova[1];
[1]National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), Bethesda, MD, [2]National Cancer Institute (NCI), Bethesda, MD

Establishment and maintenance of cell identities requires transcriptional rewiring and modulation of three-dimensional genome organization. The nucleus is subject to constant mechanical forces, both intrinsic from the cytoskeleton and extrinsic, such as compression, confinement, and stretch. Recently, work from us and others implicate mechanical force, through activating biochemical signaling pathways as well as direct nuclear deformation, in remodeling nuclear architecture, chromatin state and global gene expression patterns. Thus, we hypothesize that mechanical force plays an important role in coordinating and thresholding transcriptional responses. Here, we challenge this hypothesis by quantifying the effect of nuclear deformation on transcription in real time at single cell resolution quasi genome wide. Further, recent work elucidated that the MYC oncogene exerts global effects on transcriptional output by altering the binding dynamics of transcription factors involved in the activation and productive elongation of RNA Polymerase II. This contrasts with mechanical stress which reduces global levels of RNA Polymerase II. Here we interrogate how transcriptional output is tuned for specific genetic programs/loci by mechanical force using MYC as a paradigm.

#5643 Targeted RNA-seq of dried blood microsamples for convenient RNA biomarker monitoring.

L. Kobzik, T. Liu, M. Makhanov, D. Hu, K. Ghias, P. Diehl, **A. Chenchik**;
Cellecta, Inc., Mountain View, CA

Microsampling lancet-induced blood drops enables frequent and comprehensive analysis of various metabolites, lipids, cytokines, and proteins. This approach holds promise for monitoring immunotherapy patients using RNA biomarkers, but a suitable method for processing RNA has been lacking.
In this study, we employed a targeted RNA-sequencing protocol, the DriverMap™ EXP assay, to process 30 ul of dried blood. We compared the gene expression profile in traditionally collected blood samples with that of blood absorbed onto a Mitra® microsampling device containing an RNA-stabilization reagent. Following endotoxin incubation, RNA was extracted from stimulated and unstimulated blood samples. Targeted PCR amplification of 274 immune/inflammatory genes using the DriverMap targeted RNA-Seq protocol demonstrated robust detection and high correlation (r = 0.94) between the two methods in both unstimulated and endotoxin-stimulated blood. Moreover, differentially expressed genes (DEGs) identified in standard and microsampling methods exhibited substantial overlap with publicly available datasets from similar experiments. Furthermore, we compared whole blood extracted from Tempus™ blood RNA tubes to Mitra microsamples pre- and post-immunization with the Pneumovax® vaccine using the DriverMap EXP genome-wide 19K panel for targeted RNA-sequencing. We observed approximately 90% overlap in the top 10K genes between Tempus and Mitra microsamples. Notably, microsamples stored at 4ºC for over a year exhibited similar expression profiles to more recently drawn whole blood samples.

#5644 The impact of ATF3, JDP2, FOXR2, NAA10, FOXL2, DDX20, and p14ARF on the transactivation of p53.

W. H. Yang, W.-H. Yang;
Mercer University School of Medicine, Savannah, GA

Cancer stands as a formidable health challenge in the 21st century, evoking widespread fear. Presently, the mortality rate associated with cancer in humans ranges from approximately 11% to 25%. Numerous nuclear and cytoplasmic proteins have demonstrated interactions with p53, influencing both its activity and abundance. In our prior, unpublished findings, we established that JDP2 interacts with p53, modulating its activity. Consequently, in the present investigation, we broaden our exploration to identify novel proteins capable of regulating p53 transactivation. First, we found a synergistic effect of ATF3 and JDP2 on p53 transactivation. Moreover, deSUMOylation of ATF3 and dephosphorylation of JDP2 further enhance p53 transactivation. Secondly, FOXR2 (an epigenetically regulated pan-cancer oncogene) and NAA10 (an acetyltransferase) also remarkably increase p53 transactivation in H1299 (p53 null) cells. Thirdly, in addition to MDM2 and MDM4 (MDMX) as p53 negative regulators, we further found that FOXL2 (a transcription factor in steroidogenesis regulation), DDX20 (a transcription factor for embryonic development and ovarian function), and p14ARF (for cell cycle regulation) significantly down-regulate p53 transactivation. Taken together, our preliminary results demonstrate that several transcription factors regulate p53 transactivation and possible p53 stability and/or degradation. This data is presented to substantiate the idea that numerous newly discovered proteins may engage with p53 and control its transactivation.

#5645 HuR regulates aerobic glycolysis in triple negative breast cancer (TNBC).

A. Dev J R, A. Gogia, S. R. Mathur, S. Deo, C. Prasad;
All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Introduction: The RNA-binding protein Human Antigen R (HuR/ELAVL1) is ubiquitously expressed and exerts post-transcriptional regulation on mRNAs characterized by U/AU-rich sequences in their 3' UTR. Elevated cytoplasmic expression of HuR has been associated with various malignancies, influencing key cellular processes such as proliferation, apoptosis, angiogenesis, and metastasis. The involvement of HuR influences prognostic outcomes and hence is a potential biomarker and therapeutic target in cancer research. The present study investigates the oncogenic role of HuR in TNBCs, an aggressive subtype of breast cancer.

Methods: Immunohistochemistry was performed on TNBC patient tumor tissue (n=40) to asses the expressions of HuR and MMP9. Human TNBC cell lines MDA-MB-231 and MDA-MB-468 were used for *in vitro* studies after confirming cytoplasmic HuR accumulation in these cells via Immunofluorescence. The RNA binding activity of HuR was disrupted using CMLD2, a specific inhibitor of HuR, and subsequent physiological changes were assessed through functional assays. An exploratory investigation of HuR-moderated metabolic changes was performed employing NANOSTRING nCounter XT gene expression assay using metabolic pathways panel. Investigation and/or validation of molecular changes were done via immunoblotting.

Results: Meta-analysis using Liu-2014 TNBC dataset correlated high HuR protein expression with reduced patient survival (p=0.028). HuR (77%) and MMP9(55%) were found to be overexpressed in TNBC tissues. Inhibiting HuR with CMLD2 resulted in the downregulation of the protein and its downstream targets CDK2, MMP9, and β catenin. HuR inhibition compromised proliferation, migration, Matrigel invasion and EMT (downregulated E-Cadherin, N-Cadherin, and Vimentin) in TNBC cell lines. Further, HuR inhibition resulted in decreased clonogenicity in 2D and 3D TNBC cultures. Transcriptomics studies showed that HuR inhibition in MDA-MB-231 altered the profile of glycolytic genes in addition to other pathways such as cell cycle and DNA damage repair. In accordance, the expression of glycolytic proteins was reduced upon CMLD2 treatment. Similar results were obtained on HuR knockdown by siRNA suggesting that HuR-mediated effects on TNBC progression might be in part through its modulation of aerobic glycolysis.

Conclusion: Overall, our results demonstrate HuR as a positive regulator of aerobic glycolysis in TNBCs and the ability of CMLD2 to inhibit HuR provides a rationale to consider it as a potential anticancer agent for TNBCs.

#5646 Altered intronic polyadenylation by mutant p53 impairs transcription of DNA repair genes in lung cancer.

Liang Liu, Elizabeth Forbes, Wei Zhang

Wake Forest School of Medicine, Winston Salem, NC

Introduction: Changes in alternative pre-mRNA processing have been found in many cancers. Aberrant intronic polyadenylation (IPA) causes a stop of normal transcription resulting in the production of truncated mRNA isoform or lncRNA. We sought to examine the role of mutant p53 in pre-mRNA processing, especially in IPA regulation in lung cancer.

Methods: We established stable cell lines transfected with mutant p53 (R273H, R175H, H179Q, C238Y, and C242F) or vector control using the NSCLC cell line H1299 with a homozygous deletion of the endogenous p53. Total RNA was used to build libraries enriched in sequences near polyadenylation sites (PASs) using the 3'mRNA-Seq REV library kit (Lexogen; Greenland, NH). Sequencing reads were mapped to the human genome (GRCh37), and PASs with ≥2 supporting reads and ≥0.05 usage in any experiment were identified. Counts for each Intronic Polyadenylation (IPA) and total reads in the terminal exon were compiled into matrices for each condition. DEXseq was applied to detect changes in the relative abundance of each exon part normalized to all exons within the gene. Gene Ontology (GO) analysis was implemented using the enrichR package.

Results: We identified 32,752 IPA sites in 5,718 genes, and 26,416 distal PASs (dPASs) in the 3'UTRs of 10,298 genes. Across all five cell lines, when compared individually to the vector control, a comprehensive shift in IPA events was observed, with a concurrent decrease in dPASs. Many of IPA isoforms exhibited consistent patterns of increased or decreased abundance changes. Upon closer examination of each individual cell line, such as the p53-R273H cell line (vs. vector), significant usage changes were identified for 2,389 IPA sites, of which 1,210 were increased and 1,128 terminal exons were altered, with 650 being suppressed. At the gene level, a total of 1,183 genes had at least one significantly increased IPA isoform, a significantly decreased distal isoform, or both. GO analysis showed that these genes were highly enriched in DNA repair-related functional terms such as DNA repair, double-strand break repair, and nucleotide excision repair. The observed IPA changes in DNA-repair genes were consistently observed across the other 4 mutant lines (vs. vector). This observation was further supported by analyzing data from patients with lung adenocarcinoma (LUAD) in the TCGA cohort, where we selected samples carrying nonsense/ frameshift mutations, and/or a deep deletion as the p53-null control group, and those carrying missense mutations as the p53-mutant group.

Conclusions: Our study illustrated a novel role of p53 mutants in the regulation of intronic polyadenylation processing that contributes to deficient DNA repair. These observations offer a fresh perspective on the multifaceted roles of p53 in cellular homeostasis.

Acknowledgment: This work was supported by NCI Cancer Center Support Grant P30CA012197 and NIH/NCI grant R03CA256100.

#5647 Investigating the role of AP-2α in melanomagenesis.

N. Bartschat, J. Chang, M. Suraju, R. Nagel, Z. Li, J. White, C. Kenny, R. Weigel;
University of Iowa, Iowa City, IA

Introduction: Transcription factor AP-2α (encoded by the *TFAP2A* gene) is a protein involved in the early development of multiple tissues, particularly the neural crest. Melanocytes are derived from the neural crest and their development appears to rely on AP-2α and its paralogues, along with master regulator MITF. Prior studies have indicated that AP-2α is a crucial regulator of melanoma metastasis. However, it is unclear if AP-2α plays a role in melanomagenesis. We sought to understand the role of AP-2α in melanomagenesis, hypothesizing that knock out (KO) of *TFAP2A* would suppress malignant potential *in vitro* and downregulate genetic pathways linked to malignant transformation.

Methods: *TFAP2A* KO was generated with a single-guide RNA CRISPR/Cas9 system targeting exon 3 of the gene in the human melanoma cell line A375. Tumorigenesis phenotype was assessed by evaluating contact-independent colony formation with the *in vitro* soft agar assay. To identify downstream regulatory programs controlled by *TFAP2A*, we then utilized RNA-seq and Gene Set Enrichment Analysis (GSEA, San Diego). RNA-seq was performed on four clones each for wildtype and *TFAP2A* KO samples and the resulting data was processed using GSEA to identify gene sets modified after *TFAP2A* KO.

Results: Targeting of *TFAP2A* with CRISPR/Cas9 effectively knocked out AP-2α protein expression in the A375 melanoma cell line. Colony formation on soft agar assay was significantly decreased after *TFAP2A* KO ($P < 0.01$). RNA-seq revealed significant differential expression of 11,195 genes after *TFAP2A* KO. Gene sets with negative enrichment after *TFAP2A* KO included those overall higher in tumors versus normal tissue (FWER $P = 0.003$) and multiple signaling pathways related to malignant transformation such as TGF-β (FWER $P = 0.003$), MYC (FWER $P = 0.009$), KRAS (FWER $P = 0.03$), and Notch (FWER $P = 0.043$).

Conclusions: Our data suggests that *TFAP2A* plays a role in cutaneous melanomagenesis. *TFAP2A* may represent a therapeutic target for melanoma, though further pre-clinical studies are needed. We plan to further test this hypothesis in a melanoma mouse model with conditional *TFAP2A* KO under the control of inducible Cre recombinase driven by the mouse tyrosinase gene promoter.

#5648 Decoding the non-canonical functions of HO-1 in prostate cancer: A nuclear perspective and its association with a neuroendocrine signature.

Seniuk A. Rocio[1], Agustina Sabater[2], Pablo Sanchis[2], Juan Bizzotto[1], Gaston Pascual[1], Estefania Labanca[3], Nicolas Anselmino[3], Nora Navone[3], Elba Vazquez[1], Pia Valacco[1], Javier Cotignola[1], Ayelen Toro[1], Geraldine Gueron[1]

[1]CONICET - IQUIBICEN, Ciudad Autonoma de Buenos Aires (CABA), Argentina, [2]1-CONICET - IQUIBICEN. 2-Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), Ciudad Autonoma de Buenos Aires (CABA), Argentina, [3]Department of Genitourinary Medical Oncology and The David H. Koch Center for Applied Research of Genitourinary Cancers, The University of Texas MD Anderson Cancer Center, Houston, TX 77030, USA., Houston, TX, United States, Houston, TX

Previous studies have demonstrated the non-canonical anti-tumor effect of heme-oxygenase 1 (HO-1) in prostate cancer (PCa). Although HO-1 is crucial for free heme degradation, its nuclear expression unveils non-canonical functions beyond its enzymatic function. Understanding the specifics of its non-canonical role remains a critical unmet need. In this study, we identified nuclear interactors of HO-1 and assessed their association with PCa.PCa cells were treated with hemin (80 µM, 24 h), a specific pharmacological inducer of HO-1. Nuclear HO-1 immunoprecipitation and LC-ESI MS/MS analysis identified 11 differential nuclear associated-HO-1 proteins between control and hemin-treated PCa cells (ILF3, ILF2, BCLAF1, SAFB, DDX17, SLC25A5, CASP14, PRDX1, BRIX1, CCDC175, and GPATCH1). Next, we performed an Ingenuity Pathway Analysis (QIAGEN) showing that ILF3 appears as a master regulator of this signature. To assess the clinical relevance of these factors in PCa, we analyzed overall survival (OS), progression-free survival (PFS), relapse free survival (RFS) in multiple PCa datasets (GSE34312, GSE35988, GSE3933, GSE46602, GSE6956, GSE70768, TCGA-PRAD, GSE70770, GSE16560, GSE24136; n=1064). We performed univariable and multivariable analyses for these factors and identified the ones that significantly and independently affected the OS, RFS, PFS. Next, a risk score model was built based on the expression of 9 genes ($\sum n_i=1(Coef_i \times Expr_i)$) for the GSE70770 dataset using these factors identifying a subpopulation of PCa patients with high-risk of RFS (HR: 7.39 High vs Low score, $p<0.0001$); ascertaining the critical role of this signature in PCa. To elucidate the association of these factors with the aggressive phenotype of PCa, we analyzed RNA-seq expression data from the MDA-PCa-PDXs series (PCa Patient Derived Xenografts Program; MD Anderson Cancer Center), capturing PCa heterogeneity. Unsupervised clustering analysis revealed that samples with high expression of HO-1 nuclear interactors corresponded to neuroendocrine tumors, negative for androgen receptor staining. Principal Component Analysis identified ILF3 as the most relevant HO-1 interactor driving PDXs' samples variance, correlating with a significant decrease in relapse-free survival of PCa patients. Further, we used ChIP-Atlas to assess the epigenomic landscapes for these nuclear HO-1 interactors. Results indicated that 40% of HO-1 nuclear interactors were potential transcription regulators. Strikingly, KEGG pathways analyses revealed that their regulomes were significantly associated with neurodegenerative disorders, highlighting their relevance in neural processes. In conclusion, our findings suggest that HO-1 and its nuclear interactors may play a pivotal role in neuroendocrine PCa, shedding light on potential therapeutic targets for this aggressive form of the disease.

#5649 PRRX1-TOP2A interaction is a malignancy-promoting factor in human malignant peripheral nerve sheath tumors.

S. Takihira, E. Nakata, D. Yamada, T. Osone, T. Takao, T. Takarada, A. Hirasawa, T. Itano, T. Fujiwara, T. Kunisada, T. Ozaki;
Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan

Background: Paired related-homeobox 1 (PRRX1) is a transcription factor in the regulation of developmental morphogenetic processes. There is growing evidence that PRRX1 is highly expressed in certain cancers and is critically involved in human survival prognosis. However, the molecular mechanism of PRRX1 in cancer malignancy remains to be elucidated.
Methods: PRRX1 expression in human Malignant peripheral nerve sheath tumors (MPNSTs) samples was detected immunohistochemically to evaluate survival prognosis. MPNST models with PRRX1 gene knockdown or overexpression were constructed in vitro, and the phenotype of MPNST cells was evaluated. Bioinformatics analysis combined with co-immunoprecipitation, mass spectrometry, RNA seq, and structural prediction were used to identify proteins interacting with PRRX1.
Results: High expression of PRRX1 was associated with a poor prognosis for MPNST. PRRX1 knockdown suppressed the tumorigenic potential. PRRX1 overexpressed in MPNSTs directly interacts with topoisomerase 2A (TOP2A) to cooperatively promote epithelial-mesenchymal transition and increase expression of tumor malignancy-related gene sets including mTORC1, KRAS, and SRC signaling pathways. Etoposide, a TOP2A inhibitor used in the treatment of MPNST, may exhibit one of its anticancer effects by inhibiting the PRRX1-TOP2A interaction.
Conclusion: Targeting the PRRX1-TOP2A interaction in malignant tumors with high PRRX1 expression might provide a novel tumor-selective therapeutic strategy.
Significance: MPNST is a malignant tumor with a poor prognosis and still lacks definitive treatment. Our results could hold promise as an alternative therapeutic strategy to inhibit the interaction between PRRX1 and TOP2A, and may improve the prognosis for malignant tumor patients with high expression of PRRX1 and TOP2A such as MPNSTs.

#5650 RNA regulatory disruption by 3'-dATP: A novel approach to inhibit ribosome biogenesis in cancer.

M. Elshani[1], Y. Zhang[1], I. Um[1], R. Plummer[2], S. P. Blagden[3], S. N. Symeonides[4], N. Cook[5], T. Evans[6], A. L. Dickson[1], D. J. Harrison[1];
[1]University of St. Andrews, St. Andrews, United Kingdom, [2]Newcastle University, Newcastle Upon Tyne, United Kingdom, [3]University of Oxford, Oxford, United Kingdom, [4]The University of Edinburgh, St. Andrews, United Kingdom, [5]The University of Manchester, Manchester, United Kingdom, [6]University of Glasgow, Glasgow, United Kingdom

Background: Ribosomes are a complex ensemble of ribosomal RNA and proteins. As the site where genetic information is translated to protein, they have a key role in cell survival, growth and proliferation. Ribosome biogenesis (RiBi), the process of creating ribosomes, is a complex function governed by precise checkpoints and surveillance mechanisms which may become dysregulated in cancer leading to tumor growth and therapeutic resistance. Ribosome-targeted therapy could provide a promising treatment for cancer. NUC-7738 (3'-deoxyadenosine [3'-dA] which is phosphorylated and protected with a phosphoramidate moiety attached at the 5'-position) generates sustained intracellular levels of 3'-dATP, a molecule that profoundly influences RNA regulatory processes, including poly(A) tail length, leading to alternative polyadenylation (APA) and splicing, resulting in impaired cellular responses. NUC-7738 is currently being investigated in combination with pembrolizumab in patients with advanced melanoma in the Phase 2 part of the clinical study (NCT03829254). Here, we investigate the impact of 3'-dATP on RNA regulation and RiBi utilizing a novel bioinformatic pipeline.
Material and Methods: RNA was extracted from melanoma and renal carcinoma cell lines treated with NUC-7738 for 24h and paired biopsies (pre and post treatment) from patients treated with NUC-7738 + pembrolizumab. Sequencing libraries used for long-read PCR-cDNA sequencing were generated. Gene-level expression was quantified using Salmon DeSeq2. In addition to gene expression, poly(A) tail length, APA and isoform switch were analyzed. Protein expression was determined using JESS Western analysis. Multiplexed analysis of protein localization and expression in tissue was carried out using an in-house immunofluorescence protocol.
Results: NUC-7738 caused a global reduction in poly(A) tail length in cell lines and patient biopsies that was most pronounced in the poly(A) tail exosome targeting (PAXT) long non-coding RNA (lncRNA) transcripts, including SNHG19, 5'TOP and YAE1, all of which play a role in RiBi. PAXT lncRNAs such as SNHG3 and SNHG19 increased in abundance. Ribosomal subunit proteins such as RPS3, RPS6, RPL17 decreased in expression. Expression of YAE1, a regulator of RiBi, also decreased. Distinct APA usage of various transcripts was observed in cell lines and patient biopsies.
Conclusion: Through the development of a novel bioinformatic pipeline we have been able to demonstrate that NUC-7738 disrupts RNA regulation, leading to perturbed RiBi. Targeting RiBi provides a promising approach to treating cancers

#5651 Personalized transcriptomic profiling for advanced prostate cancer: Guiding second-generation hormonal drug selection.

L.-H. Chang[1], H.-H. Chang[1], X.-Y. Lin[1], S.-C. Wang[1], C.-P. Chuu[2], D.-N. Chen[3], S.-P. Huang[1], C.-Y. Li[1];

Introduction: Second-generation hormonal drugs have demonstrated significant efficacy in extending the survival of patients with advanced prostate cancer. These drugs operate through two distinct molecular mechanisms: inhibition of androgen biosynthesis and blockade of the androgen receptor. However, due to concerns of side effects, concurrent usage of multiple drugs is not recommended. A notable challenge is the eventual development of drug resistance, rendering all second-generation hormonal therapies ineffective. Currently, there is a lack of guidelines for helping patients choose the most suitable drug. In the context of pharmacogenomics, genetic differences can influence drug susceptibility and efficacy, with variations in genomic sequences and regulatory mechanisms impacting drug response at the transcriptional and translational levels. Considered the rapid processing capabilities of Affymetrix transcriptomic microarrays, we hypothesized that distinct gene signatures in patients who respond well or poorly to second-generation hormonal drugs could be identified and could act as a companion diagnostic tool.
Methods: We enrolled 180 advanced prostate cancer patients, who fulfilled Taiwan national health insurance criteria of using second-generation hormonal drugs, from seven medical centers or regional hospitals in Taiwan at 3 time points: prior to drug administration, 3 months after treatment started and drug resistance developed. The RNA expression data and clinical parameters were analyzed, and classification models were built using IPA and R. Good or poor responders were defined by 3-month prostate-specific antigen (PSA) lowered by 90 percent.
Results:: Differential expression and enrichment analyses post-treatment highlighted the activation of NF-kappa B signaling and various immune cell pathways. Notably, pathways related to primary immunodeficiency and IL-17 became prominent following the development of drug resistance. At the initial stages, distinct alterations in cell cycle pathways, particularly G1/S and G2/M, were observed between good and poor responders. This was elucidated through principal component analysis and subsequent dbscan clustering. To further distinguish between these responder groups, we utilized an integrative approach for feature selection, combining support vector machine, random forest classifier, and lasso regression. Despite the innovative approach, the model's error rate stood at approximately 15%, attributed mainly to the limited number of cases.
Conclusion: Our study highlights the potential of using transcriptomic analysis to predict responses to second-generation hormonal drugs in advanced prostate cancer, paving the way for personalized treatment strategies. However, the need for larger cohort studies is evident to refine these predictive models and enhance their accuracy.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Genomic Changes and Intratumoral Heterogeneity as Predictive Biomarkers for Clinical Outcome
Poster Session

#5655 Association between tumor genomic variants and the long term post surgical recurrence as detected by a tumor informed ctDNA assay.
N. Friedman, M. Richters, J. Ortiz, R. Burns, S. L. Bristow, M. C. Liu, A. Aleshin, A. Jurdi, H. A. Costa;
Natera, Inc., Austin, TX

Background: While surgical resection of early stage cancers is often curative, a number of patients will experience disease recurrence. Given the genomic heterogeneity of cancer, we hypothesized that different driver mutations present in a patient's tumor may influence whether and when recurrence occurs. To investigate this, the association between the presence of driver mutations and rates of molecular residual disease (MRD) detection by circulating tumor DNA (ctDNA) was evaluated in patients with stage I-III colorectal cancer (CRC).
Methods: This was a retrospective evaluation of patients who underwent commercial ctDNA testing (Signatera™) following curative surgical resection for stage I-III CRC from 2019 to February 2023. For this analysis, patients who were ctDNA-negative post-surgery (2-12 weeks) and had ctDNA testing performed between 6-24 months after surgery were included. Patients were stratified based on the presence or absence of mutations in driver genes and the associated percentage of patients with ctDNA-positivity over time was calculated.
Results: Of 11,436 patients with stage I-III CRC, 45.7% (5,230) had ctDNA testing performed between 2-12 weeks post-surgery. During this window, 81% (4,239/5,230) had a negative post-surgical ctDNA test result available. For this analysis, 78.4% (3,323/4,239), 46.7% (1,979/4,239), 24% (1,017/4,239) and 8.2% (348/4,239) had follow-up ctDNA testing performed for at least 6, 12, 18, and 24 months post-surgery, respectively. Certain driver mutations were associated with increased risk of post-surgical ctDNA-positivity rate. In patients with stage I CRC, *APC* mutations were associated with elevated rates of ctDNA positivity at 12 months [(*APC*-mutated: 13% (11/85) vs. *APC*-wildtype 3% (1/31); p=0.06)] and 18 months [(*APC*-mutated: 38% (12/32) vs. *APC*-wildtype: 6% (1/18); p=0.02)]. Interestingly, similar findings were not observed in stage II or stage III CRC. Similarly in patients with stage III CRC, *SMAD4* mutations exhibited a substantially increased probability of ctDNA-positivity at 6 months [(*SMAD4*-mutated: 8% (15/194) vs. wildtype: 4% (54/1267) p=0.09)], 12 months [(*SMAD4*-mutated: 25% (32/129) vs. wildtype: 12.4% (102/817); p=0.0005)], and 24 months [(*SMAD4*-mutated: 69% (41/59) vs. wildtype: 53% (149/279); p=0.02)].
Conclusions: These findings point to several genomic alterations that may underlie cancer recurrence after a long period of undetectable disease with a differential impact across different stages. This may allow, in the future, for a personalized surveillance strategy based on driver mutations and stage of the disease. Correlation of ctDNA positivity with clinical outcomes based on driver mutational status may inform to what extent tumor-specific characteristics drive patient outcomes following a successful surgery.

#5656 Longitudinal spatial profiling reveals chemoresistance mechanisms and characteristics of minimal residual disease in high-grade serous ovarian cancer.

Y. Dai, A. Knisely, B. Lawson, S. Lee, K. M. Wani, R. N. Lazcano Segura, B. Melendez, J. Chen, Y. Liu, M. Chelvanambi, L. A. Gibson, S. B. Johnson, C.-C. Yeh, D. R. Ingram, C. W. Hudgens, K. Cho, G. Pei, J. Jiang, Y. Chu, A. J. Lazar, J. Gao, J. Wargo, L. Wang, A. A. Jazaeri;
The University of Texas MD Anderson Cancer Center, Houston, TX

High-grade serous ovarian cancer (HGSOC) is the most lethal gynecologic malignancy globally. Despite an initial response to upfront surgery and platinum-based chemotherapy in most cases, over 70% will relapse. A critical source of recurrence is minimal residual disease (MRD), which persists after upfront treatment yet is clinically undetectable. In this study, we performed second look laparoscopy (SLL) on advanced stage HGSOC patients who had received neoadjuvant chemotherapy (NACT) followed by interval debulking surgery and adjuvant chemotherapy and were in complete clinical remission by imaging and CA-125 tumor marker. Surgical MRD status was determined by pathological review of SLL biopsies. Matched samples from pre-treatment biopsy, interval debulking surgery and SLL in 4 MRD+ and 3 MRD- cases were analyzed using GeoMx Digital Spatial Profiling. Among them, samples from 1 MRD+ and 1 MRD- case were also profiled with Visium. The tumor cells of MRD+ cases exhibited stronger signaling related to hypoxia, angiogenesis, and epithelial-mesenchymal transition at baseline as well as diminished apoptosis signaling after NACT. In addition, progressively upregulated expressions of ATP binding cassette transporters were also observed over time in the tumor compartment of MRD+ cases, potentially contributing to chemoresistance. In the tumor microenvironment, MRD- cases displayed increased abundance of plasma cells, conventional dendritic cells and lymphocytes in both pre-treatment and interval debulking samples compared to MRD+ cases. Notably, Visium data of the MRD- case revealed tertiary lymphoid structures (TLS) in the pre-treatment sample, which became better organized following NACT, with plasma cells disseminating into adjacent tumor areas. Conversely, TLS were fewer and poorly organized in the MRD+ case. Longitudinal comparison of the 3 timepoints in MRD+ cases revealed more regulatory T cells in the stromal compartments of the MRD lesions. Furthermore, from Visium data, exclusion of CD8 T and plasma cells from the tumor core was evident in the MRD lesion. In line with this, strong TGF-β, IL-1β, IL6 and FGF2 signaling surrounding the tumor were noted, likely contributing to immune exclusion. The spatial distribution of multiple immune checkpoint molecules highly overlapped with that of CD8 T cells, indicating T cell exhaustion in the MRD lesion. In summary, these data suggested distinct cancer phenotypic states and immune features in surgically detected MRD+ HGSOC, shedding light on potential chemoresistance and immune evasion mechanisms that contribute to the MRD phase of disease. This study represents the first systemic characterization of ovarian cancer MRD by leveraging SLL, providing insights for designing personalized therapies aimed at eradicating these chemoresistant lesions and ultimately preventing disease recurrence.

#5657 The intricate relationship between genomic damage and epidemiological lung cancer risk in ever-smokers.

M. J. Przybilla[1], A. Ammar[2], H. Selway-Clarke[2], A. R. J. Lawson[1], H. Jung[1], A. Pennycuick[2], K. Gowers[2], R. C. Khaw[2], Z. Frazer[2], K. Davies[2], I. Martincorena[1], S. Janes[2], P. J. Campbell[1];

[1]Wellcome Sanger Institute, Cambridge, United Kingdom, [2]University College London, London, United Kingdom

Extensive epidemiological studies have illuminated the intricate relationship between tobacco smoking and lung cancer. Squamous cell carcinoma (LUSC), which is clinically tied to smoking, is formed in the proximal airway of the lung, whereas adenocarcinoma (LUAD), arising in the distal airway, has a weaker connection to tobacco and often occurs in never-smokers. The cessation of smoking promotes lung health and gradually lowers cancer risk. Dissecting the impact of smoking cessation on different lung cancer types in >650,000 individuals from UK Biobank and PLCO, we confirmed previous findings of LUSC risk diminishing more rapidly after quitting smoking, while LUAD risk endures over time. We previously found that normal bronchial epithelium in the proximal airway accumulates DNA damage proportionally to an individual's smoking habits. However, our analysis identified a population of cells with near-normal mutation burden, evading tobacco-induced damage. We hypothesized that the reduction in LUSC risk with smoking cessation could be explained by the repopulation of the proximal airway by these cells. Here, we followed up on this finding by exploring the genomics of alveolar stem cells (ASCs), which are believed to be the origin of LUAD. Analyzing WGS data of >800 single-cell-derived organoids from 9 patients, we found that tobacco smoking is the major driver of increased mutation burden in ever- compared to never-smokers. More importantly, our results demonstrated no significant difference in the burden of tobacco-induced genomic damage between ex- and current-smokers, suggesting that DNA damage in the distal airway is both persistent and long-lasting. Using single-molecule sequencing in a cohort of 43 individuals with heterogeneous smoking histories confirmed this observation. Overall, contrasting this finding with the results from bronchial epithelium and the epidemiological lung cancer risk brings forth a genomic explanation for the differences in long-term cancer risk, ingrained in the abundance of near-normal mutation burden cells. By contextualizing our results within the carcinogenic process in the lung, we suggest that persistent genomic alterations are the major driver in the long-standing discussion about the reason for an epidemiological shift from LUSC to LUAD in the last 30 years. As the largest proportion of lung cancers occurs within ex-smokers, the persistent genomic damage in the distal airway will result in a relative increase in LUAD incidence compared to LUSC, likely explaining this clinical phenomenon.

#5658 Genome-scale CRISPR screen in 3D tumor models identifies EGFR-TKI resistance mechanisms in human NSCLC.

Pranay Agarwal, Soon Youn Choi, Xin Liu, Jina Song, Maya Tureez, Aashka Mehta, Un Jae Baek, Kyuho Han, **Hong-Pyo Lee**

MEDiC Life Sciences Inc., Mountain View, CA

INTRODUCTION: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) are the primary treatment for EGFR-mutated non-small-cell lung cancer (NSCLC). Despite Osimertinib, an FDA-approved EGFR-TKI, showing high selectivity for EGFR-activating mutations, resistance inevitably arises, leading to disease progression. The influence of genes within cancer on Osimertinib response remains unclear. To tackle this challenge, CRISPR screens have been extensively used. However, current CRISPR screens investigating EGFR TKI resistance heavily rely on 2D monolayer cell models, lacking the ability to replicate in vivo tumors accurately. In response, we conducted a genome-scale loss-of-function CRISPR screening employing 3D tumor models embedded in an extracellular matrix across various NSCLC cell lines. Utilizing a comprehensive panel of CRISPR screens in both 3D tumor models and 2D monolayer models, we systematically assessed how genetic alterations impact cell resistance and transformation against treatment with Osimertinib, in diverse cellular contexts.
METHOD: Genome-scale CRISPR-Cas9 screens in 10 NSCLC cell lines used 3D tumor models and 2D cells to pinpoint genes pivotal for EGFR TKI resistance. Cas9-expressing cell lines were transduced with a lentivirus carrying 60,000 sgRNAs targeting ~20,000 human genes. Cells were cultured in both models and treated with optimized Osimertinib or DMSO, inducing 20-30% cell growth inhibition for 3 days. Post-treatment, cells were recovered for 4 days. This treatment cycle was repeated 3-4 times in 3D models and 2-3 times in 2D cells. The sgRNA composition in each pool was analyzed using Next Generation Sequencing after treatment cycles in both models.
RESULTS: Upon analyzing CRISPR screening data across 10 distinct cell lines to assess drug phenotypes, we confirmed the enrichment of established resistance pathways like PI3K/AKT/mTOR, Hippo, and MAPK signaling pathways in both 2D monolayer cells and 3D tumor models. However, notable discrepancies in EGFR TKI resistance mechanisms were evident between these two models. Specifically, CRISPR screens conducted with 3D tumor models unveiled unique resistance mechanisms, notably the LKB1/AMPK/mTOR pathway (STK11, GSK3B), Ubiquitination (RNF7, ARIH2), and stabilization of E-cadherin adherens junction (NCKAP1, EXOC4) differing from those identified in conventional 2D monolayer model. Furthermore, the 3D tumor models exhibited significantly heightened enrichment of the MAPK and Hippo signaling pathways compared to their drug phenotype score in 2D monolayer cells.
CONCLUSION: This study underscores the significance of employing the 3D tumor model in drug phenotype CRISPR screen. This approach recapitulates unique gene dependency patterns and interactions linked to EGFR-TKI resistance in a 3D tumor context, revealing potential targetable vulnerabilities context-dependent.

#5659 Origin of synchronous or metachronous multiple pancreatic cancers.

T. Hirano[1], N. Kakiuchi[1], Y. Takeuchi[1], T. Anazawa[1], K. Nagai[1], T. Masui[2], S. Minamiguchi[1], H. Haga[1], T. Tanaka[3], A. Masuda[3], Y. Kodama[3], N. Uza[1], H. Seno[1], S. Miyano[4], H. Tanaka[4], S. Ogawa[1];

[Introduction] The majority of patients with pancreatic cancer are inoperable at the time of diagnosis and even those cases with successful tumor resection for early-stage tumors frequently had second tumors within the remaining pancreas shortly after the surgery, contributing to a poor clinical outcome. Additionally, synchronous multiple pancreatic cancers have been frequently documented. One of the long-standing issues about such synchronous and/or metachronous multiple pancreatic cancers is their clonal origins. This study is designed to elucidate the origin of multiple pancreatic cancers through an unbiased detection of somatic mutations in primary and metachronous cancers, along with adjacent precursor lesions.

[Methods] Serially obtained formalin-fixed paraffin-embedded surgical specimens from 20 patients who had undergone curative surgery for an early-stage pancreatic cancer were subjected to laser microdissection for the enrichment of tumor and precancerous lesions, from which DNA was extracted and analyzed for somatic mutations using whole-exome sequencing (WES) with matched normal DNA. The investigation into the shared and private mutations across different samples aimed to unveil the clonal evolution history of these lesions.

[Results] We analyzed 20 patients with multiple pancreatic cancers of 2 metachronous and synchronous, 16 metachronous, and 2 synchronous tumors. In metachronous cases, all patients exhibited margin-negative pathology for the primary cancer, with a median interval of 38.9 months (ranging from 7 to 85 months) between the initial and second surgery. In addition, a total of 20 pancreatic intraepithelial neoplasia (PanIN) from 5 of these cases were analyzed. We identified a median of 66 (range: 31-232) and 20 (14-42) somatic mutations in cancer and PanIN lesions, respectively. None of the patients have known pathogenic germline variants. All samples had one or more driver mutations. In most cases (N=19), sharing many somatic mutations, multiple tumors had a common clonal origin. In another synchronous case, the synchronous tumors shared only one mutation, suggesting that they were clonally independent tumors. By contrast, none of the mutations other than hotspot KRAS mutations were shared between precursor and cancer lesions. While multiple independent clones were observed in precancerous lesions, most of multiple cancers originated from a common ancestor. Moreover, negative pathology of the margins at the initial surgery suggested that those multiple lesions arose from distant dissemination or metastasis, rather than contiguous, intraductal invasion.

[Conclusions] In conclusion, our study suggests that even in early pancreatic cancer, dissemination within the pancreas may occur, contributing to the development of synchronous and metachronous cancers.

#5660 Gene expression signatures from FFPE to predict recurrent metastatic nasopharyngeal cancer.

J. K. Tay[1], W. K. Teo[1], J. W. Foley[1], L. Suryani[1], B. C. Wu[2], C. H. Siow[1], K. S. Loh[1];

[1]National University of Singapore, Singapore, Singapore, [2]National University Hospital, Singapore, Singapore

Nasopharyngeal cancer (NPC) is an EBV-driven epithelial cancer endemic to Southeast Asia, Southern China and the Middle East. Accurate profiling of the gene expression of NPC has been challenging because of its intense inflammatory infiltrate, as well as the 3 - 4mm size of biopsies limiting the amount of available material. Here we present a large cohort of 339 micro-dissected gene expression libraries from formalin-fixed paraffin-embedded (FFPE) biopsies from NPC patients treated at the National University Health System, Singapore, as well as healthy controls. NPC tumors from patients who subsequently developed recurrent or metastatic disease (Group A), and patients who did not develop recurrent or metastatic disease (Group B) were profiled. Tumor epithelial and microenvironment compartments were separately obtained using laser-capture microdissection, followed by library preparation performed for RNA-Seq using an in-house specialised technique. Gene signatures for NPC tumor epithelial and microenvironment content were used to validate the purity of gene expression libraries. Our preliminary analysis revealed that primary, pre-treatment tumors from patients who subsequently developed recurrence (Group A) showed downregulation of processes related to interferon gamma and interferon alpha response (p-adj <0.001 for both), while processes related to epithelial-mesenchymal transition (p-adj < 0.05) were enriched compared to patients who remained healthy (Group B). In contrast to primary tumors, recurrent tumors in Group A were enriched for cellular respiration including oxidative phosphorylation (p-adj < 0.0001). Our approach highlights the utility of whole transcriptome profiling from small quantities of archival FFPE material. The gene signatures identified from the primary tumors of high-risk patients are biologically relevant and have the potential to be used in precision medicine to guide additional targeted intervention.

#5661 Identifying and intervening rare resistant subclones to BRAF/MEK inhibitors in metastatic melanoma.

H. Wang[1], M. Nakazawa[2], O. Veiseh[1], L. Kwong[2], D. Zhang[3];
[1]Rice University, Houston, TX, [2]MD Anderson, Houston, TX, [3]NuProbe, Houston, TX

Acquired drug resistance poses a significant challenge in the treatment of cancer. This study focuses on melanoma as a model system to understand and address pre-existing subclonal resistance. The use of BRAF and MEK inhibitors (BRAFi/MEKi) in patients with metastatic melanoma harboring BRAF activating mutations has resulted in remarkable responses in the majority of cases. However, most patients have disease relapse after one year, and there are limited subsequent treatment options. One possible cause of relapse is the existence of a subpopulation of cells resistant to BRAFi/MEKi prior to treatment, raising the possibility that commencing counter-resistance treatment earlier may delay or abolish resistance to BRAFi/MEKi. We aim to enhance the detection and treatment of low-frequency resistant mutations, addressing the current oversight by existing technologies. This research is crucial due to a lack of consensus on the clinical management of these mutations. By using quantitative blocker displacement amplification (qBDA) technology and integrating patient samples with cell line models, our project seeks to determine 1) the prevalence of low-frequency resistant subclones by measuring the Variant Allele Frequency (VAF) of known resistance mutations along the MAPK/PI3K pathways in FFPE biopsies from 149 metastatic melanoma patients and 2) determine the functional impact of different VAF levels on the outgrowth of resistant subclones. We assessed 14 loci in 6 known resistance genes: NRAS, KRAS, PIK3CA, AKT1, MAP2K1, and MAP2K2, as well as BRAF itself as a positive control. As expected, all 55 patients analyzed harbored BRAF activating mutations, while 17 patients had at least one resistant subclone above our preliminary cutoff of 60% VAF. To simulate the behavior of low-VAF resistance mutations, we conducted in vitro experiments by spiking in labeled BRAF/MEK inhibitor-resistant melanoma cells into their isogenic sensitive parental cell line. Our initial data demonstrated that, at least in this model system, a 10% VAF spike-in leads to the eventual outgrowth of resistant cells, but not in a 1% VAF spike-in, suggesting that either the density or the absolute number of the pre-existing resistant cells can dictate resistance evolution. In future experiments, we will assess multiple VAFs in an independent cell line as well as *in vivo* to identify the nature of its correlation with resistance outcomes and expand to additional models. In summary, our data suggest that a substantial proportion of metastatic melanoma patients with BRAF mutations have pre-existing resistant cell subclones, and that accurately assessing its VAF could provide clinically-relevant information. Ultimately, results from this work would be the basis for future personalized counter-resistance therapies, potentially extending treatment effectiveness for patients with pre-existing resistant mutations.

#5662 *PDCD1* and *CD48* significantly impact cancer recurrence and survival in pediatric acute lymphoblastic leukemia.

S. F. N. Alotaibi[1], L. Abuhadi[2], N. Alolyani[1], M. R. Alotaibi[1], A. R. Alhoshani[1], H. As Sobeai[1];
[1]King Saud University, College of Pharmacy, Riyadh, Saudi Arabia, [2]Minstry of Health, Riyadh, Saudi Arabia

Introduction: Immune checkpoints (ICPs) play a critical role in modulating the immune response, maintaining self-tolerance, and preventing excessive immune system activation. Dysregulation of immune checkpoints has been implicated in cancer progression and treatment resistance. In this study, we aimed to screen for dysregulated immune checkpoint genes that might be associated with cancer recurrence in pediatric acute lymphoblastic leukemia (ALL) following a course of cancer treatment. We hypothesized that certain ICPs would be significantly dysregulated in relapsed ALL patients, potentially providing insights into the underlying mechanisms driving therapy resistance and disease recurrence.

Methods: 51 ICP genomic data (gene expression, copy number alterations (CNAs), and mutation) of133 patients with relapse information [relapse-free (n=29) and relapsed (n=104)] extracted from the Therapeutically Applicable Research to Generate Effective Treatments (TARGET) were examined in the study. Patient's t-test (p-value < 0.05) was used to identify significant genetic factors between relapse-free and relapsed patients. Free and overall survival analyses were performed using log-rank test (p-value < 0.05) based on patient gene expression profiles.

Results: Among the 51 genes examined, *PDCD1, PVR*, *CD70,* and *CD48* were significantly upregulated in relapsed patients compared with relapse-free patients ($P < 0.05$). No significant CNAs nor mutations were detected in these four genes. Patients with high expression profiles of *PDCD1* and *CD48* at diagnosis were 1.71 and 1.47 more likely to relapse compared to patients with low expression profiles, respectively ($P < 0.05$). Furthermore, the upregulation of *PDCD1* (P= 0.0004, HR= 1.972) and *CD48* (P= 0.0344, HR= 1.533) demonstrated significantly increased mortality rates in patients following treatment, as indicated by overall survival analyses.

Conclusion: The upregulation of *PDCD1 and CD48* was significantly associated with relapse and survival of ALL patients. Promisingly, these two ICPs can potentially be used as prognostic biomarkers for relapse risk and rationale for alternative therapeutic strategies. Our study suggests that targeting *PDCD1* and *CD48* might be beneficial in enhancing the treatment efficiency and thereby reducing the recurrence risk. The study was funded by the Deputyship for Research and Innovation, Ministry of Education, Saudi Arabia (DRI-KSU-1273).

#5663 Collagen COL26A1 correlates with poor papillary thyroid cancer prognosis and *in vitro* characteristics of metastasis indicating a potential role as a biomarker or therapeutic target.

M. Carnazza, D. Quaranto, N. DeSouza, S. Dadafarin, A. Moscatello, H. K. Islam, J. S. Di Martino, R. K. Tiwari, J. Geliebter;
New York Medical College, Valhalla, NY

Papillary thyroid cancer (PTC) is the most common cancer in young women and is increasing 3% annually in incidence. While PTC is often slow-growing and surgically resectable, recurrence years to decades later occurs in 20% of patients (now only in their 40s/50s), decreasing survival by ~60%. The identification of prognostic biomarkers and actionable therapeutic targets for high-risk PTC is critically important and an unmet need. RNASeq analysis of our repository of PTC and matched normal tissues identified collagen 26A1 (COL26A1) as significantly upregulated in patients with extrathyroidal extension (ETE), lymph node metastasis, and multifocal tumors, indicative of high-risk for recurrence. Correspondingly, survival curves of The Cancer Genome Atlas (TCGA) demonstrated increased COL26A1 expression decreases survival probability by 25% (p=0.0086) and correlated with MACIS score (q=0.001), differentiation score (q=0.025), tumor stage (q=0.025), and ETE (p=0.0038). COL26A1 expression was increased in PTC cell lines K1 (3-fold) and TPC1 (5-fold) compared to “normal” thyroid epithelial cells, NThy-ori-3-1. CRISPR knockdown of COL26A1 repressed RNA (50%) and protein (70%) expression. COL26A1 repression decreased known cancer-promoting activities of collagens, including proliferation (30%), clonogenicity (33%), anchorage-independent growth (37%), cell motility (43%), Matrigel invasion (30%), in situ gelatin degradation (70%), and migration (33%). Cell-to-cell adhesion and cell-matrix adhesion also decreased (36% and 25%, respectively). This coincided with reduced anoikis resistance (31%), increased MMP expression (50%), and reductions in mesenchymal markers (30%) and increases in epithelial markers (3-fold). Evidence that COL26A1 is a secreted protein was validated by conditioned media isolations whereby expression was decreased in knockdowns compared to control cells (70%). Preliminary data indicate the control cells’ conditioned media can restore the aggressive phenotypes, including cell motility (51%). Qiagen Ingenuity Pathway Analysis (IPA) elucidated the potential role of androgen receptor (AR) in linking COL26A1 with PTC, coinciding with the known effects of sex hormones on collagen expression and organization, and the sex disparity in PTC. Preliminary data indicate that physiologic levels of androgen decrease COL26A1 RNA (46%) and protein (45%) expression in K1 cells expressing the androgen receptor. Thus, COL26A1 may serve as a prognostic marker and actionable target for small molecule inhibitors in high-risk PTC.

#5664 Genetic alterations and pharmacological response profiles from 10 cervical cancer cell lines.

S. Scholl[1], P. Gestraud[2], E. Girard[2], L. Lecompte[2], M. Halladjian[1], L. de Koning[3], N. Servant[2], M. Kamal[1], E. Del Nery[4];
[1]Department of Drug Development and Innovation (D3i), Institut Curie, Paris, France, [2]Bioinformatics and Computational Systems Biology of Cancer, PSL Research University, Mines Paris Tech, INSERM U900, Paris, France, [3]Translational Research Department, Institut Curie, PSL University Paris, Paris, France, [4]Biophenics, Institut Curie, PSL Research University, Department of Translational Research, Cell and Tissue Imaging Facility (PICT-IBiSA), Paris, France

Background: There are significant parallels between CC cell lines (CCCL) and newly diagnosed tumors, the most prominent being HPV infection/integrations and PI3K as well as epigenetic pathway alterations. Objectives: Identify genomic alterations associated with resistance to specific drug families in pharmacological profiles in Cell Lines (CL) and in Primary Tumors.
Material and Methods: 16 public and 4 newly patient-derived CL have been extensively characterized by HPV type, genetic (WES) and protein (RPPA) profiles. Pharmacological profiling against 32 drugs was carried out in triplicate samples and repeated on 10 selected CL. Variant calling of small-scale alterations (SNVs, InDels) was performed using GATK HaplotypeCaller (v4.0.2.1). Variants annotation was performed with Annovar (v 2017/07/06) using respectively gene (refGene), known polymorphims (avsnp v147, 1000G v2015/08, ESP6500v2, ExAC) and cancer databases (COSMIC v70, ICGC v21) as well as deleterious impact predictors (dbNSFP v33). Copy number alterations were assessed using Facets (v0.5.11) with 4 blood samples from the RAIDs tumor project used to generate a “baseline” copy number profiles for CLs.
Results: All 10 cell lines had strikingly similar DSS (drug sensitivity scores) to a family of four different microtubule targeting agents (MTAs). Bioinformatics subtraction of genetic alterations present in resistant (CRL 10302, CRL 7920, CRL 1550) and absent in sensitive CLs: (IC1, IC3, IC5), revealed a consistent LoF (loss of function) alteration in one single gene: *PABPC3* ‘Poly A tail binding protein, cytoplasmic C3’, a gene involved in messenger RNA stability and translational initiation. Additionally, 50 gene alterations from the pathway “POST TRANSLATIONAL MODIFICATIONS OF TUBULIN” were variably detected in resistant CLs. In primary tumors from the RAIDS database, alterations in *PABPC3* were present in 10/301 (3%), half of which documented by at least one database: (Cosmic, ICGC, Cancer Hotspot). *All* CLs were sensitive to Bortezomib, Omipalisib and Palbociclib. A *large spectrum* activity to Vorinostat, (HDAC inhibitor) in line with frequent (sensitizing) LoF alterations in epigenetic suppressor genes, contrasted with a *selective response* to other well-known CC drugs: Methotrexate, Gemcitabine, Sorafenib. Three out of CL were highly sensitive to APR246 (Eprenetapopt) as single agent. Bioinformatics gene subtraction identified *OSBPL1A*, a marker of synthetic lethality in the ferroptosis pathway, in all three CLs.
Discussion and Conclusion: A string of LoF alterations (*CSMD2/CSMD3, ZNF717, CDC27*) had been previously associated with poor response to radiation or to chemo-radiation, in tumors and are present in most CLs which are derived from resistant tumors. Future objectives are to validate the present biomarker findings in the context of a clinical platform trial.

#5665 Native nanopore sequencing of multiple tumor sites reveals genetic and epigenetic intra-tumor heterogeneity in canine osteosarcoma.

A. Keskus[1], **S. Aganezov**[2], T. Ahmad[1], X. Dai[2], R. Walker[3], J. Beaulaurier[2], S. Hickey[2], S. Juul[2], A. K. LeBlanc[1], P. S. Meltzer[3], M. Kolmogorov[1];

[1]Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD, [2]Oxford Nanopore Technologies, New York, NY, [3]National Cancer Institute, Bethesda, MD

Osteosarcoma (OS) is an aggressive bone malignancy affecting children and young adults. Implementation and optimization of neoadjuvant chemotherapy led to significant improvements in outcome, but patients with recurrence or metastases at diagnosis continue to have poor prognosis. Whole genome sequencing (WGS) revealed that a hallmark of OS is a highly rearranged genome with complex copy number aberrations rather than point mutations. A better understanding of the key genomic and epigenetic factors driving clonal evolution may provide insights into the tumor progression and the therapy response.

Canine OS recapitulates the majority of the hallmark genetic and molecular factors of human OS and is recognized as an informative model. A significant difference is that initial surgery in canine OS allows us to explore tumor evolution unperturbed by treatment, providing invaluable resources to study the genetic and molecular landscape of tumor evolution.

Here, we present the first study to date in which we performed bulk WGS of multiple tumor sites and distal normal tissue in two dogs using nanopore long-read sequencing to analyze the genetic and epigenetic evolution of OS.

In both subjects, somatic structural variation detection using Severus revealed chromothripsis-like rearrangements in chr11, leading to the deletion of Cdkn2a, a known cell cycle regulator and tumor suppressor. Interestingly, in one of the subjects, the majority of the SVs (n = 131) shared across all the samples were localized on chr5, coinciding with perturbed copy number profiles and bi-allelic frequency of the SNVs, with all mutations identified using complementary bioinformatics analysis of the same native nanopore reads. The multi-site sample analysis identified subclonal structural alterations in TP53 and ATRX genes.

With phased nanopore reads, we observed subject-specific copy-neutral loss-of-heterozygosity events and long identical-by-descent blocks. Haplotype-specific copy-number analysis of tumors showed different aneuploidy patterns in both subjects, highlighted clonal compositions of samples from distinct sites, and identified regions of copy-number heterogeneity.

Furthermore, phased nanopore reads also revealed haplotype-specific 5mC and 5hmC methylation differences across tumor samples, where samples from different sites of the same tumor demonstrate distinct methylation patterns that overlap DLG2, RUNX2, KDR, and other genes known as mutational hotspots in canine/human OS.

Overall, we showcase how a single sequencing assay allows for a joint analysis of genetic and epigenetic tumor alterations, thus providing a richer understanding of the drivers of somatic evolution and their association with the molecular landscape in the canine OS. These findings can be translated into human disease and shed light on tumor progression and therapy response.

#5666 Exploring spatially resolved intra-tumoral heterogeneity of glioblastoma and neuronal mechanisms facilitating brain invasion.

F. Gaiti[1], Y. Wu[2], S. Mansouri[1], B. Wu[2], Y. Ellenbogen[2], X. Li[1], P. Habibi[1], J. Kant[1], P. Kossinna[1], S. Lau Rodriguez[1], G. Zadeh[1];
[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada

Glioblastoma (GBM) is a highly lethal brain cancer, comprising about half of all central nervous system malignancies. Its recurrence and resistance to aggressive treatments, such as surgery, radiation, and chemotherapy, underscore its biological complexity. A key feature of GBM is intra-tumoral heterogeneity (ITH), stemming from a diversity of transcriptional cell states within the tumor. While genetic contributions to ITH are well-researched, the role of non-genetic factors, especially in promoting transitions between the various transcriptional cell states (referred to as plasticity), is less understood. This plasticity enables GBM cells to survive treatment pressures, necessitating a deeper dive into the epigenetic underpinnings that govern it and the role of the tumor microenvironment (TME) in influencing it. We proposed that the TME significantly impacts the epigenetic landscape of both malignant and surrounding non-malignant cells, thereby promoting ITH and cell state plasticity. To assess this, we analyzed samples from different anatomical areas of GBM tumors collected using MRI-guided selection. Utilizing advanced multimodal single-cell sequencing technologies, we profiled the transcriptomes and epigenomes of individual cells, revealing their spatially dependent phenotypic and epigenetic diversity. Our results indicated a higher enrichment of progenitor-like malignant cells, resembling neural or oligodendrocyte progenitors, around the tumor margins. In contrast, the core mainly contained differentiated cells with mesenchymal-like characteristics. Intriguingly, progenitor-like cells in the peri-tumoral zone expressed a unique neuronal activity program, including elevated levels of PRC2 complex targets, which are critical for maintaining the pluripotency and self-renewal capabilities of neural stem cells. Additionally, our analysis of cell-cell interactions between neurons and malignant cells identified ligand-receptor pairs crucial for axon guidance, neurogenesis, and tumor invasion. Proneural factors, critical for neural differentiation, were more accessible in peri-tumoral progenitor-like cells, suggesting that malignant cells might exploit neurodevelopmental routes for growth and invasion. This work underscores the significant spatial cellular heterogeneity of GBM and the variation in epigenetic states across the tumor, demonstrating how GBM cells can hijack neurodevelopmental pathways to foster invasion. Although surgical resection can target the tumor core, our insights into the invasive mechanisms of malignant cells provide a foundation for developing targeted therapies to combat the highly invasive cells persisting in regions adjacent to the tumor.

#5667 Intratumoral heterogeneity in gastric cancer related with survival and tumor microenvironment.

D.-e. Gu[1], W. Kwon[2], S. Rha[3], W.-Y. Park[4];

[1]Department of Health Sciences and Technology, Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea, Republic of, [2]Song-Dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University Health System, Seoul, Korea, Republic of, [4]Samsung Genome Institute, Samsung Medical Center, Seoul, Korea, Republic of

Gastric cancer (GC), often diagnosed at an advanced stage, poses a significant therapeutic challenge due to its resistance to treatment. The understanding of intratumoral heterogeneity, crucial for tumor cell survival, remains limited in GC. We conducted a comprehensive analysis of three patient groups (intraperitoneal metastasis [IM], hematogenous metastasis [HM], and both metastasis [HIM]) undergoing immunotherapy (IO) and chemotherapy. Utilizing single-cell RNA sequencing and TCR sequencing, we examined 11 adjacent normal, 10 HM, 8 IM, and 5 HIM primary GC samples. In epithelial cells, three distinct tumor clusters (Tumor_1, Tumor_2, and Tumor_3) were identified. Trajectory analysis revealed the differentiation of chief cells into Tumor_1, subsequently dividing into more malignant cell types, Tumor_2 and Tumor_3. Tumor_2 was enriched in IM, while Tumor_1 was enriched in HM and HIM. Patients grouped by Tumor_1, 2, 3 levels showed varying survival outcomes. Surprisingly, high Tumor_2 levels correlated with increased survival, attributed to elevated HLA and PDL1 expression, promoting immune cell recruitment and robust response to IO therapy. Conversely, Tumor_3 high patients exhibited worse survival, with enrichment in metabolic pathways associated with glycolysis and hypoxia, linking to metastasis. We observed the proportion of T cells that increased presence of CD8 effector cells among patients exhibiting high levels of Tumor_1 and Tumor_2. Through TCR analysis, we found heightened clonality in both CD8 effector cells and exhausted T cells in patients with elevated Tumor_1 and Tumor_2 levels. This suggests that the activated CD8 effector T cells in these patients may enhance their ability to effectively target and attack cancer cells. In summary, this study provides a comprehensive picture of intratumoral heterogeneity in GC can impact the survival and tumor microenvironment. The unexpected high survival in Tumor_2 patients emphasizes the potential of targeting specific pathways for improved therapeutic outcomes. Additionally, the observed T cell dynamics and clonality in Tumor_1 and 2 underscore the importance of understanding the immune microenvironment for effective cancer attack.

#5668 Long non-coding RNA LINC01614 knockdown decreases carcinogenic behavior of papillary thyroid cancer *in vitro*.

D. Quaranto, M. Carnazza, N. R. DeSouza, S. Dadafarin, A. Moscatello, H. K. Islam, R. K. Tiwari, J. Geliebter;
New York Medical College, Valhalla, NY

Papillary thyroid cancer (PTC) accounts for the vast majority of thyroid cancer cases with increasing incidence over the past few decades. PTC has a significantly higher prevalence in females in their childbearing years. Despite high survival rates, disease recurrence and metastasis remain prominent issues, thus highlighting the critical need for molecular biomarker detection. A newer class of molecular regulators, known as long non-coding RNAs (lncRNAs), have demonstrated differential expression patterns in a multitude of cancers. The largest subclass of these RNA molecules in the human genome consists of long intergenic non-coding RNAs (lincRNAs) with many of their functions yet to be identified. Known functional roles of lncRNAs center on their ability to modulate gene expression and drive carcinogenic behavior, deeming them attractive biomarkers and/or therapeutic targets for study. Bioinformatic analysis of RNA sequencing data from our patient sample biobank identified LINC01614 as being significantly upregulated (~12 fold increase) in PTC, when compared to normal, matched thyroid tissue. Further, it was also upregulated ~30-fold in male PTC compared to ~5.5 fold increase in female PTC, highlighting a potential sex correlation for study. Thus, we are studying LINC01614 as a potential PTC biomarker. Gene expression analysis of LINC01614 in vitro was found to be upregulated in various thyroid cancer cell lines, specifically two PTC cell lines: TPC1 (~5 fold; RET/PTC rearrangement; female) and K1 (~2 fold; BRAFV600E; male) when compared to the immortalized “normal” thyroid cell line (Nthy-ori-3-1). For phenotypic evaluation, we utilized the CRISPRi technique to employ transcriptional repression of LINC01614 in both TPC1 and K1. LINC01614 knockdown in TPC1 and K1 resulted in decreased healing capacity (~20%), clonogenicity (~50% and ~34%, respectively), and proliferation (~55% and ~45%, respectively). Studies are currently underway to further assess invasion, morphology, and RNA localization within the cell in vitro, as well as the identification of potential protein interactions and mechanisms of action of LINC01614 in PTC. Studying lncRNAs and their regulatory roles in cancer cell function is critical in the identification of various diagnostic and prognostic biomarkers for therapeutic intervention. Our data support the potential biological role of LINC01614 in driving PTC growth and metastatic potential. Further elucidation of how LINC01614 impacts PTC development and progression is a promising avenue of exploration.

#5669 Rare germline variants on SI gene and the possibility of colorectal cancer development.

S. Kim[1], J. Bae[2], Y. Koh[2], S.-S. Yoon[2];

[1]Seoul National University, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Seoul, Korea, Republic of

Research on cancer and germline variants has been ongoing. The germline variant in CPGs has been linked to cancer development. BRCA 1/2 is a typical case and oncometabolite production due to germline variants of the FH gene can affect the cancer progression. Among the genes related to IEMs, SI (Sucrase-isomaltase) is an enzyme that converts sucrose into glucose and fructose to allow normal metabolism in the small intestine. In addition, SI is highly specifically expressed in the gastrointestinal tract (nTPM = 435.9). So, we focused on and hypothesized the biological traits of the SI gene and alteration caused by germline variants could affect colorectal cancer progression. We used the public cancer databases PCAWG and TCGA and the healthy cohorts 1000G. We confirmed carriers with SI germline variants are the top gene with a high prevalence of IEM-related genes. We also established the hypothesis the SI gene may match “Knudson’s Two-hit hypothesis”. Depending on whether germline variants in IEM-related genes or not, we performed regression and utilized LOH (Loss of heterozygosity) information for each cancer sample from the public database. In COAD and STAD which are in the gastrointestinal tract, SI was confirmed to have a high tendency for LOH according to germline prevalence. Next, we performed DEG analysis and found SI germline carriers had upregulated genes related to the IFIT (Interferon-induced proteins with tetratricopeptide repeats) family. STRING network analysis also showed significance in pathways associated with “Interferon alpha/beta signaling (FDR = 0.00058)”, “Antiviral defense (FDR = 0.0016)”, “Innate immunity (FDR = 0.0317)”, and “Tetratricopeptide repeats (FDR = 0.0413)”. The following GSEA revealed that “KEGG_CYTOSOLIC DNA-SENSING PATHWAY” and “HALLMARK_INTERFERON_ALPHA_RESPONSE” were enriched in the SI germline carriers. In summary, it can be suggested immune regulation caused by SI germline variants may lead to cancer progression. We executed a follow-up analysis using the genes with low expression levels to the SI germline carriers. Among the down-regulated genes in the DEG, REG4 (Regenerating Family Member 4) and RELMβ (Resistin-Like Molecule Beta) genes were confirmed to express and function specifically only in the gastrointestinal tract. RELMβ is essential for preserving energy balance and glucose metabolism. As a validation at the protein level, we conducted IHC (Immunohistochemistry) on tissues from Korean colorectal cancer patients and confirmed lower REG4 and RELMβ expression were associated with poor prognosis. Our results suggest that SI germline carriers may cause colorectal cancer by affecting the immune system due to decreased SI enzyme function. Additionally, the decreased REG4 and RELMβ expression levels are associated with the SI germline variant and may affect cancer progression. Further analyses and experimental validations are still required.

#5670 CRISPR-Mediated knockout of Ceruloplasmin (CP) and UCHL1 reveals angiogenic role in renal cell carcinoma (RCC) cell survival and proliferation.

W. Caravan, Y. Wu, P. Lal, K. Sato, Y. Li, N. Naser Al Deen, S. Chen, A. Abedin, F. Chen, L. Ding;
Washington University In St. Louis, Saint Louis, MO

Clear cell renal cell carcinoma (ccRCC) is the most prevalent subtype of renal cell carcinoma, accounting for approximately 70% of all cases. Therapeutic treatment for metastatic ccRCC involve tyrosine kinase inhibitors or mTOR inhibiters. While these drugs extend patient survival, it also introduces a range of adverse side effects. Utilizing snRNA sequencing, snATACseq, and spatial transcriptomics, two potential ccRCC tumor specific markers have been identified: ceruloplasmin (CP) and UCHL1. These markers are notably overexpressed in a majority of ccRCC tumor cells and elevated CP levels have been correlated with reduced patient survival. To investigate the roles of CP and UCHL1 in ccRCC, CRISPR-based knockout experiments were conducted on two RCC cell lines, namely RCC4-VHL- and Caki-1. Through cell line characterization assays, we find that the absence of CP and UCHL1 impairs the cells' capabilities to migrate, proliferate, and adhere. Additionally, Cell-Derived Xenografts (CDX) of the knockout cell lines in nude mice revealed that cells lacking UCHL1 exhibited slower tumor growth compared to their parental lines. Bulk RNA sequencing further suggested a potential interrelationship between CP and UCHL1, as CP knockout cells showed increased UCHL1 expression relative to the parental line. These findings open new avenues for potential therapeutic strategies and biomarkers in the treatment and screening of ccRCC and further elevates our understandings of the roles of CP and UCHL1 in RCC tumor progression.

#5671 Profiling intra-tumor heterogeneity and chromosomal instability in malignant peripheral nerve sheath tumors.

Y. Cheng[1], H. Yan[2], M. Tarabichi[1], Z. Zhang[1], C. Gao[1], T. Lesluyes[3], A. Flanagan[4], P. Van Loo[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]The Francis Crick Institute, London, United Kingdom, [3]IUCT Oncopole, Toulouse, France, [4]University College London, London, United Kingdom

Malignant peripheral nerve sheath tumors (MPNSTs) are rare soft-tissue sarcomas that manifest on peripheral nerves, constituting 2% of all sarcomas. While previous genomic analyses of MPNSTs have been conducted on small cohorts, often limited to single samples per patient and lacking comprehensive resolution, the extent of intra-tumor heterogeneity and the contribution of chromosomal instability to MPNST development remains unclear. To address these limitations, we developed a multi-omics integration pipeline and applied it to bulk Whole Genome Sequencing (WGS), single-cell RNA sequencing(scRNA-seq), single-cell DNA sequencing (scDNA-seq), spatial transcriptomics (ST), and Laser Capture Microsection (LCM) sequencing data. 60 tumor samples were collected from 17 patients with MPNST, and the above five techniques were applied to each sample. Overall, tumors harbor a high degree of chromosomal instability and evidence of whole-genome doubling (WGD). We reconstructed tumor phylogenetic trees from WGS data using Dirichlet Process-based methods. Intriguingly, our findings indicated that for patient 2.3, primary tumor samples PT_1 and PT_2 displayed a close phylogenetic relationship, while local recurrences LR_2 and LR_3 represented a different branch of the phylogenetic tree. Moreover, scRNA-seq analysis of patient 2.16 highlighted an enrichment of immune cells, including macrophages, B cells, and T cells. To infer copy number alterations (CNA) of tumor cells from scRNA-seq data, we leveraged inferCNV, with normal cells identified within the same sample as controls. Significant copy number gains were identified on chromosomes 5, 7, 8, and 15 in patient 2.16. The inferred copy number changes derived from scRNA-seq were validated against copy number profiles obtained through WGS using Battenberg, revealing a remarkable congruence. In the scDNA analysis of patient 2.12, we observed that all tumor cells exhibited biallelic loss of CDKN2A, with a majority showcasing WGD and chromosome 7 amplification. This finding underscored the potential significance of CDKN2A in the pathogenesis of this tumor, in keeping with the observation that CDKN2A is recurrently mutated and lost in MPNSTs. Our research profiled the tumors' evolutionary histories and intra-tumor heterogeneity down to single-cell resolution, highlighting the genotype and phenotype differences between tumor subclones. By shedding light on the genomic landscape of MPNSTs, we aspire to make profound contributions to the field of sarcoma research, ultimately improving patient outcomes.

#5672 Transcriptomic profiling of lung adenocarcinoma from never-smokers reveals molecular subtypes with clinical implications.

W. Zhao, T. Zhang, P. H. Hoang, J. Sang, M. Landi;
National Cancer Inst. - Bethesda Campus, Rockville, MD

Lung cancer is the leading cause of cancer mortality worldwide and about 10-25% of lung cancers are from never-smokers (LCINS). Previous genomic studies of LCINS identified multiple genomic subtypes with different genetic drivers and evolutionary processes. To dissect the profile of LCINS cell states and tumor microenvironment, and their relationship with genomic lesions, we sequenced and assembled a large RNA-seq data set of 685 samples of lung adenocarcinoma from never-smokers and integrated them with whole genome sequencing data, pathological features and clinical outcomes from the same subjects. We identified three transcriptomic subtypes defined by distinct gene expression patterns. The three subtypes were associated with different pathway activities and showed remarkable heterogeneity in cell composition, lineage fidelity and pathological features. The genomic driver events and mutational signatures were significantly enriched in specific subtypes. Clinical outcomes also differed across the subtypes. For example, one subtype had prolonged overall survival and was associated with predicted response to immune checkpoint blockade. This study emphasizes the importance of transcriptome-based classification of LCINS, which has profound clinical implications beyond those provided by genomic and pathological assessment.

#5673 Transposable element expression patterns in epigenetic mutational subtypes of clear cell renal cell carcinoma.

Kevin Meli[1], Cora A. Ricker[2], Sabrina Y. Camp[2], Christof C. Smith[3], Chris Labaki[2], Eddy Saad[2], Hanna Soulati[4], Brendan Reardon[2], Jihye Park[2], Natalie I. Vokes[5], Benjamin G. Vincent[6], Toni K. Choueiri[2], David A. Braun[4], Eliezer M. Van Allen[2]

[1]Harvard Medical School, Boston, MA,[2]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Department of Medicine, Brigham and Women's Hospital, Boston, MA,[4]Yale Cancer Center, Yale School of Medicine, New Haven, CT,[5]Thoracic Head and Neck Medical Oncology, MD Anderson Cancer Center, Houston, TX,[6]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Clear cell renal cell carcinoma (ccRCC) is characterized by mutations in epigenetic modulators and by aberrant transposable element (TE) expression, each of which have been separately associated with immunotherapy (IO) benefit in specific clinical contexts. However, the relationship between mutations in epigenetic regulators and TE expression, and the potential effect of both somatic mutations and TE expression on clinical outcomes, has not been fully investigated.

Methods: We utilized RNA sequencing from ccRCC patients' tumors and cell lines to quantify TE subfamily expression with *TEtranscripts* (n=123 metastatic IO-treated; CheckMate-009, 010, 025, n=355 all stage TCGA untreated, n=8 CCLE). Locus-specific endogenous retrovirus (ERV) expression was quantified using *hervQuant*. Differential TE and ERV expression was determined using *DESeq2*. Samples were stratified by mutations in *PBRM1*, *SETD2*, *BAP1* and *KDM5C*, four of the top five mutated genes in ccRCC. Multivariable CoxPH models and the log-rank test were used to compare overall (OS) and progression-free survival (PFS). Two validation metastatic ccRCC cohorts were employed: the everolimus arm of CheckMate-025 (n=78, CM025e) and IMmotion150 (n=146, IM150).

Results: Global TE expression (LTR, LINE, SINE and DNA transposons) did not differ significantly across mutational and clinical subtypes. However, 29 of 795 TE subfamilies were differentially expressed in >1 mutational subtype across datasets, and 22 of 29 were ERVs. At locus-specific resolution, 52 of 3173 ERVs were differentially expressed in >1 mutational subtype across datasets. Additionally, 6 of the 52 ERVs nominally associated with PFS, and 4 nominally associated with OS, in the IO cohort. Among them, only ERVs 544 and 2014 associated with improved PFS (multivariable CoxPH p = 0.03 and 0.02, respectively) and were expressed across all datasets. Both ERVs also exhibited increased expression in *PBRM1* mutant and decreased expression in *BAP1* mutant vs. wildtype samples, in discovery (IO, TCGA, CCLE) and validation (CM025e, IM150) cohorts. Lastly, *PBRM1* mutant patients with high ERV 544 or 2014 expression had improved PFS in the IO (log-rank p = 0.04 and 0.03, multivariable CoxPH p = 0.008 and 0.009, respectively, HR = 0.43 both), but not in the CM025e cohort, compared to other patients regardless of *PBRM1* mutations.

Conclusion: ERVs 544 and 2014 were upregulated in *PBRM1* mutant and downregulated in *BAP1* mutant samples. Coupled with *PBRM1* inactivation, their expression served as a candidate biomarker of improved PFS in IO-treated ccRCC that may have additional biological relevance. Expanded functional and clinicogenomic studies of epigenetic mutational subtype-specific patterns of TE expression, and their relation to selective IO response, may guide additional discovery and therapeutic development strategies in ccRCC.

#5674 Characterizing Cellular Heterogeneity and Identifying Potential Biomarkers in Esophageal Squamous Cell Carcinoma (ESCC) Using Single-Cell RNA Sequencing.

T.-H. Hsiao[1], C.-H. Lin[1], T.-S. Wu[1], L.-W. Lee[1], C.-P. Hsu[2];

[1]Taichung Veterans General Hospital, Taichung, Taiwan, [2]Buddhist Tzu Chi General Hospital, Hualien, Taiwan

Esophageal squamous cell carcinoma (ESCC) exhibits significant cellular heterogeneity, rendering it susceptible to developing radioresistance and recurring tumors. Single-cell RNA sequencing (scRNA-seq) is an advanced technique that allows for the exploration of distinct gene expression profiles in individual cells. To investigate cellular heterogeneity in ESCC, scRNA-seq analysis was performed on tumor tissues from ten ESCC patients, as well as adjacent non-malignant esophageal tissues. The cellular composition revealed 19 distinct cell clusters, further categorized into seven cell populations: 69.31% Fibroblast, 15.36% T cell, 5.30% Monocytes, 5.26% Endothelial cells, 2.68% plasma cell, 1.91% Epithelial cells, and 0.18% ambiguous. Notably, Fibroblast and Endothelial cells were more prevalent in non-malignant tissues, while the remaining cell types were enriched in tumor tissues. Differential gene expression analysis identified 49 genes with higher expression in tumor cells and 37 genes with lower expression. Gene Set Enrichment Analysis (GSEA) revealed the top three most relevant GO Biological Processes pathways: positive regulation of immune response, regulation of T cell activation, and positive regulation of cell migration. Furthermore, in post-treatment follow-up, four patients were observed to develop metastasis within one year. Comparative analysis between metastatic and non-metastatic patients unveiled 9 Differentially Expressed Genes (DEGs), including KRT6A and AKR1B10, which exhibited specific expression in Epithelial cells and were highly expressed in tumor tissues. Additionally, IGLC2, IGHG4, and IGHG1 demonstrated specific expression in plasma cells, with elevated expression in tumor tissues. These findings suggest that KRT6A, AKR1B10, IGLC2, IGHG4, and IGHG1 may serve as potential biomarkers for predicting post-chemotherapy metastasis in ESCC patients.

#5675 An intronic SINE-VNTR-*Alu* element insertion in *CASP8* alters gene expression and confers resistance to induction of cell death in gastrointestinal cancer.

E. W. Lin[1], J. R. Kocher[1], C. Chu[2], P. J. Park[2], D. T. Ting[1];
[1]Massachusetts General Cancer Center, Boston, MA, [2]Harvard Medical School, Boston, MA

Transposable elements are a major source of variation in the human genome. SINE-VNTR-*Alu*s (SVAs), the hominid-specific and youngest active retrotransposon family, are highly polymorphic within the human germline and can contribute to disease risk and progression. In fact, polymorphic SVAs have previously been linked to several human diseases, including rare cases of hereditary cancer syndromes such as neurofibromatosis type I and Lynch syndrome. These examples illustrate that the mobility of SVAs in the genome can significantly impact gene function. Here, we sought to evaluate the potential of SVAs inserting into known tumor suppressors and oncogenes. To this end, we surveyed genomic data from Pan-Cancer Analysis of Whole Genomes (PCAWG) and identified 1956 unique germline SVA insertions in the introns of 1933 genes. Among these, we discovered a highly prevalent polymorphic SVA_E (subfamily) in an intronic region of *CASP8*. Given caspase-8's canonical role in apoptosis, we hypothesized that this SVA may impact both caspase-8 expression as well as cell death in cancer.

We first created a panel of colon and gastric cancer cell lines genotyped by PCR for the presence or absence of the *CASP8*-SVA (SVA+/+: RKO, NCI-N87, HT29, NCI-H747, OCUM-1; SVA-/-: HCT116, LoVo, SNU-407, 23132/87, KM12). RT-qPCR analysis showed significantly higher *CASP8* expression in SVA+/+ cell lines, which was concordant with caspase-8 protein expression by immunoblot. Treatment of these cell lines with cytotoxic chemotherapy (FOLFOXIRI) *in vitro* demonstrated increased resistance to cell death in SVA+/+ cell lines. Direct induction of caspase-8-mediated apoptosis via TRAIL (TNF-related apoptosis-inducing ligand) revealed decreased TRAIL-mediated cell death in SVA+/+ cell lines; interestingly, caspase-8 enzymatic activity was also decreased in SVA+/+ cell lines upon TRAIL stimulation despite increased pro-caspase-8 expression. To further isolate the effects of the *CASP8*-SVA, we generated an isogenic cell line (RKO *CASP8*-SVA knockout) model via CRISPR-Cas9. Deletion of the *CASP8*-SVA redemonstrated decreased *CASP8* expression at the mRNA and protein levels. Treatment with FOLFOXIRI in the *CASP8*-SVA KO cell line exhibited increased sensitivity compared to empty vector control.

In summary, our findings indicate that an intronic SVA insertion in *CASP8* increases gene and protein expression but decreases canonical caspase-8 activity, which was associated with increased resistance to FOLFIRINOX or TRAIL induced cell death. Additional interrogation of SVA-induced effects on transcriptional regulation (e.g., epigenetic effects) as well as non-canonical functions of caspase-8 (e.g., activation of NF-κB) is ongoing. To our knowledge this is the first report describing the mechanistic effects of a germline SVA insertion in the context of cancer and therapeutic resistance.

#5676 Spatial 3D genome organization reveals intratumor heterogeneity in primary glioblastoma samples.

Q. Wang[1], J. Wang[1], R. Mathur[2], M. W. Youngblood[1], Q. Jin[1], Y. Hou[1], L. A. Stasiak[1], Y. Luan[1], J. F. Costello[2], F. Yue[1];
[1]Northwestern University - Chicago, Chicago, IL, [2]University of California San Francisco, San Francisco, CA

Glioblastoma (GBM) represents the most prevalent malignant primary brain tumor with highly unfavorable prognosis. Currently, most genomic studies are conducted at a single site of a tumor, which do not reflect the complete genetic or epigenetic information across the whole tumor. Furthermore, the intra-tumoral heterogeneity (ITH) of 3D genome organization has also not been studied yet. To address these gaps, we performed Hi-C experiments in 21 samples obtained from 9 GBM patients, with 15 of them being spatially mapped based on their 3D coordinates from the same patients. We identified extensive inter-tumoral and intra-tumoral heterogeneity in genome compartmentalization and chromatin interactions. Notably, in a patient with 9 spatially mapped samples from both temporal and frontal regions, we accumulated over 6 billion reads and defined high-resolution region-specific chromatin interactions, regulatory networks, and key regulators within the same patient. We detected structural variation (SV) and enhancer hijacking across all the samples, and identified recurrent events that affect known cancer-related genes such as CDKN2A/B. Finally, we introduce the concept of 'enhancer amputation', defined as the loss of enhancers due to SVs which lead to decreased expression of their original target genes. To our knowledge, this study represents the first large-scale exploration of the 3D genome in primary GBM patients and the first investigation of 3D genome organization in multiple regions of the same tumor. Our findings provide unprecedented insights into the ITH of GBM at the 3D genomic level, opening new avenues for understanding and potentially targeting this devastating disease.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: microRNAs and Other Non-coding RNAs as Cancer Genes 2
Poster Session

#5680 Circular *MALAT1* - the new kid on the block in breast-to-brain metastatic cancer.
A. Szczepaniak, A. Bronisz, J. Godlewski;
Mossakowski Medical Research Institute Polish Academy of Sciences, Warsaw, Poland

Introduction: Breast-to-brain metastatic (BTB met) cancer constitutes a great challenge for modern medicine and science. As the research on protein-coding genes brought only incremental progress in developing anticancer therapy, much attention is devoted to understanding the role of non-coding RNAs, including a relatively recently discovered group - of circular RNAs. This project aimed to determine the relationship between BTB met cancer cells and cells derived from a deadly brain tumor - glioblastoma stem-like cells (GSCs), considering the circular RNA signatures and selecting a reliable candidate for mechanistic study - a circular form of non-coding oncogene *MALAT1* (circ*MALAT1*).
Methods: The circular RNA expression profile in patient-derived BTB met cancer cells (n=4), GSCs (n=8), and neural progenitor cells (NPC) as a non-malignant control (n=3) was evaluated by the microarray approach. Expression of circ*MALAT1* was also validated in non-malignant breast epithelial cells by digital PCR and data mining in the GEO database. Circ*MALAT1* knockdown by antisense oligonucleotides was followed by functional analysis.
Results: 12,660 circular RNAs were detected using the Arraystar platform, and upon applying the cutoff of FC ≥2 and p-value <0.05, 547 circular RNAs were selected as significantly deregulated in all cancer groups compared to NPC. Circ*MALAT1* was elevated in BTB met compared to NPC and normal breast epithelial cells. Knockdown of circ*MALAT1* affected cancer cell viability and proliferation while promoting p21 expression, thus decelerating the cell cycle manifested by a reduction in 3D spheroids volume.
Conclusions: The analysis of the circular RNA landscape showed for the first time some striking similarities between BTB mets and GSCs despite different tissue-of-origin. Of note, the circRNAome of BTB mets clustered especially closely with mesenchymal GSC - the most aggressive and therapy-resistant subtype of GSCs. These results also demonstrated the role of circ*MALAT1* in shaping the oncogenic traits of these cells. Therefore, circular RNAs can serve as valuable biomarkers and promising novel mechanistic candidates whose modulation may become a paradigm-shifting therapeutic approach.

#5681 Identification of dysregulated miRNAs involved in TNBC progression.

M. Lee, Y. Kim, D. Son, S. Lim, J. Park;
Sookmyung Women's University, Seoul, Korea, Republic of

Triple negative breast cancer (TNBC) is the most aggressive type of all breast cancer subtypes. Although various studies have been performed to identify prognostic and therapeutic targets for TNBC, the TNBC specific biomarkers have not yet been elucidated. Herein, we identified dysregulated miRNAs in TNBC via analysis of miRNA microarray in breast cancer tissues and found the oncogenic RNA (miR-374a-5p) and tumor suppressive miRNAs (miR-320c, miR-371b-5p). These miRNAs were closely related to overall survival of TNBC patients and status and involved in TNBC progression or drug responsiveness. Collectively, these results suggest that dysregulated miRNAs might serve as potential prognostic marker or therapeutic target for TNBC.

#5682 Micro RNA level changes in prostate cancer cells treated with MDMX and MDM2 inhibitors.

Rojin Fatirkhorani[1], Ahmed Saleh M. Alsarrani[2], Shyam Sundar Jaganathan[2], Umamaheswari Natarajan[2], Appu Rathinavelu[2]

[1]Kiran C. Patel College of Osteopathic Medicine, Nova Southeastern University, Fort Lauderdale, FL,[2]Rumbaugh-Goodwin Institute for Cancer Research, Barry and Judy Silverman College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL

INTRODUCTION: Prostate Cancer (PCa) is the most common non-cutaneous cancer and the second leading cause of cancer death among men in the United States. Most of the PCa cases are diagnosed in men between the ages of 65-74. Due to the recent push for frequent prostate screenings, these cancers are being detected early and treated much faster, leading to a 5-year survival of a localized or regional PCa to >99%. However, the 5-year survival of PCa with distant metastasis is significantly reduced to 32%, especially with involvement of osteoblastic bone lesions, lung lesions, and brain lesions. Therefore, there is a clinical need to identify prognostic markers and new targets for developing therapies and effectively treating advanced PCa. Previous studies have shown that levels of MDMX and MDM2, oncogenic inhibitors of p53 tumor suppressor protein, are significantly elevated in PCa cells. Inhibition of MDM2 and MDMX using specific inhibitors has been shown to elevate the levels of p21, p27, and p53 in LNCaP (Lymph Node Carcinoma of the Prostate) cells leading to cell death. Recent studies have demonstrated that micro RNAs (miRNAs) play an important role in supporting the tumor suppressor function of p53 through regulating the balance between p53 and MDM2. In this regard, several miRNAs were found to be significantly altered to modulate the level and intracellular mechanisms of p53 and MDM2 in various cancers.

OBJECTIVES: To determine the relative levels of miRNA31, miRNA-34a and miRNA-128 in LNCaP cells that were treated with NSC-207895 (MDMX inhibitor), SJ-172550 (MDMX inhibitor), and RG-7388 (MDM2 inhibitor).

METHODS: LNCaP cells were treated with NSC-207895 (20 uM), SJ-172550 (20 uM) or RG-7388 (2 uM) for 24 hrs. After completing the treatments, the miRNAs were extracted from the LNCaP cells using the miRNeasy Tissue/Cells Advanced Kit from Qiagen. We analyzed the levels of miRNA-31, miRNA-34a, and miRNA-128 in the treated samples using qRT-PCR analysis method and compared the levels to the control. During the qRT-PCR analysis the cDNA was amplified using Meridian Biosciences qPCR Master Mix and specific primers for miRNAs from Origene were used according to the manufacturer's protocol.

RESULTS: Our experimental results indicate that inhibition of MDMX using NSC-207895 and SJ-172550 can elevate the levels of p21, p27, and p53 leading to cell death. Determination of cell death markers in the past revealed induction of necroptosis following drug treatments. Our current results indicate measurable changes in the levels of miRNA-31 and miRNA-34a following inhibition of MDMX using SJ-172550. We are in the process of determining the possible link between the changes in the levels of miRNAs and cell death.

ACKNOWLEDGEMENT: This research was supported by the Royal Dames of Cancer Research, Ft. Lauderdale, Florida.

#5683 lncRNA-protein interactions that predict response to endocrine therapy in HR+ breast cancer.

K. D. Waiters, M. Quttina, A. F. Khan, S. Karami, A. S. Peidl, F. Babajide, T. Bawa-Khalfe;
University of Houston, Houston, TX

Hormone receptor positive (HR+) breast cancer (BCa) is the most frequently diagnosed BCa type accounting for 70% of all breast cancer cases. A large population of HR+ BCa patients (30-40%) are resistant to mainstay endocrine therapy and develop incurable metastatic disease. Hence, it is imperative to identify viable biomarkers that stratify patients as drug responders or non-responders.

Emerging scientific literature highlights the essential role of long non-coding RNAs (lncRNA) in cancer drug resistance and metastatic transformation; lncRNA include RNAs over 200 nucleotides in length that do not encode protein. Major biological functions of lncRNA rely on association with select protein interactors. As lncRNA equally bind proteins with and without canonical RNA-binding motifs, it is unclear what facilitates this lncRNA-protein interaction. Our recent studies show that SUMO post-translational modification (or SUMOylation) of target proteins potentiates binding with lncRNA, particularly at the chromatin. Using a small-scale screening, we see that SUMO-modification works to enhance association with lncRNAs for proteins with and without a canonical RNA binding domain (RBD). SUMOylation of RBD-expressing heterochromatin protein 1 α (HP1α) drives interaction with multiple chromatin-associated lncRNA both within and outside canonical heterochromatin foci. Interaction with lncRNA supports SUMOylated HP1α's unconventional function as a transcriptional repressor at select euchromatic loci. We now report an inverse relationship in which SUMOylated HP1α directs the stability of its lncRNA binding partner. Specifically, SUMO-modified HP1α directs cell-cycle dependent recruitment of the RNA degradation machinery to the chromatin and facilitates clearance of chromatin-bound lncRNA. This dynamic lncRNA degradation process is disturbed with cancer onset and instead favors aberrant cancer cell transformation. Consistently, restoring lncRNA degradation homeostasis decreases metastatic properties of HR+ BCa cells and increases sensitivity to targeted therapeutics currently in clinical trials. Our studies define a fundamental mechanism that dictates lncRNA stability and/or degradation in BCa cells. In addition, we present viable biomarkers that predict sensitivity to ET and alternative targeted therapies.

#5684 The role of the lncRNA *Slamon* and *Slc25a13* neighbor gene in melanoma aggressiveness.

B. C. B. Tonin[1], A. L. P. Ayub[1], A. H. Lengert[1], S. W. Han[1], E. M. R. Reis[2], F. J. Slack[3], **M. G. Jasiulionis**[1];
[1]Universidade Federal de Sao Paulo (UNIFESP), Sao Paulo, Brazil, [2]Universidade de Sao Paulo (USP), Sao Paulo, Brazil, [3]Harvard Medical School, Boston, MA

Melanomas are responsible for about 80% of all deaths related to skin cancers. This is due to its high potential of metastasizing and developing resistance to treatments. Novel therapeutic modalities and the identification of biomarkers able to predict the prognosis are necessary. Studies have revealed the central role of long non-coding RNAs (lncRNAs) in regulatory networks controlling cell behavior. The disruption of these regulatory networks as a consequence of altered expression of lncRNAs can contribute to cancer development and progression. Our laboratory has developed a linear cellular model of melanoma progression consisting of distinct cell lines: melan-a (melanocytes), 4C (pre-malignant melanocytes), 4C11- (undifferentiated, slow-growing and non-metastatic melanoma cells) and 4C11+ (differentiated, highly proliferative and metastatic melanoma cells), which were analyzed for their lncRNA expression profile. Differentially expressed lncRNAs identified by RNAseq were selected by *in silico* analyses based on their proximity to differentially expressed coding-genes in the same melanoma model. Correlation analyses were performed between the expression of differentially expressed lncRNA neighboring genes and their melanoma patient survival, using two independent melanoma cohorts (TCGA and Leeds). Among those lncRNA located near genes presenting prognostic value is the lncRNA Gm20619, here named *Slamon*, neighbor to *Slc25a13* gene (mitochondrial aspartate/glutamate carrier gene), which high expression correlates with poor prognosis. Both *Slamon* lncRNA and *Slc25a13* are highly expressed in the metastatic melanoma cells 4C11+ compared to melan-a, 4C and 4C11- cell lines. The knocking down of *Slamon* or *Slc25a13* were performed in 4C11+ melanoma cells, followed by analyses of collective migration, clonogenicity, proliferation, *anoikis* resistance, and dacarbazine and MEK inhibitor treatment. By knocking down *Slamon* lead 4C11+ cells significantly less migratory and less resistant to dacarbazine, and resulted in increased expression of *Slc25a13* gene. 4C11+ melanoma cells knocked down for *Slc25a13* also presented reduced migratory, clonogenicity, proliferation and *anoikis* resistance capability, diminished sensitivity to dacarbazine and MEK inhibitor treatment, and increased expression of *Slamon* lncRNA. The analysis of genes coexpressed with *Slc25a13* revealed genes related to tumor progression, as *Cdk15*, *Lsp1* and *Pdgfrb*. Our results suggest a crucial role of the lncRNA *Slamon* and *Slc25a13* coding gene in melanoma progression which has never been described before. *Slamon* regulates tumor aggressiveness associated with *Slc25a13*, forming a regulatory network. These findings reveal the importance of lncRNAs in melanoma biology, potentially indicating transcripts that can serve as prognostic biomarkers and therapeutic targets in melanoma.

#5685 MiR-345-5p attenuates pancreatic cancer metastasis through KLK7/E-Cad/ β-Catenin/Rap1 axis.

N. Sirpu Natesh[1], S. Nethi[2], B. White[2], J. Kaifi[3], S. Batra[4], S. Mallapragada[2], S. Rachagani[1];
[1]University of Missouri - Columbia, Columbia, MO, [2]Iowa State University, Ames, IA, [3]University of Missouri, Columbia, Columbia, MO, [4]University of Nebraska Medical Center, Omaha, NE

Background: Pancreatic cancer (PC) is a highly lethal malignancy with a 5-year survival rate of 10.8%, primarily attributed to early invasion and metastasis. Epithelial-to-mesenchymal transition (EMT) plays a crucial role in the metastatic progression of PC. Existing therapies, such as Gemcitabine, Abraxane, and FOLFIRINOX, have limited efficacy, emphasizing the need for identifying molecular targets to enhance PC patient survival. Recent advancements in miRNA therapies show promise, but a detailed understanding of miRNAs regulating PC growth and metastasis remains elusive. This study aims to uncover the role of miR-345-5p in regulating PC metastasis.
Methods: A miRNA microarray analysis of KC mouse data identified miR-345-5P as one of the significantly down-regulated miRNA, targeting multiple metastasis-related genes. Expression of miR-345-5p in PC was assessed using published databases, validated through qPCR and ISH in PC cell lines, serum samples, and patient tissue. *In vitro* overexpression and *in vivo* assays elucidated the functional roles of miR-345-5p in PC metastasis. A computational approach and dual-luciferase assays were used to identify the target of miR-345-5p. Western blots, immunohistochemistry, and immunofluorescence were utilized to decipher miR-345-5p mediated molecular mechanisms.
Results: MiR-345-5p expression was downregulated in PC tissue, serum, and cell lines compared to non-tumor tissues. Restoring miR-345-5p reduced PC cell proliferation, migration, and invasion *in vitro* and *in vivo*. KLK 7 was confirmed as a direct target, and functional experiments revealed miR-345-5p's acting as a tumor-suppressor by inhibiting the E-Cad/B-catenin/Rap1 axis signaling pathway. MiR-345-5p overexpression stabilized the E-Cadherin-β-catenin complex, leading to reduced β-catenin accumulation in the nucleus and thus leading to declined transcription of crucial genes (C-myc, cyclin D1 & MMP7) responsible for PC progression. Given the pivotal role of the c-myc gene in metabolism, we performed a metabolomic analysis. The findings unveiled significant metabolic rewiring, marked by reductions in glucose and amino acid metabolism, attributable to decreased C-myc expression due to restoration of miR-345 in PC cells.
Conclusion: MiR-345-5p overexpression negatively regulates PC proliferation and EMT by directly targeting KLK7/E-Cad/β-catenin/Rap1 axis. Restoring miR-345-5p with standard care therapies could be a promising strategy for improving survival in metastatic PC patients.

#5686 Identifying rare microRNA risk variants for hereditary breast cancer in African American individuals.

S. R. Glover, T. LoBue, N. D. Merner;
Auburn University College of Veterinary Medicine, Auburn, AL

Background: In the United States, breast cancer is the most frequently diagnosed cancer in women. However, African American women tend to have a higher incidence of triple negative breast cancer cases, and an earlier age of disease onset, which are hallmark characteristics of heredity disease. Even with current breakthroughs in breast cancer research, limited research participation from women of African descent has led to a gap in our knowledge of heredity factors that are involved in disease in this population. Furthermore, most breast cancer research has focused on protein coding genes being the culprit of tumorigenesis; however, within the last three decades, research efforts have begun to focus on noncoding RNAs, like microRNAs (miRNAs), as potential factors to promote carcinogenesis. miRNAs are short, noncoding RNA molecules that control gene expression at the post-translational level. miRNAs have several mechanisms to affect gene expression of cellular processes like cell proliferation, apoptosis, invasion, and metastasis. However, the identification and functional role miRNA risk variants play in African American breast cancer is still not fully understood.
Methods: 30X whole genome sequencing (WGS) was carried out on an Illumina platform on blood- or saliva-derived DNA from 120 African American breast cancer cases from the Alabama Hereditary Cancer Cohort. The WGS data was analyzed using our established bioinformatics pipeline, which has been adapted from the Genome Analysis Toolkit (GATK) Best Practice Pipeline. Focusing on miRNA variants as risk factors, a miRNA BED file was used to extract regions harboring miRNA genes. The resulting file was then filtered for rare miRNA variants (minor allele frequency <1%) in the African American population based on the Genome Aggregation Database (gnomAD) allele frequency. P-values for variants of interest were calculated using Fisher's Exact tests.
Results: Sequencing data have revealed three rare miRNA variants from our African American cohort that can be potentially associated with breast cancer risk. Upon statistical analysis comparing allele frequencies between the African American general population and the Alabama Hereditary Cancer Cohort, *miR7850, miR3145, and miR8074* had p-values 5.21E-05, 3.58E-05, and 2.19E-04, respectively.
Conclusions: We have identified three rare miRNA variants that were not previously known to be associated with breast cancer risk. Interestingly, both *miR7850* and *miR8074* target *TP53* and *miR3145* targets *GREM1* and *PALB2*, which these targets are known breast cancer susceptibility genes. Understanding the consequence of these variants is important to add to our knowledge of miRNAs that play critical roles in carcinogenesis leading to better treatment strategies.

#5687 Downregulation of DAX-1 expression by miRNA overexpression as a mechanism to potentiate breast cancer.

N. C. DeVito, C. Tzagarakis-Foster;
University of San Francisco, San Francisco, CA

The orphan nuclear receptor DAX-1 (Dosage Sensitive Sex Reversal, Adrenal Hypoplasia Congenita, critical region on the X chromosome, gene 1) plays a key role in sex determination and the synthesis of steroid hormones. In addition to these canonical examples, DAX-1 has been shown to play a contradictory role in cancer development. While DAX-1 is overexpressed in some types of cancer, it is completely absent or downregulated in several other cancers such as prostate and breast. One of the explanations for the paradoxical role of DAX-1 in cancer development could be microRNAs (miRNAs). Recent research has demonstrated that the dysregulated expression of these short non-coding RNAs increases the proliferative and anti-apoptotic capabilities of cancer cells. After broadly surveying over 180 miRNAs historically upregulated in MCF7 cells, we compared the activity of DAX-1 in MCF7 breast cancer cells and MCF10a normal breast epithelial cells with the presence of specific miRNA inhibitors. Our primary hypothesis remains that multiple miRNAs negatively regulate the expression of DAX-1 in human breast cancer cells and are not overexpressed in normal breast cells, providing another mechanism of lifting the repression of DAX-1 expression. Quantitative PCR and western blot analysis was performed indicating that inhibiting miRNAs 29c, 199a, and 424 significantly upregulate DAX-1 expression in MCF10a cells. We examined the invasive and metastatic properties of MCF7 cells following inhibition of these specific miRNAs. This research will allow clinicians to screen for additional miRNAs that could be elevated in breast cancer patients substantially increasing the number of people diagnosed with breast cancer early on. In addition, elucidating the pathways of how more and more miRNAs influence downstream targets will offer drug designers novel targets to improve treatment for breast cancer and other cancer patients.

#5689 miR-21: A therapeutic target that delays severe liver disease and hepatocellular carcinoma under high-fat-diet conditions.

U. Jagtap[1], A. Quan[1], Y. Ono[1], J. Lee[1], K. A. Shen[2], S. Manakov[2], G. Szabo[1], I. Nasser[1], F. J. Slack[1];
[1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Eclipse BioInnovations, San Diego, CA

Liver disease is a major global health concern, claiming approximately 2 million lives worldwide annually, yet curative treatments remain elusive. In our study, we aimed to investigate the role of microRNA-21-5p (miR-21) in metabolic dysfunction-associated steatotic liver disease (previously NAFLD), metabolic-associated steatohepatitis (previously NASH), and hepatocellular carcinoma (HCC) within the context of a Western high-fat diet (HFD) and offering potential therapeutic insights. We found that reduced miR-21 levels correlated with liver disease progression in WT mice fed on HFD, while miR-21 knockout mice showed exacerbated metabolic dysfunction, including obesity, hepatomegaly, hyperglycemia, insulin resistance, steatosis, fibrosis, and HCC. Our study reveals that miR-21 plays a protective role in metabolic syndrome and in the progression of liver disease to cancer. miR-21 directly targets *Transforming growth factor beta-induced* (*Tgfbi*), a gene also known to be significantly upregulated and a potential oncogene in HCC. Further, our study showed that intervention with the administration of a miR-21 mimic in WT livers in HFD conditions effectively improves insulin sensitivity, steatosis, fibrosis, tumor burden, as well as *Tgfbi* expression. These findings indicate that miR-21 could serve as an effective strategy to delay or prevent liver disease in high-fat-diet environments.

#5690 Urinary microRNA expression in pancreatic cancer with cachexia.

M. Okada[1], S. Kondo[1], Y. Igawa[1], T. Yoshida[1], M. Havelka[2], M. Mizunuma[2], Y. Ichikawa[2], N. Yamamoto[1];
[1]National Cancer Center Hospital - Japan, Tokyo, Japan, [2]Craif Inc., Tokyo, Japan

Background: Cancer cachexia (CC) is a multifactorial syndrome characterized by appetite loss, weight loss and skeletal muscle wasting. It increases functional impairment, treatment-related toxicity, and a lower quality of life. Importantly, CC is one of the leading causes of cancer-related deaths, and its occurrence is particularly prevalent in advanced stages of pancreatic cancer (PC). The syndrome is thought to be associated with systemic inflammation and increased energy expenditure, yet the specific mechanisms remain to be fully understood. Although timely detection and intervention might be crucial in preventing CC's progression, early diagnosis of this syndrome remains challenging due to the absence of suitable biomarkers. Here, we analyzed urinary microRNAs (miRNAs) as a potential noninvasive biomarkers for detecting CC in patients (pts) with PC.

Methods: Clinical information including presence or absence of CC and urine samples were collected from pts with PC treated at National Cancer Center Hospital, Tokyo, Japan from March to October 2022. The diagnosis of CC was made according to the following definitions by Fearon. K et al. (1) weight loss of ≥5% within 6 months; (2) weight loss of ≥2% in pts with a BMI of <20 kg/m^2; or (3) weight loss of ≥2% in pts with sarcopenia. In this study, pts who met the definition of CC within 6 months of enrollment were considered to have CC.Urinary miRNA profiles from pts with PC were sequenced by NGS and analyzed using DESeq2 to identify differentially expressed miRNAs (DEMs) between pts with CC and those without. DEMs were further explored for associated pathways and target genes using miRPathDB v.2.0.

Results: Of the 64 subjects, 52 pts were included in the analysis after excluding three pts with low urine sample read coverage and nine pts with no information on CC status. Among those, 38 pts were classified as having CC. Patients' background was as follows (CC/no CC); median age 70 [range: 44-80]/ 67 [57-74], male and female 19/7 pts, respectively, cStage {I (6/0), II (1/0), III (17/4), IV (14/10)} pts, median BMI (male 22.1 [17.7-27.2]/21.7 [18.2-28.2], female 21.7 [14.6-25.2]/21.9 [16.6-27.4]) kg/m^2. Among 307 miRNAs detected in the urine of pts with PC, 49 miRNAs had previously been reported in CC research. The miR-141-5p was differentially expressed between pts with CC and those without CC (Wald test p_{BH} = 0.079). It was down-regulated in pts with CC (Mann-Whitney U test p = 6.4e-4) and most significantly associated with the FoxO signaling pathway (ORA p_{BH} = 1.84e-4), followed by the mTOR signaling pathway (ORA p_{BH} = 0.008).

Conclusions: Our study indicates that miR-141-5p holds potential as a noninvasive biomarker for the detection of CC in pts with PC. Although miR-141-5p has not been previously reported in CC, its significant association with the FoxO signaling pathway, which is one of the major pathways regulating skeletal muscle atrophy, underscores the relevance of miR-141-5p in the context of CC.

#5691 Identification of miRNA related to triple-negative breast cancer in African and European American women with obesity.

F. Hossain[1], **M. I. Gonzalez-Ramirez**[2], J. Garai[1], X.-C. Wu[1], C. Hicks[1], L. Del Valle[1], A. Ochoa[1], D. Danos[1], L. Miele[1], J. Zabaleta[1];
[1]Louisiana State University Health Sciences Center, New Orleans, LA, [2]Tulane University School of Medicine, New Orleans, LA

Triple-negative breast cancer (TNBC) represents 10-20% of all invasive breast cancers and is characterized by a lack of expression of estrogen receptor, progesterone receptor, and human epidermal growth factor receptor 2. TNBC typically manifests as high-grade tumors often diagnosed at advanced stages, and affects younger patients, especially African American (AA) women. Dysregulation of miRNA expression levels contributes to TNBC pathogenesis and prognosis. Dysregulated miRNAs in advanced-stage cancers alter tumor progression, migration, and metastasis. Obesity is associated with miRNA dysregulation in adipose tissue, which is a driver of BC development and growth. This study aimed at identifying differentially expressed (DE) miRNA in TNBC patients of European American (EA) and AA women with obesity, compared to adjacent non-tumor tissues. miRNAseq data from 48 tissue samples (TNBC tumor and adjacent non-tumor) were analyzed for differential expression. Samples were from 12 EA and 12 AA patients, with 6 patients in each ethnic group having obesity and 6 normal weight, based on BMI estimates. Stringent comparisons, with and without obesity, were conducted to identify TNBC and obesity-associated miRNAs within each ethnic group. Prediction of miRNA-target genes was performed in miRWalk and Key Pathway Advisor (KPA) was employed for pathway enrichment analysis. Differential expression analysis between obese and normal-weight patients in each ethnic group revealed 79 DE miRNAs in EA and 40 in AA. We identified 55 miRNAs associated exclusively with tumors in obese patients within the EA group and 33 miRNAs within the AA group. Target gene analysis showed that in EA, 9 out of the 55 miRNAs interacted with 68 mRNAs, with miR-204-5p and miR-181b-5p accounting for 75% of interactions. In AA, 20 out of the 33 miRNAs interacted with 284 mRNAs with miR-20a-5p, -195-5p, -34a-5p, and -130a-3p with 65% of the interactions. KPA identified 84 and 330 pathways for EA and AA, respectively, with 43 common pathways,15 of them related to cancer processes sharing the gene targets *GSKIP, TLBR1, TCF4, and TCF.* Our study outlined unique miRNA profiles in TNBC among AA and EA women with obesity. Although common mRNAs were identified between ethnic groups, leading to the identification of common pathways on KPA, more than 50% of the identified pathways are related to unique biological processes associated with TNBC and obesity for each ethnic group. These findings underscore the importance of considering ethnic-specific miRNA signatures for understanding TNBC in the context of obesity, offering insights for targeted therapeutic strategies.

#5692 Posttranscriptional molecular network facilitates KRAS-linked tumorigenesis via XRN1-miR-21 signaling in pancreatic cancers.

Y. Seo, **S. Oh**, J. Kim;
National Cancer Center, Ilsanro, Goyang, Korea, Republic of

Aberrant expression of mutant KRAS and miRNA-21 (miR-21) are commonly attribute to malignancy and tumorigenic progression of pancreatic cancers. However, few studies have explored the molecular mechanism linking these two prognostic factors. In this study, we explored the underlying molecular bridge between KRAS and miR-21 regulation in pancreatic cancer. Functional integrative analysis of KRAS, an essential oncogenic driver in pancreatic cancer progression, and together with miR-21 revealed XRN1, a 5′-3′ exoribonuclease, as RNA-linked top-scored molecule with a strong survival correlation and malignancy in pancreatic cancer patients. Depletion of XRN1 led to severe reduction in mature miR-21 expression, while unaltered precursor miR-21 levels; indicating that the XRN1 is critical in miR-21 maturation at post-Drosha step in conjunction with Dicer. Moreover, miR-21 sensor-based experiment also confirmed the critical role of XRN1 on miR-21 biogenesis. Depletion experiments showed that XRN1 positively regulates proliferation and self-renewal capacity of pancreatic cancer cells via its 5′-3′ exoribonuclease activity and concomitantly elevated the expression of PTEN and PDCD4 which are the key miR-21 cellular downstream targets. shRNA-mediated XRN1 depletion also yielded smaller tumor volume and longer survival in pancreatic cancer xenografts and syngeneic model demonstrating the therapeutic potential of targeting XRN1. Subsequent silencing of KRAS reduced XRN1 expression in pancreatic cancer cells, suggesting that KRAS plays a key role in this XRN1-miR-21 axis. Furthermore, drug-resistant pancreatic cells showed elevated expression of both KRAS and XRN1-miR-21 indicating that this axis is also associated with drug sensitivity. In sum, these results suggest that a novel KRAS-XRN1 posttranscriptional regulatory axis plays a pivotal role in tumor progression by mediating miR-21-directed signaling, and thus may suggest a novel targeting strategy for pancreatic cancer therapeutics.
Significance: This study identifies molecular regulatory interplay between KRAS and XRN1-miR-21 signaling in pancreatic cancers, elucidates how KRAS-XRN1 modulates tumorigenesis via miR-21, and demonstrates that targeting this signaling can contribute to therapeutic strategies for pancreatic cancers. [Y. Seo and S. E. Oh contributed equally to this work.]

#5694 Elucidating areca nut-induced miRNA-mRNA regulatory networks in head and neck cancer pathogenesis.

Hung-Han Huang[1], Guo-Rung You[2], Kai-Hsin Lin[2], Yin-Ju Chen[3], Ann-Joy Cheng[2]

[1]Graduate Institute of Biomedical Sciences, Chang Gung University, Taoyuan city, Taiwan,[2]Department of Medical Biotechnology and Laboratory Science, Chang Gung University, Taoyuan city, Taiwan,[3]Department of Biomedical Sciences, Chang Gung University, Taoyuan city, Taiwan

Areca nut has been considered a high-risk carcinogen for head and neck cancer (HNC) in Southeast Asia, while its molecular effects, especially on the miRNA regulatory roles, remain elusive. This study characterized miRNA-mRNA networks associated with areca nut-related HNC. We integratively analyzed the areca nut-induced mRNA profile and TCGA-HNSC gene set. A total of 2575 genes were identified, with 1971 upregulated and 604 downregulated in cancers. The KEGG pathway analysis revealed that these genes were enriched in the cellular functions related to motility and stress response. Experimental studies confirmed that arecoline promoted cell migration, invasion, and chemo-radioresistance. We further cross-analyzed the miRNAs induced by areca nut and dysregulated in TCGA-HNSC data and defined 71 molecules affected, with 35 upregulation and 36 downregulation. Using the multimiR tool to map potential mRNA-miRNA interactions, we uncovered that these miRNAs were connected to 2173 genes. These molecules participated in several oncogenic mechanisms, such as ErbB and PI3K-Akt signaling, cell adhesion, and DNA damage response. We endeavored to establish miRNA-mRNA interaction networks with the functions of cellular motility and stress response via the Cytoscape analytical method. Our data revealed nexus comprising 41 miRNAs with 83 mRNAs, and 38 miRNAs with 66 mRNAs, respectively, co-regulate these two malignant functions. A key miRNA, miR-410-3p, downregulated in HNC and decreased following areca nut treatment, was studied. Ectopic expression of miR-410-3p attenuated areca nut-induced cell invasion and exerted modulatory effects on its target oncogenes, CRK. Thus, our study delineates a comprehensive view of the miRNA-mRNA interplay altered by areca nut, illustrating a sophisticated mechanism of carcinogenesis and suggesting new avenues for diagnostic and therapeutic strategies in HNC.

#5695 miR-5787 suppresses cancer cell growth as a Fe_3O_4-nanoparticles induced pivotal miRNA.

M. Watanabe[1], H. Nakano[2], C. Matsuda[2], E. Usugi[2], H. Imai[2], Y. Hirokawa[1], K. Iijima[3];
[1]Mie University, Tsu, Japan, [2]Mie University Hospital, Tsu, Japan, [3]Yokohama National University, Tsu, Japan

Nanotechnology offers great potential for cancer diagnosis and treatments. Especially, nanoparticles (NPs) have been examined and utilized as drug delivery systems, hyperthermia and combination therapy. We have examined and reported the combined effects of Fe_3O_4-nanoparticles (Fe_3O_4-NPs) with chemotherapeutic agents on prostate cancer cell in vitro. miRNAs are an important factor in cancer progression, and elucidating the miRNA-mediated intracellular network of cancer cells could suggest new cancer treatment strategies. In this study, to identify microRNAs (miRNAs) associated with anticancer effects of Fe_3O_4-NPs, the comprehensive expression of miRNAs by Microarray (Agilent G4780A SuperPrint G3 Human v16 miRNA 8x60K Microarray kit) in A549 (lung cancer cell line), LNCaP (androgen-dependent prostate cancer cell line) and DU145 (androgen-independent prostate cancer cell line) under Fe_3O_4-NPs exposure was performed. miR-5787 was one of the increased miRNAs in three cancer cell lines under Fe_3O_4-NPs, and its increase in miR-5787 was due to the reactive oxygen species (ROS) production by Fe_3O_4-NPs. The additional analysis suggested that miR-5787 might suppressed the cancer cell growth by targeting the eIF5. In this study, we identified miR5787 as a Fe_3O_4-NPs induced pivotal miRNA in cancer cells, and can be used as a therapeutic target.

#5696 Exploring the association between miR-9-5p levels and the mTORC1/mTORC2 pathway in laryngeal cancer cell lines.

C. Gobin, M. Chang, C. C. Lattimore, K. M. Fredenburg;
University of Florida, Gainesville, FL

Background: We previously demonstrated that differing levels of miR-9-5p could predict chemosensitivity to cisplatin, and that miR-9-5p is a regulator of potential chemotherapeutic target MAP1B. As the mTOR/PIK3CA pathway has been implicated in the pathogenesis of laryngeal squamous cell carcinoma (LSCC), we sought to determine an association between differing miR-9-5p levels, mTOR pathway mediators including MAP1B, and methylation.
Methods: UM-SCC-98, UM-SCC-12, UM-SCC-11A, UM-SCC-10A (obtained from the University of Michigan) laryngeal cancer cell lines were used in this study. We previously showed UM-SCC-98 and UM-SCC-12 to have significantly lower miR-9-5p levels as compared to UM-SCC-11A and UM-SCC-10A (Northern blot analysis). The IC50 of an mTORC1 inhibitor (Rapamycin) and an mTORC1/C2 inhibitor (AZD-8055) were evaluated using the Cell Titer Blue Viability assay. Cells were treated with the de-methylating agent, 5-Azacytidine (1μM). Gene expression of mTOR pathway mediators- miR-9-5p, PTEN, EGFR, PIK3CA, and MAP1B- were determined in each cell line pre-and post-treatment via qPCR.
Results: All cell lines were resistant to treatment with Rapamycin (IC50 > 60μM) with the UM-SCC-12 cell line yielding the highest IC50 (> 150μM). Conversely, decreased cell proliferation was detected with AZD-8055. This was significantly associated with their miR-9-5p levels-- a higher AZD-8055 IC50 was associated with cell lines UM-SCC-98 (~40μM) and UM-SCC-12 (~23μM) compared to UM-SCC-10A (~16μM) and UM-SCC-11A (~8μM). Following demethylation treatment, miR-9-5p levels were significantly increased in UM-SCC-12 only (2-fold), and this corresponded to a significant decrease in MAP1B gene expression (2-fold) but not with EGFR, PIK3CA, and PTEN gene expression.
Conclusion: In conclusion, our study suggests that miR-9-5p may regulate MAP1B gene expression via the mTORC2 pathway. In addition, methylation may play a role in the regulation of the miR-9-5p gene and its downstream targets in laryngeal cancer tumorigenesis. Future studies will involve exploring epigenetic mechanisms of miR-9-5p inhibition and defining the role of key mediators of the mTOR pathway in LSCC.

#5697 MILIP drives triple-negative breast cancer through complexing with transfer RNAs to promote protein production.

Y. Feng[1], S. Zheng[2], X. Zhao[1], Y. Zhang[1], R. Xu[1], L. Xu[1], T. Preiss[3], L. Jin[1], J. Gao[2], X. Zhang[1];
[1]University of Newcastle, Callaghan, Australia, [2]Shanxi Bethune Hospital, Taiyuan, China, [3]Australian National University, Canberra, Australia

Despite the progress in endocrine therapy, targeted therapy and immunotherapy, the treatment of triple-negative breast cancer (TNBC), one of the most aggressive types of breast cancer, is challenging. This is closely associated with the lack of effective molecular targets in TNBC cells for therapeutic intervention. Here we report that the long noncoding RNA (lncRNA) MILIP drives TNBC cell survival, proliferation and tumorigenicity through complexing with transfer RNAs (tRNAs) to promote protein production, and thus represents a potential therapeutic target in TNBC.

MILIP was expressed at high levels in TNBC cells that commonly harbor loss-of-function mutations of the tumor suppressor p53, yet MILIP silencing diminished TNBC cell viability and retarded TNBC xenograft growth, indicating that MILIP functions distinctively in TNBC beyond its well-established role in repressing p53 in other types of cancers. Mechanistical investigations revealed that MILIP interacted with eukaryotic translation elongation factor 1 alpha 1 (eEF1α1) and formed an RNA-RNA duplex with $tRNA^{Leu}$ and $tRNA^{Ser}$, type II tRNAs, through their variable loops, thus facilitating the binding of eEF1α1 to these tRNAs. Disrupting the interaction between MILIP and eEF1α1 or tRNAs diminished protein production and cell viability, with therapeutic potential revealed where targeting MILIP using Gapmers inhibited TNBC growth and cooperated with the clinically available protein synthesis inhibitor omacetaxine mepesuccinate *in vivo*.

Collectively, these results identified MILIP as an RNA translation elongation factor to promote protein production in TNBC cells and demonstrated that experimental therapy with MILIP Gapmers inhibits TNBC growth, indicating MILIP targeting is a potential avenue for developing improved TNBC treatment through blocking protein synthesis.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Pharmacologic Targeting of Cell Cycle Proteins
Poster Session

#5701 AU2-94: A CDK4-specific inhibitor with the marked anti-tumor efficacy.

L. Bantie, J. Likisa, M. Rahaman, T. Teo, A. Safaroghliazar, S. K. Basnet, R. Hassankhani, B. Noll, R. Milne, **S. Wang**;
University of South Australia, Adelaide, Australia

Cyclin-dependent kinases (CDKs) are a vital family of proteins in the cell development. Several CDK4/6 inhibitor drugs significantly extended the lives of subtypes breast cancer patients. However, they have some shortcomings. Many patients do not respond to them well mainly due to off-target toxicity requiring dose reductions and treatment interruptions, and thus building resistance, which limit their effectiveness. Here, we describe AU2-94, a highly selective CDK4 inhibitor, for the treatment of CDK4-dependent tumours including breast cancer (ER+ and TNBC), colorectal cancer and glioblastoma (GBM). AU2-94 exhibits high selectivity for CDK4 (K_i = 2 nM) over CDK6 (K_i = 279 nM). Consistent with the CDK4-targeted mechanism, AU2-94 arrested the G1 cells and inhibited cancer cell proliferation. Interestingly, AU2-94 reduced cellular CDK2, Cyclin E2, Cyclin A2, Cyclin B1, and induced apoptosis via reduction of Bcl-2, FOXM1 etc. In contrast to cancer cells, AU2-94 has little impact on the cell cycle, senescence, or apoptosis of human bone marrow cells, whereas the known CDK4/6 inhibitors increased the G1 cells. AU2-94 showed little or no effect on lymphocyte and neutrophil counts whilst the clinical CDK4/6 inhibitors reduced them. This lower effect of AU2-94 on the bone marrow, neutrophils and lymphocytes might be due to its lesser effect on CDK6 compared to the clinical CDK4/6 inhibitors. AU2-94 was highly efficacious against multiple *in vivo* tumour models. In the ER+ breast cancer T47D xenografts, AU2-94 caused tumour regression. In the model of MDA-MB-453 AR+ luminal breast cancer (CDK4, $KRAS^{mut}$, $PI3KCA^{mut}$), AU2-94 demonstrated remarkable efficacy, resulting in the 6 out of 7 (86%) mice tumour-free. In the colorectal cancer HCT116 (CDK4/6, $KRAS^{mut}$) xenografts, AU2-94 inhibited tumour growth markedly in a dose-dependent manner from 25 to 200 mg/kg without any overt toxicity. The pharmacokinetic and pharmacodynamic study revealed up to 500-fold higher concentration of AU2-94 in the tumours than in the plasma, suggesting its tumour targeting specificity. Several robust biomarkers/PD markers were identified. The Rb-CDK4-Cyclin D pathway is altered in the majority of GBM due to homozygous deletion of CDKN2A/B. AU2-94 has an excellent therapeutic potential as it crossed the blood-brain-barrier effectively. In the both U87 subcutaneous and orthotopic models, AU2-94 reduced the tumour burden and increased the survival of GBM bearing mice significantly compared to vehicle. Moreover, AU2-94 synergised the anti-cancer efficacy of PI3K/Akt/mTOR and HER2 inhibitors in combination. In summary, AU2-94 is a CDK4 inhibitor with high selectivity against a panel of 360 human kinases. This selectivity can be a reason for the better safety of AU2-94 compared to the clinical CDK4/6 inhibitors. The high oral bioavailability, robust antitumor efficacy and excellent safety profiles make AU2-94 a highly attractive candidate for clinical development.

#5702 BTX-9341, a bifunctional degrader of CDK4 and CDK6 for glioblastoma multiforme.

H. Majeski, K. Chahal, A. Okano, A. Pasis, C. Carlson, A. Shakya, Q. Liu, S. Huang, A. Hoskote Chourasia, L. Fung;
Biotheryx, Inc., San Diego, CA

Glioblastoma multiforme (GBM) is an aggressive form of brain cancer with limited treatment options. GBM has a high frequency of dysregulation of the CDKN2A-cyclin D-CDK4/CDK6 signaling node and should subsequently be sensitive to CDK4/6 inhibition. Despite this, the CDK4/6 inhibitors that are approved for HR+/HER2- breast cancer have shown limited efficacy in GBM due to poor blood brain barrier (BBB) penetration. BTX-9341 is a Cereblon (CRBN) mediated CDK4/6 bifunctional degrader that we have developed for HR+/HER2- breast cancer. This degrader shows good exposure in brain tissues with a high brain to plasma ratio. Given the exposure in the brain, we explored the *in vitro* and *in vivo* efficacy of BTX-9341 in GBM cell line and xenograft models. GBM cell lines treated with BTX-9341 showed up to 86% degradation of CDK4 and CDK6 with DC_{50}s <1nM. CDK4/6 phosphorylates the protein RB which releases the transcription factor E2F, inducing the expression of genes which promote cell cycle progression. We examined RB phosphorylation by immunoblot and cell cycle progression by propidium iodide staining followed by flow cytometry. BTX-9341 was potent in all downstream assays, with phospho-RB IC_{50}s <10nM, and G0/G1 cell cycle arrest at concentrations as low as 10nM. We used a 2D colony formation assay (CFA) to assess inhibition of proliferation by cell cycle arrest. BTX-9341 potently inhibited cell proliferation with CFA IC_{50}s of 13-100nM in GBM cell lines. BTX-9341 displays excellent pharmacokinetic properties with good oral bioavailability and high brain to plasma ratios which allowed for oral dosing in both subcutaneous and orthotopic xenograft studies. We examined tumor growth inhibition efficacy in two GBM xenograft models: an intracranial U87 model and a subcutaneous U118 model and saw robust tumor growth inhibition in both models with BTX-9341 treatment. The U118 cells have partially unmethylated MGMT, which lead to a loss of efficacy of temozolomide over time, while BTX-9341 maintained inhibition of tumor growth. This indicates that BTX-9341 may be effective in patient populations for which temozolomide is ineffective. The U87 intracranial xenograft model also showed dose-dependent tumor growth inhibition upon treatment with BTX-9341, indicating that BTX-9341 can cross the BBB and reach concentrations high enough to execute cell proliferation inhibition effects. BTX-9341 treated mice also had much better survival than abemaciclib treated mice, the only CDK4/6i which has BBB penetration. These results show that BTX-9341 displays excellent single agent activity *in vitro* and *in vivo* in GBM models. The xenograft data indicates that BTX-9341 can inhibit growth of MGMT methylated and unmethylated GBM cell lines, and that BTX-9341 can inhibit tumor growth in the brain more effectively than BBB penetrant CDK4/6i. Together this data shows that BTX-9341 may be a promising candidate for treating GBM.

#5703 Development of RVL-101, a CDK4/6-selective, small molecule inhibitor with superior CNS penetration and combinability potential for the effective treatment of primary and metastatic brain tumors.

J. E. Campbell, B.-S. Pan, M. Bower, P. Bertinato, N. Perez, V. Gras Andreu, N. Rana, S. Tabchouri, A. Gupta, J. Kallenbach;
Reverie Labs, Cambridge, MA

Cyclin-dependent kinases 4 and 6 (CDK4/6) are key regulators of the cell cycle that are frequently dysregulated in cancer, leading to unchecked cell growth. CDK4/6 inhibitors have emerged as a promising class of anticancer agents that selectively target this pathway. The primary mode of action of CDK4/6 inhibitors relies on the disruption of retinoblastoma (Rb) protein phosphorylation, which thereby blocks cell cycle progression from G1 to S phase and reduces proliferation of cancer cells by a cytostatic mechanism. However, despite their efficacy, approved and clinical-stage CDK4/6 inhibitors have modest penetration of unbound drug into the brain, limiting their utility in the treatment of brain metastases and primary brain tumors. Additionally, despite the potential benefits of CDK4/6 inhibitors as combination therapies with cytotoxic agents, adjunctive treatment options remain underexplored due to the poor safety profiles of existing therapies. RVL-101 is a preclinical, investigational drug with a novel pharmacophore that has a low nanomolar activity against CDK4, is CDK2,6,7,9-sparing, and maintains >500-fold selectivity over CDK1. To maximize the potential of RVL-101 as a preferred combination partner, this novel agent has been engineered to have exquisite kinome- and safety-panel selectivity with no measured CYP inhibition or induction liabilities. RVL-101 is differentiated from approved and clinical stage CDK4/6 inhibitors having both high partitioning into the brain (Kp) and high free-brain ($Kp_{u,u}$ = 0.7) levels resulting in equal levels of unbound drug in all relevant compartments at steady state. Like other CDK4/6 agents, RVL-101 is broadly efficacious in vivo in ER+/HER2- xenograft models at well-tolerated doses. However, RVL-101 has also demonstrated robust activity in HR-/HER2+ xenograft models as a single-agent and has uniquely shown improved tumor inhibition effect in combination with approved HER2 cytotoxic therapeutics tucatinib and fam-trastuzumab-deruxtecan. RVL-101 was also tested in a GBM model as a monotherapy and in conjunction with the cytotoxic agent temozolomide (TMZ). Remarkably, QD dosing of the cytostatic agent, RVL-101, after pulsatile pretreatment with TMZ led to dramatic synergistic efficacy compared to either agent alone, leading to 100% survival of all animals on the dual therapy arm for more than 3 weeks post discontinuation of dosing. RVL-101 offers the combination of substantial therapeutic benefit and consistent free-drug levels in plasma and CNS that could lead to safe and effective treatment for a broader patient population.

#5705 Discovery of a selective slow-off CDK2 inhibitor NKT3447 with distinct features of suppressing pCDK2, downregulating cyclin E, and achieving prolonged pathway inhibition.

J. Geng[1], **K. Liu**[1], Z. Yu[1], W. Sun[1], H. Wei[1], W. Li[1], J. Lu[1], J. Deng[2], L. Geng[2], Z. Liu[1], Z. Gao[1], Y. Lou[1];
[1]NiKang Therapeutics Inc., Wilmington, DE, [2]NiKang Therapeutics Inc., Shanghai, China

CDK2 is a cell cycle kinase that plays a critical role in controlling the G1 to S-phase transition and its abnormal activation through cyclin E1(CCNE1) amplification has been indicated as the primary oncogenic driver in advanced cancers including ovarian, endometrial, and gastric cancers. In addition, cyclin E1 overexpression has emerged as a key resistance mechanism to CDK4/6 inhibitors in hormone receptor-positive breast cancer patients. Therefore, CDK2 represents a promising novel oncology target. However, development of a potent and selective CDK2 inhibitor has been challenging due to the high homology of CDK2 with other CDKs, particularly CDK1, which is essential in normal cell cycle progression. NKT3447 is a novel, orally bioavailable small molecule CDK2 inhibitor with slow-off kinetics and is highly selective against CDK1 and other CDKs. In addition, NKT3447 exhibits a distinct mechanism of action, including suppression of the Thr160 activating phosphorylation on CDK2 and downregulation of cyclin E1. In biochemical assays, NKT3447 drives a concentration dependent disruption of the CDK2/cyclin E1 and CDK2/cyclin A2 complexes, but not the CDK1/cyclin B1 complex. Consequently, NKT3447 potently inhibits the phosphorylation of Rb (pRb) and induces G1 cell cycle arrest in CCNE1 amplified OVCAR3 cells, while showing minimal or no effect on G2/M phase distribution in all the cell lines tested, including OVCAR3 and KYSE520 (CDK1-dependent) cells. Importantly, NKT3447 has a slow-off kinetics, as demonstrated by NanoBRET target engagement assay, which leads to sustained pRb inhibition after treatment withdrawal. In addition, NKT3447 treatment reduces cyclin E1 protein levels and suppresses phospho-CDK2 (Thr160), which further represses CDK2 activity and prolongs the inhibition of CDK2 signaling. NKT3447 also demonstrates a selective anti-proliferation effect in a panel of human cancer cell lines with elevated cyclin E1 expression and/or dependency on CDK2 or cyclin E1 (DepMap). In line with cellular studies, pharmacodynamic study of NKT3447 in mouse tumor models recapitulates a significant repression of pRb, pCDK2 and cyclin E1. Furthermore, NKT3447 treatment results in a dose-dependent tumor growth inhibition or tumor regression in CCNE1 amplified OVCAR3 and MKN1 tumor models. In addition, the combination of NKT3447 with carboplatin exhibits enhanced anticancer effects in OVCAR3 and MFE-280 models. These results demonstrate that NKT3447 is a potent, selective CDK2 inhibitor with distinct properties and mechanism of action, which holds great potential to effectively treat patients with aberrant CDK2/Cyclin E activation in a variety of cancer types. NKT3447 is currently being investigated in a Phase 1 clinical trial in patients with advanced solid tumors.

#5707 Preclinical evaluation of KRLS-017, a potent, highly selective and reversible CDK7 inhibitor with broad antitumor effect in preclinical models, in preparation for a Phase 1 clinical trial in advanced solid tumor malignancies.

A. L. Hannah[1], S. Ritland[2], T. Steele[3], S. Smith[4], A. Ram[5], B. Slingsby[6], K. Dhingra[7], J. Chrisman[8], R. Dua[8], Y. Tokunaga[9], S. Kono[9], Y. Aga[9]; [1]Independent Consultant, Sebastopol, CA, [2]Independent Consultant, Midway, UT, [3]Independent Consultant, Amesbury, MA, [4]Independent Consultant, San Jose, CA, [5]Independent Consultant, San Francisco, CA, [6]Co-Founder, Seattle, WA, [7]Co-Founder, Sparta, NJ, [8]Independent Consultant, Seattle, WA, [9]Employee Ube Corporation, Minato City, Japan

KRLS-017 is a potent, selective, and reversible inhibitor of Cyclin Dependent Kinase 7 (CDK7). Its molecular formula is $C_{24}H_{35}N_5O_2Si$ and its molecular weight is 453.65 Daltons. KRLS-017 is being developed for the treatment of patients with advanced solid tumor malignancies.

To differentiate KRLS-017 from other CDK7 inhibitors, we created a reversible inhibitor to allow for treatment schedule optimization and maximization of therapeutic index in clinic. High selectivity of KRLS-017 for CDK7 was confirmed using a panel of 313 recombinant human kinases. The IC50 of KRLS-017 against recombinant human CDK7 was determined to be 16 nM, and no other kinases in the panel showed IC50 values less than 300 nM. Antiproliferative activity of KRLS-017 was investigated in vitro using a broad panel of human tumor cell lines. KRLS-017 showed potent antiproliferative effect across a wide variety of both solid and hematologic tumor types, producing GI50 values <200 nM in 258/302 human tumorcell lines tested.

Antitumor activity of KRLS-017 was investigated in vivo using multiple mouse xenograft tumormodels at dose levels ranging from 25 mg/kg to 200 mg/kg using both continuous (daily) andintermittent dosing schedules. Statistically significant tumor growth inhibition was seen at doselevels of 50 mg/kg and higher, with tumor regression observed at 100 mg/kg and 200 mg/kg. Better in vivo tolerability at efficacious doses was observed using intermittent dosing schedules in mouse xenograft models, which led to adoption of an intermittent schedule in the proposed first-in-human phase 1 trial.

KRLS-017 is orally bioavailable in mice, rats, and dogs and plasma drug exposure increased in a proportional manner with dose. Comparing first dose and 28th dose in the dog, minimal plasma accumulation was observed, suggesting once daily dosing in humans would be initially tested. Repeat dose 28 day GLP toxicology studies in rat and dog showed adverse effects in highly proliferative bone marrow and gastrointestinal tissues which is consistent with the known mechanism of action for CDK7 and is considered to be monitorable and manageable in the setting of oncology.

The clinical development plan for KRLS-017 includes an initial Phase 1 dose escalation study (KRLS-017-101) in patients with refractory solid tumor malignancies to assess pharmacokinetics / pharmacodynamics and to determine an optimal dose level and treatment schedule to test in expansion cohorts. Given the potential of CDK7 inhibitors in the treatment of hormone receptor positive breast cancer, combination work with other agents (such as selective estrogen receptor degraders) is on-going.

#5708 Silence exportin 7 sensitizes esophageal squamous cell cancer to CDK4/6 inhibition through block the cell cycle coresectory.

Z. Wu[1], L. Xu[1], C. Jiang[1], A. Bass[2], **J. Zhou**[1];

[1]West China Hospital of Sichuan University, Chengdu City, China, [2]Novartis Institutes of Biomedical Research, Cambridge, MA

Introduction: There is a lack of effective target therapies for esophageal squamous cell cancer. Our previous studies have demonstrated that CDK4/6 is a potency target for ESCC and combination with ERBB inhibitors is sufficient to achieve durable response. The aim of the current study is to prospectively map the landscape of sensitivity and resistance to CDK4/6 inhibition and develop novel combination therapies in ESCC.
Experimental Procedures: We performed a genome-wide functional genetic screening and mini-pool designed CRISPR screen approaches to identify the modulators whose depletion sensitize CDK4/6 inhibition or confer resistance to the CDK4/6 inhibitor Palbociclib and elucidate new therapeutic strategies.
Results: Our screen identified RB as the most enriched sgRNA, while guides targeting CCNE1 and CDK2 as the most depletion sgRNAs after CDK4/6 inhibition. These results validates our experimental approach as RB loss and CCNE1/CDK2 reactivation is the main mechanisms of CDK4/6 resistance. After gathering potential candidates from both screens, we found that genetically ablation of Exportin 7, a nuclear export factor, strongly sensitize CDK4/6 inhibition both in vitro and in vivo. RNAseq revealed a further repression of transcriptional activity of E2F and G2M by addition of XPO7depletion under CDK4/6 inhibitor treatment. To increase our insight in the molecular mechanism that could explain the synergy between XPO7 and CDK4/6, we further performed proteomics of nuclear and cytoplasm in ESCC lines with or without CDK4/6 inhibition. We found that silence XPO7 result in nuclear accumulation of mitosis-regulated genes such as CENPM, KIF4A and WEE1. Combined CDK4/6 inhibition with XPO7 depletion results in further downregulate of CENPM and KIF4A expression in nucleus, abrogating compensatory activation of cell cycle regulation and promote the cytostatic effect in ESCC. We further validated that CENPM and KIF4A depletion also sensitize CDK4/6 inhibition, and consequentially use WEE1 inhibitor after CDK4/6 inhibitor also effectively block the growth of ESCC lines.
Conclusion: Overall, our comprehensive functional genetic screening approach revealed modulation of sensitive and resistance to the inhibition of CDK4/6 in ESCC. XPO7 was identified as a driver to change cell cycle landscape and merits as a therapeutic target combined with CDK4/6 inhibition in ESCC, which is beneficial to provide a novel treatment strategy.

#5709 PF-07104091, a first-in-class CDK2-selective inhibitor for the treatment of HR+/HER2- breast cancer and CCNE1^{high} ovarian cancer.

C. Shen, M. Qiu, N. Huser, B. Pascual, Q. Zhang, T. VanArsdale, A. Murtaza, J. Almaden, K. Kim, L. Anders, K. Eisele;
Pfizer, Inc., San Diego, CA

The selective inhibition of Cyclin\CDK complexes controlling cell cycle progression has been established as cancer therapy by selective CDK4/6 inhibitors in HR+/HER2- breast cancer. Expanding control of the cell cycle through selective inhibition of CDK2 offers novel therapeutic opportunities in cancer, including targeting CCNE1 amplified tumors and countering resistance to CDK4\6 inhibitors in ER+ breast cancer. PF-07104091 is a first-in-class CDK2-selective inhibitor under clinical investigation in patients with HR+/HER2- breast cancer and ovarian cancer. Preclinical studies using PF-07104091 establish the therapeutic impact of CDK2 inhibition in both diseases and highlight distinct mechanistic roles for CDK2 in control of cancer cell proliferation. In models of CCNE1 amplified ovarian cancer, CDK2 plays the dominant role in control of RB1 phosphorylation and the G1 checkpoint. CDK2 inhibition with PF-07104091 induces G1 growth arrest and controls tumor xenograft growth as single agent therapy. In ER+ breast models CDK2 plays a supportive role in the control of RB1 phosphorylation cooperating with CDK4\6. Whole genome CRISPR KO and CRISPR activation screens in conjunction with CDK4\6 inhibition establish CDK2 KO as a primary sensitizer to CDK4\6 inhibition, and support Cyclin E\CDK2 complexes as the driver of resistance to CDK4\6 inhibitors in ER+ breast models. PF-07104091 combined with CDK4\6 inhibitor Palbociclib or CDK4-selective inhibitor PF-0060 synergistically controls proliferation of ER+ BC cells in vitro and induces tumor regression in ER+ BC xenograft models, including PDX models with acquired resistance to CDK4\6 inhibitors and endocrine therapy.

#5710 The brain penetrant CDK4/6 inhibitor, PRT3645, is highly effective in combination with other targeted therapies in preclinical models of breast cancer, CRC and NSCLC.

Y. Zou, K. Gallagher, S. Dhar, A. Busking, S. Pawley, R. Holmes, X. Wu, M. Wang, J. Rager, T. Emm, S. Ruepp, M. Cowart, A. Combs, K. Vaddi, S. Geeganage, P. Scherle, S. Lee;
Prelude Therapeutics, Wilmington, DE

Cell cycle deregulation is a hallmark of cancer and the hyperactivation and overexpression of cyclin-dependent kinase (CDK)s are often drivers of cancer pathogenesis. CDK4/6 are critical mediators of cellular transition into S phase and important for cancer initiation, growth, and survival. Previously we reported a novel brain penetrant CDK4/6 inhibitor, PRT3645, that exhibits single digit nanomolar biochemical potency against CDK4/6 and >2000-fold selectivity against other CDKs. PRT3645 inhibits cellular phosphorylation of Rb with nanomolar potency. Furthermore, PRT3645 exhibits favorable in-vivo safety pharmacology and ADME properties, including increased brain penetration, and demonstrates oral bioavailability across rodents, dog and non-human primates. Here, we explored the therapeutic potential of PRT3645 in tumor models harboring actionable genomic alterations but lacking effective targeted treatments. Specifically, we explored the combination of PRT3645 with a selective estrogen receptor degrader (SERD), an approved treatment for patients with HR+/HER2-, ESR1-mutated advanced or metastatic breast cancer. In an ESR1 mutated breast cancer PDX model, PRT3645 not only exhibited monotherapy activity but also induced significant tumor regression in combination with a SERD through inhibiting ER-mediated signaling. We also investigated PRT3645 single agent activity and combination with a clinically validated MEK inhibitor in a BRAF class III mutant colorectal CDX model. PRT3645 was well-tolerated and demonstrated significant anti-tumor efficacy, which was further enhanced by combination therapy. To further explore comprehensive inhibition of cell cycle progression and overcome potential resistance to CDK4/6 inhibition, we investigated dual inhibition of CDK4/6 and CDK2. CDK2 is a crucial player in regulating the cell cycle by controlling the late G1/S transition, promoting DNA replication, and contributing to the DNA repair processes. Additionally, CDK2 activation has been identified as a potential mechanism of resistance to CDK4/6 inhibition. We evaluated CDK2 and CDK4/6 dual inhibition in CDKN2A loss or CCNE amplified cancer cell lines and observed enhanced proliferation suppression, cell cycle arrest and senescence induction, underscoring the potential of this combination for improved therapeutic efficacy across various cancer types. In summary, PRT3645 displays an excellent balance of potency, selectivity, pharmacokinetic parameters across species as well as brain penetrance. In preclinical studies, PRT3645 was highly efficacious when combined with other targeted therapies, offering potential benefits across a wide spectrum of cancer types. In addition, the concept of dual inhibition of CDK4/6 and CDK2 presents a rational and promising approach to enhance the efficacy of cancer therapy.

#5711 Anti-tumor effects of fadraciclib, CDK2/9 inhibitor, in biliary tract cancer.

J.-M. Kim, A.-R. Nam, K.-S. Oh, J.-H. Bang, Y. Jeong, S. Choo, S. Lee, H. Kim, J. Yoon, T.-Y. Kim, D.-Y. Oh;
Seoul National University Cancer Research Institute, Seoul, Korea, Republic of

Background: Targeting CDKs has emerged as a significant strategy in the development of new drugs. The CDK4/6 inhibitors have proven their efficacy in several tumor types, while the CDK2 and CDK9 inhibitors are currently undergoing clinical trials. In biliary tract cancer (BTC), gene expressions of CDK2 and CDK9 are elevated compared to normal tissue. CDK9, a transcriptional CDK, regulates RNA polymerase II (RNAP II), leading to enhanced transcription of oncogenes, such as MCL1. Aberrant activation of these CDKs is associated with cancer progression and evading apoptosis in BTC. Notably, MCL1 is frequently amplified in intrahepatic cholangiocarcinoma (16-21%). This finding underscores the potential significance of CDK2 and CDK9 as therapeutic targets in BTC. However, in BTC, targeting CDK2 or CDK9 has not yet been studied. In this study, we aimed to test CDK2/9 targeting and develop possible biomarker strategies in BTC.

Method: A total 9 BTC cell lines (SNU245, SNU308, SNU478, SNU869, SNU1196, SNU2670, SNU2773, TFK1, and HUCCT1) were used. Fadraciclib (CDK2/9 dual inhibitor), Olaparib (PARP inhibitor), JQ1 (BRD4 inhibitor) was used. MTT assay, Colony formation assay, Annexin-V assay, and Cell cycle analysis were performed for evaluation of anti-cancer effects. The effect of Fadraciclib on homologous recombination (HR)-mediated DNA damage repair was assessed using focus formation assay and DRGFP assay. Combination of Fadraciclib with Olaparib or JQ1 was evaluated *in vitro* and *in vivo*.

Result: The anti-tumor effect of Fadraciclib monotherapy was relatively higher in MCL1-High BTC cells (SNU869, SNU2773) compared to MCL-Low cells (SNU245, SNU2670). In MCL1-High cells, Fadraciclib inhibited CDK9, leading to downregulation of RNAP II phosphorylation at Serine 2 and MCL1. Fadraciclib also interfered with HR-mediated DNA damage response by inhibiting transcription of HR-related genes. The combination of Fadraciclib and Olaparib exhibited synergistic anti-tumor effects *in vitro* in MCL1-High cells and *in vivo* xenograft model. Conversely, in MCL1-Low cells, Fadraciclib increased BRD4 mRNA expression, leading to the restoration of CDK9-RNAP II activity. This reactivation of RNAP II restored cellular transcription homeostasis, thereby reactivating the transcription of oncogenes such as MCL1. Combination of Fadraciclib and JQ1 showed synergistic effects *in vitro* in MCL1-Low cells and *in vivo* xenograft model by inhibiting restored CDK9-RNAP II activity.

Conclusion: MCL1-High BTC cells are sensitive to CDK2/9 inhibitor and show synergism between CDK2/9 inhibitor and PARP inhibitor. In MCL1-Low BTC, a combination of a CDK2/9 inhibitor and a BRD4 inhibitor might represent an optimal strategy for new drug development.

#5712 Functional dissection of CDK7 in transcription using a highly selective CDK7 inhibitor Q901.

H. Jung[1], D. Um[1], Y. Lee[2], D. Yu[2], D. Lee[2], J. Ahn[2], J. Kim[2], S.-J. Lee[2], J. Kim[2], K. Nam[2], T.-K. Kim[1];
[1]Pohang University of Science and Technology, Pohangsi, Korea, Republic of, [2]Qurient, Seongnamsi, Korea, Republic of

CDK7 is a well-known regulator of both the cell cycle and transcription and plays a crucial role in cell cycle progression by catalyzing T-loop phosphorylation of other CDKs. CDK7 is also an integral subunit of the general transcription factor, TFIIH and regulates transcription through phosphorylation of RNA Polymerase II (Pol II) at CTD Ser5 and CDK9. We used Q901, a highly selective CDK7 inhibitor to further investigate the molecular function of CDK7 in the transcriptional process. Q901 is currently being evaluated in a phase 1 clinical study for selected advanced solid tumors. Compared to previously reported CDK7 inhibitors, Q901 has increased specificity and efficacy, but the impact on transcription have not been studied in detail. In our study, we combined RNA Pol II (pan, Ser5P, Ser2P) ChIP-seq and PRO-seq techniques in the MCF7 breast cancer cell line. The findings demonstrated that the Q901 effectively altered transcription and the RNA Pol II profile in a subset of genes, leading to a significant reduction in Ser5 phosphorylation levels in RNA Pol II. The downregulated genes were associated with critical pathways including downstream of oncogenic genes (MYC and E2F), DNA damage repair, cell cycle checkpoint, and gene expression. To verify whether these genes were the direct targets of CDK7, we performed CDK7 ChIP-seq analysis. CDK7 binding exclusively to the genes that were downregulated by Q901, without any detectable binding to upregulated genes. Despite the universal role of general transcription machinery in transcription, the data demonstrated that the highly selective inhibition of CDK7 in transcription of various oncogenic pathways underlies the potent *in vitro and in vivo* anti-cancer efficacy of this specific CDK7 inhibitor.

#5714 Synergistic effect of the CDC7 inhibitor, monzosertib (AS-0141) with current therapies in AML models.

H. Endo[1], H. Furuichi[1], A. Arimura[2], Y. Nishioka[1], M. Sawa[1];
[1]Carna Biosciences, Inc., Kobe, Japan, [2]CarnaBio USA, Inc., South San Francisco, CA

Introduction: Cell division cycle 7 (CDC7) is a highly conserved serine-threonine kinase that plays an important role in the initiation of DNA replication and cell cycle progression. Aberrant expression of CDC7 have been reported to cause uncontrolled proliferation of many cancer types, suggesting that CDC7 inhibitors may provide a great potential for the development of novel therapy for cancers. Monzosertib (AS-0141) is a potent, selective, orally bioavailable small molecule inhibitor of CDC7, and is currently being evaluated in Phase I study for the treatment of solid tumors. In a preclinical cancer cell panel study, monzosertib showed strong antiproliferative activities against a variety of cancer types, and acute myeloid lymphoma (AML) cell lines were found to be the most sensitive to monzosertib. As a single agent, treatment with monzosertib accumulates DNA damage in cancer cells and induces cell death. In this study, we aimed to investigate the antitumor effects of monzosertib alone and in combination with other anticancer drugs in AML models.
Method: Antiproliferative activity of monzosertib was examined against a panel of 35 human cancer cell lines of various cancer types. DNA metyltransferase (DNMT) inhibitors (azacitidine or decitabine) and BCL2 inhibitor (venetoclax) were evaluated for their synergistic/antagonistic effects in combination with monzosertib against human AML cell lines (THP-1, HL-60, MV4-11, MOLM-14, TF-1, U-937 and NOMO-1). The combination index (CI) was calculated using the Chou-Talalay method. Flow cytometry assay was used to analyze apoptosis. To evaluate the in vivo efficacy, tumor-bearing mice were treated with monzosertib alone or in combination with venetoclax.
Results: The combination of monzosertib with azacitidine, decitabine, or venetoclax resulted in a significant synergistic antiproliferative effects against AML cell lines in vitro. The flow cytometry assay indicated that azacitidine combination induced apoptosis and increased cell death in THP-1 cells. In vivo, oral administration of monzosertib demonstrated robust in vivo antitumor efficacy in a MV4-11 tumor bearing xenograft mouse model, both as a single agent and in combination with venetoclax.
Conclusions: Monzosertib, a selective CDC7 inhibitor, demonstrated strong antiproliferative activity against human AML cell lines, both as a single agent and in combination with standard therapies. Monzosertib exerts synergistic antitumor effect with venetoclax in a human AML xenograft mouse model. These results suggest that monzosertib has a potential to enhance the antitumor efficacy of standard of care agents for AML patients.

#5715 CDK7 modulation of Hippo-YAP activity by RNAPII phosphorylation regulates CDK4/6 inhibitor resistance in hormone positive breast cancer.

C.-J. Yu[1], Y.-J. Zhuang[1], C.-Y. Lin[1], Y.-R. Tseng[1], T.-Y. Lin[1], H.-M. Shih[2], C.-Y. Liu[3], T.-C. Chao[3], L.-M. Tseng[3], C.-C. Huang[3], Y.-F. Tsai[3], F. Tsai[2], **J.-I. Lai[1]**;
[1]National Yang Ming Chiao Tung University, Taipei, Taiwan, [2]National Taiwan University, Taipei, Taiwan, [3]Taipei Veterans General Hospital, Taipei, Taiwan

Breast cancer is the leading cause of cancer in women and poses a massive social economic burden worldwide. CDK4/6 inhibitors have roles as standard of care in advanced and adjuvant setting for hormone positive (HR (+)), HER2 negative breast cancer. CDK6 amplification has been proposed to confer resistance to CDK4/6 inhibitors. By a small molecule screen, we discovered a multi-kinase inhibitor PIK-75 that suppressed the Hippo-YAP pathway and significantly downregulated CDK6, resulting in reversal of CDK6 amplification mediated CDK4/6 inhibitor resistance. To further probe the mechanism, we discovered that PIK-75 suppressed phosphorylation of the C-terminal domain (CTD) of RNA polymerase II (RNAPII) which then resulted in downregulation of YAP expression and the Hippo pathway. Chromatin immunoprecipitation (ChIP) confirmed suppression of RNAPII Ser5 occupancy at YAP promoter after PIK-75 or shCDK7 treatment. Integrating results from RNA sequencing and proteomic analysis in breast cancer cells treated with PIK-75 revealed widespread transcription suppression and substantial spliceosome defect. Alternative splicing analysis by PIK-75 treated cells revealed a widespread splicing defect affecting multiple genes, including YAP, providing an alternative pathway for PIK-75-CDK7 mediated transcriptional regulation. We then investigated the phenotypic impact mediated by PIK-75 and CDK7 inhibition. We discovered that CDK7 silenced cells showed downregulation of YAP intranuclear translocation, impairment of cell migration, and cell cycle progression. ChiP-sequencing of RNAPII was also performed to investigate changes in global RNAPII occupancy and impact on promoter proximal pausing. In vivo studies confirmed that PIK-75 treatment demonstrated tumoricidal efficacy in CDK6 amplified HR (+) breast cancer cells, while the CDK4/6 inhibitor abemaciclib showed minimal cytotoxicity. In conclusion, we discovered a novel CDK7-RNAPII phosphorylation-Hippo/YAP-CDK6 regulation axis that when perturbed, could regulate CDK4/6 inhibitor resistance in HR (+) breast cancer. Molecular studies and multi-omic profiling elucidated the role of CDK7 in hippo pathway and characterizes multiple roles of PIK-75. Our study provides intriguing novel insights into the link between "transcriptional CDKs" and the hippo pathway that could potentially be further probed for therapeutics in HR (+) breast cancer.

#5716 CDK7 as a drug target in advanced stage uveal melanoma.

F. J. Waltrich, Jr.;
Thomas Jefferson University, Philadelphia, PA

Uveal melanoma (UM) metastasizes predominantly to the liver, and most metastatic UM are BAP1-deficient. Targeted therapies, such as MEK inhibitors, have failed clinically. There are few FDA-approved therapies for metastatic UM, but these therapies are limited to only a subset of patients and have modest survival benefits. Hence, there is a need to identify novel and effective treatment strategies. Due to the low mutational burden in UM, targeting transcriptional may be an effective strategy. Here, we identified Cyclin Dependent Kinase 7 (CDK7), a key regulator of transcription, as an essential and druggable target in UM. CDK7 directly phosphorylates RNA polymerase II and is expressed in all UMs. siRNA-mediated knockdown of CDK7 decreased the growth of three BAP1-deficient UM cell lines. We tested a clinically relevant, highly specific CDK7 inhibitor, SY-5609, developed by Syros Pharmaceuticals and similarly showed that the cell lines were sensitive to the growth inhibitory effects of SY-5609. Furthermore, we observed synergistic effects on cell growth inhibition when combined with a MEK inhibitor (Trametinib). We performed RNA sequencing and identified several Hallmark Genesets to be positively enriched, including interferon-gamma response, TGF-beta signaling, and NFκB signaling after treatment with SY-5609. These results are validated using a multi-omic approach, utilizing Reverse Phase Protein Array (RPPA) data to validate transcriptome to proteome expression of these enriched pathways. Overall, our studies indicate that targeting CDK7 in uveal melanoma is a potential treatment strategy for BAP1-deficient UM and enhances MEK inhibitor efficacy.

#5717 CDK4 inhibition suppresses Rab11 mediated collective cell migration in colon cancer cells.

Chun Pu Cheng, Chia-En Ku, Shin-Ru Lee, Yu-Chun Wang, Yu-Chien Ching, Hui-Chun Chen, Wei-Ting Chao

Tunghai University, Taichung, Taiwan

In tumor progression, cell proliferation and cell adhesion are critical for tumor growth and metastasis. It has been demonstrated cell division which associated with microtubule organization also has impact on tubulin mediated focal adhesion turnover, however, the mechanism is not clear in the cell cohort migration which is accompanied with both cell proliferation and cell migration. This study is to investigate the effect of cell cycle inhibition in the collective cell migration. HT-29 colon cancer cells were treated with CDK4 inhibitor CINK4, paclitaxel and focal adhesion inhibitor PF573228. The cell proliferation rate was determined by MTT assay, cell migration ability was analyzed by wound healing assay. Rab11, E-cadherin and focal adhesion kinase were revealed by immuno-confocal microscopy. When HT-29 cells were treated with lower dose of CDK4 inhibitor CINK4, cell migration was suppressed. Meanwhile, in the result of immunostaining, the recycling endosomal protein Rab11which is involved in E-cadherin turnover in collective cell migration was not distributed in the cell membrane after CINK4 treatment. Furthermore, when cellular FAK activity were inhibited by PF573228 and tubulin disassembly was inhibited by paclitaxel, the cell area was increased with stable attachment, however, the membrane translocation of Rab11 was not affected. This study demonstrated cell cycle inhibition in G1 phase affected Rab11 mediated collective cell migration through tubulin regulated focal adhesion turnover for cell attachment. Keywords: CDK4, cell cycle, focal adhesion kinase, paclitaxel, colon cancer

#5718 TGN-1062, a dual CDK7 and FLT3 Inhibitor, shows potent anti-AML activity and synergizes with Venetoclax.

T. Thode[1], L. Nguyen[1], B. Durbin[1], A. Weston[1], S. Ng[1], T. Ghosh Halder[1], T. Bargenquast[1], R. Soldi[1], S. Kasibhatla[1], V. Chung[2], V. Villaflor[2], M. Kaadige[1], G. Marcucci[2], S. Sharma[1];

[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [2]City of Hope, Duarte, CA

Purpose: Acute Myeloid leukemia (AML) is an aggressive malignancy of the hematopoietic system with poor survival rates. The best responses to treatment are achieved for young and fit patients who can tolerate chemotherapy followed by stem cell transplantation compared to older patients unfit to take intense chemotherapy. Since its approval venetoclax, a BCL2 inhibitor, has been the standard treatment for older patients in combination with a hypomethylating agent (HMA), such as azacitidine or decitabine, with a 76% complete response (CR). Despite this success as a frontline treatment, there is limited response for patients with relapse and refractory (r/r) and development of novel agents is required to improve overall therapeutic response. MYC has been shown to be frequently activated in AML and plays an important role in the induction of leukemogenesis and leukemic progression. While BCL2 inhibition via venetoclax has, in part, been shown to control c-MYC activation, the addition of another inhibitor which controls MYC may prove beneficial. CDK7 plays a dual role in tumor progression by regulating the cell cycle and transcription. CDK7 has also been shown to be associated with the overexpression of oncogenic driver genes such as BCL2 and MYC. Previously, we have presented the development of a potent and reversible CDK7 inhibitor, TGN-1062. Here, we have generated data supporting the potential benefit of CDK7 inhibition in combination with standard of care therapy for AML.

Methods: AML lines were co-treated with TGN-1062, venetoclax, and/or an HMA, assessed for viabilities with CellTiter-Glo, and analyzed with the Bliss synergy model. AML CDX or PDX cells were implanted subcutaneously or transplanted via tail vein, respectively, and treated with TGN-1062 and/or venetoclax. Subcutaneous tumors were measured to determine tumor growth inhibition (TGI) and correlating drug accumulation levels were measured in tumors and plasma using mass spectrometry. Leukemic burden and survival were evaluated at the end of treatment for transplanted models. Immunohistochemistry (IHC), Western blotting, and RT-PCR were performed to determine changes in relevant biomarkers in tumors and/or AML cell lines.

Results: Previously we have reported that TGN-1062 was effective in suppressing the growth of MV4-11 AML model. We extend these studies and show that TGN-1062 has activity at lower doses in both in vitro and in vivo AML models. In addition, we show synergy between TGN-1062 and other agents for AML treatment, including venetoclax or an HMA. Western blotting demonstrated significant changes in apoptotic markers. Survival of mice bearing AML was significantly increased with TGN-1062 treatment and combination treatment with venetoclax produced the longest survival.

Conclusion: Targeting CDK7 with TGN-1062 in combination with venetoclax or an HMA is a promising therapeutic approach for treatment of AML and needs further investigation.

#5719 Targeting CDK4/6 and BET proteins for the treatment of RB+ and RB- osteosarcoma.

R. Malko, P. H. Pandya, H. E. Shannon, B. J. Bailey, E. A. Dobrota, C. Young, F. Barghi, N. Riyahi, R. Justice, M. A. Trowbridge, K. L. Coy, A. L. Sinn, K. Bijangi-Vishehsaraei, M. J. Ferguson, M. Saadatzadeh, K. E. Pollok;
Indiana University School of Medicine, Indianapolis, IN

Osteosarcoma (OS) is the most common malignant bone cancer characterized by heterogeneity and genomic instability. Treatment and survival of patients have not improved in several decades, making it urgent to develop safe and effective therapies. Dysregulation of cell cycle regulators *CDKN2A*, cyclins, and CDK4/6 represent high-risk signatures in aggressive OS and can be targeted via CDK4/6 inhibitors (CDK4/6i). However, monotherapy often fails due to resistance from speculated RB loss as well as hyperactivation of compensatory signaling pathways in RB proficient cancers. In addition, >70% of OS patients have RB loss which is viewed as a biomarker of therapeutic response that negates the use of CDK4/6i. However, more research is needed in RB-deficient preclinical models to clearly define and validate the utility of RB as a biomarker for patient stratification. Based on our screening data, we hypothesize that combining CDK4/6i with bromodomain and extraterminal domain inhibitors (BETi) will potentiate anti-tumorigenic effects regardless of RB status in OS. BETi creates imbalances between transcription and replication which worsens oncogenic stress. In OS cell lines, combination index and Bliss analysis indicated additive-to-synergistic growth inhibition using CDK4/6i (abemaciclib or palbociclib) and BETi (AZD5153). Dual therapy also resulted in increased apoptosis at clinically relevant concentrations in an OS xenoline (TT2) compared to monotherapy. To determine potential for emergence of therapeutic resistance, an in-vitro longitudinal growth delay assay was established. While single agent therapies resulted in transient decreases in cell numbers over time, combination CDK4/6i+BETi resulted in cell death ($p<0.05$). To determine the effect of RB loss on therapeutic response to CDK4/6i, CRISPR mediated RB-knockout (KO) clones were developed in 143B human and K7M2 murine OS cell lines. RB KO cells exhibited sensitivity to CDK4/6i irrespective of RB status. However, levels of CDK4/6i required for 50% growth inhibition in RB KO were 1-3-fold higher using palbociclib, with negligible differences observed with abemaciclib in RB KO vs WT clones. To determine if therapeutic response is achievable in-vivo, a single-agent dosing study was conducted using palbociclib (40mg/kg, SID) and AZD5153 (1mg/kg, BID) in patient-derived xenograft (PDX) model derived from a metastatic lesion in the pelvis (TT2 PDX) harboring a CDK4/6 hyperactivation signature and monoallelic RB loss. Tumor growth reduction and survival was significantly higher in monotherapy groups compared to vehicle. However, one week after dosing was stopped, survival rates based on tumor volume endpoint were 40% and 100% for palbociclib and AZD5153 respectively. In-vivo efficacy of dual CDK46i+BETi is underway. This data provides rationale for further study of novel therapeutic options which may expand the clinical utility of CDK4/6i regardless of RB status.

#5720 Targeting CDK9 in cutaneous T-cell lymphoma using patient-derived xenograft models.

Y.-J. Liu, C.-H. Wu, L. Pincus, W. Z. Ai;
UCSF, San Francisco, CA

Cutaneous T-cell lymphoma (CTCL) is a rare form of non-Hodgkin lymphoma. Mycosis fungoides and Sézary syndrome (MF/SS) are the most common subtypes in CTCL. Early-stage MF/SS has a favorable prognosis. The advanced-stage CTCL has limited treatment options and a median survival of <5 years, highlighting the urgent need to develop targeted therapies in CTCL. Preclinical studies of CDK9 inhibitors have shown anti-tumor activity in various subtypes of hematologic malignancies. Several CDK9 inhibitors have entered clinical trials for lymphomas and leukemias. However, whether targeting CDK9 in CTCL is a therapeutic option is little known and has resulted in CTCL not being included in ongoing clinical investigations of CDK9 inhibitors. AZD4573 is a highly selective and potent CDK9 inhibitor currently under clinical investigation for Hodgkin and non-Hodgkin lymphomas. It was shown that AZD4573 induces tumor cell death through depletion of MCL-1. Overexpression of MCL-1 has been shown in CTCL cell lines and skin biopsy specimens of CTCL patients. MCL-1 expression appears to be particularly elevated in patients with advanced stage disease. Here, we investigated the ex vivo anti-tumor activity of AZD4573 using patient-derived CTCL xenograft models (PDXs).

Primary tumor cells harvested from CTCL PDX mice were activated with CD2/CD3/CD28 beads and incubated in hIL-2 and hIL-7 at an optimal cell density. Subsequently, cells were exposed to AZD4573 at various concentrations for 8 hr, then treated cells were harvested, washed, and placed in fresh media for another 48 hr. Growth inhibition was measured by the Real-Time Glo cell viability assay, and apoptotic activity was assessed by flow cytometry analysis of Caspase 3/7 activity and Annexin V + propidium iodide (PI) double staining. Additionally, we conducted RNA-seq analysis for MCL-1 expression in CTCL PDX primary tumor cells.

AZD4573 inhibited cell proliferation in a dose-dependent manner in primary tumor cells from three CTCL PDX mice (PRS-1, PRS-2 PRS-3), with GI_{50} of 43.5 nM, 175.4 nM, and 113.5 nM, respectively. Furthermore, AZD4573 significantly increased caspase 3/7 activity and apoptosis in PRS-1 and PRS-3, but not PRS-2 primary tumor cells. In addition, our RNA-seq analysis showed that compared with normal controls (normal PBMC from healthy donors), the MCL-1 gene expression is increased 10-fold (P-value <0.0001) in PRS1 cells. The MCL-1 gene expression in PRS2 and PRS3 cells is the same as normal control. Furthermore, PRS-1, which has the highest MCL-1 expression level, is most sensitive to AZD4573.

In conclusion, AZD4573 demonstrated dose-dependent growth inhibition and apoptosis induction in primary CTCL tumor cells. In addition, the expression level of MCL-1 appeared to be correlated with the ex vivo anti-tumor activity of AZD4573. Our findings provide a rationale for clinical investigation of targeting CDK9 in CTCL.

#5721 Dual targeting of CDK4/6 and CDK7 pathways augments tumor response in breast cancer.

E. Son, **S. Kim**, H. Park, M. Kim, H. Yang;
Columbia University Irving Medical Center, New York, NY

CDK7 plays a pivotal role in cell proliferation, serving as both a cell-cycle CDK regulator and a transcription machinery component. Clinical trials are currently exploring CDK7 inhibitors (CDK7i) as a second-line treatment for hormone receptor-positive (HR+) breast cancer post-CDK4/6 inhibitor (CDK4/6i) therapy progression and as a first-line treatment in triple-negative breast cancer (TNBC). This study evaluates the impact of CDK7i on transcription and CDKs activities and the synergistic potential of CDK7i in combination with CDK4/6i. Kinetic analyses indicate that CDK7i preferentially target global transcription over CDKs activities. Furthermore, a combination of CDK7i and CDK4/6i effectively suppresses cell proliferation in drug-naïve cells, albeit without the same efficacy in CDK4/6i-resistant cells. Our findings provide valuable insights into the evolving field of CDK inhibition strategies and provide critical guidance on the potential therapeutic application of CDK7i in breast cancer treatment.

#5722 Preclinical activity of CDK4/6 inhibitor alone or in sequential combination with chemotherapy using breast cancer cell line-derived organoid culture.

M. Kamita, H. Ali, E. Jiagge, J. Bensenhaver, E. Walker;
Henry Ford Health System, Detroit, MI

Breast cancer ranks as the most prevalent cancer globally, with lung and colorectal cancers following closely. Dysregulation of the cyclinD:CDK4/6:Rb axis has been shown to be a common feature in a number of human malignancies, including breast cancer. Targeting this pathway has emerged as a promising strategy for breast cancer treatment. Currently, the U.S. Food and Drug Administration has approved three CDK4/6 inhibitors for advanced hormone receptor-positive, HER2-negative breast cancer, when used in combination with endocrine therapy. However, there are still many breast cancer cases that do not qualify for these criteria and, therefore, do not benefit from CDK4/6 inhibitors prompting investigations into their potential synergy between CDK4/6 inhibitors with chemotherapy. Efforts are currently being made to test the application of these drugs in combination with chemotherapy. Previous studies have demonstrated a synergetic effect of combining CDK4/6 inhibitors and other therapies to treat breast and prostate cancers. While many studies administer these drugs concurrently, our hypothesis proposes a sequential combination approach. This method involves arresting cell cycle at the G0G1 phase using CDK 4/6 inhibitors and then releasing the drug when the cells are more vulnerable to chemotherapy treatment. Such an approach has the potential to expand the application of CDK4/6 inhibitors beyond ER+/HER2- breast cancer. The primary objective of this study is to evaluate the effectiveness of CDK4/6 inhibitors, both alone and in sequential combination with chemotherapy, across a range of breast cancer subtypes. Breast cancer cell lines (MDA-MB-231, HCC70 and T47D) were used in the study. For each cell line, a total of $3x10^5$ cells were seeded in a 6-well plate, and after an overnight incubation, the media was changed with or without a CDK4/6 inhibitor (abemaciclib) and cultured for up to 72 hours. We monitored the drug's efficacy through flow cytometry and cell counting. Abemaciclib suppressed cell proliferation and cell cycle in G0G1 phase in the treated cells compared with the control. The results were similar in both receptor-positive and triple-negative breast cancer cell lines. The effect of abemaciclib was dose-dependent, and reversible at least 48 hours after drug withdrawal, suggesting an opportune time for administering chemotherapy. Future research will delve into investigating the efficacy of sequential treatment with chemotherapy after CDK 4/6 inhibitor withdrawal, utilizing 2D and 3D culture systems.

#5723 Selectivity profiling of small molecule kinesin inhibitors using microplate-based ATPase activity assay.

B. P. Lee, S. Oh, K. Y. Horiuchi, **S. F. AbdulSalam**;
Reaction Biology Corporation, Malvern, PA

Kinesin superfamily proteins (KIFs) are a large family of molecular motor proteins, that share a highly conserved motor domain. KIFs play an important role in cell division and transport of vesicles and organelles within cells. Mitotic kinesins hydrolyze ATP through its ATPase activity to move along the spindle microtubules and carry out several functions during mitosis to facilitate precise chromosome segregation. Altered expressions of several kinesins are shown in various cancers, fueling the aggressive nature of cancers leading to genomic instability. KIF11/Eg5 overexpression is shown in various cancers including hepatic carcinoma, lung, prostate, colorectal, gastric, and pancreatic cancers. Small molecule inhibitors of KIF11/Eg5 and CENP-E are shown to result in mitotic arrest leading to apoptosis in tumor cell lines. Despite the poor clinical outcome of several Eg5 and CENP-E inhibitors entered in clinical trials, targeting kinesins remains an attractive anti-cancer therapeutic approach. Recently, an inhibitor of KIF18A has entered clinical trial for treatment of solid tumors with high chromosomal instability. Here we show development of a microplate based biochemical screening assays for a panel of kinesin motor domain proteins. We summarize kinetic characterization of kinesin proteins and study the selectivity of various previously reported KIF18A, Eg5, CENP-E inhibitors across a kinesin selectivity panel.

#5724 Preclinical evaluation of a novel CHK1 inhibitor encapsulated within the liposome, SMP-3124, for the treatment of solid cancer.

Yuka Kumagai[1], Ryosaku Inagaki[1], Kana Shimizu[1], Wataru Hirose[2], Naoaki Shimada[2], Kento Hayashi[2], Yoshiko Fukuoka[2], Makoto Matsuoka[2], Seiji Kamioka[2], Hitoshi Ban[2], Hiroki Umehara[1], Yusuke Sawayama[2]

[1]Cancer Reseach Unit, Sumitomo Pharma Co., Ltd, Osaka, Japan, [2]Sumitomo Pharma Co., Ltd, Osaka, Japan

Checkpoint kinase 1 (CHK1) is a serine/threonine kinase which plays a critical role for DNA damage responses (DDR) throughout the cell cycle in human cells. CHK1 is mainly activated by replication stress resulting in single-stranded DNA breaks induced by chemotherapeutic agents or mutations in DNA repair related genes. These kinds of stresses are reported to increase the dependency on DDR pathway molecule including CHK1. Therefore, targeting CHK1 is promising strategy for drug discovery. In fact, CHK1 inhibition induces S phase arrest and inhibits cell growth in wide range of cancer cell lines. Recently, a number of drugs in this pathway are tested in clinical trials. Although some of them showed obvious clinical responses in both monotherapy and combination therapy, their efficacies are limited because of their toxicities. To maximize the efficacy, we utilized CHK1 inhibitor with liposomal formulation which changes drug distribution to achieve longer drug retention in plasma and accumulation in tumor. Here, we generated SMP-3124, a novel and selective CHK1 inhibitor encapsulated within the liposome. SMP-3124 showed durable pharmacodynamic response due to the liposomal accumulation in the tumor in xenograft model. We confirmed potent anti-tumor activities of SMP-3124 in multiple subcutaneous xenografted models without severe side effects. In addition, SMP-3124 showed prolonged overall survival in both peritoneal dissemination and orthotopic model using human ovarian cancer cells. SMP-3124 synergistically inhibited tumor growth in combination with gemcitabine without additional hematological toxicities induced by gemcitabine. We are planning to an investigational new drug application in 2024.

#5725 Aurkin-A, a TPX2-Aurora A inhibitor disrupts alisertib-induced polyploidy in HG-diffuse large B cell lymphoma.

P. J. Conway III, B. De la Pena Avalos, J. Dao, S. Montagnino, D. Kovalskyy, E. Dray, D. Mahadevan;
UT Health Science Center at San Antonio, San Antonio, TX

Chemotherapy induced polyploidy (CIP) is a mechanism of inherited drug resistance resulting in an aggressive disease course in cancer patients. Alisertib, an Aurora Kinase A (AK-A) ATP site inhibitor, induces cell cycle disruption resulting in polyaneuploidy in high-grade (MYC and BCL2 amplified or expressed) Diffuse Large B Cell Lymphoma (HG-DLBCL). Propidium Iodide cycle flow cytometry was utilized to quantify alisertib induced polyploidy in U2932 and VAL cell lines. In U2932 cells, 1μM alisertib generated 8n+ polyploidy in 48% of the total cell population after five days of treatment. Addition of Aurkin A an AK-A/TPX2 site inhibitor, disrupted alisertib induced polyploidy in a dose-dependent manner with associated increased apoptosis in DLBCL cells. Combination of Aurkin A plus alisertib significantly reduced polyploidy and sensitized DLBCL cells to alisertib. The sensitization of alisertib with Aurkin A through complete AK-A inhibition is of high clinical importance as the alisertib dose can be significantly reduced while preventing polyploidy, enhancing efficacy, and significantly reducing toxicity to normal tissue. In clinical trials of alisertib in lymphoma, a maximum tolerated dose of 1.5μM was achieved. In U2932 cells, we found the addition of 100μM Aurkin A reduced the alisertib IC_{50} from 983nM to 34nM. We generated a stable FUCCI U2932 cell line expressing Geminin-clover (S/G2/M) and cdt1-mKO (G1), to help monitor cell cycle progression in live cells. Using this system, we identified alisertib-induced polyploidy through endomitosis, which was eliminated with Aurkin A treatment. In a VAL cell line mouse xenograft model, we show polyploidy generation in alisertib treated mice versus vehicle control or Aurkin A. Aurkin A plus alisertib significantly reduced polyploidy and tumor growth compared to vehicle control or Aurkin A levels. Finally, we performed Data-Independent Acquisition Mass Spectrometry on alisertib, Aurkin A, and combination alisertib/Aurkin A treated U2932 cells to identify therapy induced proteomic changes. This proteomic analysis has provided insight into the mechanism of alisertib polyploidy induction and the protective mechanism of within the combination therapy. Our in vitro and in vivo studies show that Aurkin A synergizes with alisertib and significantly decreases the alisertib dose needed to disrupt polyploidy while increasing apoptosis in HG-DLBCL cells.

#5726 The potential anti-cancer activity of dual TTK/PLK1 inhibitor, BAL0891, in bladder cancer.

Background: BAL0891 is a novel dual inhibitor of threonine tyrosine kinase (TTK) and polo-like kinase 1 (PLK1) which affects mitotic spindle assembly checkpoint integrity resulting in aberrant mitotic progression of cancer cells. Since unlike other organs, bladder urothelium is highly regenerative in certain circumstances, there are high chances of cell cycle inhibitors to have anti-cancer activity over bladder cancer. In this study, we investigated the therapeutic potential of BAL0891 in bladder cancer compared to single TTK or PLK1 inhibitor and discovered the best therapeutic combination partner for BAL0891.
Methods: We performed meta-analysis of the mRNA expression levels of bladder cancer using Gene Expression Profiling Interactive Analysis 2 (GEPIA2). Representative bladder cancer cell lines (253J, 253J-BV, J82, RT4, T24, J82, HT1197, and HT1376) were treated with the dual protein kinase inhibitors, BAL0891, in comparison with TTK inhibitor (BAY1217389) or PLK1 inhibitor (onvansertib). BAL0891 was combined with CDK4/6 inhibitor, another cell cycle inhibitor working at different point from BAL0891. Cell viability was assessed using CCK-8 assay during 72 hours after treatment. Expression levels of TTK and PLK1 were measured by immunoblotting. Cell cycle analysis and cell apoptosis detection were performed on T24 cell.
Results: The mRNA expression levels of both TTK (16.7 times) and PLK1 (10.0 times) were significantly upregulated only in bladder cancers compared to normal bladder tissues (P<0.05). Compared to TTK or PLK1 inhibitor, BAL0891 was sensitive in 75% of bladder cancer cell lines (IC50 <0.1 uM) and significantly reduced proliferation of bladder cancer cell lines depending on the dosage. TTK and PLK1 expression levels of cancer cells were associated with the sensitivity to BAL0891. BAL0891 significantly induced necrosis and increased in polyploidy and G2/M arrest in T24 cell. The anti-cancer activity of BAL0891 was further enhanced in certain cell lines (RT4, and J82) by combination of CDK4/6 inhibitor.
