Introduction: Emergence of resistance to immune checkpoint blockade (ICB) mandates the development of strategies for ICB sensitization. Here we employed a multi-omic approach to understand the effects of epigenetic priming in re-shaping the tumor microenvironment, together with genomic drivers of therapeutic response of epigenetic therapy followed by ICB in non-small cell lung cancer (NSCLC).

Methods: We performed whole exome sequencing (WES) on 39 baseline tumors and bulk RNA sequencing (RNAseq) on 18 serial tumors across 42 patients with metastatic immunotherapy-naïve NSCLC, who received azacitidine and entinostat followed by nivolumab (NCT01928576). WES was utilized to assess co-mutations, mutation signatures and genome-wide structural changes. RNAseq was utilized for gene and gene set enrichment analysis (GSEA) and repeat element analysis. Response after nivolumab initiation was assessed using RECIST 1.1 criteria. Patients who were progression-free at 6 months or alive at 2 years after initial treatment were defined as exceptional responders.

Results: We found an enrichment in inactivating mutations in homologous recombination genes in radiographic responders (Fisher's exact, p=0.0007). Higher germline and somatic HLA class II diversity (Mann-Whitney U-test, p=0.05 and p=0.03 respectively), and an enrichment of smoking and DNA damage mutational signatures were noted in radiographic responders (Mann-Whitney U-test, p=0.03 and p=0.15 respectively). Radiographically responding tumors harbored a higher number of mutations in genomic regions that were haploid or present in multiple copies (persistent tumor mutation burden; Mann-Whitney U-test, p=0.018). GSEA revealed an upregulation of inflammatory response gene sets post-epigenetic therapy in patients attaining an exceptional response. Antigen presentation, interferon-alpha, and interferon-gamma related gene sets were upregulated in exceptional responders post epigenetic priming (FDR-adjusted p=0.005, p=0.009, and p=0.011 respectively). Additionally, we observed an enrichment in interferon-alpha, cancer testis antigens, and interferon-gamma related gene sets in patients with a longer progression-free survival (FDR-adjusted p=0.007, p=0.011, and p=0.013 respectively). Repeat element analysis showed an increase in long terminal repeats on-therapy in exceptional responders, suggesting induction of repeat element expression with epigenetic therapy. A higher expression of MAGE family tumor associated antigens (MAGEA10, MAGEB1, MAGEB2) was noted post-epigenetic therapy in exceptional responders.

Conclusions: Genomic and transcriptomic analyses reveal the potential of epigenetic-priming to re-shape the tumor microenvironment and highlight patients that could benefit from combination epigenetic therapy with immunotherapy.

#6552 Intratumoral (ITu) delivery of mRNA-2752 encoding human OX40L/IL-23/IL-36γ in combination with durvalumab induces an immunostimulatory effect within the tumor microenvironment (TME) of patients with advanced solid tumors.

[1]Moderna, Inc., Cambridge, MA,[2]Massachusetts General Hospital, Boston, MA,[3]The University of Chicago, Chicago, IL,[4]UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA,[5]Sheba Medical Center, Ramat Gan, Israel,[6]Rambam Medical Center and Technion - Israel Institute of Technology, Haifa, Israel,[7]Oregon Health and Science University, Portland, OR,[8]Sarah Cannon Research Institute / Tennessee Oncology, PLLC, Nashville, TN,[9]Sourasky Medical Center, Tel Aviv, Israel,[10]Sarah Cannon Research Institute / Florida Cancer Specialists, Sarasota, FL,[11]One Clinical Research and Edith Cowan University, Perth, Australia,[12]Westmead Hospital, Sydney, Australia,[13]Melanoma Institute Australia, The University of Sydney and Royal North Shore and Mater Hospitals, Sydney, Australia

Background mRNA-2752 is a first-in-class ITu therapy composed of mRNA encoding human OX40L/IL-23/IL-36γ in a lipid nanoparticle. The combination of T cell costimulation and proinflammatory cytokines were developed to modulate the TME and allow a more robust immune response. Here we show evidence of the pharmacodynamic effect of ITu administration of mRNA-2752 in combination with PD-L1 antibody.

Methods In this ongoing phase 1 study (NCT03739931), patients (pts) with advanced solid tumors received 0.25-8 mg mRNA-2752 alone (Arm A) or in combination with 1500 mg IV durvalumab (Arm B)[1,2]. Pre and on-treatment peripheral and tumor samples were collected to monitor changes in cytokines by ligand binding assays, gene signatures by RNA sequencing, and T cell infiltration by immunohistochemistry. Tumor biopsies were taken at baseline, 24h, 15 and 28 days post treatment.

Results mRNA-2752 administration in combination with durvalumab revealed ≥2-fold plasma level increases of IL-23 (34/40, 85%) and IFN-γ (50/65, 77%) at 24h after first injection; exposure was induced in a dose-dependent manner. We observed induction of CD8 T cell abundance (20/49, 41%) and proliferation (23/49, 47%), and OX40L protein expression (28/49, 57%) in pts with evaluable post-treatment injected lesion biopsies. CD8 T cell abundance increased in 2 pts with evaluable post-treatment un-injected lesion biopsies. A positive correlation was observed between T cell abundance and T cell effector genes. All three mRNA (IL-23, IL-36γ, and OX40L) encoded genes were detected post treatment in tumor samples from 43 evaluable patients. In 18 pts with injected lesion biopsy samples at baseline and day 28 samples, the genes related to cytotoxic function (*IFNG, GZMB, PRF1)*, T cell migration (*CCL21, CCR7, KLF2*), T cell activation/memory phenotype (*TCF7, CD69, ITGAE*), and conventional type 1 dendritic cells (*CLEC9A, XCR1*) were induced 28 days post-treatment in pts with complete/partial response or stable disease (CR/PR/SD, n=7) compared to progressive disease (PD, n=11) pts. RNA-Seq transcriptome analysis showed increases in the immune inflamed gene signatures related to antitumor activity in 24/43 (56%) pts post-treatment, and the pre-existing immune inflamed phenotype within the TME was associated with clinical benefit.

Conclusions mRNA-2752 ITu injection induced a systemic immunomodulatory effect by elevating effector cytokines. This was associated with pharmacodynamic changes within the TME, including increases in T cell abundance and proliferation, and upregulation of immune gene signatures that correlate with antitumor response.

#6553 Targeting macrophages and regulatory T cells improves response to chemotherapy in high-grade serous ovarian cancer.

S. Elorbany[1], C. Berlato[1], L. Carnevalli[2], S. Barry[3], E. Maniati[1], J. Wang[1], R. Manchanda[1], J. Kzhyshkowska[4], F. Balkwill[1];
[1]Queen Mary University of London, London, United Kingdom, [2]Roche, London, United Kingdom, [3]AstraZeneca, Cambridge Biomedical campus, London, United Kingdom, [4]Institute of Transfusion Medicine and Immunology, Mannheim, Germany

Despite the initial response to chemotherapy, most high-grade serous ovarian cancer (HGSOC) patients will suffer disease relapse within two years of diagnosis with no currently successful immunotherapy options.We performed single-cell RNA sequencing (scRNAseq) on omental metastasis from HGSOC patients. Analysis of 64,097 immune cells showed that neoadjuvant chemotherapy (NACT) induced immunosuppressive mechanisms that counteracted its potentially positive effects. We showed that while NACT enhanced phagocytosis and antigen presentation, this was counterbalanced by upregulation of Stabilin1 (STAB1) in eight out of eleven macrophage subpopulations we identified. The NACT associated increase in macrophage STAB1 expression was validated in a separate cohort of eighty HGSOC patients at the protein level. STAB1 is a macrophage scavenger receptor that transports phagocytosed targets to undergo significant lysosomal degradation reducing the efficiency of antigen presentation. In vitro anti-stabilin1 antibody (anti-stab1 ab) -treated macrophages had significantly reduced antigen degradation and higher CD11C expression than isotype-treated ones. Furthermore, T cells co-cultured with anti-stab1 ab -treated macrophages had increased T cell proliferation and killing.We identified thirteen CD4 subpopulations by scRNAseq, five of which were Tregs. We showed that NACT significantly upregulated and activated Tregs. Tregs displayed a shared developmental trajectory with naïve and effector T cells suggesting that those are induced rather than natural Tregs. This was supported by TCR clonal sharing between Tregs and other effector cells. In vitro T cells treated with FOXP3 anti-sense oligonucleotide (ASO), AZD8701, had an anti-tumor cytokine profile and enhanced tumor cell killing. Analysis of 69,781 scRNAseq cells from control and chemotherapy-treated HGSOC syngeneic mouse model showed similar responses. In two HGSOC syngeneic mouse models (HGS2 and 30200), combinations of chemotherapy with anti-stab1 ab and/or Foxp3-ASO significantly increased median survival of mice with established peritoneal disease compared to chemotherapy alone. Bulk RNAseq of tumors treated with anti-stab1 ab were enriched with CXCL9 positive macrophages, while Foxp3-ASO treatment showed significant increase in T helper cell infiltration and activation. Potentially cured long-term survivors (300 days+) were resistant to tumor rechallenge.In a third HGSOC mouse model (60577), in which tumors relapsed after a good initial response to chemotherapy, combinations of chemotherapy with anti-stab1 ab and/or Foxp3-ASO significantly increased the post relapse survival compared to chemotherapy alone.We believe that modulating Tregs and STAB1 could improve response to chemotherapy and can have translational potential as each AZD8701 and a humanized anti-stab1 ab are in phase I clinical trials.

#6554 Lurbinectedin induces multimodal immune activation and augments the anti-tumor immune response in small-cell lung cancer.

S. Chakraborty[1], Y. Mahendravarman[1], U. Sen[1], A. Banerjee[1], C. Coleman[2], D. Demircioglu[2], D. Hasson[2], T. Sen[3];
[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Tisch Cancer Institute and Icahn School of Medicine at Mount Sinai, New York, NY, [3]Tisch Cancer Institute at Mount Sinai, Icahn School of Medicine at Mount Sinai,, New York, NY

Background: Small cell lung cancer (SCLC) is the most aggressive subtype of lung cancer, with a very poor prognosis and limited therapeutic options. Repression of the MHC-I and reduced tumor infiltration of cytotoxic T-lymphocytes is often associated with immunotherapy resistance in SCLC. Lurbinectedin is FDA-approved as a second-line treatment for SCLC and we previously showed lurbinectedin as an effective therapeutic strategy in SCLC preclinical models. There are ongoing clinical trials combining immune checkpoint blockade with lurbinectedin in ES-SCLC. However, there is no insight into the effect of lurbinectedin on the immune microenvironment in SCLC. In this study, we evaluated the effect of lurbinectedin on the immune microenvironment and the anti-tumor effect with or without PD-L1 blockade.

Results: To determine the effect of lurbinectedin in SCLC models, we treated immunocompetent flank RPP (*Rb1, Trp53, and p130*) and RPM (*Rb1, Trp53*, and *MYCT58A*) tumor-bearing mice with lurbinectedin (0.2 mg/kg, 1/7days) and/or anti-PD-L1 (300µg, 1/7days) for 3 weeks. Mice treated with anti-PD-L1 alone showed no anti-tumor response, and single-agent lurbinectedin caused a delay in tumor growth. However, 6 of the 10 mice treated with the combination of lurbinectedin and anti-PD-L1, had a complete response (100% reduction) and the other 4 had 90% tumor regression. Tumors were resected and analyzed by multicolor flow cytometry for changes in tumor-infiltrating lymphocytes (TILs). Furthermore, analysis of immune cells infiltrating into the tumors post- treatment showed significant induction of cytotoxic T-cells and a reduction of exhausted and regulatory T cells in the combination treatment arm. Similarly, pro-inflammatory M1 type macrophages and dendritic cells were increased, while immunosuppressive M2 type macrophages and MDSC cells were decreased. These effects are consistent with data showing that lurbinectedin treatment leads to an activation of the cGAS/STING pathway, type I/II interferons (IFNα/β), and pro-inflammatory chemokines (CCL5, CXCL10) in tumors. Interestingly, lurbinectedin treatment led to significant upregulation of mRNA and surface expression of MHC class-I genes (HLA-A/B/C) *in vitro* and *in vivo.* Finally, bulk RNA sequencing as well as RT-PCR of pre- and post-lurbinectedin treatment demonstrated an increase in DAMPs associated with immunogenic cell death.

Conclusion: We provide the first mechanistic insight into the lurbinectedin-induced multimodal immune modulation in SCLC leading to a dramatic anti-tumor activity accompanied by the establishment of a strong anti-tumor immune microenvironment. Since lurbinectedin is already approved as a second-line agent in SCLC, our preclinical data provide a strong rationale for combining this regimen with inhibitors of the PD-L1 pathway and also highlight the immune subsets that the combination targets.

#6555 scRNAseq and TCR repertoire analysis identifies immune correlates of response to combined BRAF/MEK/PD1 inhibition in a phase 2 trial.

H. Yao[1], V. Jorgji[1], A. L. Tang[2], D. Lieb[2], S. X. Chao[2], D. J. Stein[1], M. Spurrell[3], L. Elmelech[2], J. Tian[1], M. Sade-Feldman[1], K. Pelka[4], R. B. Corcoran[1], N. Hacohen[1], I. Korsunsky[1], J. Chen[1];

[1]Harvard Medical School, Boston, MA, [2]Broad Institute of Massachusetts Institute of Technology (MIT) and Harvard, Cambridge, MA, [3]Yale University, New Haven, CT, [4]Gladstone Institutes, San Francisco, CA

Background

Our recent clinical trial of combined BRAF, MEK, and PD-1 inhibition showed a 24% response rate in BRAF V600E mutant colon cancer (PMID: 36702949). Analysis of epithelial single-cell RNA sequencing data showed an increase in interferon-stimulated genes (ISG) and inhibition of the MAPK pathway in responders. MAPK inhibition in organoids also induced ISGs. These data suggest a synergy between MAPK inhibition and induction of immune responses.

Methods

We analyzed over 100,000 immune and stromal cells from 23 paired scRNAseq profiles of pre- and day 15 on-treatment tumor biopsies. Progression free survival greater than 6 months was defined as a clinical response. We performed traditional differentially expressed gene and gene program analyses, and tracked TCR repertoire in tumor and blood. We developed a novel approach based on supervised clustering (PMID: 34675423) to identify fine-grained cell subtypes associated with response. We applied supervised clustering separately to T and myeloid cells, and tested the association of each cluster's abundance with response.

Results

We applied supervised clustering to T cells and identified a CD74+IFNG+ CD8 T cell cluster that increased in only responders (p=0.0078). In the myeloid compartment, we identified two populations of CXCL10+ macrophages: one whose abundance increased in all patients and a CCL3+CCL4+ activation state expanded (p=0.01) only in responders. Pathway analysis of the expanded populations suggests an enrichment of ISGs in both CD74+IFNG+ CD8 T cells and CXCL10+CCL3+CCL4+ macrophages, with specific enrichment of interferon-gamma responsive genes GBP1 and GBP4 in the macrophages.

T cell analysis yielded two responders with marked clonal expansion within the CXCL13+ population, which likely represent tumor-specific T cells. Within the blood, these CXCL13+ clonotypes underwent a short-lived burst at day 15, yet represented only a minor population. We saw concomitant expansion of both CXCL13+ CD4 and CD8 populations within patients, suggesting CXCL13+ CD4s might provide help to the CXCL13+ CD8 T cells. The same two responders had increased stem-like TCF7+PD1+ CD8 T cells previously implicated in immunotherapy response and an increase in CCL19+ fibroblasts associated with stem-immunity hubs.

Conclusions

Our analysis of pre- and on-therapy biopsy scRNAseq data from our clinical trial of MAPK and PD-1 inhibition found expansion of ISG enriched CD74+IFNG+ CD8 T cells and CXCL10+CCL3+CCL4+ macrophages in responders. Both populations are enriched in ISGs: this coordinated expansion may result from a shared, interferon-rich microenvironment. Ongoing work will explore this hypothesis using spatial transcriptomics to identify these activated cells and their microenvironments.

Ethics approval

#6556 Targeting mesenchymal tumor cell-intrinsic factors sensitizes refractory tumors to immune checkpoint blockade therapy.

K. M. Bakhle, C. H. Sams, A. Dongre;
Cornell Univ. College of Veterinary Med., Ithaca, NY

Immune checkpoint blockade (ICB) therapy has emerged as a promising approach for treating breast cancer, however, only a fraction of patients derives clinical benefit and the underlying reasons for heterogeneous responses remain elusive. The epithelial-to-mesenchymal transition (EMT) enables these carcinomas to metastasize and acquire resistance to chemotherapy. We have recently demonstrated that the EMT program also confers resistance to immunotherapies. Specifically, epithelial tumors recruit $CD8^{\pm}$ T-cells to the tumor microenvironment and are sensitive to anti-CTLA4 ICB. In contrast, mesenchymal tumors assemble an immunosuppressive tumor microenvironment and are resistant to the same treatment. Furthermore, mesenchymal tumors express multiple immunosuppressive paracrine factors relative to their epithelial counterparts. Of these, abrogation of CSF1 or SPP1 from mesenchymal cancer cells generates partial responses to ICB therapy. Strikingly, abrogation of CD73 from mesenchymal carcinoma cells completely sensitizes otherwise refractory tumors to immunotherapy. While targeting cancer cell-intrinsic factors can sensitize mesenchymal tumors to ICB, the mechanisms that dictate partial versus complete responses are unclear. Furthermore, whether abrogation of CD73 can also sensitize mesenchymal tumors to other forms of ICB remains unknown. By performing immunofluorescent analysis of tumor sections, we observed that knockout of CD73 promoted the greatest infiltration of both $CD4^{\pm}$ and $CD8^{\pm}$ T-cells in response to anti-CTLA4 ICB compared to tumors knocked out for CSF1 and SPP1, which showed only intermediate levels of infiltration. Moreover, treatment of mesenchymal tumor-bearing mice with anti-CD73 generated synergistic responses with anti-CTLA4 ICB, but not with anti-PD1, or combinations of anti-CTLA4 and anti-PD1. In conclusion, our results demonstrate that the EMT program in cancer cells is predictive of responses to ICB. Targeting CD73 in mesenchymal breast tumors promotes an influx of both $CD4^{\pm}$ and $CD8^{\pm}$ T-cells and potentiates the efficacy of anti-CTLA4 ICB. Through mining of canine mammary tumor RNA sequencing data, we have found that canine tumors associated with EMT have increased expression of CD73, which suggests that these mechanisms of immune evasion may translate across species. These findings could promote therapies for both animals and humans that sensitize highly refractory populations of more-mesenchymal cancer cells.

CLINICAL RESEARCH: Liquid Biopsy
Minisymposium

#6557 Longitudinal cell-free tumor load dynamics represent an early endpoint for immunotherapy response in non-small cell lung cancer.

Lavanya Sivapalan[1], Bahar Alipanahi[2], Archana Balan[1], Jamie E. Medina[2], Noushin Niknafs[1], Erica Peters[2], Jaime Wehr[1], Alissa Konicki[2], Mimi Najjar[1], Bryan Chesnick[2], Gavin Pereira[1], Sarah Rongione[2], Nisha Rao[1], Michael Rongione[2], Brittany Shavatt[2], Lorenzo Rinaldi[2], Benjamin Levy[1], Victor E. Velculescu[1], Patrick M. Forde[1], Valsamo Anagnostou[1]

[1]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Delfi Diagnostics, Inc., Baltimore, MD

Background: Liquid biopsies can inform treatment strategies by rapidly and accurately assessing tumor burden; with emerging data supporting the clinical utility of circulating cell-free tumor DNA (ctDNA) as an early endpoint of immunotherapy response.
Methods: We performed targeted error-correction sequencing of ctDNA (n=330) and matched white blood cell (WBC) DNA (n=109) from 109 patients with advanced non-small cell lung cancer (NSCLC) who received immune checkpoint inhibitor monotherapy (n=79) or immunotherapy-containing combination regimens (n=30). Variant cellular origin was determined using a tumor-independent WBC DNA-informed approach. The maximum mutant allele fraction (maxMAF) of tumor-derived mutations was tracked longitudinally to assess changes in total cell-free tumor load (cfTL).
Results: Among 3,418 variants with resolved cellular origin, 2,452 (72%) were tumor-derived, 125 (4%) were germline, while 841 (25%) were related to clonal haematopoiesis (CH). Cell-free DNA fragments harbouring tumor-derived mutations were significantly shorter than fragments containing wild-type alleles; however, fragment length alone was insufficient to distinguish CH variants from wild-type. Overall, 97 (89%) patients with >1 detectable tumor mutation were considered for cfTL tracking and molecular response assessment. Clearance of cfTL indicated molecular response (mR) whereas persistence indicated molecular progression (mPD). Time-course analyses, aiming to establish the optimal timing for molecular response assessment, revealed that early cfTL clearance within 3-9 weeks was significantly linked to improved survival outcomes. Notably, blood tumor mutation burden above or below 16 mutations/megabase showed no association with overall survival (OS; log rank p=0.98) or progression-free survival (PFS; log rank p=0.95). Of 81 patients evaluated for early on-therapy molecular responses, 28 (35%) were classified as having an mR, while 53 (65%) patients were classified in the mPD category. The median time to mR was 5 weeks in patients receiving immune checkpoint monotherapy and 6 weeks in patients receiving chemo-immunotherapy combination regimens. Patients in the mR group achieved longer OS (log rank p=0.001) and PFS (log rank p=0.0003) compared to those with mPD. Assessment of landmark PFS at 6 months demonstrated a significant association between ctDNA molecular response and durable clinical benefit (DCB) in patients receiving immune checkpoint monotherapy ($p < 0.001$, Fisher's exact test), and a numerical association with DCB in patients on chemo-immunotherapy (p=0.07, Fisher's exact test).
Conclusions: Longitudinal tracking of ctDNA provides a real-time and accurate approach for monitoring immunotherapy response. These findings underscore the clinical utility of employing ctDNA molecular response to inform clinical decision-making.

#6558 Ultra-sensitive ctDNA detection predicts response to immune checkpoint inhibition in advanced melanoma patients.

C. Gebhardt[1], L. Keller[1], I. Heidrich[1], J. Koett[1], G. Geidel[1], D. J. Smit[1], R. Simon[1], S. W. Schneider[1], J. Pugh[2], C. W. Abbott[2], S. Boyle[2], R. O. Chen[2], K. Pantel[1];

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Personalis Inc., Menlo Park, CA

Immune checkpoint inhibition (ICI) provides clinical benefit to a subset of cancer patients. Monitoring circulating tumor DNA (ctDNA) in peripheral blood may allow clinicians to predict ICI response or resistance earlier than imaging and track response more frequently. In this study, melanoma patients receiving ICI were profiled using an ultra-sensitive, tumor-informed ctDNA detection platform, and the findings were correlated with clinical outcome. In this retrospective study, 188 plasma samples were collected from 23 advanced melanoma patients receiving immune checkpoint inhibitor (ICI) treatment, spanning a period of up to 40 months. Levels of ctDNA were then profiled using the NeXT Personal® assay. NeXT Personal is a liquid biopsy platform that utilizes whole-genome sequencing of tumor and normal samples to create a customized panel for each patient, encompassing up to 1,800 genetic somatic variants. This enables the detection of molecular residual disease (MRD) down to a limit of detection (LOD) of 1-3 parts per million (PPM). We subsequently compared the results obtained through NeXT Personal with RECIST-defined measurements and clinical outcomes. Ultra-sensitive ctDNA detection was achieved across a wide dynamic range, spanning from 2.3 PPM to over 130,000 PPM (median LOD = 2 PPM). A significant number of detections were attained at low PPM levels, with 30% (31/105) occurring below 100 PPM and 25% (26/105) occurring below 50 PPM. 94% (17/18) of baseline samples were ctDNA+ among patients without recent second-line therapy, including all patients who progressed. All ctDNA+ detections aligned with imaging results that indicated the presence of tumor. Likewise, all plasma timepoints corresponding to complete responses (CR) assessed via RECIST were ctDNA-. Early increase in ctDNA from baseline to treatment cycle 3 significantly predicted PFS (log-rank 0.003; Wald p=0.01, HR=8.35, 95% CI 1.62-43.15). Survival was predicted by both imaging CR (log-rank p=0.018) and ctDNA clearance (log-rank p=0.003). Molecular progression, defined as a 20% increase in ctDNA, significantly predicted OS (log-rank p=0.023), whereas imaging PD status did not predict OS (log-rank p=0.09). We achieved detection of ctDNA with an LOD down to 1.3 PPM in this cohort, with nearly a third of detections occurring below 100 PPM, suggesting the importance of an ultra-sensitive ctDNA approach even in late stage patients. Our findings suggest that ctDNA changes arepredictive of ICI response in late stage melanoma. These results highlight the potential for patient-specific ctDNA monitoring to inform patient management and for clincal trial design.

#6559 Clinical validity of post-surgery circulating tumor DNA testing in stage III colon cancer patients treated with adjuvant chemotherapy: The PROVENC3 study.

[1]Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Personal Genome Diagnostics, Labcorp, Baltimore, MD, [3]University Medical Center Utrecht, Utrecht, Netherlands, [4]Amsterdam University Medical Centres, Location VU Medical Center, Amsterdam, Netherlands, [5]Julius Center, University Medical Center Utrecht, Utrecht, Netherlands, [6]Johns Hopkins University School of Medicine, Baltimore, MD, [7]University Medical Center Utrecht, Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands

Introduction: Surgery followed by adjuvant chemotherapy (ACT) is standard of care in stage III colon cancer. However, only 15-20% of patients benefit from ACT, as half of patients are cured by surgery, and 25-30% still experience a recurrence. Detection of circulating tumor DNA (ctDNA) after resection of the primary tumor is a strong prognostic biomarker in non-metastatic colon cancer and offers a promising approach to better stratify stage III colon cancer patients for ACT treatment decisions.

Aim: The PROVENC3 study aims to determine the clinical validity of post-surgery ctDNA detection in patients with stage III colon cancer treated with ACT.

Methods: Blood was collected pre-surgery, post-surgery and post-ACT for stage III colon cancer patients treated with ACT. Tumor-informed detection of ctDNA was performed through integrated whole genome sequencing (WGS) analyses of formalin-fixed paraffin-embedded tumor tissue DNA (80x), germline DNA (40x), and plasma cell-free DNA (30x). The primary outcome was time to recurrence (TTR).

Results: Results from 209 patients (median follow up: 40 months) show that ctDNA-positive patients post-surgery (n=28) had a higher risk of developing a recurrence than ctDNA-negative patients (HR: 6.3, [95%CI: 3.5-11.3], $P<10^{-8}$). 38% of patients with a recurrence within 3 years were ctDNA-positive post-surgery. Combination of post-surgery ctDNA status with established clinicopathological risk classification of low-risk (T1-3 and N1) and high-risk (T4 and/or N2) resulted in a 3-year cumulative recurrence risk of 82% for clinical high-risk ctDNA-positive patients compared to 7% for clinical low-risk ctDNA-negative patients (HR 28.9 [95%CI: 10.6-78.2]; $P<10^{-10}$). Results from 170 patients with post-ACT blood available showed that post-ACT ctDNA-positive patients (n=24) were at a higher risk of developing a recurrence (HR 7.9 [95%CI: 3.5-15.9]; $P<10^{-8}$) than ctDNA-negative patients. The patients experiencing a recurrence had higher aggregate ctDNA variant allele frequencies than patients not experiencing a recurrence post-surgery or post-ACT (P<0.001 and P<0.001, respectively).

Conclusion: Post-surgery ctDNA detection by tumor-informed WGS is a strong prognostic biomarker in stage III colon cancer patients, and improves the current risk stratification. Importantly, the post-surgery ctDNA-positive patients who did not experience a recurrence were likely cured by ACT. These data enable the design of clinical practice-changing ctDNA-guided interventional trials in stage III colon cancer to personalize adjuvant treatment decisions.

#6560 Cell-free RNA analysis for non-invasive cancer detection and characterization.

Blood-based liquid biopsies enable non-invasive characterization of cancers. Cell-free RNA (cfRNA) analysis could potentially complement circulating tumor DNA (ctDNA) analysis and allow broader molecular characterization of cancers but has not been extensively explored. Here, we describe RARE-Seq, a novel cfRNA sequencing method designed to maximize sensitivity by targeting rare, tissue-specific transcripts, and simultaneously detecting both tumor-derived expression signatures and somatic mutations in circulating tumor RNA (ctRNA).

To interrogate samples for specific gene expression signatures, we developed and optimized a framework to measure tumor- and tissue-specific enrichment scores (ES) within cfRNA. We then empirically determined the limit of detection (LOD95) of RARE-Seq using admixtures of tumor cell line RNA and control cfRNA across a wide range of fractions. We found RARE-Seq to have an estimated LOD95 of 0.05% for cancer-derived RNA, which was 52-fold better than whole transcriptome cfRNA profiling.

To explore its potential clinical utility, we profiled 192 samples from 170 subjects with various cancers and non-cancer controls using RARE-Seq. Non-small cell lung cancer (NSCLC) expression signatures were significantly detected in 40 out of 51 NSCLC samples (78% sensitivity at 90% specificity). Detection increased with stage, ranging from 40% in stage I to 87% in stage IV. In a subset of stage IV NSCLC patients with matching ctDNA data (n=16), ctRNA levels were significantly correlated with ctDNA allele frequencies (Pearson R=0.84, P=0.005). Intriguingly, 86% of samples with undetectable ctDNA contained detectable ctRNA, suggesting potential complementarity of ctRNA and ctDNA analysis for cancer detection. We also developed and benchmarked a direct ctRNA genotyping approach, allowing noninvasive detection of driver mutations in 42% of patients with advanced NSCLC. When applied to other tumors, RARE-Seq demonstrated 80-100% sensitivity at 90% specificity for detection of pancreatic adenocarcinomas (PAAD), prostate adenocarcinomas (PRAD), and hepatocellular carcinomas (LIHC). Furthermore, when evaluating tissue of origin (TOO) classification performance, RARE-Seq achieved 85% median accuracy for the top predicted tissue and 96% median accuracy for the top two tissues.

These results highlight the potential value of ultrasensitive cfRNA analysis, providing proof-of-principle for detection of multiple tumor types using RARE-Seq.

#6561 Phenotypic and genotypic characterization of single circulating tumor cells in the follow-up of high-grade serous ovarian cancer.

S. Kasimir-Bauer[1], N. H. Stoecklein[2], R. P. L. Neves[2], S. T. Liffers[1], J. D. Kuhlmann[3], P. Wimberger[3], P. Buderath[1], R. Kimmig[1], C. Salmon[1];
[1]University Hospital Essen, Essen, Germany, [2]University Hospital Duesseldorf, Duesseldorf, Germany, [3]Medical Faculty and University Hospital Carl Gustav Carus, Technische Universitat Dresden, Dresden, Germany

Background: Ovarian Cancer (OC) is one of the leading causes of death among gynecological tumors with an insufficient understanding of OC disease evolution. Since tumor tissue is not always available, blood allows the investigation of single circulating tumor cells (sCTC) over time. We combined immunomagnetic enrichment and image-based sCTC sorting for phenotypic and genotypic analysis of sCTCs in the follow-up of OC to provide insights into sCTC heterogeneity and their malignant character.

Patients and Methods: 10 ml blood of high-grade serous OC patients (pts) at the time of primary diagnosis (n=42), after chemotherapy (n=23) and after Avastin (n=11) was analyzed for sCTCs using density-gradient centrifugation to further apply MACS® using CD45 and CD235a antibodies coupled to MACS® MicroBeads. For image-based sCTC sorting (DEPArray®), an immunofluorescence protocol staining for Hoechst, cytokeratin (CK), the folate receptor alpha (FRa), Vimentin (Vim) and CD45 was applied. Whole genome amplification (WGA) was performed in recovered single cells, comprising cell lysis, DNA digestion, adaptor ligation and an amplification PCR for subsequent copy number alteration (CNA) analysis. Ampli1™ low-pass analysis was used to analyze single cell WGA products. 21 primary tumors (PT) were assessed for whole-genome CNA and the Ampli 1™ OncoSeek panel was used for deep sequencing of sCTCs.

Results: Phenotypic assessment revealed FRa-positive cells in 28/42 (67%) pts, CK-positive cells in 32/42 (76%) pts and CK-FRa-double-positive cells in 15/42 (36%) pts, respectively, with a significant (p= 0.0205) reduction of cells after chemotherapy only documented for FRa-positive cells. Interestingly, cells with a high nuclear staining but no expression of target antigens were found in 37/42 pts (88%) and significantly (p=0.002) expanded during treatment. Genotyping revealed that only 7% (19/289) of single cells deriving from 13 different pts were aberrant. Whole genome CNA analysis in all pre-treatment sCTCs revealed enriched CNAs in chromosomes 2, 7 and 12. In post-treatment sCTCs, CNA dynamics highlighted the adaptive potential of the homologous recombination pathway and suggested further investigation of MAPK signaling in resistant OC. Low-pass CNA comparison between sCTCs and the PT was feasible in nine pts, 2/9 with persistent PT characteristics in sCTCs at different sampling times. TP53 variants were the most frequently detected ones, persistent CNA in the *CDK4* oncogene and emerging CNA in the *ALK* oncogene were found in sCTCs from two pts.

Conclusion: We identified sCTCs in the follow-up of OC and demonstrated interpatient as well as intrapatient heterogeneity of sCTCs. Matched sCTCs and PT data showed similar CNAs to a certain amount. Our low percentage of aberrant cells suggests that higher patient numbers are needed to confirm our findings to understand disease progression.

#6562 Comprehensive liquid biopsy: Multi-analyte evaluation of cellular and plasma components of blood in prostate cancer from a single blood collection tube.

J. Ladd, E. Bayer, B. Bartels, A. Tischner, R. Ponting, E. Kaldjian, A. Ramirez;
RareCyte, Inc., Seattle, WA

Background Liquid biopsy samples offer a non-invasive method for investigating drug targets and biomarkers in solid tumors. In this study, we describe a comprehensive liquid biopsy analysis of whole blood to identify circulating tumor cells (CTCs), large extracellular vesicles and CTC fragments, and CTC-white blood cell hybrids; quantify protein biomarker expression on CTCs; perform targeted mutation profiling on CTCs and cell-free DNA (cfDNA) from plasma; and analyze protein expression on white blood cells (WBCs) from a single 7.5 mL blood sample. This array of tests was applied to blood samples from patients with Stage IV prostate cancer to demonstrate clinical feasibility.

Methods A novel dual biomarker CTC assay was developed to measure protein expression of PSMA and ARv7 on CTCs from stage IV prostate cancer patients. Nucleated cells from clinical samples were processed to microscope slides using AccuCyte®, an unbiased, density-based separation method that also allows for plasma collection for downstream analysis. Slides were fixed and stained with antibodies to cytokeratin, EpCAM, and CD45 to detect CTCs and exclude WBCs, and with PSMA and ARv7 to evaluate protein biomarker expression on identified CTCs. The slides were imaged with the CyteFinder® automated immunofluorescence scanning microscope that identifies CTCs for confirmation by trained reviewers and quantitatively measures protein mean fluorescence intensity (MFI) on any cells detected on the slides (CTCs, CTC-WBC hybrids, large extracellular vesicles and CTC fragments and WBCs). Individual CTCs and control pools of WBCs from clinical samples with at least 4 CTCs were picked using CytePicker®, a needle-based system used to isolate single cells. cfDNA was isolated from plasma removed during the AccuCyte® process using a QIAamp MinElute ccfDNA kit. Picked CTCs, WBC pools, and isolated ctDNA were sequenced using the OncoZoom Cancer HotSpot panel from Paragon Genomics.

Results Nine progressing Stage IV prostate cancer patient blood samples were stained with a novel PSMA/ARv7 dual biomarker assay. CTCs were identified in all clinical samples (median 4, range 1 - 384). PSMA positivity in clinical samples ranged from 0% to 75%, and ARv7 positivity ranged from 33% to 100%, and. Additional analysis using QuPath was performed to determine PSMA/ARv7 protein expression on WBCs and CTC fragments. ctDNA analysis from 5 individual samples was compared to sequencing results from individual CTCs from the same samples.

Conclusions Using a single 7.5 mL blood liquid biopsy, we can measure protein expression on enumerated CTCs and quantify these same protein biomarkers on WBCs and CTC fragments/oncosomes, determine the genetic makeup of the tumor through the sequencing of cfDNA, and monitor genetic mutations in intact CTCs in circulation.

#6563 PSMA-based detection and global proteome-based analysis of circulating tumor cells in castration resistant prostate cancer patients.

J. M. Drake[1], A. Arafa[1], A. Horrmann[2], K. J. Kamalanathan[2], C. Galeano-Garces[2], Z. Sychev[1], N. Heller[2], M. Ahmadi[2], M. Ludwig[1], O. Hedeen[2], A. Hesch[2], G. Schaap[2], J. Hapke[2], J. Miller[2], I. Babris[2], T. Lee[2], T. Clacko[2], J. Hwang[1], J. Hong[1], B. Konety[3], J. Parthasarathy[2], E. Antonarakis[1];

In recent years, many new targeted and immuno-therapies have entered the cancer treatment landscape with the potential to drastically improve patient outcomes; however, selecting the optimal drug target especially as the disease progresses becomes increasingly important. Liquid biopsies show great promise in providing insights on the current disease state, but generally rely on a small number of protein markers identified through immunofluorescence staining or genomic mutations determined from cell-free DNA which limits the amount of information available to make treatment decisions. One way to better select the optimal drug target is to generate unbiased mass-spectrometry based proteomic data from the circulating tumor cells (CTCs) isolated from blood. In this study, we collaborated with Astrin Biosciences using their patented isolation technology to enrich CTCs with high purity from the blood of 57 metastatic castration resistant prostate cancer (mCRPC) patients. The CTC-enriched sample (along with a patient-matched control sample consisting primarily of white blood cells) was analyzed in real time for either PSMA protein (Lutetium-PSMA-617 study, n=32) or via mass-spectrometry (CTC proteomics study, n=25). Over 1,500 peptides corresponding to greater than 600 proteins were identified from each patient's CTCs. These included increased epithelial cell markers in the CTC-enriched sample and increased WBC markers in the control sample. Specifically, detection of the androgen receptor protein was identified in the CTC-enriched sample which is of particular interest in mCRPC patients. Furthermore, this method is able to detect and quantify PSMA expression, which is of clear relevance in the context of PSMA-directed therapeutics. This study demonstrates the feasibility of obtaining large scale proteomic data from a liquid biopsy. Future studies will focus on cancer signaling mechanisms and biomarkers to elucidate the clinical utility of such data. As more patients are analyzed, we will compare proteomic data with known tissue proteome information when available and to correlate these with drug response to improve treatment selection and patient outcomes.

CLINICAL RESEARCH: Novel Approaches for Targeted Therapies
Minisymposium

#6564 SOS1 inhibitor treatment improves response to Venetoclax in acute myeloid leukemia.

K. Kostyrko[1], M. Hinkel[1], M. G. Rees[2], M. M. Ronan[2], J. A. Roth[2], D. Gerlach[1], I. Waizenegger[1];
[1]Boehringer Ingelheim RCV GmbH & Co. KG, Vienna, Austria, [2]Broad Institute of MIT and Harvard, Cambridge, MA

Acute myeloid leukemia (AML) is the most common type of acute leukemia in adults. First-line treatment of AML patients consists primarily of chemotherapy, sometimes combined with a targeted therapy. However, elderly patients unfit for chemotherapy receive venetoclax, a BCL2 inhibitor, combined with azacitadine or decitabine. While responses in these patients are high (50-70%, with median OS of 10-17 months), around 30-50% of them do not respond and most relapse within 1-10 years. Increased MAPK pathway activity or low frequency RAS pathway mutations have been identified as key mediators of resistance to standard-of-care targeted therapies for AML, including venetoclax. Here, we found that in DepMap whole-genome CRISPR screens, leukemia cell lines, including AML, show a particular dependency on SOS1. A subsequent PRISM screen with a selective inhibitor of SOS1 confirmed these results. To validate these results in vitro, we treated 7 AML cell lines showing strongest dependency on SOS1 based on DepMap and PRISM screens, with SOS1i or a SHP2 inhibitor. We found that in 4 of 7 cell lines treatment with SOS1i or SHP2i strongly impaired proliferation. In 3 of 4 responding cell lines, the anti-proliferative effect with either SOS1i or SHP2i was stronger than azacytidine single agent treatment. We next treated 29 primary ex vivo cultures of AML with SOS1i and found that the treatment induced strong or intermediate anti-proliferative effect in 21 of 29 models (72%). In two AML PDX models, treatment with SOS1i as a single agent resulted in approximately 25% reduction of human CD45+ AML blast cells in both models. Venetoclax treatment led to approximately 75% decrease in AML blasts, while the combined venetoclax and SOS1i treatment resulted in near complete eradication of the disease. Annexin V staining of AML monoblasts demonstrated that this decrease was due to an increase in apoptosis in the combination groups. In summary, we demonstrate that SOS1 inhibitor treatment may be used to improve responses to venetoclax in AML patients.

#6565 Improving survival of atypical teratoid/rhabdoid tumor orthotopic xenografts through the combination of PI3K inhibitor paxalisib and nucleoside analog gemcitabine.

T. Findlay, K. Malebranche, A. Geethadevi, C. Eberhart, J. Rubens, E. Raabe;
Johns Hopkins University School of Medicine, Baltimore, MD

Atypical teratoid/rhabdoid tumors (AT/RT) are an aggressive infantile brain tumor with a dismal four-year event-free survival of 37%. We have previously identified high activation of mTORC1 and mTORC2 within AT/RT and shown that the highly brain penetrant PI3K inhibitor paxalisib is capable of simultaneously inhibiting mTORC1/2 by acting upstream of both complexes. In two orthotopic xenograft models, paxalisib slowed tumor growth and significantly extended survival (CHLA-06: 40 to 54 days, p=0.001; BT-12: 21 to 35 days, p=0.02). RNAseq analysis following mTOR inhibition in AT/RT cell lines showed an upregulation of genes involved in the activation of the integrated stress response (ISR) (*ATF4*, *CHOP*, *PPP1R15A* *t*-test p<0.05). Analysis of primary pediatric brain tumors through the Children's Brain Tumor Network showed increased levels of *ATF4* mRNA and eIF2α protein and mRNA in AT/RT compared to other indolent pediatric brain tumors. Increased expression of ISR components suggests this pathway may be a dependency in AT/RT. Activation of this pathway is known to be cytoprotective, however persistent over-activation drives cell death through induction of pro-apoptotic factors. Gemcitabine is a pyrimidine analog functioning to inhibit DNA synthesis and induce DNA damage; notably, recent literature has correlated DNA damage to activation of the ISR with downstream phosphorylation of eIF2α. We hypothesize that due to high baseline activation of ISR for AT/RT, paxalisib combined with gemcitabine will result in an over-activation of the ISR leading to AT/RT cell death. Western blot analysis of combination therapy compared to DMSO control showed induction of phospho-eIF2α, ATF4, and CHOP, denoting an activation of the ISR. Combination therapy in AT/RT cells induces cell death (Western blot analysis cPARP, MUSE Annexin V assay, SynergyFinder BLISS score [viability] CHLA-06: 21.50, CHLA-266: 22.60) and synergizes to decrease cell growth (SynergyFinder BLISS score [inhibition] CHLA-06: 16.80, BT-12: 14.30, CHLA-266: 13.90, BT-37: 11.40, CHLA-05: 10.40). Paxalisib/gemcitabine combination therapy in murine orthotopic xenograft models of AT/RT has slowed tumor growth (bioluminescent imaging) and led to significant extension of survival. Mice bearing BT-37 orthotopic xenografts and treated with vehicle control had a median survival of 56 days, while all of the paxalisib/gemcitabine treated mice were alive at 100 days of treatment (p<0.0001). In CHLA-06 orthotopic tumors combination therapy extended median survival from 22 days for control to 82.5 days (p<0.0001). Based on these findings, the Pacific Pediatric Neuro-Oncology Consortium (PNOC) is planning to include paxalisib/gemcitabine combination therapy in the next international clinical trial for patients with relapsed/recurrent AT/RT.

#6566 Clinical evaluation of functional combinatorial precision medicine platform to predict treatment outcomes and enhance combination therapy design in soft tissue sarcomas.

E. K. Chow[1], S. P. Y. Chan[1], T. Toh[1], M. Rashid[2], V. S. Yang[3];

[1]National University of Singapore (NUS), Singapore, Singapore, [2]KYAN Technologies, Singapore, Singapore, [3]National Cancer Centre Singapore, Singapore, Singapore

Purpose: Soft tissue sarcomas (STS) are a collection of heterogenous cancers with limited range of treatment options and poor outcomes. First line treatment for most STS is anthracycline-based, with gemcitabine-based combinations, pazopanib or ifosfamide as treatment options in refractory/relapsed STS. There is a clinical unmet need to improve treatment options for STS as median time to progression following second- and third-line treatments is less than 4 months. We have previously demonstrated in a 71-patient relapsed/refractory non-Hodgkin's lymphoma clinical study that a functional precision medicine platform can effectively guide treatment, with several exceptional responders (Science Translational Medicine, 2022). This ex vivo drug sensitivity platform, quadratic phenotypic optimization platform (QPOP), analyses a predesigned array of 155 test combinations performed on a primary patient sample to rank and compare all possible therapeutic combinations from a 12-drug set. In this study, we evaluated clinical concordance of QPOP to predict treatment outcomes in an STS cohort. We also explored QPOP's combination therapy ranking function to identify novel combinations that may benefit larger groups of STS patients when appropriately guided.

Experimental Detail: A 12-drug set comprised of STS standard of care, FDA approved drugs and promising investigational drugs was evaluated in QPOP analysis of primary STS tumor samples. Ex vivo cultures of primary STS samples were treated with a predesigned array of 155 test combinations to provide a quantitative phenotypic output for each test combination. This dataset was analyzed by QPOP to rank all possible drug combinations towards a predicted treatment outcome. Concordance analysis was then performed comparing patient sample results with either parallel treatment initiated at time of sample collection or physician choice to use QPOP-guided treatment. Validation of QPOP-derived top-ranked drug combinations was also performed.

Results: 12-drug, 3-level QPOP was successfully performed on 45 of 51 primary patient samples. Clinical concordance analysis showed QPOP had a total predictive value (TPV) of 76.9% and an AUC_{ROC} of 85.7%. Exceptional responders to guided treatment with pazopanib or eribulin were observed. Additionally, top-ranked epigenetic-based combinations were identified as effective across multiple STS subtypes and validated preclinically.

Conclusion: The results show the potential for QPOP to predict clinical response in solid cancers, such as STS. Furthermore, QPOP can improve drug development pipelines through patient samples-based design of effective combinations with investigational drugs or underutilized drugs that may benefit larger populations of patients or specific subgroups of patients.

#6567 Affinity and cooperativity modulate ternary complex formation to drive degradation of SMARCA2.

I. Archibeque[1], K. Dellamaggiore[1], K. Rex[1], S. Ghimire-Rijal[2], K. Choi[2], S. Kate[2], A. Amegadzie[2], N. Chen[2], X. Li[2], R. Wurz[2], A. Vaish[2], P. Hughes[1], **D. Mohl**[1]; [1]Amgen Oncology, Thousand Oaks, CA, [2]Amgen, Therapeutic Discovery, Thousand Oaks, CA

Small molecules that hijack the ubiquitin-proteasome system to degrade target proteins have gained traction as tools for chemical biology and as promising clinical candidates. Targeted degradation strategies encompass relatively large hetero-bifunctional small molecules (hSMs) that are built from target and effector ligands joined by a linker to much smaller molecular glues that have limited affinity for the target or effector proteins outside of a ternary complex. There is good reason for medicinal chemists to move from linkered hSMs toward glue-like scaffolds. Molecular glues can be considerably smaller, e.g., the IMiDs, and thus are less likely to possess atoms and functional motifs that add up to poor permeability and higher protein binding.

Guided by the principle that hSMs with reduced molecular weight will have superior druglike properties, we have used SMARCA2, a potential therapeutic target in patients that have both copies of SMARCA4 inactivated, as a test of our own ability to drive rapid target degradation in relevant models. The hetero-bifunctional degraders that resulted from our work trade conventional linkers for chemical spacers that orient SMARCA2 and VHL to promote fortuitous protein-protein contacts in the ternary complex. Following in the footsteps of previously published works, we employed surface plasmon resonance (SPR), x-ray crystallography, and molecular modeling to understand the relationships between our cell-based metrics of degrader activity and the biophysical parameters that describe the ternary complex. Consequently, we found that cooperativity (α) and ternary complex affinity (K_{LPT}) correlated well with both DC50 and initial rate of degradation. Within our series of novel SMARCA2 degraders, compound 1 exhibited exceptional cooperativity and ternary complex affinity, α = 12.8 and K_{LPT} = 4.7 ± 1. The result of high cooperativity and enhanced affinity was rapid and near complete SMARCA2 degradation. Treatment of a cancer cell line with compound 1 resulted in 50% of SMARCA2 being degraded
in under 30 minutes, and greater than 90% degradation in 2 hours. Most importantly, the near complete degradation of SMARCA2 resulted in potent effects on SWI/SNF dependent transcription in vitro and in inhibition of tumor cell growth both in vitro and in vivo.

#6568 *PTCH1* loss-of-function alterations: Mutational landscape and therapeutic outcomes to hedgehog pathway inhibitors in non-canonical histologies.

Antoine Desilets, Matteo Repetto, Soo Ryum Yang, Monica Chen, Dazhi Liu, Nikhil Rizvi, Ezra Rosen, Alan L. Ho, Alexander Drilon, Yonina R. Murciano-Goroff

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Loss-of-function (LOF) alterations of the *PTCH1* tumor suppressor gene represent canonical events involved in basal cell carcinoma (BCC) oncogenesis. Hedgehog pathway inhibitors (HPIs) are approved for the treatment of advanced BCC, but genomic characterization and therapeutic outcomes remain limited in tumor agnostic cohorts.

Methods: Using the MSK Clinical Sequencing Cohort, we performed a mutational landscape analysis of *PTCH1* LOF alterations in non-BCC histologies, including Fraction and Allele-Specific Copy Number Estimates from Tumor Sequencing (FACETS) annotation, and analyzed response and progression-free survival (PFS) with HPIs.

Results: Out of 115,619 samples, 1972 samples from advanced solid tumors with *PTCH1* LOF alterations were identified. Excluding 1306 variants of unknown significance (VUSs) using OncoKB knowledge base as well as 44 BCC samples, a total of 622 samples from 570 patients with oncogenic *PTCH1* alterations were identified across histologies. In addition, 124 patients received ≥1 line(s) of HPI at our institution between 2013 and 2023, including 16 patients with non-BCC histologies presenting *PTCH1* alterations. At the patient level (n=570), *PTCH1* LOF alterations were present across 33 primary sites, including colorectal cancer (CRC; 34%; n=192), endometrial cancer (17%; n=98), gastroesophageal adenocarcinomas (ADC) (8%; n=46), non-small cell lung cancer (NSCLC; 6%; n=34) and soft tissue sarcomas (STS; 4%; n=25). At the sample level (n=622), TMB ≥10 was seen in 83% (n=516), including 324 samples with MSI-high status. *PTCH1* alterations most frequently involved frameshift (fs) indels (69%; n=429), followed by nonsense mutations (18%; n=114), splice site mutations (8%; n=47) and fusions (5%; n=32). Recurrent fs events involved S1203Afs*52 (24%; n=150) and R1308Efs*64 (14%; n=89), among others. When comparing monoallelic (monoall) vs biallelic (biall) *PTCH1* alterations through FACETS annotation, monoall showed a strong association with higher TMB ($p<0.01$) whereas biall were associated with higher loss of heterozygosity (LOH; $p<0.01$). In the 16 non-BCC patients treated with HPIs, histologies included lung squamous cell cancer (SCC; n=4), cutaneous SCC (n=2), medulloblastoma (n=2), carcinosarcoma (n=2), osteosarcoma, chondrosarcoma, chordoma, sebaceous ADC, anal SCC and CRC (each n=1). TMB ≥10 was seen in 31% (n=5), all of which were MSI-low. Tumor regressions on HPI were seen in 50% (n=8), including lung SCC, cutaneous SCC, sebaceous ADC and medulloblastoma, with median time to response of 3.6 months (mo). Median PFS on HPI was 3.9 mo and median OS was 22.7 mo. Median PFS was higher in patients with TMB ≥10 vs TMB <10 (11.8 vs. 1.8 mo, $p=0.02$).

Conclusion: *PTCH1* LOF alterations appear actionable in non-BCC cutaneous/adnexal primaries, lung SCC and medulloblastoma, including TMB-high tumors.

#6569 KLIPP: Precision targeting of cancer with CRISPR.

M. Ljungman, H. Yang, R. Hulbatte, N. Gratsch, A. Kelher, J. Raupp, Y. Wang, K. Dorsey, T. Halseth, A. Schwendeman, P. Palmbos;
University of Michigan Medical School, Ann Arbor, MI

Current cancer therapeutic treatments are typically associated with significant collateral damage to normal tissues and the emergence of treatment resistance. Thus, there is an unmet need to develop therapies that are uniquely cancer specific and unhindered by the emergence of resistance. We have developed an RNA therapy approach based on CRISPR technology, known as “KLIPP”, that targets cancer-specific structural variant junctions (SVJs), a so far untapped cancer “Achilles heel”, that are highly abundant across cancer types. KLIPP uses a “split enzyme” system consisting of dCas9 conjugated to an endonuclease, Fok1, that requires dimerization for its activity. By designing sgRNAs that bind to sequences flanking the cancer-specific SVJs, Fok1-dCas9 dimers are formed, leading to the induction of DNA double strand breaks (DSBs) specifically at SVJs in cancer cells. We verify induction of DSBs by γH2AX foci staining in the nucleus of KLIPP-treated cells and resulting loss of clonogenic survival and induction of apoptosis, while cells lacking the targeted SVJs are unaffected. Importantly, we show elimination of orthotopic bladder cancer tumors *in vivo* after turning on expression of the KLIPP reagents by doxycycline in the drinking water. Finally, we show successful lipid nanoparticle delivery of KLIPP reagents to orthotopic bladder tumors *in vivo* using catheter-mediated delivery, leading to specific targeting of bladder cancer cells. Independently of the cancer-driving mutations, the omnipresence of cancer-specific SVJs is exploited by KLIPP to force cancer cells into apoptosis while leaving normal cells unperturbed. We believe that the successful implementation of precision KLIPP therapy could be transformative for the treatment of cancer patients.

#6570 *HLA* genotyping and HLA-based clinical trial matching using MSK-IMPACT, a targeted next-generation sequencing assay.

M. F. Chen, M. V. Gormally, A. Noronha, K. Panageas, M. Reynolds, K. Kohlasch, B. Novak, T. Kee-Velez, N. Clarke, C. Kyi, C. Friedman, S. D'Angelo, M. G. Kris, C. A. Klebanoff, R. Shah, M. Berger, C. Bandlamudi, A. Drilon, M. T. A. Donoghue;
Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Performing tumor next-generation sequencing (NGS) and human leukocyte antigen (*HLA*) typing in a single test can maximize the likelihood of matching patients with cancer to clinical trials. We investigated the utility of a clinical-grade NGS assay for this purpose.
Methods: HLA class I genotypes were determined on an investigational basis by MSK-IMPACT (FDA-authorized hybrid-capture, tumor and matched normal DNA-based NGS) using POLYSOLVER for patients with cancers of any histology between March 2014 and September 2023. Patient *HLA* genotype matches for phase I clinical trials were identified; for a subset of patients, concordance between *HLA* genotyping was compared to a CLIA-certified laboratory test.
Results: 60,565 patients successfully underwent complete class I *HLA* genotyping (two alleles each of *HLA-A, HLA-B,* and *HLA-C*). The median age at diagnosis was 64 years old and most patients were female (55%) and white (76%). The most common genotypes were *HLA-A*02:01* (42%, n=25,457), *HLA-C*04:01* (28%, n=17,274), *HLA-A*01:01* (25%, n=14,867), *HLA-C*07:01* (24%, n=14,538), *HLA-A*03:01* (21%, n=12,668), *HLA-C*07:02* (21%, n=12,493), and *HLA-B*07:02* (16%, n=9,787). Most patients (96%, n=58,287) were *HLA* genotype eligible [*HLA-A*02:01* (n=28), *HLA-A*11:01* (n=3), *HLA-A*01:01* (n=1), and *HLA-C*07:02* (n=1)] for ≥1 of 33 active early phase adoptive T cell therapy or T cell receptor bispecific trials on Clinicialtrials.gov. 280 patients with *HLA* class I matches were screened for phase I trial candidacy by the MSK phase I group. 117 were candidates for confirmatory *HLA* and neoantigen testing, of whom 43 patients were enrolled on a trial after additional screening. 72 patients had *HLA* genotyping both by MSK-IMPACT and an outside CLIA-certified laboratory; 100% (72/72) of these subjects had concordant genotypes.
Conclusions: MSK-IMPACT successfully determined class I *HLA* genotypes in a large, multi-ethnic population of patients. A substantial proportion of patients were identified as potential candidates for *HLA*-matched trials, supporting local trial enrollment.

#6571 O-GlcNAc sites on progesterone receptor are critical for its ligand independent repression of interferon signaling in breast cancer.
H. I. Saunders, S. Holloran, E. Chowanec, J. Tinoco, C. Slawson, C. Hagan;
University of Kansas Medical Center, Kansas City, KS

The role of hormone receptors in breast cancer has been well established as a key contributor to breast cancer tumorigenesis. Estrogen receptor and progesterone receptors are present in nearly 70% of breast cancers. Estrogen receptor and estrogens in breast cancer has been extensively studied and targeted effectively through endocrine therapy, however the impact of progesterone and the progesterone receptor (PR) independent of estrogen is not well understood. We have previously demonstrated that PR promotes tumor growth and drives an immune suppressive environment, therefore understanding the biology of PR in breast cancer is critical. We demonstrated that PR attenuates type 1 interferon signaling via inhibition of STAT1 phosphorylation and increased degradation of STAT2. In this study we investigated the mechanism of PR regulation of IFN signaling. Post-translational modifications such as phosphorylation and SUMOylation can influence PR target gene promoter selectivity thereby altering its function. We have identified that PR is modified by O-GlcNAc, a single N-acetyl-glucosamine sugar that cycles on and off and serine or threonine amino acids in nuclear, cytoplasmic and mitochondrial proteins. Levels of total O-GlcNAc staining are higher in breast cancer tissue compared to adjacent normal tissue. Active O-GlcNAcylation, as evidenced by immunohistochemistry staining of O-GlcNAc-transferase (OGT), is elevated in patients with PR+ tumors compared to PR-. Using T47D breast cancer cells (an ER/PR-positive tumor line), mass spectrometry analysis revealed an O-GlcNAc site at S499, S733 and S735 on PR. Using a naturally occurring PR-negative variant of T47D cells, we introduced stable expression of a mutant PR with serine to alanine substitution at the O-GlcNAc sites (S499A, S733A, S75A), thereby blocking O-GlcNAc flux, in addition to wt PR as a control. RNA-Seq analysis of these cells following treatment with progesterone revealed ligand dependent PR gene regulation, however major differences were observed in gene expression of the two cell lines independent of ligand. These results indicate ligand independent PR suppression of IFN signaling requires O-GlcNAc at these three sites. Additionally, T47D-mutant PR cell lines implanted into immune deficient mice had significantly decreased growth compared to WT-PR control tumors. Together these findings indicate O-GlcNAcylation of PR contributes to PR driven breast cancer tumor growth and immune evasion via modulation of IFN signaling.

#6572 Screening of drug library targeting neural signaling identifies cholecystokinin B receptor as a potential therapeutic target in small cell lung cancer.

M. Tokunaga, N. Nakagawa, M. Ka, Y. Sugiura, T. Iida, T. Ando, K. Watanabe, H. Kage, M. Kawakami;
The University of Tokyo Hospital, Tokyo, Japan

Small cell lung cancer (SCLC) is characterized by poor prognosis with limited therapeutic agents. Development of a new therapeutic strategy is urgently needed. SCLC can be classified into subtypes based on the expression levels of four transcription factors: ASCL1, NEUROD1, POU2F3, and YAP1 (SCLC-A, SCLC-N, SCLC-P, and SCLC-Y, respectively). SCLC-A and SCLC-N are neuroendocrine (NE)-type tumors that secrete neurotransmitters and express their receptors. Recently, neural activity has been noted as a key regulator of cancer growth that affects cancer and other cells in the tumor microenvironment. We hypothesized that neurotransmitters that regulate the biology of NE-type SCLC (SCLC-A, SCLC-N) can be therapeutic targets. To explore this, we created a drug library consisting of 560 drugs known to target neural signaling including various G protein-coupled receptors and examined their growth-inhibitory effects in SCLC cell lines. When three NE-type SCLC cell lines (NCI-H146, SHP-77, and NCI-H446) were treated with 10 μM of the drugs as the first screening, 56 drugs in the library exhibited more than 50% inhibition of cell growth. After excluding drugs with possible nonspecific effects, the IC50 values of 24 drugs were examined in an expanded panel of 20 SCLC cell lines (7 of SCLC-A, 5 of SCLC-N, 3 of SCLC-P, and 5 of SCLC-Y cell lines) as the second screening. Sograzepide, a cholecystokinin B receptor (CCKBR) inhibitor exhibited distinctly lower IC50s in NE-type SCLC cells relative to non-NE-type cells, suggesting that CCKBR is potentially a specific therapeutic target for NE-type SCLC. CCK plays roles both as a neuropeptide in the central nervous system and as a peptide hormone in the gut. In our *in silico* analysis, CCKBR expression was high in the brain and the stomach, but not detectable in the lung when normal tissues were analyzed with NCBI database. Interestingly, when cancer cells were analyzed with CCLE database, CCKBR expression was substantially high in NE-type SCLC cells, compared with other cancer cells. Furthermore, we found that the growth-inhibitory effects of sograzepide examined in the drug screening were correlated with CCKBR expression levels. Then, we conducted functional analysis of CCKBR in NE-type SCLC cell lines with high CCKBR expression: NCI-H146 (SCLC-A), H209 (SCLC-A), and H524 (SCLC-N) cells. Knockdown of CCKBR by siRNAs inhibited cell proliferation and induced apoptosis. When treated with sograzepide, apoptosis was induced dose-dependently, and cell cycle assays showed increase in sub G1 phase in these cells. Collectively, we identified CCKBR as a potential therapeutic target in NE-type SCLC through screening of drug library targeting neural signaling. Further studies are warranted to reveal the mechanism for antineoplastic effects of antagonizing this neuropeptide receptor in SCLC.

#6573 Targeting DLK1, a Notch ligand, with an antibody-drug conjugate in adrenocortical carcinoma.

N.-Y. Sun[1], S. Kumar[1], A. Weiner[2], Y. Kim[1], A. Mendoza[1], R. Nguyen[1], R. Okada[1], Y. Pommier[1], D. Martinez[3], J. Pogoriler[3], S. Diskin[4], J. Maris[2], J. Del Rivero[1], N. Roper[1];

[1]National Cancer Institute Center for Cancer Research, Bethesda, MD, [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]Perelman School of Medicine, University of Pennsylvania,, Philadelphia, PA

Adrenocortical carcinoma (ACC) is an aggressive and rare endocrine malignancy with poor prognosis. First-line therapy (adrenolytic agent mitotane in combination with chemotherapy) for recurrent and metastatic ACC has limited efficacy and there are no approved second-line therapies. Antibody-drug conjugates (ADCs) are an emerging immunotherapeutic class in which a cytotoxic payload is directed to tumor cells via antibodies to cell surface proteins. As Notch ligands, such as DLL3, are ADC targets in neuroendocrine cancers, we screened for expression of Notch ligands in ACC. Among Notch ligands (DLL1, DLL3, DLK1, JAG1, JAG2), DLK1 (delta-like non-canonical Notch ligand 1) was the most highly expressed. Moreover, ACC had the near highest expression of DLK1 across all TCGA tumors likely because this ligand is of adrenal origin (with limited expression in other normal tissues apart from the pituitary gland and ovaries). By immunohistochemistry, we verified DLK1 to be expressed, at variable levels, in 97% of ACC tumors (n=30/31). We then tested a DLK1-directed antibody-drug conjugate (ADCT-701; DLK1-PBD), consisting of a humanized anti-DLK1 monoclonal antibody coupled to DNA damaging pyrrolobenzodiazepine (PBD) dimers (SG3199; drug-to-antibody ratio~1.8) via a cleavable linker in ACC pre-clinical models. ADCT-701 exhibited potent, nanomolar cytotoxicity in DLK1-expressing ACC cell lines and ACC patient-derived short-term organoid cultures. ADCT-701 cytotoxicity was dependent on *DLK1* expression as *DLK1* knockout and *DLK1* overexpression abrogated and facilitated cytotoxicity, respectively. Mechanistically, ADCT-701 induced cytotoxicity through DLK1 dependent receptor-mediated internalization and DNA damage (γH2AX) as well as apoptosis (annexin V/PI positive cells, cleaved PARP, and cleaved caspase-3). *In vivo* studies showed that ADCT-701 was highly effective against DLK1-positive ACC xenografts and PDX models with durable anti-tumor activity. Our pre-clinical data demonstrate DLK1 as an important therapeutic target in ACC and support an upcoming phase I clinical trial of ADCT-701 in patients with neuroendocrine tumors including ACC (NCT06041516).

#6574 UCHL1 is a molecular indicator and a therapeutic target for neuroendocrine carcinomas.

S. Liu[1], T. Chai[2], F. Marques[2], Q. Yin[2], E.-C. Hsu[2], M. Shen[1], A. Toland[2], A. Bermudez[2], A. B. Hartono[1], C. F. Massey[1], C. S. Lee[1], L. Zheng[2], M. Baron[2], C. J. Denning[2], M. Aslan[2], H. Nguyen[3], R. Nolley[2], A. Zoubeidi[4], M. Das[2], C. Kunder[2], B. Howitt[2], H. Soh[2], I. L. Weissman[2], M. A. Liss[5], A. I. Chin[1], J. D. Brooks[2], E. Corey[3], S. Pitteri[2], J. Huang[6], **T. I. Stoyanova**[1];

[1]University of California Los Angeles, Los Angeles, CA, [2]Stanford University, Palo Alto, CA, [3]University of Washington, seattle, WA, [4]University of British Columbia, Vancouver, BC, Canada, [5]UT Health San Antonio, San Antonio, TX, [6]Duke University, Durham, NC

Neuroendocrine carcinomas, such as neuroendocrine prostate cancer (NEPC), small cell lung cancer (SCLC), and neuroblastoma, share common histological features, including expression of neuroendocrine markers, rapid relapse after treatment, and poor prognosis. Due to the poor clinical outcome of patients with neuroendocrine carcinomas, there is a critical need to identify new drivers, therapeutic targets, and effective therapeutic strategies for these malignancies. Ubiquitin carboxy-terminal hydrolase L1 (UCHL1) is a protease that has a dual function in regulating protein stability. We demonstrated that UCHL1 is significantly elevated in tissues from patients with NEPC, SCLC, and neuroblastoma. Loss of UCHL1 decreases tumor growth and inhibits metastasis of these malignancies. UCHL1 maintains neuroendocrine differentiation and promotes cancer progression by regulating nucleoporin, POM121, and p53. UCHL1 binds, deubiquitinates, and stabilizes POM121 to regulate POM121-associated nuclear transport of key transcriptional factors, E2F1 and c-MYC. Conversely, UCHL1 binds p53 and promotes p53 degradation. Importantly, treatment with UCHL1 inhibitors significantly reduces tumor growth and metastasis of neuroendocrine carcinomas. The combination of UCHL1 inhibitors with cisplatin, the standard of care used for neuroendocrine carcinomas, halts tumor growth in pre-clinical settings. Our study reveals new mechanisms of UCHL1 function in neuroendocrine carcinomas tumorigenesis and identifies UCHL1 as a therapeutic target and potential molecular indicator for diagnosis and monitoring treatment responses in neuroendocrine carcinomas.

#6575 Selective targeting of integrins αVβ8 and αVβ1 within the dynamic ecosystem of pancreatic cancer to improve the overall anti-tumor response.

D. Upton[1], D. Chacon Fajardo[1], S. Omari[1], S. Porazinski[1], B. McLean[1], D. Schuhmacher[1], A. Istadi[1], Australian Pancreatic Cancer Genome Initiative, V. Kothari[2], D. Finkelstein[2], T. Machajewski[2], F. Rock[2], S. Turner[2], M. Pajic[3];

[1]Garvan Institute of Medical Research, University of New South Wales, Sydney, Australia, [2]Pliant Therapeutics, South San Francisco, CA, [3]Garvan Institute of Medical Research, Darlinghurst, Australia

Pancreatic ductal adenocarcinoma (PDA) has a 5-year survival of less than 10% and remains the 3rd leading cause of cancer-related death in Western societies. New treatment options are urgently needed. TGF-β promotes stromal cell reprogramming, immunosuppression, and fibrinogenesis in cancers, including PDA. Integrins αVβ8 and αVβ1 are important activators of TGF-β signalling. Selective integrin blockade has recently emerged as a promising therapeutic approach to address TGF-β-mediated immunotherapy resistance and improve anti-tumour response across cancer models. The purpose of this study was to assess the in vivo efficacy of small molecule inhibitor PLN-104, a selective inhibitor of αVβ1, and PLN-101095, a dual inhibitor of αVβ8 and αVβ1, in well-annotated models of advanced PDA.

We determined the preclinical efficacy and detailed anti-stromal effect of PLN-101095 inhibitor in genetically defined and patient-derived PDA models, including clinically relevant combinations with standard of care (SoC) chemotherapy and anti-programmed death receptor-1 antibody (anti-mPD-1). Mechanistic assessment of alterations in tumour cell-stromal cell crosstalk was performed using comprehensive transcriptomics and immunofluorescence approaches.

Dual targeting of αVβ8 and αVβ1 with PLN-101095 in the syngeneic LSL-KrasG12D/+;LSL-Trp53R172H/+;Pdx1-Cre (KPC) model effectively reduced tumour growth by 45% in comparison to the vehicle, and significantly delayed disease progression *in vivo*. Single-cell analysis of PLN-101095-treated KPC pancreatic tumours revealed a positive reprogramming of malignant cells from a mesenchymal to a more epithelial-like state. This effect was further associated with an upregulation of MHC type I/II markers and corresponding downregulation of pro-metastatic factors across diverse cancer sub-populations. Additionally, combining PLN-101095 with anti-mPD-1 antibody further improved survival in this aggressive model of metastatic PDA. In a second syngeneic model, Pan02, PLN-101095 in combination with anti-mPD-1 antibody significantly reduced tumour growth, while increasing CD8+ lymphocyte infiltration. The combination of PLN-101095 with Anti-PD1 increased MHC and IFN gene expression. Finally, utilizing patient-derived models of metastatic PDA revealed that both PLN-104 and PLN-101095 significantly blocked tumour growth, improved the response to SoC chemotherapy Gemcitabine/Abraxane, and reduced metastatic spread to distant sites. In conclusion, these data provide scientific rationale for the design of future PLN-101095 and SoC chemotherapy as well as immunotherapy combinations in pancreatic cancer, with Phase I first-in-human oncology studies with PLN-101095 plus ICB already underway.

#6576 Discovery of potent and selective novel small molecule drugs to target estrogen receptor mutants in endocrine-resistant breast cancer.

A. Devakrishnan, C. Madasu, S. A. Fuqua, M. M. Matzuk, **M. Palaniappan**;
Baylor College of Medicine, Houston, TX

Introduction: The acquisition of estrogen receptor alpha (ERα) gene (*ESR1*) mutations is a key driver for the development of resistance to current endocrine therapy in breast cancer. Clinical studies have shown that *ESR1* mutations are frequently observed in metastatic ER-positive breast cancer patients and are associated with poor survival. It is well appreciated that activating *ESR1* somatic mutations, especially Y537S and D538G, can drive estrogen-independent activities. In addition, these *ESR1* mutations diminish the potency of the current standard-of-care agents (tamoxifen and fulvestrant) that bind ERα directly. Therefore, it is an unmet need to develop next-generation antiestrogens that inhibit ERα mutant signaling in breast cancer to improve patient survival. Here, we search for small molecule inhibitors against ERα mutants Y537S and D538G using DNA-encoded chemical library (DEL).

Methods: ERα ligand binding domain (LBD) proteins corresponding to wild type (WT), Y537S and D538G mutants were expressed in *E. coli* and purified by Ni-NTA, anion exchange, and size exclusion chromatography. The ability of these purified proteins to bind ligands was tested in biochemical assays to validate their use in DEL selections. We conducted a DEL affinity selection using our in-house collection of 6 billion small molecule compounds against WT, Y537S and D538G mutants ER LBD proteins in the presence and absence of estradiol. Selection hits that enriched with these targets were resynthesized off-DNA and tested in biochemical and functional studies using CRISPR-Cas9 knock-in Y537S or D538G mutant breast cancer cells.

Results: We have successfully purified microgram amounts of ERα LBD for WT, Y537S, and D538G proteins. In our biochemical assay, the SRC3 peptide binds to the WT ERα LBD in the presence of estradiol, whereas Y537S and D538G LBDs bind the SRC3 peptide in the absence of estradiol, consistent with these mutants constitutively binding to SRC3. Our multibillion small molecule collections of DELs can screen and identify several hits in WT and mutant ERα LBDs. To confirm the selection output, we synthesized off-DNA compounds and validated these in biochemical and cell-based studies. Compounds CDD-1274 and CDD-1802 dramatically decrease the WT and mutant ERα protein levels in multiple ER+ breast cancer cells. These compounds greatly reduce protein levels for GREB1, TFF1, c-MYC, E2F1, and survivin in wildtype and mutant breast cancer cells, and they increase levels of cleaved PARP, a marker for apoptosis in wildtype and mutant ER+ breast cancer cells but not in ER-negative breast cancer cells.

Conclusion: Our study rapidly identified potent and novel small molecule drugs to target estrogen receptor mutants using our DNA-encoded chemical library platform.

Acknowledgments: Funding sources (NIH/NCI R03 CA259664 and CPRIT RP220524 to MP).

#6577 Chemoproteomic evaluation of PROTACs targeting estrogen receptor alpha for ER+ breast cancer.

Z. Sandusky, M. Brown;
Dana-Farber Cancer Institute, Boston, MA

In our investigation of estrogen receptor (ER) targeted protein degraders for advanced ER+ breast cancer, we assessed three proteolysis targeting chimeras (PROTACs), ARV471, ERD308, and ERD3111. Global proteomic analysis unveiled off-target protein degradation of progesterone receptor (PR) and phosphodiesterase 6D (PDE6D) by ER targeted PROTACs, but not selective ER degraders (SERDs). PR and PDE6D have previously been implicated as targets in cancer treatment. Protein degradation is rescued in CRBN- or VHL-knockout cells. Co-treating ER+ breast cancer cells with ligands for PR or PDE6D outcompeted PROTAC-mediated degradation and stabilized the respective protein, demonstrating the PROTACs are targeting the PR and PDE6D ligand-binding domains. Competition assays in ER-negative cell lines confirmed PR and PDE6D protein degradation is ER-independent. These findings underscore the importance of understanding off-target effects for developing more selective and effective therapeutics in ER+ breast cancer.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Discovery 2: New Therapies
Minisymposium

#6578 N17465, a systemically deliverable elastase, attenuates tumorigenesis and stimulates anti-tumor immunity.
R. Gujar, C. Cui, C. Lee, M. Fumagalli, N. Martinez, H. Liu, N. Grigaitis, S. Feau, L. Becker;
Onchilles Pharma, Inc., San Diego, CA

Background. Neutrophil elastase (ELANE) - a neutrophil-derived serine protease - kills a wide range of cancer cells without harming non-cancer cells through a unique killing program involving histone H1 and the death domain of CD95. Although ELANE attenuates tumor growth and induces anti-tumor immunity following intratumoral delivery (Cui et al., Cell, 2021), systemic delivery is stymied by the presence of serine protease inhibitors in blood (eg. alpha-1-antitrypsin (A1AT) which rapidly inhibit its enzymatic activity essential for its anti-cancer function. To overcome this challenge, we developed N17465, an enzyme that resists serine protease inhibitors in blood, and tested its effects on tumor growth, both as a monotherapy and in combination with checkpoint inhibitors.
Methods. Enzymatic properties: N17465 enzymatic activity was quantified in the +/- of A1AT or plasma in vitro, and in blood following intravenous (I.V) injection into tumor-bearing mice. Enzyme activity assays included a fluorogenic substrate AAPV-AMC and the C-terminal domain of CD95 (amino acids212-335). Anti-cancer properties: For in vitro studies, cells were treated with N17465 and viability was quantified by calcein-AM and immunogenic cell death (ICD) markers. Cancer/non-cancer cells included human/murine cell lines and primary cells from ovarian cancer (OvCa) patients. For in vivo studies, N17465 was injected I.V and effects on tumor growth, immunology and survival were assessed as monotherapy or in combination with a checkpoint inhibitor (anti-CTLA4) in pre-clinical models.
Results. N17465 maintained enzymatic activity following incubation with A1AT or mouse/human plasma in vitro, and following I.V injection into CT26 tumor-bearing mice in vivo. Importantly, protecting N17465 from serine protease inhibitors did not interfere with its ability to cleave CD95 (therapeutic target) or selectively kill cancer cells in vitro. Indeed, N17465 induced ICD markers, killed a wide range of murine/human cancer cells and also well tolerated by non-cancer cells. Systemically delivered N17465 produced durable tumor regression in a murine CT26 colon cancer model resulting in ~50% tumor-free mice, induced a favorable immune profile, and synergized with anti-CTLA4. N17465 also exhibited efficacy across a range of xenograft models spanning human colon, prostate, and lung cancer, as well as OvCa patient-derived CDX models.
Conclusions. Altogether, our data demonstrate that N17465 selectively kills cancer cells, produces durable responses in mice, induces favorable immunology and synergies with checkpoint inhibitors in pre-clinical models. Its ability to maintain enzymatic activity in blood following systemic delivery, selectively kill a wide range of cancer cells, and stimulate anti-tumor immunity warrants further investigation of this unique therapeutic modality across a wide range of solid tumors.

#6579 DS-3939a, a novel TA-MUC1-targeting antibody-drug conjugate (ADC) with a DNA topoisomerase I inhibitor DXd, exhibits potent antitumor activity in preclinical models.

M. Yukiura[1], **K. Takano**[1], K. Takahashi[1], A. Zembutsu[1], M. Kitamura[1], Y. Shiose[2], K. Honda[1], K. Oyama[1], W. Obuchi[1], M. Yamada[1], R. Goto[1], K. Sakurai[1], K. Kumagai[1], T. Kagari[1], Y. Abe[1], T. Agatsuma[1];

[1]Daiichi Sankyo Co., Ltd., Tokyo, Japan, [2]Daiichi Sankyo, Inc., Basking Ridge, NJ

Background: Tumor-associated mucin-1 (TA-MUC1) is a tumor-specific transmembrane glycoprotein with aberrant glycosylation. It is highly expressed in various human epithelial cancers, making it an attractive target for cancer therapy. DS-3939a is a TA-MUC1 targeting antibody-drug conjugate (ADC) structurally composed of a humanized anti-TA-MUC1 antibody, an enzymatically cleavable tetrapeptide-based linker, and a DNA topoisomerase I inhibitor (DXd) with a high drug-to-antibody ratio (DAR). In this study, the pharmacological activity of DS-3939a was evaluated using preclinical in vitro and in vivo models.
Methods: TA-MUC1 expression was assessed by immunohistochemistry and flow cytometry. Binding specificity of DS-3939a was confirmed by enzyme-linked immunosorbent assay. Induction of DNA damage and apoptosis to cancer cells by DS-3939a treatment were detected by Simple Western System. In vitro cell growth inhibitory and in vivo antitumor activities of DS-3939a were evaluated using various cancer cell lines and patient-derived xenograft (PDX) models.
Results: Many specimens across multiple cancer types showed positive staining for TA-MUC1, with a particularly high positive rate observed in bladder, lung, and breast cancers. DS-3939a specifically bound to aberrantly glycosylated MUC1 peptides by recognizing both the glycan and backbone peptide moiety of MUC1. In vitro, DS-3939a inhibited the growth of TA-MUC1-positive cancer cells but not of TA-MUC1-negative cancer cells. Neither a parental anti-TA-MUC1 antibody nor isotype control ADC inhibited the growth of these cells. In addition, treatment with DS-3939a and DXd alone induced DNA damage and apoptosis in cancer cells. These results demonstrate that DS-3939a exhibits TA-MUC1-dependent cell growth inhibition through DXd-mediated cytotoxic effect. Moreover, DS-3939a exhibited significant antitumor effects in the several TA-MUC1-positive cancer cell line-derived xenograft models and various PDX models. DS-3939a also induced strong tumor regression even after treatment of other cytotoxic ADCs in several xenograft models.
Conclusion: Based on these preclinical results, DS-3939a could provide valuable therapy with potential benefits for patients with TA-MUC1-expressing tumors. A first-in-human phase 1/2 study in patients with advanced solid tumors is currently in progress (NCT05875168).

#6580 A Novel EGFR x cMET bispecific ADC PRO1286 demonstrated broad antitumor activity and promising tolerability in preclinical models.

Y. Xiao[1], H. Huang[1], J. Yin[1], X. Qiu[1], L. Wang[1], H. Liu[1], B. Zhao[2], **Z. Chen**[2];
[1]ProfoundBio (Suzhou) Co., Ltd., Suzhou, China, [2]Profound Bio US Co., Seattle, WA

EGFR and cMET are frequently co-expressed on tumor cells, often upregulated as the escape mechanism for each other, and both well-validated targets in oncology. Small molecule TKIs and amivantamab have been approved for non-small cell lung cancer with relevant actionable genomic alterations (AGA), and monoclonal antibodies offer treatment options for EGFR-expressing head and neck and colorectal cancers without AGA. Yet high unmet need in these tumors still exists. We sought to develop an EGFR and cMET dual-targeting ADC using our proprietary technology platform with carefully chosen design features for the many tumors expressing EGFR and cMET with or without AGA. PRO1286 is comprised of a monovalent bispecific human IgG1 (dubbed as “Bsab”) with fine-tuned affinity on EGFR and cMET, and the proprietary topoisomerase 1 inhibitor-based linker-drug, sesutecan. Sesutecan previously demonstrated promising characteristics in preclinical studies with multiple targets and conferred an encouraging benefit:risk profile in the clinic with a FRα-directed ADC (rinatabart sesutecan). PRO1286 at DAR8 displays high hydrophilicity and excellent stability and developability in vitro. PRO1286 binds selectively and specifically to each target with a low nanomolar EC_{50} in the CHO-K1 cells overexpressing each target. PRO1286 exhibited efficient internalization (~50-80% internalized in 4 hrs) and strong cytotoxicity (sub-nanomolar IC_{50}) against a broad panel of tumor cell lines with higher potency than the parent mAbs. PRO1286 produced marked and dose dependent anti-tumor activity in mouse xenograft models encompassing a wide range of target expression levels, tumor types (head and neck, lung, esophageal, gastric, colorectal), and genomic landscape (with or without AGA in EGFR or cMET; with diverse additional co-mutations). Sustained tumor growth inhibition or complete remission was observed in several xenograft models after treatment with a single dose (2 mg/kg) of PRO1286. PRO1286 was more efficacious than benchmarking molecules in the mouse studies. In an exploratory toxicity study in cynomolgus monkeys, PRO1286 was well tolerated at 30 mg/kg with the main toxicity being payload-driven and residing in bone marrow. PRO1286 exhibited a stable PK profile that was similar to that of the Bsab in rats and favorable PK characteristics in monkeys. In summary, PRO1286 demonstrated promising physiochemical properties, PK/PD, antitumor activity, and tolerability in preclinical studies. It may carry an expanded therapeutic index compared to other EGFR- and/or cMET-directed ADCs. It may also differentiate from existing EGFR- and/or cMET-targeting agents on broad coverage of EGFR and cMET-expressing tumors with or without the respective AGAs. Effort is under way to advance a DAR optimized molecule to the clinic for the treatment of many EGFR- or cMET-expressing solid tumors.

#6581 DX126-262 combined with chemotherapy (Cisplatin and 5-Fu) demonstrates promising antitumor efficacy in HER2-positive gastric cancer.

X. Cai, M. Cao, H. Guo, Q. Yang, X. Kong, Y. Du, Z. Ye, Z. Guo, L. Zhang, L. Bai, J. Jia, Y. Zheng, Y. Chen, M. Chen, W. Zheng, J. Zheng, W. Li, Y. Huang, M. Liu, Z. Fan, H. Ye, Y. Xu, B. Chen, M. Dai, **R. Y. Zhao**;
Hangzhou DAC Biotechnology Co., Ltd., Hangzhou City, China

Gastric cancer is a common malignant tumor of the digestive system, and its morbidity and mortality rank among the top five in the world. Although significant progress has been made in cytotoxic chemotherapy, immunotherapy and targeted therapy in recent years, the long-term prognosis of patients with advanced or metastatic gastric cancer is still poor. Trastuzumab combined with chemotherapy is the first-line standard of care (SOC) for HER2-positive advanced or metastatic gastric cancer. Two ADC drugs targeting HER2, DS-8201 and RC-48, have also been approved for the treatment of gastric cancer. However, their limited clinical benefits and occurrence of adverse events still present a significant challenge. Therefore, minimizing the off-target toxicity and collateral damage while achieving significant chemotherapy efficacy has become the focus of gastric cancer treatment. DX126-262 is a novel HER2-targeting antibody-drug conjugate (ADC), generated by conjugating a Tubulysin B analogue to a recombinant humanized anti-HER2 monoclonal antibody through a linker containing branched hydrophilic polyethylene glycol, using thiol-maleimide chemistry to achieve drug antibody ratio (DAR) of 3.8. Previous studies have confirmed that DX126-262 monotherapy showed excellent efficacy in HER2-positive gastric cancer NCI-N87 cells in vitro and in vivo. And the efficacy has also been demonstrated in clinical trials (now in phase II, CTR20211871). Based on above results, we intended to further explore whether combination therapy of DX126-262 with Cisplatin and 5-FU can improve the anti-tumor efficacy compared with SOC (Herceptin plus Cisplatin and 5-FU) or DS-8201 monotherapy. The triple-drug combination therapy demonstrated much better therapeutic efficacy than single drug (DX126-262, Cisplatin, 5-FU, Herceptin, or DS-8201) or double-drug combination (Cisplatin plus 5-FU) or SOC (Herceptin plus Cisplatin and 5-FU) on human gastric cancer cells in vitro and in vivo. Meanwhile, triple-drug combination therapy did not exhibit superimposed toxicity, judging by the body weight of mice and hemal biochemistry assays. These results suggested that DX126-262 plus Cisplatin and 5-FU might be a promising strategy for treatment of HER2-positive advanced or metastatic gastric cancer in clinic.

#6582 Preclinical characterization of IPH45, a novel topoisomerase I inhibitor ADC targeting Nectin-4 for the treatment of Nectin-4 expressing tumors.

R. Remark, C. Bonnafous, L. Chiossone, C. Soulas, C. Perrier, G. Habif, S. Bokobza, A. Maguer, R. Courtois, J. Lopez, G. Fenaux, O. Benac, B. Carrette, R. Letay-Drouet, R. Bonifay, S. Augier, L. Simon, B. Rossi, A. Morel, A. Represa, N. Beltraminelli, Y. Morel, C. Paturel, E. Vivier;
Innate Pharma, Marseille, France

Background: Nectin-4 is a cell membrane adhesion protein overexpressed in several solid tumors, including urothelial, breast, lung, ovarian, and pancreatic cancers, with limited expression in normal tissues, making it an ideal target for antibody-drug conjugates (ADC). Enfortumab Vedotin (EV, PADCEV®) is an ADC targeting Nectin-4 with a monomethyl auristatin E (MMAE) payload approved for the treatment of patients with urothelial carcinoma (UC), but with limited clinical activity reported beyond UC. In addition, EV causes peripheral neuropathy and skin toxicity, leading to treatment discontinuation. To overcome these limitations and the mechanism of resistance to EV, IPH45, a novel topoisomerase I inhibitor ADC targeting Nectin-4 with an improved therapeutic index, was developed.
Methods: *In vitro* studies were performed to investigate internalization, tumor cell killing and bystander effect, antibody-dependent cellular cytotoxicity (ADCC) and complement activation. *In vivo* efficacy studies were performed on cell line-derived xenografts (CDX) of triple negative breast cancer, patient-derived xenografts (PDX) of urothelial carcinoma and syngeneic tumor models expressing human Nectin-4. IPH45 efficacy was compared to EV. Toxicology studies to determine the dose range were conducted in rat and non-human primates (NHP).
Results: IPH45 consists of a humanized IgG1 targeting a unique epitope in human Nectin-4, non-overlapping with EV, a cleavable linker, and a topoisomerase I inhibitor with a high drug-to-antibody ratio (DAR). *In vitro*, IPH45 is internalized upon binding to its target and induces direct killing of Nectin-4–expressing tumor cells as well as bystander killing of Nectin-4 non-expressing tumor cells in mixed culture. IPH45 mediates ADCC and complement-mediated killing. IPH45 demonstrates activity in CDX and PDX models with similar effective dose as EV. Moreover, IPH45 shows anti-tumor efficacy *in vitro* and *in vivo* in primary and secondary EV resistant models. In dose-range finding toxicology studies in rats and NHP, IPH45, unlike EV, does not elicit skin toxicity. IPH45 remains well tolerated up to the highest dose tested, suggesting a potentially larger therapeutic index than MMAE-based ADCs. Pharmacokinetic analyses in mice, rats, and NHP show minimal release of free toxin in the serum and half-life compatible with Q2W or less frequent dosing schedules in clinic.
Conclusion: IPH45 is a topoisomerase I ADC targeting Nectin-4 with the potential for larger therapeutic index than EV, improved safety and dosing regimen, and ability to overcome primary and secondary resistance to EV or other Nectin-4 ADC in development. IPH45 is progressing to the clinic where the translatability of this unique profile into improved patient outcomes will be assessed across indications.

#6583 Developing a selective cancer chemotherapy by small molecule-based targeting of PCNA protein.

J. Jossart, L. Gu, P. Haratipour, C. Li, R. Lingeman, R. Hickey, L. Malkas, **J. J. P. Perry**;
Beckman Research Institute of The City of Hope, Duarte, CA

Proliferating cell nuclear antigen (PCNA) is a proliferation biomarker in a variety of human tumors and has critical cellular functions in DNA replication and repair. We previously identified a unique cancer-associated isoform of the protein, termed caPCNA, which allows for structure-based drug discovery studies to develop inhibitors for selective therapeutic targeting of cancer cells. Distinct strategies have been used to develop caPCNA targeting agents, which includes peptide and small molecule-based compounds, although the success in developing therapeutically tractable compounds has been limited so far. Here, we present the crystal structures and corresponding biochemical characterizations of our novel small molecule-based caPCNA inhibitors, which bind into the PIP-box binding pocket of PCNA. Our lead compound selectively kills cancer cells, and it appears to induce replication stress, apoptosis and increase cancer cell sensitivity to genotoxic agents, while these effects are not observed in non-malignant cell controls. This caPCNA inhibitor is orally administrable, metabolic stable and it suppresses tumor growth as a monotherapy or as a combination treatment and is now an investigational new drug in Phase 1 clinical trials. PCNA plays a critical role enabling the replication fork to proceed from transcription replication conflict sites, by temporarily dislodging RNA polymerase II. Thus, structure-based drug discovery against caPCNA may open a novel therapeutic avenue for the development of selective chemotherapeutics, through targeting a cancer cell's vulnerability to unresolved transcription replication conflicts.

#6584 Aberrant TRIM7 expression potentiates RACO-1 mediated proliferation and dysregulated interferon responsiveness in the setting of anti-PD-1 acquired resistance in cancer.

T.-A. T. Nguyen[1], M. Morra[1], K. Li[2], U. Bhatt[2], J. Mwangi[1], Y. Rivera-Molina[1], N. Oien[1], J. Medina[2], T. H. Schreiber[1], **G. Fromm**[1];
[1]Shattuck Labs, Durham, NC, [2]R2M Pharma, Inc, San Francisco, CA

While checkpoint inhibitor treatment has extended the survival of many cancer patients, most initial responders will later develop disease progression through a variety of poorly understood acquired resistance mechanisms (CPI-AR). One such recently described mechanism involves the transcriptional hyperactivation of genes associated with interferon (IFN) signaling, JAK/STAT, and antigen processing/presentation pathways. Aberrant IFN regulation in the setting of AR suggests that tumor cell intrinsic mechanisms have conferred a growth advantage despite the presence of immune-mediated pressure unleashed by PD-1/L1 antibody blockade. Analysis of transcripts progressively upregulated during acquisition of AR *in vivo* and transcripts upregulated by IFN exposure of isolated AR cell lines *in vitro* identified the E3 ubiquitin ligase TRIM7 as a candidate mediator of the AR phenotype. A specific pocket on the PRY/SPRY domain of TRIM7 has been shown to bind viral peptides, resulting in ubiquitination and degradation as a mechanism to mitigate viral propagation. Here we describe the evaluation of small molecule inhibitors (SMI) designed to the TRIM7 PRY/SPRY viral-pocket domain, where binding specificity was confirmed using mass spec analysis. These SMI competitively inhibited TRIM7 mediated stabilization of RACO-1, resulting in decreased cancer cell proliferation which was associated with altered c-Jun/AP-1 transcription. TRIM7 SMI also disrupted STING and MAVS ubiquitination and restored IFN responsiveness and sensitivity to PD-1 inhibitor treatment. Finally, given the position of TRIM7 downstream of growth factor receptor and kras signaling, combination of TRIM7 inhibitors with kras, braf, and/or MEK inhibitors was shown to additively suppress proliferation of tumor cells with kras mutations. These results provide evidence that upregulation of TRIM7 mediates both a pro-proliferative and IFN resistant phenotype in the setting of CPI-AR, and that inhibition of TRIM7 with small molecule inhibitors may prevent or reverse AR to PD-1/L1 blockade.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 5
Minisymposium

#6585 Combination RAS^{G12C}(ON) and RAS^{MULTI}(ON) inhibition overcomes resistance and prolongs durability in preclinical models of mutant KRAS^{G12C}-driven cancers.

X. Wei, M. Holderfield, Y. Yang, K. Seamon, J. Dinglasan, N. Montazar, B. Lee, S. Cai, L. Lai, I. Aronchik, S. Chang, Z. Wang, P. Wildes, J. A. Smith, J. Jiang, M. Singh;
Revolution Medicines, Inc., Redwood City, CA

Inhibitors of the GDP-bound state of mutant KRAS^{G12C} protein (KRAS^{G12C}(OFF)), e.g., adagrasib and sotorasib, have shown clinical activity in patients with KRAS^{G12C}-driven NSCLC, CRC and PDAC. However, most patients exhibit progression on monotherapy treatment in months, underlining the need for combination therapeutic approaches that improve the durability of the anti-tumor activity seen with KRAS^{G12C} inhibitors.

RMC-6291 is a mutant-selective covalent inhibitor of the GTP-bound RAS(ON) form of RAS^{G12C}, while RMC-6236 is a non-covalent RAS^{MULTI}(ON) inhibitor of both mutant and wild-type variants of canonical RAS isoforms. In models harboring diverse alterations driving resistance mechanisms to KRAS^{G12C}(OFF) inhibitors -- including reactivation of KRAS^{G12C} and wild-type RAS by increased RTK signaling, acquired secondary oncogenic RAS mutations, and KRAS amplification -- both RMC-6291 and RMC-6236 exhibited superior anti-cancer activity as single agents when compared to KRAS^{G12C}(OFF) inhibitors. Thus, we hypothesized that a combination of RMC-6291 and RMC-6236 could address a broad spectrum of observed clinically relevant resistance mechanisms to KRAS^{G12C}(OFF) inhibitors that reactivate RAS signaling via mutant and wild-type RAS isoforms and compromise the depth and durability of anti-tumor response.

In a mouse clinical trial with KRAS^{G12C} xenograft models, daily oral administration of RMC-6291 induced objective responses in 18 out of 25 NSCLC PDX and CDX models as assessed by mRECIST. In a subpanel of 7 NSCLC models that are relatively refractory to KRAS^{G12C}(OFF) inhibitor monotherapy, RMC-6236 alone somewhat prolonged the durability of response, while the combination of RMC-6291 with RMC-6236 improved the depth of response and significantly extended the durability thereof. In contrast to NSCLC, in models of KRAS^{G12C} CRC tumors a more heterogeneous response to RMC-6291 monotherapy was observed with objective responses in 4 out of 15 CRC models. The addition of RMC-6236 to RMC-6291 substantially improved the depth and duration of anti-tumor response in the resistant models to KRAS^{G12C} inhibitor alone. The combination of RMC-6291 with RMC-6236 at preclinical target doses did not affect the systemic or tumor exposures of each compound and was well tolerated in tumor-bearing immune-deficient animals.

Both investigational agents RMC-6236 and RMC-6291 have shown promising anti-tumor activity as monotherapies in preclinical models and, more recently, showed preliminary clinical activity in patients with RAS-driven tumors at exposures that were well tolerated. The addition of RMC-6236 to RMC-6291 shows combinatorial activity in preclinical models that are relatively less responsive to either inhibitor alone. A clinical trial combining RMC-6291 with RMC-6236 in patients with mutant KRAS^{G12C} tumors is currently enrolling.

#6586 ORIC-944, a potent and selective allosteric PRC2 inhibitor with best-in-class properties, demonstrates combination synergy with AR pathway inhibitors in prostate cancer models.

A. Daemen[1], N. Yuen[1], A. Wang[1], A. Pankov[1], L. Ulicna[1], C. Chen[1], F. L. Duong[1], J. Long[1], M. A. Marx[2], J. G. Christensen[2], L. S. Friedman[1], M. R. Junttila[1]; [1]ORIC Pharmaceuticals, South San Francisco, CA, [2]Mirati Therapeutics, San Diego, CA

Polycomb repressive complex 2 (PRC2) dysregulation occurs in multiple tumor types and is associated with poor prognosis in patients with prostate cancer. In patients treated with androgen receptor pathway inhibitors (ARPI), emergence of tumor cell plasticity is associated with resistance to therapy. Dysregulation of epigenetic reprogramming factors, including PRC2, creates an environment that is permissive for such lineage plasticity. Inhibition of the PRC2 complex therefore may provide an opportunity to overcome or prevent the emergence of plasticity in prostate cancer. Notably, emerging clinical trial data has demonstrated the potential of ARPI and PRC2 inhibitor combination therapy to improve outcomes in patients with metastatic prostate cancer.

PRC2 tri-methylates histone H3 at lysine 27 (H3K27me3), leading to long-term transcriptional silencing, a key mechanism regulating cellular functions such as cell growth and differentiation. Three core subunits comprise PRC2: the catalytic subunit enhancer of zeste homolog 2 (EZH2), suppressor of zeste 12 (SUZ12) and embryonic ectoderm development (EED). EED is essential for the histone methyltransferase activity of PRC2. First-generation PRC2 inhibitors, which target EZH2, exhibit poor drug properties, drug-drug interaction liabilities and short half-life requiring twice daily dosing at high doses in patients.

We developed a second generation PRC2 inhibitor, ORIC-944, an allosteric inhibitor of PRC2 that binds the EED subunit. ORIC-944 is a potent, highly selective, orally bioavailable inhibitor with best-in-class properties. ORIC-944 demonstrated single agent tumor growth inhibition in a spectrum of in vivo prostate cancer models, including AR-positive, AR-mutant, ARv7, ARPI-responsive and ARPI-resistant models. In vitro analysis of the combination of ARPIs and ORIC-944 showed synergy in multiple prostate cancer cells, utilizing BLISS and other quantitative methods. In vivo studies revealed that ORIC-944 demonstrated increased efficacy in combination with ARPI, consistent with the in vitro synergy. RNA-seq analysis of transcriptional changes induced by ORIC-944 provided mechanistic insight into the role of PRC2 in prostate cancer lineage plasticity and combination response.

These results position ORIC-944 as a best-in-class PRC2 inhibitor for evaluation in combination with ARPI in patients with metastatic prostate cancer. A phase 1b trial of ORIC-944 is ongoing (NCT05413421).

#6587 Discovery of molecular glue of FBXW7:MYC interaction using small molecule microarray.

Shenghao Guo[1], Morgan Stilgenbauer[2], Bocheng Wu[2], Yatin Mankan[2], Angela N. Koehler[2]

[1]Biological Engineering, Massachusetts Institute of Technology (MIT), Cambridge, MA,[2]Koch Institute For Integrative Cancer Research at MIT, Cambridge, MA

MYC deregulation is a key driver and feature of many human cancers. Yet, despite its importance in cancer progression, MYC is considered “undruggable” by small molecules due to its disordered conformation. Therefore, interfering with its interactions with protein partners to modulate MYC activity appears viable. FBXW7 is an E3 ligase, which serves as a constituent of the SCF (Skp1-Cul1-F box) ubiquitin ligase complex. It mediates the degradation of both c-Myc and Cyclin E through ubiquitin-dependent proteolysis. FBXW7 mutations are found in various human tumor types, establishing its role as a general human tumor suppressor. Specifically, FBXW7 down-regulation increases MYC level, and its expression correlates to lethal outcomes of breast epithelial cells, poor prognosis in glioblastoma, and T cell acute lymphoblastic leukemia remission. Therefore, our project aims to discover potent small molecule glues that would enhance the interaction between FBXW7 and MYC, leading to MYC degradation through proteolysis and eventually suppression of various cancers. Taking advantage of our high throughput screening technology, Small Molecule Microarrays (SMMs), we successfully identified 29 compounds that potently bind to both c-Myc and FBXW7 after screening our 65,000 ‘drug-like’ small molecule library. We then performed secondary assays using a mCherry-GFP MYC reporter cell line to identify our lead compound, KI-FBX-001, which decreases MYC’s expression:transcription ratio by over 50% compared to control. Additionally, this down-regulation can be rescued by protease inhibitor MG132, indicating that the effect is achieved via proteolysis. *In vitro* dose-response and time-course treatment revealed an optimal drugging concentration at 15uM in K562 cells, with inhibition reaching its peak at the 4-hour time point at over 60%. Using the Qiagen MYC reporter assay, the in vitro IC50 of KI-FBX-001 is found at 7.42uM. Beyond the protein level, the qPCR result also reveals a decrease in MYC mRNA level at over 70%. Surface Plasmon Resonance (SPR) is used to confirm direct binding between FBXW7 and KI-FBX-001, which showed promising binding with kd=0.17μM. Proximity Ligation Assay further confirms KI-FBX-001’s effect in enhancing FBXW7:MYC interaction in the cell. In summary, our findings proved that KI-FBX-001 is a promising molecular glue in the FBXW7:MYC interaction, and can effectively modulate the MYC level for future therapeutic purposes.

#6588 Discovery of ASTX295, a potent, next-generation small molecule antagonist of MDM2 with differentiated pharmacokinetic profile.

M. Ahn[1], L. Bevan[1], I. Buck[1], C. Cano[2], J. Castro[1], B. Cons[1], J. Endicott[2], L. Fazal[1], N. Ferrari[1], I. Hardcastle[2], K. Hearn[1], R. Holvey[1], S. Howard[1], C. Johnson[1], C. Jennings[2], J. Kucia-Tran[1], S. Kyle[2], J. Lunec[3], J. Lyons[1], D. Miller[2], D. Rees[1], M. Noble[2], D. R. Newell[2], J. Reeks[1], H. Saini[1], J. St. Denis[1], E. Tamanini[1], H. Thomas[2], N. Thompson[1], M. Vinkovic[1], G. Ward[1], N. Wallis[1], H. Walton[1], S. Wedge[2], P. Williams[1], E. Willmore[2], N. Wilsher[1], Y. Zhao[2], G. Chessari[1],

[1]Astex Pharmaceuticals, Cambridge, United Kingdom, [2]Cancer Research Horizons Therapeutic Innovation, Newcastle Drug Discovery Group, Newcastle University, Newcastle upon Tyne, United Kingdom, [3]Biosciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom

In response to cellular stress, the tumor suppressor p53 is activated to modulate cell cycle progression, DNA repair, and apoptosis. Inhibition of the MDM2-p53 interaction in tumors carrying wild-type p53 prevents its degradation and can reactivate p53 to elicit an anti-cancer effect. Targeting the p53-MDM2 interaction therefore remains a promising strategy for cancer therapy. However, development of first generation MDM2 antagonists has been challenged by dose-limiting, on-target bone marrow toxicities. Understanding of differential effects of p53 pathway activation in normal hematopoietic versus cancer cells (to be presented in a separate abstract) together with our expertise in structure-based drug design have led to the discovery of ASTX295, a potent MDM2 antagonist with differentiated pharmacokinetic profile aimed at sparing bone marrow toxicities and increasing the therapeutic index. Here, we present the first disclosure of the structure and pre-clinical characterisation of ASTX295. ASTX295 exhibits potent activity (IC_{50}<1 nM) against MDM2 in an ELISA-based *in vitro* assay and induces significant growth reduction in p53 wild-type, MDM2-amplified SJSA-1 cells (GI_{50}=27 nM). Antiproliferative activity of ASTX295 was further demonstrated in a panel of 219 p53 wild-type cell lines, with 143 cell lines showing GI_{50} values less than 1 µM and 50 showing values less than 0.1 µM. Effects of ASTX295 are shown in cell lines carrying functional p53 as confirmed in three p53 wild-type and mutant cell line pairs (SJSA1 and SN40R2, A2780 and A2780CP, HCT116 and HCT116 $p53^{-/-}$). In addition to inhibiting cell cycle progression and cell proliferation, ASTX295 also potently induces apoptosis following 24-48 hour treatment. Further in vitro analyses of ASTX295 demonstrated an increase in the levels of p53 (EC_{50}=10 nM after 2 hours) and its transcriptional targets such as p21 and MDM2. In vivo, ASTX295 shows robust induction of p53 and its target genes at 3 and 6 hours after oral administration together with dose-dependent inhibition of tumour growth in the SJSA-1 xenograft model. Importantly, ASTX295 exhibits optimised pharmacokinetic and pharmacodynamic profiles with relatively short duration of pathway modulation and a desired predicted human half-life of 2-8 hours. Based on our pre-clinical hypothesis on differential time-dependent sensitivities of normal versus cancer cells to p53 activation, achieving such a profile while maintaining potency may increase the therapeutic index. These data highlight the therapeutic potential of ASTX295, which is currently being tested in a Phase 1/2 clinical trial in advanced solid tumors with wild-type p53 (NCT03975387). We plan to present preliminary clinical data in a separate abstract at this meeting.

#6589 Discovery of potent and selective pan-TEAD autopalmitoylation inhibitors for the treatment of Hippo-pathway altered cancers.

J. A. Gordon[1], J. Dubauskaite[1], M. DuPont[1], N. Guan[1], G. Holdgate[2], S. Mlynarski[1], N. Umbreit[1], D. Sanchez[1], A. Srivastava[2], J. Suski[1], N. Su[1], R. Richards[1], S. Cosulich[2], C. Reimer[1], J. Brownell[1];

[1]AstraZeneca, Boston, MA, [2]AstraZeneca, Cambridge, United Kingdom

TEAD1-4 are DNA bound transcription factors regulated by the Hippo tumor suppressor pathway that bind the coactivators YAP/TAZ to activate oncogenic gene expression programs involved in cell survival, proliferation, and drug resistance. TEAD-dependent transcription is activated in many tumor types through a variety of mechanisms including LOF Hippo pathway mutations (e.g. NF2, LATS) and YAP/TAZ amplification, and also as an adaptive resistance mechanism, for example in response to EGFR TKI and KRAS inhibition. Here, we report the initial characterization of a novel pan-TEAD inhibitor, AZ4331, which was identified following a structure-guided drug design campaign. AZ4331 disrupts the post-translational palmitoylation of TEAD proteins through covalent binding to a conserved cysteine residue resulting in inhibition of TEAD-dependent transcriptional output. AZ4331 inhibited the proliferation of NF2m NCI-H226 cells (GI50: 92 nM) while having no effect on Hippo-wild type NCI-H2452 (GI50: undetermined). Cell-based metabolic labeling studies demonstrated the ability of AZ4331 to inhibit palmitoylation of all four TEAD paralogs and led to disruption of the YAP/TEAD complex assessed by immunoprecipitation resulting in reduced TEAD transcriptional output as assessed by qPCR. Furthermore, in vivo profiling showed AZ4331 achieved sufficient exposures (plasma free Cmax: 2.7 µM) and robust target engagement as measured through reduction of multiple canonical TEAD target genes (CTGF [IC50: 0.127 µM] , ANKRD1, AMOTL2 and CYR61) in Hippo-altered mesothelioma xenograft tumors. This target engagement in turn drove inhibition of tumor proliferation in xenograft models representing common Hippo-alterations. AZ4331 treatment of NF2m NCI-H226 and LATS1/2 loss MSTO-211H mesothelioma xenografts drove 50% and 93% regression of tumors, respectively. While treatment of head and neck squamous cell carcinoma FAT1m FaDu and YAP1amp Detroit562 xenografts lead to 58% tumor growth inhibition and 35% tumor regression, respectively. These findings identify AZ4331 as a potent inhibitor of the TEAD transcription factor family and further validate the inhibition of TEAD in Hippo-altered cancers as a potential therapeutic strategy.

#6590 Novel WRN helicase inhibitors selectively target microsatellite unstable cancer cells.

G. Picco[1], Y. Rao[2], A. Al Saedi[1], S. F. Vieira[1], Y. Lee[2], R. Shenje[2], S. Bhosle[1], S. Walker[1], K. May[3], C. Herranz-Ors[1], C. Dicer[1], F. Gibson[1], R. Banerjee[1], T. Werner[4], J. Cottom[2], Y. Peng[2], N. Deng[5], P. Landis[2], T. Angel[2], J. Bush[6], M. G. Rees[7], M. M. Ronan[7], J. A. Roth[1], H. Lightfoot[1], F. Zappacosta[2], J. Pettinger[6], S. Barthorpe[1], C. Eberl[4], B. Jones[8], J. Schneck[2], D. Murphy[2], J. Taygerly[8], M. DeMartino[2], M. Coelho[1], J. Houseley[3], B. Schwartz[2], M. J. Garnett[1];
[1]Wellcome Sanger Institute, Hinxton, United Kingdom, [2]GSK, Upper Providence, PA, [3]Babraham Institute, Cambridge, United Kingdom, [4]GSK, Heidelberg, Germany, [5]GSK, Cambridge, MA, [6]GSK, Stevenage, United Kingdom, [7]Broad Institute of MIT and Harvard, Cambridge, MA, [8]IDEAYA, San Francisco, CA

Microsatellite-unstable (MSI) cancers depend on the WRN helicase to resolve replication stress from expanded (TA)-dinucleotide repeats. WRN is a promising synthetic lethal target for MSI tumours and WRN inhibitors are being developed. Here, we used CRISPR-Cas9 base editing to map WRN residues critical for MSI synthetic lethality, validating the helicase domain as the primary target and guiding inhibitor discovery. Fragment-based screening led to the discovery of potent and highly selective WRN helicase covalent inhibitors from the same chemical series. These compounds strikingly and selectively suppressed MSI model growth in vitro and in vivo by mimicking genetic WRN loss, inducing DNA double-strand breaks at expanded TA repeats and DNA damage response. We characterized WRN inhibition across cancer cell lines and patient-derived tumour organoids, enabling biomarker assessment of TA-repeat expansions and MMR status to refine patient selection, with compound efficacy correlating with TA-repeat expansions in MSI cells. Efficacy was also confirmed in patient-derived organoids and PDX models refractory to immunotherapy. The discovery of potent and selective covalent WRN inhibitors provides proof-of-concept for targeting MSI cancers and provides tools to unlock the molecular dissection of the WRN biology and MSI synthetic lethality.

IMMUNOLOGY: New Insights for Therapies Modulating Antitumor T-Cell Responses
Minisymposium

#6592 Deciphering the effects of age on T cell immunity and immunotherapy.

S. Han[1], P. Georgiev[1], J. Schneider[1], A. Huang[1], Z. Nugmanova[1], T. H. Nguyen[1], C. Yao[1], S. Johnson[1], S. Joshi[1], I. Dhiman[1], J. M. Drijvers[1], M. Fung[1], J. H. Rowe[1], B. C. Miller[2], G. J. Freeman[3], A. E. Ringel[4], M. C. Haigis[1], A. H. Sharpe[1];
[1]Harvard Medical School, Boston, MA, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA, [4]Massachusetts Institute of Technology, Boston, MA

Aging induces profound alterations in host biology and correlates with unfavorable clinical outcomes in age-related diseases such as cancer. While the pivotal role of the immune system in regulating tumor progression is well-acknowledged, the precise mechanisms through which aging influences anti-tumor T cell immunity and responsiveness to immune checkpoint blockade (ICB) remain elusive. In this study, we employed syngeneic murine tumor models (B16, MC38, and E0771) in young (2-4 months) and aged (20-24 months) cohorts to elucidate the early impacts of aging on tumor development and T cell responses. Our findings demonstrate that aged mice exhibit accelerated tumor growth across various models. In-depth analysis of tumor-infiltrating lymphocytes (TILs) uncovered distinct alterations in the $CD8^{\pm}$ T cell population, characterized by decreased activation status and diminished tumor specificity in aged mice. Correspondingly, aged mice exhibited resistance to anti-PD-1 immunotherapy. To unravel the underlying environmental factors contributing to compromised anti-tumor T cell responses and ICB resistance, we characterized the immune and metabolic landscapes of the aged tumor-draining lymph nodes and tumors. Furthermore, we established a genetically engineered mouse model of lung adenocarcinoma in both young and aged mice, unveiling novel functions and mechanisms associated with age-related T cells actively impeding effective tumor control. In the context of increasing average life expectancy, comprehending the intricate interplay between age-related T cell dysfunction and cancer assumes paramount importance. Such insights hold the key to the development of innovative therapeutic strategies tailored for the growing population of older patients.

#6593 Rejuvenation of tumor-infiltrating lymphocytes (TIL): A novel strategy to revitalize TIL antitumor function for cell therapy.

R. Vizcardo, Y. Huang, J. Fioravanti, T. Maeda, N. Tamaoki, Y. Yamazaki, B. Kutlu, K. Bahl, B. Wang, Z. Zhong, S. Potluri, N. P. Restifo, G. Lee;
Lyell Immunopharma, South San Francisco, CA

TIL therapy is a promising approach for the treatment of metastatic solid tumors, but its efficacy is limited by T-cell exhaustion and terminal differentiation. In addition, recent studies have underscored the adverse effects of aging on T cells. Reprogramming T cells into induced pluripotent stem cells (iPSC) and differentiating them back to the T-cell lineage has proven to be complex and time-consuming. In particular for TIL applications, de novo T cell production via iPSCs requires each TCR in the final product to be derived from an independently established iPSC clone. To overcome these barriers, we developed a novel technology called Rejuvenation, which bypasses the need for reprogramming of T cells into iPSCs. Rejuvenated TIL products retain their TCR diversity while offering several significant advantages, including reduced T-cell epigenetic age, improved expansion capacity, stem cell-like phenotype, and enhanced secretion of cytokines upon activation by target antigens. In this study, we used TIL derived from patients with melanoma and NSCLC. Rejuvenated TIL were generated by the transient expression of transcription factors in a process called 'Partial Reprogramming' and returned back to a T-cell lineage phenotype by a process called 'Redirection'. Partially reprogrammed TIL showed an altered morphology resembling adherent stromal cells and down-regulated conventional T-cell markers including CD3, CD4, and CD8. Redirected T cells reacquired a conventional CD4/CD8 phenotype including morphology, surface markers and function, and demonstrated decreased epigenetic age (>7 years younger, N=3). We also observed a higher proliferative capacity, improved metabolic state, and increased expression of biomarkers associated with T-cell stemness, including CCR7 and CD62L, when compared with untreated TIL. Rejuvenated TIL demonstrated improved cytokine secretion, including IFNγ, TNFα and IL-2 in functional assays. Immune repertoire analysis revealed a significant polyclonal population of putative tumor-reactive TCRs. In vivo functionality was also evaluated using a xenograft model of engineered A375 melanoma cell line that agonizes T-cells in hIL2-NOG mice. Adoptive transfer of rejuvenated TIL resulted in significantly improved suppression of tumor growth and prolonged survival compared with TIL expanded by conventional methods. These results were also confirmed in other surrogate models, including rejuvenated PBMC, TCR and CAR T cells, demonstrating the broad applicability of Rejuvenation technology. Our results indicate TIL Rejuvenation enhances the functionality and antitumor characteristics of T cells, while preserving a broad TCR repertoire. This technology holds substantial promise and may pave the way for the development of the first rejuvenated autologous polyclonal TIL therapy for treatment of advanced solid tumors.

#6594 4-1BB: A double-edged sword for T cells.

L. Yang, T. P. Sheets, Y. Feng, K.-S. Hsu, G. Yu, S. Seaman, P. Bajgain, D. So, J. Lee, R. Chari, B. St. Croix;
National Institutes of Health (NIH), Frederick, MD

Background: The costimulatory receptor 4-1BB (CD137) is expressed on the surface of activated T cells, playing a pivotal role in enhancing T cell responses and emerging as a promising target for cancer immunotherapy. Its primary ligand, 4-1BBL (CD137L), is found on antigen-presenting cells and various immune cells. The interaction between 4-1BBL and 4-1BB provides crucial costimulatory signals to both CD4+ and CD8+ T cells, amplifying their activation and effector functions. However, recent studies have shed light on a distinct role of 4-1BB in T cells. Prior work has revealed that 4-1BB can distinguish intratumoral regulatory T cells (Tregs) from peripheral Tregs and other CD4 lineage T cells in cancer patients, and the overexpression of 4-1BB on Tregs has been associated with unfavorable survival outcomes. Additionally, targeting 4-1BB with IgG2a isotype antibodies has shown significant anti-tumor efficacy in preclinical models by depleting Tregs. Furthermore, agonist monoclonal antibodies targeting 4-1BB have not only shown promise in inducing tumor regressions but also demonstrated improved outcomes in mouse models of autoimmune diseases induced by autoreactive CD4+ T cells. These findings indicate the existence of specific ligands or factors that modulate 4-1BB function on T cells that can vary depending on the disease state.
Methods: To identify potential ligand(s) involved in the modulation of 4-1BB function, we developed an innovative CRISPR/Cas9-based transcriptional activation (CRISPRa) screening system that integrates CRISPR/Cas9-guide mediated gene activation, high avidity bead-based selection, serial enrichment, and flow cytometry-based monitoring. This screening platform provides enhanced sensitivity for identifying extracellular interactions between receptor-ligand partners that have not been fully characterized before, even with low-affinity.
Results: Through our unbiased CRISPRa screen, we discovered that Myelin-Associated Glycoprotein (MAG), also known as siglec-4, a member of the siglec (sialic acid-binding immunoglobulin-like lectins) family, interacts with 4-1BB *in trans*. Our study demonstrated that MAG binds to activated T cells via 4-1BB and inhibits their activation and proliferation, suggesting a potential role of the MAG-4-1BB interaction in modulating T cell function. Notably, our data revealed that trans-binding to MAG-positive cells inhibits c-Jun signaling in activated T cells. Furthermore, the presence of MAG on target cells can hinder Chimeric Antigen Receptor (CAR) T-cell activity.
Conclusion: Utilizing a highly efficient cell-based CRISPRa system, we discovered a novel interactor of 4-1BB capable of modulating T cell activation through its interaction with 4-1BB. This interaction suggests an immunosuppressive role of 4-1BB, explaining the paradoxical roles of 4-1BB in T cells. These findings provide crucial insights for the development of precise therapeutics targeting 4-1BB.

#6595 HDAC8 targeting impairs Foxp3+Treg cell function and promotes anti-tumor immunity.

F. Kong[1], L. Wang[2], A. Beeler[3], **W. W. Hancock**[4];

[1]Zhongnan Hospital of Wuhan University, Hubei, China, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Boston University, Boston, MA, [4]Children's Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA

HDAC8 is an evolutionarily distinct, X-linked, zinc-dependent class I histone/protein deacetylase implicated in developmental disorders, parasitic infections, myopathy, and cancers such as neuroblastoma, gastric cancer, hepatocellular carcinoma, oral squamous cell carcinoma, and childhood acute lymphoblastic leukemia. Here, we highlight a hitherto unknown role of HDAC8 in immune cells by presenting data on conditional targeting of HDAC8 in T cells and the effects of selective HDAC8 inhibitors (HDAC8i) on T cell-dependent immune responses. First, as a genetic approach, we produced C57BL/6 mice with floxed exon 3 of the HDAC8 gene suitable for targeted deletion of HDAC8 and, after crossing with syngeneic CD4cre mice, demonstrated conditional deletion of HDAC8 and enhanced acetylation of SMC3, a classic HDAC8 substrate, in their T-cells. Next, in a pharmacologic approach, we tested isoform-selective inhibitors of HDAC8 (OJ-1, PCI-34051) and assessed effects on Foxp3+ T-regulatory (Treg) cell suppressive function. Finally, we performed flow cytometry, RNAseq, CHIP-seq and mass spectrometry to investigate the underlying mechanisms by which HDAC8 knockout affected Treg function. Our data demonstrate that knocking down or inhibiting HDAC8: (i) impaired murine Treg suppressive function in vitro and in vivo, including inhibiting the ability of Tregs to promote mouse cardiac allograft survival ($p<0.01$); (ii) decreased Treg function in homeostatic proliferation assays ($p<0.01$), e.g., involving adoptive transfer of WT or HDAC8-/- Tregs plus WT conventional T cells into immunodeficient hosts; (iii) decreased intratumoral Tregs, increased CD4 and CD8 T cells, increased production of effectors such as IFN-g and granzyme-B, and limited growth of syngeneic mouse non-small cell lung cancer cell lines ($p<0.01$) (whereas no effect of Hdac8i on tumor growth was seen in immunodeficient hosts, indicating the key action was via immune cell targeting). Mechanistically, HDAC8 co-precipitated with Foxp3 and NFAT5 and promoted the deacetylation of Foxp3 and NFAT5, and knockout of HDAC8 enhanced the acetylation level of NFAT5 and promoted cytokine expression. Hence, our combined genetic and pharmacologic studies establish the importance of HDAC8 in Foxp3+ Treg cells and show that therapy with selective HDAC8 inhibitors can be a novel therapeutic approach in immuno-oncology.

#6596 BRMS1 downregulation alters the tumor microenvironment and induces immunotherapy resistance in lung adenocarcinoma.

M. B. Lankadasari[1], Y. Liu[1], B. Mastrogiacomo[1], Y. Zhu[1], E. G. Dunne[1], C. N. Fick[1], C. Harsha[1], J. S. Reis-Filho[2], D. R. Jones[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]AstraZeneca, Gaithersburg, MD

Background: Lung cancer is the leading cause of cancer-related deaths globally. During cancer progression, tumor cells interact with tumor-infiltrating immune cells (TIICs) creating an immunosuppressive microenvironment. Therefore, it is essential to delineate the communication dynamics between cancer cells and TIICs to identify novel pathways for therapeutic targeting. *BRMS1* is a metastasis suppressor gene that is frequently downregulated in lung adenocarcinoma (LUAD). We, and others, have shown that loss of BRMS1 results in increased distant metastatic disease. Given the strong correlation between immune suppression, metastasis, and immunotherapy resistance we sought to elucidate if BRMS1 contributes to these processes. Specifically, we hypothesized that loss of BRMS1 in LUAD cells influences the immune cell composition, shaping an immunosuppressive microenvironment and decreasing tumor response to immunotherapy.

Methods: To experimentally address our hypothesis, we generated *Kras*^{G12D} *P53*$^{fl/fl}$ *Brms1*$^{-/-}$ mice inducing spontaneous tumors with Ad-Cre intratracheal inoculation. RNA-seq scRNA-seq on *Brms1*$^{+/+}$ and *Brms1*$^{-/-}$ tumors, coupled with cell type annotations using mMCP-counter and DCATS were used to identify diverse TIIC subsets. To validate our observation, we performed immunofluorescence and flow cytometry to assess the number of TIICs. To explore the impact of *Brms1* loss on the efficacy of anti-PD1 immunotherapy, a syngeneic CMT167 mouse model with *BRMS1*^{KD} cells implanted in the flank was treated with an anti-PD1 antibody.

Results: Differential gene expression analysis of RNA-seq data revealed a reduction in CCL9, CCL24, CLEC1B, PYCARD and other proinflammatory molecules in *Brms1*$^{-/-}$ tumors. Gene ontology and GSEA highlighted a diminished immune response signature in *Brms1*$^{-/-}$ tumors. In contrast, hallmark gene sets like IFNγ response, IL6 signaling, and inflammation are highly enriched in *Brms1*$^{+/+}$ tumors. mMCP-counter suggested a decrease in CD8+ T cells in *Brms1*$^{-/-}$ tumors. Likewise, scRNA-seq data confirmed a significant decrease in cytotoxic CD8+ T cells in the *Brms1*$^{-/-}$ mice. Immunofluorescence and flow cytometric analysis showed a reduction in cytotoxic CD8+ T cells with low proliferative potential (Ki67+) in the *Brms1*$^{-/-}$ mice. Postmortem on our syngeneic mouse tumors after a 30-day anti-PD1 antibody treatment revealed a significantly larger mean tumor size in the *BRMS1*^{KD} group compared to the WT group (942.4 mm^3 vs. 184 mm^3; $p<0.023$). Immunophenotyping on these tumors using flow cytometry also demonstrated reduced cytotoxic CD8+ T cells in the KD group post-treatment.

Conclusion: Our data suggest that reduced BRMS1 expression in LUAD alters CD8+ T cell composition and primary tumor response to immunotherapy. Implications of our findings underscore the potential of BRMS1 as a therapeutic target in the context of immunotherapy-resistant LUAD.

#6597 CD40 agonism induces CD4 T cell mediated rejection of major histocompatibility complex class I deficient pancreatic tumors.

M. E. Haerr[1], S. I. Kim[2], C. Arora[2], K. P. Gribbin[1], R. H. Vonderheide[2], K. T. Byrne[1];

[1]Oregon Health & Science University, Portland, OR, [2]University of Pennsylvania, Philadelphia, PA

Cytotoxic CD8 T cells are the canonical mediators of tumor clearance by the adaptive immune system. As such, current immunotherapies, including immune checkpoint blockade (ICB), target exhausted CD8 T cells with the hope of reinvigorating the CD8 T cells to drive tumor clearance. However, many tumors, including pancreatic ductal adenocarcinoma (PDAC), can evade CD8 T cell detection via downregulation of the antigen presentation molecule, major histocompatibility complex I (MHC I) as either primary or acquired resistance to immunotherapy. We have previously reported that agonistic CD40 antibody (αCD40), which promotes the maturation and licensing of dendritic cells to drive T cell priming, synergizes with ICB to induce tumor rejection dependent on both CD4 and CD8 T cells in mouse models of PDAC. Given the potential mechanisms of resistance to CD8 T cell immunity, we hypothesized that interrogation of the mechanisms underlying αCD40-induced CD4 T cell rejection of PDAC will reveal targets for improving CD4 T cell-directed immunotherapies. Here, we show that implantation of an MHC I deficient PDAC cell line derived from the genetically engineered *Kras*^{G12D}*Trp53*^{R172H}*Pdx1-Cre* (KPC) mouse model results in normal tumor establishment and progression. Upon treatment with combined αCD40 and ICB, tumor growth was significantly decreased in a CD4, but not CD8, T cell-dependent manner. Using genetic knockout mice, we determined that tumor regression was perforin-independent and identified host expression of IFNγ as requisite for therapeutic efficacy. To identify the cellular subset mediating CD4 T cell-rejection of the tumor, we assessed the major histocompatibility complex II (MHC II) positive cells in the tumor microenvironment (TME), which possess the ability to directly synapse with CD4 T cells to drive anti-tumorigenic T cell programs. We determined that macrophage and myeloid cells were dispensable for treatment efficacy, however non-immune cells in the TME can also interact with CD4 T cells through expression of MHC II. Interrogation of stromal cells reveals an increase in the proportion of MHC II+ subsets after combined αCD40/ICB treatment, with a concomitant decrease in the proportion of MHC II+ tumor cells. These data support the notion that CD4 T cell control of tumors may be mediated by both direct and indirect mechanisms of tumor killing. Findings from this work will elucidate non-canonical mechanisms of CD4 T cell-mediated rejection of tumors and may be leveraged to discover novel translational targets for immunotherapy.

#6598 Inhibition of cGAS as a strategy to restore anti-tumor immunity response to STING agonist in chromosomally unstable tumors.

Christy Hong[1], Lindsay Caprio[2], Mercedes Duran[1], Meri Rogava[2], Hsiang-His Ling[2], Sreeharsha Gurrapu[2], Leon Ebel[2], Melody Di Bona[1], Benjamin Izar[2], Samuel F. Bakhoum[1]

The activation of STING (stimulator of interferon genes) has been widely shown to induce signaling pathways, triggering type I interferon and ultimately generating anti-tumor immunity. Whereas initial preclinical studies on STING agonists exhibited boost in anti-tumor response, clinical trials combining STING agonist and immune checkpoint blockade agent PD-1 reported that only small subset of patients benefited from the treatment. This study highlights a potential key mechanism underlying the lack of benefit from STING agonist observed in most clinical trial patients. We reveal a phenomenon known as chromosomal instability (CIN), characterized by persistent chromosome segregation errors over multiple rounds of mitosis, drives chronic activation of cGAS (cyclic GMP–AMP synthase) through continuously supplying its substrate in the form of micronuclei. Chronic activation of cGAS stimulates degradation of its downstream target STING in a feedback-loop manner. This consequently attenuates type I interferon signaling upon STING activation, blunting its anti-tumor response. Remarkably, we show suppression of CIN, achieved through introduction of mitotic centromere-associated kinesin (MCAK), or inhibition of cGAS activity, either by pharmacological agent or total genetic ablation of cGAS using CRISPR-Cas9, restores type I interferon production and anti-tumor immunity upon the administration of STING agonist, MSA-2 in four of the five advanced tumor models. Furthermore, we show this restoration of type I interferon signaling and anti-tumor immunity is cancer cell STING-dependent as genetic deletion of STING in the tumor cells nullifies this effect. In summary, we provide a mechanistic insight underlying the limited anti-tumor response observed in STING agonist trials and propose potential strategies, through finetuning of CIN level or inhibition of cGAS activity, to illicit stronger anti-tumor immunity in combination with STING agonist treatment.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Chromatin and Transcriptional Regulatory Mechanisms in Cancer Minisymposium

#6599 3D genomic analysis reveals novel enhancer hijacking mechanisms caused by complex structural alterations that drive oncogene overexpression.

Katelyn L. Mortenson[1], Courtney Dawes[2], Emily R. Wilson[1], Nathan E. Patchen[2], Hailey Johnson[1], Jason Gertz[1], Swneke D. Bailey[3], Yan Liu[2], Katherine E. Varley[1], Xiaoyang Zhang[1]

[1]Oncological Sciences, University of Utah, Salt Lake City, UT,[2]Biochemistry, University of Utah, Salt Lake City, UT,[3]Surgery and Human Genetics, McGill University, Montreal, QC, Canada

Enhancer hijacking, caused by structural alterations on chromosomes as well as extrachromosomal DNA (ecDNA), is a common cancer driver event. The complexity and ubiquity of structural alterations in cancer genomes make it difficult to identify enhancer hijacking with genome sequencing alone. Here we describe a 3D genomics-based analysis called HAPI (Highly Active Promoter Interactions) to characterize enhancer hijacking caused by various types of structural alterations. Applying HAPI analysis to HiChIP data from 34 cancer cell lines, we identified novel enhancers hijacked through chromosomal rearrangements to activate both known and potentially novel oncogenes such as *MYC, CCND1*, *ETV1*, *CRKL*, and *ID4*, which we validated using CRISPRi assays and RNA-seq analysis. Furthermore, we found that ecDNAs often contain multiple oncogenes from different chromosomes, which cause nested enhancer hijacking among them. For instance, we found that *MYC* ecDNAs relocate additional oncogenes from other chromosomes such as *CDX2, ERBB2,* or *CD44* near the *MYC* locus, co-opting *MYC*'s enhancers for their overexpression, which we validated using dual-color DNA FISH and CRISPRi assays. This multiple oncogenes-involved enhancer hijacking mechanism may suggest novel therapeutic strategies such as targeting either the co-opting oncogenes or the hijacked enhancers for ecDNAs. Our study provides a robust strategy to detect enhancer hijacking events using our publicly available HAPI analysis tool and reveals novel mechanisms underlying oncogene activation caused by chromosomal and extrachromosomal structural alterations.

#6600 Investigating molecular regulators of a dual identity state in lung adenocarcinoma.

G. Fort[1], S. Camolotto[2], R. Tariq[1], P. Fang[1], K. L. Gillis[1], C. Stubben[1], E. L. Snyder[1];

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]Recursion Pharmaceuticals, Salt Lake City, UT

Lung adenocarcinoma (LUAD) is the largest subtype of lung cancer and is the most common cause of cancer related death. LUAD progression is driven by both genetic alterations and epigenetic changes that confer increased lineage plasticity and heterogeneity, but underlying mechanisms dictating cell identity in LUAD remain incompletely understood. The lineage defining transcription factors, NKX2-1 and FoxA1/2, coordinately maintain a pulmonary identity in LUAD. Recent work suggests that NKX2-1-positive (NKX2-1+) LUAD evolves from an alveolar-like state and adopts various disparate cell fates that drive progression, including “dual-identity” states, characterized by acquisition of gastrointestinal (GI) and pulmonary-like states in the same cell. Using sophisticated genetically engineered mouse models and 3D organoid cultures, we demonstrated that the gastrointestinal transcription factor HNF4α, which robustly marks the dual-identity state, is critical for growth in NKX2-1+ LUAD. We performed bulk RNA-seq and single cell RNA-seq in vitro and in vivo, and we found that loss of HNF4α alters the differentiation state of NKX2-1+ LUAD, causing cells to shed elements of their gastric identity in favor of alternate differentiation states. Using paired chromatin immunoprecipitation sequencing and RNA-seq in dual-identity organoids, we found that HNF4α can access and activate many of its canonical gastrointestinal target genes despite being aberrantly expressed in the lung, where it is typically epigenetically silenced early in development. Surprisingly, HNF4α also colocalizes with NKX2-1 and FoxA1/2 and binds at novel sites, suggesting that HNF4α acquires expanded activity in this state beyond its canonical roles. Together, our work unveils key insights into the mechanisms by which lineage defining transcription factors regulate cellular identity and growth in LUAD.

#6601 Menin drives oncogenesis in Ewing sarcoma cells by activating transcription of key metastatic factors.

K. A. Braun[1], A. Miyaki[1], N. M. Garcia[1], D. Tu[1], F. Wu[2], J. F. Sarthy[1], E. R. Lawlor[1];

[1]Seattle Children's Research Institute, Seattle, WA, [2]Fred Hutchinson Cancer Research Center, Seattle, WA

Ewing sarcoma (EwS) is a bone and soft tissue tumor that is driven by the fusion of FET and ETS genes, most commonly resulting in creation of the EWS::FLI1 chimeric oncoprotein. The scaffolding protein Menin regulates transcription through interactions with transcription factors and chromatin modifying enzymes and has both oncogenic and tumor suppressive roles, depending on the cellular context. The half-life of Menin is prolonged in EwS cells leading to high levels of the protein that is dependent on EWS::FLI1 expression. To investigate tumorigenic functions of Menin in EwS, we used CRISPR/Cas9 to generate clonal A673 and TC32 Menin knockout cells. Consistent with our earlier studies using shRNA-mediated knockdown, loss of Menin had little effect on proliferation in 2-D culture but resulted in reduced anchorage-independent growth in soft agar assays. When MEN1-KO cells were injected into NSG mice, either subcutaneously or by tail vein, tumor formation was delayed. Injection of MEN1-KO cells into the renal subcapsule of NSG mice resulted in locally invasive tumors but their capacity to metastasize to the liver was reduced compared to control cells. To elucidate how loss of Menin led to diminished tumorigenic and metastatic potential, we performed RNA-seq of control and MEN1-KO cells. This analysis revealed significant and reproducible down-regulation of MYC target genes and up-regulation of the epithelial to mesenchymal transition pathway and extracellular matrix protein-encoding genes in MEN1-KO cells. To determine if genes altered in MEN1-KO cells were dependent on the role of Menin in Menin/MLL methyltransferase complexes, we analyzed transcriptomes of EwS cells that had been exposed to the Menin/MLL interaction inhibitor, VTP-50469. Only a subset of genes altered by the MEN1-KO were also altered by the Menin/MLL inhibitor, suggesting that Menin regulates gene expression in EwS cells by both MLL-dependent and MLL-independent mechanisms. To test this, we performed CUT&RUN to define Menin binding sites and discovered that Menin binds not only at H3K4me3-marked gene promoters but also at intragenic enhancers marked by H3K27Ac. Importantly, comparison of RNA-seq data revealed substantial overlap between Menin-regulated and established EWS::FLI1 target genes and we identified that a subset of EWS::FLI1-bound intragenic enhancers are also bound by Menin. Significantly, these co-bound, co-regulated loci encode for pro-metastatic genes, including *IL1RAP*, *STEAP1*, and *CAV1*. Finally, we found that Menin and EWS::FLI1 co-immunoprecipitate in EwS nuclear extracts suggesting that they may exist in complex with one another at sites of shared gene regulation. Taken together, these data indicate that Menin promotes EwS metastasis and that this is achieved by its function as a scaffolding protein that augments the transcriptional activity of EWS::FLI1 at intragenic enhancers of pro-metastasis genes.

#6602 Targeting the SWI/SNF complex in POU2F-POU2AF transcription factor-driven malignancies.

L. Xiao[1], T. He[1], O. Klingbeil[2], Y. Eleanor[1], X. Wu[2], Y. Qiao[1], A. Parolia[1], S. Eyunni[1], R. Mannan[1], S. Mahapatra[1], N. Kim[1], H. Zheng[1], F. Su[1], X. Cao[1], S. Samajdar[3], M. Ramachandra[3], C. R. Vakoc[2], A. M. Chinnaiyan[1];

[1]University of Michigan, Ann Arbor, MI, [2]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, [3]Aurigene Oncology, Bengaluru, India

Background: Small cell lung cancer (SCLC) is a rapidly progressing subtype of lung cancer with a high growth rate and early metastasis propensity, often resulting in a more advanced disease stage at diagnosis. A recent transcriptome analysis of human SCLC tumors revealed that SCLC could be characterized by the expression pattern of certain transcription factors (TFs), including ASCL1 (achaete-scute family bHLH transcription factor 1) and POU2F3 (POU domain class 2 transcription factor 3), exemplifying SCLC as a TF-driven malignancy. ASCL1-driven SCLC (SCLC-A) manifests a neuroendocrine phenotype, while POU2F3-driven SCLC (SCLC-P) is characterized as a tuft-cell-like variant. Recent studies revealed that POU domain class 2 transcription factors uniquely rely on coactivators to achieve their lineage-defining functions in the tuft cell and B cell lineages. In tuft-cell-like SCLC cells, the coactivators of POU2F3 (POU2AF2 and POU2AF3) endow POU2F3 with a critical transactivation domain by forming a master regulator complex, which supports enhancer-mediated cancer-promoting gene activation in SCLC-P cells. This indicates a potential therapeutic vulnerability of tuft-cell-like SCLC whereby strategies aimed at blocking POU2F3-POU2AF2/3 function may lead to clinical benefit.

Methods: We conducted a domain-targeted CRISPR screen to identify druggable targets for SCLC-P, followed by pharmacological validation in preclinical SCLC models. Multi-omics techniques, including ATAC-seq, ChIP-seq, RNA-seq, and RIME, were employed to elucidate the SWI/SNF complex's regulatory influence on the POU2F-POU2AF axis.

Results: Here we identified that the POU2F3 molecular subtype of SCLC (SCLC-P) exhibits an exquisite dependence on the activity of the SWI/SNF epigenetic complex. SCLC-P cell lines were sensitive to low nanomolar levels of a SWI/SNF ATPase degrader when compared to other molecular subtypes of SCLC. Co-factors of POU2F were found to interact with components of the SWI/SNF complex. The POU2F3 transcription factor complex is evicted from chromatin upon SWI/SNF ATPase degradation. A novel, orally bioavailable SWI/SNF ATPase PROTAC degrader demonstrated preferential efficacy in SCLC-P relative to the SCLC-A subtype. The SWI/SNF ATPase PROTAC degrader did not alter normal tuft cell numbers in lung or colon, nor did it exhibit toxicity in mice. B cell malignancies which displayed a dependency on the POU2F co-factor, POU2AF1, were also remarkably sensitive to SWI/SNF ATPase degradation. In a POU2AF1-dependent, disseminated murine model of multiple myeloma, AU-24118 had an enhanced survival benefit as compared to pomalidomide, an approved treatment for multiple myeloma.

Conclusions: Taken together, our studies suggest that POU2F-POU2AF driven malignancies have an intrinsic dependence on the SWI/SNF complex representing a striking therapeutic vulnerability.

#6603 A TBX2-driven signaling switch from androgen receptor to glucocorticoid receptor confers enzalutamide resistance in prostate cancer.

S. Dutta, G. K. Patel, H. Khedmatgozar, D. Latour, J. Welsh, M. Tripathi, S. Nandana;
Texas Tech University Health Sciences Center, Lubbock, TX

Background: Recent studies suggest that glucocorticoid receptor (GR) activation can cause enzalutamide resistance in advanced prostate cancer (PCa) via functional bypass of androgen receptor (AR) signaling. However, the specific molecular mechanism(s) driving this process remain unknown. In an effort to identify drivers of prostate cancer progression, in a previous study, we determined that TBX2, a developmental T-box transcription factor (TF) master regulator, is over-expressed in CRPC and drives bone metastatic progression. A recent report confirmed that TBX2 and GR are two of the four TFs that drive enzalutamide resistance in advanced PCa. Our current study demonstrates that TBX2 with known repressor and activator functions, is the molecular switch that represses AR levels while activating GR expression thereby resulting in the replacement of AR signaling to control tumor growth.
Methods: We genetically modulated TBX2 using multiple approaches: a) dominant negative, DN, to block TBX2 (TBX2DN), and b) overexpression, OE, to increase TBX2 expression (TBX2OE), c) shRNA mediated knockdown (shTBX2). RNA-seq was performed, and qRT-PCR, Western blot and immunohistochemical (IHC) analyses were used for validation. Further, we used chromatin immunoprecipitation (ChIP) and site directed mutagenesis (SDM) to confirm TBX2 binding on the AR promoter. We also used co-immunoprecipitation (Co-IP) to determine protein partners of TBX2.
Results: Mechanistically, our studies revealed that TBX2 bound to the promoters of both AR and GATA2, an AR coregulator, thereby resulting in a bimodal repression of AR expression. Conversely, TBX2 upregulated GR via direct GR promoter binding and TBX2-GR protein-protein interaction. Together, concurrent repression of the AR and activation of GR resulted in enzalutamide resistance. Importantly, we found that SP2509, an allosteric inhibitor of the demethylase-independent function of LSD1, a TBX2-interacting protein in the COREST complex, can disrupt both TBX2-LSD1 and TBX2-GR protein-protein interactions thereby uncovering a unique mode of SP2509 action in CRPC. Together, our study supports a molecular model of CRPC wherein: 1) TBX2, LSD1 and GR proteins interface with each other, and 2) pharmacological inhibition of LSD1 blocks the TBX2-driven AR-to-GR switch through disruption of TBX2-GR interaction.
Conclusions: In summary, our study identifies TBX2 as the molecular switch that drives the AR to GR signaling bypass thereby conferring enzalutamide resistance. Further, our study provides key insights into a potential therapeutic modality for targeting the AR to GR signaling switch via disruption of the TBX2-LSD1 and TBX2-GR protein-protein interactions

#6604 Spatial transcriptomics delineates tumor heterogeneity in NACT triple-negative breast cancer.

I. Wall[1], J. Quist[1], S. Pinder[1], K. Cancer Biobank[1], S. Irshad[1], C. Gillet[1], V. Seewaldt[2], K. Mukund[3], D. Frankhouser[2], S. Subramaniam[3], M. Parsons[1], A. Grigoriadis[1];

[1]King's College London, London, United Kingdom, [2]City of Hope, Duarte, CA, [3]University of California, San Diego, CA

BACKGROUND: Triple-Negative Breast Cancer (TNBC) is a highly aggressive subtype of breast cancer and only ~40% of TNBC patients achieve a pathological complete response (pCR) following neoadjuvant chemotherapy (NACT). Since molecular heterogeneity of TNBC may contribute to variable responses to NACT, we aimed to deconvolute TNBC's histological and spatial transcriptomics (ST) patterns.

METHODS: In total, 90 pre-treatment biopsies were collected from NACT-treated TNBC patients from archival samples and the ongoing FORCE (NCT03238144) clinical trial at Guy's Hospital, London, UK. Of these, 38 achieved pCR (Responder), 46 had residual disease (Non-Responder) whilst 6 are currently undergoing NACT; 46 post-treatment surgical resections were collected from Non-Responders.Each sample was H&E stained, imaged, and annotated by a pathologist. A 6-digit classifier was designed to capture the histology of each region of interest (ROI), characterizing the tumour region, epithelial type and immune cell localization, population, distribution, and abundance.H&Es were used to guide ST profiling of serial sections which was performed on the GeoMx Digital Spatial Profiler. Tissues were stained with fluorescent antibodies against PanCK and CD45 to visualize the tissue, select ROIs and illuminate spatially resolved tumor and immune-enriched compartments, defined as PanCK+/CD45- and PanCK-/CD45+, respectively.Data analysis was performed in R 4.3.1 using the limma, dplyr, EdgeR, GeoMx Tools, GeoMx Workflows, RUV4, Spatial Experiment, SpatialDecon and GSVA packages, facilitating quality control, batch correction, differential and topographical gene expression, immune cell deconvolution and gene set enrichment analysis (GSEA), respectively.

RESULTS: To date, we have performed ST profiling of 120 TNBC samples from 82 patients (46 Non-Responders; 36 Responders), totaling 3917 tumor or immune-cell enriched regions. Preliminary analyses revealed KEGG pathways involved in tissue adhesion are upregulated in tumor compartments of Non-Responders compared to Responders, whilst those involved in genomic integrity are suppressed. Unsupervised clustering of PanCK+CD45- regions in Non-Responders identified tumor clusters present in both pre- and post-NACT samples, suggesting potential chemo-resistant properties. Moreover, immune cell deconvolution of the PanCK-/CD45+ regions revealed spatially distinct patters of immune cell composition mapped to histological annotations identified by our ROI classifier.

CONCLUSION: (S)Large scale ST of TNBC before and after NACT reveals novel patterns associated with response to treatment. We have designed a novel ROI classifier to spatially resolved transcriptomes of histological features, as such provide an in-depth characterization of the histo-genomics of TNBC.

#6605 Understanding the role of sumoylated Etv1 in mammary oncogenesis.

Z. Li[1], K. E. Koch[2], D. T. Thompson[1], D. M. Van der Heide[1], J. Chang[1], C. M. Franke[1], M. O. Suraju[1], A. C. Beck[3], A. W. Lorenzen[1], J. R. White[1], M. V. Kulak[1], D. K. Meyerholz[1], C. Kenny[1], R. J. Weigel[1];

[1]University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA, [2]Yale New Haven Hospital, New Haven, CT, [3]University of Wisconsin, Madison, WI

The Small Ubiquitin-like Modifier (SUMO) pathway is a major post-translational regulatory mechanism involved in a variety of cellular functions including the DNA damage response, transcriptional regulation, and carcinogenesis. Recent discoveries by our group demonstrated that inhibiting the SUMO pathway can repress the growth of breast cancer xenografts and Neu-driven mammary oncogenesis in a genetically engineered mouse model with conditional knockout (CKO) of the SUMOylation E2 conjugating enzyme, *Ube2i*. However, despite the consistency of the findings, there remains considerable debate concerning the mechanisms through which SUMO inhibition represses tumorigenesis. Our downstream analysis suggested ETS Translocation Variant 1, encoded by *ETV1* gene, acts as a SUMO-sensitive transcription factor that drives mammary oncogenesis and cancer growth. To examine oncogenic properties of SUMO-conjugated ETV1 in breast cancer, we cloned HA-tagged WT Etv1, SUMO-resistant Etv1^{5xKR}, or SUMO mimetic SUMO-1-Etv1^{5xKR} into a lentiviral vector with a GFP cassette. Proliferation, colony formation in soft agar, and *in vivo* xenograft assays were evaluated in the Ube2iF/F cell line derived from a tumor in a MMTV-*c-neu/Ube2i*$^{fl/fl}$ animal. We did ChIP-seq in Ube2iF/F cells using SUMO-1 and Etv1 antibodies to examine the effects of SUMO conjugation on Etv1 genomic occupancy. RNA-seq using siEtv1 or AdCre was also performed to compare changes in gene expression with SUMO-conjugated Etv1 genomic occupancy. Inhibition of SUMOylation via AdCre caused a significant reduction in proliferation and colony formation *in vitro* and completely block the formation of flank xenografts *in vivo*. Interestingly, expressing a SUMO-resistant ETV1^{5xKR} rescued *in vitro* growth effects, whereas a SUMO mimetic SUMO-1-ETV1^{5xKR} had no effect on restoring proliferation. On the contrary, *in vivo* xenograft assays demonstrated that the Etv1^{5xKR}-SUMO1 efficiently induced tumor formation despite the loss of Ube2i while the sumo-resistant Etv1^{5xKR} was unable to rescue tumorigenesis. Bulk RNA-seq and ChIP seq performed demonstrated different patterns of gene regulation between sumoylated and unsumoylated Etv1. Gene set enrichment analysis (GSEA) showed genes associated with cancer stemness were significantly enriched in cells expressing Etv1^{5xKR}-SUMO1. Collectively, these observations support Etv1 acting as a SUMO-sensitive transcription factor that drives a stem cell phenotype necessary for mammary oncogenesis and progression.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Metabolism and Cancer Minisymposium

#6606 HK2 is conditionally essential for growth in human cancer cells.

Kimberly S. Huggler, Kyle M. Flickinger, Jason R. Cantor

Biochemistry, University of Wisconsin - Madison, Madison, WI

The genetic drivers of cell growth can depend on an interplay of intrinsic factors and environmental context. However, there is often little consideration into how nutrient availability affects the genetic dependencies of proliferating human cells. Moreover, efforts such as DepMap have catalogued cell fitness genes using *in vitro* CRISPR screens across hundreds of cancer cell lines cultured in traditional media, which poorly replicate nutrient conditions found in the body. We recently tested the hypothesis that the nutrient environment can affect gene essentiality in human cells. By performing CRISPR screens with blood cancer cell lines, we identified sets of genes differentially required for cells cultured in traditional (e.g., RPMI) versus Human Plasma-Like Medium (HPLM). Among the strongest HPLM-essential hits was *HK2*, which encodes for the glycolytic enzyme hexokinase 2. Notably, most cancer cell lines co-express two hexokinases (HK1; HK2) that can each catalyze the phosphorylation of glucose to glucose-6-phosphate. Interestingly, while these two HKs share high degrees of structural and biochemical similarity, only *HK2* deletion had differentially stronger effects in HPLM. Further, both HK1 and HK2 contain an N-terminal region that permits association with the outer mitochondrial membrane (OMM). To investigate the conditional phenotype for loss of *HK2*, we generated *HK2*-knockout K562 leukemia cells, which displayed *HK1* expression levels comparable to those measured in control cells. We also confirmed that our *HK2*-knockout cells showed a stronger relative growth defect in HPLM versus RPMI. Importantly, the expression of HK2 cDNA normalized this defect. By contrast, the expression of kinase-dead HK2 did not provide any rescue effects, suggesting that HK activity is required for the conditionally essential role of HK2. We also engineered a cytosol-restricted HK2 by truncating its N-terminal OMM binding region. When we expressed this cDNA in our *HK2*-knockout cells, we observed complete rescue of the relative growth defect, suggesting that subcellular HK2 activity contributes to conditional *HK2* essentiality. We are now purifying mitochondria to ask how the subcellular distributions of HK1 and HK2 vary with nutrient conditions. In addition, we are also comparing the tracing patterns of 13C glucose in *HK2*-knockout and control cells to ask how *HK2* deletion affects glucose utilization. Finally, given that we normalized glucose levels across our screening conditions, we are applying a systematic approach to determine the gene-nutrient interaction that underlies the conditional phenotype for *HK2* deletion. Collectively, our data suggest that HK2 serves a non-redundant and conditionally essential role. We expect to generate novel insights into how *HK2* supports human cell growth and why this role can further depend on nutrient availability.

#6607 Serine depletion promotes antitumor immunity throughmitochondrial DNA-mediated cGAS/STING1 activation.

S. Saha[1], M. Ghosh[1], L. Jinyu[1], A. Wen[1], L. Galluzzi[2], L. Martinez[1], **D. C. Montrose**[1];
[1]Stony Brook University Hospital, Stony Brook, NY, [2]Weill Cornell Medicine, New York, NY

Serine is critical for supporting cancer metabolism, and as such, depriving malignant cells of this non-essential amino acid exerts anticancer effects, in large part, through disrupting their metabolic pathways. However, the impact of these metabolic defects on tumor-targeting immunity remains poorly understood. Here, we show that restricting endogenous and exogenous serine in colorectal cancer (CRC) cells results in mitochondrial dysfunction coupled to cytosolic mitochondrial DNA accumulation and cGAS/STING1-dependent type I interferon secretion. Serine-deprived tumors have suppressed growth, accompanied by type I interferon signaling and tumor infiltration by immune effector cells. Blocking cGAS/STING1 signaling in tumor cells limits the immunostimulatory and anticancer effects of serine deprivation. Moreover, serine-depleted tumors exhibit increased sensitivity to a programmed cell death 1 blocker. Lastly, transcriptomic data from human CRCs suggest that malignant lesions with reduced serine abundance have higher immune infiltration. Taken together, our findings reveal a novel role for serine as a gatekeeper of mitochondrial integrity and hence a suppressor of anticancerimmunity.

#6608 Therapeutic enzyme depletion of L-serine for the treatment of serine auxotrophic tumors.

Vipin Rawat[1], Huiping Zhao[1], Ladan Mashouri[2], Prarthana Prasanth[1], Kelly Conger[1], Sarita Bhetawal[2], Alessandra Araujo[2], Everett Stone[2], Jonathan Coloff[1]

[1]Physiology and Biophysics, University of Illinois College of Med. at Chicago, Chicago, IL, [2]University of Texas at Austin, Austin, TX

The non-essential amino acid L-serine (serine) plays an important role in cancer cell growth due to its diverse biosynthetic functions. In many cancer cells, serine can be taken up from the circulation or can be synthesized through the serine synthesis pathway (SSP) . We have recently discovered that luminal breast tumors are auxotrophic for serine due to lineage-specific silencing of the SSP gene *PSAT1*, rendering luminal breast cancer cells sensitive to serine deprivation both *in vitro* and *in vivo*. At present the only way to reduce serine availability for tumors *in vivo* is through dietary serine starvation, which in mice reduces circulating serine levels by ~50% and has been shown to inhibit the growth of numerous mouse models of cancer. Importantly, dietary serine is achieved in mice using a synthetic protein-free diet that may be difficult for humans to sustain. Nevertheless, dietary serine starvation is currently being explored in a clinical trial for pancreatic cancer. To circumvent some of the challenges associated with dietary serine starvation, we have developed a therapeutic serine degrading enzyme that we are exploring as a potential treatment for serine auxotrophic tumors. Our enzyme, eSDH, is based on the human serine dehydratase enzyme that facilitates the pyridoxal phosphate-dependent irreversible deamination of serine to pyruvate and ammonia. Relative to wild-type serine dehydratase, eSDH has significantly improved stability in serum as well increased activity towards serine. Injection of eSDH into mice is well-tolerated and leads to long-term, near-complete (>95%) reduction in circulating serine levels without the need for dietary changes. Importantly, eSDH treatment inhibits the growth of serine auxotrophic cancer cells *in vitro* and *in vivo*. We are currently assessing the efficacy of eSDH treatment in advanced models of luminal/ER+ breast cancer and when utilized in combination with endocrine therapy and other standard-of-care treatments for luminal/ER+ cancer patients. In addition to the degradation of serine, eSDH also depletes circulating L-threonine (threonine), which could contribute to the *in vivo* activity of eSDH. However, we have recently developed new eSDH variants that are highly selective for serine over threonine and show enhanced specificity for serine auxotrophic cancer cells. In conclusion, we have developed a prototypical therapeutic serine degrading enzyme that may provide an opportunity to clinically achieve more complete serine starvation in patients without the need for restrictive dietary changes.

#6609 NRF2/ACSS2 axis regulates alcohol-induced metabolic reprogramming in esophageal squamous epithelial cells.

Z. Xiong[1], B. Subramaniyan[2], C. Paiboonrungruang[1], Y. Li[2], W. He[3], H. Yuan[4], G. Zhang[3], X. Chen[1];
[1]Coriell Institute for Medical Research, Camden, NJ, [2]Cooper University Health Care, Camden, NJ, [3]Duke University Medical Center, Durham, NC, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC

Esophageal diseases such as gastroesophageal reflux disease (GERD) and esophageal cancer have a strong association with alcohol drinking. However, the molecular mechanisms of alcohol-induced esophageal pathology remain unclear. In our previous study, we identified acyl-CoA synthetase short-chain family member 2 (ACSS2) as a transcriptional target of nuclear factor erythroid 2-related factor 2 (NRF2) in the esophageal epithelial cells *in vitro* and *in vivo*. Ethanol exposure enhanced *de novo* lipogenesis in $NRF2^{high}$ cells and generated a more energetic and invasive phenotype. In this study, we aimed to investigate the role of the NRF2/ACSS2 axis in regulating alcohol-induced metabolic reprogramming in esophageal squamous epithelial cells. We first demonstrated that ethanol exposure activated NRF2 signaling and upregulated the expression of NRF2 and ACSS2 in human esophageal squamous epithelial cells. ^{13}C-ethanol/^{13}C-acetate metabolic flux assay showed a dramatic NRF2-dependent increase of labeling of the TCA cycle intermediates and *de novo* lipogenesis in $NRF2^{high}$ cells in comparison with $NRF2^{null}$ or $NRF2^{low}$ cells. Long-term ethanol exposure caused metabolic reprogramming, in particular induced *de novo* lipogenesis, in the mouse esophagus according to metabolomics profiling of 833 metabolites. PET/CT and autoradiography showed increased ^{11}C-acetate uptake in the $NRF2^{high}$ esophagus of a conditional tissue-specific mouse (*Sox2CreER;LSL-Nrf2*^{E79Q}) due to upregulation of transporters and metabolic enzymes. In summary, Our data demonstrated the functional role of the NRF2-ACSS2 axis in alcohol-induced metabolic reprogramming in esophageal squamous epithelial cells both *in vitro* and *in vivo*, suggesting NRF2/ACSS2 inhibition as a novel mechanism-based prevention for alcohol-associated esophageal pathology.

#6610 Metabolic patterns of pancreatic cancer cachexia: Cross-tissue lipid networks predict cachexia progression.

D. Mathur[1], B. Majem[1], C. Beaulieu[2], L. Dailey[2], S. Jeanfavre[2], J. Xavier[3], C. Clish[2], N. Kalaany[1];

[1]Boston Children's Hospital, Boston, MA, [2]The Broad Institute, Boston, MA, [3]Memorial Sloan Kettering Cancer Center, New York, NY

Pancreatic ductal adenocarcinoma (PDAC) is among the most lethal of all cancer types. A key — yet poorly understood — facet in the disease state is cachexia, a multi-organ pathological state characterized by physical wasting and tissue catabolism. It occurs in 80% of PDAC patients, and to date there are no preventative or early detection methods. Cachexia leads to limited tolerance to anti-cancer therapy and contributes to disease lethality. Here, we present the first-of-its-kind systemic metabolomic analysis across cachectic stages to better understand disease progression.

We used the well-established mutant $KRAS^{G12D}$(LSL/+) mutant p53 inducible mouse model of PDAC. Model physiology faithfully recaptures human cachexia: we observe progressive overall weight loss as well as loss of skeletal muscle and adipose tissue. As with human disease, weight loss occurs prior to loss of appetite in the animals, suggesting physiological changes independent of nutrition. Importantly, our model captures the period prior to weight loss (pre-CAC), as well as early-CAC (<10% weight loss) and late-CAC (>10% weight loss).

We profiled the metabolomes of the pancreas, interstitial fluid, plasma, liver, 3 different adipose tissues, and 3 skeletal muscles, from male and female mice, control and tumor-bearing, across all 3 stages of cachexia. Each tissue has a unique metabolic trajectory across cachexia stages; pathway and correlation analyses showed a particular emphasis on lipid alterations in peripheral tissues. Strikingly, we find systemic metabolic changes prior to tissue wasting, including rewiring in the liver before the presence of metastases. This indicates systemic alterations as early as pre-CAC.

We therefore used computational modeling to identify metabolites that may be participating in cross-tissue networks. A key finding, confirmed by ^{13}C tracing, was the circulation of lactate and glucose and their uptake by the liver and pancreas. Network maps also suggest lipid rewiring in distal tissues, changes in abundances of these same lipid species in plasma, and their consequent alterations in the tumor and liver.

A fundamental question remains: can we predict cachexia development before the manifestation of symptoms? We used feature selection algorithms based on statistical learning, training the models only on a subset of data. Specific sphingolipids and triglycerides were the key lipid species that distinguished control and pre-CAC. We find that the model — trained only on pre-CAC — is able to determine early-CAC with an 85% accuracy and late-CAC with a 90% accuracy. Thus, a limited set of metabolites that are altered in pre-CAC could have predictive value for future cachexia development.

Overall, our work provides a resource for the field and advances our understanding of systemic metabolism in PDAC cachexia. We hope this will lay the foundation for cachexia prevention and treatment.

#6611 Unbiased functional genetic screens reveal essential RNA modifications in human cancer and drug resistance.

C. Pauli[1], M. Kienhofer[1], C. Muller-Tidow[1], **M. Frye**[2];
[1]Heidelberg University Hospital, Heidelberg, Germany, [2]DKFZ German Cancer Research Center, Heidelberg, Germany

RNA modification pathways are mis-regulated in multiple types of human cancer. To comprehensively identify cancer-relevant RNA modifications and their regulators, we screened all 150 annotated human RNA modifying proteins across 18 different normal and cancer cell lines using a CRISPR-based genetic knockout system. Fifty RNA modifying proteins were essential for survival of at least one cell type. A third of these essential genes were amplified in 38 different human primary cancer types and potentially drive cancer growth. Unexpectedly, the number of essential genes per cell line varied considerably, and this variation was not due to tissue of origin. Instead, we found that cancer cell-specific mitochondrial metabolic plasticity was responsible for the unique requirement of certain RNA modifications. For example, leukemia cells with high intrinsic drug tolerance required mitochondrial flexibility to survive treatment with the anti-leukemic drugs cytarabine and venetoclax. Synthetic lethality screens revealed that drug-resistance is abolished by deleting the mitochondrial methyltransferase TRMT5, which is responsible for the formation of N1-methylguanosine (m1G) in the tRNA anticodon loop. In summary, our study identifies cancer-relevant RNA modifying enzymes, and reveals a novel promising drug target for therapy-resistant acute myeloid leukemia.

#6612 Therapy-resistant endocycling cancer cells alter mitochondrial structure and metabolism to survive therapeutic stress.

M. Li, S. R. Amend, K. J. Pienta;
Johns Hopkins University School of Medicine, Baltimore, MD

Therapy resistance is responsible for 90% of cancer-related deaths. We identified a novel mechanism of therapy resistance in which cancer cells enter an endocycling cell state, undergoing repeated S and G phases without dividing. As a result, resistant endocycling cells are 40 times larger than mitotic cancer cell controls. Interestingly, we observed that these non-proliferative endocycling cells can eventually give rise to proliferative progeny weeks after chemotherapy is removed, modeling cancer recurrence. We hypothesize that this endocycling cancer cell state is a critical driver of therapy resistance and cancer lethality.

We evaluated oxidative stress in endocycling cells that survived the days and weeks following chemotherapy treatment using DCF-DA staining. We found increased levels of reactive oxygen species (ROS) in endocycling prostate cancer cells compared to untreated mitotic cells when normalized to cell size. Given that mitochondria are major producers and regulators of ROS, we hypothesize that cells surviving in this resistant state alter mitochondrial structure and function in response to increased oxidative stress. We performed immunofluorescence and confocal microscopy on mitochondria in untreated cells and cells following chemotherapy treatment to observe their morphology. Surviving endocycling cells had increased mitochondrial fragmentation when compared to the untreated group, a result that was further supported by reduced expression of phospho-DRP1 Ser637 via western blot.

To assess changes in glucose metabolism, we then utilized isotope tracing-based metabolomics with [U-^{13}C]glucose on untreated and surviving endocycling cells following chemotherapy. Endocycling cells had decreased labeling of ^{13}C in TCA cycle metabolites, suggesting a decrease in mitochondrial function when compared to untreated cells. Ongoing work involves further studying metabolic reprogramming as cells enter this resistant state with parallel labeling experiments using [1,2-^{13}C]glucose and [U-^{13}C]glutamine to perform mathematical modeling-based ^{13}C-metabolic flux analysis. In addition, we engineered a cell line to track mitochondria in real-time to quantify mitochondrial dynamics underlying the morphology observed in untreated and surviving cells.

Our goal is to characterize how this therapy-resistant cell state alters its mitochondrial structure and function to survive therapeutic stress. Identifying vulnerabilities of this phenotype will enable new approaches for eliminating drug resistance in cancer.

#6613 Understanding the causes of head and neck cancer using mutational signature analysis.

L. Torrens[1], S. Moody[2], C. De Carvalho[1], S. Senkin[1], S. Cheema[2], M. Kazachkova[3], V. Gaborieau[1], B. Abedi-Ardekani[1], R. Cortez Cardoso Penha[1], J. Atkins[1], P. Chopard[1], J. Wang[2], S. Fitzgerald[2], C. Latimer[2], C. Carreira[1], T. Cattiaux[1], M. Diaz-Gay[3], L. Humphreys[2], L. B. Alexandrov[3], M. R. Stratton[2], S. Perdomo[1], P. Brennan[1], HEADSpAcE consortium;

[1]International Agency for Research on Cancer (IARC/WHO), Lyon, France, [2]Wellcome Sanger Institute, Cambridge, United Kingdom, [3]University of California San Diego, La Jolla, CA

The geographical incidence of head and neck cancer (HNC) is heterogeneous, reflecting the prevalence of its main risk factors. Tobacco, either alone or combined with alcohol, is the predominant cause of HNC, while the potential of alcohol as an independent carcinogen is uncertain. Moreover, the etiology remains unknown for ~28% of cases. In this study, we used mutational signature analysis to 1) track the exposure to known and putative risk factors for HNC across multiple geographical regions and subsites, 2) evaluate whether an alcohol signature is present in HNC, and 3) assess its interaction with tobacco or other risk factors.

Whole-genome sequencing data was generated from 265 HNC cases from retrospective HNC studies in Europe and South America with available lifestyle and environmental exposure data. Mutational and copy number (CN) signatures were extracted with SigProfilerExtractor and decomposed into COSMIC reference signatures. Associations between the mutational signatures and epidemiological or molecular data were assessed using multivariate regression analysis.

The analysis revealed known and previously unreported signatures of endogenous and exogenous exposures. APOBEC-driven signatures (SBS2, SBS13) were identified in 97% (258/265) of cases. We observed differences in tobacco-related mutagenesis across anatomical subsites. While known tobacco signatures (SBS4, SBS92, DBS2, and ID3) were found in larynx cases, the novel signature SBS1536I was enriched in oral cavity cases from ever-smokers, which suggests a site-specific mutagenic effect from different tobacco carcinogens. Furthermore, we demonstrate that signatures associated with alcohol consumption (SBS16, DBS4, and ID11) were enriched in cases exposed to both tobacco and alcohol, indicating an interaction between the two. We also extracted signatures indicative of ultraviolet (UV) light exposure (SBS7a-c, DBS1, and ID13) in cases from the inner lip, tongue, and floor of the mouth, implying a role of UV exposure in oral cavity carcinogenesis. Finally, hierarchical clustering analysis revealed three distinct CN profiles in HNC, each linked to different risk factors and driver mutations: 1) A CN-rich polyploid cluster associated with tobacco smoking and CN signatures of chromosomal instability, including one novel signature (CN48G) enriched in samples from South America, 2) a CN-rich diploid cluster comprising cases related to both tobacco and human papillomavirus infection; and 3) a CN-neutral cluster enriched in samples with unknown etiology.

This study uncovers APOBEC signaling, tobacco, alcohol, and potentially UV light exposure, as potent mutagenic agents in HNC. Our findings suggest that the mutational impact of tobacco in HNC is tissue-specific, and that tobacco may enhance the oncogenic effects of alcohol. Finally, the CN profile in HNC is strongly influenced by exposure to risk factors and driver mutations in the tumors.

#6614 Integrating single-cell RNA-seq and large genome-wide association study data to identify colorectal cancer cell-of-origin populations.

C. Li[1], Z. Chen[1], Q. Li[1], J. Choi[2], Q. Sheng[1], W. Wen[1], X. Shu[3], X.-o. Shu[1], J. Long[1], Q. Cai[1], B. Singh[1], M. J. Shrubsole[1], K. S. Lau[4], W. Zheng[1], **X. Guo**[1]; [1]Vanderbilt University Medical Center, Brentwood, TN, [2]Korea University College of Medicine, Ansan, Korea, Republic of, [3]Memorial Sloan Kettering Cancer Center, New York, NY, [4]Vanderbilt University School of Medicine, Brentwood, TN

Background: Single-cell RNA sequencing (scRNA-seq) enables the precise identification of distinct cell populations and the measurement of gene expression within each population. Recently, integrating scRNA-seq and genome-wide association study (GWAS) data has shown promise in identifying cell-of-origin populations in human diseases. Colorectal cancer (CRC) progresses through a phenotypic continuum from normal colon to adenoma, and ultimately CRC. However, the specific disease cell-of-origin populations underlying each stage of CRC development at a single-cell resolution have not been well studied. Additionally, while transcriptome-wide association studies (TWAS) have identified more than 200 putative risk genes in CRC, the precise disease cell-of-origin populations associated with these genes remain elusive.

Materials and methods: We analyzed scRNA-seq datasets from 31 normal colon, 8 colon serrated polyps, and 15 conventional adenoma tissues of individuals participated the Colorectal Molecular Atlas Project (COLON MAP). We next conducted an integrative analysis of the aforementioned scRNA-seq data, with extensive epigenomics data and summary statistics from a large CRC GWAS conducted among European ancestry populations (78,473 CRC cases and 107,143 controls) using single-cell disease relevance score (scDRS), to investigate cell-of-origin populations underlying the CRC development. We conducted correlation analysis between gene expression and individual cell risk scores derived from scDRS. Additionally, we performed differential expression analysis comparing disease cell-of-origin populations with other cell populations at each stage.

Results: We identified multiple cell-of-origin populations associated with CRC, including absorptive cells (ABS) ($P < 1 \times 10\text{-}4$) and goblet cells (GOB) ($P < 7 \times 10\text{-}3$) in the normal colon, ABS ($P < 2 \times 10\text{-}3$), enteroendocrine cells (EE) ($P < 0.04$), and serrated-specific cells (SSC) ($P < 1 \times 10\text{-}4$) in serrated polyps, and ABS ($P < 9 \times 10\text{-}3$) and SSC ($P < 6 \times 10\text{-}4$) in adenomas. Among the previously reported 205 risk genes from TWAS, a majority show high correlations of their expressions with the risk scores of the single cells (median value $R^2 = 0.07, 0.14, 0.137$ at normal colon, serrated polyps, adenoma, respectively). Moreover, 57 of these TWAS-reported genes (27.8% of 205 genes) exhibited evidence of differential expression in disease cell-of-origin populations compared to other cell populations at a nominal p-value < 0.05 in at least one stage (Binomial test, $P < 0.01$ for all).

Conclusion: This study reveals the cell-of-origin populations that influence the development of CRC, and provides evidence of the role of risk genes in these populations. These findings are crucial for identifying causal genes and understanding the cellular mechanisms that drive the biology and etiology of CRC.

#6615 Reduced penetrance *BRCA1* and *BRCA2* pathogenic variants in clinical germline genetic testing.

T. Pal[1], E. Mundt[2], M. Richardson[3], E. Chao[3], T. Pesaran[3], T. P. Slavin[2], F. Couch[4], **A. N. Monteiro[5]**;
[1]Vanderbilt-Ingram Cancer Center, University Medical Center, Vanderbilt University, Nashville, TN, [2]Myriad Genetics, Salt Lake City, UT, [3]Ambry Genetics, Aliso Viejo, CA, [4]Mayo Clinic, Rochester, MN, [5]Moffitt Cancer Center, Tampa, FL

Despite the current binary clinical classification of variants (pathogenic versus benign), it is widely recognized that risk is a continuum. Prior studies have suggested the existence of reduced penetrance pathogenic variants (RPPVs), which pose challenges for identification, reporting, patient counseling and care. Through the current study, we sought to establish RPPVs as a new category of variants, with efforts focused specifically on *BRCA1* and *BRCA2* (*BRCA*).
We compiled, compared, and assessed data for *BRCA* RPPVs from two large clinical diagnostic laboratories to establish an initial set of reduced penetrance pathogenic variants. Specifically, candidate *BRCA* RPPVs provided by clinical diagnostic laboratories were compiled to identify those with the highest prior likelihood of being a RPPV, based on concordant interpretations. Evidence of reduced penetrance included: 1) the identification of biallelic Fanconi Anemia-affected carriers; 2) splicing, missense, and nonsense-mediated RNA decay (NMD)-escaping variants; 3) laboratory-validated cancer history weighting models; 4) published variant-specific risk estimation data; 5) extrapolation of a reduced-risk interpretation onto close match variants that are expected to have the same effect; and 6) functional data.
Sixteen candidate *BRCA* RPPV present in both lists from both laboratories were systematically assessed. For *BRCA1,* variants included c.5096G>A p.(Arg1699Gln) and variants impacting the canonical c.671 splice acceptor site. For *BRCA2,* variants included three frameshift (c.658_658delGT, c.9672dupA, c.9699_9702delTATG), two spliceogenic (c.8488-1G>A and c.8488-1G>T), and three missense (c.7878G>C, T, p.(Trp2626Cys); and c.9302T>G p.(Leu3101Arg)) variants.
Our study is the first to clearly evaluate and establish *BRCA* RPPVs as a new class of variants, based on consistency in results across 16 variants using different interpretation strategies between laboratories. These variants impart a moderately increased risk of breast cancer, often considered to be between 2-4 fold, which should be considered when determining risk-informed cancer prevention strategies. Furthermore, our study establishes a framework to harmonize interpretation and standardize reporting of *BRCA* RPPV, by providing evidence to support this new classification for 16 variants. Further work to define clinically meaningful risk thresholds and categories for reporting *BRCA* RPPV are needed to personalize cancer risks in conjunction with other risk factors.

#6616 Polygenic risk score associated with risk of upgrading and tumor features in a prospective cohort of prostate cancer patients on active surveillance.

L. B. Goss[1], M. Liu[2], Y. Zheng[2], B. Guo[1], D. V. Conti[3], C. A. Haiman[3], W. J. Catalona[4], J. S. Witte[5], D. W. Lin[1], L. F. Newcomb[2], B. F. Darst[2]; [1]University of Washington, Seattle, WA, [2]Fred Hutchinson Cancer Center, Seattle, WA, [3]University of Southern California, Los Angeles, CA, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]Stanford University, Stanford, CA

BACKGROUND: Active surveillance (AS) is now the preferred treatment strategy for the >50% of prostate cancer (PCa) patients diagnosed with low-risk disease, where five-year survival rates are >99%. However, AS requires frequent and costly healthcare visits. In a case-only study of AS patients, we investigated whether polygenic risk scores (PRS) could identify patients who may benefit from intensive vs passive surveillance to reduce these burdens.

METHODS: This study included 1,220 PCa patients on AS in the Canary Prostate Active Surveillance Study (PASS). A previously developed multi-ancestry PRS of 451 PCa risk variants (PRS_{451}) was constructed in PASS, along with a PRS of 400 variants, excluding 51 PSA-associated variants (PRS_{400}). Outcomes included upgrading and extreme upgrading at follow up and prostate volume, PSA, percent of biopsy cores with cancer, and Gleason grade at diagnosis. We investigated PRS associations with risk of upgrading with Cox proportional hazards regression adjusting for age at diagnosis and 10 principal components (PCs) of ancestry. Associations with risk of extreme upgrading were performed similarly but with a competing risk analysis, where the competing event was treatment. Discriminative ability was evaluated with Harrell's C-index. To better account for population structure, we also fit mixed models with fixed effects for PRS, age at diagnosis, and 10 PCs, with a random effect for a genetic relationship matrix.

RESULTS: Of the 1,220 AS patients, 38.5% (n=470) upgraded during the median 4.2 years of follow up and 85% (n=1041) self-reported as non-Hispanic White. In time-to-event analyses, each SD unit increase in PRS_{451} was associated with a 23% increased risk of upgrading ($P=4.2x10^{-5}$), while PRS_{400} was associated with a 27% increased risk ($P=1.6x10^{-6}$). PRS were similarly associated with 21% (95% CI=1.02-1.44, P=0.03) and 27% (95% CI=1.06-1.52, P=0.01) increased risk of extreme upgrading, respectively. Compared to a model with age at diagnosis, PCs, and clinical risk factors (C-index=0.617, 95% CI=0.590-0.644), including PRS_{400} slightly improved the ability to detect risk of upgrading (C-index=0.632, 95% CI=0.604-0.659). Mixed model results were highly consistent. Each SD unit increase in PRS_{400} was associated with 1.38 higher percentage points of biopsy cores with cancer (95% CI=0.76-2.00, $P=1.1x10^{-5}$), 1.48 cc smaller prostate volume (95% CI=-2.82, -0.14, P=0.03), and 0.18 ng/mL higher PSA (95% CI=0.01-0.35, P=0.05) at diagnosis. Except for PSA, associations were similar or weaker for PRS_{451}.

CONCLUSION: In patients on AS, high PRS was associated with increased risk of upgrading, extreme upgrading, smaller prostate volume, and possibly tumor multifocality. As such, PRS could inform the intensity of surveillance for low-risk PCa patients, reducing the burden of AS for patients with low risk of disease progression.

#6617 Oral microbiome and subsequent risk for head and neck squamous cell cancer development.

S. Kwak[1], M. Usyk[1], F. Wu[1], N. D. Freedman[2], W.-Y. Huang[2], M. L. Mccullough[3], C. Y. Um[3], M. J. Shrubsole[4], Q. Cai[4], C. Wang[1], H. Li[1], J. Ahn[1], R. B. Hayes[1];

[1]NYU Grossman School of Medicine, New York, NY, [2]National Cancer Institute, Bethesda, MD, [3]American Cancer Society, Atlanta, GA, [4]Vanderbilt-Ingram Cancer Center, Nashville, TN

Background: The oral microbiota may be involved in head and neck squamous cell cancer (HNSCC) etiology, yet current evidence is largely limited to bacterial 16S amplicon sequencing or small retrospective case-control studies. We tested whether any oral bacteria and/or fungi influence the subsequent risk of HNSCC development.

Methods: We conducted a prospective case-control study nested within three epidemiological cohorts: the ACS-Cancer Prevention Study-II Nutrition Cohort (ACS-CPS-II), the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO), and the Southern Community Cohort Study (SCCS). Among 159,840 cohort participants, 236 individuals developed HNSCC during an average of 5.1 years of follow-up, and 485 controls who remained HNSCC-free were selected by 2:1 frequency matching, by cohort, age, sex, race/ethnicity, and time since mouthwash collection. All participants provided mouthwash samples and were cancer-free at baseline. We characterized the oral bacterial microbiome, using whole-genome shotgun sequencing, and the oral fungal microbiome, using ITS sequencing. We assessed relative abundance of microbiome-wide bacterial and fungal taxa for association with HNSCC by ANCOM-BC analysis. We also evaluated selected oral pathogen complexes for association with HNSCC by logistic regression. A microbial risk score (MRS) for HNSCC risk was calculated from all risk-associated microbes.

Results: Overall microbiome diversity at baseline was not related to the subsequent risk of HNSCC; however, we found that 13 oral bacterial species were differentially associated with development of this disease (P<0.05), including newly identified *Prevotella salivae*, *Streptococcus sanguinis*, *Leptotrichia sp*, and several species belonging to *Beta-* and *Gamma-proteobacteria*. Furthermore, *a priori* periodontal pathogen complexes were associated with a higher risk of HNSCC ("red/orange" complex, OR=1.06, 95% CI=1.00-1.12). We did not identify any fungal taxa associated with HNSCC risk. Together, an MRS constructed for risk-associated bacteria and bacterial periodontal complexes conferred a 50% increase in HNSCC risk, per standard deviation increase in the MRS (multivariate OR=1.50, 95% CI=1.21-1.85).

Conclusions: Our research yields compelling evidence that oral bacteria are a risk factor for the development of HNSCC. The identified bacteria and bacterial complexes hold promise for identifying high-risk individuals and may further lead to personalized prevention approaches for HNSCC.

#6618 Pleiotropic GATA3 locus is associated with multiple childhood cancers: harnessing the existing data from the St. Jude Lifetime Cohort and the Childhood Cancer Survivor Study for genetic etiology research.

C. Chen[1], X. Zhang[2], Q. Dong[2], H. L. Mulder[2], J. Easton[2], X. Ma[2], J. Zhang[2], J. Yang[2], K. E. Nichols[2], G. T. Armstong[2], K. K. Ness[2], M. M. Hudson[2], H. Wang[1], N. Chatterjee[3], C. Im[4], Z. Wang[2];

[1]Shanghai Jiao Tong Univ., School of Med., Shanghai, China, [2]St.Jude Children's Research Hospital, Memphis, TN, [3]Johns Hopkins University, Baltimore, MD, [4]University of Minnesota, Minneapolis, MN

Background: A genetic variant (rs3824662) at *GATA3* was previously associated with risk of Philadelphia chromosome-like acute lymphoblastic leukemia (Ph-like ALL) and relapse. Our recently published childhood Hodgkin lymphoma (HL) study identified a genome-wide significant association for another genetic variant (rs3781093) in high linkage disequilibrium (D'=1.0, R^2=0.91) with rs3824662. We hypothesize that *GATA3* is a pleiotropic locus associated with multiple childhood cancers.

Methods: The study was performed by combining 3 cohorts of childhood cancer survivors: the St Jude Lifetime Cohort Study (SJLIFE), the original and expansion cohorts of the Childhood Cancer Survivor Study (CCSS). The CCSS original cohort had SNP array genotyping and imputation, and the SJLIFE and CCSS expansion cohort underwent whole-genome sequencing. Associations between the variants mapped to *GATA3* and risks of different cancer types were analyzed (a specific cancer type was selected as the case group and all other unselected cancer types served as controls, then repeated for 13 cancer types). Summary statistics were subsequently analyzed with the ASSET (Association analysis for SubSETs) method which is powerful for pooling association signals across multiple cancer types when true effects may exist only in a subset and be in opposite directions across cancer types.

Results: Genotype data were available for 11623 childhood cancer survivors (5325 from the CCSS original cohort, 2428 from the CCSS expansion cohort, and 3870 from the SJLIFE, all European ancestry) were initially considered. After excluding individuals with dual enrollment or as outliers in the principal components analysis (n=667), a total of 10956 individuals remained for genetic association analysis. We identified a bi-directional association for a subset of childhood cancers with rs3781093 (2-sided P value of 6.22×10^{-19}): the same effect allele (C) was associated with increased risk of ALL or soft tissue sarcoma [STS] (OR=1.21; 95% CI=1.13-1.29; $P=7.4\times10^{-9}$), and was associated with decreased risk of HL (OR=0.66; 95% CI=0.59-074; $P=1.80\times10^{-12}$). The frequencies of the effect allele (C) for rs3781093 in ALL cases (17.9%), STS cases (17.8%) and HL cases (12.5%) relative to non-cancer community controls in the SJLIFE (15.6%) and non-cancer gnomAD samples (14.9%) corroborate this finding. In our combined dataset, there were 1380 Hodgkin lymphoma cases, 2961 ALL cases and 692 STS cases.

Conclusion: We discovered a novel variant in the *GATA3* locus exhibiting pleiotropy with both tumor-promoting and protective effects, suggesting a shared mechanistic pathway involving *GATA3* may underlie the carcinogenesis for ALL, STS and HL. Conducting systematic searches for childhood cancer pleiotropy represents an important research direction.

#6619 Dynamic prediction with repeated mammogram images improves 5-year breast cancer risk performance.

G. A. Colditz[1], R. M. Tamimi[2], B. Rosner[3], **S. Jiang**[1];

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Weill Cornell Medical School, New York, NY, [3]Harvard medical school, Boston, MA

Background: Increasing use of digital screening mammography opens potential to add individualized dynamic measures of breast image history to predict future breast cancer risk. Current prediction models use a single mammogram measure, usually breast density, at one point in time, to add to prediction models based on established risk factors. Our previous work has shown that change in each breast over time is related to risk of diagnosis with breast cancer.

Methods: We apply a dynamic prediction model that includes full field digital mammogram in each breast to predict future 5-year risk. Data from Joanne Knight Breast Health Cohort (JKBHC) serve as training population with 290 pathology-confirmed breast cancer cases and 658 controls sampled with a total number of 8,712 craniocaudal (CC) view mammograms for analysis. Nurses' Health Study 2 (NHS2) serves as the external validation with 188 cases and 462 controls sampled with a total number of 3,712 CC-views. The dynamic risk prediction model aims to estimate the probability of future breast cancer risk conditional on the past history of the longitudinal mammograms. We train the model on the JKBH cohort, retaining 20% for testing and 15% for validation. We report a time dependent AUC when evaluating model performance.

Results: The mean age of women was 56.6 years at entry to cohort; 81.3% were white. Adding trajectory of mammogram images in each breast to a model improved performance. The mean number of mammograms conditional on 5 years of observation in JKBHC was 3.36 (1.49) and in NHS2 2.36 (1.53). We obtained a 5-year dynamic AUC of 0.81 (0.05) in the JKBHC internal validation and 0.77 (0.06) in the NHS2 external validation. Model performance was comparable in pre- and postmenopausal women. Because breasts with high mammographic density hinder detection of tumors we stratify analyses by dense and non-dense at baseline. Among women with dense breasts at baseline (BIRADS C and D), we observe a dynamic 5-year risk AUC = 0.77. In the subgroup with less dense breasts (BIRADS A and B) we observe AUC = 0.74.

Conclusions: With this approach we can accommodate the irregularly observed time-varying images and project only partial information prior to doing the prediction. Adding trajectory of mammogram history in each breast improves 5-year breast cancer risk prediction beyond models used in clinic today.

TUMOR BIOLOGY: Nonclinical Models of Cancer

#6620 PDX models of TNBC established from pre- and post-therapy tumors identify vulnerabilities of resistant disease.

A. L. Rinkenbaugh[1], Y. Qi[1], R. T. Powell[2], S. Cai[1], J. Shao[1], F. Baameur Hancock[1], L. Guo[2], X. Zhang[1], S. Jeter-Jones[1], C. Fu[1], R. Gould[1], J. B. White[1], C. Stephan[2], G. V. Echeverria[1], P. J. Davies[2], S. Moulder[1], W. Symmans[1], J. T. Chang[3], H. Piwnica-Worms[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Texas A&M Health Science Center, Houston, TX, [3]University of Texas Health Science Center, Houston, TX

Chemotherapy, along with the PD1 inhibitor pembrolizumab, is the recommended standard of care for patients with primary triple negative breast cancer (TNBC). Nearly half of TNBC patients treated with standard neoadjuvant chemotherapy (NACT) have excellent responses. However, those patients with significant residual cancer burden (RCB) after NACT are at high risk of recurrence or metastatic relapse within two years. Due to the challenges posed by the inter- and intratumoral heterogeneity of TNBC, it is critical to develop appropriate models for predicting and overcoming therapy resistance. We established a collection of 92 orthotopic patient-derived xenograft (PDX) models of TNBC from 84 patients before, during, and after NACT while they were enrolled in the ARTEMIS trial (NCT02276443) at MD Anderson Cancer Center. Serial biopsies were obtained from patients prior to treatment (pre-NACT), from poorly responsive disease after four cycles of Adriamycin and cyclophosphamide (AC, mid-NACT), after a 3-month course of additional chemotherapy and/or different experimental therapies in cases of AC resistance (post-NACT), and from the metastatic lesions of two patients. The collection includes 12 longitudinal sets. Models were established from chemo-sensitive and -resistant tumors, but engraftment success was higher from those cancers that proved to be treatment resistant (RCB II/III). The PDX collection includes models encompassing a broad heterogeneity of chemotherapy responses, histologic features, and molecular TNBC subtypes. In addition, the majority of models develop spontaneous lung metastases. Whole exome sequencing demonstrated conservation of mutations between patient tumors and corresponding PDX models, with *TP53* being the most commonly mutated gene. A similar comparison of patient and PDX transcriptomes revealed conservation of signaling pathway signatures, with those related to immune and stromal interactions being the most variable, as anticipated when adapting human tumors to growth in mice. The subclonal architecture of the tumors exhibited little overall change throughout NACT, suggesting that selection for resistant subclones is not likely to be a significant contributor to resistance. Tumor cells from the longitudinal PDX collections were subjected to high throughput drug susceptibility profiling to identify targetable vulnerabilities associated with resistance to NACT. We found that post-NACT tumors exhibited enhanced sensitivity to drugs targeting protein homeostasis pathways. Preclinical studies with pevonedistat validated the neddylation pathway as an effective target in chemoresistant TNBC.

#6621 Development of a melanocyte lineage-specific knockout system in zebrafish.

S. Perlee[1], Y. Ma[1], J. Swanson[2], Z. Ming[3], J. Xia[1], T. Lionnet[2], M. McGrail[3], R. White[4];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]NYU Grossman School of Medicine, New York, NY, [3]Iowa State University, Ames, IA, [4]Ludwig Cancer Institute, Oxford, United Kingdom

Zebrafish have emerged as an ideal model organism for investigating melanocyte and melanoma biology. While CRISPR-Cas9 technology has significantly advanced our understanding of gene functions in zebrafish, two challenges remain: 1) how do we knock out embryonic lethal genes in adult melanocytes? and 2) how do we knock out tumor promoting genes (rather than tumor suppressors)? To address this, we have developed a new transgenic line in which Cas9 is knocked into the melanocyte-specific endogenous *mitfa* locus. To test this system in normal melanocytes, Tg(mitfa:Cas9) embryos were injected with a plasmid containing albino sgRNA. Cells with integration of this plasmid exhibited almost complete loss of pigmentation, demonstrating the high efficiency of our approach. This system can now be rapidly used to knock out embryonic essential genes specifically in melanocytes and evaluate the phenotype of adult fish. In melanoma, the commonly available zebrafish lines overexpress the oncogene BRAFV600E in melanocytes with germline knockout of tp53. This is not comparable to the situation in humans, where global p53 loss is rare. By utilizing our mitfa:Cas9 system, we have generated tumors with melanoma-specific loss of tp53 or ptena/b, thereby eliminating non-specific tumors that originate from knockout of tumor suppressors in other cell types. Using this system, we are now testing whether knockout of tumor promoting genes delays melanoma onset and progression, something that has previously been difficult to efficiently achieve in zebrafish. In addition to specificity, an additional advantage of our system is that we can create nearly complete knockout of genes in the melanocytes by the F1, rather than the F2 generation. This saves several months of time and reduces the number of uninformative animals without the relevant genotype. Collectively, our system provides a highly efficient mechanism to study essential genes in melanocytes and melanoma in the zebrafish system.

#6622 Identification of early oncogenic lesions following concomitant Vhl and Pbrm1 loss in the murine kidney.

Joanna Lima, Samvid Kurlekar, Norma Masson, Ayslan B. Barros, Maria Fernanda Soares, Christopher W. Pugh, Julie Adam, Peter J. Ratcliffe

University of Oxford, Oxford, United Kingdom

Characterizing the early events preceding tumorigenesis is a major challenge in understanding cancer. To address this, we are investigating the paradigm of clear cell renal cell carcinoma (ccRCC) that is driven by the biallelic loss of the von Hippel Lindau (*VHL*) tumor suppressor gene. Though VHL loss is required, additional mutations have been found in the evolution of the cancer, most commonly in Polybromo-1 (*PBRM1)*, a subunit of the PBAF SWI/SNF chromatin remodeling complex. Concomitant *Vhl* and *Pbrm1* deletion, but not *Vhl* deletion alone, in the renal tubular epithelium (RTE) has been reported to be sufficient to drive the formation of renal tumors in mice. However, the early *in vivo* consequences of *Vhl* loss, and the exact requirement for *Pbrm1* loss to tumorigenesis remain poorly studied. We have previously reported the development of a novel lineage-tracing model of *Vhl* deletion that directly couples loss of a conditional *Vhl* allele to the expression of a tdTomato reporter and allows accurate identification and retrieval of marked *Vhl*-null cells. In the work reported here, we have combined this system with conditional *Pbrm1* deletion using an RTE-restricted *Pax8-CreERT2* to precisely identify and assay *Vhl*/*Pbrm1*-null cells. We describe the histological abnormalities specifically comprising *Vhl*/*Pbrm1*-null cells observed at early (1-3 weeks), intermediate (10 months), and late (17 months) intervals post recombination. We found that *Vhl*/*Pbrm1*-null cells formed extensive 'tumorlets', disorganized, multilayered tubules, and cystic dilated tubules specifically in the renal cortex at 17 months post recombination. Immunohistochemistry confirmed that all epithelial cells in the lesions were *Vhl*/*Pbrm1* null and expressed HIF1 and HIF2. These lesions contained cycling cells as identified by dual tdTomato/Ki67 staining, foci of immune cells and were strikingly surrounded by cells expressing high levels of p-ERK. We then traced these lesions to earlier timepoints, and observed *Vhl*/*Pbrm1*-null lesions resembling 'tumorlet' precursors and disorganized tubules at 10 months post recombination specifically in the renal cortex. Interestingly, these precursors were encompassed by macrophages and could be discerned *in situ* by a ring of p-ERK-expressing cells surrounding these lesions. No similar lesions were detected at 3 weeks after recombination. Interestingly, the presence of cortical lesions was associated with a region-specific expansion of the total *Vhl*/*Pbrm1*-null population over time. Our data suggest that morphological abnormalities arise after a general proliferation of *Vhl*/*Pbrm1*-null cells in the renal cortex and from a subset of cells expressing specific markers. We are now comparing the differential gene expression patterns of *Vhl*-null cells and *Vhl*/*Pbrm1*-null normal and transformed cells at single cell resolution to expand on these observations.

#6623 Ala59 mutants of KRAS cooperate with Nf1 loss to enhance colon tumorigenesis.

C. W. Johnson[1], E. M. Terrell[2], J. Cook[1], B. Shui[1], E. O'Donoghue[1], S. Hull[1], M. Hee Yang[1], S. Sheth[1], R. Yaeger[3], S. Kopetz[4], D. K. Morrison[2], K. Haigis[1]; [1]Dana-Farber Cancer Institute, Boston, MA, [2]National Cancer Institute, Frederick, MD, [3]Memorial Sloan Kettering Cancer Center, New York, NY, [4]MD Anderson Cancer Center, Houston, TX

Understanding the role of KRAS allele heterogeneity in tumor development, and its influence on therapeutic efficacy, is critical for the improvement of cancer treatment. The Kirsten rat sarcoma (*KRAS*) gene is the most frequently mutated oncogene in colorectal cancer (CRC) and patients with CRC tumors positive for KRAS mutations have poorer outcomes and limited treatment options. Extensive work over the past four decades has shown that common oncogenic alleles of *KRAS* are associated with hyperactivation of the MAPK signaling pathway (i.e. RAF/MEK/ERK), and it is for this reason that patients with KRAS mutant tumors are excluded from targeted therapies against EGFR. Recently, we characterized two alleles of KRAS, $KRAS^{A59T}$ and $KRAS^{A59E}$, that paradoxically promote KRAS activation but are impaired in their ability to promote BRAF dimerization (*Johnson et al. Mol Cell. 2022. PMID: 35202574*). Consistent with these biochemical functions, $KRAS^{A59T}$ and $KRAS^{A59E}$ are enriched in CRC tumors that already have genetic alterations in genes that regulate MAPK signaling (e.g. EGFR, BRAF, NRAS, NF1). Further, unlike other described oncogenic alleles of KRAS, clinical data suggest that these $KRAS^{A59T}$ and $KRAS^{A59E}$ may not confer intrinsic resistance to anti-EGFR therapies at all. While $KRAS^{A59T}$ and $KRAS^{A59E}$ may not promote BRAF dimers, here we show that $KRAS^{A59T}$ and $KRAS^{A59E}$ does promote dimerization between ARAF and CRAF, and using an unpublished conditional mouse mode of K-Ras (i.e. LSL-K-Ras^{A59E}) we tested (1) whether Ala59 alleles are oncogenic or (2) require cooperation with additional MAPK pathway activating mutations, and (3) whether Ala59 alleles can promote intrinsic resistance to EGFR inhibition. Here, we show that endogenous K-Ras^{A59E} can disturb colon homeostasis and decrease mouse survival in an autochthonous colon tumor model, demonstrating that A59E alone is an oncogenic allele of KRAS in the colon. Breeding of LSL-K-Ras^{A59E} mice with mice harboring a conditional knockout of Nf1 (i.e. $Nf1^{fl/fl}$), a GTPase activating protein (GAP) that promotes activation of wildtype RAS, show that combined expression of K-Ras^{A59E} and wildtype RAS activation cooperatively perturb colon homeostasis and decrease mouse survival. Thus, while $KRAS^{A59E}$ may not require a second genetic alteration to activate the MAPK signaling pathway, it can cooperate with these alterations to increase the severity of disease. Finally, using mouse colon derived organoids, we show that endogenous K-Ras^{A59E} neither promotes EGF independence of organoid growth nor confers on these organoids a resistance to EGFR inhibition. Thus, our data support a unique role for RAF dimer function in in KRAS mutant tumors of the colon in both development and sensitivity to drugs, as well as argue for the inclusion of $KRAS^{A59T}$ and $KRAS^{A59E}$ bearing CRC tumors in anti-EGFR therapies.

#6624 MYC promotes lobuloalveologenesis and mammary tumorigenesis in male mice.

E. M. Pulver[1], E. van der Burg[1], A. Drenth[1], J. Yemelyanenko[1], N. Ravensbergen[1], R. de Bruijn[1], S. Klarenbeek[1], J.-Y. Song[1], M. Boeije[1], B. Siteur[1], N. Proost[1], C. Scheele[2], P. Bouwman[3], J. Jonkers[1];

[1]Netherlands Cancer Institute, Amsterdam, Netherlands, [2]KU Leuven, Leuven, Belgium, [3]Leiden University, Leiden, Netherlands

Male breast cancer is a rare disease that is largely overlooked and clinically regarded to recapitulate female breast cancer biology. The worse overall outcome for male patients compared to females, however, underscores inadequate disease management and a sex-based divergence in disease biology. To gain more insight into male breast biology and pathology, we used mouse models of triple-negative breast cancer and 3D whole-mount confocal imaging techniques to evaluate both *in vivo* and *ex vivo* mammary gland development, tumor formation, and hormone signaling dependence. Our results show that *Myc* overexpression in collaboration with *Trp53* deficiency drives mammary tumorigenesis in male mice. We show that MYC overexpression promotes estrogen-independent formation of lobuloalveolar structures, which progress into tumors with a similar histology and immune landscape as female mammary tumors but with significantly more genomic instability. In female mice, MYC overexpression bypasses the dependency on paracrine estrogen signaling in mammary tumorigenesis. These data provide robust evidence that MYC overrides mammary tumor estrogen dependence and abolishes the tumor-preventive effect of a low-estrogen environment. Supporting this notion, *in vitro* experiments in human female breast cancer cell lines indicate that MYC overexpression may functionally contribute to endocrine therapy resistance and therefore could possibly serve as a prognostic biomarker or clinically targetable pathway for treating both male and female breast cancers. Collectively, this preclinical work presents new insights into male mammary gland biology and mechanisms of cancer progression that might translate to a broader range of breast cancers in the clinic.

#6625 Development of novel mixed-cell models to capture heterogeneity in castration-resistant prostate cancer.

S. Jena[1], D. Kim[1], A. M. Lee[1], W. Zhang[1], S. Dehm[2], R. Huang[1];
[1]University of Minnesota, College of Pharmacy, Minneapolis, MN, [2]University of Minnesota, Medical School, Minneapolis, MN

Heterogeneity is ubiquitous in cancer and treatment responses among patient cohorts are highly variable, leading to drug resistance and disease relapse. Yet, preclinical drug screening is usually performed in cell lines or patient cells, one at a time, without consideration of cancer heterogeneity. Consequentially, positive outcomes obtained in the preclinical stage do not translate well into subsequent clinical successes. Castration-resistant prostate cancer (CRPC) is a highly lethal form of prostate cancer (PC) exhibiting a high degree of genetic and phenotypic heterogeneity with very few therapeutic options. Therefore, we created mixed-cell models depicting heterogeneity in various clinical contexts, where multiple PC cell lines representative of distinct CRPC tumor variants were labeled and combined in co-cultures to mimic the complex molecular landscape of CRPC patient cohorts. Specifically, transcriptomic profiles of PC cell lines were clustered with patient tumor specimens to identify cell lines that are genetically similar to distinct patient clusters representing CRPC tumor subtypes. Since heterogeneity has been linked to the clinical efficacy of combinatorial therapies, we applied these models to evaluate drug combinations. A combination of docetaxel and dasatinib that was previously assessed in a PC trial, was tested in the mixed-cell model and experimental findings concurred with the published clinical results, demonstrating the utility and accuracy of the model. Additionally, a computational model, IDACombo, was employed to nominate novel potentially efficacious drug combinations using monotherapy response data of cancer cell lines, a number of which were successfully validated in the mixed-cell model. More importantly, we demonstrated that while individual cell line screens may result in erroneous conclusions, combination efficacy can be accurately measured in a heterogeneous cell pool emulating a diverse patient cohort. We further explored phenotypic heterogeneity in advanced disease states, by mixing parent and standard-of-care (SOC)-resistant CRPC clonal variants. Drugs with selective potency in the resistant (vs. the parent) clone were computational prioritized and when combined with the SOC and tested in the mixed-cell models, outperformed either monotherapy. Additionally, we investigated the effects of altering the relative proportion of the constituent clones to mimic different stages of acquired therapy resistance. Furthermore, we generated mixed-cell xenograft models by subcutaneously injecting the labeled cell-line mixtures in mice and characterized the harvested tumors to detect and quantify the individual subpopulations. Development of these preclinical models holds enormous promise not only for advancing novel therapeutic strategies for cancer, but also for providing insights into the mechanisms of resistance and recurrence.

#6626 Functional and molecular interrogation of a high-plasticity cell state in lung cancer.

J. E. Chan[1], C.-H. Pan[1], C. Sussman[1], H. Styers[1], E. Brown[1], G. Hartmann[1], B. Meskauskaitė[1], M. Blum[1], S. Ding[1], S. Torborg[2], Z. Li[3], S. Joost[1], E. Rivas-Hernandez[1], T. Norman[1], R. Chaligne[1], Y. Yan[1], T. Tammela[1],

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Tri-Institutional MD-PhD Program, New York, NY, [3]Weill-Cornell Graduate School of Medical Sciences, New York, NY

Despite recent advancements in lung adenocarcinoma (LUAD) treatment, mortality remains high. Thus, a need exists for novel therapeutic concepts to enhance treatment efficacy and improve patient survival. Cancer cell plasticity, the capacity for cancer cells to differentiate and adapt to cell-extrinsic pressures, drives LUAD progression and enables treatment resistance. We discovered a molecularly distinct "high-plasticity cell state" (HPCS), which emerges during the initial stages of tumor development and is maintained in established tumors, comprising 10-15% of the cancer cell pool. We hypothesized that the HPCS is critical for tumor progression and drug resistance. To functionally interrogate this cell state, we engineered a novel genetic system that enables both *in situ* ablation (via a suicide gene) and longitudinal lineage tracing (via secreted luciferases) of the HPCS in an autochthonous genetically engineered mouse LUAD model. Lineage-tracing revealed the HPCS harbors high differentiation potential (plasticity) and growth potential *in situ*. Strikingly, ablation of the HPCS led to robust tumor regression and growth suppression. Motivated by these findings, we sought to identify molecular drivers of the HPCS using an *in vivo* multiplexed gene perturbation approach coupled to single-cell RNA sequencing. This effort led to the identification of central transcriptional plasticity drivers. This study motivates the therapeutic targeting of the HPCS in lung cancer and uncovers candidate targets.

TUMOR BIOLOGY: The Microenvironment: Beyond Surrounding the Tumor
Minisymposium

#6627 Boosting macrophage-specific BCAA oxidation enhances immune activation within the tumor microenvironment and diminishes tumor growth in pancreatic cancer.

G. Mirji[1], S. A. Bhat[1], Z. Schug[1], B. Z. Stanger[2], Z. Arany[2], R. S. Shinde[1];
[1]The Wistar Institute, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA

Treating pancreatic ductal adenocarcinoma (PDAC) poses a significant challenge, mainly due to therapy resistance linked to the immunosuppressive tumor microenvironment (TME) within PDAC tumors. This TME is characterized by a fibrotic stroma and an abundance of immunosuppressive cells, notably tumor-associated macrophages (TAMs). TAMs crucially hinder effector T cell activity and contribute to T cell exhaustion. Redirecting TAMs toward an immunostimulatory state has emerged as a promising approach in PDAC treatment. Recent investigations, including our own studies, reveal a profound influence of metabolic pathways on the immune phenotype of TAMs. Specifically, dysregulation in branched-chain amino acid (BCAA) metabolism has been observed in PDAC patients, manifesting as elevated circulating BCAA levels correlating with a doubled risk of PDAC development. However, the extent to which BCAA metabolism influences TAM phenotype and anti-tumor immune responses remains a largely unexplored territory, presenting a challenge for PDAC treatment. Our focus revolves around understanding how heightened BCAA levels in PDAC affect TAM phenotype, the immunosuppressive tumor environment, and tumor progression. Employing an orthotopic PDAC model and genetically modified mice, specifically BCKDKfl/fl BCKDK LysMcre/+ (mimicking increased BCAA oxidation), alongside a BCKDK-targeting pharmacological inhibitor (BT-2), multicolor flow cytometry, and in vitro models, our research has revealed crucial insights. We found a diminished expression of BCAA oxidation genes in TAMs compared to normal pancreatic macrophages. Interestingly, M1 and M2 macrophages seemed to utilize BCAAs differently, reflected in varying levels of TCA cycle intermediates derived from BCAA oxidation. Notably, boosting BCAA oxidation specifically in TAMs through genetic modifications resulted in reduced PDAC growth associated with an enhanced immunostimulatory TAM phenotype and activation of CD8+ T cells in the TME. Conversely, administering BCAAs induced an immunosuppressive TAM phenotype, fostering PDAC growth, suggesting a direct influence of BCAAs on TAM phenotype. Pharmacologically enhancing BCAA oxidation via BT-2 bolstered immune activation within the tumor environment and reduced PDAC growth. Intriguingly, our analysis of publicly available data unveiled a significant correlation between high BCAA oxidation and favorable responses to anti-PD1 therapy in cancer patients. Our findings emphasize the pivotal role of BCAA metabolism in shaping the immune landscape of PDAC, offering potential avenues for therapeutic interventions targeting TAMs and mitigating TME immunosuppression.

#6628 Mapping the spatial and molecular determinants of macrophage heterogeneity in breast cancer.

[1]Medicine, Weill Cornell Medicine, New York, NY,[2]Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Center of Comparative Medicine and Pathology, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Immunology Program, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[6]Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY,[7]Cancer Biology and Genetics Program, Memorial Sloan Kettering Cancer Center, New York, NY,[8]Department of Biological Regulation, Weizmann Institute of Science, Rehovot, Israel,[9]Department of Oncology, University of Lausanne, Lausanne, Switzerland

Tumor-infiltrating macrophages support critical steps in tumor progression, and their accumulation in the tumor microenvironment (TME) is associated with adverse outcomes and therapeutic resistance across human cancers. In the TME, macrophages adopt diverse phenotypic alterations, giving rise to heterogeneous immune activation states and induction of cell cycle. While the transcriptional profiles of these activation states are well-annotated across human cancers, the underlying signals that regulate macrophage heterogeneity and accumulation remain incompletely understood. Here, we leveraged a novel ex vivo organotypic TME (oTME) model of breast cancer, in vivo murine models, and human samples to map the determinants of functional heterogeneity of TME macrophages. We identified a subset of F4/80high Sca-1+ self-renewing macrophages maintained by type-I interferon (IFN) signaling and requiring physical contact with cancer-associated fibroblasts. We discovered that the contact-dependent self-renewal of TME macrophages is mediated via Notch4, and its inhibition abrogated tumor growth of breast and ovarian carcinomas in vivo, as well as lung dissemination in a PDX model of triple-negative breast cancer (TNBC). Through spatial multi-omic profiling of protein markers and transcriptomes, we found that the localization of macrophages further dictates functionally distinct but reversible phenotypes, regardless of their ontogeny. Whereas immune-stimulatory macrophages (CD11C+CD86+) populated the tumor epithelial nests, the stroma-associated macrophages (SAMs) were proliferative, immunosuppressive (Sca-1+CD206+PD-L1+), resistant to CSF-1R depletion, and associated with worse patient outcomes. Notably, following cessation of CSF-1R depletion, macrophages rebounded primarily to the SAM phenotype, which was associated with accelerated growth of mammary tumors. Our work reveals the spatial determinants of macrophage heterogeneity in breast cancer and highlights the disruption of macrophage self-renewal as a potential new therapeutic strategy.

#6629 Cancer-associated nerves regulate anti-tumor immunity in pancreatic cancer.

Ruiyuan Xu, Jianlu Song, Yuan Chen, Xinpeng Yin, Chengcheng Wang, Yupei Zhao

Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Nerves serve an emerging component of the tumor microenvironment (TME), contributing to tumorigenesis and cancer progression. Neural invasion (NI) is a common feature of pancreatic ductal adenocarcinoma (PDAC), accounting for distant metastasis and local recurrence. However, the mechanism by which tumor associated nerves (TANs) regulate anti-tumor immunity remains largely elusive. Here, we investigated the association between TANs and immunosuppressive TME to develop more effective therapeutic strategies for PDAC. Using tumor samples of PDAC patients, we identified that the nerves invaded by cancer cells showed increased adrenergic activation accompanied with no parasympathetic or sensory innervation changes. Patients with severe NI were associated with increased catecholamine levels. Additionally, single-cell RNA-sequencing and spatial transcriptome analysis of tumors from patients with PDAC revealed that peri-neural niches of severe NI patients were characterized by decreased $CD8^{\pm}$ T cells and increased activity of M2 polarization of tumor-associated macrophages (TAMs), and regulatory T (Treg) cells, which was validated by multiplexed immunofluorescence staining. We further identified that $CD8^{\pm}$ T cells expressing β-adrenaline receptors (β-ARs) reduced proliferation and cytokine production when exposure to catecholamines in a dose-dependent manner or co-cultured with dorsal root ganglia pretreated with cancer cells. $Kras^{LSL\text{-}G12D}$; $p53^{LoxP}$; Pdx1-CreER (KPC) mice treated with catecholamines accelerated tumor progression by inhibiting T cell-mediated antitumor responses, which was abrogated by surgical sympathectomy of KPC mice. Especially, in an orthotopic PDAC model, nonselective β-blocker propranolol in combination with immune checkpoint blockade (ICB) significantly enhanced active $CD8^{\pm}$ T cells with concurrent reduced tumor growth. We suggest a novel regulatory mechanism of inhibiting anti-tumor immunity that can promote cancer progression mediated by TANs invasion. These data establish a close connection between the nerves, cancer cells, and immune cells and provide the potential novel targets of therapeutic approaches in PDAC.

#6630 Non-cell-autonomous cancer progression from chromosomal instability.

J. Li[1], M. Hubisz[2], E. Earlie[2], M. Duran[1], C. Hong[1], A. Varela[2], E. Lettera[1], M. Deyell[2], B. Tavora[3], J. Havel[3], P. Su[3], A. Dipak Amin[4], K. Budre[2], E. Kamiya[2], J.-A. Cavallo[1], C. Garris[5], S. Powell[1], J. Reis-Filho[1], H. Wen[1], S. Bettigole[3], A. Khan[1], B. Izar[4], E. Parkes[6], A. Laughney[2], S. Bakhoum[1];
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Weill Cornell Medicine, New York, NY, [3]Volastra Therapeutics Inc, New York, NY, [4]Columbia University Medical Center, New York, NY, [5]Harvard Medical School, Boston, MA, [6]University of Oxford, Oxford, United Kingdom

Chromosomal instability (CIN) is a driver of cancer metastasis, yet the extent to which this effect depends on the immune system remains unknown. Using ContactTracing—a newly developed, validated and benchmarked tool to infer the nature and conditional dependence of cell-cell interactions from single-cell transcriptomic data—we show that CIN-induced chronic activation of the cGAS-STING pathway promotes downstream signal re-wiring in cancer cells, leading to a pro-metastatic tumor microenvironment. This re-wiring is manifested by type I interferon tachyphylaxis selectively downstream of STING and a corresponding increase in cancer cell-derived endoplasmic reticulum (ER) stress response. Reversal of CIN, depletion of cancer cell STING or inhibition of ER stress response signaling abrogates CIN-dependent effects on the tumor microenvironment and suppresses metastasis in immune competent, but not severely immune compromised, settings. Treatment with STING inhibitors reduces CIN-driven metastasis in melanoma, breast and colorectal cancers in a manner dependent on tumor cell-intrinsic STING. Finally, we show that CIN and pervasive cGAS activation in micronuclei are associated with ER stress signaling, immune suppression and metastasis in human triple-negative breast cancer, highlighting a viable strategy to identify and therapeutically intervene in tumors spurred by CIN-induced inflammation.

#6631 Aging influences the pancreatic ductal adenocarcinoma tumor immune microenvironment to promote features of immunosuppression.

E. Kartalia[1], J. M. Leatherman[1], J. W. Lee[1], E. M. Jaffee[1], A. T. Weeraratna[2], **D. J. Zabransky**[1];
[1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Public Health, Baltimore, MD

Advancing age is the strongest independent risk factor for the development of pancreatic ductal adenocarcinoma (PDAC) and a negative prognostic factor. PDACs are typically immunologically “cold” tumors and do not often respond to currently approved immunotherapy treatment approaches. How aging may alter non-malignant cells, such as fibroblasts and immune cell populations, in the PDAC tumor microenvironment (TME) to decrease anti-tumor immune responses is not understood.

We identified that aged microenvironments significantly alter the growth and progression of PDAC tumors. Orthotopic KPC and Panc02 mouse PDAC cell line injections into the pancreata of aged (>64-week-old) compared to young (6-8-week-old) C57BL/6 mice result in more rapid tumor growth and increased frequency of liver metastases *in vivo*. Tumors from aged mice have high expression of the TGFβ family member GDF-15 and hyperactivation of AKT signaling driven by the release of secreted factors from aged pancreatic fibroblasts.

We found that in aged microenvironments there is a marked reduction in the number of CD8+ T cells and an increase in FoxP3+ regulatory T cells in primary orthotopic pancreatic tumors using the KPC and Panc02 models. In addition, we performed portal vein injections to establish liver metastases to study the differences in immune cell infiltration in metastases from young vs. aged microenvironments. Aged mice form more and larger liver metastases compared to young mice, and metastatic lesions in aged mice have decreased CD8+ T cell infiltration when compared to young mice.

Since tumors in aged microenvironments have increased AKT activation compared to young microenvironments, we next tested if AKT signaling was sufficient to alter immune cell infiltration in PDAC tumors. In young mice, treatment with recombinant GDF-15, which activates AKT signaling, reduced CD8+ T cell infiltration into tumors. Conversely, in KPC tumors grown in aged mice treated with the AKT inhibitor MK-2206, there was a trend toward increased CD8+ T cell infiltration and a significant reduction in immunosuppressive FoxP3+ Tregs.

Together, these data highlight age-dependent differences in the immune infiltration in PDAC tumors. They suggest that activation of AKT signaling can drive features of immunosuppression in PDAC, providing the rationale for targeting AKT signaling to improve antitumor immune responses in PDAC.

#6632 Adipocyte death drives dormant breast cancer cell reactivation.

X. Yuan, Q. Ren, S. A. Stewart;
Washington University In St. Louis, St. Louis, MO

Despite significant responses to initial treatments, upwards of 30% of breast cancer patients will experience a recurrence of their disease. Unfortunately, there are few clinical features that predict which patients will recur, relegating patients and their doctors to a wait-and-see approach where they must remain vigilant. Recent studies have reported that the presence of disseminated tumor cells (DTCs) in the bone marrow of early-stage breast cancer patients predicts a higher chance of recurrence and that obese patients experience 35%-40% higher rates of recurrence than lean patients. Interestingly, in addition to increased adipocyte size, obese patients experience higher rates of adipocyte apoptosis, macrophage recruitment to adipocyte tissue, and increased inflammation, shown as the formation of crown-like structures (CLSs). Given the rising prevalence of obesity, the need for mechanistic studies to elucidate its contribution to breast cancer dormancy and recurrence is urgent. To investigate how microenvironmental changes associated with obesity affect breast cancer dormancy, we utilized a well-established syngeneic mouse model of ER+ breast cancer dormancy (D2.0R). We found that D2.0R cells remained dormant in the visceral fat of wildtype mice but were reactivated upon adipocyte death due to obesity or genetic manipulation, and this reactivation required the recruitment of macrophages. To understand why macrophages were recruited to the adipose tissue and how they led to dormant tumor cell reactivation, we profiled the microenvironmental changes in visceral fat using single-cell RNA-sequencing and found that the infiltrating macrophages exhibited unique pro-inflammatory and lipid regulatory phenotypes. Further investigation revealed that macrophages activated the integrin-focal adhesion kinase (FAK) pathway in dormant D2.0R cells and the inhibition of integrin and FAK inhibited this activation. Given tumor cells can metastasize to visceral fat depots in breast cancer patients, our findings provide an important model to determine what drives dormant tumor cell growth in adipose tissue. Our study provides novel insights into how tumor microenvironment (TME) impacts breast cancer dormancy and also highlights the importance of adipose tissue as a unique reservoir that potentiates cancer relapse.

#6633 Tracking cell-cell interactions using intercellular barcode transfer.

N. Q. Tay, T. Juan, J. J. Muldoon, J. Eyquem, M. T. McManus;
University of California, San Francisco, San Francisco, CA

Cell-cell interaction is one of the fundamental biological mechanisms by which cells communicate and is a key modality by which cancer cells interact with other cells in their microenvironment. Current methods, such as enzymatic labeling and proximity-based tagging, allow the experimental tracking of these interactions but are not compatible with sequencing-based readouts, which are essential for high-throughput analyses. We have developed a highly scalable intercellular barcode transfer technology that bridges this gap. Our novel “Relay” technology offers a scalable solution to monitor cell-cell interactions with unprecedented single-cell resolution, seamlessly integrating with existing high-throughput and sequencing platforms. Relay employs RNA barcodes to mark and track cell interaction events, providing definitive quantitative data on cell interaction partners. We used Relay to track interactions between cancer cells and T cells, capturing both potent antigen-specific engagements and subtler contacts involved in antigen sampling. Additionally, by integrating CRISPR libraries with Relay, we pioneered a novel approach for pooled CRISPR screens, focusing on intercellular interactions across different cell types. In this context, the cell harboring genetic perturbation may differ from the cell under analysis. To demonstrate this, we are conducting genome-wide perturbations in cancer cells and interrogating cancer cell factors that affect antigen sampling and trogocytosis by T cells and macrophages. Beyond its application in CRISPR screening, Relay can also be used with single-cell RNA sequencing to directly track and measure immune-cancer and immune-immune cell interactions at the single cell level. We applied single-cell Relay to a dendritic cell-T cell system to link dendritic cell signatures to T cell signatures based on direct cell contact and regulatory signaling. The design of Relay as a highly modular system extends its utility beyond cancer research, making it broadly applicable across various biological models and systems where cell-cell communication is a fundamental property in complex multicellular settings. This tool promises to accelerate the transition from theoretical understanding to practical exploration of cell-cell interactions, with profound implications for immunology, oncology, and beyond.

IMMUNOLOGY: Immune Modulation by Viruses, Bacteria, Radiation, and Other Modalities
Poster Session

#6637 The Haemophilus influenzae vaccine mitigates pancreatic tumor progression and lowers immunoregulatory cell levels in the tumor microenvironment.

E. F. Giurini, S. G. Pappas, K. H. Gupta;
Rush University Medical Center, Chicago, IL

Pancreatic ductal adenocarcinoma (PDAC) is a devastating disease projected to become the second leading cause of cancer deaths by 2030. First-line chemotherapies gemcitabine and FOLFIRINOX provide little therapeutic benefit and are accompanied by severe adverse toxicities, precluding long-term treatment. In addition, PDAC is notoriously refractory to checkpoint inhibitor immunotherapies, due to poor immunogenicity and a tumor microenvironment dominated by suppressive cell types. Thus, there is an unmet need for innovative, immune-based strategies to combat PDAC. A previous study utilized engineered bacteria to effectively kill PDAC tumor cells by directly delivering immunogenic tetanus toxoid to the tumor. Given the potential toxicity in using live bacteria, our group utilized a less toxic alternative, an FDA-approved *Haemophilus influenzae* type b vaccine (HibVx) also containing a tetanus toxoid component. To determine the antitumor potential of HibVx, our group used a physiologically relevant murine model, low T cell clone murine PDAC tumor model 641c95 and clinically relevant KPC mice model for PDAC. After tumors were established, animals received three consecutive daily treatments of HibVx via intraperitoneal injection. HibVx-treated animals experienced a dramatic reduction in tumor growth compared to PBS-treated controls ($p<0.001$). Given that tetanus toxoid is highly immunogenic in nature, changes in intratumoral immune cell populations following HibVx treatments were of great interest. Using flow cytometry analysis, HibVx-treated tumors had a significant increase in natural killer cells compared to control tumors ($p\leq0.05$). In addition, HibVx affected myeloid-derived suppressor cell populations (MDSCs), which are heavily implicated in the suppressive nature of PDAC tumors. HibVx also significantly decreased MDSCs within the tumor ($p<0.05$). In all, these findings position HibVx as an effective immunostimulatory agent that can be used as an alternative to live bacteria-based therapy for the treatment of PDAC.

#6639 Mechanisms of action of a killed, bacteria-based, multiple immune receptor agonist in development for pulsed anti-tumor immunotherapy.

M. J. Newman, D. Singh;
Indaptus Therapeutics, Inc., New York, NY

Activation of immune receptors, such as Toll-like (TLR), NOD-like (NLR) and Stimulator of Interferon Genes (STING) is required for efficient innate and adaptive immunity. Gram-negative bacteria (G-NB) contain multiple TLR, NOD and STING agonists. Potential utility of G-NB for cancer immunotherapy is supported by observations of tumor regression in the setting of infection and Coley's Toxins. Coley reported that intravenous (i.v.) administration was likely most effective but produced toxicity. The discovery of TLRs and their agonists, particularly the potent/multi-functional TLR4 agonist lipopolysaccharide (LPS)-endotoxin, comprising ~75% of the outer membrane of G-NB, suggests that it may be both a critical active ingredient and responsible for dose-limiting toxicity of i.v. G-NB. We have produced killed, intact bacteria products from non-pathogenic G-NB with ~90% reduction of LPS activity. One product, Decoy10, contained TLR2,4,8,9, NOD2 and STING agonist activity and exhibited reduced i.v. toxicity in mice and rabbits relative to unprocessed cells. Decoy10 and closely related Decoy20 produced single agent activity or combination-mediated durable regressions, with immunological memory, in mice with syngeneic or human breast, colorectal, hepatocellular, pancreatic carcinomas or non-Hodgkin's lymphoma. Regressions were observed in combination with chemotherapy, a non-steroidal anti-inflammatory drug, anti-PD-1, or rituximab, were associated with induction of 18-26 plasma cytokines/chemokines, activation of innate and adaptive immune pathways in tumors, and were dependent on NK, CD4+ and CD8+ T cells (Newman, Cancer Res 2023;83(7 Suppl):Abstract nr 4165). These and preliminary clinical results demonstrating rapid clearance of Decoy20 with transient induction of >50 plasma cytokines/chemokines (Newman et al., J Immunother Cancer 2023;11(Suppl 2)782-E:A1770) are supportive of a "pulse-prime" mechanism, whereby Decoy bacteria produce transient, but broad innate and adaptive immune activation. We have now analyzed immune activation by Decoy bacteria *in vitro* using human peripheral blood mononuclear cells (PBMCs). Decoy10 enhanced polarization of CD14+ monocytes to M1 macrophages and inhibited Treg polarization. Decoy10 enhanced monocyte-derived dendritic cell maturation and enhanced Th1, Th2 and Th17 CD4+ polarization, with Th1 at 10-100-fold lower Decoy10 concentrations than Th2 or Th17. Decoy10 also activated NKT and T cells, and enhanced PBMC-mediated tumor cell killing. The results demonstrate that Decoy bacteria stimulate polarization, maturation, or activation of cellular mediators of innate and adaptive anti-tumor immune responses, inhibit an immune-suppressive mechanism, and enhance immune cell killing of tumor cells. The results are consistent with and significantly extend our previously reported *in vivo* data.

#6640 Zap! Irreversible electroporation in pancreatic cancer cells induces proinflammatory cell death and improves progression free survival.

M. Powar, K. Imran, I. Allen, R. Davalos, Z. Salamah, K. Aycock, R. Brock, S. Coutermarsh-Ott, K. Orr;
Virginia Tech, Blacksburg, VA

Pancreatic cancer is the third leading cause of cancer-related death due to its late diagnosis, few treatment options, and extremely low survival rates due to its immunosuppressive microenvironment. Irreversible electroporation (IRE),is a tumor non-thermal ablation technique that applies high-voltage electrical pulses to permeabilize the cell membrane that is irreversible and leads to necrotic cell death. IRE has had strong success in clinical trials nevertheless, little is known about the effect of IRE beyond the initiation of cell death in the tumor tissue. We hypothesize that IRE can not only induce cell death by membrane disruption to facilitate a proinflammatory microenvironment but also causes death via cell cycle arrest. We utilized in-vitro, and immunocompetent in-vivo murine models to investigate changes to pancreatic cancer and the tumor microenvironment. Our findings show that treating the cells with an increasing voltage of IRE induces more cell death. We observed cell cycle arrest in the G1 phase which may have been caused by DNA damage. There was upregulation of DNA damage repair machinery in the treated samples. Our histopathology data suggests increased necrosis on the tumor treated with IRE, as also PCR array analysis showed more proinflammatory cell death caused by pyroptosis. Finally, we demonstrated a reduction in the tumor size and a better survival rate aftertreatment. Our data suggest that Irreversible electroporation has a promising future in inducing proinflammatory type of cell death in the tumor and benefits increased patient survival. More investigation is needed to define ideal parameters for the electrical pulses and device development for tumor ablation in larger animals like porcine models.

#6641 Improving response to bladder-sparing therapies by combining radiotherapy to immuno-potentiating agents in immunologically cold models of bladder cancer.

E. Michaud[1], S. Fehric[1], G. Marcq[1], J. Huang[1], F. Cury[2], M. Koti[3], **J. Mansure**[1], C. Piccirillo[4], W. Kassouf[2];
[1]McGill University Health Centre Research Institute, Montreal, QC, Canada, [2]Division of Urology, Department of Surgery, McGill University Health Centre, Montreal, QC, Canada, [3]Dept. of Biomedical and Molecular Sciences, Queen's University, Kingston, ON, Canada, [4]4Dept. of Microbiology and Immunology, McGill University, Montreal, QC, Canada

INTRODUCTION: Radiation therapy (RT) is a promising approach for bladder-sparing in muscle-invasive bladder cancer (MIBC). Despite its efficacy, 30% of patients develop radioresistant tumors necessitating salvage surgery. Combining RT with immune checkpoint inhibitor was reported to have synergic effects on anti-tumor immunity. In addition, activation of the STING pathway induces cell death, cancer cell antigens release and presentation, and promote T cells trafficking into tumors. Previous *in vivo* results from our team using the immunologically 'hot' murine tumor model MB49 demonstrated significant improvement of survival and immune cell infiltration upon STING agonist treatment, when combined with RT and anti-PDL1 treatment. Oppositely, treating the 'cold' tumor model UPPL with a combination of RT and anti-PDL1 treatment did not improve survival compared to RT alone. Consistently, UPPL tumors present low T cell and high neutrophil infiltration *in vivo*. Thus, the main objective of the present study is to evaluate whether combining RT, anti-PDL-1 and STING agonist treatments can improve the immunogenicity of UPPL tumors.
METHODS: Male C57BL/6 mice were subcutaneously injected with 5.106 UPPL cells then randomized into various treatment combinations of RT, anti-PDL-1 and STING agonist. Midpoint and endpoint tumors were harvested for flow cytometry and IHC and stools for 16S-sequencing.
RESULTS: We report that RT-combined treatments delayed tumor growth and prolonged survival in vivo. Neighborhood analyses in tissue revealed that response to RT combinations associated with increased macrophages density in the vicinity of infiltrating CD8+ T cells and with gut enrichment in *Faecalibaculum*, *Bifidobacterium*, and *Candidatus arthomitus*. Network analyses showed strong positive correlations between pro-tumor neutrophil recruitment and beneficial gut microbes in non-responders. Network analyses revealed positive correlations between pro-tumor neutrophil recruitment and dysbiotic gut microbes in non-responders. Conversely, these same neutrophil populations were associated to families associated to gut health in responding mice.
CONCLUSIONS: Our results suggest combining RT in cold tumors enhances the TME, boosting T cell function *via* macrophage support. Furthermore, distal gut microbes may impact local anti-tumor immunity by influencing neutrophil polarization. This study contributes to the limited literature exploring immune modulation in a conventionally 'cold' bladder tumor cell lines, which has implications for treating human resistant tumors.

#6642 Exploring the x-ray psoralen activated cancer therapy mechanism of action in a genetically engineered mouse model of soft tissue sarcoma.

Beatrice Schleupner[1], Alexandra Hunter Aitchison[2], Elle MacAlpine[3], Nicole Cantor[4], Sorana Morrissy[5], Kiran Narta[5], Jason Somarelli[6], Brian Brigman[1], Julia Visgauss[1], Michael Monument[7], William Eward[1]

[1]Department of Orthopaedic Surgery, Duke University Medical Center, Durham, NC,[2]Duke University School of Medicine, Durham, NC,[3]Department of Orthopaedics, Washington University School of Medicine, St. Louis, MO,[4]Campbell University School of Osteopathic Medicine, Lillington, NC,[5]Department of Biochemistry & Molecular Biology, University of Calgary, Calgary, AB, Canada,[6]Department of Medicine, Duke University Cancer Institute, Durham, NC,[7]Department of Orthopaedic Surgery, University of Calgary, Calgary, AB, Canada

BACKGROUND: Psoralen is a natural ultraviolet activated compound that has been used for over 70 years to treat skin cancer, psoriasis, and vitiligo. Recently, to expand its use beyond external treatment, a novel therapeutic called X-PACT (X-ray psoralen activated cancer therapy) was created to treat internal tumors. A combination of 8-methoxypsoralen and phosphors that convert low doses of x-ray radiation to ultraviolet (UV) light are injected into solid tumors and subsequently activated by x-ray photons with considerable antineoplastic effect. Notably, canine clinical trials have observed significant abscopal effects of X-PACT therapy on metastatic lesions throughout patients, but the immunomodulatory mechanisms of action are unclear (Nolan *et al*, in submission). Here, we present preliminary data investigating the immune response to X-PACT therapy in a murine soft tissue sarcoma (STS) model.
METHODS: Six mice of the inducible KrasG12D/+; p53flox/flox (KP) murine STS model with palpable, gastrocnemius tumors were used in this initial study. Four mice underwent treatment with X-PACT. In this group, psoralen was mixed with energy converters and injected into the tumor. The mice then received low-level radiation to activate the drug. Treatment was performed five times over a 15-day period and the animals were sacrificed within 48 hours of final treatment. The other two mice with induced tumors received no treatment prior to sacrifice. For both groups, a cardiac blood draw was performed at the time of sacrifice to obtain plasma serum for analysis. Luminex xMAP technology was used for multiplexed quantification of 45 mouse cytokines, chemokines and growth factors.
RESULTS: There were five markers that showed significantly different levels between the treated and control groups. Results indicated significantly higher ($p = 0.006$) plasma concentrations of macrophage derived chemokine (MDC) following five rounds of treatment with X-PACT therapy. Additionally, the treated mice displayed significantly lower concentrations of granulocyte colony-stimulating factor (G-CSF, $p = 0.003$), eotaxin ($p = 0.016$), tissue inhibitor of matrix metalloproteinase 1 (TIMP1, $p = 0.024$), and interleukin-1β (IL-1β, $p = 0.033$) compared to untreated mice with STS.
CONCLUSION: In humans, MDC levels are associated with longer survival and lower cancer severity. G-CSF, eotaxin, TIMP1, and IL-1β are upregulated in cancer patients and correlate with disease severity. Together, the lower concentrations of G-CSF, Eotaxin, TIMP1, and IL-1β suggest a softening of cancer severity following X-PACT treatment. Further studies and larger sample sizes are necessary to confirm and expand upon these preliminary findings.

#6643 Hyperthermic induction of immunotherapeutic response in *in vitro* melanoma model.

T. Jarboe[1], D. Quaranto[1], N. R. DeSouza[1], K. Kopec[1], J. Geliebter[1], R. K. Tiwari[1], M. D. Hurwitz[2];
[1]New York Medical College, Valhalla, NY, [2]Westchester Medical Center, Valhalla, NY

Immunotherapy has revolutionized the treatment of advanced melanoma, yet challenges persist with non-responders, development of resistance, and dosage concerns. Our strategy to enhance checkpoint inhibitor efficacy is to combine it with hyperthermia. Moderate hyperthermia, 39-45°C, is an interesting anti-neoplastic therapy which induces production of tumor associated antigens rendering tumor sites more amenable to immunotherapy. To investigate temperature-induced alterations on carcinogenic phenotypes in vitro, B16-F10 melanoma cells were grown at 37°C under normal culture conditions, or incubated at 41°C for 2 hours for moderate, febrile hyperthermic induction. Hyperthermia-induced changes were analyzed by trypan blue exclusion assay, scratch wound assay, collection of conditioned media for cytokine array, and protein isolation for Western Blot. Conditioned media from the hyperthermia-treated group showed an inflammatory shift in cytokine and chemokine expression, with increased TNFa and decreased IL-4 expression. Prior studies found the hyperthermia-induced apoptotic effect is directly correlated to endogenous TNFa levels, elucidating a potential molecular mechanism. Treatment for two hours at 41°C decreased proliferation of B16-F10 cells by 62% after 48 hours and 94% after 72 hours. Additionally, hyperthermia decreased cellular migration by 70% after 24 hours. Further evaluation of cellular interactions in important pathways responsible for these hyperthermia-induced changes were investigated via Western blot. Expression of constitutively active MAPK signaling cascade effectors pERK and ERK was decreased by 86% and 50%, respectively, helping to regulate pro-tumorigenic proliferative signaling. Some cancer cells have been demonstrated to resist hyperthermia via mechanisms to inhibit induction of caspase-3, however, in our model caspase-3 expression increased by 31% following 41°C treatment, thus allowing for induction of apoptosis via caspase-3 in this model. Cellular stress may induce these cell death pathways, as well as heat shock responses. Following febrile hyperthermic induction, hsp70 expression increased by 188% compared to cells cultured at 37°C. Hsp70 has a well-established role in supporting tumor-specific immune responses. Induction of hyperthermia in combination with anti-PDL1, anti-PD-1, or IL-15 immunotherapy is currently being evaluated in a C57BL/6 mouse model by our group. These studies aim to assess if hyperthermia augments response to immunotherapies in vivo. Our current works suggests that moderate, non-ablative hyperthermia helps initiate anti-tumor immune responses, assisting in the induction of anti-tumorigenic cell programs and, potentially, the production of additional tumor associated antigens, thereby making it an interesting candidate for combination with immune checkpoint inhibition and other immunotherapeutic approaches.

#6644 aPD1 treatment of urothelial cancers is synergistically enhanced by activating anti tumor immunity using vascular targeted photodynamic therapy.

Lilach Agemy, Keren Sasson, Tamar Yechezkel, Rachel Hamri, Raz Robas, David Kain, Avigdor Scherz

Weizmann Institute of Science, Rehovot, Israel

Background: Recurrence and progression rate following surgical treatment of locally advanced urothelial cancer is high, underscoring the unmet need to develop an effective, well tolerated treatment strategies, particularly for high grade upper tract urothelial cancer (HG-UTUC). The treatment success of low grade UTUC by vascular targeted photodynamic therapy (VTP) with WST11 (Padeliporfin) in phase I clinical trials led the FDA to approve Phase 3 trial in a fast track, orphan drug designation for low grade UTUC (ENLIGHT). Recently, treatment with immune checkpoint inhibitor (ICIs) of the PD1/PD-L1 axis has been approved for treatment of HG-UTUC. Yet, the failure rate of aPD1 therapy in HG-UTUC is high.We hypothesized that immune checkpoint inhibition needs to be complemented by the massive priming and accrual of newly activated anti-tumor immune cells through tumor immunogenic cell death. Early evidence indicated that WST11 VTP promotes anti-tumor immunity suggesting that VTP/aPD1 combinations may significantly improve the treatment success of HG-UTUC.
Methods: Mice bearing s.c. MB49-Luc, were subjected to WST11 VTP at 14d post implantation at suboptimal dose of drug or partial area of illumination. 4 or 5 doses of aPD1 were intraperitonealy administrated every 3 days starting at 1d post VTP (aPD1+1), or every 3 days till 10 days post-treatment starting at 2 days before VTP (aPD1-2). Tumor progression was followed up to 90 days post treatment using IVIS. Hematoxylin-eosin staining, and multiplex immunohistochemistry (mIHC) were performed on controls and treated animals.
Results: WST11 VTP with suboptimal drug dose, aPD1+1, and aPD1-2 resulted in 17%, 23% and 43% cure at day 90 post VTP. VTP at suboptimal drug dose combined with aPD1+1 or aPD1-2, resulted in 50% and 77% cure rate at 90 days, respectively. VTP with optimal drug dose (5mg/kg) but partial illumination resulted in 20% cure rate while combining this treatment modality with aPD1-2 resulted in 90% animal cure rate at day 90.At 24h post VTP mIHC showed a 2-3 fold increase of cytotoxic T cells, dendritic and NK cells, and a ~4 folds overexpression of PD1 and PD-L1 in the treated tumor tissue. At 2 days post aPD1-2 initiation, PD1 and PD-L1 apparent expression dropped to 0 and 2 folds higher than control, respectively. Following the combined VTP and aPD1-2 treatment, both PD1 and PDL-1 contents dropped down to zero and the CD8 content reached 3 folds enhancement compared to control.
Conclusions: These observations indicate that elevating the content of anti-tumor immune cells in the tumor microenvironment by VTP in combination with ICI synergistically enhances the therapeutic effect providing a much higher complete cure compared with the individual therapies. The cure rate extent strongly depends on the synchronization of the two modalities providing guidelines for the clinical management of HG-UTUC treatment.

#6645 Temporal immune profiling reveals systemic anti tumor immunity in triple negative breast cancer(TNBC) patients treated with immunotherapy and radiation.

V. Devarakonda, J. Viramontes, S. Stevens, T. Dar, E. Ko, E. Canesco, K. Anderson, J. Guarnerio, S. Knott, S. Shiao;
Cedars-Sinai Medical Center, Los Angeles, CA

Combining pembrolizumab (anti-PD1) with radiation therapy (RT) has shown to enhance response rates in TNBC. We hypothesize that this improved efficacy is not just localized to the tumor bed, but also involves a broader systemic immune response, although the precise mechanisms are yet to be fully understood. Therefore, in this study, we aimed to investigate T cell clonal dynamics in Tumor and peripheral blood mononuclear cells (PBMCs) in 9 patients (6 responders(R) and 3 non-responders (NR)) from 3 different timepoints (before therapy (Baseline), after anti-PD1 alone and after anti-PD1+RT). CD45+ positive stained cells were sorted for subsequent single-cell RNA and T-cell receptor (TCR) sequencing analysis.Through single-cell analysis, we identified increased proportions of exhausted CD8+ and Treg cells from baseline to both treatment points, whereas exhaustedCD4+ T cells increased in proportions after PD1 alone in Responders. We aimed to then understand the origin of these cells, and how they might contribute to systemic immunity. Hence, by TCR overlap between Tumor and PBMC's we detected 590 overlapped clones in CD8 and 1000 overlapped clones in CD4 T cells. Neo-TCR score was higher in these overlapped clones, suggesting tumor reactive clones can be identified in PBMC's. Compared to exhausted CD4, exhausted CD8 T cell and Treg had higher overlapped clones between Tumor and PBMC. We also found that exhausted CD8+T cells clonal expansion after treatment was higher in pre-existing clones, compared to new clones in Responders. These pre-existing clones consisted of overlapped clones, suggesting tumor reactivity to be present in PBMC's before treatment. Further investigation suggested that exhausted CD8+ cells also showed increased transition to TEMRA (in PBMC) and a tissue-resident memory CD8 T cell subset, under combination therapy. This pattern was not seen in exhausted CD4+Tcells or Treg cells, indicating that CD8+ T cell subsets in the blood are crucial in driving systemic anti-tumor immunity. Overall, this study has identified the systemic immune response triggered by the combination of anti-PD1 and radiation therapy highlighting its potential to inform and refine future therapeutic strategies in TNBC treatment.

#6646 Investigating the combination of radiation and subsequent immune checkpoint inhibitor treatment in head and neck squamous cell carcinoma models.

H. Lind[1], A. A. Strait[2], S. Hall[2], J. B. Goon[1], J. D. Aleman[2], S. Chen[2], P. Owens[2], J. H. Wang[3], C. Young[2], X.-J. Wang[1];
[1]UC Davis Comprehensive Cancer Center, Sacramento, CA, [2]University of Colorado, Anschutz Medical Center, Aurora, CO, [3]University of Pittsburgh, Pittsburgh, PA

Purpose: Head and neck squamous cell carcinoma (HNSCC) is often marked by an immunosuppressive tumor microenvironment, which contributes to the dismal 10-20% response rate to immune checkpoint inhibitor (ICI) therapy in HNSCC patients. Radiotherapy (RT) is a currently standard of care and frontline therapy for HNSCC, yet resistance is common. We sought to examine the combination therapy of RT followed by ICI therapy to test if RT induces an *in situ vaccination* which enhances the efficacy of subsequent ICI.

Methods: We utilized SCC cell lines derived from K15.Kras^{G12D}/Smad4$^{-/-}$ SCCs, which mimic the progression of HPV-unrelated HNSCC, and transplanted SCC cells into immune-competent C57BL/6J mouse recipients. Mice were subjected to RT followed by anti-PD-L1/anti-TGFb therapy. CD8$^{\pm}$ splenic T cells of responder or non-responder mice were examined by paired single-cell VDJ sequencing and single cell RNA sequencing (TCR/sc-RNAseq) to look for adaptations of the cytotoxic T cell compartment following combination therapy. Responder and non-responder tumor lines or tumors were treated with RT alone *in vitro* and *in vivo*, respectively, to examine major histocompatibility complex I (MHC-I) levels on tumor cells.

Results: Responders to this combination therapy exhibited complete tumor eradication while non-responders displayed rapid tumor progression. When re-challenged with same HNSCCs cells, responders rejected implanted tumor cells while naïve recipients rapidly developed HNSCCs. Single-cell TCR sequencing of splenic CD8$^{\pm}$ T cells revealed that responders, but not naïve recipients exhibited multiclonal CD8$^{\pm}$ T cell expansion specifically of memory cell populations. Responder tumor cells exhibited greater levels of MHC-I protein level presentation than non-responders when stimulated with RT.

Conclusions: Our data suggest that 1) elevated MHC-I by SCC tumor cells presentation driven by RT and ICI combination therapy facilitate a systemic expansion of memory CD8$^{\pm}$ T cell clonotypes which drive anti-tumor immunity and 2) MHC-I expression at baseline or when induced by RT may serve as a predictive marker for therapeutic response to RT and ICI combination therapy in HNSCCs.

#6647 Established 3D tumor-spheroid co-culture models demonstrate macrophage plasticity and unveil potential supportive roles of macrophages in the T cell-tumor-macrophage crosstalk post radiation therapy.

Aanchal Preet Kaur, Alejandro F. Alice, Megan R. Potuznik, Gwen Kramer, Jason Baird, David J. Friedman, Marka R. Crittenden, Michael J. Gough

Earle A. Chiles Research Institute, Providence Cancer Institute, Portland, OR

Ionizing radiation therapy (RT) has been characterized as an immunogenic event that in some tumors results in cell-death mediated activation of innate inflammatory and immunostimulatory mediators. These inflammatory mediators in turn modulate lymphocyte effector function in the tumor environment that can contribute to radiation-mediated control of tumors. We aim to model these interactions ex vivo, to identify the critical signals regulating immune function. We demonstrate that it is necessary to establish a three-dimensional model for crosstalk between tumor cells and immune cells to recapitulate myeloid and T cell responses to radiation. We have established 3D tumor spheroid co-culture models using murine MC38 colon carcinoma and Panc02-SIY pancreatic carcinoma cell lines with bone-marrow derived macrophages (BMDM). The spheroid cultures were exposed to 12 Gy RT and maintained in culture over a period of 5 days. Analyses were done using live-cell imaging and flow cytometry. Our findings demonstrate a decrease in hypoxia post RT, and exposure to RT increased the phagocytosis of dying cancer cells by macrophages. This was followed by a significant increase in CD80 and CD86 expression on the surface of macrophages in co-cultures on day 3 and day 4 post RT. These data matched our analyses of tumors treated in vivo with radiation and analyzed on day 4 post RT. In addition to RT-mediated upregulation of costimulatory molecules on macrophages, we also observed an increase in PD-L1 expression that may also impact T cell responses. To test T cell function in the 3D model, antigen-specific T cells were added to the Panc-02-SIY and BMDM spheroid co-cultures, which resulted in enhanced T cell proliferation in RT-treated groups. To assess the mechanism of macrophage activation in co-cultures, we evaluated HMGB1 as an innate adjuvant that may cause TLR4-mediated macrophage activation; however, the pattern of activation did not match that of RT. The involvement of the nucleic acid sensing cGAS-STING pathway was assessed by using BMDM from STING knockout (KO) mice in the 3D co-cultures. Similar upregulation of CD80 and CD86 were observed on STING KO macrophages in 3D co-cultures on day 4 post RT, indicating the observed phenomena to be independent of STING signaling. Ongoing studies aim to decrypt the innate downstream signaling pathways involved in RT-mediated polarization of macrophages so as to identify potential targeted therapies for tumor-associated macrophages, and also translate this to patient tumors.

#6648 Low-intensity pulsed ultrasound enhances the presentation of brain-derived antigens by facilitating the migration of antigen-presenting cells from the brain to the periphery.

M. Gallus[1], V. Andres Arrieta[2], A. Saijo[1], P. Chuntova[1], A. Yamamichi[1], J. Haegelin[1], S. Phyu[1], L. Phung[1], S. Amir-Kabirian[1], S. Lakshmanachetty[1], L. Chen[2], K. Habashy[2], A. Gould[2], C. Amidei[2], C. Lee Chang[2], R. Stupp[2], M. Canney[3], H. Okada[1];

[1]University of California San Francisco, San Francisco, CA, [2]Northwestern University, Chicago, IL, [3]Carthera, Lyon, France

Gliomas, the most common primary brain tumors, remain largely incurable despite advancements in surgical and adjuvant therapies. While immunotherapies offer promising avenues, their efficacy has been limited by formidable anatomical barriers, such as the blood-brain barrier (BBB), which restricts the migration of immune cells into the brain and impedes the efficient drainage of brain-derived antigens, establishing an immune-privileged environment. Consequently, neoplastic formations within the brain often escape detection by the peripheral immune system, complicating therapeutic interventions. The application of low-intensity pulsed ultrasound with microbubbles (LIPU/MB) has emerged as a potential solution, enabling the transient opening of the BBB. This facilitates drug transport and immune cell trafficking, including Chimeric Antigen Receptor (CAR) T cells, into brain tumors. However, challenges such as antigen-loss escape persist with CAR T cells. One proposed solution involves promoting antigen/epitope spreading by inducing the presentation of brain (tumor) antigens to the systemic immune system. To investigate this, we conducted intravital imaging using Colony-stimulating factor receptor 1 (CSFR1) and CX3CR1 reporter mice, visualizing antigen-presenting cell locomotion in the brain before and after LIPU/MB treatment using two-photon microscopy. Within one hour after LIPU/MB, we observed the migration of CSFR1+ and CX3CR1+ immune cells from the brain parenchyma and perivascular space into the bloodstream, a phenomenon absent prior to LIPU/MB treatment. Beyond that, flow cytometry identified $CD45^{intermediate}CD11b^{\pm}$-$CX3CR1^{\pm}$-$TMEM119^{\pm}$-$P2RY12^{\pm}$microglia-like' cells in the blood. To further assess the immunological effects of LIPU/MB on brain antigen presentation, we utilized transgenic mice expressing a minigene encoding four immunogenic peptides under the glial fibrillary acidic protein (GFAP) promoter. LIPU/MB treatment was associated with increased proliferation and priming of adoptively transferred CNS antigen-specific naïve T cells in cervical lymph nodes, ultimately homing into the CNS, indicating enhanced antigen presentation. Furthermore, in a subset of glioblastoma (GBM) patients undergoing LIPU/MB combined with doxorubicin and anti-PD-1 blocking antibodies, CD11b+CD14+P2YR12+ microglia were detected in blood samples during cycles 3-6 of treatment. This increase was absent in blood samples from healthy donors.Collectively, our findings suggest that LIPU/MB represents a novel approach to augment brain-antigen presentation in the periphery, holding potential implications for improving the immunotherapeutic management of gliomas.[M.G., V.A.A., A.M.S., and H.O. contributed equally to this work.]

#6649 Tumor treating fields (TTFields) induce an anti-tumor immune response in a pancreatic cancer mouse model.

T. Kan, T. Haj Khalil, Y. Barsheshet, **T. Voloshin**, A. Vorontsov, B. Brant, L. Koren, R. Blatt, S. Cahal, E. Zemer-Tov, R. Paz, A. Klein-Goldberg, C. Tempel Brami, S. Jacobovitch, A. Volodin, B. Koltun, C. David, A. Haber, M. Giladi, U. Weinberg, Y. Palti;
Novocure, Haifa, Israel

Background: Pancreatic ductal adenocarcinoma (PDAC) is a deadly malignancy with few therapeutic options. Tumor Treating Fields (TTFields) are low-intensity electric fields that disrupt cellular processes critical for cancer cell division and tumor progression and are approved for the treatment of glioblastoma and pleural mesothelioma. A phase 3 clinical trial is in progress to test the efficacy and safety of TTFields concomitant with standard-of-care gemcitabine and nab-paclitaxel (GnP) as front-line treatment of locally advanced PDAC. TTFields have been shown to induce immunogenic cell death (ICD) in cancer cells and elicit a systemic anti-cancer immune response. Accordingly, the benefit of applying TTFields together with immune checkpoint inhibitors (ICI) was demonstrated in a phase 3 study in patients with non-small cell lung carcinoma. This preclinical study investigated TTFields-induced immune responses in PDAC.
Methods: An orthotopic PDAC tumor model was established by inoculating 4X105 Panc02 pancreatic cancer cells with stable luciferase expression into the pancreas tail of immune-competent C57BL/6 mice. The mice were randomized into four groups following bioluminescence detection of tumor volume: control, TTFields (150 kHz, 10 days), GnP (50 mg/kg for each drug, i.p. injected once a week for a total of two administrations), and GnP + TTFields. At the end of treatment, tumor volume was measured using caliper, and blood was collected for spectral flow cytometry-based immunophenotyping and ELISA testing for the ICD marker HMGB-1. In vitro, Panc02 cells were treated for 72h with TTFields (150 kHz, 1.62 V/cm RMS) and examined by flow cytometry for apoptosis and ATP secretion (using quinacrine staining) and surface exposure of calreticulin.
Results: TTFields markedly reduced the tumor size in Panc02 tumor-bearing mice compared to control mice. Analysis of peripheral blood effector (CD62L-CD44+) and central (CD62L+CD44+) memory T cells demonstrated the induction of circulating effector-memory cytotoxic CD8+ T cells. Additionally, serum HMGB-1 concentrations were significantly elevated in mice treated with TTFields compared to control mice, implying the involvement of ICD in the response to TTFields. In vitro, TTFields application induced apoptosis of Panc02 cells and increased ICD, as indicated by increased surface exposure of calreticulin and ATP depletion. When TTFields were used in Panc02 tumor bearing mice concomitantly with GnP, a substantial reduction in tumor size was detected, and a complete tumor regression was observed in a number of mice.
Conclusions: Our results suggest that TTFields may enhance the effects of standard-of-care chemotherapy for the treatment of PDAC. Furthermore, TTFields were shown to induce ICD and activate an antitumor immune response in PDAC, supporting future studies evaluating the efficacy of TTFields together with ICI in PDAC.

#6650 Macrophage pro-inflammatory phenotype skewing by the application of tumor treating fields (TTFields).

T. Kan, Y. Barsheshet, B. Brant, T. Haj Khalil, **T. Voloshin**, A. Volodin, L. Koren, B. Koltun, A. Klein-Goldberg, E. Zemer-Tov, R. Paz, A. Haber, M. Giladi, U. Weinberg, Y. Palti;
Novocure Ltd, Haifa, Israel

Introduction: Tumor Treating Fields (TTFields) are low intensity electric fields that disrupt cellular processes critical for cancer cell viability. TTFields have previously been shown to induce immunogenic cell death, promote dendritic cell maturation, and elicit a systemic anti-cancer immune response in preclinical models. The benefit of applying TTFields together with immune checkpoint inhibitors (ICI) was demonstrated in a phase 3 study in non-small cell lung carcinoma. In the current research, we investigated possible effects of TTFields on regulation of macrophage phenotype.
Methods: Bone marrow-derived macrophages (BMDMs) were generated from the femurs and tibias of 5-8-week-old Balb\C mice. LPS+IFN-γ or IL-4 were applied to the BMDMs to induce polarization (M1 and M2, respectively). The BMDMs were then treated with TTFields (150 kHz, 24 h), and then examined by flow cytometry for surface expression of the macrophage biomarker F4/80 and the activation markers CD80, major histocompatibility complex class II (MHC II), inducible nitric oxide synthase (iNOS), CD206, and ARG-1. Cell supernatants were collected and analyzed by multiplexed secretion assay for secretion levels of CXCL1 (KC), IL-18, IL-23, IL-12p70, IL6, TNF-α, IL-12p40, TGF-β1, CCL22 (MDC), IL-10, IL-6, G-CSF, CCL17 (TARC), and IL-1β. Cell lysates were examined using a RhoA activation kit and Western blot to determine GEF-H1, c-Jun, and p65 phosphorylation levels.
Results: BMDMs exposed to TTFields demonstrated elevated expression of the pro-inflammatory M1 markers $CD80^{+}$ and MHC II^{high}, and decreased expression of the M2 markers CD206 and ARG-1. A pro-inflammatory secretion pattern was detected, with increased levels of CXCL1, IL-18, IL-23, IL-12p70, TNF-α, IL-12p40, CCL22, G-CSF, CCL17 and IL-1β. The treated cells further demonstrated RhoA activation and GEF-H1 phosphorylation, with subsequent activation of the transcription factors c-Jun and p65.
Conclusions: This study reveals a novel immunomodulatory role for TTFields, promoting *in vitro* pro-inflammatory polarization of macrophage.

#6651 Compromised TGFβ signaling and DNA repair primes immune poor tumors response to immune checkpoint blockade by activating NK cells.

J. T. Moore, J. Gkantalis, I. Guix, M. Barcellos-Hoff;
UCSF - University of California San Francisco, San Francisco, CA

We investigated the interplay between transforming growth factor beta (TGFβ) regulation of immunosuppressive signaling and immunogenic DNA repair. Loss of TGFβ signaling by cancer cells is accompanied by increased use of error-prone repair. We described a transcriptomic score, βAlt, that reports the TGFβ/DNA repair functional relationship. Pan-cancer analysis showed that high βAlt cancers (i.e., low TGFβ and high error-prone DNA repair) are sensitive to chemoradiation and have a greater fraction of genome altered compared to low βAlt cancers. Defective mismatch repair is associated with T cell infiltration and response to immune checkpoint blockade (ICB), hence we investigated the immune context of bAlt. Unsupervised clustering of RNAseq profiles 12 independent immunocompetent mouse tumor derived transplant (mTDT) tumors based on βAlt score indicated that high βAlt was associated with immune poor phenotype and lack of type I interferon signatures. A similar relationship was evident in the bladder, breast, and lung TCGA data. A high βAlt, immune poor mTDT in which T cells were only 20% of 10% CD45 were treated with monotherapy consisting of single fraction 10 Gy radiation, anti-PD-L1 or TGFβ inhibition, dual or triple treatment. Only monotherapy or combinations with radiation significantly increased survival. However, these ICB resistant tumors responded to triple treatment. Response was accompanied by increased tumor infiltrating $CD45^{+}$ cells ($P=0.02$), circulating CD8 T cells ($P<0.001$) and natural killer (NK) cells ($P<0.001$). As NK cells tripled and TGFβ broadly impairs NK cell effector function, we depleted NK cells to test whether they were required for the response to triple treatment. NK depletion completely abrogated response ($P<0.00001$) indicating NK cells can provoke an ICB response in high βAlt immune poor tumors. Both mouse tumors and human cancers show that loss of TGFβ signaling resulting in error-prone DNA damage response is strongly associated with immune poor tumors and suggests that TGFβ inhibition can override NK cell dysfunction to create vulnerability to ICB.

#6652 Advanced glioblastoma immunotherapy: Attenuated herpes oncolytic virus armed with anti-PD-1 antibody and IL-12.

L. Wang, X. Zhou, **X. Chen**, Y. Liu, Y. Zheng, R. Yan, Y. Liu, J. Zhao, G. Zhou;
ImmVira Co.,Ltd., Shenzhen, China

Background: Glioblastoma (GBM), the most common and deadly primary brain tumor in adults, has limited treatment options with poor outcomes. The urgent need for innovative treatments has spurred research into immunotherapy and oncolytic virus therapy as promising alternatives. Herein, we have developed a new generation oncolytic herpes simplex virus (oHSV) armed with IL-12 and anti-PD-1 antibody to provide a synergistic anti-GBM efficacy for immune-oncolytic therapy.

Methods: MVR-C5252, a novel oHSV, was created by genetic engineering, which included the removal of a 15-kb internal repeat (IR) region and both copies of the γ34.5 genes, along with the insertion of two exogenous genes encoding the anti-PD-1 antibody and IL-12. MVR-C5252 was characterized and assessed for its anti-GBM activities through a series of experiments as follows: 1) Safety assessments, including evaluations of neurotoxicity and latency-reactivation characteristics, were conducted in Balb/C mice. 2) Anti-tumor activities were evaluated in cell cultures, subcutaneous and orthotopic xenograft mouse models, and immunocompetent mouse models. 3) Mechanistic studies were performed to uncover the mode of action of MVR-C5252, with a specific focus on its ability to induce cell death in GBM cells and activate the immune response *in vivo*.

Results: 1) *In vitro* studies showed that MVR-C5252 is highly replication attenuated but with higher cell-killing activity in GBM cells compared to the first generation oHSV, R3616, which has γ34.5 deletions only. 2) Mechanistic studies showed that MVR-C5252 infection increased cell death by reducing CNTNRα expression, which typically prevents caspase 3 activation and has an anti-apoptotic effect in glioma cells. 3) Intracranial injection of MVR-C5252 revealed a remarkable safety profile, with over an 800-fold reduction in virulence compared to wild-type HSV-1. Furthermore, the mouse trigeminal ganglion (TG) infection model suggested that MVR-C5252 was unable to establish latency or reactivate in the TG. 4) *In vivo* subcutaneous and orthotopic xenograft mouse models showed that compared to the R3616 group, enhanced anti-tumor activity and extended survival were observed in the MVR-C5252 group. Additionally, in the syngeneic mice model, MVR-C5252 exhibited superior anti-tumor activity and immune activation over the backbone virus.

Conclusions: With the unique combination of safety, potent anti-tumor activity, and immune-stimulatory properties, MVR-C5252 makes it a big potential candidate to address the pressing need for effective treatment strategies of GBM.

#6653 Oncolytic virotherapy induces a long-term immune antitumoral response leading to glioma eradication.

Francesca Piaggio[1], Francesco Alessandrini[2], Chiara Riviera[3], Irene Appolloni[3], Davide Ceresa[1], Daniela Marubbi[3], Tatiana Gianni[4], Gabriella Campadelli-Fiume[4], **Paolo Malatesta**[3]

[1]IRCCS Ospedale Policlinico San Martino, Genova, Italy,[2]Department of Neurology, Northwestern University , Feinberg School of Medicine, Chicago, IL,[3]Department of Experimental Medicine (DIMES), University of Genoa, Genova, Italy,[4]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy

Oncolytic herpes simplex viruses (oHSVs) have shown promise as effective treatments against various cancers. Our study evaluated the efficacy of R-115, an oHSV retargeted to human Her2 (hHer2), fully virulent in its target cells and expressing murine interleukin 12 (mIL12), in a high-grade, immunocompetent murine glioma model. This model is based on orthotopically transplant of cells derived from PDGFB-induced primary gliomas in syngeneic mice, engineered to express hHer2. Our experimental design compared the impact of R-115 on gliomas where all cells expressed hHer2 against a setup where only about 50% of cells expressed hHer2. The latter aimed to replicate the heterogeneity of patient's high-grade gliomas, where not all cells express the target molecule. Strikingly, results in terms of overall survival and tumor eradication were similar in both setups, with about a quarter of animals showing complete glioma eradication. This suggests that mIL12-armed oHSV's impact is less about direct viral-induced cell death and more about the immune response elicited by the mIL12-expressing virus. This response effectively targets cells lacking the viral-targeted protein but likely sharing other neoantigens with hHer2-positive cells. Mice cured in both experimental setups were rechallenged with purely hHer2-negative cells. Almost all did not develop gliomas, indicating a strong immune response capable of rejecting the tumor. Plasma analysis revealed that R-115-treated mice from both setups were more immunoreactive against both hHer2-positive and negative cells compared to untreated mice. Further, co-culturing long-surviving mice's splenocytes with glioma cells showed increased cell division in CD8, CD4 and CD19 populations, and elevated IFN-γ, granzyme B, and TNF-α production. These findings underscore R-115's profound anti-cancer potential, especially its capacity to elicit an immune response effective against glioma cells, irrespective of their expression of the target molecule. This outcome, coupled with the results of the rechallenge experiments, is pivotal. It suggests that in a clinical context, an interleukin-12-expressing oHSV could effectively target not only residual cells post-surgical resection but also infiltrating cells that are distant from the site of virus administration. Encouraged by these promising findings, we are currently advancing our research with a novel oHSV that expresses mIL12 and targets EGFRvIII, a mutation found exclusively in tumor cells. This is aimed at enhancing the safety and translatability of this therapeutic approach.

#6654 Oncolytic virotherapy targeting high-grade glioma tumor antigens.

J. Hedberg, A. Martin, D. Kim, J. Navarro, A. Rivaldi, Y. Kim, I. Hernandez-Aguirre, E. Garfinkle, K. Miller, K. Cassady, E. Mardis;
Nationwide Children's Hospital, Columbus, OH

Glioblastoma, the most common primary brain malignancy in adults, is an aggressive cancer with five-year median survival of ~6.8%. New treatment options are urgently needed for glioblastoma and other high-grade gliomas (HGGs). Oncolytic viruses (OVs) are an emerging class of cancer therapy currently being evaluated as treatments for a variety of malignancies, including glioblastoma. Our labs developed OV C134, now under evaluation in a phase I clinical trial of recurrent glioblastoma (NCT03657576). In addition to directly infecting and lysing tumor cells, OVs are capable of stimulating anti-tumor immune responses. We previously showed in the CT2A syngeneic mouse model of HGG that treatment with a version of C134 engineered to express the shared tumor antigen Ephrin-A2 (EPHA2; commonly upregulated in glioblastoma) significantly increased survival and produced EPHA2-specific T cell responses. This finding led us to hypothesize that C134 could be further engineered to stimulate antigen-specific immune responses against tumor-specific neoantigens. We first assessed the impact of C134 treatment on immune cell dynamics in HGGs, by performing single cell RNA sequencing of CD45+ immune cell infiltrate from CT2A HGGs treated with C134 or saline (control). Clustering of these data identified 17 distinct immune cell types, and differential expression analyses revealed several C134-induced changes. These included increased expression of genes involved in antigen presentation and STAT signaling in microglia and macrophage subsets, the proliferation marker *Mki67* in germinal center B cells, the chemokine *Ccl12* from microglia, and tissue-resident memory marker genes *Fos* and *Jun* in T cells. These data suggest C134 treatment poises the tumor immune microenvironment for antigen presentation and antigen-specific immune responses. Next, we evaluated CT2A to identify candidate tumor neoantigens by isolating DNA and RNA from orthotopic tumors and DNA from tail snips of mice treated with saline or C134. We carried out RNA sequencing (tumors) and whole exome sequencing (tumor and normal), and employed the Personalized Variant Antigens by Cancer Sequencing (pVAC-Seq) computational pipeline. This pipeline takes somatic variant calls from the exome comparison of tumor to normal DNA, validates RNA expression of called variants, and feeds corresponding peptide sequences into algorithms that predict the binding of variant-containing peptides to major histocompatibility complex (MHC), thereby assessing for potential neoantigens. Our pVAC-Seq analysis revealed a conserved set of 1,264 tumor-exclusive variants expressed at the RNA level with high (ic50<500nm) predicted binding to mouse MHC. I will present details of C134-induced immune remodeling in syngeneic HGG models, and describe a plan to engineer C134 to express a prioritized set of neoantigens to evaluate how efficacy from OV therapy may be further enhanced in a patient-specific manner.

#6655 Oncolytic adenovirus dually expressing interferon beta and membrane-stable CD40 ligand increases polyfunctional $CD8^+$ T cells associated with antitumor activity.

M. J. Cantwell[1], A. N. Saltos[2], H. Zheng[2], D. Foresman[2], A. A. Beg[2];
[1]Memgen Inc., Houston, TX, [2]Moffitt Cancer Center, Tampa, FL

MEM-288 is a dual-transgene armed oncolytic adenovirus in phase 1 clinical development as a standalone agent and in combination with immune checkpoint inhibitors (ICI). It encodes two potent immune agonists: IFNβ and a recombinant membrane-stable chimeric form of CD40L (MEM40). We previously demonstrated this agonist combination is better than either agonist individually to activate conventional dendritic cells type 1 (cDC1) crucial for $CD8^+$ T cell cross-priming, and to increase tumor-antigen reactive $CD8^+$ T cells. Furthermore, first-in-human Phase 1 clinical trial (NCT05076760) results of MEM-288 for advanced non-small cell lung cancer (NSCLC) and other solid tumors showed MEM-288 tumor shrinkage was associated with systemic antitumor T cell immunity as demonstrated by cytokine, T cell clonotype, and tumor neoantigen analysis. Here, we investigated the precise nature of the localized and systemic T cell response induced by MEM40 + IFNβ in preclinical tumor models. Single-cell RNA sequencing of tumor infiltrating T lymphocytes (TILs) revealed that MEM40 + IFNβ elicited a strong increase in T cells expressing Granzyme B and PRF1, key effector cytokines and cytotoxicity mediators. We tracked the $CD8^+$ T cell response in CD45.1 C57BL/6 mice implanted with syngeneic B16 tumor expressing the model antigen OVA. Interestingly, intratumoral treatment with adenovirus encoding MEM40 + IFNβ did not cause an appreciable increase in absolute numbers of antigen-reactive $CD8^+$ T cells, despite tumor growth inhibition. However, MEM40 + IFNβ compared to control unarmed adenovirus induced a significant ($p < 0.005$) 5-fold increase in polyfunctional $IFNγ^+TNFα^+PRF1^+$ and $IFNγ^+TNFα^+$Granzyme B^+ $CD8^+$ T cells. Polyfunctional $CD8^+$ T cells have the capacity to simultaneously produce effector cytokines and cytotoxicity mediators and are known to be strongly associated with antitumor T cell activity. The robust polyfunctional $CD8^+$ T cell response in these studies is consistent with T cell-driven antitumor activity found in both our preclinical tumor experiments and our clinical studies in advanced NSCLC patients responding to MEM-288. Overall, our findings suggest MEM40 + IFNβ generates a strong polyfunctional $CD8^+$ T cell response in the TME that warrants continued evaluation to understand the pleiotropic mechanisms of this cancer immunotherapy.

#6656 Revolutionizing solid tumor treatment : Viral protein-targeted CAR-T with oncolytic virus.

S. Choi[1], K. Kim[1], S. Lee[1], J. Choi[1], S.-J. Lee[1], Y. Lee[2], J. Kim[3], H. Lee[3], K. Kim[3], M.-S. Park[3], S.-W. Song[1];

[1]R&D center, CellabMED Inc., Seoul, Korea, Republic of, [2]Hanyang University, Ansan, Korea, Republic of, [3]Vaccine Innovation Center, Institute for Viral Diseases, Korea University College of Medicine, Seoul, Korea, Republic of

Major challenges for CAR-T cell therapy in solid tumors include various limitations due to the issue of appropriate antigen selection, tumor heterogeneity, and the immune-suppressive tumor microenvironment (TME). To overcome these hurdles, we've developed a novel therapy, CLM-202 which is a combination therapy of oncolytic Newcastle disease virus (NDV) and NDV F protein-targeted CAR-T cell therapy (NDV F CAR-T). After NDV infects tumor cells, NDV envelope protein F is expressed on the tumor cell surface. NDV F CAR-T recognizes NDV F protein and kills the tumor cells. This approach can be applied to patients with various indications, regardless of the presence of the target protein. Using NDV to deliver antigens minimizes the risk of tumor recurrence due to tumor heterogeneity. Furthermore, it mitigates off-target toxicity by targeting oncolytic virus-derived proteins, not human proteins. Oncolytic NDV also triggers a potent immune response within the tumor microenvironment, thereby altering the immunosuppressive conditions of the tumor and improving CAR-T efficacy. Therefore, CLM-202 can be a multipurpose solution for solid tumors. We have developed a second-generation CAR-T cell therapy, NDV F CAR-T, which can be used in combination with an oncolytic virus known as NDV. NDV F CAR-T is designed to specifically target the F protein expressed when cells are infected by NDV. It incorporates a single-chain variable fragment (scFv) derived from an antibody that can bind specifically to the F protein of NDV-infected cells. To assess the activity of NDV F CAR-T in tumor cells against a variety of solid tumors as indications, we conducted several experiments. We initially confirmed the expression of the F protein in NDV-infected tumor cells. We also conducted cytotoxicity tests to confirm NDV F CAR-T's ability to induce death in NDV-infected tumor cell lines. Furthermore, to assess the efficacy of NDV F CAR-T in an in vivo model, we established an orthotopic mouse model. In this model, we administered NDV via intratumoral injection, followed by the single-dose administration of NDV F CAR-T to perform the efficacy test. We have confirmed that NDV infects all solid tumor cell lines representing different indications and induces the expression of the F protein in infected tumor cells. Furthermore, we have observed that NDV infection in these diverse tumor cells results in robust tumor cell-killing activity by NDV F CAR-T and the subsequent activation of CAR-T. Moreover, in an orthotopic mouse model, we have demonstrated that the administration of NDV followed by NDV F CAR-T induces potent tumor growth inhibition. In summary, our research proposes a novel therapeutic strategy, CLM-202 that utilizes NDV F CAR-T and NDV to overcome the limitations of CAR-T cell therapy in solid tumors, including tumor heterogeneity and immune-suppressive tumor microenvironments. This approach aims to effectively treat a wide range of indications.

#6657 Oncolytic Vaccinia Virus Carrying OPCML Tumor Suppressor is active in Epithelial Ovarian Cancer.

Y. Tang[1], Y. Liu[2], M. Deng[1], F. Huang[1], J. Wang[3], P. Blake[4], H. Gabra[4], **Q. Wang**[2];
[1]Guangxi Medical University, Nanning, China, [2]Guangxi Medical University Cancer Hospital (Guangxi Tumor Control Institute), Nanning, China, [3]Genvira Biosciences Inc., Ottawa, ON, Canada, [4]Papyrus Therapeutics Inc., West Chester, PA

Objective: Epithelial Ovarian cancer (EOC) has the highest mortality rate among gynecologic malignancies, necessitating novel therapeutic approaches. Viral oncolytic immunotherapy with recombinant oncolytic vaccinia virus (OVV) offers promise for advanced-stage cancer treatment. OPCML is a GPI-anchored 3 Ig-domain tumor suppressor inactivated by somatic methylation in 87% of EOC. OVV with OPCML (OVV-OPCML) gene insertion may have potential as a therapeutic agent. This study explores the oncolytic, signaling-inhibitory, anti-angiogenic and synergistic immunotherapeutic properties of OVV-OPCML in EOC treatment, evaluating its therapeutic potential.

Methods: To create OVV-OPCML, the virulent vaccinia virus Copenhagen strain F3L site was modified with OPCML cDNA, confirmed by qPCR and western blot. Oncolytic potential was assessed through in vitro and in vivo EOC cell infection with OVV-OPCML. Real-time cell analysis (RTCA) assessed cell proliferation. Xenograft tumor models in nude mice were used to evaluate in vivo oncolytic activity, while OVV-OPCML combined with anti-PD-1 treatment was tested using a syngeneic orthotopic EOC mouse model (ID8) in C57BL/6 immunocompetent mice. Serum IFN-γ and TNF-α were quantified via ELISA. Receptor Tyrosine Kinases, angiogenesis and phosphorylation together with immune markers were examined by western blotting and by multiplex immunohistochemistry (mIHC) analysis of tumor sections.

Results: OVV-OPCML selectively infected OC cells, leading to viral replication and tumor cell death, while sparing normal ovarian cells in-vitro. OPCML protein expression increased post-infection. OVV-OPCML reduced ERBB2, EGFR, and FGFR1 expression in SKVO3 OV cells. Intratumoral or intraperitoneal (IP) OVV-OPCML administration in human ovarian cancer nude mouse models reduced tumor growth and improved survival. IP in-vivo OVV-OPCML in combination with anti-PD-1 treatment in vivo, in the IP ID8 syngeneic model demonstrated synergy with survival improvement. H&E staining showed tumor cell damage without significant harm to normal tissues. Protein expression of ERBB2, EGFR, FGFR1, and their phosphorylated forms decreased. CD31, VEGFR2, p-VEGFR2 (Tyr1175), and p-VEGFR2 (Tyr1214) downregulation suggested tumor angiogenesis disruption. OVV-OPCML treatment elevated serum TNF-α and INF-γ levels and increased CD8+ T cells and PD-L1 expression in OVV-OPCML treated syngeneic tumors.

Conclusions: OPCML gene enhances OVV selectivity against OC cells through direct oncolysis and OPCML protein production, inhibiting specific RTKs, suppressing angiogenesis, and activating antitumor immune responses synergistically with anti-PD-1. OVV-OPCML therapy shows promise as a targeted strategy for ovarian cancer treatment.

#6658 TcE armed oncolytic virus VSV-GP combines oncolysis and T-cell retargeting for improved efficacy.

A. Ponnurangam[1], T. Schwaiger[1], S. Walter[2], S. Bartl[1], M. Mayr[1], M. Petersson[1], T. Schoenberger[3], F. Heinemann[3], P. Gross[3], W. Rist[3], S. Kasturirangan[4], C. Lempp[3], J. Petschenka[3], **K. Das**[1], N. Tobias[1];

[1]ViraTherapeutics GmbH, Rum, Austria, [2]Boehringer Ingelheim RCV GmbH & Co KG, Vienna, Austria, [3]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach a.d. Riss, Germany, [4]Boehringer Ingelheim Pharmaceutical, Inc., Ridgefield, CT

Background: Oncolytic viruses, such as the chimeric vesicular stomatitis virus variant VSV-GP have dual modes of action, direct tumor-cell killing, and activation of tumor-specific immunity. While tumor cells deficient in type I interferon (IFN) response are permissive to VSV-GP replication and killing, IFN competent tumor cells are protected from VSV-GP-mediated oncolysis. Our previous data demonstrated that VSV-GP therapy turns immunologically 'cold' tumors 'hot' by increasing infiltration of T cells into the tumor. The aim of this study was to use the VSV-GP platform to locally express a T cell engager (TcE) molecule to redirect these T cells to destroy non-permissive IFN competent tumor cells expressing the target of the TcE on their cell surface.

Methods: We selected EpCAM as the target antigen and used a bispecific EpCAM-TcE molecule consisting of two variable single chain fragments against EpCAM and CD3, respectively. VSV-GP encoding EpCAM-TcE (VSV-GP-EpCAM-TcE) or an invariant control TcE (VSV-GP-TNP-TcE) were generated as previously described. T cells were co-cultured with human target cells expressing EpCAM on their cell surface, either infected with the VSV-GP-EpCAM-TcE virus or with supernatant from VSV-GP-EpCAM-TcE infected cells. T cell activation, proliferation, degranulation and cytokine secretion were analyzed by flow cytometry and multiplex cytokine assays as a measure of TcE mediated cross-linking of T cells to their target on cancer cells. Patient-derived head and neck squamous cell carcinoma (HNSCC) tumors were sectioned into approximately 200 µM slices and infected with the virus. T cell activation was measured by cytokine secretion. The therapeutic potential of VSV-GP-EpCAM-TcE was tested *in vivo* in cell-line derived xenograft (CDX) models implanted in immunodeficient mice humanized with donor-derived PBMCs or CD34+ cells.

Results: Virus fitness was maintained for VSV-GP encoding the TcE molecule. Using co-culture assays, we demonstrated that EpCAM-TcE molecule is successfully expressed by VSV-GP and can activate both CD4+ and CD8+ T cells resulting in proliferation, degranulation, and cytokine secretion. Furthermore, we validated the concept using patient-derived HNSCC tumor slices which are representative of complex human tumor ecosystems. We could confirm that cancer cells infected by VSV-GP-EpCAM-TcE virus express functional TcE molecule and activates T cells to secrete IFNγ and TNFα. Finally, we tested the concept in two different CDX models where VSV-GP-EpCAM-TcE showed improved tumor growth inhibition due to a combined effect of oncolysis and T cell activation by EpCAM-CD3 TcE.

Summary: The oncolytic virus VSV-GP can be successfully armed with a TcE to redirect tumor-infiltrating T cells to destroy tumor cells which are not permissive to viral replication. This resulted in an enhanced therapeutic efficacy compared to just the oncolytic effect.

#6659 Oncolytic herpes simplex virus expressing XCL1 and FLT3L modulate the intratumoral immune response and improve the anti-tumor efficacy in a metastatic breast tumor model.

Himanshu Soni[1], Liqun Gu[2], Sylvie Roberge[2], Heena Kumra[2], Hiroshi Nakashima[1], E. Antonio Chiocca[1], Yves Boucher[2]

[1]Harvey W. Cushing Neuro-oncology Laboratories (HCNL), Department of Neurosurgery, Harvard Medical School and Brigham and Women's Hospital, Boston, MA,[2]Edwin L. Steele Laboratories, Radiation Oncology, Massachusetts General Hospital, Boston, MA

Patients with metastatic breast cancer (MBC) have a dismal prognosis, with a 5-year survival rate of only 26%. The inadequate infiltration of immune cells targeting the tumor microenvironment (TME) is a key factor contributing to this low survival rate. Immune effector cells, including CD8+ cytotoxic T cells, NKT cells, and NK cells, play a crucial role in targeting tumor cells. The activation of immune effector cells relies on the presence of conventional type I dendritic cells (cDC1), which present tumor-specific antigenic peptides on their surface. Recent studies have identified the chemokine XCL1 and growth factor FLT3L as critical factors involved in the intratumoral recruitment and expansion of dendritic cells. To enhance the activity of cDC1 in the TME we designed an oncolytic herpes simplex virus (oHSV) expressing XCL1 and FLT3L. The recombinant oHSV, rQ1-XF, was generated by incorporating LoxP sites into the viral genome through recombination with a carrier plasmid carrying the polycistronic cassette. To enhance the intratumoral penetration of oHSV injected intravenously in primary tumors and MBC lesions in the lung, we employed the cancer drug ganetespib, which can increase the permeability of tumor blood vessels. In comparison to untreated mice, ganetespib combined with rQ1-XF reduced the size of primary tumors and induced a short but significant increase in the survival of mice. Additionally, compared to the ganetespib alone treatment, ganetespib combined with rQ1-XF reduced MBC burden in the lung. The flow cytometry analysis of immune cells revealed an increased infiltration of CD11c+CD11b- dendritic cells in primary tumors treated with oHSV combination therapy compared to the ganetespib only control. A similar trend was also observed in CD4 T cells and CD8 T cells in primary tumors. As expected, there was a negative correlation between tumor burden and the infiltration of CD4+ T cells and CD8+ T cells in primary tumors. Ganetespib combined with oHSV also reduced the infiltration of CD4+ regulatory T cells (Tregs) in primary tumors, however the number of Tregs increased with primary tumor size as well as tumor burden in the lung. This could potentially lead to reduced efficacy of tumor-infiltrating dendritic cells in activating effector T cells in tumors treated with ganetespib and rQ1-XF. Moreover, the combination therapy did not yield significant alterations in the populations of DCs, CD4+ T cells, and CD8+ T cells in lungs with metastatic lesions. Further studies are underway to investigate whether the depletion of Treg cells in combination with rQ1-XF enhances effector T cell activation against metastatic breast tumor cells. The findings of this study will provide valuable insights into the effectiveness of using XCL1 and FLT3L-armed oncolytic viruses in patients with MBC.

#6660 The novel codon-modified Zika virus CDX-602 shows anti-tumor efficacy and remodels the tumor microenvironment in preclinical models.

N. Jahan[1], Y. Zhao[1], K. Blagovic[1], Y. Wang[2], J. Coleman[2], S. Mueller[2], **J. K. Kaufmann**[1];
[1]Codagenix, Inc., Cambridge, MA, [2]Codagenix, Inc., Farmingdale, NY

Multiple oncolytic viruses have been shown to induce multifaceted changes in the tumor microenvironment, that ultimately support induction of anti-tumor immune responses. We have previously demonstrated that CodaLytic, a codon-modified influenza virus, can kickstart the cancer immunity cycle at various steps in several mouse models with differing baseline immune contextures. Here, we are describing the activity of a new codon-modified virotherapeutic derived from the same synthetic viral engineering platform [Coleman *et al.*, Science 2008]. Zika virus strain MR766 was synthetically codon-modified at 664 positions in the envelop gene to yield CDX-602. Virus was originally passaged in Vero cells and working stocks were expanded in BSR-T7 cells for *in vivo* use after titration on MA104.1 cells. Efficacy after intratumoral injection of 10^7 PFU/dose CDX-602 alone or in combination with 200 µg/dose αPD-1 blockade (RMP1-14, i.p.) was determined in subcutaneous B16-F10 melanoma and orthotopic EMT6 breast cancer models (n = 10). Changes in the tumor immune infiltrate were characterized using flow cytometry 6 or 8 days after treatment initiation, respectively (n = 5). In the immunotherapy-resistant B16-F10 model, CDX-602 monotherapy led to highly reproducible tumor growth inhibition (TGI, 52%, $p < 0.0001$ vs vehicle control), resulting in modest, but significant prolongation of median survival (25%, $p < 0.01$). Anti-tumor efficacy correlated with increased tumor immune infiltration with $CD4^+$ and $CD8^+$ T cells ($R^2 = 0.68$ and 0.67, respectively, $p < 0.01$). Importantly, frequencies of cross-presenting dendritic cells (cDC) were increased 3.8-fold ($p < 0.0001$) after virus treatment, while no compensatory influx of $CD206^+$ macrophages was observed, suggesting immune contexture changes conducive to anti-tumor immune induction. Efficacy was confirmed in the EMT6 model, in which monotherapy TGI was 44% and thus on par with αPD-1 blockade (50%, both $p < 0.0001$ vs control). Combination viroimmunotherapy in this model further improved efficacy, leading to 71% TGI and a doubling in complete regressions to 40%. Inclusion of CDX-602 in the treatment regimen led to similar changes in immune infiltration, in particular recruitment of $CD8^+$ T cells and cDCs (9.7-fold and 6.9-fold increase after combination, respectively). Additional *ex vivo* analyses to confirm induction of anti-tumor immune responses are ongoing. Taken together, this preclinical data establishes CDX-602 as a novel virotherapeutic candidate that engages multiple mechanisms of action that contribute to anti-tumor activity. CDX-602 is the second virotherapeutic candidate derived from Codagenix's codon modification platform, further supporting the utility of this synthetic viral engineering technology for viroimmunotherapy of cancer and highlighting its potential across multiple viral species.

#6661 Profiling response to oncolytic adenovirus and immune checkpoint inhibitors by mass cytometry in a triple negative breast cancer mouse model.

W. Xu[1], Q. Lin[2], Y. Li[2], B. Filimon[1], S. Shin[1], M. Olson[2], M. Chen[2];

[1]NorthShore University HealthSystem, Chicago, IL, [2]The University of Chicago, Chicago, IL

Immune checkpoint inhibitors (ICIs) based immunotherapy has found success in treating breast cancers but for more immunosuppressive cancer types, especially most of triple negative breast cancers (TNBCs), response rates generally are low. Also, combination immunotherapy with oncolytic adenoviruses (OAVs) has been shown to induce a more immune inflamed phenotype in many pre-clinical studies. Here, by using a 40-antibody panel for mass cytometry, we profiled comprehensive changes of cell phenotypes in a TNBC mouse model both systemically and in the tumor microenvironment in response to the treatment of ICIs and/or a new systemically delivered, TGFβ signaling inhibiting OAV, mHAdLyp.sT. The samples in this study were collected on day 16 of tumor cell inoculation, while mHAdLyp.sT were applied by tail vein on day 7 and 9, and anti-PD-1 and anti-CTLA-4 antibodies were injected Intraperitoneally on day 8, 10, 12, 14. After sample processing and data acquisition on Helios system, a standard workflow was applied for data preprocessing including normalization, compensation, transformation, diagnostic analysis, marker ranking, cell population identification, visual representation, differential analysis, and statistical analysis. In blood samples, for T cell clusters, percentages of effector $CD8^{\pm}$ T cells, naïve $CD8^{\pm}$ T cells, and $CD44^{low}CD62L^{low}$ $CD8^{\pm}$ T cells among total cells were increased by mHAdLyp.sT, anti-PD-1, and anti-CTLA-4 combination when compared to the buffer group but none of these significant changes were observed in groups treated with mHAdLyp.sT or ICI antibodies alone. Combination treatment also increased percentages of clusters of $CD272^{high}CD44^{high}$ DCs, $CD44^{high}CD62L^{low}$ B cells, and $CD44^{high}$ macrophages significantly. In spleen, combination treatment significantly increased several T cell clusters, including $TCR\beta^{high}CD38^{high}ROR\gamma t^{high}$ T cells, $TCR\beta^{high}$ $CD4^{\pm}$ T cells, effector $CD8^{\pm}$ T cells, $TCR\beta^{high}CD44^{low}CD62L^{low}$ $CD8^{\pm}$ T cells, and $CD11b^{high}$ $CD8^{\pm}$ T cells when compared to the buffer group. Interestingly, while ICIs treatment increased several macrophage clusters, such as $CD44^{high}$Ly-6G/C^{high} macrophages, $CD11b^{low}$ macrophages, and $CD44^{high}CD11b^{high}$ macrophages, they are not significantly increased in the combination treatment group. In the tumor, we did not detect any significant changes by the combination treatment in the clusters we identified now although the average percentages of several clusters were either increased or decreased. We will refine these algorithm-generated clusters from tumors once we obtain our data from day 24 sample collection point for advanced analysis. In short, our current results suggested that the combination therapy is more potent in generating cytotoxic T cells and other anti-tumor immune cell populations systemically in the early stage of the treatment and tumor progression.

#6662 Modified oncolytic viruses with immunomodulatory genes enhance anti-tumor efficacy.

Z. Song, G. Ding, A. Xia, W. Ma, Q. Li, C. He, X. Chen, Z. Zhang, Q. Gu;
WuXi AppTec, Nantong, China

While chemotherapy and radiotherapy are considered first-line treatments for most cancers, their significant side effects have prompted ongoing innovation and the discovery of novel cancer treatment strategies. Oncolytic viruses (OV) as one of the most advanced cancer treatments have shown promising results in treating otherwise untreatable types of cancer in last two decades. After selectively targeting tumor cells, OVs could directly kill cancer cells, and induce a powerful anti-cancer immunity.

Recently, we evaluated the anti-tumor effect of a modified OV (mOV) *in vitro* and *in vivo*. Firstly, the expression of the transgenes were validated on different tumor cells by FCM and ELISA assay. The results showed that a susceptible cell line was identified which has high expression efficiency of transgenes. In order to evaluate the cytotoxicity of mOV, CCK-8 assay was performed on 30+ tumor cell lines. It indicated that mOV has stronger killing effect on susceptible cells through inducing cellular apoptosis. To further evaluate the biological activity of the transgenes on immune cells, mOV-infected tumor cells and supernatant were collected to treat T cell, NK cell or MoDC. The results demonstrated that mOV infection could significantly promote T cell and NK cell activation, and increase the maturation of moDC cells, resulting in the secretion of IFN-γ by CD8+ T cells. In the *in vivo* efficacy study, MC38 syngeneic model was used to test the anti-tumor effect of mOV. The result showed that mOV could significantly inhibit the growth of the treatment side tumor, and reduce the contralateral tumor to a certain extent. Blood FCM analysis revealed that the percentage of IFN-γ+CD3+, IFN-γ+CD4+ and IFN-γ+CD8+ T cells were markedly increased by mOV treatment compared with vehicle. In addition, IHC analysis of tumor showed that mOV treatment could promote the infiltration of CD4+, CD8+ and CD86+ positive cells. To study the safety or PK of the mOV, viral bio-distribution and shedding assay were performed to detect viral genome at different tissues or excreta. It indicated that mOV was almost undetectable or at very low levels for 14 days after administration. In conclusion, our study revealed that modified OVs with immunomodulatory genes have good anti-tumor efficacy both *in vitro* and *in vivo*, which could obviously induce the activation of several immune cells. Moreover, the mOV genome was almost undetectable or at very low levels in mouse tissues and excreta.

Keywords: Oncolytic virus, immunotherapy, immunomodulatory genes

#6663 Innovative CPMV immunotherapy: A canine model for poor-prognosis breast cancer treatment.

G. Valdivia[1], D. Perez-Alenza[1], L. Barreno[1], A. Alonso-Diez[1], J. Affonso de Oliveira[2], M. Suarez-Redondo[1], S. F. Fiering[3], N. F. Steinmetz[2], **L. Pena**[1];
[1]Complutense University of Madrid, Madrid, Spain, [2]University of California San Diego, San Diego, CA, [3]Geisel School of Medicine at Dartmouth, Madrid, NH

Cowpea Mosaic Virus (CPMV) is a plant comovirus non-infectious to humans or animals. In mice models, intratumor immunotherapy (ITI) with CPMV devoid of nucleic acids (empty CPMV, eCPMV) and full CPMV results in a highly potent, systemic, antitumor immune response, with full CPMV being much more effective. Dogs with spontaneous mammary (breast) cancer (MC) serve as a valuable model for studying breast cancer (BC), bridging the gap between studies in rodents and human clinical trials. Canine MC develops in the presence of an intact immune system and has a unique advantage of shorter endpoint periods compared to women BC clinical trials. New immunotherapeutic approaches are necessary for poor-prognosis BC, such as triple-negative BC, metastatic BC, and the very aggressive and lethal inflammatory BC (IBC). Previous studies by our group using eCPMV ITI in dogs with MC revealed a substantial reduction in tumor size in both injected and non-injected tumors (abscopal effect), extended survival, and improved quality of life without any adverse effects or toxicity. In this clinical trial, we employed full CPMV nanoparticles ITI in dogs with poor-prognosis (inoperable) MC, comparing them with untreated controls. Regular tumor volume assessments and clinical evaluations have been conducted. Histopathology and immunohistochemistry of immune cell populations were performed to study tumor microenvironment (TME) modifications. Thus far, 5 dogs have been treated: four cases of inflammatory mammary cancer (IMC) and one case of metastatic MC. After at least two weekly CPMV ITI sessions, a significant reduction in tumor volumes was observed. In IMC cases, marked clinical improvement of typical signs (warmth, edema, erythema, and cutaneous pain) was observed in 3 out of 4 cases, and tumor reduction was so remarkable in one dog that surgery was recommended and successfully carried out. In IMC CPMV ITI cases, the survival of 2 dogs exceeded historical IMC records; the dog with metastatic MC maintains stable disease after one year, which is also superior to controls. TME studies showed that eCPMV immunotherapy significantly increased intratumor inflammatory infiltrates, neutrophils, T lymphocytes, and macrophages. Additionally, Treg cells (FOXP3+)/T lymphocytes (CD3+) ratio was significantly reduced. Our results demonstrate that immunotherapy with eCPMV induces a potent immunostimulatory effect on dogs with poor-prognosis MC by recruiting and activating neutrophils as the main drivers of the inflammatory response. This process reduces the immunosuppressive action of regulatory T lymphocytes and produces a breakdown of tumor immune suppression. These findings underscore the therapeutic potential of CPMV nanoparticles ITI in the management of canine IMC and metastatic MC. From a translational point of view, this study lays the groundwork for advancing the treatment of human breast cancer.

#6664 In situ vaccination with hyper-interferon sensitive influenza induces adaptive immune response and sensitizes murine non-small cell lung cancer to PD-1 blockade.

R. Salehi-Rad, Y. Du, T. Zhang, Y. Shi, B. Liu, S. Ren;
UCLA - University of California Los Angeles, Los Angeles, CA

Despite recent advances in immunotherapy with immune checkpoint inhibitors (ICI), many patients with non-small cell lung cancer (NSCLC) fail to respond or develop resistance after an initial response. The exclusion of T cells from the tumor or the presence of a dysfunctional T cell compartment within the tumor microenvironment (TME) constitute two central hallmarks of resistance to ICI in patients with NSCLC. Seminal studies have identified that loss of LKB1 in *KRAS*-mutant NSCLC drives resistance to ICI, potentially by suppressing STING, thereby leading to dysregulation of the interferon (IFN) signaling. There is a pressing demand for the development of innovative immune therapies designed to bolster anti-tumor T cell responses to overcome resistance to ICI. *In situ* vaccination (ISV) with oncolytic viruses has emerged as a promising, antigen-agnostic strategy capable of conditioning the TME and amplifying anti-tumor T cell responses. We engineered a live attenuated viral vaccine, Hyper-Interferon Sensitive virus (HIS), by conducting a genome-wide functional screening and introducing eight interferon (IFN)-sensitive mutations in the influenza A genome. We utilized multiple syngeneic murine models of NSCLC with distinct driver mutations [$Kras^{G12D}/P53^{+/-}/Lkb1^{-/-}$ (KPL); $Kras^{G12D}/P53^{+/-}$ (KP); and $Kras^{G12D}$ (K)] and varying tumor mutational burden to assess the safety and efficacy of intratumoral HIS virotherapy. Compared to wild-type (WT) influenza, HIS replication was attenuated, enhancing its potential as a safe option for cancer therapy. HIS ISV elicited robust yet transient type I IFN responses in murine NSCLCs, leading an influx of polyfunctional effector Th1 CD4 and cytotoxic CD8 T cells into the tumor. HIS ISV demonstrated enhanced anti-tumor efficacy compared to WT in multiple syngeneic murine models of NSCLC. This efficacy was dependent on host type 1 IFN responses and T lymphocytes. HIS ISV synergized with anti-PD-1 to eradicate immune resistant LKB-1 deficient NSCLC in a subset of mice, resulting in improved overall survival and enduring systemic tumor-specific immunity. These studies provide compelling evidence to support further clinical evaluation of HIS as a novel ‘off-the-shelf’ ISV strategy for patients with NSCLC refractory to ICI.

#6666 Leveraging an obligate anaerobic salmonella strain for targeted cargo delivery in the tumor microenvironment to restore immunotherapy sensitivity.

Y. He, J. Huang;
University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Pok Fu Lam, Hong Kong

Tumor immunotherapy is often hindered by unresponsive cold tumor microenvironments (TME). Although *Salmonella*-based immunotherapy has shown potential in overcoming these cold immune environments, safety concerns remain. Our study introduces a genetically reprogrammed *Salmonella typhimurium* strain (OASL) with a dual safety lock to enhance safety and modify immunosuppressive TME, sensitizing tumors to immunotherapies. We propose using OASL to alter the cold TME and locally release therapeutic cargos such as PDL1 nanobodies and tumor-specific neoantigen peptides identified through bioinformatic algorithms, activating immune cells within the tumor while minimizing side effects. We selected YB1, an obligate anaerobic Salmonella strain that thrives in hypoxic environments, as our base strain and incorporated a self-lysis genetic circuit for controlled bacterial growth and cargo release upon reaching a specific population density within the tumor core. We assembled and evaluated the self-lysis gene circuit in vitro, documenting the event using an optical density (OD) reader and confirming OASL's ability to express genetic cargos through western blot analysis. We then investigated OASL's therapeutic effect in vivo and characterized TME changes using flow cytometry and immunohistochemistry staining. Our results indicate that OASL undergoes lysis and releases cargos upon reaching a specific population density in vitro. Additionally, OASL-delivered neoantigen peptides elicited a tumor-specific immune response in vivo. OASL also demonstrated the capacity to modify the TME and restore sensitivity to PDL1 in previously unresponsive tumors, enhancing therapeutic effects.

#6670 Could immunotherapy offer potential in managing bacterial dysbiosis in prostate cancer?.

T. Oliver[1], B. Nedjai[2], E. Lane[2], F. Chinegwundoh[3], P. Rajan[1], J. Cuzick[2];
[1]Barts Cancer Centre, London, United Kingdom, [2]Wolfson Institute, London, United Kingdom, [3]Barts Cancer Institute, London, United Kingdom

Background: Since 2006 three studies, involving 289,089 adolescents, demonstrated a significant association (1.67(0.79-3.55),1.7(1.03-2.70),2.37(1.19-4.73)) between pubertal acne and poor outcome prostate cancer(PC) 30+ years later. This suggested *Cutibacterium acnes*, amicroaerophylic bacterium, might be contributing to PC bacterial dysbiosis analogous to the role of *H. pylori* in stomach cancer and explain why circumcision reduces PC risk. Six years ago, using MALDI-TOF, we demonstrated that the presence of seven obligate anaerobe species in addition to *C. acnes* were increased in PC and linked to increased PSA. This presentation studies stored samples from the PROVENT chemoprevention randomised PC active surveillance phase 2 trial analysed using 16S rDNA sequencing, and comparing obligate anaerobe frequency with those detected by culture and MALDI-TOF identification and their influence on PSA expression.
Methods: 89 urines of PROVENT trial patients were studied using 16S rDNA sequencing and followed for 24 months. In addition, 39 previously reported MALDI-TOF screened cohort patients (21 PCs and 18 BPHs) followed for 43 months. The frequency of 7 obligate bacterial genera (Actinobaculum, Finegoldia, Prevotella, Peptoniphilus, Peptostreptococcus & Viellonella) was studied.
Results: Twenty six of 89 (29%) PROVENT urine samples had a majority of bacteria detected as obligate anaerobes (mean=68%), while it was 12 of the 39 (31%) in PC tested in MALDI-TOF. In the combined series, those patients (n=38) with obligate anaerobes had mean PSA of 9.59 ug/L, while those without obligate anaerobes had a mean PSA of 6.29 ug/L (n=90), (t=-2.925, p = 0.0058). In the MALDI-TOF series, statistically increased urological intervention rate was associated with the presence of anaerobes (p=0.045, Fisher's exact test).
Discussion: These findings suggest that obligate anaerobe bacterial dysbiosis could be contributing to raised PSA through prostate cell damage, and possibly participating in the chronic inflammation and hypervascular changes that are seen in precancerous lesions. Checkpoint inhibitors have shown little benefit in prostate cancer. Recent reports from animal model studies of BCG resistance have suggested a short course combination of anti PDLI and anti NKG2a could break immune tolerance associated with expression of HLA-E and this approach could be of use to break tolerance to bacterial dysbiosis in the future.

#6671 Harnessing radiation and microbiome modulation for enhanced antitumor immune response in early-stage NSCLC treatment.

S. J. Feigenberg, F. Costabile, S. Pierini, N. Kostopoulos, R. Perales-Linares, M. Uribe-Herranz, E. Ben-Josef, C. Koumeis, **A. Facciabene**;
Univ. of Pennsylvania, Philadelphia, PA

In recent years, research has highlighted radiotherapy's (RT) capacity to induce Immunogenic Cell Death (ICD), activating tumor-infiltrating Dendritic Cells (DCs) for cross-presenting tumor-associated antigens (TAAs), leading to robust systemic immune responses. Simultaneously, emerging studies underscore the gut microbiota's crucial role in modulating immunity across diverse human diseases. Our investigation focuses on gut microbiome modulation, specifically using oral Vancomycin, a locally acting antibiotic. This approach enhances the direct and abscopal antitumor effects of RT, evident across multiple cancer models. Findings demonstrate Vancomycin significantly increases CD8+ T cell infiltration, targeting TAAs in primary and abscopal tumors, leading to elevated IFN-β and IFN-γ expression in tumor-derived lymph nodes (TDLNs). Vancomycin's remarkable influence on RT effectiveness directly traces back to its impact on the gut microbiome composition, including a shift from gram-positive to gram-negative bacteria, enrichment of Vancomycin-resistant strains, reduced bacterial diversity, and decreased SCFA concentrations.. Building on these compelling outcomes, we initiated a randomized pilot study involving stage I non-small cell lung cancer (NSCLC) patients undergoing stereotactic body RT (SBRT). Patients were randomized to receive Vancomycin versus placebo, administered at 125 mg four times daily, commencing one week before SBRT and continuing during and after treatment for five total weeks. In an interim analysis, despite a small sample size, significant improvements in Progression-Free Survival (PFS) and Overall Survival (OS) were observed in those receiving the combination therapy. Additional investigations have reaffirmed our earlier findings in mice, emphasizing the depletion of specific bacterial populations, the rise in Vancomycin-resistant strains, and substantial reductions in SCFA concentrations in stool samples. Pathway analysis further underscores the impact of oral Vancomycin on gene expression related to the cross-presentation of TAAs. Together, these findings from both murine and human studies robustly affirm the concept that modulating the gut microbiome with Vancomycin can augment the ability of RT to trigger an anti-cancer immune response. We posit that this pioneering strategy is not only cost-effective but also holds the promise of substantially enhancing patient outcomes.

#6672 Unraveling the microbiome: antibiotic impact on CAR T therapy and the synergistic potential of vancomycin in enhancing antitumor immunity.

A. Facciabene, M. Uribe-Herranz, V. Bhoj;
Univ. of Pennsylvania, Philadelphia, PA

The landscape of treating hematologic malignancies has undergone a revolutionary transformation with the advent of Anti-CD19 chimeric antigen receptor T cell therapy (CART-19). Despite its success, persistent challenges like disease relapse and CAR-mediated toxicities remain. A comprehensive multicenter study involving 228 individuals revealed a significant association between antibiotic administration, particularly piperacillin/tazobactam, meropenem, and imipenem/cilastatin (P-I-M), targeting anaerobes within four weeks preceding CART-19 therapy, and adverse outcomes, including worsened survival and increased neurotoxicity. Intriguingly, another antibiotic, Cefepime, also used for neutropenic fever, displayed a positive trend when compared with P-I-M. This highlights the intricate relationship between the modulation of the intestinal microbiome and outcomes in CART-19 therapy for B cell malignancies. Building on these critical observations, our study delved into the impact of vancomycin-induced gut microbiota dysbiosis on chimeric antigen receptor (CAR) T immunotherapy. Utilizing preclinical models of CD19+ A20 lymphoma and CD19+ B16 melanoma, we discovered that mice receiving vancomycin alongside CART-19 therapy exhibited enhanced tumor control and increased cross-presentation of tumor-associated antigens (TAAs) compared to those receiving CART-19 alone. This effect was further validated through fecal microbiota transplants from healthy human donors to pre-conditioned mice, replicating the favorable findings. Importantly, our study extends to clinical correlates, as B cell acute lymphoblastic leukemia patients treated with CART-19 and oral vancomycin displayed elevated CART-19 peak expansion compared to unexposed patients. These compelling results underscore the profound influence of the gut microbiota on CAR T cell therapy and suggest that vancomycin-induced gut microbiota modulation may emerge as a potent strategy to enhance therapeutic outcomes across various tumor types.

#6673 Tumor microbial burden is regulated by mast cells and determines immunotherapy responses.

H. Rajaei[1], J.-H. Jang[1], H. Liu[1], E. Faraoni[1], O. Le Roux[1], V. Chandra[1], V. Tahan[1], L. Li[1], E. Riquelme[2], J. White[3], L. Diaz Jr.[4], F. McAllister[1];

Immune checkpoint inhibitors (ICI) have notably improved overall survival rates across various cancers, particularly in cases of mismatch repair deficient cancer (MMRd). However, numerous factors influence patient response following ICI treatment. Beyond genetic factors, mutations, and levels of immune cell infiltration, several studies highlight the correlation between the gut microbiome and treatment response rates. Furthermore, specific bacterial compositions have been observed to shift during therapeutic interventions. Notably, studies have demonstrated that patients who used antibiotics before and during ICI treatment exhibited lower progression-free survival and overall survival, serving as evidence for this association. Our previous investigations elucidated the impact of distinct tumor microbial burdens on modulating immune activation. Consequently, our hypothesis posits the substantive involvement of the interplay between tumor microbial burden and the immune system response to ICI treatment.

We evaluated the presence of intra-tumoral microbes within Colorectal cancers (CRC) by examining TCGA data. Patients with elevated microbial levels demonstrated heightened immune activity and better survival rates. Using cybersport analysis, we validated increased mast cell infiltration in CRC patients with abundant microbes. Quantification involved assessing bacterial burden through 16s rRNA via FISH staining and mast cell counts using tryptase via IHC staining. Reducing bacterial load in MC38 cancer model, achieved by locally administering antibiotics, led to a diminished immune response when PD-1 was introduced to these mice. Cross-referencing TCGA data, we identified upregulated genes in CRC patients with high microbial burden and downregulated genes in mice receiving local antibiotics after MC38 cell implantation. The common genes were associated with immune responses, suggesting a strong correlation between bacterial burden and immune activity in CRCs. In conclusion, the high burden of bacteria in CRC improves immune response to ICI and increases the infiltration of mast cells, which all contribute to better survival rates.

#6674 Fungi utilizes exocytosis pathway to facilitate the release of DAMPs from pancreatic cancer cells.

A. Alam, S. S. Mayengbam,, S. Senchanthisai, B. Irmak, P. Dey;
Roswell Park Comprehensive Cancer Center, Buffalo, NY

Recent studies overwhelmingly show that microbiome is pervasive to tumor and play key role in immunotherapy response and reprograming tumor immune microenvironment (TIME). However, it remains unknown how microbiome facilitates the host-immune cell crosstalk and promote tumorigenesis. Our recent study in pancreatic ductal adenocarcinoma (PDAC) show that intratumor fungal microbiome facilitate the release of a damage associated molecular pattern (DAMP) molecule IL-33 from cancer cells. The secreted IL33 from cancer cells in turns recruits ILC2 and T_H2 cells which promotes PDAC tumorigenesis. However, the mechanism of fungal mediated IL-33 release from PDAC cells remains unknown. Our follow up studies using high throughput integrated proteomic profiling and immunoprecipitation revealed a group of exocyst complex proteins interacting with IL-33 in the presence of fungus. The exocyst complex consists of eight sub-unit proteins that tethers the secretory vesicles to the plasma membrane and implicated in cellular exocytosis. We found EXOC6B a component of exocyst complex, modulates IL-33 release via exocytosis pathway from the PDAC cells. Genetic depletion of EXOC6B resulted in shunted IL-33 release and significantly abrogated PDAC tumor progression. Mechanistically, we found that mycobiome activates a non-canonical TLR2-CARD9 pathway, thereby driving IL-33 nucleocytoplasmic transport and exocytosis. This study identifies a unique mechanism of EXOC6B mediated release of IL-33 that expands our knowledge on how host-mycobiome interaction shapes PDAC tumor microenvironment by intricate molecular mechanism. Our study identifies EXOC6B as a new therapeutics target involved in the mycobiome driven IL-33 secretion in pancreatic cancer.

#6675 Dissecting the relationship between mucin 5AC and the lung/gut microbiome in the pathogenesis of K-ras mutant lung cancer.

M. T. Grimaldo[1], M. J. Clowers[1], A. Krishna[1], K. E. Larsen[2], N. Karimi[2], Y. H. Rezai[2], A. Gaitonde[2], F. Khalaj[2], H. Liu[1], F. McAllister[2], S. Moghaddam[2]; [1]The University of Texas MD Anderson Cancer Center UTHealth Houston Graduate School of Biomedical Sciences, Houston, TX, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Non-small cell lung cancer, including its most common subtype, lung adenocarcinoma (LUAD), is one of the most prevalent and lethal forms of cancer worldwide. This is largely due to patients having progressed to an advanced stage of disease by the time of diagnosis. Thus, better understanding the pathogenesis of early LUAD is paramount for the identification of key targets and development of preventive and therapeutic strategies for clinical management of the disease. *KRAS* mutations are the most common oncogenic driver alteration in human LUAD. Previously, we have found that *KRAS* mutant LUAD patients whose tumors harbor high expression of Mucin 5 AC (MUC5AC), a main airway secretory mucin, have significantly lower survival and poor prognosis. Mucins are membrane-bound and secreted hydrophilic proteins essential in clearance of allergens, pathogens, and debris in the lung airway. However, overproduction of mucins, such as MUC5AC, plays roles in the pathogenesis of airway diseases such as chronic obstructive pulmonary disease (COPD) and lung cancer. Given the known effect of mucin polymers on bacterial growth and the immune microenvironment in the context of other airway inflammatory diseases, in this study, our objective is to better understand the MUC5AC-to-microbiome relationship using a lung epithelial specific mouse model of KRAS-mutant LUAD (CC-LR) and test the combinatorial effects of genetic deletion of MUC5AC (CC-LR/Muc5ac$^{-/-}$) and the pan-microbiome depletion on tumor progression, the lung immune contexture, and microbiome (lung and gut). Thus far, we found that genetic deletion of MUC5AC or pan-microbiome depletion significantly decreases the tumor burden (66% vs 50%, respectively). Additionally, both groups show to have a significantly decreased percentage of tumor-specific Ki67+ cells, a cell proliferation marker, and ERG+ cells, an angiogenesis marker, in comparison to the CC-LR controls. The combination of the lack of MUC5AC with pan-microbiome depletion has also shown to reduce tumor development that needs further investigation. These findings highlight the need to better understand the mechanistic interaction between mucins and the lung/gut microbiome in the context of KRAS-mutant lung cancer which we are currently exploring. It also suggests that their relationship could be a key target for modulation, potentially leading to the development of a minimally invasive alternative preventive and/or treatment modality against *KRAS*-mutant LUAD.

#6676 Microbiome modification impacts PSCA directed chimeric antigen receptor (CAR) T cell therapy for prostate cancer.

J. P. Murad[1], L. Christian[1], Y. Yamaguchi[1], L. Lopez[1], C. Ouyang[1], H. Sato[2], B. Jarman[2], S. Stromberg[2], S. J. Forman[1], S. Van Dien[2], S. Culler[2], S. J. Priceman[1];

[1]City of Hope National Medical Center, Duarte, CA, [2]Persephone Biosciences, San Diego, CA

Background: There is growing evidence that responsiveness to immunotherapy is influenced by the composition of a patient's gut microbiota. Recent analysis identified strong correlations between abundance of gut microbial species and positive response to immune based therapies in cancer patients. Further, enrichment of commensal microbes can promote immunostimulatory effects, immune based anti-tumor responses, and increased cytotoxic T cell abundance within the TME. Conversely, the presence of gut microbes known to cause inflammatory states in gut tissues may be correlated to negative immunotherapy outcomes or toxicities. To this end, we aimed to evaluate the impact of microbiome manipulation on gut microbe diversity, systemic immunity, local TME, and PSCA-targeted chimeric antigen receptor (CAR) T cell therapy in our established syngeneic prostate cancer mouse model.

Methods: In an immune competent mouse model of PSCA+ prostate cancer developed in our lab, we sequentially modified the gut microbiome using antibiotic clearance followed by distinct human derived fecal matter transfers (CPI-FMT, HD-FMT, or No-FMT). Simultaneously, we treated microbiome modified tumor bearing mice with PSCA-targeting CAR T cells and measured differences in anti-tumor efficacy and survival. To provide mechanistic insight, we performed longitudinal whole genome sequencing (WGS) of fecal matter microbes and RNA sequencing on spleen and tissues following FMT administration.

Results: In our model, a unique checkpoint inhibitor (CPI) treated patient derived human FMT (CPI-FMT) improved PSCA-CAR anti-tumor responses relative to healthy donor (HD-FMT) or No-FMT treatment controls. CPI-FMT administration also significantly improved overall survival in CAR T cell and non-targeting T cell control treated mice. Temporal analysis of microbes present in the gut following CPI-FMT and HD-FMT treatment show CPI-FMT treated mice exhibit favorable maintenance of gut microbe species richness and significant increase in microbiota diversity. We identify CPI-FMT provides an enrichment of specific microbes associated with preservation of gut homeostasis and improved immune response. RNA sequencing analysis on tumor tissues show differential transcription of immune related pathways following FMT which may influence immune and CAR T cell function.

Conclusions: We show that our mouse prostate cancer model is sensitive microbiome modulation and can significantly impact PSCA-CAR T cell directed anti-tumor responses. Temporal WGS analysis of gut fecal matter reveal enrichment suggest specific species abundances which may promote gut homeostasis over dysbiosis or inflammatory states and may account for improved CAR T cell response. We aim to further develop this model to interrogate candidate targeted microbiome modifiers which may impact mechanisms which promote CAR T cell and immune function.

#6678 Microbial regulation of anti-tumor immunity in colorectal cancer.

C. Chung[1], E. Ozcelik[1], J. Habel[1], J. Zhang[1], Y. Qin[1], L. Garcia[1], J. Merrill[1], T. Chung[1], S. Lyons[1], Z. Shen[2], J. G. Fox[2], P. Westcott[1], S. Beyaz[1];
[1]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, [2]MIT, Cambridge, MA

Colorectal cancer (CRC) is the 3rd leading site of cancers and cause of cancer cell death. Although Immunotherapies revolutionized cancer therapy, the majority of CRC patients, particularly with metastatic disease, do not respond to the treatments. This necessitates a better mechanistic understanding of the tumor-immune cell interactions in the context of CRC. Microbiome influences multiple biological aspects of the host including immune responses against cancers. Here, we show that the gut microbiome influences cancer MHC-I and -II expression levels and restricts tumor progression and metastasis, resulting in longer survival in 3 different CRC models and two different mouse strains. We found that the anti-tumor effects are dependent on T cells and B cells. Interestingly, depletion of B cell negated anti-metastatic effects of gut microbiome. Mechanistically, MHC-II expression in cancer cells mediates the anti-tumor effects of the microbiome. MHC-II upregulation on human CRC organoids enhances cancer-immune cell interactions and associated apoptosis, demonstrating an anti-tumor role and significance of MHC-II in human CRC. Thus, gut microbes that enhance MHC-II antigen presentation promotes anti-tumor immunity and may be utilized to enhance efficacy of immunotherapy in metastatic CRC.

#6679 Deciphering the mechanism of action of a live biotherapeutic product for the treatment of cancer.

E. Katkeviciute, F. Ferraro, M. Schwill, P. Busenhart, A. Montalban-Arques;
University of Zurich, Zurich, Switzerland

Intestinal microbiota is essential in shaping the immune system and its functions. In our effort to harness the potential of beneficial gut microbiota, we identified specific bacterial species that are less abundant in colorectal cancer patients compared to healthy individuals. Oral supplementation of these bacteria causes an effective anti-tumor activity in various cancer models through specific activation of cytotoxic T-cells. Based on these results, we aimed to identify the mechanism of action of this bacterial treatment. In vivo studies were performed in C57BL/6 and BALB/c mice. MC-38, CT-26, B16, LLC1.1 and 4T1 cells were used for the heterotopic tumor injections. Immunophenotyping was performed using flow cytometry and immunohistochemistry. Metagenomics analysis and whole genome sequence were performed to identify the bacterial strains. Metabolomics analyses were conducted to analyze bacterial supernatant and serum compositions of mice and patients. Since we found that the bacterial treatment led to a systemic anti-tumor effect, we analyzed serum of the mice that received the bacteria and found that a specific metabolite was highly upregulated compared to untreated mice. Analysis of the medium supernatant from cultures of the bacterial strains led to the discovery that metabolite identified in the serum is being produced by our bacteria. Applying this bacterial metabolite alone in the mouse cancer models led to a similar immune activation and anti-tumor effect as the supplementation with our bacterial strains. Furthermore, we identified the receptor that is targeted by this molecule through experiments with known agonists and antagonists for the target. The anti-tumor effect of the bacteria as well as the bacterial metabolite was blocked through the application of a receptor antagonist, proving that activation of this receptor is the mechanism that drives the enhanced anti-tumor immune response. Activation of the receptor, which is mainly expressed on macrophages led to enhanced IL-12 production and recruitment of cytotoxic T-cells into the tumor. Together, we have fully characterized the mechanism of action of our bacterial treatment, including the secreted active metabolite, the target receptor, and the activated immune cells. We are developing a live biotherapeutic product for the treatment of cancer based on oral administration of lyophilized bacteria. The known mechanism of action of our bacteria helps us to optimize the efficacy of our product, define the right dosage and understand possible side effects. Additionally, it enables us to improve patient selection and prediction of treatment response. Since our product is based on commensal bacteria that are commonly present in healthy individuals, we expect a very good safety and tolerability profile. Therefore, our therapy aims to significantly improve the efficacy of cancer treatment as well as the quality of life of cancer patients.

#6680 High-fiber diet induces favorable gut microbiota, reduces immunosuppression, and inhibits lung cancer development.

Manvi Sharma[1], Yuejiang Liu[1], Hannah Moreno[2], Inti C. T. Reischle[1], Mohamed A. Jamal[3], Tieling Zhou[1], Zahraa Rahal[1], Chidera O. Chukwuocha[1], Ke Liang[1], Robert R. Jenq[3], Matthew C. Ross[2], Kristi L. Hoffman[2], Humam Kadara[1]

[1]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[2]Molecular Virology and Microbiology, Baylor College of Medicine, Houston, TX,[3]Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX

Emerging evidence suggests that resident microbial communities act as a central regulator of host homeostasis. The dynamic structure, composition, and function of gut microbiota can be influenced by numerous factors, among which nutritional profile act as most crucial determinant. Microbial consortia inhabiting the gut have been implicated in the etiology and pathogenesis of various cancers and are known to influence cancer immunosurveillance and response to immunotherapy. Despite these known associations, the underlying mechanisms by which dietary interventions such as those rich in fiber (high-fiber diet) regulate gut-immune axis in prevention of lung cancer are poorly defined. Here, we employed a human-relevant mouse model in which knockout of G-protein coupled receptor 5A (*Gprc5a*$^{-/-}$) and exposure to tobacco lead to development of preneoplasia and lung adenocarcinoma (LUAD). Mice were randomly grouped based on dietary treatment: no fiber (control), 10% cellulose, 10% pectin-inulin following weaning (early life) or after transplant of MDA-F471 NNK-induced LUAD cells (dietary intervention). Tumor growth and volumes were most significantly reduced in mice fed a high-fiber pectin-inulin diet. Notably, anti-tumor effects of the high-fiber diet were observed in both early life and later dietary intervention settings. 16S rRNA-Seq analysis of fecal pellets revealed significant differences in gut alpha as well as beta diversity, the latter indicating clear separation of community structure between fiber-deprived versus high-fiber diet groups. Evidently, gut microbiota of pectin-inulin fed mice displayed significantly elevated relative abundance of *Bacteroides sartorii*, *Bacteroides caecimuris*, *Akkermansia muciniphila* and *Bifidobacterium pseudolongum,* taxa that have been reported to be strongly associated with favorable responses to immunotherapy. High-fiber fed mice also showed significantly reduced fractions of tumor-promoting genera such as *Odoribacter* and *Alistipes.* These effects were accompanied by widespread changes in the tumor immune microenvironment between fiber-rich and fiber-poor groups. Pectin-inulin fed mice displayed enhanced antitumor immune responses evident by remarkably increased fractions of B lineage cells, cDC1s and M1-likemacrophages and, conversely, reduced levels of activated cDC2s, M2 macrophages and polymorphonuclear myeloid-derived suppressor cells. Our findings inform on novel mechanisms by which dietary fiber robustly impacts gut consortia and immune milieu in the inhibition of LUAD. Our findings also suggest that the incorporation of dietary fiber in cancer treatment (e.g., immunotherapy) could improve outcomes for patients with LUAD.

#6681 Altered microbial community stability and increases in circulating B cells are associated with the development of severe immune related adverse events during ICI-immunotherapy.

R. C. Simpson[1], E. R. Shanahan[2], I. P. Silva[1], I. L. Reijers[3], J. M. Versluis[3], A. M. Menzies[1], G. Maria[1], U. Palendira[2], J. S. Wilmott[1], C. Blank[3], R. A. Scolyer[1], G. V. Long[1];

[1]Melanoma Institute Australia, Sydney, Australia, [2]The University of Sydney, Sydney, Australia, [3]Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Immune related adverse events (irAEs) are a major hurdle to the success of immune checkpoint inhibitor (ICI) immunotherapy. There is increasing evidence that the gut microbiota influences irAE development, however the microbe-immune crosstalk underpinning this remains cryptic.

Methods: Paired pre- & post-treatment (baseline/week 6) stool samples from 129 Australian and Dutch melanoma patients treated on trial with neo-adjuvant combination anti-PD1/anti-CTLA4 immunotherapy were analyzed with 16S rRNA gene sequencing. Matched PBMCs at both timepoints were analyzed using mass cytometry (n=71).

Results: ICI immunotherapy resulted in changes in the relative abundance of specific bacterial groups in the faecal microbiota, however the microbial community as a whole remained relatively stable. In particular enhanced oralization of the gut microbiome was observed with treatment, including a significant increase in the relative abundance of oral *Streptococcus* species in the gut (P=0.0004). These changes were particularly evident in patients whose microbial communities were *Bacteroidaceae* (Ba)-dominated at baseline, and those who developed severe (grade 3+) irAEs. Indeed, Ba-dominated microbiomes were linked with comparatively higher rates of severe irAEs compared to patients with *Ruminococcaceae* (Ru)-dominated gut microbiomes (P= 0.0440). Furthermore, Ba patients developed severe irAEs earlier during treatment, prior to week 6 (P=0.0016). A significant reduction in transitional B cells (CD24+ CD38hi CD27-) (P<0.0001) and an increase in activated B cells subsets (CD27- CD38- CD24- populations) (P=0.0022) were observed between baseline and week 6 across all patients who developed or went on to develop severe irAEs. Most notably, Ba patients who developed early, severe irAEs specifically had significantly higher frequencies of overall circulating B cells (P=0.0018) and lower frequencies of ICOS+ Tregs at week 6 post treatment (P=0.0005), which was not observed in Ru-dominated irAE patients.

Conclusions: Higher risk of early, severe irAEs were associated with *Bacteroidaceae*-dominated gut microbiomes, reduced microbial community stability, and increases in activated circulating B cells during treatment. We postulate that differing baseline microbial community assemblages are associated with altered pre-established intestinal homeostasis influencing the likelihood of irAE development. Together, the data highlights a potential relationship between B cells, the gut microbiota and irAE development which may point to early steps in the induction of irAEs during ICI immunotherapy.

#6682 Bile acid profiles and racial disparities in colorectal cancer: Exploring the protective role of secondary bile acid derivatives.

H. Dai[1], P. G. Wolf[2], L. Tussing-Humphreys[3], E. Mutlu[3], J. M. Ridlon[1], R. Gaskins[1];
[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Purdue University, West Lafayette, IN, [3]University of Illinois at Chicago, Chicago, IL

Background: Colorectal cancer (CRC) is the third leading cause of cancer death in the United States, with diet and gut microbiota-derived bile acids implicated as long-term risk factors. The interplay between bile acids and immune cell differentiation, particularly of macrophages and T-cells, is a crucial aspect of the CRC microenvironment. Given the high-animal-fat diets' influence on the microbiome's production of hydrophobic secondary bile acids such as deoxycholic acid (DCA) and lithocholic acid (LCA), this study investigates the potential immunomodulatory effects of their lower concentrations and their isomers in possibly fostering M2-like macrophage expansion.
Methods: Clinical samples were obtained during colonoscopies with no tumor findings at Rush University Medical Center, Chicago. RNA was extracted from colonoscopy biopsies for NanoString RNA expression analysis, while bile acids were isolated from both lyophilized stool and frozen serum samples. To explore the immunological effects of secondary bile acids, the macrophage RAW 264.7 cell line, alongside peritoneal macrophages and bone marrow-derived macrophages (BMDMs) from C57BL/6J mice, were treated with LCA and LCA isomers. Following the bile acid treatment, LPS (100 ng/mL) or IL-4 (40 ng/ml) was added to elicit pro-inflammatory or anti-inflammatory states, respectively. After 48 hours, conditioned media were collected for enzyme-linked immunosorbent assay (ELISA), while cells were analyzed by flow cytometry and rt-qPCR.
Results: Contrary to initial hypotheses, the levels of DCA and LCA levels were not significantly different between African American and non-Hispanic White subjects. Notably, allo-isomers and oxo-derivatives of these bile acids, which may promote Treg and M2-like macrophage expansion, were substantially lower in African American subjects. Ex vivo treatments with isoalloLCA and IsoLCA led to notable changes in the M2 macrophage differentiation and shifts in PGE2 production upon exposure to inflammatory or anti-inflammatory stimuli, suggesting a nuanced alteration in the macrophage-mediated inflammatory response.
Conclusion: This study highlights a significant ethnic variation in bile acid profiles, with a potential impact on immune modulation and CRC risk. The reduced presence of certain bile acid isomers in African American subjects may influence the risk of CRC through altered macrophage differentiation and function. These findings emphasize the need for personalized dietary and therapeutic strategies to modulate the bile acid metabolome, potentially reducing CRC disparities.

#6683 The abundance of *Fusobacteria nucleatum* in tumor tissue is a prognostic factor in patients of right-sided colorectal cancer.

T. Miyasaka, T. Yamada, S. Kuriyama, A. Matsuda, K. Uehara, S. Shinji, Y. Yokoyama, G. Takahashi, T. Iwai, K. Takeda, S. Kanaka, H. Yoshida;
Nippon Medical School, Tokyo, Japan

Background: A significant association between the gut microbiome and colorectal carcinogenesis, as well as cancer progression. It has been reported that *Fusobacteria nucleatum* (*F. nucleatum*) is one of the most famous bacteria associated with colorectal cancer (CRC). It has been reported that the abundance of *F. nucleatum* is associated with colorectal cancer-specific survival (CSS), however it remains unclear for association with *F. nulceatum* and relapse-free survival (RFS). If *F. nucleatum* has a significant involvement in tumor progression of colorectal cancer, the abundance of *F. nucleatum* should be associated with not only CSS but also RFS in colorectal cancer. In this study, we measured the bacterial mass of F. nucleatum in tumor tissue of CRC patients in Stage II-III to explore the differences in prognosis. **Methods**: We included patients with CRC in stage II-III who underwent surgical treatment at Nippon Medical School Hospital between January 2017 and December 2020 except patients who received preoperative chemoradiotherapy and had multiple cancers. We measured the absolute of *F. nucleatum* copy number of the DNA exacted tumor tissues using droplet digital PCR. **Results**: 253 patients with CRC were included. 128 patients had pathological stage II and 125 patients had pathological stage III. Among 253 patients, 104 patients had right-sided CRC, 89 patients had left-sided, and 60 patients had rectal cancer. *F. nucleatum* was detected in 166 patients (65.6%), and the median of *F. nucleatum* copy number was 1.08 (range; 0.00 - 2791.3). *F. nucleatum* copy number was more abundant in right-sided CRC than in left-sided and rectal cancer (p= 0.02, p=0.01). There was no significant difference between stage II CRC and stage III. We categorized patients into two groups based on the median cut point of *F. nucleatum* copy number: the *F. nucleatum-high* group and the *F. nucleatum*-low group for comparison with clinicopathological features and prognosis. Patients with high abundance of *F. nucleatum* exhibited T4 of tumor depth (p=0.03), right-sided CRC (p=0.01), longer tumor circumference (p <0.001), longer tumor length (p <0.001), and no lymph node metastasis (p=0.024). There was no significant difference in relapse-free survival between the *F. nucleatum*-high group and *F. nucleatum*-low group among whole patients (p=0.53). Analyzing divided tumor location, in right-sided CRC high abundance of *F. nucleatum* was significantly associated with shorter relapse-free survival than low abundance (p=0.02), while in left-sided and rectal cancer there was no significant difference (p=0.61). **Conclusion**: *F. nucleatum* was more abundant in right-sided CRC and associated with relapse-free survival only in right-sided CRC. *F. nucleatum* may make a greater impact on right-sided CRC than on left-sided and rectal cancer.

#6684 Impact of fecal microbiome on the efficacy of neoadjuvant chemo-immunotherapy and colitis adverse events: Findings from the NADIM II Trial.

Introduction: The balance and composition of the gut microbiome play a pivotal role in modulating the host immune system, and they have been associated with survival outcomes in patients undergoing immunotherapy-based treatments and immune-related adverse events. In this study, our objective was to analyze the fecal microbiota of non-small-cell lung cancer (NSCLC) patients with locally advanced disease undergoing neoadjuvant chemo-immunotherapy (IO-CT).
Methods and patients: Baseline stool samples were collected from 86 resectable stage IIIA/B NSCLC patients enrolled in the NADIM II clinical trial (NCT03838159). The patients were randomly assigned to receive either neoadjuvant nivolumab plus chemotherapy (CT) or CT alone. DNA extraction was performed using the QIAamp PowerFecal DNA Kit (Qiagen), and the samples were analyzed using the Ion AmpliSeq Microbiome Health Research assay (ThermoFisher). The NGS analysis utilized the AmpliSeq Microbiome Health w1.3 workflow. Alpha diversity was assessed using the Simpson and Chao1 Index.
Results: Among the 86 collected stool samples, 77 were deemed valid for analysis. *Bacteroides* were the most common genus with a relative percentage (RP) of 18.9% ± 14.8 followed by *Faecalibacterium* (13.4% ± 7.8). The presence of bacteria from the genera *Bifidobacterium*, and *Faecalibacterium* was associated with improved progression-free survival (PFS) [HR = 0.4 (0.16-0.98), and HR = 0.08 (0.01-0.72), respectively] and overall survival (OS) [HR = 0.19 (0.06-0.62)], and HR = 0.04 [0.01-0.43], respectively), in the experimental arm. The detection of *Faecalibacterium prausnitzii* (validated by qPCR) was associated with improved PFS [HR = 0.17 (0.04-0.76)] and OS [HR = 0.05 (0.01-0.29)] in the experimental. On the other hand, detection of bacteria from the genera *Synergistes*, *Lactobacillus*, and *Anaerotruncus* was associated to higher risk of disease progression [HR = 9.9 (1.2-85), HR = 3.7 (1.5-9.1), and HR = 12 (1.4-110)] and death [HR = 51 (3.2-820), HR = 6.7 (2-23), and HR = 25 (2.3-280)] in this set of patients.In the entire cohort, patients whose samples were in the highest tertile of alpha diversity, had significantly prolonged PFS compared to those with intermediate or low diversity [HR = 0.39 (0.16-0.94)]. Finally, 25 colitis adverse events (CAE) occurred in 18 patients, including two Grade 3 (2.3%) and four Grade 2 (4.6%) events. A higher RP of *Bacteroides* were found in patients who did not suffer colitis events (P = 0.016), whereas higher RP of *Coriobacterium* were detected in patients who suffered CAE (P = 0.023).
Conclusions: Our findings suggest that composition of the gut microbiome may play a crucial role in the effectiveness of neoadjuvant IO-CT in NSCLC patients. Specifically, the presence of *F. prausnitzii* may enhance the antitumor activity of these treatments.

#6685 Control of melanoma development by *B. rodentium* in germ free mice.

X. Diaz Olea[1], K. Beede[2], A. Osterman[1], D. Scott[1], C. Petucci[3], D. Kelly[3], A. Ramer-Tait[2], Z. Ronai[1];
[1]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, California, CA, [2]University of Nebraska-Lincoln, Lincoln, NE, [3]University of Pennsylvania, Philadelphia, PA

Growing evidence supports the importance of the gut microbiota in controlling tumor development, often via activation of anti-tumor immunity. Earlier studies from our laboratory identified 11 bacterial strains that were sufficient to inhibit melanoma development by inducing anti-tumor immunity in germ-free mice. Of these, three were predominant at the time of tumor collection. We thus set out to address whether fewer bacterial strains may be sufficient for melanoma growth inhibition. Here, we demonstrate that the administration of one bacterial strain, *B. rodentium*, was sufficient to attenuate melanoma growth in gnotobiotic mice. In all cases, gnotobiotic mice were also administered the altered Schadler flora (ASF), a mixture of 8 bacterial strains that are provided to establish minimal flora in these mice. RNAseq-based gene expression studies identified enrichment of immune-related genes, suggesting enhanced anti-tumor immunity. Metabolomic analysis identified reduced levels of tryptophane and isoleucine, which were implicated in control of immune system function. These findings point to a mechanism which may provide novel means to alter anti-tumor immunity and limit melanoma growth.

#6686 The mechanism of gut microbiome-mediated immune activation on the clinical efficacy of PD-1 blocking treatment in solid tumors.

N.-T. Lin[1], S. Fukuoka[1], D. Motooka[2], Y. Shigeno[3], T. Irie[1], D. M. Tourlousse[4], K. Murotomi[4], Y. Sekiguchi[4], H. Tamaki[5], M. Shindo[6], T. Tsuji[6], H. Wake[6], K. Goto[7], T. Doi[8], K. Shitara[8], K. Watanabe[9], Y. Maeda[9], S. Nakamura[2], Y. Benno[10], H. Nishikawa[1], S. Koyama[1];

Gut microbiota is associated with antitumor efficacy of immune checkpoint blockade therapies, yet the mechanism is not largely understood. Here, we show that a novel bacterial strain of *Ruminococcaceae* isolated from the feces of patients who respond to PD-1 (programmed cell death 1) blockade efficiently primes/activates tumor-specific $CD8^{\pm}$ T cells through effective stimulation/maturation of $CD103^{\pm}$ dendritic cells (DCs) during migration from the gut to the tumor microenvironment (TME). The administration of this bacteria strain with PD-1 blockade significantly inhibited tumor growth, even when adding them to fecal transplantation of non-responder patients in animal models. Mechanistically, the bacterial strain promoted the IRF8-driven differentiation of $CD103^{\pm}$ DCs by stimulating multiple Toll-like receptors and the accumulation of these DCs in tumors and tumor-draining lymph nodes. These $CD103^{\pm}$ DCs prolonged engagement with cognate antigen-specific $CD8^{\pm}$ T cells, which induced the activation of $CD8^{\pm}$ T cells specific for a wide variety of tumor antigens and fostered their PD-1 expression through enhanced T-cell activation signals with NFATc1 nuclear translocation, thereby leading to abundant $PD\text{-}1^{\pm}CD8^{\pm}$ T cells, a key effector cell population in PD-1 blockade, with a broader T-cell receptor repertoire in the TME. Our findings with novel single bacterium isolated from feces of responder patients demonstrate the mode of action by gut microbiota to augment antitumor immunity.

#6687 Evaluation of a new co-cultured microbiome ecosystem therapy candidate (MaaT034) for clinical testing as adjuvant/neoadjuvant to immune checkpoint inhibitors in solid tumors.

B. Laperrousaz, J. Reygner, C. Gasc, C. Petitjean, A. Duquenoy, L. Martin, V. Bonnaud, M. Robin, S. Declomesnil, C. Schwintner, N. Corvaia;
MaaT Pharma, Lyon, France

Background: Increasing evidence suggests that gut microbiome composition modulates tumor response to therapies, including immune checkpoint inhibitors (ICI). Clinical proofs of concept were obtained in pilot studies using healthy or ICI-responder donor-derived fecal matter transplants to modulate the gut microbiome of non-responding cancer patients and improve their response to ICI. These results support the development of Microbiome Ecosystem Therapies™ (MET) replicating at large industrial scale the effects of ICI-responders gut microbiome. MaaT Pharma, a clinical-stage biotech, has developed a unique, ground-breaking, patented co-culture process (MET-C). MaaT034, the first-in-class co-cultured microbiome product, has been selected for optimizing intestinal homeostasis and to activate immune functions alone and in combination with an ICI treatment.
Method: We combined metagenomic analysis, metabolite quantification by LC-MRM/MS, Caco-2/THP-1 leaky gut model, PBMC assay and mixed lymphocyte reaction (MLR) to assess the impact of MaaT034 on gut homeostasis and immune activation.
Results: Metagenomic analysis demonstrates that MaaT034 replicates the richness and diversity of native-based microbiome ecosystems. Metabolite quantification also revealed that MaaT034 microbes secrete anti-inflammatory metabolites such as short chain fatty acids and indoles, as well as metabolites associated with ICI response such as secondary biliary acids. Using a Caco-2/THP-1 leaky gut model, we then demonstrate that MaaT034 conditioned medium was able to restore the integrity of a THP-1-induced damaged gut barrier. This was associated with and a reduction of inflammatory signals. We further performed a human PBMC assay to evaluate the impact of MaaT034 on immune cell activation. We observed the secretion of immunostimulatory cytokines associated with myeloid cell activation in response to MaaT034 conditioned medium. Notably, anti-CD3 mediated T-cells activation was further increased in response to MaaT034 conditioned medium as evidenced by increased IFNγ release associated with increased Granzyme B and CD25. Finally, MLR was performed to determine the immunomodulatory potential of MaaT034 through the interaction between T-cells and monocytes-derived dendritic cells (moDC). Interestingly, MaaT034 conditioned medium improved moDC maturation as well as moDC-induced T-cell activation. MaaT034 conditioned medium further increased anti-PD-1 mediated T-cell activation, as evidenced by IFNγ release.
Conclusion: Altogether, these results highlight the potential of MaaT034 to produce metabolites involved in the restoration of gut barrier integrity and stimulation of immune cell response to ICI therapy, with potential benefit for solid tumors treatment.

#6688 Peripheral CCR6$^{\pm}$ T-cell profile in healthy volunteers after ingestion of *Lactobacillus*-derived exopolysaccharide which was reported as an ICI-efficacy enhancer *in vivo*.

H. Kawanabe-Matsuda[1], T. Yokoo[2], S. Tou[2], S. Ishii[2], M. Nakamura[1], R. Watanabe[2], M. Ogawa[2], K. Takeda[3], T. Sashihara[2], H. Shimizu[1];
[1]Meiji Holdings Co., Ltd., Hachioji, Japan, [2]Meiji Co., Ltd., Hachioji, Japan, [3]Juntendo University, Tokyo, Japan

Introduction: Exopolysaccharides (EPS) are high-molecular-weight polymers composed of sugar residues secreted by bacteria into the surrounding environment. We (Juntendo University and Meiji Holdings) recently reported that oral administration of EPS derived from *Lactobacillus delbrueckii* subsp. *bulgaricus* OLL1073R-1 (R-1EPS) enhanced therapeutic efficacies of immune-checkpoint inhibitors (ICIs) *in vivo* (Kawanabe-Matsuda *et al*. *Cancer Discov*. 2022.). Briefly, R-1EPS increased CCR6$^{\pm}$ CD8$^{\pm}$ T cells in the small intestine, and these T cells migrated into the tumor tissue to improve the immune microenvironment via a high IFN-γ productivity. As an early step for a medicine, we tested the R-1EPS on healthy volunteers, focusing on the peripheral immune profiling, especially for CCR6-expressing T cells.

Methods: This trial was randomized, placebo-controlled, double-blinded, and parallel-grouped. Japanese healthy adults were divided into R-1EPS and placebo groups and ingested daily test substance for four weeks. We collected PBMCs from all subjects before and after the ingestion to analyze by mass-cytometry based on Maxpar Direct^{TM} Immune Profiling Assay with T Cell Expansion Panel 2 [Standard BioTools, *N* = 44 (R-1EPS) and *N* = 43 (placebo)].

Results: By manual gating strategy, we found that MAIT/NKT cells (CD45$^{\pm}$CD66b^{-}CD19^{-}CD20^{-}CD14^{-}CD11c^{-}CD3$^{\pm}$TCRγδ^{-}CD4^{-}CD28$^{\pm}$CD161^{high}) were increased in the R-1EPS group. Most MAIT/NKT (about 60 - 90 %) were CCR6$^{\pm}$ CD8$^{\pm}$ cells. Moreover, we characterized three distinct CCR6$^{\pm}$ CD4$^{\pm}$ T-cell clusters by analyzing the CITRUS (cluster identification, characterization, and regression) algorithm, and found that CCR6$^{\pm}$ Th1-like CD4$^{\pm}$ T cells were also increased in the R-1EPS group. Notably, these CCR6$^{\pm}$ Th1-like CD4$^{\pm}$ T cells are phenotypically similar to Th7R cells, that was previously reported as a peripheral correlative biomarker of ICI response (Kagamu *et al. Cancer Immunol Res*. 2020., Kagamu *et al. Cancer Res*. 2022.).

Conclusion: These results suggested that oral administration of R-1EPS for humans specifically increased some CCR6$^{\pm}$ CD8$^{\pm}$ T cells, as previously reported *in vivo*, and CCR6$^{\pm}$ Th1-like CD4$^{\pm}$ T cells. Therefore, we (Meiji Holdings Co., Ltd.) consider a clinical trial for the drug development using R-1EPS to treat cancer patients with ICIs.

#6689 Modulation of MAITs by the tumor microbiome in anti-PD1 treated cancers.

P. Birla, L. Yang, C. Sears, F. Shaikh, D. Pardoll, F. Housseau;
Johns Hopkins University School of Medicine, Baltimore, MD

Mucosal associated invariant T (MAIT) cells are innate like T-cells that recognize non-peptide metabolite antigens presented on monomorphic MHC related-1 (MR1) making them an attractive off the shelf tool for cancer immunotherapy. In this study, we investigate the function of MAITs in the tumor microenvironment of neoadjuvant anti-PD1 treated lung cancer patients (NCT02259621)). Paired single cell RNA/TCR sequencing analysis revealed an oligoclonal expansion of MAITs comprising of canonical TRAV1-2+ and non-canonical MAITs TRAV1-2-. TCR capture from canonical MAIT clonotypes confirmed their *in vitro* recognition of 5-OP-RU, bacteria derived riboflavin derivative as well as MR1 dependent recognition of live bacteria present in the tumor. However, the nature of antigens recognized by non-canonical MAITs remains poorly understood. On mining transcriptional profiles of MAITs, we observed that canonical MAITs were characterized by high clonal amplification whereas the non-canonical clonotypes expressed a strong activation/exhaustion gene signature. This suggests that both these MAIT populations recognize different types of antigens, differentially activate, and respond to immune checkpoint blockade (ICB), the non-canonical MAITs being highly dysfunctional. Using bacterial 16S RNA amplicon and metagenomics sequencing, we seek to identify microbial and metabolomics signatures associated with MAIT activation and response to ICB. We identified MAITs to express a cytotoxic signature making them a potential target for cancer immunotherapy. Our findings will provide further insights into the nature of ligands recognized by MAITs and the mechanisms associated with MR1 dependent recognition and tumor killing. Investigating the role of unconventional T-cells in response to ICB has the potential to reveal new tumor-associated antigens which could open avenues into innovative combination immunotherapies.

#6690 Gut microbial metabolite butyrate facilitates antitumor efficacy of telomerase-specific oncolytic adenovirus via MHC-I and cGAS-STING pathway activation.

M. Sakamoto;
Okayama University Hospital, Okayama City, Japan

Introduction: Gut microbiota has been reported to have a potential to modulate tumor sensitivity to chemo- or immuno-therapies although the underlying mechanism is still unclear. Oncolytic virotherapy is a promising antitumor treatment that selectively induces oncolytic cell death in tumor cells. We have previously developed OBP-702, a telomerase-specific oncolytic adenovirus armed with the p53 tumor suppressor gene, highlighting potent antitumor effects across different cancer types. To explore the potential of gut microbial metabolites, particularly butyrate, in augmenting the antitumor efficacy of oncolytic virotherapy.
Materials and Methods: We assessed the synergistic antitumor effects of butyrate and OBP-702 in cytotoxic assay using two human (HCT116, SW48) and two murine (CT26, MC38) colorectal cancer cell lines in vitro, and the in vivo antitumor effects in subcutaneous tumor models using HCT116 and CT26. We explored underlying mechanisms of the synergistic effects, focusing on the influences of butylate on viral infectivity via Coxsackie-Adenovirus Receptor (CAR) and integrins, and antitumor immunity via tumor MHC-I expression and CD8-positive T cells.
Results: Butyrate and OBP-702 showed potent synergistic effects in all four cell lines in vitro, and the combination suppressed tumor growth significantly in HCT116 and CT26 subcutaneous tumors compared to each monotherapy. These synergistic effects were produced by butyrate increasing the potential of OBP-702 by enhancing viral infection efficiency via upregulating expressions of CAR and integrins on tumor cells. Butyrate also increased MHC-I expression on tumor cells by activating the cGAS-STING pathway, leading to increased CXCL10 expression, which led to activation of antitumor immunity through recruitment of CD8-positive T cells in tumor tissues. The synergistic effects of butyrate and OBP-702 were proved in an orthotopic colorectal tumor model with liver metastases using CT26 cells expressing luciferase, in which this combination not only reduced tumor growth, but also improved survival by activating antitumor immunity via CD8-positive T cells.
Conclusion: Butyrate and OBP-702 showed synergistic antitumor effects via activation of systemic antitumor immunity in addition to direct effects of butyrate on viral cytotoxic potential, which provides valuable insights into the development of innovative cancer treatment strategies.

#6691 Engraftment as a determinant of response in fecal microbiome transplantation interventions for immunotherapy in melanoma.

M. Chelvanambi[1], A. V. Damania[1], S. B. Johnson[1], G. Morad[1], R. N. Lazcano[1], B. A. Helmink[1], L. W. Fong[1], K. Wani[1], Y. D. Seo[1], E. M. Park[1], R. I. Ayabe[1], B. Singh[1], M. C. Wong[1], D. R. Ingram[1], M. G. White[1], A. J. Lazar[1], A. K. Mishra[2], N. J. Ajami[1], E. N. Baruch[1], J. A. Wargo[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Georgia, Athens, GA

Background: Distinct gut microbiome signatures are associated with response, resistance, and toxicity to immune checkpoint blockade (ICB). Fecal microbiome transplants (FMT) have validated the importance of the gut microbiome in enhancing response and overcoming resistance to immunotherapy. However, donor selection remains a key challenge for FMT. Heterogenous responses using Healthy Donors (HD) and ICB Complete Responders (CR) as FMT donors suggest donor characteristics alone do not determine response. Here, we posit that donor-recipient relationships are critical in determining clinical responses to FMT.

Methods: We studied a cohort of ICB-refractory, metastatic melanoma patients treated with combined FMT and ICB (10 recipients, 2 donors). Patient gut microbiomes were profiled using whole metagenomic sequencing (WMS) of longitudinal stool collections (baseline, day 7, day 31, and day 65 post-FMT). Immune infiltration of on-treatment tumor and colon biopsies was quantified with immunohistochemistry. mTraCX, an Earth Mover's Distance-based algorithm, was used to evaluate taxonomic engraftment between donors and recipients. Bray-Curtis distance was used to measure functional similarities between donor and recipient gut microbiome. Clinical findings were validated in pre-clinical FMT experiments performed on $Braf^{V600E}Pten^{-/-}$ melanoma-bearing mice.

Results: One-third of recipients (3/10) developed an objective response (R) to ICB following FMT. mTraCX demonstrated an association between clinical response to FMT and durable engraftment of donor microbiota at day 65 post-FMT (p=0.025). Taxonomic engraftment (mTraCX) correlated positively with functional engraftment (Bray-Curtis distance) (r=0.89, p<0.0001). Enhanced engraftment was associated with increased CD4 (r = -0.87, p=0.0045) and CD8 (r = -0.6, p=0.09) T-cell infiltration in the colon, and a trend towards increased CD8 T-cell infiltration (r = -0.5, p=0.2) in the tumor following treatment with FMT+ICB. Pre-clinical models paralleled our clinical findings as responding mice showed better donor engraftment than non-responding mice (p<0.0001 on day 4 and day 24 following FMT).

Conclusions: Our data shows that donor engraftment is a favorable prognostic factor for ICB treatments combined with FMT. Future investigations will aim to develop donor-recipient matching criteria to enhance the feasibility and integration of FMTs into clinical practice.

#6692 Intermittent fasting-remodeled gut microbiota improves anti-tumor immunity in pancreatic cancer.

L. Li[1], V. Chandra[1], O. L. Roux[1], R. M. Howell[1], V. Tahan[1], N. Putluri[2], J. Petrosino[2], A. Sreekumar[2], J. K. Kolls[3], J. White[4], F. McAllister[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]Tulane University School of Medicine, New Orleans, LA, [4]Resphera Biosciences, Baltimore, MD

Pancreatic ductal adenocarcinoma (PDAC) has become the third leading cause of cancer-related death in the United States with high resistance to therapies, presentation at late stages and aggressive biology. Immunotherapy has revolutionized cancer therapy by offering survival benefit in many solid malignancies, however, it is still not effective in pancreatic cancer. Host factors are crucial modulators of responses to immunotherapy. The roles of gut microbiome in modulating the immune system and determining cancer outcomes have been well established. Eating patterns can alter the gut microbiota and metabolic output, both of which affect anti-tumor immune responses. Intermittent fasting (IF), a form of dietary restriction which is characterized by limited feeding with unlimited calorie consumption during a certain time window. IF has been shown to affect gut microbiota composition, modulate immunity, and metabolic processes. Despite the well-known beneficial role of fasting in pancreatic conditions, including pancreatitis and diabetes, its effect in the treatment of pancreatic cancer has not been explored. Our study found that IF reverses immunotherapy resistance in PDAC. IF can reshape gut microbiota composition and reprogram the metabolism of host. We found that IF improves anti-tumor immunity through modulating gut microbiota. Depletion of gut microbiota can abrogate the beneficial effect of IF on anti-tumor response, while fecal microbiota transplantation from mice exposed to IF can sensitize the anti-tumor effects of immunotherapy. Using 16S rRNA sequencing, metabolic profiling and transcriptomic sequencing, our findings elucidate the mechanism of IF-remodeled gut bacteria influencing metabolic molecules which drive immune cells activation. Our study suggests that IF-based interventions have potential utility for the prevention and treatment of PDAC.

#6693 Deleted in malignant brain tumors 1 (DMBT1) glycoprotein is lost in colonic dysplasia.

Emily H. Green[1], Subhag R. Kotrannavar[1], Megan E. Rutherford[2], Harsimran Kaur[1], Hannah M. Lunnemann[2], Cody N. Heiser[1], Shaoguang Wu[3], Hua Ding[3], J. Alan Simmons[1], Xiao Liu[2], D. Borden Lacy[4], Martha J. Shrubsole[2], Qi Liu[2], Ken S. Lau[1], Cynthia L. Sears[3], Robert J. Coffey[2], Julia L. Drewes[3], Nicholas O. Markham[4]

[1]Vanderbilt University, Nashville, TN,[2]Vanderbilt University Medical Center, Nashville, TN,[3]Johns Hopkins University, Baltimore, MD,[4]Department of Veterans Affairs, Nashville, TN

Colorectal cancer (CRC) is the third most common cancer in the United States and is responsible for more than 50,000 deaths annually. Emerging evidence strongly supports a causal role for specific pro-carcinogenic driver bacteria within the colonic microbiota. Invasive bacterial biofilms may initiate or accelerate CRC through epithelium-autonomous or inflammation-dependent mechanisms. To better understand host-microbe interactions during colonic tumorigenesis, we combined single-cell RNA-sequencing (scRNA-seq), spatial transcriptomics, and immunofluorescence to define the molecular spatial organization of colonic tissue from germ-free *Apc*$^{Min/+}$ mice colonized with bacteria from human biofilm-associated CRC. In absorptive colonocytes, differential gene expression analysis showed the gastric metaplasia-associated glycoprotein *Deleted in Malignant Brain Tumors 1 (DMBT1)* is highly upregulated by *C. difficile*. Surprisingly, our spatial transcriptomic analysis showed *DMBT1* was dramatically downregulated in dysplastic foci compared with normal-appearing tissue. We show that DMBT1 protein is downregulated in 100% of dysplastic foci across 3 different mouse models of colonic tumorigenesis: *C. difficile*-associated tumorigenesis in *Apc*$^{Min/+}$, azoxymethane/dextran sodium sulfate, and *Lrig1*$^{CreER/+}$;*Apc*$^{fl/+}$ mice (n = 57 foci from 11 mice). Immunofluorescent staining of DMBT1 is markedly downregulated compared with normal adjacent crypts. Using scRNA-seq data and tissue microscopy in human CRC, we confirmed the same pattern of downregulated DMBT1 expression in dysplastic crypts compared with normal-appearing crypts. We present data from a human mucosal biofilm-associated colonic tumorigenesis murine model at single-cell resolution to reveal interesting cell type-specific transitions and generalizable mechanisms of tumorigenesis. We hypothesize that DMBT1 is a component of the gut epithelial response to pathogens and a critical regulator of proliferation and differentiation during post-injury restitution. We are now functionally testing how the loss of DMBT1 impacts tumorigenesis using human organoids. Ultimately, these studies aim to reveal novel biomarkers and/or targets for therapeutic intervention in CRC.

#6694 Gut microbial drivers of response to bladder-sparing therapy in human muscle-invasive bladder cancer enhance immunotherapy efficacy and limit immunosuppression following fecal microbiome transplantation *in vivo*.

E. Michaud[1], S. Fehric[1], C. Faubert[2], B. Routy[3], I. King[4], J. Mansure[1], W. Kassouf[5],

[1]McGill University Health Centre Research Institute, Montreal, QC, Canada, [2]McGill Interdisciplinary Initiative in Infection and Immunity, Montreal, QC, Canada, [3]Hematology-Oncology Division, Department of Medicine, Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada, [4]Meakins-Christie Laboratories, Department of Medicine, McGill University Health Centre, Montreal, QC, Canada, [5]Division of Urology, Department of Surgery, McGill University Health Centre, Montreal, QC, Canada

BACKGROUND: Radiation therapy (RT) is a bladder-sparing option for Muscle-Invasive Bladder Cancer (MIBC), yet encounters a 30% non-response rate, with half of the patients succumbing to metastasis. Preclinical models demonstrate enhanced antitumor responses with RT combined with PD-1/PD-L1 blockade but give limited insight into the determinants of success for such combination therapies (CT). The gut microbiome, pivotal in conditioning local and peripheral immunity, influences PD-1-based immunotherapy efficacy in various cancers. Immune profiling indicates heightened systemic and antitumor immunity in responders with a favorable gut microbiome, enriched in *Akkermansia muciniphila, Bifidobacterium*, and *Faecalibacterium*. Oral gavage of immunogenic bacteria further enhances combined RT and anti-PD-L1 therapy. We thus aim to 1) elucidate the role of patients' microbiome in shaping anti-tumor immune responses to CT, and 2) use its composition as a predictive factor for CT success.

METHODS: We performed shotgun metagenomics on microbial DNA from fecal materials of MIBC RT responders (R, n=26) and non-responders (NR, n=11). Fecal homogenates from donors were gavaged into germ-free (GF) mice. Three weeks post-gavage, MB49 tumor cells were subcutaneously delivered to mice, randomized into four groups: control, anti-PD-L1, RT, and RT + anti-PD-L1. Tumors were harvested seven days post-treatment for single-cell RNA-seq and TCR sequencing (10X Genomics), while stool samples were collected weekly for 16S sequencing.

RESULTS: Significant gut microbial disparities were observed between R and NR MIBC patients, with particular enrichment in known promoters of anti-PD-L1 response, such as *Phocaeicola dorei* in R. Transplantation of R microbiome into GF mice resulted in significant increases in predicted survival, tumor growth delay, and counts of effector $CD4^{\pm}$ T cell infiltration in the RT+PD-L1 arm. Conversely, NR microbiome transplantation correlated with increased neutrophil and T_{reg} infiltration, abrogating the survival tumor growth delay benefits of the combination arm. Spatial tissue analyses revealed higher neutrophil densities around $CD8^{\pm}$ T cells in all NR arms. Single-cell RNA-seq of tumor-infiltrating immune cells unveiled skewed CD4 and CD8 polarization between R and NR *in vivo* batches.

SIGNIFICANCE: To our knowledge, this is the first study to use FMT as a modulator of response in the context of radiation therapy combinations in MIBC. Our results highlight that the gut microbiome alone may condition a favorable immune terrain for combinatorial therapies involving radiation. This offers strong predictive value for personalized therapeutic approaches in selecting patients who will benefit the most from bladder-sparing therapies.

#6696 Microbial signatures and serum markers in colon cancer of African American patients.

S. C. Tortora[1], E. Vogtmann[2], L. Martello-Rooney[1];
[1]SUNY Downstate Health Sciences University, New York, NY, [2]National Cancer Institute, Bethesda, MD

Among all the racial/ethnic groups, African American (AA) patients have the highest incidence of CRC and mortality rate. There is growing evidence indicating that the oral bacteria might translocate to the intestine, potentially causing disruptions in the balance of gut microbes. Our study delves into the complex interplay between oral pathogens, gut microbiota, and colon carcinogenesis in AA patients. Methods: 16S rRNA sequencing of tumor and non-tumor tissues, utilized qPCR for detection of oral bacteria *Fusobacterium nucleatum* (Fn) and *Porphyromonas gingivalis* (Pg) relative abundance, performed cytokine profiling via multiplex ELISA, and employed NAPPA for antibody response assessment. Results: Colon tumor tissues had lower microbial diversity, notably in right-sided tumors, with distinct biofilm-associated bacteria. Novel discoveries emerged from differential abundance testing, revealing *Prevotella intermedia* and *Treponema socranski to be* associated with early cancer stage and left-sided location, and *Fusobacterium necrophorum* with advanced cancer stage and right-sided location. qPCR demonstrated Fn and Pg elevation in right-sided tumors and late cancer stages. Both were detected in 45% of tumors versus 37% in non-tumor tissues and 19.15% of tumors and 25.53% in non-tumor tissues, respectively. Fn-positive groups exhibited distinct microbial signatures, with altered bacterial abundances and dysbiosis, including increased CRC-associated bacteria *Faecalibacterium and Helicobacter*, increased oral pathogen abundance (*Fusobacterium, Porphyromonas, Prevotella, Treponema*), and reduced beneficial bacteria. Serological analysis highlighted elevated levels of IL-2, IL-10, IFN-γ, and RANK in advanced cancer stages and increased CRP levels in right-sided tumors. By NAPPA analysis, 30 bacterial proteins (anti-IgG) showed a seroprevalence of more than 15% in the samples, with those being the most seroprevalent anti-HP131 and anti-HP-1564 (68% and 61% of all samples) of *Helicobacter pylori*, and anti-msnK (64%) of *Streptococcus gallolyticus*. Conclusions: Our study emphasized the reduced diversity in tumor tissues, particularly in right-sided tumors in AA colon cancer. Fn presence in colonic tumors correlated with CRC-associated bacteria and oral pathogen aggregation, suggesting its potential role in cancer pathogenesis. Combining the analysis of cytokines and pathogenic bacteria antibodies may serve as broader serological biomarkers for disease severity and location. These findings advance our comprehension of microbiota-cancer interactions, directing personalized diagnostics and treatments in this population.

#6697 The role of microbiomes in pediatric cancer prevention: A survey of population awareness.

A. Abd Elmoneim, M. A. Alshanqiti, Y. S. Aljohani, L. H. Alomari;
Taibah University, Madinah, Saudi Arabia

Background: Gut microbiome includes the genome of all gut microorganisms; it plays a crucial role in the body's nutritional, metabolic, physiological, and immunological processes. Persistent imbalance of the gut microbial community is associated with the onset of metabolic and inflammatory disorders, including cancer. The environment has a major role in the great variability of microbiome composition among different people. This high heterogeneity between individuals may be a source of differences in susceptibility to disease. Dietary and lifestyle choices as well as social interactions play a significant role in makeup and function of the gut microbiota, which may affect microbiome-associated diseases. Therefore, strategies that might favorably modulate the gut microbiota to reduce the risk of cancer through diet and lifestyle changes are of great interest.
Aim: To detect and increase self-awareness about gut microbiota and its relation to diet and lifestyle habits.
Methods: A survey questionnaire is provided asking for microbiome knowledge and lifestyle habits and distributed among the population in Madina city in Saudi Arabia. Study population are the children aged 2-18 years. Data gathered from older children or the parents/guardian of young children.
Results: A profile involving each participant' diet, physical activity, and sociodemographic characteristics through self- reporting questionnaire is obtained.
Discussion: Gut microbiota can regulate many functions of the tumor-bearing meta-organism, typically through immunomodulation. Known microbial mechanisms can alter non-hematopoietic and hematopoietic components of the gut epithelial barrier, modulate lymphoid organ activities, and regulate immune tone of the tumor microenvironment (TME).
Conclusion: Understanding information about microbiome and its role in causing diseases as well as each participant' diet, physical activity and other sociodemographic characteristics help to raise participants' awareness about the importance of taking care of their gut health.

#6698 Tumor microbiota associated with immune enrichment in breast tumor.

L.-F. Yeo[1], B. K. Lim[2], T. Islam[3], L.-Y. Teoh[3], S. Jamaris[3], M.-H. See[3], L.-M. Looi[3], N. Mohd Taib[3], C.-H. Yip[4], P. Rajadurai[4], S.-H. Teo[1], J. Pan[1];
[1]Cancer Research Malaysia, Subang Jaya, Malaysia, [2]Universiti Kebangsaan Malaysia, Selangor, Malaysia, [3]University Malaya, Kuala Lumpur, Malaysia, [4]Subang Jaya Medical Centre, Subang Jaya, Malaysia

Asian cancer patients have enriched immune profiles when compared to Caucasians. This is associated with improved overall survival and potentially better response to immunotherapy. Yet the reason behind enriched Asian immune profiles is unclear. This study investigated microbes found in Malaysian breast tumors in association with immune profiles. We used an existing dataset of RNA-seq data from fresh frozen breast tumor tissue (n=978). Sequencing reads were trimmed and filtered to remove human reads. Non-human reads were mapped to Kraken2 and relative abundance was estimated using Bracken. Microbiome analysis was conducted on R following Microbiome OMA guidebook. The top five genera found in the Malaysian Breast Cancer (MyBrCa) cohort were *Pseudomonas, Siphoviridae, Bacillus, Escherichia and Klebsiella*. Alpha diversity of basal subtype microbiota was significantly higher than Her2 subtype (Shannon index, p=0.027) whilst the other subtypes were more homogenous. MyBrCa patients with low immune scores were significantly different from high immune scores while controlling for age, stage, grade, ethnicity and PAM50 subtype (PERMANOVA, F-statistic = 1.656, p=0.05). Differential abundance analysis revealed *Sulfidibacter* and *Priestia* to be significantly different in abundance between high vs low IFNg groups (FDR-adjusted p-value < 0.05) using ALDEx2, ANCOM-BC2 and ZicoSeq and LinDA algorithms. *Sulfidibacter* was significantly different between high vs low immune group for Bindea combined immune score and ESTIMATE score groups (FDR-adjusted p-value <0.05). An independent breast cancer cohort (n=419) was used as validation where *Sulfidibacter* and *Priestia* were also significantly different in abundance for immune high vs low groups. Machine learning using Random Forest model predicted immune group with an AUC of 0.79 (CI = 0.74, 0.83; p-value < 0.01). The top five most important features contributing to the random forest model were *Sulfidibacter, Prestia, Cutibacterium, Acinetobacter* and *Rhizobium*. This study is the largest to date that characterize the tumor microbiota of an Asian cohort of breast cancers, where *Sulfidibacter* and *Priestia*, both relatively new and uncharacterized bacteria, were differentially abundant among patients with high vs low immune scores.

#6699 Delineating germline, tumor and extrinsic factors driving mucosal melanoma (MM) risk and response to immune checkpoint inhibitor (ICI) treatment.

F. Dimitriou, P. Nagarajan, S. Prabhakaran, N. Bota, M. Knafl, R. A. Chu, A. V. Damania, P. V. Sahasrabhojane, Y. Hoballah, J. S. Losh, N. J. Ajami, S. E. Woodman, J. A. Wargo, A. Futreal, J. L. McQuade;
UT MD Anderson Cancer Center, Houston, TX

Introduction MM is a rare melanoma subtype with distinct biology, low immunogenicity and tumor mutational burden, and subsequently lower response rates to ICIs. The biology of MM is poorly understood. We sought to prospectively, uniformly, and comprehensively profile a cohort of MM patients to determine the interplay of molecular variation, germline predisposition, immunity, gut, mucosal and tumor microbiome and modifiable risk factors on ICI response and resistance in advanced MM.

Methods Patients (pts) with MM treated with standard-of-care ICI as any treatment line presenting to MD Anderson are being prospectively enrolled for longitudinal collection for molecular, microbiome, and lifestyle factor profiling. Planned analyses include: whole genome sequencing of normal and tumor tissue, RNA sequencing, and T cell receptor sequencing from fresh tumor samples; germline sequencing and genotype analyses; NanoString Digital Spatial Profiling (DSP) from formalin-fixed paraffin embedded (FFPE) specimens; whole genome shotgun, microbiome profiling and 16S rRNA gene sequencing (16S) of fecal specimens and affected mucosal and tumor sites (swabs); participant lifestyle and patient reported outcomes (PROs) assessments. Fresh tissue is collected and used to develop PDX models and cell lines.

Results 98 pts have been enrolled to date; 83 (85%) Caucasians, 8 (8%) Hispanic, 4 (4%) Asians. 67 (68%) females. Median age at MM diagnosis is 64 years (range 32-91 years). MM primary sites include 24 (24%) naso-oral, 29 (30%) urogenital, 26 (27%) anorectal, 7 (7%) conjunctival and 12 (12%) other. Clinical somatic mutation testing was performed in 76 (76%) pts and common mutations were *KIT* (n = 12, 16%), *NRAS* (n = 8, 11%) and *BRAF* V600 or non-V600 (n = 9, 12%). At data cut-off (November 2023), 18 (18%) pts deceased. Median follow-up from first diagnosis to last visit/death was 16 months (range 1-178 months). Sample collections at data cut-off include: blood samples (n = 95; 219 samples); fecal specimens (n = 50; 97 samples); mucosal swabs (tumor/tumor adjacent/oral cavity; n = 38; 101 samples); fresh frozen tumor/normal (n = 38; 55 samples), fresh tumor/normal (n = 28; 36 samples) and FFPE tumor (n = 21; 37 samples) tissue. PROs and dietary assessments have been collected from 47 pts. Fresh tissue for PDX model and cell line development has been collected from 11 pts.

Conclusion This is an ongoing prospective study that is expected to drive insights into the tumor/microenvironment/host interactions and factors regulating immunogenicity to predict response and resistance to ICIs in a rare and understudied melanoma subtype. Interrogation of the role of the gut microbiome and its modifiable determinants will lead to the investigation of new therapeutic strategies to modulate the microbiome to improve treatment outcomes in MM. Data will be presented from initial cohort analyses.

IMMUNOLOGY: Targeted Immune Cell Engagers
Poster Session

#6703 Innovative mRNA strategies to encode CD19/CD3 T cell engagers in the treatment of B cell hematological malignancies.

Xia Zhong, Liang Du, Zhenxing Yang, Xiaoli Xu, **Jijun Yuan**, Bo Ying

Abogen Bioscience, Suzhou, China

The advent of T Cell Engager (TCE) immunotherapies marks a transformative shift in cancer treatment paradigms, introducing a novel action mechanism. Blinatumomab, a bispecific CD19/CD3 TCE, has shown remarkable efficacy in treating refractory or relapsed B-cell Acute Lymphoblastic Leukaemia (B-ALL), including cases resistant to conventional chemotherapy, leading to its global approval for B-ALL management. Despite its pronounced clinical success, Blinatumomab faces challenges with patient adherence, primarily due to the protein's short half-life. This necessitates continuous administration requested 24 hours injection throughout the treatment course. Additionally, the drug's association with the induction of cytokine release syndrome (CRS), presumably linked to the hyperactivation of the cytokine network, presents a significant concern.

To address these limitations, we leverage mRNA modality to develop innovative therapeutic mRNAs encoding CD19/CD3 TCE. These mRNA drugs hold the potential to improve protein exposure *in vivo* with a steady production of encoded protein in-situ. On the other hand, with the gradual expression of protein, mRNA shifted the transient, "pulse"-like pharmacokinetic (PK) feature of the protein drugs to a more "plateau"PK curve, which allows a natural priming of T cells to reduce the risk of CRS induction.

In this work, we developed a series of mRNAs encoding CD19/CD3 TCE through our mRNA technology platform and LNP delivery platform. Comparative analyses demonstrated that the TCEs produced *in vivo* by these mRNAs match the structure and function of recombinantly expressed proteins. PK studies in both mice and non-human primates confirmed a favorable PK profile with over 10-fold increase in TCE exposure compared to their protein counterparts. This increased exposure correlated with superior antitumor efficacy in both ALL and lymphoma models, evidenced by the potent effects of single mRNA doses compared to multiple doses of protein-based treatments. Meanwhile IL6 cytokines induced in mRNA treated mice were significantly alleviated than those in protein treated animals, indicating a reduced risk of induction of CRS. One candidate mRNA demonstrated an optimal "plateau" pharmacokinetic profile, achieving extensive target cell eradication over 20 days with a single low dose of 0.001 mpk in non-human primates.

An investigator-initiated clinical study with mRNA encoding CD19/CD3 TCE is underway in relapsed and/or refractory acute lymphoblastic leukemia patients. The preliminary data from the on-going study showed ABO2015 with an acceptable safety profile, and activation of peripheral T cells was observed in one patient with low dose.

These findings underscore the significant clinical potential of mRNA-encoded CD19/CD3 TCE in treating B-cell malignancies, heralding a paradigm shift in the clinical application of protein-based T cell engagers.

#6704 Development and characterization of a tri-specific selective CD8 T cell engager (CD8xCD3xCD19) for treatment of B cell lymphoma.

Zheng Yang[1], Wuzhong Shen[1], Guiyun Tu[1], Shenjie Xue[1], Ying Tan[1], Bingbin Xie[1], Jason Xu[2], Hanyang Chen[1], Shui Liu[1], **Xiaoqiang Yan**[1]

[1]ITabMed Ltd., Shanghai, China,[2]University of pennsylvania, Philadelphia, PA

The recent development of CD3 bi-specific antibodies (BsAbs) targeting CD20, BCMA, GPRC5D and CD19 to treat B cell malignancies have resulted in significant clinical benefit to patients. However, long-term remission rates and survival remain to be demonstrated. Current CD3 BsAbs preferentially bind to and activate CD4 T cells. However, CD8 cytotoxic T cells also play the key role in anti-tumor response and T cell exhaustion in cancer immunity. To potentially enhance anti-tumor efficacy by augmenting CD8 T-cell response, we developed a novel tri-specific T cell engager (TriTE) IM-8319, which simultaneously binds human CD3, CD8 and CD19 epitopes with K_D at 14.2 nM, 3.3 nM and 0.3 nM, respectively. The binding affinity to human CD8 T cells and CD4 T cells was measured with EC_{50} at 0.02 nM and 1.2 nM, respectively. In human PBMC-killing assays, IM-8319 was found to preferentially activate CD8 T cells with EC_{50} of 6.0 pM, compared to an EC_{50} of 94 pM for activating CD4 T cells. Unique cytokine release responses were seen with IM-8319 treatment. Compared to bi-specific TCE controls without CD8 binding domain, IM-8319 in human PBMC assays increased INFγ and TNFα in CD8 T cells and blunted IL-2 release in CD4 T cells. We observed robust cytotoxic killing of $CD19^{\pm}$ B cells with IM-8319. Compared the bi-specific TCE controls lacking CD8 binding domain, *in vitro* $CD19^{\pm}$ B-cell depletion was increased 6-fold with IM-8319. In addition, we observed notable structure activity relationships, with >100-fold increases in TriTE cytotoxicity with a weak CD3 binding domain. T-cell fratricide has hindered the development of antibodies containing 2+ T-cell epitopes. We observed correctable, dose-dependent CD8 T cell depletion at high concentrations of CD8xCD3xCD19 TriTEs *in vitro* and xenograft mouse models. This unwanted biological effect was not a surprise when the TriTE binds to CD8 T cells in *trans*. However, by structure engineering IM-8319 to allow for *cis* binding of CD3 and CD8, we effectively eliminated CD8 T cell fratricide at therapeutic doses. In a Raji-inoculated murine xenograft that was reconstituted with human PBMC, IM-8319 significantly inhibited tumor growth without obvious CD8 T cell depletion. In summary, we report a novel TriTE (IM-8319) that selectively binds to and activates CD8 T cells. IM-8319 results in robust on-target cytotoxicty with specific activation of CD8 T cells, suggesting potential to reduce systemic toxicities such as cytokine release syndrome (CRS) while augmenting direct antitumor efficacy. Further preclinical evaluation of IM-8319 is warranted in patients with B-cell leukemias and lymphomas.

#6705 A novel tri-specific T cell engager targeting the intracellular oncoprotein WT1.

S. Gao[1], L. Yang[1], J. Du[2], W. Jiang[1], **L. Fang**[1];

[1]Concept to Medicine Biotech Co., Ltd., Shanghai, China, [2]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

Background: Wilms' tumor gene 1 (WT1) is considered an oncogenic factor, with high expression observed in several hematological malignancies and solid tumors. However, its expression is rarely found in normal adult tissue. WT1 can be degraded by the proteasome, processed and presented on the cell surface as major histocompatibility complex (MHC) I epitopes and recognized by T cell receptors (TCR). Here, we described the development of WT1-TOPAbody, a novel tri-specific T cell engager (TCE), that activated T cells by both CD3 and 4-1BB signaling upon recognition of WT1 in the context of HLA-A02, leading to superior anti-tumor efficacy.

Materials and Methods: WT1-TOPAbody was evaluated for its antigen binding activity and target specificity by a series protein/peptide and cell-based assays. In vitro cytotoxicity and T cell activation mediated by WT1-TOPAbody was further assessed in a panel of WT1$^{\pm}$ tumor cell lines in coculture with effector cells. Anti-tumor activity was investigated in a humanized syngeneic mice model bearing WT1/HLA-A02 expressing tumors. Safety assessment including cytokine release assay (CRA) and preliminary CMC developability was also performed.

Results: WT1-TOPAbody exhibited superior binding affinity to the WT1/HLA-A02 complex while displaying lower binding to off-target peptides and CD34$^{\pm}$ HSC from healthy donor than clinical benchmark WT1-CD3 bispecific antibody, RG-6007. WT1-TOPAbody effectively induced tumor lysis in multiple WT1$^{\pm}$ tumors including leukemia, ovarian, breast, and colon cancer cells. Moreover, serial killing of tumor cells were observed in WT1-TOPAbody treated T cells, accompanied by lower exhaustion markers expressed, suggesting a prolonged anti-tumor inhibition effect of WT1-TOPAbody. In a humanized CD3e/4-1BB/HLA-A2.1 mouse model, WT1-TOPAbody significantly inhibited tumor growth in a dose-dependent manner and the efficacy was superior than that of the benchmark. Additionally, IL-6 release was minimal in PBMC upon treatment of the antibody, indicating a reduced risk of inducing cytokine release syndrome (CRS). Drug developability assessment indicated that the leading WT1-TOPAbody was a reasonably developable molecule to be taken forward.

Conclusion: WT1-TOPAbody is a differentiated WT1/HLA-A02 targeted T cell engagers that displayed potent and durable anti-tumor activity. These results collectively support the potential of WT1-TOPAbody as a novel therapeutic agent against WT1/HLA-A02$^{\pm}$ cancers and warrant its further development.

#6706 An anti-claudin 18.2/CD3 bispecific antibody for the treatment of claudin 18.2 positive gastric cancer.

L. Zhao[1], G. Zhang[2], Z. Liu[2], J. Xu[2], L. Zhao[2], G. Li[2], B. Li[2], Z. Zhu[2], W. Peng[2], Y. Zhu[2], Z. Chen[2], **Z. Li**[2];
[1]Lunan New Time Bio-tech Co., Ltd., Linyi, China, [2]Lunan Pharmaceutical Group Co. Ltd., Linyi, China

The claudin18.2 (CLDN18.2) protein shows four transmembrane domains (TMDs) with two extracellular loops (ECL), ECL-1 and ECL-2. It is a highly selective biomarker with limited expression in normal tissues and often exhibits abnormal expression during the occurrence and development of various primary malignant tumors. The specific expression pattern supports the notion that CLDN18.2 is a distinctive molecule for targeted therapy in various cancers, particularly gastric and pancreatic cancers. Various drugs targeting CLDN18.2, including monoclonal antibodies, ADCs, CAR-T, and bispecific antibodies, have also entered clinical trials. As of this writing, there are currently no commercially available products worldwide that specifically target CLDN18.2. However, Zolbetuximab (IMAB362) has successfully reached the Phase III end point, indicating positive clinical outcomes and establishing CLDN18.2 as a promising cellular and antibody therapeutic option. Here, we describe LNF2007, an anti-CLDN 18.2/CD3 bispecific antibody that can redirect CD3+ effector T cells to CLDN18.2+ tumor sites, resulting in the activation of T cells and subsequent killing of target cells. The design of LNF2007 focuses on selecting a relatively weak and reasonable affinity to CD3, accompanied by the suppression of Fc-mediated effector functions. This aim is to minimize off-target toxicity and maximize therapeutic efficacy. In vitro data demonstrate that LNF2007 binds more strongly to CLDN18.2+cells than to CD3+ cells. LNF2007 exhibited good dose-dependent activation and cytotoxicity against engineered cell lines BXPC3-hCLDN18.2-Luc and CHOK1-hCLDN18.2-Luc, which are positive for CLDN18.2 expression .In the in vivo pharmacodynamics assay, LNF2007 also demonstrated superior efficacy in the humanized NUGC4-CLDN18.2 model and BxPC3-CLDN18.2 model. Furthermore, a 4-week repeated dose (up to 1 mg/kg) toxicity study in cynomolgus monkeys showed that LNF2007 was safe and well tolerated. In vitro cytokine release was lower in the LNF2007 group than that in the AMG 910 and AZD5863 (two another anti-claudin18.2/CD3 bispecific antibody) groups. In conclusion, the novel anti-CLDN18.2 × anti-CD3 bispecific antibody LNF2007 demonstrates similar efficacy to AMG 910 and AZD5863 and is safer. LNF2007 provides a promising therapy for claudin 18.2-positive cancer patients.Taishan Industry Leading Talents Project of Shandong Province was a sponsor of this research.

#6707 IgG based B7-H3xCD3 bispecific antibody for treatment of gynecological tumors.

S. M. Greiner, J. Mauermann, M. Lutz, I. Hagelstein, E. Tobias, A. Koch, H. Andreas, B. Sara, L. Zekri, M. Marklin;
University Hospital and Medical Faculty Tubingen, Tubingen, Germany

Ovarian cancer is characterized by late stage disease and a poor prognosis. Endometrial cancer is a heterogeneous disease with different prognoses depending on the molecular subtype. Novel treatment strategies are needed to improve patient survival in both entities.
T cell-based immunotherapy has significantly improved the treatment options for many malignancies. B7-H3 (CD276) is an interesting target for immunotherapeutic approaches because it is overexpressed on a wide range of tumor entities and has characteristics of immune checkpoint molecules. Its expression not only on tumor cells but also on the tumor vasculature allows improved infiltration of immune effector cells into the tumor to overcome the major limitation of T cell-based therapy of solid tumors, which is the access of immune cells to the tumor site. A novel bispecific antibody in an IgG-based format called CC-3 with B7-H3xCD3 specificity has already been shown to efficiently induce T cell responses against gastrointestinal malignancies.
Here we show that B7-H3 is highly expressed on endometrial and ovarian cancer cell lines. Treatment with CC-3 induced T cell activation and degranulation as well as secretion of IL-2, IFNγ and perforin. These results demonstrate CC-3 induced T cell reactivity against ovarian and endometrial cancer cells. In addition, CC-3 induced efficient T cell proliferation and formation of T cell memory subsets. This resulted in potent target cell lysis.
Taken together, our results underscore the potential of CC-3, which is currently in GMP manufacturing, to enable clinical evaluation for the treatment of gynecologic malignancies.

#6708 MAIT engagers: Bispecific antibody-mediated redirection of mucosal associated invariant T cells to treat solid tumors.

S. E. Plyte[1], M. Fraudeau[1], D. Winterberg[2], C. Germain[1], C. Rousseau[1], G. Sodaro[1], L. Fenou[3], M. Audin[1], A. Ivagnes[1], H.-H. Oberg[2], P. Gerard[1], I. Navarro-Teulon[3], D. Wesch[2], M. Peipp[2], J. Prigent[1];

[1]Biomunex Pharmaceuticals, Paris, France, [2]Universitatsklinikum Schleswig-Holstein, Kiel, Germany, [3]IRCM, University of Montpellier, Montpellier, France

Background. Using bispecific antibodies (BiXAb) to redirect T cells to engage and kill cancer cells is an efficacious modality in the treatment of haematological cancers but has had limited success in the treatment of solid tumors. Mucosal-Associated Invariant T cells (MAITs) are an abundant subset of non-conventional T-cells with potent cytotoxic capacity (up to 20% of circulating T-cells) that are naturally resident in many tissues and solid tumors. MAIT cells utilize a semi-invariant TCR and recognize bacterial metabolites presented in the context of the MR1 protein. Biomunex has generated bispecific antibodies that bind the MAIT semi-invariant TCR (iTCR) and the HER2 receptor tyrosine kinase expressed on tumor cells. At difference to classical T-cell engagers that activate all T-cell subsets, MAIT engagers only modulate the activity of the cytotoxic MAIT cells leading to efficient tumor control and greater safety profile.

Methods. Using the Biomunex proprietary BiXAb platform, bispecific, tetravalent antibodies were generated that target the MAIT iTCR and the HER2. MAIT-cell activation, proliferation and degranulation were followed by gating on MAIT cells within a purified CD8 cell population. Tumor cell lines (varying in [HER2] expression) were co-cultured with MAIT cells and the BiXAbs in several cytotoxic assays (evaluated by Chromium release). Cytokine release was assessed by Legend Plex assays or ELISA. Cytotoxicity of tumor-resident MAITs, from fresh patient samples, was determined by impedence measurements and in patient-derived 3D organoids by The Hub organoids (imaging). For in vivo analysis, sub-cutaneous tumor growth was measured with callipers.

Results. MAIT engagers induce the rapid activation, proliferation and degranulation of MAIT cells leading to efficient killing of engaged HER2+ cancer cells with a potency similar to that of a classical HER2-directed TCE (in clinical development). The MAIT engager did not activate the regulatory T cells or other CD4/CD8 subsets. In addition, using PBMCs, total cytokine release was 1000-fold less with the MAIT engager compared to a classical TCE, opening up a large therapeutic window, which should permit effective treatment of solid tumors. *Ex vivo* cytotoxicity of tumor-resident MAIT cells using dissociated ovarian cancer samples at “real E:T ratios”, MAIT engager-mediated cytotoxicity of patient-derived organoids (CRC) and *in vivo* evaluation of tumor control will be shown.

Conclusions. MAIT cell redirection is a promising approach for the treatment of solid tumors that has the potency and efficacy of a classical TCE but with a significantly improved cytokine safety profile leading to a larger therapeutic window.

#6709 P329G-Engager: A novel universal antibody-based adaptor platform for cancer immunotherapy.

M. Surowka[1], I. Hutter-Karakoc[1], D. Darowski[1], C. Claus[1], C. Ferrara Koller[1], A. Freimoser-Grundschober[1], T. Hofer[1], A. Sobieniecki[1], D. Assisi[1], S. Leclair[2], E. Moessner[1], P. Umana[1], M. Amann[1], C. Klein[1];

[1]Roche Innovation Center Zurich, Schlieren, Switzerland, [2]Roche Innovation Center Munich, Penzberg, Germany

Bispecific immune cell engagers are showing promise in cancer immunotherapy. To achieve optimal efficacy, there is a growing need for patient personalization, tackling intra-tumor heterogeneity, and simplified combination therapies.

Here, we present a novel modular anti-P329G adaptor platform aiming to address these issues, which is based on the recognition of the P329G mutation in the Fc portion of a targeting adaptor antibody. This P329G mutation can serve to recruit different anti-P329G effector cell engagers, including innate cell engagers, T cell engagers, costimulators or immunocytokines. Specifically, upon identifying patient-specific tumor surface targets, the primary antigen-binding IgG1 antibodies bearing Fc-silencing P329G LALA mutations are applied. Subsequently, based on the tumor's immune profile, the best-suited anti-tumoral effector cell type is chosen for recruitment and activation. Based on this information, the secondary antibody recognizing the P329G mutation is chosen from an array of effector cell engagers with different modes of action: P329G-T cell bispecifics (P329G-TCB), ADCC-competent P329G innate cell engagers (P329G-ICE), P329G costimulatory molecules (P329G-CD28/4-1BBL) or P329G immunocytokines (P329G-IL2v).

In vitro assays showed all P329G modalities inducing anti-tumoral and/or immunomodulatory cell activity. Anti-tumoral efficacy of secondary antibodies was observed only in presence of tumor-targeted P329G adaptors, while no effect was observed in their absence. The readouts consisted of tumor killing quantification, CD4+ and CD8+ T cell activation, cytokine release and cytokine receptor signaling. As a proof of concept study *in vivo*, an experiment in MKN-45 (CEACAM5+)-bearing humanized mice was performed, using an anti-CEACAM5 P329G-IgG adaptor and a P329G-TCB. Both tumor volume shrinkage and T cell infiltration into the tumor confirmed anti-tumoral efficacy of the platform, as compared to a conventional CEACAM5-targeted TCB. Neither the individual P329G IgG nor the individual P329G-TCB induced anti-tumoral efficacy, validating the requirement for primary and secondary antibody binding for T cell engaging activity.

These results provide *in vitro* and *in vivo* evidence that the universal P329G engager platform can be used as an efficacious cancer treatment. Ultimately, this modular approach may enable off-the-shelf personalization *via* combination of patient-specific antibodies and universal effector cell engagers based on the patient's tumor target and immune profile.

#6712 LBL-043, a novel LILRB4xCD3 T cell engager, for the treatment of LILRB4 positive leukemia.

Yujia Dang, Xiao Huang, Yurong Qin, Xiaoya Liu, Min Chen, Duqing Jiang, Guojin Wu, Mi Ye, Jianming Sun, Baohui Wang, Jing Guan, Tingting Li, Jordan Zhu, Shoupeng Lai, Xiaoqiang Kang, **Hong Ling**

Nanjing Leads Biolabs Co., Ltd., Nanjing, China

Background: Acute myeloid leukemia (AML) is a malignant clonal disorder linked to a broad spectrum of molecular alterations. It is still an incurable cancer, the prognosis is even worse in elderly patients, where overall survival (OS) at 1 year is approximately 10-15%. Now, several CD3 bispecific immunotherapies that harness T cells against AML are at various stages of preclinical and clinical development, but most of them are hampered by the lack of specific targets to distinguish tumor cells from normal hematopoietic stem cells (HSC). Leukocyte immunoglobulin-like receptor B4 (LILRB4) is an immune checkpoint inhibitory receptor, which is highly expressed on FAB M4 and M5 AML cells with a lack of expression on normal HSC and progenitor cells. LILRB4 expression level inversely correlates with OS of patients with M4 and M5 AML. All of these indicate that LILRB4 represents a promising target for developing a T cell redirecting bispecific antibody to treat patients with AML, especially for more aggressive M4 and M5 subtype. Herein a novel bispecific antibody targeting LILRB4 and CD3, LBL-043, is developed to specifically kill LILRB4 positive tumor cells by engaging T cells.

Methods: LBL-043 was constructed using our proprietary LeadsBody^{TM} T cell engager platform, which is a 2:1 format bispecific antibody with two VHH arms targeting LILRB4 with high affinity and one scFv arm targeting CD3 with fine-tuned low affinity. The binding affinity of LBL-043 to LILRB4 and CD3 was determined with Fortebio, while the activity was measured using several cell based assays including reporter gene and TDCC assays. The anti-tumor activity of LBL-043 was investigated in B-NDG/hu-PBMC reconstructed mice implanted with MOLM-13 (human AML-M5a) tumor model.

Results: The binding affinity of LBL-043 to LILRB4 and CD3 protein was 0.724 nM and 35.7 nM, respectively. In CD3 reporter gene assays, LBL-043 could activate the NFAT reporter signaling through LILRB4 binding dependent CD3 cross-linking with an EC_{50} value of 2.459 nM. LBL-043 was shown a potent TDCC activity in different LILRB4 expression level MOLM-13 cells and HL-60 cells with T cell activation and cytokine release. In B-NDG/hu-PBMC reconstructed mice implanted with MOLM-13 tumor cells, LBL-043 was shown significant anti-tumor activity. Simultaneously, LBL-043 can effectively improve the survival rate and maintain relatively stable body weight in the study compared to the vehicle group.

Conclusion: LBL-043, a novel bispecific antibody targeting CD3 and LILRB4 with affinity differentiation, induces T cell killing of AML cells by simultaneously binding LILRB4 expressed on tumor cells and CD3 on T cells, redirecting T cells to efficiently killing of AML cells. It is also shown a great anti-tumor efficacy in CDX mouse models. These data support LBL-043 as a novel therapeutic bispecific antibody for the treatment of LILRB4 positive AML and CMML leukemia patients.

#6713 TICTE, A trispecific T-cell engager with immune checkpoint modulation for solid tumors.

X. Wu, X. Min, Y. Wu, L. Liu, J. Zhou, S. Hudson, S.-p. Chen, J. Li, W. Draper, S. Dash, S. Ma, H. Chen, **Z. Wang**;
RemeGen Biosciences, Inc., South San Francisco, CA

Background: Bispecific T-cell engager (BiTE) is a targeted cancer immunotherapy which bridges T-cells to cancer cells, leading to activation of T-cells and killing cancer cells. While BiTEs have shown promising therapeutic efficacy in the treatment of hematological malignancies, therapeutic benefit of T-cell engagers are still in exploration for the treatment of solid tumors. Upregulation of immune checkpoints presents one of the major resistant mechanisms of the BiTE therapy. Here, we report a Trispecific Immune Check-point T-Cell Engager (TICTE) platform that targets both CD3 and PD-L1 simultaneously, which activates the T-cells as well as modulates the immune checkpoint blockade through the PD/PD-L1 axis, respectively. Our *in vitro* and *in vivo* studies demonstrate that the TICTEs induce dramatic and superior antitumor activity compared to its counterpart BiTE alone and the BiTE with anti-PD-L1 combination. These studies suggest that the TICTE (CD3xTAAxPD-L1), a single-agent with dual function of T-cell activation and immune checkpoint modulation, may provide an efficacious therapy to patients with solid tumors.

Methods: Various TICTEs and BiTEs formats using the human IgG like architecture in three different TAA examples were generated. Their biophysical and biological activities were characterized. The cell binding activity and antigen density of cell lines were determined using flow cytometry. TDCC activity was measured using xCELLigence RTCA eSight system. In vitro efficacy was evaluated with multiple cancer cell lines and toxicity was evaluated with normal cell lines. The humanized xenograft models were utilized to investigate the TICTEs efficacy *in vivo*.

Results: All TICTEs adopted their intended forms and showed robust biophysical properties. The TICTEs demonstrated the blockade activity of PD1/PD-L1 axis, as well preferentially targeted tumor cells expressed both TAAs and PD-L1. Large therapeutic windows were observed in three TAA (cMET, Her2 and Trop2) TICTEs. TICTEs showed a superior efficacy compared to counterpart BiTEs and combination of BiTE with a PD-L1 inhibitor *in vitro* and *in vivo*. Low cytokine release was observed compared to combination of BiTEs with a PD-L1 inhibitor, signifying the reduced risk of cytokine release syndrome (CRS) often associated with BiTE therapy.

Conclusion: A single agent of the TICTE platform with unique biological property, superior efficacy and low cytokine release could represent an alternative combination immunotherapy for solid tumors.

#6714 AI-guided tailor-made anti-TROP2 T-cell engagers for T-cell mediated cancer immunotherapy with enhanced therapeutic index.

Chuan Chen, Liang Tian, Chenpeng Su, Dandan Liu, Xiaoqian Chen, Yifei Zhou, Suze Jiang, Guifang Wang, Jiyuan Tian, Yuan Yuan, Bing Yang, Jian Peng

Helixon, New York, NY

Bispecific T-cell engagers (TCEs) have shown significant therapeutic advances in the treatment of hematologic cancers. However, the clinical efficacy of TCEs in treating solid tumors remains to be demonstrated. Accumulating evidence suggests novel TCE modalities that simultaneously engage both CD3 (signal 1) and CD28 (signal 2) co-stimulatory signals may offer potential advantage to enhance clinical efficacy of TCEs with improved therapeutic index. To explore the full potential of TCEs as a powerful approach of immunotherapy for solid tumors, we developed an integrated AI-guided TCE platform to streamline the discovery, optimization and high-throughput function screening and characterization of TCE molecules. Here we report the construction and characterization of a novel panel of TROP2-targeting TCEs by leveraging our AI-guided optimization technology, plus a high-throughput in vitro screening platform. These tailor-made TCE molecules exhibit favorable developability and functional properties. Our data show that a novel TROP2 × CD3 x CD28 trispecific TCE that contains a CD3-targeting arm in concomitant with a CD28-targeting arm can induce potent T-cell co-stimulation and promising synergistic T cell-mediated tumor cell killing in vitro, compared to its counterparts with a single CD3-targeting arm. We further generate a trivalent TROP2 x CD3 bispecific TCE constructed as an asymmetric '2+1' format with bivalent binding to TROP2 but a monovalent CD3-targeting arm. This molecule stimulates very low levels of cytokine release, but drives robust antigen-specific killing in in vitro assessment. Anti-tumor activity of the various TROP2 x CD3 TCEs is currently being investigated in multiple tumor xenograft mouse models.

#6715 CLDN6: Biological insight into therapeutic potency of SAIL66, a next generation of T-cell engager targeting CLDN6.

N. Kimura[1], K. Taniguchi[1], T. Kamikawa[1], **M. Yoshimoto**[1], S. Ishii[1], M. Muraoka[1], M. Shimada[1], M. Kamata-Sakurai[1], T. Kitazawa[1], T. Igawa[2];
[1]Chugai Pharmaceutical Co., Ltd., Yokohama, Kanagawa, Japan, [2]Chugai Pharmaceutical Co., Ltd., Tokyo, Japan

Background: Because of high recurrence rate, ovarian cancer continues to demand new treatments. Recently, we have developed a next-generation T-cell engager SAIL66, which is a tri-specific monoclonal antibody designed to bind to CLDN6 on cancer cells with one Fab arm and to both CD3 and CD137 with the other Fab arm. By boosting T cell activation through both CD3 and CD137 binding, SAIL66 shows potent anti tumor efficacy against CLDN6-positive cancers and are currently being evaluated in patients with CLDN6-positive solid cancers including ovarian cancer (NCT05735366). CLDN6 is upregulated in many solid tumors but shows minimal or no expression in healthy adult tissues. Due to its cancer specific expression profile, CLDN6 has been utilized as a target for cancer immune therapies. Here, we demonstrate that CLDN6 is an attractive therapeutic target from its biological perspective in ovarian cancer.
Methods and Results: In a HuNOG tumor-bearing mouse model transplanted with CLDN6-positive ovarian cancer cells (OV90, OVCAR3), SAIL66 showed potent antitumor activity as a single agent. Surprisingly, CLDN6 expression in transplanted tumors was significantly lower compared to in vitro cultured cells, suggesting that CLDN6 expression is highly variable. In vitro, CLDN6 expression reversibly fluctuated depending on cell density, and its expression was consistent with the expression of epithelial-mesenchymal transition (EMT) and stemness-related genes. Furthermore, FACS and qPCR revealed that chemotherapeutic agents increased CLDN6-positive cells, and this fluctuation was accompanied by the expression of EMT and stemness-related genes. Based on this biology, we tested the combination effect of SAIL66 and chemotherapies in a non-clinical tumor-bearing mouse model. As a result, significant tumor regression was observed in mice treated with SAIL66 in combination with carboplatin.
Conclusion and Discussion: Ovarian cancer is characterized by significant tumor heterogeneity. The presence of cancer stem/stem-like cells or EMT has been proposed to elucidate the underlying mechanisms of the heterogeneity. Our study potentially could offer valuable insights into the biology of CLDN6-positive cells and the causes of ovarian cancer heterogeneity. Furthermore, it could help in patient selection, the development of combination strategies, and future clinical validation of SAIL66.

#6716 DLL3 TriTCE Co-Stim: A next generation trispecific T cell engager with integrated CD28 costimulation for the treatment of DLL3-expressing cancers.

P. Repenning, D. Lau, D. C. Hernaez, A. Robinson, D. P. Escanda, M. Rocha, B. S. Moreno, J. Zhang, P. Shao, N. Escalante, L. Newhook, P. Bhojane, C. L. Piscitelli, P. A. Moore, T. Spreter Von Kreudenstein, N. E. Weisser;
Zymeworks BC Inc., Vancouver, BC, Canada

Small cell lung cancer (SCLC) is an aggressive neuroendocrine cancer with a poor prognosis and high unmet medical need. Current standards of care, including chemotherapy, targeted therapy and immunotherapy, are associated with limited duration of response. Furthermore, SCLC is characterized by an immunosuppressive microenvironment and poor T cell infiltration which present additional treatment challenges. Delta-like ligand 3 (DLL3) is an inhibitory Notch ligand that is aberrantly overexpressed in SCLC and other neuroendocrine tumors, but minimally expressed in normal tissues, and is a new therapeutic target. Bispecific T cell engagers (TCE) targeting DLL3 have entered the clinic and demonstrated promising anti-tumor activity in SCLC patients; however, we believe there is room to improve on the rate and depth of response. To address treatment challenges and enhance the durability and sustainability of T cell activation, we have engineered a trispecific co-stimulatory T cell engager (TriTCE Co-stim) molecule that optimally engages CD3 and CD28 and redirects and enhances cytotoxic T cell responses to DLL3-expressing tumor cells while maintaining a desired safety profile. A panel of DLL3xCD3xCD28 trispecific antibodies (Abs) was engineered with a conventional anti-CD28 agonist paratope in a variety of Ab formats, geometries, paratope affinities and specificities. Geometry and design features of the tri-specific Abs were informed by prior TriTCE Co-stim molecule optimization[1]. Azymetric™ and EFECT™ platforms were used to facilitate heterodimeric multi-chain antibody assembly with silenced Fc gamma function. Lead TriTCE Co-stim Abs were selected for enhanced DLL3-dependent antitumor cytotoxic activity and increased T cell function including T cell activation, proliferation and cytokine production, compared to competitor bispecific TCEs. DLL3-independent activity and cytokine release were assessed with human PBMCs in solid and solution phase assays to evaluate the potential for cytokine release induction. In summary, we have identified multiple TriTCE Co-Stim Ab formats with improved DLL3-dependent cytotoxicity and T cell activation over competitor bispecific TCEs across multiple DLL3-expressing tumors. By screening various Ab formats, geometries and paratope affinities, we have selected lead DLL3 TriTCE Co-stim Abs displaying target-dependent activation of T cells with potent anti-tumor activity which may translate to improved and more durable antitumor responses in the treatment DLL3-expressing cancers.

#6717 Targeting mutant KRAS proteins with novel TCR-mimic fully human antibodies.

J. Du, W. Tang, X. Jiao, L. Zhao, P. Du, Y. Zhang, J. Bao, H. Chen, **C. Guo**, W. An;
Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

Mutated KRAS proteins are ideal cancer targets, as they are expressed frequently and specifically in certain solid tumors. A large proportion of human colorectal cancer and pancreatic ductal adenocarcinoma express the tumor driver KRAS gene mutations G12V/G12D, but drugs targeting G12V/G12D are not available, revealing a huge unmet clinical need. While small molecules often fail to target the KRAS mutation G12V/G12D, T cell receptor-mimic (TCR-mimic) antibodies can specifically recognize KRAS mutations presented by human leukocyte antigen (HLA), opening up possibilities for targeting such intracellular antigens. Here, we discovered novel antibodies highly specific to G12V/HLA and G12D/HLA complexes by immunizing our proprietary RenTCR-mimic™ mice and using high-throughput Beacon-based screening. These TCR-mimic antibodies have higher affinities compared to endogenous TCRs, which may effectively reduce the possibility of tumor escape. Germline distribution analysis indicated their high sequence diversity, which suggests diverse epitope targeting. Although pancreatic cancer is extremely difficult to treat and has an extremely low KRAS mutant peptide-HLA complex density on the cell surface, our TCR-mimic antibodies exhibited potent in vitro tumor lysis activity when assembled into CD3 T cell engagers. Furthermore, these antibodies demonstrated convincing off-target safety. Together, our results indicate promising therapeutic potential of these KRAS mutation-targeted TCR-mimic antibodies for the treatment of solid tumors.

#6718 Evaluating toxicity and efficacy of bispecific EGFRXCD3 T cell engager in solid tumor-bearing humanized animal model.

G. Yang, L.-C. Yao, J. G. Keck, M. Cheng;
The Jackson Laboratory, Sacramento, CA

Background: Cancer immunotherapy has currently become a highly active research area of oncology and a common treatment strategy for several cancer types. One prominent reason is that the utilized animal models could not accurately predict the of toxic response of human immune system to anti-cancer drug. For improving the safety of immune drug development, it is urgent to establish a predictive nonclinical animal platform that can accurately predict human immune response to the drugs and detect potential unwanted toxicity to human patient will be critical. We have demonstrated a disseminated tumor-bearing humanized mouse model that can evaluate the toxicity and efficacy of bispecific T cell engager (BiTE). In this study, we co-engrafted disseminated and solid tumor cells to the same mice and compared with mice engrafted with disseminated tumor or solid tumor. The purpose is to develop a novel tumor-bearing mouse model that can simultaneously evaluate the long-term efficacy against solid tumors in addition to cytokine level assessment.
Method: Epidermal growth factor receptor (EGFR) expressing human triple negative breast cancer MDA-MB-231/Luciferase-2A-GFP (MDA) cell line was utilized to establish solid tumors in mice. The cells were implanted into PBMC humanized NSG-MHC class I/II double knock out (DKO) mice via orthotopic injection into mammary fat pad (MFP). Disseminated MDA cells were injected intravenously (IV) and tumor cells normally colonize in mouse lungs. Following EGFRxCD3 BiTE dosing initiation, tumor burden in MFP and lungs were evaluated via in vivo Xenogen imaging system, and solid tumor volume in MFP was measured 2 to 3 times a week by a digital caliper. To evaluate the toxicity in response to EGFRxCD3 BiTE treatment, human inflammatory cytokine levels was analyzed by BD cytometric bead. Clinical observations and body weight change, and human immune cell activation were evaluated.
Result: EGFRxCD3 BiTE treatments significantly inhibited MFP solid tumor growth regardless the presence of IV implanted with MDA cells. EGFRxCD3 BiTE treatment induced elevated human inflammatory cytokines from humanized mice implanted with combined MFP and IV tumors. By comparison, the serum cytokine levels were low in mice implanted with MDA cells via MFP alone, suggesting that disseminated tumor cells are required for cytokine production induced by EGFRxCD3 BiTE.
Conclusion: Without disseminated tumor, MFP solid tumor-bearing mice can be served as a model for drug efficacy but did not induce inflammatory cytokines by EGFRxCD3 BiTE treatment. Combination of solid and disseminated tumor models in the same mice provide a new approach for simultaneously evaluating the toxic cytokine release and efficacy of immunotherapy drugs.

#6719 TriTCE Co-Stim: A next generation trispecific T cell engager platform with integrated CD28 costimulation, engineered to improve responses in the treatment of solid tumors.

L. Newhook, P. Bhojane, K. Stahl, N. E. Escalante, P. Repenning, D. Perez Escanda, P. Shao, M. C. Poffenberger, A. Robinson, K. Patel, A. Livernois, C. L. Piscitelli, N. Afacan, P. A. Moore, N. E. Weisser, T. Spreter von Kreudenstein;
Zymeworks BC Inc., Vancouver, BC, Canada

Bispecific T cell engagers (TCEs) have exhibited clinical successes in the treatment of hematological cancers, while treatment of solid tumors remains a challenge. Treatment of solid tumors with conventional CD3-engaging TCEs can result in limited T cell proliferation and recruitment to the tumor site, and treatment related T cell anergy, thus restricting the ability of bispecific TCEs to inhibit growth of these poorly infiltrated tumors and rapidly growing tumors. Next generation tumor-targeting, trispecific T cell engagers with integrated costimulation (TriTCE Co-Stim) have the potential to provide more durable responses and re-invigorate T cell responses by mediating integrated signaling through CD3 (signal 1) and co-stimulation through CD28 (signal 2). Superagonist anti-CD28 antibodies activate T cells but resulted in clinical toxicities with severe cytokine release syndrome (CRS). Therefore, achieving a balance between signal 1 and 2 is critical for optimal T cell activation and proliferation. Using our Azymetric™ and EFECT™ platforms, we generated heterodimeric TriTCE Co-Stim antibody formats with various geometries and affinities to optimize T cell response and widen the therapeutic window for the treatment of solid tumors.

We have previously described screening and interrogation of different TriTCE Co-stim formats and paratope affinities, and the selection of a lead format with optimized CD3 and CD28 T cell activation. Here, we have further expanded our validation of the TriTCE Co-stim platform with our lead CLDN18.2 TriTCE co-stim format, to include a tolerability assessment in nonhuman primates.Our lead TriTCE Co-Stim format exhibited a favorable safety profile *in vitro* and mediated target-dependent induction of T cell activity, with enhanced proliferation, survival, and T cell-mediated cytotoxic potency compared to bispecific TCEs. In a predictive *in vivo* model of CRS, our lead TriTCE Co-Stim did not exhibit systemic toxicity or peripheral cytokine release. TriTCE Co-Stim mediated enhanced tumor growth regression *in* vivo with an increase of T cells within the tumor and no increase of T cells within the periphery.

Repeat doses of the lead TriTCE Co-Stim molecule at 3 mg/kg were well-tolerated in nonhuman primates with no abnormal clinical signs. Minor decreases in body weight and food consumption were observed. Clinical pathology changes were consistent with a mild systemic inflammatory response.

In summary, our lead TriTCE co-stim molecule has enhanced target-dependent antitumor activity vs. bispecific benchmarks and is tolerated a murine CRS model and repeat dose non-human primate study. These data suggest TriTCE Co-stim may provide tolerable and more durable antitumor responses and contribute to improved clinical outcomes.

#6720 HINT1 steric masked, protease-activatable bispecific protein nanorings direct human T and NK cells to eradicate EGFR+ solid tumors.

A. Kulkarni, D. Paul, D. Dahlberg, K. Ligori, F. Rodriguez, L. Rozumalski, B. Walcheck, C. R. Wagner;
University of Minnesota, Minneapolis, MN

Introduction/Purpose: The Wagner lab has developed a protein nanoring based platform to direct human immune cells to combat solid tumors. These nanorings are bispecific, comprised of tumor-targeting and immune cell-targeting dihydrofolate reductase ($DHFR^2$) fusion proteins. These protein nanorings direct immune cells to target and destroy cancer cells. For treating solid tumors, we aimed to target epidermal growth factor receptor (EGFR). However, targeting EGFR could lead to potential "*on-target, off-tumor*" effects due to expression of EGFR in healthy tissue. Matrix metalloproteinases are overexpressed in a variety of solid tumors. Therefore, to improve tumor specificity, we hypothesized that masking the immune cell targeting $DHFR^2$ protein through a matrix metalloproteinase-2 (MMP-2) sensitive linker will prevent engagement and activation of immune cells outside the tumor microenvironment (TME). Once these protease-activatable nanorings enter the TME and bind to EGFR, cleavage by MMP-2 will lead to unmasking of the immune cell binder, thereby crosslinking and activating immune cells, causing targeted cancer cell lysis.

Methods: We designed human histidine triad nucleotide binding protein-1 (HINT1) masked anti-immune cell targeting nanobody-$DHFR^2$ fusion proteins. HINT1 was hypothesized to sterically block the engagement of immune cells outside the tumor. HINT1-anti-TCR-$DHFR^2$ (TCR = T cell receptor) and HINT1-anti-CD16-$DHFR^2$ were cloned, expressed, purified, and characterized. Their apparent binding affinities were determined using flow cytometry. The anti-tumor efficacy of these nanorings was evaluated against EGFR overexpressing A431 (human epidermoid carcinoma) cells.

Results: HINT1-anti-TCR-$DHFR^2$ and HINT1-anti-CD16-$DHFR^2$ rings showed reduced binding to T and NK-92-CD16 cells, respectively. *In vitro* MMP-2 cleavage assay showed complete removal of the HINT1 mask within 2 hours. Western blot analysis showed that both proteins were stable in human serum up to 3 days. 2D cytotoxicity assays with protein nanorings assembled using anti-EGFR-$DHFR^2$ and anti-TCR-$DHFR^2$ or anti-CD16-$DHFR^2$ with T and NK-92-CD16 cells respectively, showed a potent lysis of A431 cells. The EGFR-targeted lysis was diminished in the presence of HINT1 mask, thereby providing proof-of-concept for the steric masking of the anti-immune cell targeting nanobodies.

Conclusion: Protease-activatable nanorings can selectively lyse EGFR+ tumor cells *in vitro*. Their antitumor efficacy and safety are currently being evaluated using a previously established *in vivo* mouse model. Therefore, HINT1-steric masking can serve as a simple and effective strategy to address off-tumor toxicities associated with bispecific immunotherapies.

#6721 AI-guided generation of novel GUCY2C-targeting T-cell engagers for the treatment of colorectal cancer.

Liang Tian, Jinxiu Hou, Chenpeng Su, Xiaoou Xu, Xiaoqian Chen, Dandan Liu, Jiyuan Tian, Rui Shen, Yi Pan, Yuan Yuan, Lisha Dong, Tingting Gu, Jian Peng

Helixon, New York, NY

Colorectal cancer (CRC) ranks as one of the most lethal cancers worldwide. Given the advances in immunotherapy and targeted therapy, the survival time in CRC has been improving recently. However, the development of novel and effective therapies for CRC still remains an unmet medical need. Guanylyl cyclase C (GUCY2C) is a transmembrane receptor expressed on the surface of intestinal epithelial cells. Recent studies have demonstrated that GUCY2C is causally linked to intestinal inflammation, dysbiosis, and tumorigenesis. To this end, GUCY2C has emerged as a promising target for immunotherapy and a diagnostic marker of primary and metastatic cancer. Here we describe the discovery and optimization of a novel panel of GUCY2C-targeting T cell engagers (TCEs) developed via our streamlined AI-guided TCE development platform. We have identified a number of anti-GUCY2C antibodies with various binding epitopes on GUCY2C, and subsequently generated a panel of novel GUCY2C-targeting multispecific antibodies with favorable developability and functionalities via our AI-driven engineering technology. Our data demonstrate that a biparatopic GUCY2C x CD3 TCE engineered as an asymmetric ‘1+2’ format can recognize two distinct epitopes on GUCY2C. This biparatopic GUCY2C x CD3 TCE shows enhanced tumor cell binding affinity and superior T cell-mediated cytotoxicity compared to the ‘1+1’ GUCY2C x CD3 TCE and ‘1+2’ bivalent GUCY2C x CD3 TCE where the two GUCY2C targeting arms can only bind to an identical epitope on GUCY2C. In addition, we have engineered a novel GUCY2C × CD3 x CD28 trispecific TCE, in which the CD3-targeting arm in tandem with the co-stimulating CD28-targeting arm mediate the interaction with T cells. This anti-GUCY2C trispecific TCE induces favorable synergistic T cell activation and tumor cell killing in vitro compared to the bispecific counterparts. In vivo anti-tumor activity assessments of these multispecific TCE molecules in various tumor xenograft mouse models are currently ongoing.

#6722 A CD33 antigen targeted Gamma Delta T-cell engager in combination with zoledronate promotes Vg9Vd2^{+} T cell proliferation and cytotoxicity against acute myeloid leukemia.

A. Y. Lai[1], C. Wang[2], D. C. Baiu[2], K. Smith[2], A. Patel[1], K. Evans[1], N. Murr[1], D. Franklin[1], M. Hussain[1], J. Pate[1], N. Oien[1], V. Makani[1], A. Shukla[1], K. Wilson[1], G. Fromm[1], T. H. Schreiber[1], J. E. Gumperz[2], S. De Silva[1];

[1]Shattuck Labs, Durham, NC, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI

Vγ9Vδ2^{+} T cell (GDT) targeted immunotherapy is of interest to harness its MHC-independent cytotoxic potential to promote anti-tumor immunity. However, it remains unclear whether GDT (1-5% of total T cells) are present at sufficient numbers to be therapeutically relevant. Accumulation of intracellular phosphoantigens promotes heterodimerization of butyrophilin (BTN) 2A1 and BTN3A1 on the cell surface, leading to TCR-mediated activation of GDT. To date, clinical trials in cancer patients have failed to demonstrate monotherapy activity using a variety of GDT activating agents, including aminobisphosphonates such as zoledronic acid (ZA), Vδ2^{+} targeted T cell engagers and BTN3A1 targeted antibodies. These data leave fundamental questions regarding the therapeutic potential of GDT unanswered, including whether they are present in sufficient numbers, whether the agents in question are providing adequate GDT activation, and whether GDT are being directed to tumor cell targets. The studies herein were thus designed to further understand the role of phosphoantigens, butyrophilins and antigen presenting cells (APCs) in activating GDT. Specifically, APC mediated GDT activation was studied in an in vitro co-culture system in the presence and absence of ZA or a CD33-directed GDT engager incorporating a heterodimer of BTN2A1 and BTN3A1 to dissect the contribution of phosphoantigens, butyrophilins and other costimulatory molecules on GDT proliferation and activation. To this end, while BTN2A1/3A1-Fc-CD33scFv treatment alone in T and monocyte-derived dendritic cell (mDC) co-cultures or in unfractionated PBMCs increased the frequency of GDT by 2 to 10-fold after 7-12 days, the combination with low dose ZA (0.5 to 2 μM) synergistically increased GDT proliferation by 40 to 100-fold. These results indicate that GDT proliferation relies both on the abundance of BTN2A1/3A1 heterodimers and other costimulatory signals activated by ZA. Synergistic effects of ZA and BTN2A1/3A1-Fc-CD33scFv in GDT proliferation was similarly observed in human PBMC-engrafted NSG-IL-15tg mice 12 days after treatment. Importantly, the addition of BTN2A1/3A1-Fc-CD33scFv to T (or PBMC) and CD33^{+} AML co-cultures enhanced both GDT proliferation and anti-leukemic activity while sparing healthy CD33^{+} immune cells. Collectively, these results demonstrate that GDT proliferation and effector function is dependent both upon the abundance of butyrophilin heterodimers, and other cell surface molecules which are modulated by intracellular phosphoantigen accumulation.

#6724 Mechanistic validation of MAIT cell engagers in HUB patient-derived organoids (PDO) co-culture model.

Y. Abouleila[1], J. Prigent[2], M. Doorn[1], C. Germain[2], S. Boj[1], S. Plyte[2], C. Verissimo[1];
[1]HUB Organoids, Utrecht, Netherlands, [2]BIOMUNEX Pharmaceuticals, Paris, France

In the field of cancer immunotherapy, bispecific antibodies have emerged as a promising approach for redirecting T-cells to target and combat tumors. However, their efficacy is limited to only a subset of patients. A major challenge that hinders the development of bispecific antibody targets is the lack of preclinical models that preserve patient-specific tumor antigens and recapitulate the complex interaction between the human immune system and tumor cells. HUB Organoids technology presents a valuable platform for novel immunotherapies testing and validation as they are directly derived from patient tumor tissues, accurately reflecting patient-specific tumor antigens. BIOMUNEX Pharmaceuticals has developed the BiXAb® technology platform, a computational modeling approach that rapidly generates bispecific antibodies from various monospecific monoclonal antibodies, eliminating the need for extensive engineering. This platform includes a bivalent T cell engager specifically targeting MAIT cells and human epithelial growth factor receptor (HER2), a tumor antigen highly expressed in some colorectal cancer (CRC) patients. This innovative approach forms an efficient immunological synapse, allowing exclusive redirection of MAIT cells to directly eliminate cancer cells. In a collaborative research initiative between HUB Organoids® and BIOMUNEX Pharmaceuticals, the mechanisms by which BiXAb® induce tumor cell killing were confirmed using CRC patient-derived organoids (HUB Organoids® or PDOs) co-cultured with allogenic MAIT cells in an *in vitro* model. The study results depicted BiXAb® induced MAIT-cell activation in a dose-dependent manner, as detected by FACS and ELISA. Furthermore, BiXAb®-mediated MAIT-cell-specific killing of CRC PDOs was observed in a HER2-dependent manner, determined using an image-based viability assay. In conclusion, the co-culture platform of CRC PDOs-MAIT cells described here effectively captured the activation and targeted killing of MAIT cells mediated by BiXAb®, underscoring the added value of this PDO-based co-culture platform in developing novel immunotherapies.

#6725 NTX-470, a novel multispecific T cell engager expressed from mRNA targets PSMA and STEAP1 prostate cancer antigens to generate enhanced functional activity.

C. Rae[1], S. Adusumilli[1], S. Bandi[1], S. Lal[1], P. Dhungel[1], K. Ferry[1], S. Gholizadeh[1], A. Sharma[1], A. Sallets[1], W. Liu[1], E. McCartney-Melstad[1], P.-K. Hsu[1], R. Low[1], C. McKinlay[1], M. Leong[1], D. Y. Oh[2], L. Fong[2], G. Kannan[1], S. Deutsch[1], O. Haabeth[1];
[1]Nutcracker Therapeutics, Inc., Emeryville, CA, [2]University of California, San Francisco, San Francisco, CA

Prostate cancer is the most common cancer in American men and the second leading cause of cancer death in men in western countries. Most metastatic patients develop castration resistant prostate cancer, which despite advances in immunotherapy, is limited in treatment options and represents a critical unmet need. Bi-specific T cell engagers (TCEs) targeting prostate cancer antigens represent a modality that has demonstrated preliminary clinical activity. Clinically validated antigens that are highly expressed in prostate cancers include Prostate-Specific Membrane Antigen (PSMA) and Six Transmembrane Epithelial Antigen of the Prostate 1 (STEAP1). TCEs targeting either PSMA or STEAP1 individually have shown promising clinical activity, but challenges with durability and toxicity have been reported, potentially attributable to antigen escape, target-independent T cell activation (bystander activation) and specificity issues. Contrary to its name, PSMA expression is not exclusive to prostate cells and can be found in several other tissues and/or conditions, including normal nonprostatic epithelial cells, inflammation/infection, nonprostatic neoplastic cells and nonprostatic tumor-associated neovasculature. The widespread expression of PSMA may limit the therapeutic window of PSMA-specific TCEs and drive immunotoxicity by increased on-target, off-tumor binding. To address these issues, Nutcracker Therapeutics (NTX) has developed novel and highly complex multispecific TCE molecules that target both PSMA and STEAP1, which can be expressed using NTX's proprietary mRNA therapeutics platform. A wide library of molecules was designed with attenuated PSMA and CD3 binding to mitigate on-target, off-tumor binding and target-independent T cell activation. Molecules were screened and selected based on their propensity to cause bystander T cell activation and the strength of PSMA binding. We identified a small number of molecules that are capable of engaging CD3 T cells but display minimal activity in the absence of STEAP1 or PSMA expressing target cells, including molecules that retain low bystander activity and attenuated PSMA binding yet maintain robust target cell killing. These molecules include NTX-470, which targets both STEAP1 and PSMA on tumor cells with minimal bystander activity.

#6726 Costimulatory IgM T-cell engagers with enhanced and durable cytotoxicity.

J. Xue, K. Li, P. Yakkundi, P. Chadasama, T. Mao, Z. Malik, V. Rao, M. Joglekar, K. Mai, G. Li, D. Pandya, R. Rosete, Z. Ye, L. Tahrani, J. Wang, N. Hanna, E. Perez, Y. Wang, S. Ahmed, L. Widjaja, P. Hinton, K. Bzymek, B. Keyt, M. Oyasu, L. Liu, **A. Sinclair**, U. S. Muchhal;
IGM Biosciences, Inc., Mountain View, CA

T-cell engagers (TCEs) have established therapeutic effect in treatment of various cancers by harnessing the power of the immune system against tumors in a targeted manner. IgM-based TCEs may offer high avidity, specificity, and safety advantages over other modalities because of their multivalent architecture and unique positioning of the CD3 binding domain on the J-chain. We have built a costimulatory IgM TCE platform that engages both signal 1 and signal 2 on T-cells, with the goal of enabling their optimal activation and survival for more robust and durable cytotoxic activity.

Multiple antigen targeting costimulatory IgM TCEs were generated and activity was evaluated both in vitro and in vivo to assess the role of CD28 co-stimulation. Costimulatory IgM TCEs engaged both CD3 and CD28 on the T-cell surface, enhancing in vitro cytotoxicity and T-cell activation. Levels of IL-2 increased significantly with dual signal engagement promoting proliferation and survival of T-cells. In long-term culture assays, costimulatory IgM TCEs promoted better T-cell proliferation and survival compared to IgM TCEs with only a CD3 binder, and was even more pronounced at low E:T ratios. In the absence of CD3 engagement, CD28 binding alone did not induce any T-cell activation, cytotoxicity, or cytokines. Activation of T-cells was also fully dependent on the presence of target cells, underscoring the safety profile of the platform.

In Hu-PBMC xenograft tumor models, costimulatory IgM TCEs exhibited stronger in vivo anti-tumor activity compared to TCEs only engaging CD3. Tumor growth inhibition was maintained for longer after dosing was stopped with costimulatory IgM TCEs, indicating the durability of responses. Costimulatory IgM TCEs suppressed tumor growth in xenograft studies using cell lines that expressed both high and low target copy numbers suggestive of their broad utility against multiple tumor types. Enhanced in vivo anti-tumor activity of costimulatory IgM TCEs was associated with significant increases in intra-tumoral CD8/CD3^{+}T-cells.Both peripheral and intra-tumoral T-cells exhibited enhanced anti-apoptotic and cytotoxic phenotypes indicative of the costimulatory activation.

IgM-based costimulatory TCEs provide enhanced cytotoxicity through optimal T-cell activation and proliferation/survival. This dual engagement of T-cell activation signals, along with the high avidity target binding offered by IgM platform, could enable the creation of effective therapeutics targeting pathogenic cells in autoimmune diseases and solid tumors that will maintain activity even in conditions with low T-cell counts.

#6727 QL335, a novel T cell engager with enhanced safety profile targeting MSS colorectal cancer.

S. Gu[1], G. Guo[1], H. Yee[1], H. V. Tran[1], S. Chen[1], C. Cao[2], K. Liu[2], C. Jin[2], W. Lun[2], R. Ma[2], L. Ren[2];
[1]QLSF Biotherapeutics, South San Francisco, CA, [2]Qilu Pharmaceutical Co., Ltd., Jinan, China

Colorectal cancer (CRC) is the fourth leading cause of death in the world with a global mortality rate of over 700,000 annually. While recent advancement in diagnosis and prevention has reduced the overall number of deaths, the lack of effective and durable treatment has not significantly improved survival rate. Emerging modalities in immunotherapy such as T cell engagers have paved new ways for disease management. However, a common challenge to advancing T cell engagers in the clinic is poor target specificity and high toxicity associated with non-specific T cell activation and cytokine release. To overcome these shortcomings, we have developed QL335, a bispecific antibody bridging LY6G6D antigen on tumor cells and CD3 on T cells. LY6G6D or Lymphocyte Antigen 6 Family Member G6D, is a GPI-anchored membrane protein that, according to TCGA RNAseq data, is highly expressed in microsatellite stable (MSS) colorectal cancer but not in normal tissues. We analyzed LY6G6D expression by IHC in over 200 CRC patient tumors and 40+ normal tissue samples from different organs, confirming its highly restricted CRC expression pattern. We constructed our bispecific antibody in a 2+1 format, comprising two high affinity LY6G6D binding domains and one reduced affinity CD3 binding domain. Such format allows for higher tumor accumulation while mitigating non-specific T cell activation in the periphery. In vitro evaluation showed that QL335 induced potent yet highly specific T cell activation and killing of only target cells expressing LY6G6D. QL335 demonstrated robust anti-tumor efficacy in vivo against human colon cancer xenograft models with human PBMC reconstitution. Importantly, QL335 was well tolerated in cynomolgus monkeys dosed up to 50 mg/kg, supporting the enhanced safety profile by design of this therapeutic candidate. QL335 is currently being evaluated in a phase 1 clinical trial.

#6728 Preclinical development of QL325, a novel T cell engager targeting CLEC12A-positive AML.

S. Gu[1], H. V. Tran[1], S. Chen[1], K. Liu[2], X. Zhang[2], L. Jia[2], R. Ma[2], J. Fu[2];

[1]QLSF Biotherapeutics, South San Francisco, CA, [2]Qilu Pharmaceutical Co., Ltd., Jinan, China

Despite advancement in targeted therapies, treatment options for patients with acute myeloid leukemia (AML) that provide a tolerable and durable response remain elusive. We have developed a CD3 bispecific antibody, QL325, targeting CLEC12A, a c-type lectin protein that is highly expressed on AML blasts. Normally, CLEC12A expression is mostly confined to the CD34+CD38- progenitor population and largely absent on normal and regenerating bone marrow stem cells. Our bispecific antibody is configured in a 2 + 1 format, with bivalent avidity binding to CLEC12A, monovalent low affinity binding to CD3, and an effector-null Fc for extending half-life. In our preclinical studies, QL325 induced CLEC12A -dependent activation and proliferation of T cells. Redirected T cell-dependent cytotoxicity mediated by QL325 was restricted to AML cancer cells expressing CLEC12A. QL325 demonstrated dose dependent suppression of tumor growth in xenograft models of AML, significantly more potent than a clinical benchmark antibody. In non-human primates, QL325 was tolerated up to 0.03 mg/kg for IV dosing and under 0.1 mg/kg for SC dosing, well above the predicted effective therapeutic dose. A phase 1 clinical trial is currently ongoing to determine the safety and early efficacy in patients with refractory or relapsed AML.

IMMUNOLOGY: Vaccines, Antigens, and Antigen Presentation 2

Introduction: Antibody drug conjugates (ADCs) targeting cancer-cell antigens can improve therapeutic index and show prominent clinical impact. Limited studies have used ADCs to target antigens present in non-malignant cells in the tumor microenvironment or to deliver immunomodulatory agents. We developed an immune-cell directed antibody drug conjugate (iADC) TAK-500 that selectively activates STING in C-C chemokine receptor type 2 (CCR2) expressing cells to achieve enhanced efficacy over non-targeted STING agonists. Here, we spatially mapped CCR2 protein in human NSCLC and studied the immunomodulatory role and anti-tumor effect of the novel iADC TAK-500 on human lung cancer tumor explants *ex vivo*.
Methods: Using multiplexed quantitative immunofluorescence (mQIF) panels we measured the levels of CCR2 protein, myeloid cell populations and tumor infiltrating lymphocyte (TIL) subsets in 411 primary NSCLC carcinomas from treatment-naïve patients in 2 independent cohorts and determined their clinical significance. In addition, we longitudinally studied CCR2 levels, myeloid cells (DAPI/CCR2/CD68/CD11b), TILs (DAPI/CK/CD4/CD8/CD20), T-cell functional markers (DAPI/CK/CD3/Ki-67/GZMB [Granzyme B]) and cancer-cell death/proliferation markers (DAPI/CK/TFR1/Ki-67/CC3 [Cleaved Caspase 3]) in 314 primary cultured tissue fragments from paired tumor and non-tumor specimens resected from 11 lung cancer patients at Yale New Haven Hospital between 2021-2023 (8 adenocarcinomas, 2 small cell carcinomas, and 1 squamous cell carcinoma). Each biopsy was divided into 4-mm^2 fragments, cultured in extracellular matrix for 5 days with or without TAK-500 treatment. Samples were processed into FFPE tissue and stained with mQIF panels using a tissue microarray format.
Results: CCR2 protein was detected in 386 of 411 (94%) NSCLCs from 2 independent cohorts predominantly localized in CD11b+ intratumor myeloid cells and CD68+ tumor-associated macrophages (TAMs). Elevated CCR2 was associated with adenocarcinoma histology, increased PD-L1, activating KRAS mutations and longer survival. Treatment with TAK-500 for 5 days reduced CCR2 levels in myeloid cells and CD68+ TAMs, without significant changes in TIL or T-cell GZMB/Ki-67 levels. TAK-500 also significantly reduced tumor proliferation (Ki-67 expression) and increased tumor cell apoptosis (CC3 levels) after 5 days of treatment. Notably, these TAK-500-induced changes were observed only in tumor specimens with high baseline CCR2 levels above the median in retrospective NSCLC cohorts. No significant effect was observed in the paired non-tumor fragments.
Conclusion: Our results reveal prominent myeloid CCR2 expression in a subset of human NSCLCs with distinct clinicopathologic/molecular characteristics. Using a novel lung cancer explant *ex vivo* system, we demonstrate a CCR2-dependent immunomodulatory and anti-tumor effect of TAK-500 iADC.

#6733 Multiomics analysis of impact of CD8+ and other cell populations in STING agonist treated *ex vivo* mesothelioma samples.

E. Ivanova[1], S. R. Park[1], A. P. Zlota[1], N. Spicer[1], M. Ha[1], S. Kivlehan[1], I. Gjeci[1], S. Innocenti[2], L. Zasadil[1], P. Lizotte[1], M. Y. Tolstorukov[1], K. Ding[3], A. O. Abu-Yousif[3], J. Raizer[3], V. A. Appleman[3], R. Bueno[2], D. A. Barbie[1], C. P. Paweletz[1];

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Takeda, Lexington, MA

Background: Collective evidence highlights that agonism of the host STING pathway plays a critical role in eliciting robust and durable anti-tumor immunity. Dazostinag (TAK-676) is a novel systemically delivered STING agonist that ignites the innate immune system and mobilizes adaptive immunity. Preclinical studies with dazostinag demonstrated a strong, persistent CD8+ T cell anti-tumor response driven by innate immune derived type I IFN and pro-inflammatory cytokines. The role of CD8+ T cells in response to dazostinag was further supported by a previously demonstrated correlation between response and CD8+ T cell frequency in a patient-derived organotypic tumor spheroids (PDOTS) model of mesothelioma. Within the current work, we sought to determine the extent to which response to dazostinag in mesothelioma depends on CD8+ T cells versus the contribution of other immune cells.

Methods: Surgical mesothelioma cases were collected along with clinicopathological variables at Brigham and Women's Hospital under an IRB-approved protocol. PDOTS were generated as described previously. Ex vivo response was determined by fluorescent life/dead imaging, and orthogonally evaluated by multiplexed cytokine array, immunofluorescence, and flow cytometry; subset of tumors was studied using single cell RNA sequencing (scRNAseq).

Results: Dazostinag-driven tumor cell killing was evaluated in 20 mesothelioma PDOTS. 11 samples were characterized as responders (R) with a cut-off of ≥30% reduction in live cell area; 9 as non-responders (NR). In 12 out of 20 PDOTS, CD8 neutralization effect was assessed: four were TAK-676 NR, and out of 8 R 4 had at least 20% killing abrogated by aCD8. Effect did not depend on the baseline amount of CD8+ T cells in the sample. scRNAseq analysis showed that R and NR T cells have different activation/exhaustion phenotypes and varying levels of interferon stimulated genes (ISG) in response to STING agonism. Other cell populations emerged as candidates for dazostinag resistance: NR cases carried remodeled immunosuppressive myeloid cells or matrix metalloproteinases-expressing fibroblasts. In general, myeloid cell abundance at baseline characterized by flow had a trend in negatively correlating with dazostinag response. Intrinsic expression of type I interferons shown by multiplexed cytokine array was linked to dazostinag sensitivity (R vs. NR IFN-β p=0.028; IFNα2a p=0.016) and can potentially be used as a predictor for response.

Conclusion: We evaluated immune modulations in mesothelioma after treatment with a systemic STING agonist dazostinag using human tumor ex vivo culture. Innate interferon type I expression was higher in responding samples. TAK-676 efficacy was partially reduced in absence of effector lymphocytes, however other cells, such as immunosuppressive myeloid cells and fibroblasts, can have a negative impact on dazostinag response in mesothelioma.

#6734 Preclinical impact of pretreatment with CRS mitigation agents on pharmacodynamic response to TAK-500, a systemically delivered CCR2-targeted STING agonist iADC.

E. Rosentrater, M. Ganno, T. Hatten, H. Mack, A. Bollampalli, D. Zhang, A. Parent, J. Raizer, R. Gregory, N. Lineberry, V. Appleman;
Takeda Development Center Americas, Inc. (TDCA), Lexington, MA

Background: Stimulator of interferon genes (STING) agonists elicit potent innate immune enhancement and mobilize robust adaptive immune responses. Given the potential risk of immunotoxicity from associated cytokine release due to STING agonist treatment, there is a need to identify mitigation strategies that minimize immune-related toxicity while offering a therapeutic window for STING-mediated anti-tumor effects. This strategy is particularly relevant for myeloid-targeted immunotherapies, as cytokine release syndrome (CRS) can be myeloid cell-mediated. We utilized preclinical models to evaluate the pharmacological impact of pretreatment with agents routinely used for management of CRS in advance of delivering TAK-500, a novel, systemic, immune-cell directed STING agonist antibody drug conjugate (iADC) that selectively targets CCR2+ myeloid cells.

Methods: Dexamethasone and anti-IL-6R antibodies were tested at clinically relevant doses 1 hour prior to treatment with TAK-500 or mTAK-500, a murine surrogate, to study immunomodulatory and anti-tumor effects in preclinical models. Induction of innate and adaptive immune responses and cytokine release was evaluated in human, ex vivo, and in tumor-bearing mouse models to characterize potential impact of premedication strategies on drug pharmacology and anti-tumor efficacy.

Results: TAK-500 triggered dose-dependent monocyte activation and cytokine secretion ex vivo. Monocyte activation was minimally impacted by dexamethasone or anti-IL-6R pretreatment. Suppression of IL-6 and IFN-γ and increase in IL-10 were observed following dexamethasone pretreatment, whereas anti-IL-6R maintained a more proinflammatory milieu. In syngeneic mouse models, pretreatment with dexamethasone and anti-mouse IL-6R had minimal impact on mTAK-500 anti-tumor efficacy. Key pharmacodynamic effects, including innate immune cell activation in periphery and tumor-draining lymph node and intratumoral CD8+ T cell accumulation, were minimally impacted by either pretreatment agent. Serum cytokine analyses demonstrated suppression of IL-6, IFN-γ and increases in IL-10 with dexamethasone, but not with anti-IL-6R, similar to ex vivo findings.

Conclusion: Premedication of TAK-500 and mTAK-500 with dexamethasone or anti-IL-6R antibodies does not substantially impact STING-mediated innate immune activation, mobilization of adaptive immune responses or anti-tumor efficacy, despite altered cytokine profiles compared to (m)TAK-500 without premedication. Clinically, these premedication strategies have been effective in mitigating immunotherapy-associated CRS with T cell therapeutics, and here resulted in maintained anti-tumor activity when used in combination with TAK-500, suggesting a viable potential strategy for mitigation of STING-induced immunotoxicities in patients.

#6735 A systemically administered non-nucleotide STING agonist in albumin nanoformulation with potent antitumor activity and low toxicity.

JINSONG TAO, Hongyi Zhao, Zhongwei Liu, Hanning Wen, Chengyi Li, Qiuxia Li, Miao He, Bo Wen, Wei Gao, Duxin Sun

Department of Pharmaceutical Sciences, College of Pharmacy, Rogel Cancer Center, University of Michigan, Ann Arbor, MI

Background: Stimulator of interferon genes (STING), a dimeric transmembrane adapter protein, plays a pivotal role in regulating tumor immune microenvironment and has been explored as a therapeutic strategy against tumors. Most STING agonists were tested in clinical trials using intratumoral injection with limited systemic efficacy. Several systemically administered STING agonists have progressed to clinical trials, with their efficacy yet to be determined, while their systemic toxicity may limit their application. Our study aimed to develop a novel systemically administrated non-nucleotide STING agonist formulated within albumin nanoparticles, demonstrating potent antitumor activity and low systemic toxicity.

Methods & Results: We synthesized a novel non-nucleotide small molecule STING dimer ZSA-51D. The acid form of ZSA-51D exhibited a high binding affinity (EC 50: 1.3 nM) to human STING. ZSA-51D demonstrated potent STING activation in THP1-Blue™ ISG cells, with an EC50 of 5.1 nM. To enable systemic delivery, ZSA-51D was encapsulated in albumin nanoparticles (nano ZSA-51D) with a particle size of 115 nm. Surprisingly, nano ZSA-51D exhibited a tenfold increase in STING activation (EC50 of 0.44 nM) compared to free ZSA-51D. Furthermore, nano ZSA-51D demonstrated sevenfold greater activation of bone marrow-derived dendritic cells (EC 50 of 3.5 nM), and eightfold enhanced repolarization of bone marrow-derived macrophages (EC 50 of 4.2 nM) from M2 to M1 compared to free ZSA-51D. The *in-vivo* anticancer efficacy was evaluated on MC-38 and KPC 6620 xenograft in C57BL/6 mice using intravenous administration of ZSA-51D (1 mg/kg) or nano ZSA-51D, in combination with PD-1 antibody (α-PD1, 100 μg) for 5 dose every 3 days. The results revealed that nano ZSA-51D exhibited superior anticancer effects compared to free ZSA-51D. Remarkedly, nano ZSA-51D, in combination with α-PD1, completely eradicated cancer in the MC-38 xenograft model. These cured mice completely rejected the rechallenge with MC38 cells 120 days after the initial tumor inoculation, indicating potent and long-term anticancer immune memory for anticancer activity. In addition, we performed the toxicity evaluation of nano ZSA-51D and free ZSA-51D at the same dose regime as the efficacy study. Nano ZSA-51D shows no hematological and liver toxicity. However, free ZSA-51D has a sever local inflammation after injections, whereas nano ZSA-51D has no local toxicity.

Conclusion: In this study, we developed a novel systemically administered non-nucleotide sting agonist formulated within albumin nanoparticles. Nano ZSA-51, in combination with α-PD1, demonstrated superior anticancer efficacy and low toxicity, holding the potential for future clinical trials. The significantly enhanced STING activation and in vivo efficacy of nano ZSA-51D warrant further investigation into its underlying mechanisms.

#6736 Overcome the challenge for intratumoral injection of STING agonist for pancreatic cancer by systemic administration.

Keyu Li[1], Junke Wang[1], Birginia Espinoza[2], Yirui Xiong[3], Nan Niu[4], Jianxin Wang[5], Noelle Jurcak[2], Noah Rozich[2], Arsen Osipov[6], MacKenzie Henderson[2], Vanessa Funes[2], Melissa Lyman[2], Alex B. Blair[2], Brian Herbst[2], Mengni He[2], Jialong Yuan[2], Diego Trafton[2], Chunhui Yuan[7], Michael Wichroski[8], Xubao Liu[1], Yuquan Wei[3], Lei Zheng[2]

[1]Department of General Surgery, West China Hospital of Sichuan University, Chengdu, China,[2]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[3]State Key Laboratory of Biotherapy, West China Hospital of Sichuan University, Chengdu, China,[4]Zhejiang Provisional People's Hospital, Hangzhou, China,[5]The First-affiliated Hospital of Zhejiang University, Hangzhou, China,[6]Cedars-Sinai Medical Center, Los Angeles, CA,[7]Peking University Third Hospital, Beijing, China,[8]Bristol Myers Squibb Co, Princeton, NJ

Objective: Due to the challenge for intratumoral administration, innate agonists have not made it beyond preclinical studies for efficacy testing in most of tumor types. Pancreatic ductal adenocarcinoma (PDAC) has a T-cell excluded or deserted tumor microenvironment. Innate agonist treatments may serve as a T cell priming mechanism to sensitize PDACs to anti-PD-1 antibody (a-PD-1) treatment.
Design: Using a transplant murine model with spontaneously formed liver metastasis and also the genetically engineered KPC mouse model that spontaneously develops PDAC, we compared the antitumor efficacy between intrahepatic/intratumoral and intramuscular systemic administration of BMS-986301, a next-generation STING agonist. Flow cytometry, Nanostring, and cytokine assays were used to evaluate local and systemic immune responses.
Results: The study demonstrated that administration of STING agonist systemically via intramuscular injection is equivalent or potentially superior to its intratumoral injection in inducing both effector T cell response and antitumor efficacy. Compared to intratumoral administration, T cell exhaustion and immunosuppressive signals induced by systemic administration were attenuated. Nonetheless, either local or systemic treatment of STING agonist was associated with increased expression of CTLA-4 in the tumors. However, the combination of a-PD-1 and anti-CTLA-4 antibody with systemic STING agonist demonstrated the antitumor efficacy in the KPC mouse spontaneous PDAC model. Our study also demonstrated the feasibility and antitumor efficacy of systemic administration of BMS-986299, a new NLRP3 agonist.
Conclusion: For the first time, our study supports the clinical development of innate agonists via systemic administration, instead of local administration, for treating PDAC.

#6737 Pharmacologic modulation of nonsense-mediated decay induces anti-tumor immunogenicity in *ex vivo* patient tumors.

R. Vendramin[1], H. Fu[1], Y. Zhao[1], S. Fernandez-Patel[1], D. Qian[1], L. Ligammari[1], G. Beattie[1], R. Levy[2], P. Greenberg[2], O. Bartok[2], K. Thakkar[1], J. Murai[1], D. Karagianni[1], C. Sng[1], M. Shah[1], F. Galvez-Cancino[1], K. Djikstra[3], S. Quezada[1], Y. Samuels[2], TRACERx consortium, J. Reading[1], C. Swanton[3], K. Litchfield[1]; [1]University College London (UCL) Cancer Institute, London, United Kingdom, [2]Weizmann Institute of Science, Rehovot, Israel, [3]The Francis Crick Institute, London, United Kingdom

Introduction: Immunogenic neoantigens derived from somatic tumor mutations are essential to initiate and sustain robust anti-tumor immune responses. Frameshift insertion/deletions (fs-indels) are a key source of immunogenic neoantigens. However, fs-indels often result in the introduction of premature termination codons (PTCs), leading to mRNA degradation by the nonsense-mediated mRNA decay (NMD) pathway. In human malignancies, NMD activity is increased in response to the heightened burden of somatic fs-indel mutations and effectively prevents the generation of highly immunogenic tumor-specific neoantigens, thereby promoting immune evasion.

Approach: Here, we pharmacologically targeted SMG1, a core component of the NMD pathway, for the first time in patient tumor and normal samples as well as in a panel of human cancer cell lines and patient-derived organoids, to prevent the degradation of highly immunogenic frame-shifted transcripts. We analyzed the changes in transcriptome, proteome and immunopeptidome following SMG1 inhibition (SMG1i). We then made use of tumor-T cell co-cultures and Patient-Derived Tumor Fragments (PDTFs) to assess the effects of SMG1i on anti-tumor immunogenicity. Ex vivo immunological responses were measured by high-dimensional flow cytometry, cytometric bead array and single cell RNA and TCR sequencing.

Results: Our data demonstrates a significant increase in T cell activation, expansion of tumor-reactive intratumoural $CD8^{\pm}$ lymphocytes and cytokine secretion following SMG1 inhibition in ex vivo PTDFs (n=15) but not in matched normal-adjacent tissue (n=10). Mechanistically, SMG1 inhibition increased the abundance of frame-shifted mRNA transcripts, and aberrant HLA-presented peptides. Co-culture of tumor cells and patient-derived organoids with $CD8^{\pm}$ T cells upon SMG1 inhibition induced potent MHC class I antigen-dependent T cell activation and tumor cell killing.

Conclusion: Our findings, in a clinically relevant platform, highlight SMG1 inhibition as a novel cancer immunotherapy approach to promote neoantigen production and to induce anti-tumor immunogenicity irrespective of the tumor type or TMB status.

#6738 Overlapping and distinct mechanisms of effective neoantigen cancer vaccines and immune checkpoint therapy.

S. Keshari, A. S. Shavkunov, Q. Miao, A. Saha, C. D. Williams, J. E. Pineda, K. Hu, K. E. Pauken, K. Chen, M. M. Gubin;
UT MD Anderson Cancer Center, Houston, TX

The goal of cancer vaccines and immune checkpoint therapy (ICT) is to expand and sustain T cells with enhanced anti-tumor capabilities. Here, we asked whether these distinct immunotherapies utilize similar cellular and functional mechanisms. We used multiple approaches to compare effective therapeutic mutant neoantigen (NeoAg) cancer vaccines with αPD-1, αCTLA-4, or αPD-1 and αCTLA-4 ICT in preclinical *Braf*^{V600E}*Pten*$^{-/-}$*Cdkn2a*$^{-/-}$ melanoma models. Synthetic long peptide (SLP) MHC-I NeoAg vaccines induced a more than 3-fold expansion of proliferating intratumoral NeoAg-specific CD8 T cells that were functional despite high expression of PD-1 and TIM-3. NeoAg vaccines required not only CD8, but also CD4 T cells for efficacy. αCTLA-4 and/or αPD-1 ICT also increased the frequency and effector capabilities of CD8 T cells but to much less of an extent than NeoAg vaccines. These included NeoAg-specific CD8 T cells that displayed reduced expression of PD-1 and TIM-3. αCTLA-4 treated tumors displayed robust induction of ICOS^{+} Th1-like CD4 T cells expressing Bhlhe40 that resembled Th1-like CD4 T cells described in αCTLA-4-treated patients and when αCTLA-4 was combined with αPD-1, a small subset of Th2-like CD4 T cells was observed. Remarkably, we noted divergent effects on certain subsets of intratumoral macrophage populations induced by NeoAg vaccines as compared to ICT. Although effective NeoAg vaccines expanded M1-like iNOS^{+} macrophages with ICT also following this same pattern, NeoAg vaccines expanded rather than suppressed (as observed with ICT) distinct subpopulations of M2-like CX3CR1^{+} CD206^{+} macrophages. CODEX spatial imaging using a 46-marker panel revealed tumors from mice treated with NeoAg vaccines displayed concentrations of CD8 T cells expressing functional markers and the proliferation marker Ki67, with mice treated with αCTLA-4 or αPD-1 displaying both Ki67^{+} conventional CD4 and CD8 T cells within interior regions of tumor. Interestingly, these regions contained prominent blood vessels, along with MHC-II^{+} dendritic cells and iNOS^{+} macrophages. Our work shows that NeoAg vaccines lead to distinct, as well as overlapping alterations when compared to ICT. These distinct alterations provided a rationale for combination therapies that we validated in both our melanoma model, as well as the MC38 tumor model, where delayed treatment with NeoAg vaccines combined with αCTLA-4 or αPD-1 yielded anti-tumor immunity that was superior to combination αPD-1 and αCTLA-4. These findings suggest that NeoAg vaccines combined with single-agent ICT may be an effective therapy with potentially less toxicity than αPD-1/αCTLA-4 combination ICT. Further, we hypothesize that immunotherapies that deplete CX3CR1^{+} CD206^{+} macrophages may synergize with NeoAg cancer vaccines, which we are currently assessing.

#6739 Efficacy and toxicity of microbial mimetic mesoporous silica nanoparticles in a mouse model of ovarian cancer.

L. Y. Medina, R. E. Serda, B. Marwedel, M. S. Jun, J. Adogola;
University of New Mexico, Albuquerque, NM

Ovarian cancer is predominately left undetected and untreated until the later stages of the disease where it becomes incredibly difficult to treat. Preclinical studies demonstrate that immunotherapy can be highly effective. Our lab has been working on an immunotherapy approach to treat women with ovarian cancer that utilizes mesoporous silica nanoparticles(MSN). MSN that present pathogen-associated molecular patterns (PAMPS) are able to significantly reduce tumor burden in mouse models of serous epithelial ovarian cancer when administered by intraperitoneal injection. These microbial mimetic particles are decorated with polyethyleneimine (PEI), CpG oligonucleotide, and monophosphoryl lipid A (MPLA). When in the presence of antigen presenting cells, they bind to Toll-like receptors (TLR) present on the cell surface and within the endosome. To better understand mechanisms underlying their efficacy, we injected fluorescent MSN-PEI-CpG-MPLA (100 or 500 nm) or unmodified MSN into mice with advanced ovarian cancer. The particles, regardless of the presence of TLR-agonists, were rapidly internalized by myeloid cells, with trafficking almost exclusively to immune clusters located in tumor-burdened adipose tissues when administered by intraperitoneal injection. Conversely, intravenous injection of MSN-PEI-CpG-MPLA led to predominate accumulation in liver, with no particles found in tertiary lymphoid clusters 24 hours post injection. Furthermore, unlike intraperitoneal injection, intravenous injection of MSN-PEI-CpG-MPLA was without therapeutic effect. Currently we are studying MSN safety and the impact of administration route and dose on efficacy and cytotoxicity. In summary, MSN, with and without TLR agonists, are trafficked by myeloid cells to tumor-burdened fat-associated lymphoid clusters when administered by intraperitoneal injection. Intraperitoneal injection of TLR-agonist modified MSN effectively reduces tumor burden in mice with ovarian cancer.

#6740 Next-generation LNPs induce effective anti-tumor T cell responses.

D. G. Millar[1], **M. J. Gold**[2], K. Olsen[2], Y. Wu[2], Y. Karpov[2], R. Nechanitzky[2], H. Menon[2], R. Krishnan[2], R. Georgantas[2], P. Ohashi[1], N. Martin-Orozco[2];
[1]Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Providence Therapeutics Inc, Calgary, AB, Canada

mRNA immunotherapies have gained interest for the treatment of tumors from various origins, however, their ability to provide long -term durable tumor control has been underwhelming. Here we report that novel mRNA lipid nanoparticle (LNP) vaccinations induce robust expansion of antigen-specific T cells, although this does not always correlate with their ability to infiltrate and kill solid tumors. Using a portfolio of novel ionizable lipids and a robust *in vivo* model that reliably identifies LNPs with prominent anti-tissue T cell activity we have identified a putative LNP candidate that provides long term tumor control in a murine syngeneic tumor model.

We utilized the model antigen glycoprotein (Gp), from the lymphocytic choriomeningitis virus (LCMV), and produced mRNA encoding the immunodominant epitopes $gp33_{33-41}$, $gp61_{61-80}$ and $gp276_{276-286}$ (3GP-mRNA). This mRNA was encapsulated in various novel LNP formulations and administered i.m. into naïve C57Bl/6 mice to track the induction of a robust $CD8^{\pm}$ T cell response identified using tetramers to gp33 and gp276. Successful candidate LNPs were then tested in the RIPgp model of autoimmune diabetes. RIPgp transgenic mice express LCMV-Gp in the pancreatic β cells and offer a robust assay for the ability to induce antigen-specific T cells capable of breaking self-tolerance and infiltrating and killing target tissue. Utilizing the RIPgp model to screen LNP candidates we identified a lead candidate, C2-5A, that both induced a robust expansion of antigen-specific T cells and tissue destruction. When utilized in a colon adenocarcinoma model expressing the LCMV-Gp antigen (MC38-Gp), therapeutic dosing of LNP C2-5A as a monotherapy lead to long term tumor clearance in 40% of the treated animals. We believe this screening platform allows the selection of LNP candidates capable of breaking self-tolerance, and one such candidate C2-5A provides a potent vehicle and adjuvant for mRNA based cancer vaccines.

#6741 Targeting glutamine metabolism potentiates antigen presentation in colorectal cancer.

T. Yu, K. Van der Jeught, H. Zhu, Z. Zhou, S. Sharma, S. Liu, K. So, H. Eyvani, X. Wang, G. E. Sandusky, Y. Liu, M. Opyrchal, S. Cao, J. Wan, C. Zhang, X. Zhang;
Indiana University School of Medicine, Indianapolis, IN

Colorectal cancer (CRC) ranks among the most prevalent cancers worldwide, causing substantial mortality. The urgent need for effective treatments has driven research into immune checkpoint blockade (ICB) therapies, which have demonstrated significant clinical benefits across various cancer types. Despite the success of ICB therapies, a significant proportion of CRC patients exhibit resistance to treatment, prompting the identification of mechanisms that hinder therapy resistance or enhance treatment response. CRC cells display remarkable adaptability, orchestrating metabolic changes that confer growth advantages, pro-tumor microenvironment, and therapeutic resistance. One such metabolic change occurs in glutamine metabolism. In this study, we found that colorectal tumors with high glutaminase (GLS) expression exhibit reduced T-cell infiltration and cytotoxicity, leading to poor clinical outcomes. To validate these findings, we applied the ovalbumin (OVA)/OT-I T cell-based cytotoxicity assay and the CRC patient-derived organoids (PDOs)/autologous T cell killing assay. Our results indicated that inhibition of GLS significantly enhanced T-cell cytotoxicity in vitro and ex vivo. Mechanistically, we elucidated that inhibition of GLS activated reactive oxygen species-related signaling pathways in tumor cells, thereby potentially increasing tumor immunogenicity by promoting antigen presentation. The combinational therapy of GLS inhibitor and ICB exhibited a superior tumor growth inhibitory effect in comparison with either of the monotherapies. These findings shed new light on clinical therapeutic strategies for CRC patients, offering a promising approach to enhance the efficacy of ICB therapy.

#6742 PV 10 induces endoplasmic reticulum stress and autophagy, triggering immunogenic cell death and anti-tumor immunity in head and neck squamous cell carcinoma.

S. Thatikonda[1], R. Chaudhary[1], Y. Meshkovska[1], M. I. Biernacki[1], R. Slebos[1], S. P. Thomas[1], A. L. Antonio[1], E. A. Wachter[2], C. H. Chung[1];
[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]Provectus Biopharmaceuticals, Knoxville, TN

Introduction: Head and neck squamous cell carcinoma (HNSCC) are complex, diverse cancers affecting mucosal linings of the upper aerodigestive tract. Globally, HNSCC is the sixth most common cancer, leading to over 890,000 new cases and more than 450,000 deaths annually. Primary risk factors include human papillomavirus (HPV) infection (HPV-positive HNSCC) and exposure to tobacco and excessive alcohol (HPV-negative HNSCC). Despite multimodal treatments, survival rates remain low due to recurrence and metastasis (R/M HNSCC), creating a need for safe, innovative therapies to reduce tumor burden with minimal adverse events. PV-10 (10% rose bengal sodium) is a novel intratumoral immunotherapeutic agent that has demonstrated promising anti-tumor activity in multiple solid tumor cancer types with few adverse effects in pre-clinical research and clinical trials. However, the role of PV-10 in HNSCCs and its role in enhancing immune response warrants further investigation.

Methods: Cell viability was assessed using Alamar blue assay after PV-10 treatment of murine mEER and MTE-RAS HNSCC tumor cell lines. To evaluate the immunomodulatory properties of PV-10, we employed flow cytometry, confocal analysis, and luminescence-based assays. Additionally, we performed a DCFDA assay to measure the reactive oxygen species (ROS) and an Alexa Fluor 488 Annexin V/dead cell apoptosis assay to evaluate apoptosis. To gain insights into the mechanisms underlying PV-10's immunomodulatory effects in cancer cells and tumors from mice, western blotting and multiplex immunohistochemistry (mIHC) were used.

Results: Our *in vitro* findings reveal that PV-10 induces cytotoxicity in both mEER and MTE-RAS cells. Notably, PV-10 promotes a significant increase in ROS, leading to an elevation in late apoptotic cells. Markers of immunogenic cell death (ICD), including a statistically significant increase in the release of damage-associated molecular pattern molecules HMGB1 and ATP, as well as enhanced surface expression of calreticulin, HSP-70, and HSP-90, were observed. At the molecular level, a remarkable activation of endoplasmic reticulum (ER) stress, pro-apoptotic protein, and autophagy markers were observed. Intratumoral PV-10 injection *in vivo* has shown significant tumor regression in both mEER and MTE-RAS tumors, and a complete response was noticed in some mice, indicating that PV-10 induces potent ICD in both mEER and MTE-RAS tumors.

Conclusion: Our collated evidence strongly suggests that PV-10 induces ICD-associated immunogenicity in both mEER and MTE-RAS *in vitro* and *in vivo,* fostered by ROS-based ER stress and apoptosis. These findings hold promise for potential therapeutic avenues to manage HNSCC.

#6743 Identifying new cellular adjuvants for cancer vaccines and immunotherapies.

J. Rucker, N. Nwogu, N. M. Molino, A. Snyder, J. T. Sullivan, B. J. Doranz;
Integral Molecular, Philadelphia, PA

Background: Cancer vaccines represent a promising strategy for antitumor immunotherapy. Despite considerable research efforts and progress, the effectiveness of cancer vaccines remains a challenge. This is primarily due to relatively low immune responses against tumors, stemming from issues of poor immunogenicity and the immunosuppressive microenvironment commonly found in many solid tumors. Use of an optimal adjuvant can augment immune responses against tumor antigens and guide them towards a specific adaptive immune enhancement. Dendritic cells (DCs) play a primary role in initiating immunes response to vaccines, often through activation of toll-like receptors (TLRs). Identifying novel immunomodulatory proteins that regulate DCs or TLR activation can identify novel adjuvant candidates with applications for cancer immunotherapy.
Methods: We constructed a Membrane Proteome Array (MPA) encompassing ~6,000 structurally intact human membrane proteins in their native conformation (94% of the entire membrane proteome) and used it to screen for cellular proteins that can modulate response to vaccination through DCs and TLRs. To identify proteins that interact with TLRs, the library was expressed in live TLR reporter cells, and these cells were tested for response to known activators. In addition, cells expressing the MPA were presented to DCs to identify membrane proteins that modulate DC activity. TLR-expressing cell activation was measuring using an NF-kB-activated luciferase reporter, while DC assays used upregulation of cell surface markers (CD80, CD83, and MHCII) to measure the activation of immature monocyte-derived dendritic cells.
Results: Screening of TLR2, TLR3, and TLR5 reporter cell lines identified both known and novel regulators of TLR activation. Activators common to several TLRs were identified as well as activators unique to individual TLRs. Screening of primary human DCs likewise identified known regulators of activation (for example CD40L) and several novel targets. Putative novel regulators of DC activation are being further investigated to determine their biological significance.
Conclusion: Discovering novel immunomodulatory targets and proteins that regulate DCs and TLR activation can identify novel adjuvant candidates with targeted immune outcomes, such as immune stimulating and anti-cancer responses. This study identified novel regulators of immune activation which are being further investigated as adjuvant candidates for cancer vaccines.

#6744 Activating anti-MDS immunity with polarized dendritic cell vaccines.

D. Alvarado[1], J. Peresie[1], A. Brinkman[1], C. Allen[1], W. Jiang[1], P. Kalinski[1], **T. Tanaka**[2], E. Griffiths[1], M. Nemeth[1];
[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]UC San Diego Moores Cancer Center, La Jolla, CA

Less than 50% of patients with higher-risk myelodysplastic syndromes (MDS) show clinical response to standard-of-care hypomethylating (HMA) therapy. Significant enthusiasm existed for immunotherapy/HMA combinations for these patients, but studies have failed to deliver on the initial promise. We have demonstrated that patients with MDS have a deficiency in antigen-presenting cells, called CD141^{Hi} dendritic cells (DC). DC-deficient MDS patients have reduced response to HMAs, worse overall survival, and show less response to cancer vaccination. We hypothesized that restoration of this population using a novel DC vaccination approach - alpha-type-1 polarized dendritic cells (αDC1) - might compensate for this deficiency and restore immunity. To generate αDC1s, we collected monocytes from MDS patients and healthy donors (HD) and cultured them for 6 days *in vitro* in the presence of recombinant human GM-CSF and IL-4 followed by an additional 18-24 hours in the presence of αDC1 maturation factors (poly-I:C/IFNα/IFNγ/TNFα/IL-1β). Overall, we attempted to generate αDC1s from 15 MDS samples; 13/15 exhibited intermediate to very high-risk disease and 10/15 are currently receiving HMA therapy. We successfully cultured cells from 8/15 samples (53%). Of the 8 MDS samples, 5 were collected from patients receiving HMA therapy (62.5%). We were unable to successfully culture αDC1s from the other 5 patients receiving HMA therapy, and thus the effect of HMA therapy on aDC1 generation remains unclear. To test the function of MDS αDC1s, we focused on two signals necessary to activate immune responses: 1) the expression of co-stimulatory molecules and 2) the production of IL-12p70. Flow cytometric analysis on αDC1s and immature DCs from MDS samples revealed intra-patient variation in the fold-change surface expression of CD40/80/83/86 and HLA-DR proteins. Additionally, there was a trend towards decreased up-regulation of CD80 and CD86 in MDS specimens compared to HD. To assess production of IL-12p70, we stimulated immature DCs and αDC1s with CD40L and performed ELISA analysis on the media supernatant. We found that 3 out of 4 samples could produce IL-12p70 (range 27 - 5,480 pg/ml). To date, our results suggest that generation of MDS patient-derived αDC1 cells is feasible and additional work is being performed to fully characterize their ability to activate anti-MDS immune responses. Since αDC1s have an established safety profile in patients with solid tumors, we anticipate that we will be able to rapidly translate our results to the clinic.

#6745 Crafting hyaluronic acid-based nanoparticles for enhanced LN targeting as a potent priming tool in immunotherapy.

T. Nakai[1], F. Momose[2], K. Yabuuchi[1], M. Yamane[2], T. Hayashi[2], L. Wang[2], Y. Nakagawa[1], S. Aso[1], T. Katsumata[1], T. Shimoboji[1], Y. Miyahara[2];
[1]Asahi Kasei, Fuji, Japan, [2]Mie University Graduate School of Medicine, Tsu, Japan

Background: Cholesterol-conjugated hyaluronic acid, synthesized by grafting cholesterol moieties onto hyaluronic acid, spontaneously formed nano-sized hydrogel of approximately 30-100nm in water. This hyaluronic acid derivative (HA nanogel) has demonstrated the ability to encapsulate various modalities, including low- and medium-sized molecules, peptides, and proteins. Previous reports have highlighted its efficacy in solubilizing poorly water-soluble drugs and serving as a sustained-release matrix. In this study, we explore the potential of HA nanogels encapsulating antigen peptides with adjuvant as a cancer vaccine and a priming tool for combinational immunotherapy.
Method: We prepared HA nanogels as a novel peptide carrier for cancer vaccines and attempted to encapsulate various peptides, including neoantigen (mERK2) peptides expressed in immune checkpoint inhibitor (ICI) therapy-resistant fibrosarcoma cell line CMS5a, gp-100 peptides expressed in metastatic melanoma cell line B16F10, and MAGEA4. Our experiments covered APC uptake, antigen-specific CTL induction, and anti-tumor studies to demonstrate the utility of HA nanogels in these applications.
Results: HA nanogel efficiently formed stable complexes with mERK2, gp-100 and MAGEA4 long peptides, each with diameters of 30-100nm. The facile and simple vaccine formulation processes with HA nanogel achieved high drug content and high encapsulation efficiency of 90% or higher. Fluorescently labeled mERK2 long peptide encapsulated in HA nanogel vaccines were subcutaneously administered to BALB/c mice, and uptake analysis of mERK2 long peptides in draining lymph nodes (dLN) was performed using flow cytometry. In comparison to the group receiving mERK2 long peptide without nanogel encapsulation, the HA nanogel group exhibited higher uptake by macrophages and dendritic cells in the dLN. Administering HA nanogel vaccines containing mERK2 long peptides with CpG oligoDNA resulted in higher antigen-specific $CD8^{+}$ T cells compared to the group receiving mERK2 long peptides without encapsulation. Strong anti-tumor effects were demonstrated in mice models with subcutaneously transplanted CMS5a and B16F10 cell lines. The enhanced efficacy through co-administration with ICI was also confirmed.
Conclusion: HA nanogel vaccines efficiently deliver antigen peptides to macrophages and dendritic cells, inducing antigen-specific CTL responses, thereby demonstrating anti-tumor effects against cold tumors such as CMS5a and B16F10. HA nanogels have the potential not only as carriers for cancer vaccines but also as priming tools for combinational immunotherapy.

#6746 A B-cell targeted TLR9 agonist antibody conjugate potentiates cancer vaccine efficacy and rejuvenates vaccine responses in the elderly.

M. Z. Bonacorsi, A. Chen, O. Harrabi, M. Li, E. R. B. Sangalang, D. Fontaine, J. Sim, P. Strop, H. I. Wan, M. Costa;
Tallac Therapeutics, Burlingame, CA

TLR9 agonists (unmethylated CpG oligodeoxynucleotides) are clinically validated as vaccine adjuvants and cancer therapeutics[1,2]. We developed a Toll-like Receptor Agonist Antibody Conjugate (TRAAC) comprised of a potent TLR9 agonist (T-CpG) conjugated to an antibody against CD22, a receptor restricted to B cells (TAC-001). Systemically administered TAC-001 delivers T-CpG to B cells, resulting in TLR9 activation, and innate and adaptive anti-tumor immunity[3]. TAC-001 is being evaluated as an immunotherapy in a Phase 1 clinical trial in patients with advanced solid tumors (NCT05399654)[4]. In this study, we investigated whether TAC-001 mouse surrogate, mCD22 TRAAC, can potentiate cancer vaccine efficacy using preclinical vaccination models. Human Nectin-4 ectodomain protein (N4, 94% homology to its mouse ortholog) was used as a neoantigen-like vaccine, alone and in combination with mCD22 TRAAC, MPLA (a TLR4 agonist), or unconjugated T-CpG. Mice were immunized, then challenged 2 months later with syngeneic CT26 tumors expressing N4. Mice in treatment combination cohorts that resisted tumor development were split into two groups and rechallenged 3.5 months later with a more aggressive tumor, syngeneic 4T1 or 4T1 expressing N4. The combination of vaccine with mCD22 TRAAC was the only treatment able to inhibit growth of the 4T1-N4 tumor. No efficacy was observed in mice inoculated with parental 4T1, thereby demonstrating neoantigen vaccine specific anti-tumor immunity. An MHCI restricted peptide of HER2/neu, GP2, fused to a B cell epitope peptide, P4, and conjugated to KLH, was used as another vaccine model[5]. GP2-P4-KLH was administered to mice alone or in combination with mCD22 TRAAC or unconjugated T-CpG. *Ex vivo* GP2/GP2-P4 stimulation of lymphoid organ immune cells from mice treated with vaccine plus mCD22 TRAAC resulted in elevated Granzyme B, IFNγ and IL17A levels, indicating that mCD22 TRAAC enhances T cell activation and cytotoxic activity. Lastly, to investigate the effect of mCD22 TRAAC in elderly mice, SARS-CoV-2 spike protein was used as a vaccine. Spike was administered alone or in combination with mCD22 TRAAC, MPLA or T-CpG. Combining mCD22 TRAAC with vaccine resulted in high levels of spike neutralizing IgG in both youth and elderly cohorts, showing that mCD22 TRAAC rejuvenates vaccine responses in elderly. In all studies, mCD22 TRAAC led to the most potent vaccine recall response, with high antigen specific IgG titers skewing towards a Th1 phenotype, as shown by elevated levels of effector function antibodies of IgG2a subclass and increased IFNγ production. These findings provide a strong rationale for combining TAC-001 with cancer vaccines. #6747 Engineering M13 filamentous phages to target dendritic cells and elicit anti-tumor immunity.

Y. Au-Yeung, Z. Zeng, J. Huang;
University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong

Filamentous phage is a safe and effective vaccine vector that can elicit robust immune responses by activating Toll-like receptor pathways. However, engineering neoantigen-displaying phages for cancer vaccines using phage display technology has been challenging and yielded inconsistent results.
We developed a dendritic cell (DC)-targeting cancer vaccine platform with M13 filamentous phages using the phage display technology. The engineered phages express DC-targeting peptides (SLS) on p3 sites and spy-catcher proteins on p8 positions, allowing neoantigens and proteins of interest to be linked to the phage vector. We named our platform SCP (SLS-spy catcher phage). Imaging and western blot showed that spy-tagged proteins can be easily attached to SCP by simple mixing. Further studies demonstrated that targeting DCs can enhance antigen presentation and anti-cancer immunity.
We tested SCP in MB49 and B16 mouse models and the serum, spleen and tumor tissues were isolated for further investigation of immune response upon treatment. We found that SCP effectively suppressed tumor growth by inducing systemic anti-tumor humoral and cell-mediated immunity. SCP also showed efficacy in late-stage tumor models. SCP treatment triggered particularly robust local anti-tumor response. Histological and flow cytometry analysis revealed increased infiltration of innate and adaptive immune cells, reduced PDL1 expression, and restricted neovascularization in the tumor microenvironment after intratumoral administration of SCP.
Our study demonstrated that SCP can induce multifactorial modifications in the tumor microenvironment to impede tumor growth. SCP overcomes the limitations of traditional phage display technology, enabling a wide variety of peptides and proteins to be loaded onto the phage vectors. SCP is also cost-effective and scalable as phage production and purification processes are relatively mature. We propose that SCP can serve as a universal platform for cancer immunotherapy, and may offer novel treatment options for patients.

#6748 Intramuscular delivery of tumor associated antigen DNA vaccines elicits strong cellular immune response, delays tumor growth and prolongs survival.

K. Rayavara[1], J. Henderson[1], M. Kinsella[1], J. Kim[1], M. Matar[1], S. Sood[1], O. Signer[1], C. Bellmon[1], C. Le Goff[2], K. Anwer[1], J. Boyer[1];
[1]Imunon Inc, Huntsville, AL, [2]Imunon Inc, Lawrenceville, NJ

The development of effective cancer vaccines that can trigger strong and enduring memory T cell responses against specific tumor associated antigens (TAAs) is crucial for advancing immunotherapy. DNA-based cancer vaccines have shown promise in generating precise and long-lasting immune responses. In particular DNA vaccines are capable of inducing both humoral and cellular immune responses. In this study, we aimed to investigate the effectiveness of DNA vaccines targeting the mouse Tyrosine-related protein-2 (Trp2) and human New York esophageal squamous cell carcinoma 1 (NY-ESO-1) TAAs in mouse melanoma model. These DNA vaccines were formulated with a functionalized polymer designed to protect DNA from degradation and improve its bioavailability. DNA vaccines targeting both mouse Trp2 (pVACTR) and human NYESO-1 (pVACNY) were constructed. A mouse melanoma cell line (B16F10-NY) overexpressing human NYESO-1 was also generated and demonstrated to induce tumors in C57BL/6 mice. Female C57BL/6 mice received two doses of intramuscular (i.m.) injection of formulated pVACTR or pVACNY or a combination *thereof*, formulated with the synthetic functionalized polymer, with a 3-week interval. The DNA vaccination induced a potent T cell response, as evidenced by ELISPOT assays showing strong IFN-γ secreting T cells against NYESO-1 and Trp2. Flow cytometry analysis of spleenocytes showed strong IFN-γ and TNF-α secreting CD4 T cells against NYESO-1. We further evaluated the prophylactic and therapeutic efficacy of DNA vaccines targeting both Trp2 and NYESO-1 using a murine syngeneic model. Animals were challenged with a lethal dose of B16F10-NY two weeks after the second immunization exhibited a significant ($p<0.0001$) delay in tumor progression and a substantial increase in survival compared to the mock control group. In the therapeutic testing, animals challenged with B16F10-NY and subsequently vaccinated at 4, 11, and 25 days also demonstrated delayed tumor growth and prolonged survival. These findings indicate that formulated DNA vaccine delivered via i.m. triggers robust T cell responses and exhibit both prophylactic and therapeutic efficacy, leading to significantly prolonged survival and delayed tumor growth. A DNA-based vaccine independent of viral vector or device has potential to elicit potent anti-tumor responses with better safety and compliance.

#6749 A dendritic cell targeted nanosystem to overcome immune suppression and enhance the efficacy of the standard of care for pancreatic cancer.

R. Kleiner[1], D. Vaskovich-Koubi[1], R. Acurcio[2], B. Carreira[2], H. Florindo[3], R. Satchi-Fainaro[4];

[1]Sackler Faculty of Medicine Tel Aviv Univ., Tel Aviv, Israel, [2]Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisbon, Lisbon, Portugal, [3]Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Lisbon, Portugal, [4]Sackler Faculty of Medicine Tel Aviv University, Tel Aviv, Israel

The development of novel therapies for pancreatic ductal adenocarcinoma (PDAC) remains an urgent unmet medical need, as it was proven to be refractory to most conventional anti-neoplastic therapies. PDAC is characterized by highly dense stroma, immunosuppressive tumor microenvironment (TME), high resistance to chemotherapy, and poor presentation of tumor-associated antigens (TAA) by dendritic cells (DC), which results in low immune cell infiltration to the tumor site. To that end, we designed a DC-targeted nanovaccine (NV) containing PDAC TAA and TLR agonists to modulate the PDAC immune-microenvironment. In recent years, the combination of immunotherapy with chemotherapy has been explored for PDAC therapy to improve efficacy. Therefore, we demonstrate the effect of our NV on the anti-tumor immune-mediated response in PDAC-bearing mice, alone and in combination with Gemcitabine and Nab-Paclitaxel (Gem/NabP). Our DC-targeted NV was formulated by the double emulsion method and loaded with PDAC's TAA and immune potentiators. We conjugated the NV to a mannose moiety as a targeting moiety for the mannose receptor expressed on DC to increase the NV uptake, which resulted in the enhanced presentation of the encapsulated TAA. Followed by physicochemical characterization and evaluation of preclinical safety of the NV, the stimulation of T cell-specific response against PDAC tumor was assessed *in vivo* and *ex vivo*. The NV induced significant changes in PDAC's TME, such as increased $CD8^{+}$ T cells, decreased $CD4^{+}$ T regulatory cells, and induced memory immunity in the tumor site. The combination of NV and Gem/NabP inhibited tumor growth and prolonged survival compared to mice treated with Gem/NabP alone. This could also be related to the immunogenic cell death effect caused by the chemotherapies. In addition to our mice model of PDAC, we also established a patient-derived model, in which we generate 3D-spheroids from the patient's tumor and activate PBMCs with our NV from the same patient. This unique 3D model enables us to evaluate *ex vivo* the NV effect in a more clinically relevant manner. The NV proposed herein could induce a strong antigen-specific immune response against PDAC with restricted tumor growth while re-shaping PDAC immunosuppressive TME. Furthermore, our 3D patient-derived PDAC model allows us to assess the ability of our NV to generate specific immune responses in patients and to test other possible drug combinations predicting the clinical outcome.

#6750 Validation of a platform to develop new dendritic cell vaccines for cancer immunotherapy.

V. Alonso-Camino, W. Mirsch;
Mill Creek Life Sciences, Rochester, MN

Osteosarcoma is the most common malignant form of bone cancer that generally causes patients to die of pulmonary metastasis. If detected before the tumor has metastasized, osteosarcoma has a 75% survival at 5 years after the conventional therapy with surgery and chemotherapy. However, most osteosarcomas are high-grade tumors that grow quickly and spread before being detected, lowering patient survival to 20%.

Our unique protocol using the human platelet lysate PLTMax® allows establishing tumor cell lines without genetically modifying cells and with minimal genetic drift. The use of PLTMax® and allogeneic tumor cell cultures has proven to be a major advantage for the generation of large amounts of rich tumor antigen libraries for dendritic cell (DC) vaccines. This protocol was used in an autologous dendritic cell / allogeneic tumor lysate vaccine developed at the Mayo Clinic and licensed to Mill Creek Life Sciences (MCLS) to treat newly diagnosed glioblastoma (GBM), which normally has a poor survival rate at only 2%. The technology was used in a phase I clinical trial (MC1272) performed at the Mayo Clinic. The clinical outcomes proved over a 10 time increase in survival rate of patients that received the DC vaccine after the conventional therapy, providing over 20% three-year survival rate.

Our technology differs from other clinically used DC vaccines in three primary ways:

a) Highly efficient cell line establishment: The unique method for generating tumor cell lines uses Mill Creek Life Sciences' PLTMax®, a media supplement derived from human platelets. PLTMax® more closely mimics the native microenvironment of tumors and is used to reduce genetic drift and senescence.

b) High genetic fidelity: GBM tumor cells expanded via PLTMax® maintain genetic fidelity and TAA expression—a feat that has not been previously achieved by any other GBM cell culture method.

c) Reduction of treatment delays and inclusion of all patients that qualify for treatment: Because we will use allogeneic tumor cell lines, we will be able to avoid delays in treatment caused by the time required to culture autologous tumor cell lines, and all patients may receive treatment without exclusion.

Through our preliminary work we transferred the technology from a labor-intensive, small-scale approach, to an automated scalable system. Our ultimate goal is to apply this strategy to not only osteosarcoma, but also several other tumor types to validate it as a platform. Like osteosarcoma, there are other therapy-refractory cancers that we believe can benefit from the use of our platform technology, through the use of DC vaccines that offer an immune response against a wider panel of tumor antigens.

#6751 *In situ* vaccination with *Flt3l* gene modified CD103+ type 1 conventional dendritic cells synergizes with anti-PD-1 checkpoint blockade in murine models of non-small cell lung cancer .

J. W. Abascal, R. J. Lim, R. Salehi-Rad, Z. Jing, M. S. Oh, W. P. Crosson, B. P. Kahangi, E. Perez Reyes, C. Dumitras, D. Reyimjan, J. Yhu, L. M. Tran, M. Paul, K. Krysan, B. Liu, S. M. Dubinett;
UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA

A major hurdle in treatment of Non-Small Cell Lung Cancer (NSCLC) with anti-PD-1 immune checkpoint blockade (ICB) therapy is a lack of response (primary resistance) and relapse after an initial response (acquired resistance). Recent studies reveal that responses to PD-1/PD-L1 blockade are associated with high tumor mutational burden (TMB), increased $CD8^+$ T cell infiltration and high baseline PD-L1 expression within the tumor microenvironment (TME), while impaired tumor antigen presentation and the immunosuppressive TME have been associated with resistance to ICB. One approach to overcome anti-PD-1 resistance is to intratumorally vaccinate NSCLC tumors with gene modified conventional dendritic cells (cDC), specifically the type I conventional DC (cDC1) lineage. Recent studies have established that generation of an anti-tumor immune response driven by $CD8^+$ T cells requires the cross presentation of tumor associated antigens and that cDC1s are the primary cross presenting APC subtype *in vivo,* which can license $CD8^+$ T cells to initiate an adaptive anti-tumor immune response. In addition, previous studies have shown that intratumoral administration of the FMS-like tyrosine kinase 3 ligand (FLT3L) protein can expand endogenous $CD103^+$ cDC1s in the TME and augment anti-tumor immune responses to ICB therapy. Here, we engineered murine $CD103^+$ cDC1s to constitutively secrete soluble FLT3L (FLT3L_cDC1) and performed *in situ* vaccination studies on anti-PD1 resistant murine models of NSCLC with LKB1-deficiency and elevated TMB that better represents human disease. *In situ* vaccination with FLT3L_cDC1 enhances anti-tumor efficacy compared to non-modified cDC1 vaccination and synergizes with anti-PD-1 ICB to inhibit tumor growth. FLT3L_cDC1 + anti-PD-1 combination therapy induces significant activation and expansion T cells and cDC1s within the TME. Furthermore, combination therapy significantly increases DC progenitor numbers within the tumor draining lymph node, including DC progenitors that are committed to the cDC1 lineage. Our data suggests *in situ* vaccination with FLT3L_cDC1 may represent a promising strategy to potentiate the efficacy of ICB and improve outcomes for patients with primary resistance PD-1/PD-L1 monotherapy.

#6752 Targeting of neoantigen cancer vaccines to antigen presenting cells results in faster and broader T cell responses whether encoded in DNA or mRNA.

B. T. Weinert[1], L. Skullerud[1], E. Solbakken[1], A. Textor[1], M. Durkoop[2], I. Winge[1], G. Norheim[1], E. Stubsrud[1], S. Granum[1], M. W. Pedersen[1], H. Norell[1];
[1]Nykode Therapeutics ASA, Oslo, Norway, [2]Oslo University Hospital, Oslo, Norway

Individualized cancer vaccines based on patient-specific neoantigens represent a groundbreaking approach in oncology, offering a highly individualized treatment option for cancer patients. Unlike traditional vaccines, which are designed to prevent diseases by stimulating an immune response against a specific pathogen, personalized cancer vaccines are therapeutic, aiming to treat cancer by training the immune system to recognize and attack the patient's own cancer cells. The key is to induce a fast, strong, broad, and persistent CD8+ T cell response.

Nykode Therapeutics has developed a platform that targets antigens directly to antigen presenting cells (APCs) using a modular dimeric protein format known as a Vaccibody™. Individualized neoantigen vaccines delivered in a DNA-encoded Vaccibody format have been shown to induce strong and broad T cell responses in pre-clinical and clinical settings.

Here, we wanted to determine if the APC-targeted approach leads to superior T cell responses if Vaccibody vaccines are encoded in mRNA and administered in a lipid nanoparticle (LNP) formulation. For this purpose, we designed and evaluated a model cancer vaccine composed of 20 unstructured 27 amino acid long neoantigens derived from the murine MC38 tumor model.

A DNA-encoded Vaccibody vaccine elicited faster T cell responses compared to an untargeted mRNA-LNP-encoded vaccine. DNA-encoded Vaccibody responses were also broader, targeting a substantially greater number of neoantigens.

Next, we compared the APC-targeting Vaccibody vaccine to an untargeted vaccine when both were formulated in an mRNA-LNP format. The APC-targeting Vaccibody vaccine elicited a greater breath and magnitude of T cell responses compared to the untargeted vaccine. Further studies to evaluate the functional differences associated with the various formats, in terms of T cell phenotype and response to tumor challenge, are ongoing.

In summary, the data demonstrate that an APC-targeted Vaccibody vaccine containing MC38 neoantigens can be encoded in both DNA and mRNA-LNP to induce faster, broader, and stronger T cell responses compared to a non-targeted neoantigen vaccine.

#6753 Bria-OTS immunotherapy platform: Harnessing gene-modified tumor cells to reinvigorate the cancer immunity cycle for precision anti-tumor responses.

M. A. Lopez-Lago, V. Bhardwaj, P. Kesarwani, X. Zheng, S. Pachhal, P. Cournoo, R. Cortez, C. L. Wiseman, W. V. Williams;
BriaCell, Philadelphia, PA

Background: For an immune response to lead to an effective anti-tumor response, a series of stepwise events involving a complex network of iterative cellular and molecular interactions must take place. Cancer, however, often derails this immune cycle, prompting contemporary cancer immunotherapy approaches to seek its reinstatement. Despite significant advances, the inherent disruption of the cancer immunity cycle at multiple junctures, coupled with current therapeutic strategies focusing on isolated stages within this intricate process, has left the attainment of curative therapies as an aspirational goal. We believe that targeting multiple immune processes can restore natural anti-cancer immunity and yield sustained responses. To this end, BriaCell is utilizing gene-modified tumor cells as an immunotherapeutic platform. Our initial version, SV-BR-1-GM, a breast cancer cell line expressing GM-CSF, demonstrates promising clinical outcomes by directly activating CD4+ T-cells in an antigen-specific, HLA-restricted manner. Building on our findings, we hypothesize that tumor cells not only supply antigens but also directly stimulate the immune system. Presenting our second-generation platform, we enhance antigen cross-presentation and direct immune activation through the expression of cytokines, co-stimulatory factors, and HLA alleles.

Methods: To achieve this objective, we have developed Bria-OTS cell lines derived from various cancer types with the following genetic modifications: 1) Expression of costimulatory molecules (CD80, CD86, 4-1BBL, CD40) and immunomodulatory cytokines (GM-CSF, IFNα, IL-12 and IL-7). This modification aims to improve the cell's ability to present antigens and activate the host immune system. 2) Expanding HLA alleles to create semi-allogeneic cell lines matching at least one HLA allele across the population aims to enhance the host immune response, enabling recognition of tumor-associated antigens in the context of syngeneic HLA molecules

Results: We generated four cell lines for each tumor type, and these cell lines secreted GM-CSF, IFNα, IL12 & IL7, while also expressing CD80, CD86, CD40, and different combinations of both Class I and Class II HLA alleles. In functional assays, our cell lines demonstrated potent antigen presentation, effectively triggering anti-tumor immune responses across diverse immune populations, including T-, NK, and NKT cells.

Conclusions: The Bria-OTS cell lines will offer the following key features: 1) multimodal mechanisms of action including thwarting some mechanisms of cancer immune escape. 2) Precision Therapy; Bria-OTS will be precisely matched to individual patients based on their HLA alleles, encompassing over 99% of the U.S. population. 3) rapid, cost-effective treatment as our 'off-the-shelf' cell lines eliminate the need for personalized manufacturing.

#6754 A microneedle array patch chemo-immunotherapy for cutaneous squamous cell carcinoma.

Y. Yang, H. Zhang, C. D. Carey, J. Zhang, S. C. Balmert, E. Korkmaz, L. D. Falo, Jr.;
University of Pittsburgh, Pittsburgh, PA

Cutaneous squamous cell carcinoma (cSCC) is the second most common human malignancy worldwide. Current therapies, including surgical excision, are associated with significant morbidities and considerable expense. Multiple efforts are now underway to develop novel therapies that are effective, durable, safe, cost-effective, and patient-friendly. Here, we report ongoing efforts to develop a localized dissolvable microneedle array patch (MAP) based therapy for cSCC. Our approach is based on the hypothesis that the delivery of an immunogenic cell death (ICD) inducing chemotherapeutic agent to the tumor microenvironment (TME) of accessible cSCCs could kill tumor cells as a source of antigen and induce a proinflammatory TME to generate a potent patient-specific anti-tumor immune response. Specifically, we evaluated MAP therapy using a UV-induced preclinical cSCC mouse model. We applied MAPs delivering the potent ICD-inducing chemotherapeutic agent, doxorubicin (DOX) to UV-induced tumors. MAPs efficiently delivered DOX to the tumor microenvironment. Compared to traditional needle injection, MAP delivery resulted in sustained high levels of DOX in the TME with minimally systemic exposure. Cell death was evident in MAP-DOX-treated tumors, and treatment resulted in tumor regression, increased survival, and long-term immune protection. Further, we found that tumor regression was associated with an early proinflammatory neutrophilic infiltrate. Taken together, our results suggest that MAP delivery of doxorubicin may be a promising approach to cSCC treatment, and that proinflammatory neutrophils are likely an important component of the early infiltrate that leads to tumor regression.

#6755 NKT activation enhanced the therapeutic efficacy of neoantigen vaccine in hepatocellular carcinoma.

R. Li, J.-C. Hu, L. Rong, Y. Wu, Y. He, J. Huang;
University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Pok Fu Lam, Hong Kong, China

One sentence introduction: This study indicated the potential of combinational therapy of neoantigen vaccine and iNKT activator α-GalCer in Hepatocellular carcinoma. Hepatocellular carcinoma (HCC) is a leading cause of death around the world. Current immune checkpoint blockade therapies only show effectiveness in some cancer patients, so there is an urgent need for more effective immunotherapy strategies. One alternative is the use of neoantigen-based cancer vaccines, which target tumor-specific antigens (neoantigens) on cancer cells and induce strong T-cell responses. Advances in technology now allow for precise identification of tumor neoantigens using bioinformatic analysis or mass spectrometry. While cancer vaccines have demonstrated strong anti-tumor immune responses and therapeutic effectiveness in some cancer types, their success in HCC remains limited. A contributing factor is the suppressive tumor microenvironment (TME) found in advanced HCC. Some studies suggest that combining neoantigen vaccines with anti-PD1/PD-L1 therapies can significantly enhance HCC treatment outcomes. Overcoming the suppressive immune microenvironment is crucial in cancer treatment, and reactivating intratumoral immunity is essential. In our study, we developed an HCC cancer vaccine using transcriptome sequencing and bioinformatics analysis. Our ELISpot assay results showed that this vaccine induced strong tumor-specific immune responses and significantly inhibited tumor growth in early-stage orthotopic HCC mouse models when administered five days after tumor inoculation. However, the effectiveness decreased in advanced tumors when administered ten days after tumor inoculation. We also discovered a significant relationship between the therapeutic effectiveness of the neoantigen vaccine and the activation of intratumoral NKT cells in HCC. Our study suggested that the type-I NKT cell activator, α-Galactosylceramide (α-GalCer), significantly improved the therapeutic outcomes of the cancer neoantigen vaccine in advanced orthotopic HCC mouse models. In some cases, tumors were almost completely eliminated. This indicates the potential of combining iNKT activators with neoantigen vaccines for HCC treatment. To further understand the role of NKT cells in HCC's TME, we plan to investigate intratumoral NKT cell subtypes following neoantigen vaccine therapy. Additionally, we will develop a new delivery system to deliver type I NKT cell activators and type II NKT inhibitors to tumor sites, aiming to reactivate the suppressive TME in HCC after neoantigen vaccine therapy.

#6756 Our RNA production platform and the associated tools facilitate the development of RNA-based vaccine.

C. Bosso-Lefevre, E. Cirri, **E. Mennesson**, D. Szymczak, F. Carpentier, A. Foucher, A. Komarkova, M. Rochet, A. Vindrios, R. Goulay;
Tebubio, Le Perray-en-Yvelines, France

mRNA vaccines have shown their full potential in the Covid-19 pandemic. The application of these technologies for the treatment of cancers represents significant hope, but clinical effectiveness remains to be demonstrated. For this purpose, researchers require high quality production of vaccine mRNA and accurate and cost-saving test tools that are adapted to oncology research. Since 2021, Tebubio has developed a miniscale RNA production platform for providing RNAs (from 100 µg to 1 mg) to researchers around the world. This service is completed by offers on RNA delivery solutions using lipid nanoparticles (LNPs) and cellular tests with biomarker analysis. Through an ingenious design, our DNA matrix for mRNA is easily transferable for GMP production for clinical studies. Recently, Tebubio has developed DNA matrices for circular RNA production. Indeed, circular RNA has many advantages by being less immunogenic and more stable than linear RNA. We compared the quality and the quantity of CAP1 capped linear RNA and circular RNA produced from our DNA templates. We also assessed the stability of both RNAs expressing GFP and the typical tumor antigen, p53, and their relative expression into antigen-presenting cells (APCs). Finally, we quantified the response of the APCs expressing p53 by using our biomarker multiplex analysis system. This new type of RNA and its efficiency testing in APCs will constitute a new addition to our pipeline of RNA production and testing for preclinical studies.

#6757 The anti-tumor efficacy of Th1-specific TROP2 vaccine (AST-07X) in a triple-negative breast cancer murine model.

J. Kang[1], H.-H. Park[1], J. Choi[2], S.-Y. Jang[3], M.-A. Kim[3], M.-K. Park[3], A. Y. Kim[4], E. Joung[1], H. Jung[1];

[1]Aston Sci., Seoul, Korea, Republic of, [2]Jeonbuk National University Medical School, Jeonju, Korea, Republic of, [3]Korea testing & Research institute, Hwasun, Korea, Republic of, [4]Aston Sci. USA, Inc., Seattle, WA

Background: The trophoblast cell-surface antigen 2 (TROP2) is associated with enhanced tumor proliferation and poor prognosis in breast cancer. TROP2 overexpresses on various epithelial cancer cell surfaces, and is commonly found in prostate, colon, pancreas, lung, and breast cancer. Therefore, anticancer strategy targeting TROP2 may be a potential treatment option for patients with metastatic triple-negative breast cancer (TNBC). Sacituzumab govitecan, a Trop-2-directed antibody drug conjugate (ADC), has shown significant benefits associated with progression-free and overall survival compared to standard chemotherapy for treating metastatic TNBC; however, its toxic effects were more frequent than that of chemotherapy (NCT02574455). In this study, we discovered TROP2 target peptides with T-helper 1 (Th1) polarization and anticancer efficacy. We then evaluated the anti-tumor efficacy of these epitopes and possibility of co-administration with ADC in a TNBC murine model.

Materials and Methods: Th1 peptides were identified using the Th-Vac® platform and the predictive binding affinity ranking that indicates potential immunogenicity points of interest for HLA class II. Human peripheral blood mononuclear cell (PBMC) Th1-specific polarization-induced activity and in vivo immunogenicity (Module 2b) were evaluated using flow cytometry and ELISpot analysis. The anti-tumor efficacy of the selected Th1 peptide was evaluated against MDA-MB-23 inoculated athymic Balb/c mice. Each peptide was administered intradermally once weekly for a total of four times at a concentration of 100 μg/head. Sacituzumab govitecan (0.81 mg/kg) was administered intravenously once weekly, for a total of two times.

Results: Ten peptides with high affinity for HLA class II were selected, and three epitopes that induce differentiation of T cells secreting TROP2-specific IFN-γ were subsequently selected. These epitopes (p1, p3 and p6) showed tumor growth inhibition efficacy of 52.4%, 38.5%, and 57.2%, respectively, compared to the control (vehicle) group in the TNBC tumor-bearing mice. The cocktail vaccine (AST-07X), which combined these epitopes, was the most dominant at 65.4%. The anti-tumor efficacy of the combination group of the cocktail vaccine and ADC was 77.4% compared with the control group, showing a potent synergistic effect compared to the 46.1% anti-tumor efficacy of the ADC-mono group.

Conclusion: AST-07X that induce TROP2-specific Th1 anticancer immune responses, showed sufficient anti-tumor efficacy; these effects were evident under immunodeficient conditions, such as those of TNBC tumor-bearing athymic mice. Synergy effects were also induced via combined ADC administration. We are currently conducting further research on humanized mice to address the limitations of the immunodeficient murine model.

#6758 Eradication of tumors and development of immunity from pHLIP-targeted intracellular delivery of STINGa.

M. DuPont[1], A. Moshnikova[1], M. Iraca[1], C. Klumpp[1], H. Visca[1], D. Allababidi[1], P. Pelzer[1], D. Engelman[2], O. Andreev[1], Y. Reshetnyak[1];
[1]University of Rhode Island, Kingston, RI, [2]Yale, New Haven, CT

Activation of the stimulator of interferon genes (STING) pathway causes the release of factors that trigger the immune response in the tumor microenvironment (TME). Transient strong activation leads to immune activation and tumor suppression, while prolonged weak activation leads to immuno-suppression promoting tumor development. Reprogramming of M2-type tumor-associated macrophages (M2-TAMs) toward an M1 phenotype, suppression of cancer-associated fibroblasts (CAFs) and myeloid-derived suppressor cells (mMDSCs), as well as activation of dendritic cells (DCs) to train T-cells are advantageous, while the activation of STING pathway in T-cells is leads to their apoptosis. Thus, targeted delivery of STINGa to specific cells with TME to induce strong transient activation may be a key to therapy. We have developed a delivery approach that uses one or two pH Low Insertion Peptides (pHLIPs) that collaborate in the targeted intracellular delivery of a STINGa. STINGa were conjugated with pHLIPs via S-S cleavable self-immolating linkers. Biophysical studies were performed to ensure proper interactions of pHLIP-STINGa agents with membrane lipid bilayers. pHLIPs extend the lifetime of STINGa in the blood and target them to acidic cancer and stromal cells (CAFs), as well as M2-TAMs, mMDSCs and DCs within TME. The targeting results in selective cytokine activation in tumors with no systemic activation, which triggers the eradication of small (100 mm3) and large (400-700 mm3) CT26 tumors in mice after one or two doses of pHLIP-STINGa. The tumor stroma was destroyed, intratumoral hemorrhage developed, and the level of acidity within the TME was reduced. No tumors developed in mice re-challenged by an additional injection of cancer cells in a 90-day experiment. Thus, targeted delivery of STINGa to cancer cells, tumor stroma and TAMs induces activation of signaling, potentially resulting in the recruitment and infiltration of T- and NK-cells, which gain access to the tumor core. The cytotoxic activity of T- and NK-cells is not impaired by the acidic environment and immune memory is developed. The pHLIP technology may allow transformation of immuno-activating agents into more potent therapeutics, since pHLIP can target and deliver these agents to cancer cells, tumor stroma and myeloid cells.

#6759 Antigen-pHLIP for tumor treatment.

M. DuPont[1], H. Visca[1], A. Moshnikova[1], D. Engelman[2], Y. Reshetnyak[1], O. Andreev[1];
[1]University of Rhode Island, Kingston, RI, [2]Yale, New Haven, CT

Targeted antigen delivery allows activation of the immune system to kill tumor cells. Among the immunogenic epitopes widely investigated is α-Gal, since humans exhibit specific anti-Gal reactivity. However, the repertoire of immunogenic epitopes could be significantly enhanced if therapeutic efficacy did not rely on the presence of natural antibodies, but instead relied on the production of anti-epitope endogenous antibodies induced by immunization against the selected epitope. Therefore, we designed and tested several HA-pHLIP agents, where the HA peptide (YPYDVPDYA) from the influenza virus was selected as an exogenous highly immunogenic epitope, since it is absent in the human genome, and a pH Low Insertion Peptide (pHLIP) was selected as the tumor targeting agent. HA peptides were attached to the N-termini of pHLIPs either directly or via PEG polymers. To enhance the overall binding affinity of HA-pHLIP to anti-HA antibodies, double headed HA-pHLIP agents were introduced, where two HA epitopes were linked to a single pHLIP peptide via PEG12 polymers. The pHLIP sequence was modified to ensure proper pKs of insertion into cell membranes. HA epitopes were targeted to cancer cells in mouse tumors, and remained exposed to the extracelullar space within tumors for about 24 hours. Double-headed HA-pHLIP treatments of imunized mice (a high titer of anti-HA antibodies was developed in mice after immunization with KLH-HA), bearing 4T1 triple negative or B16F10 MHC-I negative melanoma tumors resulted in a 55% reduction of tumor growth. Further reduction of tumor growth was impossible to achive, since all of the anti-HA antibodies in the blood were captured after 3 injections of HA-pHLIP and additional boosts would be required to restore the level of free anti-HA antibodies to induce a more significant therapeutic efficacy.

TUMOR BIOLOGY: 3D and Tissue Recombinant Models of Cancer

#6763 A human-relevant vascularized organ-on-a chip platform for anti-tumor drug efficacy and liver injury assessment.
J. Navarro-Yepes, Q. Dasgupta, P. Purkayastha, K. Janson, C. Mello, A. Narkar, S. Ng, T. Pereira;
SYSTEMIC BIO, LLC, Houston, TX

Cancer global burden accounts for 19.3 million new cases and 10 million deaths in 2020. Despite advances on the understanding of disease progression and efforts to find successful therapeutic strategies, most drugs fail in clinical stages. Lack of models with clinical mimicry recapitulating the *in vivo* pathophysiology and the organ microenvironment where the tumor forms is a key driver reducing the success rate of anti-cancer drugs. Animal models remain the gold standard for preclinical research but fail to recapitulate the complex human tumor microenvironment, a critical component determining tumor development, progression, and response to treatments. Organ-on-a-chip models allow to control the environment and organization of cells in an *in vivo*-like arrangement by culturing multiple cell types to better replicate human conditions, and by implementing different biochemical and physical stimuli, such as fluid shear stress, chemical/nutrient gradients, and perfusion/flow to recapitulate the human vascular system physiology. We leverage our 3D bioprinting technologies to develop complex vascularized organ-on-a-chip models aimed to recapitulate the tumor and liver niche. Both organ-systems are interconnected by our h-VIOS™ platform, allowing dynamic perfusion for 21 days and enabling the simultaneous assessment of anti-tumor therapeutic efficacy and drug-induced liver injury. Our hydrogels feature a complex perfusable vasculature that interfaces with an interstitial chamber where tissues of interest are grown. The vasculature allows for continued and controlled delivery of nutrients, oxygen, and small molecule drugs. Dextran diffusion studies revealed diffusion coefficients ranging from 43.2 $\mu m^2/s$ (4kDa) to 8 $\mu m^2/s$ (70kDa). Vascular architectures are lined with endothelial cells forming a functional barrier expressing the junctional markers ZO-1 and PECAM-1. Moreover, we can modulate the permeability of our vasculature architecture, allowing the extravasation of immune and cancer cells. PBMC-derived T cells and Jurkat cells undergo transendothelial migration in response to a CXCL12 gradient, highlighting the applicability of our model for immunotherapeutic efficacy studies. The tumor interstitial chamber incorporates co-culture of cancer spheroids or tumoroids, fibroblasts, endothelial and immune cells. Colon carcinoma spheroids effectively integrate into the tumor niche with no growth arrest. The liver model consists of an interstitial chamber with a lobular microstructure supporting the monoculture of primary human hepatocytes, and sustaining their viability and function for 9 days as demonstrated by high albumin production, urea synthesis and CYP activity. Our organ-on-a-chip models are fully customizable and anticipated to contribute to advance personalized medicine and improve clinical translation rates.

#6764 Vascularized tumor-on-chip model for evaluating chemotherapeutic-mediated damage to adjacent healthy tissue.

D. Ramsey, J. Rosano, C. Gordon, G. Fewell;
SYNVIVO INC., Huntsville, AL

Introduction: Systemic chemotherapy is an effective anticancer treatment for all stages of breast cancer, with intravenous (IV) infusion being the principal method of administration. In addition to targeting cancer, systemic chemotherapy can impact the viability and function of surrounding normal tissues and vasculature. Early-discovery research tools comparing novel and existing systemic treatment strategies are urgently needed to support predictive efficacy and toxicity efforts. Microfluidic systems have the potential to fill this need while simultaneously reducing animal use. The overall goal of the study is to use an advanced microfluidic tumor-on-chip system to simultaneously evaluate the therapeutic and toxic effects of IV chemotherapy on normal and cancerous tissues.
Materials and Methods: Synthetic Tumor Networks, which are comprised of primary and secondary tissue sites separated by an interconnected vasculature, were developed using in vivo images and fabricated using soft lithography. Primary vascular endothelial cells were used to establish microvasculature. A normal breast cell line (MCF 10A), or a GFP-labeled metastatic human breast cancer cell line (MDA-MB-231/GFP), were cultured in the tissue sites in a three-dimensional (3D) environment using a human-derived hydrogel. The vascular networks were perfused with endothelial cell media under physiological fluid flow conditions to establish the model. An EZH2 methyltransferase inhibitor (EZH2 inhibitor III) was delivered by IV infusion to the model tissues. Real-time monitoring of cellular growth, tumor invasion and extravasation, and cellular viability were performed using fluorescence microscopy over a two-week period.
Results and Discussion: Metastatic MDA-MB-231/GFP breast cancer cells proliferated rapidly in the primary tumor site. Tumor intravasation into the vascular channels was observed in models that received no anticancer treatment, as well as extravasation into the secondary tissue site and invasion of the healthy breast tissue. Differences in tumor viability and migratory behavior were observed between untreated models or models receiving IV infusions of the EZH2 inhibitor through the vascular networks. Vascular barrier integrity and normal breast tissue viability were monitored at early (24-72 hr) and late (7-14 days) timepoints after anticancer treatment to measure short- and long-term adverse drug impacts. These results provide a unique perspective on the in vivo realism of an in vitro system for monitoring both therapeutic and toxic effects of systemic chemotherapies.
Conclusions: We have developed a 3D vascularized tumor-on-chip model for monitoring the impacts of systemic chemotherapeutic agents on tumor and healthy tissues. This model can be used to investigate therapeutic and toxic effects on multiple tissue types simultaneously using real-time imaging techniques.

#6765 A patient-derived hepatocellular carcinoma multicellular spheroid platform harnessing autologous patient serum to model the tumor microenvironment and treatment response.

E. Crouchet[1], N. Almeida[1], S. C. Durand[1], M. Parnot[1], M. A. Oudot[1], F. Giannone[2], C. Gadenne[1], S. Cherradi[1], N. Roehlen[1], A. Saviano[2], E. Emanuele Felli[2], P. Pessaux[2], K. Chayama[3], H. F. Duong[1], T. F. Baumert[1], C. Schuster[1],

[1]University of Strasbourg, Strasbourg, France, [2]Institut hospitalo-universitaire (IHU), University of Strasbourg, Strasbourg, France, [3]Institute of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan

Hepatocellular carcinoma (HCC) is the third leading and fastest rising cause of cancer-related death worldwide. The discovery and preclinical development of compounds targeting HCC is hampered by the absence of authentic tractable systems recapitulating the heterogeneity of patient HCC tumors and the tumor microenvironment (TME). Here, we established a novel, simple and robust patient-derived multicellular tumorspheroid model based on clinical HCC tumor tissues combined with the autologous patient serum. The model was robust and reproducible independently from cancer etiology and grade recapitulating key functional features of original tissue. We show that the use of autologous patient serum was essential for the TME function. The tumorspheroids comprised the main cell compartments including epithelial cancer cells as well as all major cell populations of the TME (cancer-associated fibroblasts, macrophages and T cells). Cell type proportions were variable between tumorspheroids reflecting HCC heterogeneity. Moreover, we observed differential responses to FDA HCC approved drugs (including tyrosine kinase and checkpoint inhibitors as well as VEGF-targeting agents) between donors as in patients. This patient HCC serum-tumorspheroid model provides novel opportunities for drug discovery and development as well mechanism of action studies including compounds targeting the TME. In conclusion, this HCC serum-tumorspheroid platform will contribute to improve the dismal outcome of patients with HCC.

#6766 Assessing the impact of immunotherapies and cell therapies in 3D heterospheroid models mimicking tumor microenvironments.

N. H. Madsen[1], B. S. Nielsen[1], K. Holmstrom[1], G. H. Olofsson[2], P. t. Straten[3], S. Skov[4], C. Rodriguez-Pardo[5], M. Ormhoj[5], J. Larsen[1], M. Gad[1];
[1]Bioneer A/S, Horsholm, Denmark, [2]Copenhagen University Hospital Herlev and Gentofte, Herlev, Denmark, [3]Copenhagen University Hospital Herlev and Gentofte, University of Copenhagen, Copenhagen, Denmark, [4]University of Copenhagen, Copenhagen, Denmark, [5]Technical University of Denmark, Lyngby, Denmark

Immunotherapies and cell therapies show substantial potential in the treatment of cancer. However, their efficacy within the complex microenvironment of solid tumors remains a critical area of investigation. In this study, we employ physiologically relevant 3D multicellular heterospheroid models to quantitatively assess the impact of these therapies on immune and tumor cells residing in tumor-like microenvironments. The spheroids are composed of cancer cell lines, fibroblasts and various primary immune cell types matched to the specific target of immunotherapy.

We have previously reported that interactions between cancer cells and fibroblasts promote a tumor-like environment, recruiting and polarizing monocytes into M2 macrophages. Treatment of spheroids with immunomodulating compounds successfully reprogrammed the macrophages into M1-like macrophages with increased pro-inflammatory cytokine secretion.

To mimic tumor-specific T cell responses observed in cancer patients, we here educated T cells to recognize target cell antigens through a 14-day co-culture of PBMCs and PANC-1 tumor cells. Subsequent re-challenge with PANC-1 heterospheroids revealed 70% specific killing by educated T cells, whereas T cells educated with a breast cancer cell line did not exhibit this targeted cytotoxicity. FACS analysis demonstrated increased expression of activation markers and immune checkpoint molecules such as PD-1, LAG-3 and TIGIT on educated T cells. Furthermore, we observed infiltration of educated $CD4^{\pm}$ and $CD8^{\pm}$ T cells into heterospheroids by immunohistochemistry, indicating the replication of a tumor-specific response within solid tumors. We are currently investigating the enhancement of educated T cell killing using various immune checkpoint inhibitors including antibodies targeting PD-1, TIGIT and LAG-3. Another means of eliciting tumor-specific responses is by employing CAR T cells. Antigen-specific CAR-T cells or untransduced CAR-T cells derived from the same donor were added to HT-29 and HCT-116 heterospheroids at various target-to-effector ratios. By using cancer cells genetically engineered to express a luciferase enzyme, we assessed the specific killing of cancer cells within the heterospheroids. Analysis showed a clear dose-dependent increase in luminescence, indicating greater antigen-specific CAR-T cell killing potential (60-80% specific lysis) compared to the non-specific killing observed with untransduced CAR-T cells (<5% specific lysis). Additionally, preliminary data demonstrate the killing of heterospheroids by γδ T cells and that this killing is enhanced by immune checkpoint inhibitors.

In conclusion, we have developed 3D heterospheroids from various cancer types that faithfully mimic tumor-like microenvironments, enabling us to evaluate the effects of immunotherapies and cell therapies in physiologically relevant models.

#6767 Multivariate analysis of *ex vivo* kidney 3D immune-microtumors for functional precision medicine.

E. Peerani[1], K. Nan[1], D. A. Wiskerke[1], T. D. L. Richardson[1], P. Maximchick[1], J. Kearney[1], G. R. T. de Fraine[1], K. L. Loughrey[1], J. Ient[1], J. A. Hudson[1], A. Kaffa[1], A. M. Crawley[1], N. K. Bah[1], E. G. Lopez Molina[1], E. Tham[1], F. Iori[1], M. H. Williams[1], M. G. B. Tran[2], D. N. B. Ranatunga[1];
[1]Ourotech Ltd t/a Pear Bio, London, United Kingdom, [2]Royal Free London NHS Foundation Trust, London, United Kingdom

Immuno-oncology (IO) represents a significant paradigm shift in cancer treatment, focused on leveraging and mobilizing a patient's own immune response and anti-tumor capabilities. Despite accounting for the majority of available treatment options, there are currently no diagnostic tests capable of predicting combination immunotherapy response in kidney cancer. We have developed a fully human 3D IO model for clinical drug efficacy prediction through multivariate analysis of the tumor-immune microenvironment (TiME) combining functional assays, artificial intelligence and multi-omics. These immune-microtumors recapitulate a patient's unique pathophysiology and allow 3D spatio-temporal analyses of functional metrics at both bulk and single-cell resolutions.
Renal cell carcinoma (RCC) resections and matched blood were collected and processed for single cell isolation of tumor and PBMCs (N=20, ISRCTN10001405). Flow cytometry (FC) and immunofluorescence (IF) were used to characterize TiME cell subpopulations (cancer, immune, stromal etc.) in pellets and 3D cultures, and to deconvolute bulk RNAseq data. Target (tumor) and effector cells (PBMCs and CD8+) were stained with fluorescent probes, activated using αCD3 and encapsulated in TiME-mimicking 3D matrices. 3D immune-microtumors were treated with FDA-approved regimens including immunotherapies (ipilimumab, nivolumab, pembrolizumab) and receptor-tyrosine kinase inhibitors (TKIs)(cabozantinib, lenvatinib, axitinib) as monotherapies or combination therapies. Differential drug efficacies were functionally quantified over 4 days using 3D confocal microscopy and computer vision pipelines to extract cell behavior metrics such as immune cell infiltration, immune/tumor cell migration speed, and tumor killing/viability.
We devised a specialized RCC hydrogel formulation with superior viability compared to MatrigelTM alone (N=7). FC/IF/RNAseq were used to quantify relative cell subpopulations after isolation and show protein/transcriptional signature retention after 3D culture (N=7). The platform was conducive to the testing of various drugs with varying MoAs including immunotherapies, TKIs, targeted therapies and cell therapies. Treatment with pembrolizumab led to 26% higher PBMC infiltration, 14% higher CD8+ infiltration and 15% increased tumor cell death compared to control. When in combination, pembrolizumab reduced cell viability by 10% and 19% with lenvatinib and axitinib respectively (N=1). Population analyses revealed intra-patient response heterogeneity (N=7).
In conclusion, we showed MoA-agnostic, patient-dependent responses to FDA-approved clinical treatment regimens via molecular and functional spatio-temporal analyses. Clinical outcome correlation is currently underway in our advanced RCC study PEAR-TREE2 as well as in breast NCT05435352 and brain NCT06038760 tumors.

#6768 Matched XPDX™derivative models as a platform for continuity across preclinical drug development.

M. Millard[1], A. Carlson[1], D. Y. Nadeau[1], K. J. Burgess[1], A. Simonson[2], A. Diaz III[2], M. Wick[2], T. M. DesRochers[1];
[1]Kiyatec Inc., Greenville, SC, [2]XenoSTART, San Antonio, TX

Drug discovery is a reductive process in which druglike entities are carried through increasingly complex assay formats to tease out the compounds best suited for human studies. *In vivo* efficacy remains the benchmark for successful preclinical drug development. Cell-based models are a mainstay in early stages but translatability of different models across platforms remains a challenge. In oncology, patient-derived xenografts (PDX) are the gold standard for animal studies because they recapitulate key features of human tumors including the cellular heterogeneity, growth patterns, and drug response of the original patient tumor. *Ex vivo*, PDX derivatives have the potential to harness these same traits thereby extending the utility of PDX models to earlier stages of preclinical drug development. The KIYA-Predict™ platform is a clinically validated tool for the assessment of *ex vivo* drug responses across a broad range of drug classes that when applied to XPDX models shows good correlation to *in vivo* drug responses and excellent intra-sample reproducibility over time. Working with the well-characterized XenoSTART™ XPDX model repository, Kiyatec has derived 2D cell lines and organotypic 3D-expansion cultures to complement the *ex vivo* predictive value of our KIYA-PREDICT™ XPDX drug response profiling (DRP) platform. The development of syngeneic models applicable to simpler, high-throughput library screening (2D formats) and lower-throughput more complex mechanistic studies (3D organotypic models) could alleviate the burden and pitfalls of extrapolating data across unrelated models. Matched sets of 2D cell lines (2D-XPDX™) and 3D organotypic (XPDXO™) cultures were established from single cell suspensions of digested, mouse-cell depleted XPDX™ tissue samples. Drug response profiling of the XPDX™ in their various *ex vivo* culture formats showed relative similarities across platforms. Genomic profiling of the derivates confirmed shared tissue origin and retention of genomic and phenotypic signatures to varying degrees across models. Mechanistic evaluation of 3D organotypic culture demonstrated that disease-relevant biomarkers and processes are maintained. Together these results demonstrate the feasibility of this novel drug discovery platform that avoids ambiguity imparted by discordant models.

#6769 Applications of a novel fibrous extracellular matrix for advanced *in vitro* cancer models.

N. Kaur[1], D. Yang[2], J. Ali[1];
[1]FAMU-FSU College of Engineering, Tallahassee, FL, [2]Acrogenic Technologies Inc., Rockville, MD

Compared to traditional *in vitro* two-dimensional (2D) planar cell culture system, three-dimensional (3D) mammalian cell culture can better recapitulate physiological environments and the complexity of natural tissues, hence they are crucial in modern biomedical research. Extracellular matrices (ECM) play a key role in *in vitro* mammalian cell culture systems. The role of the ECM on *in vitro* 3D cell culture are: 1) to simulate an *in vivo*-like physiological environment, 2) support cell-cell and cell-ECM interactions, 3) promote cell adhesion, migration, and communication, 4) aid in tissue development, morphogenesis, differentiation, and functioning. Although basal membrane extracts (BME) are the most popular type of ECM supporting 3D modeling *in vitro*, they often have significant limitations including limited long-term stability, significant batch to batch heterogeneity, restricted cell movement, and relatively high cost for culturing many cancer cell lines. In this investigation, we employ a novel micro-fibrous scaffold that closely mimics natural ECM, providing porous and interconnected networks for 3D culturing of hepatic cells, lung cancer, breast cancer, pancreatic cancer. As revealed by optical and scanning electron microscopy, the scaffold promotes significant cell-to-cell and cell-to-matrix interactions. Moreover, we observed improved cell growth in 3D culture over longer periods than 2D culture systems for all cell types examined. We also evaluated the anticancer efficiency of different drugs including Lapatinib, Cisplatin, Docetaxel, Doxorubicin and observed that 2D cultured cells were more sensitive to drugs treatment in comparison to 3D. Furthermore, ECM was observed to support 3D growth and structure formation with cell pools of primary cells achieved from disassociated human tumors. Tumor organoids were able to form within seven days and ready for anticancer screening within 14 days. We achieved an 80% success rate in developing breast cancer organoids from patient tissues. Additionally, tissue granules were also able to be cultured under the same condition, which allowed us to investigate the invasion of cancer cells into tissue. The primary cells from human tumors formed cell clusters resembling the original tumor tissue's structure. In conclusion, the novel micro-fibrous scaffold, closely mimicking natural extracellular matrixes, promotes significant cell-to-cell and cell-to-matrix interactions, while also facilitating cell growth over extended periods providing a more physiologically relevant platform for evaluating drug responses for various cancer cell types, further showing the importance of 3D culture systems in cancer research.

#6770 Acquired temozolomide resistance instructs patterns of glioblastoma cell motility and proteome expression within gelatin hydrogels.

Viktoriia Kriuchkovskaia[1], Ela Eames[1], Rebecca Riggins[2], Brendan Harley[1]

[1]University of Illinois Urbana-Champaign, Champaign, IL,[2]Georgetown University, Washington, DC

Acquired drug resistance in glioblastoma (GBM) presents a major clinical challenge and is one of the key factors contributing to the abysmal prognosis with less than 15 months median overall survival. The aggressive chemotherapy with the frontline therapeutic, temozolomide (TMZ), ultimately fails to kill residual, highly invasive tumor cells after surgical resection and radiotherapy. Here, we present a robust three-dimensional (3D) *in vitro* hydrogel model of acquired temozolomide (TMZ) resistance using isogenically-matched glioblastoma (GBM) cell lines. We demonstrate distinct drug response patterns between TMZ-sensitive and TMZ-resistant GBM cells, emphasizing our model's promise for future pre-clinical investigations aimed at developing novel therapies targeting drug-resistant GBM. Importantly, our model detects apoptosis-related protein changes in response to TMZ, validating its ability to study drug-induced molecular changes. Furthermore, our study delves into the migratory potential of GBM cells within the 3D extracellular matrix environment. Additionally, we uncover significant alterations in cytokine expression associated with matrix remodeling and angiogenesis, providing new avenues for therapeutic investigation. Although our findings are derived from a specific set of isogenically-matched cell lines, this model highlights the potential to explore personalized treatment strategies. Ongoing research in our lab is dedicated to gaining a more profound understanding of matrix remodeling and the migratory potential of TMZ-resistant GBM cells. Moreover, our future work will aim to expand our study to include a wider range of cell lines and patient-derived xenografts within our advanced microphysiological systems that include key elements of GBM tumor microenvironment such as perivascular niche. This endeavor seeks to establish connections between observed therapeutic behaviors and clinical outcomes, ultimately contributing to the development of more effective treatments for GBM patients.

#6771 Tumor-microenvironment-on-chip: an *ex vivo* drug screening platform enabling real-time observation of regional tumor responses during drug development and clinical treatments.

Chiao-Min Lin[1], Hsaun-Yu Mu[1], Li-An Chu[1], Ya-Hui Lin[1], Ji Li[1], Chao-Yu Liu[1], Hsi-Chien Huang[1], Sheng-Liang Cheng[1], Tsung-Ying Lee[1], Hsin Mei Lee[1], Hsin-Min Chen[1], Yun-Jen Tsai[1], Tzu-Hung Hsiao[2], Kee-Ming Man[3], Yunching Chen[1], Jen-Huang Huang[1]

[1]National Tsing Hua University, Hsinchu, Taiwan,[2]Taichung Veterans General Hospital, Taichung, Taiwan,[3]China Medical University Hospital, Hsinchu, Taiwan

Background: Current tumor models face challenges in accurately replicating the intricate and dynamic conditions of the tumor microenvironment (TME), limiting predictions of drug efficacy in drug development and personalized treatment. Furthermore, the continuous and real-time observation of drug responses variations resulting from tumor heterogeneity poses challenges in existing models, including patient-derived organoids and animal models. To address these limitations, our study introduces a novel approach through a tumor-microenvironment-on-chip (TMoC) that combines 3D tissue cultivation and a circulation system, incorporating physiological gradients of oxygen and nutrients. Serving as a tool to faithfully replicate the intricate TME, TMoC facilitates highly accurate drug screening for enhanced therapeutic precision.

Method: Based on organ-on-chip and microfluidic systems, our platform reconstructs the cellular heterogeneity of the TME using tumor tissue-dissociated cells in collagen I or Matrigel within a strip-shaped 3D cultivation space, enabling simple analysis of regional responses. A circulation system, powered by a peristaltic pump, aids medication and immune cell entry for combination immunotherapy assessment. Real-time apoptosis analysis via fluorescence microscopy and sample retrieval for in-depth analysis are enabled. In drug screening, TMoC results are compared with mouse model outcomes and medication records for various cancers and treatments.

Result: TMoC reconstructed physiological-like gradients, including oxygen levels, and facilitated the infiltration of cytotoxic $CD8^+$ T cells, providing a distinctive model for assessing the synergistic impact of immune checkpoint inhibitors and chemotherapy drugs. Additionally, tissues cultured in TMoC retained their original cellular composition. TMoC demonstrated efficacy in drug screening across various cancer models, including breast, pancreatic, and colorectal cancers. In clinical studies, tumor tissue-derived cells from patients were cultivated on the TMoC, and the treating results are subsequently compared with clinical outcomes. Whether in animal models or clinical cases, the drug screening outcomes of TMoC consistently aligned with *in vivo* drug responses.

Conclusion: The TMoC offering a platform that modeling some complex characteristics of TME. With applications in drug screening and clinical studies, it shows promising correlations between TMoC and *in vivo* responses.

#6772 A 3D model of breast cancer-bone metastasis to mimic dysregulation of bone remodeling and drug response.

M. Tai, E. C. Gonzalez Diaz, C. E. Monette, J. Wu, F. Yang;
Stanford University, Stanford, CA

Introduction: Bone metastases are common among advanced stage breast cancer patients and induce dysregulation of bone remodeling. Crosstalk between cancer cells and the bone niche drives the vicious cycle of bone loss and breast cancer growth. To accelerate discovery of targeted therapies, there is a critical need for experimental models that can mimic breast cancer-induced dysregulation of bone remodeling in patients. Mouse models are the current gold standard, but are low throughput, costly, and cannot fully recapitulate human-human cell interactions. To address these limitations, our goal is to engineer a fully human 3D *in vitro* model of breast cancer-bone metastasis that can mimic dysregulation of bone remodeling and drug responses in patients, and enable screening of potential new drug candidates.

Methods: Two human breast cancer cell lines (MDA-MB-231, MCF-7) were chosen given their well characterized clinical features and tendency to invade bone. Our 3D model comprises an outer ring of tissue engineered (TE) bone and a center of breast cancer cells to mimic invasion through the bone marrow/long bone interface. Human mesenchymal stem cells were encapsulated in 3D gelatin microribbon scaffolds and cultured in osteogenic media for 28 days to form TE bone. Human monocyte-derived osteoclasts were seeded onto the bone, and the center was replaced with GFP-labeled breast cancer cells. Denosumab and zoledronic acid were selected as they are standard treatments for reducing bone loss in patients, and were used to treat the model at 30 µg/mL and 2 µg/mL, respectively. Intermittent parathyroid hormone (iPTH) treatment was selected as it showed efficacy in animal models, and was used to treat the model at 10 µg/mL for 6 hours daily. All groups were treated with drugs for 14 days. Bone volume was assessed using microCT. Cancer cell proliferation and invasion into bone was monitored with fluorescence confocal microscopy.

Results: MicroCT imaging showed both breast cancer cell lines induced bone loss in the triculture model, compared to the control with no breast cancer cells in the center. Consistent with known clinical features, the more aggressive cell line (MDA-MB-231) induced a greater amount of bone loss than the less aggressive breast cancer cell line (MCF-7). Consistent with clinical findings, both denosumab and zoledronic acid reduced bone loss in our 3D model, and zoledronic acid further reduced breast cancer cell invasion and proliferation. Finally, the 3D model recapitulated the *in vivo* drug response of iPTH treatment, reducing bone resorption and breast cancer invasion.

Conclusions: Here we report a fully human triculture model of breast cancer-bone metastasis that can mimic key clinical features of breast cancer-induced bone resorption and drug response in patients. Such a 3D model could enable screening of drug candidates with reduced time and cost and enable identification of novel druggable targets.

#6773 Tissue engineered colorectal cancer microspheres for drug screening.

Y. Tian[1], M. Hashemi[1], B. Anbiah[1], R. Zhang[2], I. Hassani[1], R. Boohaker[3], E. Lipke[1];
[1]Auburn University, Auburn, AL, [2]Biocytogen, Waltham, MA, [3]Southern Research, Birmingham, AL

Three-dimensional (3D) disease models have garnered widespread interest for use in later stages of the drug discovery process, such as preclinical efficacy and toxicology studies, due to their pathophysiologically relevant properties. However, there is a need and opportunity for 3D cancer models to be used earlier in the drug screening process. To meet this need, the 3D models must strike a balance between throughput, which includes scalability and uniformity, and physiological relevance, such as the ability to modulate key attribute of the tumor microenvironment.

Here we report the creation of 3D colorectal cancer (CRC) tissue models, referred to as VivoSpheres, and demonstrated their relevance to cancer drug screening. The VivoSphere production platform couples tissue engineering toolkits with microfluidics, enabling the scalable production of engineered cancer microspheres. The model supports the long-term maintenance of the cancer cell phenotype. In a preliminary study, we were able to generate more physiologically relevant drug responses.

We formed CRC VivoSpheres by encapsulating HT-29 CRC cells within poly(ethylene glycol)-fibrinogen hydrogel microspheres using our previously developed microfluidic platform. CRC VivoSpheres were rapidly produced with high cell densities (20×10^6 cells/ml) and high uniformity on day 0 with a coefficient of variation (COV) < 7%. This high uniformity was maintained for 15 days (COV ≤ 10%), which is critical for long-term dose studies. The cells maintained high viability and showed high proliferative capability with a significant increase in colony size and expression of Ki67 up to day 29. The encapsulated cells maintained the CRC phenotype over time with the expression of CD44 (cancer stem cell marker) and CK20 (CRC marker).

After establishing shipping conditions that maintained cell viability for remote use, the HT-29 VivoSpheres were shipped to the oncology team at Southern Research for drug testing. The CRC VivoSpheres were treated with DMSO, GANT61, and SRI-38832, the latter two of which are GLI1 inhibitors. Phase contrast images and western blot were used to assess the response of CRC VivoSpheres to the treatments. Oncogenic GLI1 transcription activity and NBS1 overexpression have been found to contribute to chemotherapeutic resistance, negating the anti-tumor effects of 5-fluorouracil. While 2D cultured HT-29s responded to treatment with GANT61, HT-29 VivoSpheres continued to express NBS1 following GANT1 treatment, but downregulated NBS1 in response to the GLI1 inhibitor SRI-38832, which is the same response Southern Research has seen in *in vivo* tumor models.

In conclusion, we have developed tissue-engineered 3D CRC models that hold promise for use in drug screening. These models have demonstrated an initial capability to reproduce the CRC phenotype and mimic *in vivo* drug response.

#6774 Establishment and optimization of an air liquid interface co-culture system to evaluate phenotypic changes in primary human Barrett's esophagus cells upon different environmental exposures.

A. Chatterjee[1], J. Azevedo-Martins[1], C. C. Tanyolac[1], Q.-U. Ain[1], H. Yu[1], S. Camilleri-Broet[2], L. Ferri[2], P. Gascard[1], T. D. Tlsty[1], M. D. Stachler[1];
[1]University of California, San Francisco, CA, [2]Montreal General Hospital, McGill University, Montreal, QC, Canada

Esophageal adenocarcinoma (EAC) is a deadly cancer with an increasing incidence which arises out of it's precancerous precursor, termed Barrett's esophagus (BE). A better understanding of the factors that influence BE progression is essential for early detection and novel therapeutics. 3D Air Liquid Interface (ALI) cultures provide an edge over traditional 2D cultures as they better mimic the in vivo conditions of the esophagus. The aim of the study was to establish conditions for a BE ALI model and to evaluate the phenotypic and molecular changes in primary human BE cells upon interaction with different types of esophageal fibroblasts (EF) and exposure to bile acids(BA) (a major component of gastroesophageal reflux). ALI conditions that allowed growth of both primary BE and fibroblast for at least 30 days were optimized. Non dysplastic BE cells from two patients were utilized with one having EAC (P) and the other with no history of progression (NP). The BE cells were cultured in our ALI model with 3 types of EFs: normal esophageal fibroblasts(NFs), BE associated fibroblasts(BFs) and EAC associated fibroblasts(CFs). To determine the effect of BA exposure, ALI cultures underwent daily 1 hour exposure to bile salts. To determine if BE cells that lacked p53 responded differently to BA exposure, CRISPR Cas9 was utilized to knockout *TP53*. ALI cultures were conducted for 28 days. Phenotypic differences were determined by H&E staining and immunofluorescence (IF). Changes in cell proliferation was evaluated by Ki67 IF. Successful ALI cultures were validated by positive expression of laminin, pan-cytokeratin, Muc2 and Muc5ac by IF. Upon co-culture, we observed opposing histologic changes in the BE cells from the P and NP patients. The NP BE cells had a less complex structure upon culture with the BFs and CFs compared to NFs. The P BE cells showed the development of a complex morphology upon culture with the CFs compared to the BFs and the NFs. In both patients, we observed an increase in Ki67 positivity with fibroblast co culture; NFs (NP: 6.91%, p=0.070, P: 10.6%, p=0.001), BFs (NP: 12.49%, p=0.0001, P: 11.196%, p=0.003) and CFs (NP: 19.88%, p<0.0001, P:14.63 %, p=0.0001) compared to no fibroblasts (NP = 5.32%, P= 7.25% Ki67+). Co-culture with CFs increased Ki67 staining compared to either NFs or BFs (p=0.007,0.014). Exposure to BA showed a thinning but intact BE epithelial surface in both patients with and without *TP53* knockout. Overall, primary BE cells and fibroblasts can be maintained long term in an ALI culture and co-culture with fibroblasts drive increased proliferation in BE cells. The histology changes observed in NP and P cell could be an indication of possible activation and interaction of differential signaling pathways. Ongoing studies aim to identify these pathways and determine transcriptional changes due to co-culture and BA exposure.

#6775 3D culture aggregation morphology depends on cell phenotype and gene expression profiles in lung cancer.

Naohiro Hayashi[1], Shimpei Tsudaka[1], Ken Suzawa[2], Tomoaki Higashihara[1], Yin Min Thu[1], Atsushi Matsuoka[1], Daisuke Mizuno[1], Ryo Yoshichika[1], Fumiaki Mukohara[1], Mao Yoshikawa[1], Kazuhiko Shien[2], Hiromasa Yamamoto[2], Shinichi Toyooka[1]

[1]Department of General Thoracic Surgery and Breast and Endocrinological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan,[2]Department of Thoracic Surgery, Okayama University Hospital, Okayama, Japan

Background: Three-dimensional (3D) cell culture allows for the reproduction of tissue structure and function in a state more akin to the in vivo environment compared to two-dimensional (2D) cell culture. It is established that 3D culture more faithfully replicates cell morphology, differentiation, proliferation, gene and protein expression, and responsiveness to stimulation, as well as drug metabolism. Focusing on the observation that lung cancer cell lines exhibit different clustering morphologies in 3D cell culture, we conducted a comparative study on the relationship between these clustering morphologies and the characteristics of the lung cancer cell lines.

Methods: We cultured 30 lung cancer cell lines using 3D culture plate, and classified the types of cell clustering morphologies formed. We evaluated the molecular and cellular biology characteristics of all cell lines. Additionally, comprehensive gene expression analysis using RNA sequencing was performed on the 30 3D-cultured cell samples, and the characteristics of gene expression between different clustering types were compared.

Results: The 3D culture aggregation morphology of 30 lung cancer cell lines were classified into three types (monolayer sheet, NOS, spheroid). Monolayer sheet-type cells exhibited higher proliferation, migration, and invasion capabilities compared to spheroid-type cells. In the transcriptomic bioinformatics analysis of the acquired gene expression data, GSEA analysis using Hallmark gene sets showed that the enrichment of epithelial-mesenchymal transition (EMT) and cancer metastasis-related genes in the monolayer type cells significantly compared to the spheroid type cells. Conversely, cell adhesion and intercellular binding-related gene sets were highly enriched in the spheroid type cells.

Conclusion: 3D culture aggregation morphology represents phenotypic properties and transcriptomic profiles in non-small cell lung cancer cells.

#6777 An *ex-vivo* organotypic culture platform of mucinous carcinomatosis peritonei identifies CDK4-6 inhibition as a novel treatment.

J. Weitz[1], D. Nishizaki[1], J. Patel[1], I. Ng[1], S. Sun[1], D. Ramms[1], J. Zou[2], J. Baumgartner[1], K. Kelly[3], H. Patel[1], R. White[1], J. Veerapong[1], P. Vu[1], S. Gutkind[1], H. Tiriac[1], S. Kato[1], A. Lowy[1];

[1]UCSD Moores Cancer Center, San Diego, CA, [2]UCSD, San Diego, CA, [3]University of Wisconsin, Madison, WI

Concomitant mutations in *KRAS* and *GNAS* have been linked to mucinous histology in gastrointestinal neoplasms of the appendix, colon, and pancreas (IPMN). Upon progression, these tumors are characterized by metastasis which favors the peritoneal surface, resulting in mucinous carcinomatosis peritonei (MCP). Recently we have described a novel technique which allows for long term culture and drug intervention of human MCP tumors *ex-vivo*. With evidence of durable clinical benefit of CDK4-6 inhibition in a single patient with chemo refractory MCP of appendiceal origin, we sought to further investigate anti-tumor responses using CDK4-6 inhibition in *ex-vivo* tumor slices, in order to identify candidates for a personalized clinical therapy trial. Here, in a comparison of *ex-vivo* patient tumor slices from 18 individual donors, treatment using CDK4-6 inhibitors revealed *a* significant reduction in cancer cell specific proliferation in mucinous *GNAS-mut* tumors compared to non-mucinous cancers. Anti-tumor responses of CDK4-6 were determined to be tumor-cell intrinsic, as CDK4-6 inhibition blocked proliferation of stromal cells in the TME independently of patient tumor mutational and mucin status. Based on these finding a personalized clinical trial was conducted where we report that 13 of 16 patients (81%) enrolled with MCP treated with palbociclib had at least a 10% decrease in CEA, as compared to historical chemotherapy responses rates reported from 14-30%. These results indicate that CDK4/6 inhibition is a novel and efficacious treatment for patients with MCP.

#6778 New microplate platform with cryopreserved 3D tumor spheroids for faster and convenient pre-clinical testing.

N. Goedecke[1], S. Stroebel[1], S. Hutter[1], T. Issa[1], I. Agarkova[1], L.-A. Ligeon[1], O. Frey[1], **M. Nag**[2];
[1]InSphero AG, Schlieren, Switzerland, [2]InSphero AG, Brunswick, ME

Drug discovery and safety testing depend on predictive *in vitro* models, including multicellular tissues with organotypic functions. While traditional 2D tumor cell cultures have been extensively used in early drug screening due to their user-friendly nature, automation compatibility, and high throughput, they fall short in representing the intricate 3-dimensional structure, physiology, and complex multicellular nature of actual tumors. However, generating such 3D tissues for each test campaign is labor intensive. In addition, not all researchers have the resources to establish these 3D models. To pave the way, we developed a new platform that offers a range of cryopreserved 3D tumor models in micro plate format allowing for high-content screening. It enables users to start testing compounds within a 3-to-5 days simply by thawing an ARCTis™ plate (Always Ready Cryo Tissues) and following clear instructions. Another advantage of these cryopreserved 3D models derives from the fact that they are made in larger batches which means the start point for compound testing is always the same. This improves data quality, maximizes the test window length, and makes the data comparable across work groups. Currently, our growing portfolio consists of 25 tumor cell lines from ATCC representing the most common solid tumors. Their functionality has been determined based on efficacy tests for each cell line with the apoptotic agent Staurosporine. Various cell lines exhibited compact spheroids with a round morphology, less compact aggregates with non-spherical morphology, or loose cell-cell interaction aggregates, which can correlate with their tumor site of origin. Upon treatment with Staurosporine the dose-response profiles indicated growth inhibition, tumor shrinkage, or tumor cell killing effects based on size assessment and cell metabolic analysis (ATP). Moreover, we demonstrated the robust performance of these assays from plates stored for up to 6 months at -80°C.In conclusion, this groundbreaking approach addresses the limitations of traditional 2D cell cultures by providing a high-throughput, in-plate frozen, 3D cell culture platform. By offering a combination of a more physiologically relevant representation of tumors with a robust frozen-storage and time flexible assay platform our method holds great promise for advancing cancer drug discovery by easing the exploration of complex drug testing screens *in vitro*.

#6779 Modality agnostic tumor models of cancer which can more accurately define drug efficacy and mechanism to help develop more effective therapeutics.

P. Samuel, D. O. Ochola, H. Del Mundo, **B. Dave**;
Spanios, Houston, TX

Introduction: In the path to clinic, researchers require robust tools to effectively evaluate the capacity of novel therapeutic modalities to generate anti-tumor responses. Using human-relevant, translational ex-vivo models is widely considered to reduce attrition during drug discovery and development for a more effective prediction of clinical outcomes during preclinical testing of drug candidates. **Methods:** The three levels of our patient derived tumoroid model platform, COMPASS (Custom Organoid Modeling Platform for Accurate SolutionS) was built to be versatile modality-agnostic human on human model system for pre-clinical testing. COMPASS 1 has stroma with epithelium; COMPASS 2 has stroma, epithelium, and immune components (from PBMCs) and COMPASS 3 has stroma, epithelium, immune components, and oxygenation. For widespread adaptation and utilization of our COMPASS platform we encourage extensive characterization by articulating the context of use to help build confidence in cases where limited knowledge and only few real-life cases exist. **Results:** Our proof-of-concept examples articulating the context of use demonstrate the modality-agnostic adaptability our COMPASS platform brings to the field of preclinical testing. We encourage a collaborative approach with researchers to support their testing needs to build confidence in our model to enable transition from existing screens, assays, and animal models. We envision preclinical use of COMPASS to help stratify patients for clinical trials, identify subpopulations that need dose modification and predict the response of patients and/or their risk of adverse effects. **Conclusion:** Due to its greater physiological relevance and ability to encompass downstream processes in a time and cost-efficient way, industry and academia should deliberate the impact platform such as COMPASS would have on their workflow and consider adapting to using these models routinely.

#6781 Maintaining the tumor microenvironment: Serum-free cell culture for an advanced 3D in vitro tissue model.

A. Siebenmorgen[1], C. Wohle[1], K. Lamfried[1], L. Martinez Carrera[1], B. Heller[2], K. Lupar[2], G. Bergamini[2], D. Poeckel[2], O. Hardt[1], **B. Theek**[1];
[1]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany, [2]Cellzome GmbH, a GSK company, Heidelberg, Germany

Cancer research has made significant progress in recent years, especially in the field of immunotherapy that uses immune modulators. A significant portion of these novel therapeutic strategies focuses on manipulating the tumor microenvironment (TME). The TME is a complex structure that comprises various cellular elements, including cancer cells, immune cells, and structural components, such as secreted factors and extracellular matrix proteins. However, replicating the human TME in experimental murine models has proved challenging. Therefore, researchers have started to develop ex vivo cultivation protocols of tumor tissues, particularly precision-cut slices (PCS), that offer a three-dimensional representation of the TME. It is essential to select the best culture conditions to ensure the preservation of the TME that closely resembles the in vivo conditions. To further this research, a serum-free cell culture medium has been developed to propagate primary epithelial tumor cells originating from pancreatic, renal, and ovarian tissues. The optimized media formulation was successfully employed in the derivation and expansion of tumor cell lines, sourced from both primary and xenotransplanted tumors. An additional serum-free cell culture medium has been designed to cultivate primary lung cancer cells. Suitable culturing conditions have been introduced that maintain TME composition ex vivo cultured PCS prepared from fresh non-small cell lung carcinoma (NSCLC) tissue. Lung TumorMACS Medium and a serum-containing medium were compared, and it was found that the cellular composition of PCS cultivated in Lung TumorMACS was comparable to the original composition. At the same time, PCS cultivated in Lung TumorMACS showed a lower expression of stress genes, compared to the serum-containing alternative.

#6782 3D-EXpress - an *ex vivo* platform using viably cryopreserved tumoroids for rapid assessment of targeted therapeutic outcomes.

V. Garrido, M. Ataya, N. R. Dhanushkodi, S. Currlin, A. Humphrey, J. Ehrhart, R. Chakraborty;
Nilogen Oncosystems, Tampa, FL

Background: it has been a significant challenge to select, combine, and sequence the multiple FDA-approved IO therapies and pharmaceutical agents, highlighting the need to develop a precision oncology platform to explore novel combination treatments. 3D-EXpress is a unique *ex vivo* therapeutics testing platform using a biorepository of fresh patient tumoroids that were never dissociated, propagated, or reassembled to retain an intact microenvironment. Therefore, these specimens provide an excellent *ex vivo* platform to investigate the efficacy of therapeutics targeting the tumor microenvironment. Here, we employed the 3D-EXpress platform to compare the efficacy of different therapeutic modalities targeting tumor antigens and immune checkpoint *ex vivo*.
Methods: Tumoroids measuring 150 µm in size retaining tumor cell heterogeneity, tumor-resident immune cells, stromal components, and extracellular matrix interaction were prepared from human endometrial and colorectal tumors. Tumoroids were cryopreserved and were selected based on tumor antigen status. Samples were treated for 72 hours *ex vivo* with antibody-drug conjugates, chimeric antigen receptor (CAR)T cells, or bispecific antibodies alone and in combinations. Treatment-mediated changes in tumor cell killing and tumor immune microenvironment were investigated.
Results: 3D high throughput confocal imaging and Nilogen Oncosystem's proprietary algorithm were used to detect and analyze treatment-induced tumor cell killing activity in tumoroids. The impact of *ex vivo* treatment by different modalities in combination with chemotherapeutic agents upon tumor resident immune cell populations was monitored by deep immune phenotyping and multiplex cytokine release assay. Based on the *ex vivo* responses tumors were assigned to treatment sensitive and resistant groups. Correlative analysis was performed and compared with detailed clinicopathologic data that is readily available for Biorepository tumors.
Conclusions: The 3D-EXpress platform using cryopreserved 3D tumoroids with intact tumor microenvironment is an effective tool for the pre-clinical assessment of rational drug combinations for treatment of solid tumors. Furthermore, the 3D-EXpress platform provides unique insight into the microenvironment of both treatment responsive and non-responsive tumors and can aid in the development of patient-centered therapeutic regimens.

#6784 Cancer cell heterospheroids with stromal component used as drug testing and immune cell infiltration models.

B. S. Nielsen, N. H. Madsen, J. Larsen, M. Gad, K. Holmstrom;
Bioneer A/S, Horsholm, Denmark

3D cancer cell cultures have enabled new opportunities for replacing compound testing in experimental animals. However, driven by increased understanding of the need for more complex cancer cell models that consider drug resistance and penetration, hypoxia, and immuno-oncology applications, we have developed multicellular tumor heterospheroids composed of cancer cell lines, fibroblasts and immune cells. We have studied heterospheroids of cancer cell lines, HT29, MCF7, PANC1 and SW480 co-cultured with fibroblasts and 1) explored the architectural organization, 2) performed whole transcriptome analysis (WTA) of mono and co-cultures and 3) tested their capacity of immune cell infiltration. The architectural organization was studied in embedded heterospheroids. HT29 and MCF7 cells developed spheroids with the cancer cells surrounding the fibroblasts, whereas PANC1 cells mingled with the fibroblasts and SW480 cells were surrounded by fibroblasts. The fibroblasts expressed FAP-α mRNA as determined by ISH as well as collagen-1 as determined by immunohistochemistry. The hypoxia marker, Ca-IX, and the apoptosis marker, cleaved-Caspase-3, were dominating in the central core of the spheroids but the Ca-IX and Caspase-3 expression was not coordinated. In addition, WTA performed on day-7 heterospheroids, showed upregulated LOX, indicating that hypoxia-related markers known from genuine cancers are upregulated also in heterospheroids. WTA of day-7 mono-cell cultured and hetero-cultured spheroids, showed abundant ECM-, EMT-, and fibrosis-related expression in heterospheroids, thus reflecting a representative tumor-like microenvironment in heterospheroids compared to mono-culture spheroids. In particular, PANC1 spheroids showed a strong EMT profile with abundant FOXC2, TGF-β and TWIST expression. Genes related to Akt/mTOR and EGF pathways were consistently expressed in the tested heterospheroids. Evaluation of the cytotoxicity of anti-cancer compounds was performed using both cell viability and apoptosis assays. Exposure of the NCI drug library composed of 166 cytotoxic compounds to the heterospheroids, interestingly, revealed a complex output with limited correlation between cytotoxic and apoptotic effects. A subset of drug candidates is currently being further examined. PBMC-derived immune cells infiltrate heterospheroids and their infiltration is strongly enhanced after activation. The T cells' ability to infiltrate heterospheroids of different cancer types may serve as models of cold and hot tumors. We conclude that the cancer cell lines determine the architectural structure of heterospheroids, that ECM development is a prevalent part of the heterospheroids, and that the different heterospheroids possess varying ability of immune cell infiltration.

#6785 KIYA-PREDICT™ XPDX: An *ex vivo* 3D spheroid platform for modeling *in vivo* responses to multiple classes of oncology therapeutics.

A. L. Carlson[1], N. W. Dance[1], K. J. Burgess[1], D. Y. Nadeau[1], M. Millard[1], A. Simonson[2], A. Diaz III[2], M. Wick[2], T. M. DesRochers[1];
[1]Kiyatec, Greenville, SC, [2]XenoSTART, San Antonio, TX

Patient-derived xenografts (PDX) are a powerful and commonly used tool in preclinical drug development as they represent an *in vivo* platform for screening drug response in human tumors that recapitulate many molecular and histological features of the original patient tumor. However, these models are costly and time-intensive, necessitating the development of *ex vivo* platforms for assessing drug response to PDX-derived tumors to de-risk *in vivo* studies by aiding in model selection and reducing the number of animals and costs associated with *in vivo* experimentation. The KIYA-PREDICT™ platform is a clinically validated, *ex vivo* 3D cell culture platform with demonstrated ability to predict patient response to chemotherapy in high grade glioma and ovarian cancer. Here, we apply this platform to profiling XPDX from XenoSTART's comprehensive library of well-characterized models as a tool for assessing drug response and mechanism of action *ex vivo* while also aiding in model selection for *in vivo* studies. Over 100 XPDX models have been profiled *ex vivo* for response to several classes of cancer therapeutics, including chemotherapy, targeted therapy, and antibody-drug conjugates (ADCs), demonstrating robust concordance with *in vivo* drug response. CDK4/6 inhibitors palbociclib and ribociclib evaluated *ex vivo* in breast XPDX display strong correlation to *in vivo* response and recapitulate palbociclib resistance. Similarly, G12C inhibitors sotorasib (AMG-510) and adagrasib (MRTX849) screened against a panel of non-small cell lung cancer XPDX *ex vivo* match *in vivo* response and drug resistance. Finally, *ex vivo* and *in vivo* responses to FDA approved ADC enfortumab vedotin were evaluated in a panel of bladder cancer PDX, with *ex vivo* and *in vivo* responses showing good concordance and expected modulation based on Nectin-4 expression levels. The combination of the KIYA-PREDICT™ platform with XenoSTART's XPDX catalogue is a flexible and powerful tool that can be utilized for streamlining preclinical drug development for a wide range of therapeutic classes.

#6786 Assessment of immune cell infiltration and cancer metastatic potential in Akura™ Immune Flow Chip - A microfluidic 3D spheroid system.

T. Hafeli[1], S. Riss[1], C. Lohasz[2], D. Hasanova[2], S. Lutzow[2], L. Holting[1], M. Rudnik[1], F. Linke[3], W. M van Weerden[3], **L.-A. Ligeon**[1], A. Hierlemann[2], M. Modena[2], O. Frey[1];

[1]InSphero AG, Schlieren, Switzerland, [2]ETH Zurich, Department of Biosystems Science and Engineering, Basel, Switzerland, [3]Experimental Urology, Cancer Institute, Erasmus Medical Center, Rotterdam, Netherlands

Evaluation of novel therapeutics often fails to reliably predict severe complications in patients, especially when circulating cells are involved. The reasons may include inter-species differences upon using animal models or the lack of relevant *in vitro* systems. Moreover, existing *in vitro* systems mostly rely on static investigations of different cell types leading to overestimation of effects due to non-representative cell-tissue interactions. The incorporation of medium flow may facilitate to mimic physiological conditions more closely. To tackle current limitations of perfused organ-on-chip approaches, we developed a microfluidic chip and operation concept, which prevents undesired sedimentation and accumulation of cells in suspensions. The Akura™ Immune Flow platform was designed to study flow-dependent recruitment of circulating cells to different tissue spheroids via gravity-driven perfusion over several days. The Akura™ Immune Flow platform features standardized formats for co-culturing up to seven spheroids with suspended cells in each microfluidic channel. On-chip staining protocols enabled monitoring of the co-culture. The system allowed for application and extractions of cellular components and liquid for further off-chip analysis. Primary tissue and cell line spheroids (liver and tumor) could be retained in the respective chambers and remained viable over six to 14 days. Circulating cells were kept viable and in suspension for up to six days (PBMCs) and14 days (Prostate Cancer (PCa) cells) respectively. PBMCs were not activated by flow-induced shear forces. Unspecific stimulation of T-cells led to physiological expression of early and late activation markers (CD69 and CD25), which were detected by flow cytometry in periodically collected cells. Multi-photon microscopy imaging confirmed that PBMCs interacted with and infiltrated into 3D tumor spheroids. Application of PCa cells to primary liver spheroids, cultured in Akura™ Immune Flow chips allowed for assessment of their invasive potential. Confocal imaging revealed adhesion of cancer cells to the liver spheroids and offers the potential to study the ability of tissue invasion at later time points. The simple design of the chip facilitates user-friendly operation and high-throughput implementation in cancer research and drug testing. The selected applications support the relevance of using flow solutions for physiologically more complex processes. This work constitutes an important step towards device application as a tool for basic research as well as for efficacy studies of immunotherapeutic drug candidates

#6787 Evaluation of CAR-T cytotoxicity in solid tumors: A screening workflow using 3D patient-derived tumoroids.

X. Yang[1], M. Mafreshi[1], G. Wong[1], V. Chandra[1], C. Paul[2], C. Yankaskas[2], B. Balhouse[2], J. Sharp[1], M. Dallas[2], E. Willems[1], D. Kuninger[2];
[1]Thermo Fisher Scientific, Carlsbad, CA, [2]Thermo Fisher Scientific, Frederick, MD

Introduction: Over the last decade, chimeric antigen receptor T cell (CAR-T)-based immunotherapy has achieved unprecedented clinical benefits for the treatment of hematological malignancies. However, application of CAR-T therapy to solid tumors remains challenging, in part due to tumor antigen heterogeneity and microenvironmental complexity present in these tumors. Therefore, selecting physiologically-relevant models is critical for validation of the on-target efficacy and off-target effect of CAR-T therapy. Emerging 3D patient-derived tumoroid models better recapitulate the morphological organization, mutational status, and gene expression levels of patient tumors. Hereby, we propose a screening platform to evaluate mesothelin (MSLN)-targeted CAR-T therapy for solid tumors using patient-derived tumoroids.

Methods: T cells were isolated from peripheral blood mononuclear cells of healthy human donors. Meso3 (region III of MSLN) or CD19 CARs (served as control) were knocked-in (KI) to activated T cells using electroporation-based CRISPR/Cas9 system followed by CAR Cassette containing adeno-associated virus (AAV) transduction. T-cell receptor (TCR) knockout (KO) and CAR-KI efficiency were validated by flow cytometry. Patient-derived tumoroids with high and low MSLN expression were co-cultured with various effector-to-target ratios of Meso3 CAR, CD19 CAR and Control (TCR KO without CAR KI) T cells. Cytotoxicity was evaluated by caspase-based live cell imaging. Key cytokine secretion was measured using a multiplexing platform 2-3 days post co-culture.

Results: T-cell electroporation of CRISPR/Cas9 yielded a high KO efficiency (>90%) of TCR as well as high AAV-mediated CAR cassette-KI efficiency (>70%). The killing efficiency of Meso3 CAR-T cells with different effector to target ratios was successfully captured in a ratio-dependent manner via live cell imaging and analysis platform in the MSLN-high tumoroids, while minimum killing was observed in MSLN-low tumoroids. As expected, control and CD19 CAR-T cells showed no killing towards MSLN-high or -low tumoroids, which do not express CD19. Moreover, the observed killing ability correlated with secretion of cytokines associated with T cell-mediated cytotoxicity.

Conclusion: These findings demonstrated the ability of 3D patient-derived models as a screening platform for validations of CAR-T cell therapy in vitro. This platform has potential advantages over commonly used impedance-based and flow cytometry-based killing assay since it better captures the 3D architecture and microenvironment of the tumor origin and allows real-time quantification. With the ability of accurately detecting on and off-target killing, quick turn-around time, and cost-effectiveness compared to in vivo systems, this platform allows for high-throughput screening workflows for CAR-T cell therapies.

#6788 Comparative analysis of anti-HER2 antibody-drug conjugates in tumor spheroid models.

K. McBain, K. Barnes, N. Bevan;
Sartorius, Royston, United Kingdom

Robust techniques are needed to screen the anti-tumor activity of antibody-drug conjugates (ADCs) *in vitro*. Traditional monolayer models provide a cost-effective and scalable option but lack many features of the tumor microenvironment, such as complex cell-cell and cell-extracellular matrix interactions. Tumor spheroids afford a more translational model for quantification of ADCs. Here, spheroids are used to compare the mechanism of action (MoA) of anti-HER2 ADCs. Single spheroids were formed from mono- or co-cultures of HER2 over-expressing cancer cells and HER2 negative control cells. Incucyte® Nuclight Green Lentivirus was used to label HER2 positive BT474 cells, whilst HER2 negative MDA-MB-231 cells were left unlabeled. Antibodies were added after 72 hours of spheroid formation in 96-well ultra-low attachment plates. Brightfield and fluorescence images were captured every 3 hours using the Incucyte® Live-Cell Analysis System and quantified, for metrics such as spheroid size and fluorescence intensity, to give an indication of ADC cytotoxicity. Co-culture spheroids were dissociated at assay endpoint and the remaining proportion of green and unlabeled cells was measured using the iQue® Advanced Flow Cytometry Platform. The area of the BT474 mono-culture spheroids decreased in a concentration-dependent manner in the presence of both ADCs tested (trastuzumab emtansine and trastuzumab deruxtecan), indicating increased cytotoxicity. In contrast, only the highest concentration of trastuzumab, which is the monoclonal antibody backbone on which they are based, resulted in a reduction in spheroid size. This displays the increased anti-tumor activity due to the addition of the ADC payloads. In the co-culture model, only the trastuzumab deruxtecan induced a reduction in spheroid area, with the size of the spheroids in the presence of trastuzumab emtansine and trastuzumab remaining comparable to control levels. Analysis of the spheroid composition using flow cytometry showed that for the BT474 cells, again, percentage cell death compared to the IgG control was greater for the two ADCs, at 96.4% and 97.2%, respectively. This death was greater than with trastuzumab, which induced 46.4% cell death. Unlike in the mono-culture assays, a high level of death of the HER2 low expressing cells was also seen in the co-culture in the presence of trastuzumab deruxtecan (94.1% death compared to control). This displays the unique bystander activity of trastuzumab deruxtecan, which has led to its approval as a treatment for both HER2 high and HER2 low breast cancers. These data display how the Incucyte® Live-Cell Analysis System combined with iQue® Advanced Flow Cytometry can be leveraged to provide comprehensive assessment of the *in vitro* function of ADCs and how it can enable differences in their MoAs to be distinguished in 3D spheroid models.

#6789 Development of an *in vitro* gastric cancer 3D co-culture platform using a microphysiological system (MPS) to improve outcomes in oncology clinical trials.

Y. Choi[1], S. Kim[1], Y. Song[1], Y. Kim[1], J. Jang[1], S. Kim[1], J. Baek[1], D. Donnelly[1], B. Rajiput[1], B. Lee[1], W. Kwon[2], T.-L. Liu[1], K. Baek[1], S. Yoo[1], S. Rha[2]; [1]Qureator, Inc., San Diego, CA, [2]Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: Despite significant advancements in scientific and diagnostic technologies, clinical trials for cancer often fail due to a lack of efficacy. Access to a platform that accurately predicts patient response is crucial to increase the success rate of clinical studies, and to minimize unnecessary exposure to ineffective and potentially harmful drug testing for patients. Because of the complexity of the disease, it would be beneficial to deploy patient samples for drug testing in a side-by-side comparison during the clinical trial. An accurate prediction of patient response earlier in the clinical study would aid decision making to determine the appropriate duration of treatment for each patient.

Methods: We developed a 3D human cell co-culture model using our proprietary MPS technology, the Curio-spheroid Curiochip. Using patient samples isolated and expanded from either ascites fluids or biopsies to recapitulate the clinical phenotypes of advanced gastric cancer, we quantified the migratory properties of the patient cancer cells (i.e., the unique metastatic potential), and measured the level of secretion of VEGF. Somatic mutational analyses using NGS and RNAseq were performed for subtyping and clustering the samples. The patient cancer cells were expanded within 2 weeks post-collection, and used to form a spheroid that was loaded into a hydrogel embedded within the Curio-Spheroid, enabling the patient spheroids to interact through the hydrogel with neighboring (healthy) human endothelial cells. The patient spheroids induced aggressive vasculogenesis in the co-culture model, which was subdued by the anti-VEGFR2 antibody Ramucirumab. The platform was retrospectively validated with the Standard-of-Care (SOC) treatments that the patients received.

Results: The patient cell testing took 3-4 weeks from sample collection to imaging. The patient cells preserved their migratory capacity, pro-angiogenic potential and drug responses in the vascularized model. The dose responses to SOC in the platform were consistent with the actual patient response assessments based on RECIST criteria, supporting the potential to use this platform to accurately predict patient clinical responses.

Conclusions: The Curio-spheroid 3D co-culture model of vascularized gastric cancer provides a dynamic microenvironment to preserve the phenotypes of the patient cells and cell-cell interactions that are known to influence drug responses. This platform is compatible with high-throughput screening (HTS) for target or drug discovery with a good assay window. The ability to accurately recapitulate patient responses to SOC in the clinic make the Curio-Spheroid platform a promising method to test patient samples and measure drug responses of patients in real time during ongoing clinical trials.

#6790 Breaking barriers: A high-throughput 3D drug discovery platform for ovarian cancer.

E. George[1], D. I. Pedro[1], A. Pepe[1], A. M. Rivera[1], R. A. Smolchek[2], J. E. Famiglietti[2], W. Sawyer[1];
[1]Moffitt Cancer Center, Tampa, FL, [2]Aurita Bioscience, Gainesville, FL

Background: Ovarian Cancer (OVCA) is a formidable challenge in oncology and remains the most lethal gynecologic malignancy with many cases (~80%) diagnosed at a late stage with an equally high rate of recurrence. Yet, no established OVCA models exist that faithfully recapitulate the biological complexity of metastatic OVCA. This multidisciplinary team developed a new in vitro high-throughput model that maintains the characteristics of the patient's tumor including resident immune cells. Key breakthroughs include long term (>21 day) culture of patient-derived microtumors, a functional and perfusable microgel medium (Liquid Like Solids - LLS™), microplates with controlled "pumpless" perfusion of culture media (Darcy Plates™), and integrated in situ imaging.
Methods: We designed, fabricated, and validated a new 3D culture device in the standard SBS microplate format (Darcy Plate) that integrates in situ microscopy and perfusion through a bio-conjugated microgel bed (LLS). Patient tumors were collected during debulking surgery, micronized into 1 µl microtumors, suspended in LLS, and plated into the 48-well Darcy Plate. Viability and proliferation were assessed over 21 days in situ using a standard LIVE/DEAD™ kit and EDU staining, respectively. Epithelial OVCA cells and immune cells were identified with immunofluorescence microscopy.
Results: Optimal media conditions (HPLM media with 10% FBS, 1% Pen/Strep, 2.5 mg L^{-1} Amphotericin B, 10 mM HEPES, 0.5 µM A83-01 -TGF-β inhibitor-, and ITS) and perfusion flow rates (100 µl/day per well) were identified that resulted in outstanding cell viability after 21 days (~100% - no detectable cell death using LIVE/DEAD™). PAX8 nuclear expression, a marker for epithelial metastatic OVCA, was retained. EDU staining confirmed cell proliferation and CD45 staining revealed retention of viable immune cells on and within the microtumor at 21 days. Drug testing to evaluate tumor response to chemotherapeutic agents, carboplatin, and emerging targeted therapies was performed by dosing the feed-wells at different concentrations and evaluating cell death through LIVE/DEAD imaging after 5 days of treatment.
Conclusions: OVCA is a challenging disease with understudied biological complexity and extensive metastatic involvement. This study demonstrates that drug screening with 3D microtumors has important clinical implications and provides a unique opportunity to evaluate drug responses and personalized treatment strategies. These patient-derived microtumors retain crosstalk between diverse cell populations and the tumor microenvironment, which increases the likelihood of identifying effective therapies and drug candidates. This system retains patient-specific tumor heterogeneity and microenvironmental complexity of OVCA, offering a promising platform for drug screening, high-throughput assays, biomarker discovery, and ultimately improving treatment outcomes.

#6791 Investigation of sex hormone effects in an organ chip model of endothelial barrier dysfunction in the triple negative breast cancer microenvironment.

D. Carlino, A. Martier, Y. Maurice, G. Kpeli, M. Burow, M. Mondrinos;
Tulane University, New Orleans, LA

Inflammation and pathological vasculature are common features of the tumor microenvironment (TME). Sex hormones potently modulate vascular physiology and immune cell functions, and there are established correlations with the outcomes of triple negative (TNBC) despite the defining feature of receptor negativity. Circulating estrogens and androgens have been hypothesized as drivers of TNBC through the actions exerted by receptor-positive cells in the TME. Here, we present an organ chip model of the TNBC microenvironment for quantifying the impact of configurable TME variables such as the ECM composition and the relative densities and phenotypes of tumor cells, cancer associated fibroblasts, and myeloid cells on endothelial barrier function. After establishing baselines of vascular permeability in the presence and absence of TNBC cells, we tested the effect of estradiol, estrone, and dihydrotestosterone on barrier permeability. Multilayer polydimethylsiloxane (PDMS) organ chips were fabricated using standard soft lithography. The layers of the device were separated with semi-permeable membranes that allow exchange of soluble factors. Once assembled, the upper channel was loaded with female (XX) human umbilical vein endothelial cells. Collagen hydrogels were injected into the tissue layer and the devices were cultured on a rocker to induce endothelial barrier alignment via application of an average shear stress of 5 dynes/cm^2. We optimized rocking conditions by assessing endothelial layer alignment, junctional organization, and permeability. TNBC cells and XX mammary carcinoma fibroblasts were added to the hydrogel to model the effects of TME-derived signals on endothelial barrier permeability. 40 kDa FITC- Dextran was chosen to assay permeability as it can show leakage due to active disruption of the barrier. Staining for F-actin and ZO-1 allowed for quantification of junctional organization. Sex hormone modulation of proinflammatory gene expression was assessed by RT-qPCR. The presence of TNBC cells significantly increased transport of 40kDa FITC-Dextran across the endothelial barrier, disrupted intercellular junction quality, and induced the expression of inflammatory adhesion molecules including ICAM-1. Our results demonstrate that sex hormones modulate TNBC-associated changes in endothelial cell bioenergetics, junctional organization, and macromolecular barrier permeability. Ongoing work will investigate the effects of age-matched XX monocyte derived macrophages on barrier function in the model. This organ chip platform provides an assay for measuring altered vascular inflammation and permeability in the TNBC microenvironment and may provide a venue for investigating vascular-normalizing effects of various candidate therapeutics.

#6792 Investigating differential expression of Palladin isoform 3 in 2D and 3D pancreatic cancer cell cultures.

S. Biswas, J. A. Bush;
California State University, Fresno, Fresno, CA

Palladin (*PALLD*) is an actin-binding protein widely expressed in mammalian tissues that modulates cytoskeletal dynamics. Palladin is linked to the progression of breast, pancreatic, and renal cancers. There are at least 9 known isoforms of PALLD but isoforms 3 (iso3) and 4 (iso4) appear most significant in cancer cells and associated fibroblasts. Our goal is to understand iso3 in pancreatic cancer (PC) cell lines grown in various culture environments to shed light on the intricate interplay between culture conditions and gene regulation. Cell models were developed as 3D spheroids from hanging drops after optimizing culture conditions by utilizing a combination of inexpensive methylcellulose (MC) and rat tail collagen viscosity ranges across cell seeding densities. The quality of the developed spheroids was assessed using multiple parameters, like diameter, integrity, and circularity to determine ideal spheroid characteristics. Spheroids that formed at a lower MC viscosity range (350-550 mPa·s) led to peripheral loose cells and a higher viscosity range (7,000-10,000 mPa·s) resulted in elongated shapes. Moderate viscosity ranges (1,000-1,800 mPa·s and 3,500-5,600 mPa·s) consistently produced circular and compact spheroids. Optimal incubation times varied from 72 to 96 hr depending on the cell line. Invasion dynamics within collagen-MC gels revealed that PANC-1 had significantly higher invasion potential compared to BxPC-3 and a control cell line C2C12. RT-qPCR results show that *PALLD* iso3 was particularly overexpressed in the 3D culture environment of PANC-1, suggesting that elevated *PALLD* isoform 3 expression may be a characteristic of 3D culture, particularly in invasive PC types. Taken together, the study validates the importance of extracellular viscosity for influencing spheroid characteristics toward generating reproducible 3D spheroids. The investigation also highlights *PALLD* iso3 as a potentially valuable biomarker for aggressive forms of pancreatic cancer.

TUMOR BIOLOGY: Chemokines and Cytokines in Cancer
Poster Session

#6797 CCR5/CCL4 axis in lung cancer clinicopathological significance and its therapeutic application.
S. K. Singh, R. Singh;
Morehouse School of Medicine, Atlanta, GA

Lung cancer (LC) is the most prevalent type of cancer globally and the leading cause of cancer-related deaths. Based on the histology and type of treatments, LC is divided into small-cells and non-small cell lung cancer (NSCLC) carcinomas, which are more aggressive and less responsive to chemotherapy. Since LC is known to be a highly heterogeneous cell population, treatment is challenging. It has been observed that chemokine receptor-ligand interaction is essential for cancer cells homing to distant sites. Most malignancies, including LC, have established disease status indicators concerning elevated levels of CCL4, a structurally unique chemokine, and its receptor (CCR5). Therefore, treatment strategies that inhibit the LC cell's tumor environment may improve patients' quality of life. However, the CCR5/CCL4 interface in LC invasion and metastasis is poorly understood. In this study, we examined the expression and function of the CCR5/CCL4 axis in the development and invasiveness of LC patient's clinical tissues and cell lines. We conducted immunohistochemistry (IHC) dual staining of CCR5/CCL4 antibodies in LC tissues. Our findings demonstrated significantly ($p < 0.001$) higher expression of CCR5 and CCL4 in advanced-stage malignant tissues than in normal tissues. The in-vitro analysis of the human LC cell lines NCI-H1437, NCI-H1573, and NCI-H1975 revealed CCL4 activation expressing higher CCR5, determined by immunofluorescence, western blots, flow cytometry, 3D-invasion assay, and RT-qPCR methods. Further, a calcium mobilization assay confirmed the direct interaction between CCR5 and CCL4. However, treating with Maraviroc, a small molecule inhibitor of CCR5, to LC cells blocks their ability to proliferate, demonstrating the crucial role that CCR5-CCL4 chemotaxis plays in LC metastasis. Our findings show both the biological and clinical significance of CCR5 and CCL4 expression, which may serve as potential indicators for metastatic LC. Therefore, inhibiting the CCR5/CCL4 interaction may offer a more effective therapeutic approach for managing the progression of LC.

#6799 The impact of targeting TRAF2 and NCK-interacting protein kinase on anti-tumor effect and tumor immune environment in cMYC-high small cell lung cancer.

A. Tanimoto, K. Ramkumar, A. Stewart, B. Zhang, R. Cardnell, S. Li, Q. Wang, J. Wang, C. Gay, L. A. Byers;
The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Small cell lung cancer (SCLC) is a highly lethal malignancy with rapidly acquired chemotherapy resistance. While the inflamed SCLC subtype is associated with a significantly improved response to immunotherapy, the non-inflamed SCLC subtypes, encompassing most SCLC patients, experience only modest survival gains with chemo-immunotherapy. Wnt signaling pathway activation is associated with resistance to chemotherapy and an immune checkpoint inhibitor in several tumors. TRAF2 and NCK-interacting protein kinase (TNIK), which interacts with downstream effectors, TCF4/β-catenin transcriptional complex, is an essential activator of Wnt target genes. TNIK is highly expressed in several cancers, but the efficacy of TNIK inhibition in SCLC has not previously been researched. We previously demonstrated that single agent TNIK inhibitors are effective in a subset of SCLC. Here, we hypothesize that targeting TNIK will show an anti-tumor effect based on specific biomarkers and also modify the tumor immune environment in SCLC.

Methods: We evaluated susceptibility to a small molecule TNIK inhibitor, NCB-0846, in 29 human-derived SCLC cell lines using 96-hour proliferation assays. To investigate efficacy biomarkers, we correlated NCB-0846 IC50 values with proteomic expression (profiled using reverse phase protein array). cMYC and FOXK1 expression was reduced by siRNA. Chemokine concentrations were determined by ELISA.

Results: SCLC cell lines with high cMYC levels, were more sensitive to the TNIK inhibitor, NCB-0846 (F.C.=-2.07, p=0.01), while SCLC cell lines with high expression of TTF-1 were more resistant (F.C.=2.48, p<0.01). Knockdown of cMYC conferred resistance to NCB-0846 in cMYC-high cells, while NCB-0846 treatment resulted in decreased cMYC expression in a concentration-dependent manner. Additionally, NCB-0846 treatment decreased the immunosuppressive chemokine CCL2 levels in the supernatant of human-derived SCLC cell lines and GEMM-derived cell lines. The expression of FOXK1, a transcription factor of CCL2, was also reduced in cell lines treated with NCB-0846.

Conclusions: These findings show that TNIK inhibition is more effective in cMYC-high SCLC, acting through downregulating cMYC levels. TNIK inhibition also decreases the production of CCL2, an immunosuppressive chemokine implicated in resistance to anti-PD-L1 immunotherapy. Together, these findings highlight the promising potential of TNIK inhibitors in cMYC-high SCLC. Additionally, suppressing CCL2 by TNIK inhibition supports the rationale for combining the TNIK inhibitor and an anti-PD-L1 antibody in the non-inflamed SCLC subtypes.

#6800 The tumor progression mechanism of increasing CXCL16-CXCR6 pathway within the tumor microenvironment in TNBC.

Y. Lee, C. Lee, S. Ha, S. Lee, J. Yang, Y. Kim, S. Kim, S. Kim;
Cellus, Seoul, Korea, Republic of

Background: Triple negative breast cancer (TNBC) is characterized rapid progression, higher relapse, and poor prognosis, so the establishment of an effective therapeutic target is required. CXCL16, a chemokine abundantly present in the TNBC tumor microenvironment (TME), is secreted by tumor-associated macrophages (TAM) and is known to promote tumor growth and metastasis. However, the exact mechanism through which CXCL16 facilitates tumor growth and metastasis remains unclear. This study aims to study the role of CXCL16 in the tumor progression and confirm the anti-tumor effects of CXCL16 neutralization in TNBC model.

Method: MDA-MB-231 human TNBC cell lines were utilized for in vitro validation, and a syngeneic model involving 4T1 mouse TNBC cell lines and Balb/c mice was used for in vivo studies.

Results: Stimulation of TNBC cells with recombinant human CXCL16 protein (rhCXCL16) activates the tumor growth signaling pathways, including pAKT and STAT3, as well as EMT markers. These results shows that CXCL16 can promote tumor growth and metastasis. Treatment with CXCL16 neutralizing antibodies inhibited the promotion of cancer growth and metastasis by rhCXCL16. Additionally, combination treatment of CXCL16 antibodies with PD-1 antibodies in the 4T1 syngeneic model increased the proportion of $CD8^{+}$ T cells and $CD80^{+}$ M1 like macrophages. These results shows that neutralization of CXCL16 can regulate polarization of macrophage and proportion of T cells. These regulation and changes of immune cells allow neutralization of CXCL16 control the TME to resist tumor cells, suggesting that optimal condition can be constructed to maximize the effectiveness of anti-cancer drugs.

Conclusion: This study confirms that the CXCL16-CXCR6 pathway within the TME triggers tumor growth and metastasis, while neutralization of CXCL16 can inhibit tumor progression. This effect is attributed to the increase in $CD8^{+}$ T cell and M1 macrophage proportions within the TME. In conclusion, these research findings propose the potential of CXCL16 as a novel biomarker and therapeutic target for TNBC.

#6801 Cellular senescence involves spatial evolution in colorectal cancer.

T. Park, S. Kang, J. Kim, H. Lee, Y. Choi, S. Park, Y.-K. Lee;
Ajou University School of Medicine, Suwon, Korea, Republic of

Cancer evolution is a continuous process involving cellular changes that promote progression and metastasis. Recent studies demonstrate that cancer evolution is spatially associated: a phenomenon called “the spatial evolution of cancer.” In our data, colorectal cancer cells gradually evolve from an adenoid to a collective invasion morphology, ultimately developing a partial epithelial-mesenchymal transition phenotype as they form an invasive front. Trajectory analysis showed that cancer cells at the invasive front of a tumor exhibit a totally different gene expression pattern from those at the center, and that cellular senescence plays a crucial role in this transition. Epigenetic changes in the promoter/exon1 region of the *CDKN2A* gene caused by increased reactive oxygen species level are crucial for expression of $p16^{INK4A}$ and induction of senescence in the cancer cells. Two types of senescent tumor cells (type I and type II) were observed, and they played different roles in cancer progression due to different gene expression. Type II senescent tumor cells ($p16^{INK4A+}$/$LAMC2^{\pm}$/$MMP7^{\pm}$), a final evolved form of cancer cells, are strongly associated with local invasion and lymph node metastasis of colorectal cancer and worsen the prognosis for patients.

#6802 CXCR4 transgene improves in vivo migration and efficacy of engineered iPSC-derived natural killer cells.

H. J. Millar, D. Walker, L. R. Campion, C. Budd, A. Kolluri, H. Sharma, B. Gurung, J. M. Carton, D. J. Perry, N. Alexander, H. Levitsky, M. Naso, B. A. Morse; Century Therapeutics LLC, Philadelphia, PA

Chimeric antigen receptor (CAR)-engineered induced pluripotent stem cell (iPSC)-derived natural killer (iNK) cells have shown a favorable safety profile and early evidence of clinical efficacy in the treatment of patients with certain hematologic malignancies. CAR-iNK cells retain phenotypic and functional similarities to primary natural killer cells, with additional capabilities for recognition of tumors. For the treatment of cancers that are located in the bone marrow, it is critical that iNK cells are able to migrate efficiently to relevant sites of disease. CXCR4 (C-X-C chemokine receptor type 4) is a chemokine receptor specific for stromal-derived-factor-1 (SDF-1), and mediates the migration of hematopoietic cells to the bone marrow upon binding SDF-1. Here we describe novel engineering of iPSCs resulting in efficient migration and efficacy of iNK cells. iPSC were sequentially engineered at defined loci with Crispr/MAD7/HDR to incorporate Allo-Evasion^{TM} edits, a CAR targeting antigens expressed on different hematological malignancies, constitutive interleukin-15 (IL-15) cytokine support, with and without wild-type CXCR4. iPSCs were then differentiated into natural killer cells using a proprietary differentiation process. Cytolysis of a panel of target cells by iNK was evaluated using an Incucyte-based killing assay. Anti-tumor efficacy was tested in disseminated xenograft models of hematological malignancies following intravenous injection of engineered iNK cells. Additionally, in vivo migration was evaluated using immunohistochemistry (IHC) and flow cytometry (FACS) of blood, bone marrow, and other organs. Engineering with CXCR4 resulted in a bulk population of iNK with a heterogenous expression of CXCR4. No significant impact of CXCR4 engineering was detected on iPSC differentiation, phenotype, or iNK yield. iNK^{CXCR4+} and iNK^{CXCR4-} cells had equivalent target tumor cell cytolysis in vitro, indicating the CXCR4 transgene does not affect killing potential. In vivo, iNK^{CXCR4+} cells migrated to the bone marrow of both tumor-bearing and non-tumor-bearing animals, and the presence of these cells was enhanced in tumor-bearing mice, indicating CXCR4-mediated migration and possibly CAR-mediated expansion and/or retention of iNK. Migration to the bone marrow was not observed with iNK^{CXCR4-} cells. As a result, iNK^{CXCR4+} cells significantly impacted anti-tumor efficacy, effectively eliminating bone disease. We have demonstrated the CAR-specific killing and enhanced iNK migration and subsequent tumor killing in the bone marrow, with the addition of a CXCR4 transgene in iPSC-derived NK cells. The addition of the CXCR4 transgene in iPSC-derived effector cells may allow for a higher therapeutic response in axial-skeletal located tumors.

#6803 TRIM16 regulates IL-6 secretion in head and neck cancer-associated fibroblasts.

T. Ly[1], B. Pickard[1], A. Pandey[1], N. Martinez-Rivera[2], E. Rosa-Molinar[2], M. Washburn[1], W.-X. Ding[1], S. M. Thomas[1];
[1]University of Kansas Medical Center, Kansas City, KS, [2]University of Kansas, Lawrence, KS

Despite current therapy, head and neck squamous cell carcinoma (HNSCC), the 7th most common cancer worldwide, is associated with high morbidity and mortality. Response to current therapies could be improved with a better understanding of the tumor microenvironment of HNSCC. We previously reported that cancer-associated fibroblasts (CAFs), the most abundant stromal cell type in the HNSCC microenvironment, have elevated levels of basal autophagy than oral fibroblasts from cancer-free subjects (NF). Disrupting autophagy in CAFs with Beclin-1 siRNA reduced secretion of IL-6, IL-8, and other factors known to promote HNSCC progression. The recent emerging role of autophagy in secretion of tumor promoting factors has high impact because (i) the mechanism can provide a new target to block the secretion of protumor factors from CAFs that contribute to HNSCC progression, and (ii) these cytokines can serve as potential indicators for the efficacy of autophagy-targeted therapies. To this end, we carried out an unbiased assessment of the proteins associated with autophagosomes in primary CAFs from HNSCC samples using mass spectrometry. We performed immunoprecipitation of LC3B from the isolated small vesicles of the CAFs, identified and validated the association of several trafficking proteins in secretory autophagy including VAMP3 and SNAP23. Further, the tripartite motif (TRIM) proteins have been shown to mediate the fate of autophagosomes either for degradation or secretion. We hypothesized that TRIM proteins are involved in transport of secretory autophagosomes. Our data demonstrate CAFs express higher levels of TRIM16 mRNA than NF. We demonstrate immunogold labeling of TRIM16 or IL-6 localized to the autophagosomes using transmission electron microscopy. Further, using immunofluorescence, we demonstrated the colocalization of TRIM16 and IL-6, as well as IL-6 and LC3B in cytoplasmic puncta. In addition, we used proximity ligation assays to confirm the interaction of TRIM16 and IL-6, as well as IL-6 and LC3B. TRIM16 knockdown using siRNA in CAFs reduced the secretion of IL-6 as measured by ELISA. In conclusion, we demonstrate an important role of TRIM16 in secretory autophagy making it a potential therapeutic target to mitigate CAF-mediated HNSCC growth.

#6804 High IL12family levels are associated with pathologic complete response amongst HER2- patients in the neoadjuvant I-SPY2 TRIAL.

Kingsley V. Chow[1], Silver Al Khafaji[1], Denise Wolf[1], Christina Yau[1], Kailey Dubinsky[1], Elene Tsopurashvili[1], Kirthiga Ramalingam[1], Fluorentine van Nouhuijs[1], Zheyun Xun[1], Anna van Montfort[1], Diane Heditsian[2], Douglas Yee[3], Laura Esserman[1], Michael Campbell[1], Laura van't Veer[1], Rosalyn W. Sayaman[1]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]Breast Science Advocacy Core, UCSF - University of California San Francisco, San Francisco, CA,[3]University of Minnesota, Minneapolis, Minneapolis, MN

Background: Immune contexture of the tumor microenvironment (TME) is associated with response to therapy. We hypothesize that expression of interleukin (IL) family of cytokines which plays essential roles in the activation and differentiation of immune cells, shapes the landscape of therapeutic response in breast cancers. We leverage published gene expression, molecular and clinical data from the I-SPY2 Trial (PMID35623341) - a neoadjuvant trial for locally advanced breast cancers. We explored the contribution of expression-based signatures of IL signaling at pre-treatment in relation to pathological complete response (pCR).

Methods: We curated 32 IL gene sets from literature. Signatures scores characterizing IL signaling were calculated from gene expression profiles of pre-treatment tumor samples from 987 I-SPY2 patients in the first 10 treatment arms of the trial. Association of IL signatures with pCR in HR/HER2 receptor subtypes, and the five I-SPY response-predictive subtypes (RPS) were evaluated using non-parametric tests. Significance levels were defined at adj. $p < 0.05$. Correlations of IL signatures with multiplex immunofluorescence staining of immune infiltrates in the PD1-inhibitor (PD1i) arm were also assessed.

Results: High expression of IL signatures in HER2- patients, regardless of HR status, was associated with pCR especially in the Trebananib, Veliparib/Carboplatin (VC) and PD1i arms. In the PD1i arm, expression of almost all IL signatures was highly correlated with density of T, CD8+ cytotoxic T, CD8- T, and B cells and their colocalization with tumor cells; IL-6 signatures correlated with density of proliferating tumor cells.Within RPS subtypes, enrichment of IL signatures in HER2-/Immune+ such as pro-inflammatory IL-1 and IL-12 signaling was associated with pCR in the VC, PD1i, Ganetespib, and control arms. Furthermore, we identified an IL-12 signature in the HER2-/Immune-/DRD- subtype associated with pCR, with responders characterized by high IL-12 family signaling (Fisher adj. $p < 0.05$). IL-12 family signaling was positively associated with CD8+ cytotoxic T, Th1 and B cell enrichment, IFN-γ signaling, and inflammatory response overall and in HER2- breast cancers.

Conclusion: High pre-treatment expression of IL signatures was associated with HER2- receptor and RPS HER2-/Immune+ subtype-specific response to I-SPY2 agents, and the colocalization of immune and tumor cells in the tumor bed. In HER2- breast cancers, high levels of IL-12 family signaling were associated with response to therapy and enrichment of known IL-12-related pathways that stimulate effective anti-cancer response including CD8+ T cell expansion, Th1 cell differentiation, B cell activation, IFN-γ secretion, and inflammatory response. These findings suggest that IL signaling may serve as a valuable predictive biomarker in this patient population.

#6805 CD81 and CD82 in tumor infiltrating lymphocytes within the NSCLC tumor microenvironment play a crucial role in T cell activation and cytokine production.

K. Na[1], S. Lee[1], D. Kim[1], Y. Kim[1], J. Hwang[1], S.-s. Kang[2], S. Baek[1], C. Lee[1], S. Yang[1], Y. Han[1], M. Kim[1], H. Han[1], Y. Kim[1], J. Kim[1], S. Jeon[1], Y. Byeon[1], J. Lee[1], S. Lim[1], M. Hong[1], K.-H. Pyo[1], B. Cho[1];

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]JEUK Co., Ltd., Seoul, Korea, Republic of

Background: The role of tetraspanins, particularly CD81 and CD82, in T cell activation, shedding light on their contribution to anti-tumor effects in the tumor microenvironment. The findings provide insights for potential applications of these tetraspanins in immunotherapy.

Method: The study employed 10x Genomics for single-cell RNA sequencing and processed the data using Seurat. It focused on the tumor microenvironment, categorizing cell types, especially TIL subsets. T cells were sorted based on CD81 and CD82 expression and activated, and their activation markers and cytokine production were analyzed. Bulk RNA sequencing was performed on both sorted T cells and tumor samples, and the TCR repertoire was examined. Cytotoxicity of CD81 and CD82 transduced cells was measured using the xCELLigence RTCA HT system.

Result: Tetraspanins have been linked to T cell co-stimulation and activation, with CD81 and CD82 playing a significant role in TCR signaling and activation. Single-cell and bulk RNA sequencing data from lung cancer patients reveal high expression of CD81 and CD82 in the tumor microenvironment, especially in T cells, correlating with T cell activation and cytokine production. In vitro experiments confirm the activation and effector cytokines, especially IFN-γ, TNF-α, and IL-2, producing potential of T cells expressing CD81 and CD82, suggesting their importance in anti-cancer immunity. Overexpression of CD81 and CD82 enhances T cell cytotoxicity against cancer cells, further supporting their role in T cell function. Despite some limitations, these findings shed light on the significant impact of tetraspanins in modulating immune responses, particularly in the context of cancer immunotherapy.

Conclusion: We report that CD81 and CD82 serve as specific markers for activated T cells within the TME. CD81 and CD82 are correlated with the activation and regulation of T cells, and they may also mediate the regulation of relevant cytokines. Overall, our findings provide better insights into the molecular mechanisms regulating TILs present in the TME of non-small cell carcinoma and propose CD81 and CD82 as associated markers. These discoveries could serve as a foundation for the development of new immunotherapies targeting the TME.

#6806 Single cell RNA sequencing of human and murine cancers demonstrates metastases-specific neutrophil phenotypes driven by the IL-1β/CXCR2 signaling axis - Disruption of this pathway abrogates neutrophil immunosuppressive effects and reduces tumor burden.

A. S. McLaren, R. Fetit, M. White, M. L. Mills, T. Lannagan, J. Falconer, X. Cortes-Lavaud, K. Gilroy, R. Ridgway, C. Nixon, V. Naiker, R. Njunge, C. J. Clarke, D. Whyte, K. Kirschner, R. Jackstadt, J. C. Norman, L. M. Carlin, A. D. Campbell, O. J. Sansom, C. W. Steele;
CRUK Scotland Institute, Glasgow, United Kingdom

Introduction: Neutrophils are a highly heterogenous, plastic cell population, known to play a vital role in the tumor microenvironment and progression of CMS4 colorectal cancer (CRC) metastases. We have performed a comprehensive examination of different neutrophil transcriptional states, through utilization of single-cell RNA sequencing of publicly available and independently generated data across health and malignancy in human and murine disease, and validated findings using in vivo and in vitro models of CMS4 subtype CRC.

Methods: Publicly available and independently generated breast, lung and CRC datasets from human disease mouse models were integrated to establish and validate reproducibility of neutrophil-gene signatures, and pseudo-time analysis was used to identify genes driving neutrophil development along a lineage from health to tumor using Seurat on R. Findings were validated in healthy and *Kras*$^{G12D/+}$, *Trp53*$^{fl/fl}$, *Rosa*$^{26N1CD/+}$ (KPN) tumor-bearing wild type or Mrp8CreCxcr2$^{fl/fl}$ genetically engineered mouse models with neutrophil-specific loss of Cxcr2.

Results: We have identified distinct neutrophil subtypes in health and primary tumors, preserved in murine and human cancer and across multiple tumor types. In CRC metastases, discrete neutrophil transcriptomic subtypes are identified, with phenotypes from health to those identified in metastases driven by the IL-1β/CXCL8/CXCR2 signalling axis. Assessment of global signalling of single-cell transcripts has identified CD4+ T cells and macrophages as dominant regulators of the metastatic niche. Neutrophils sorted from the metastatic niche strongly suppress T cell proliferation, identifying them as immunosuppressive. Loss of neutrophil-specific Cxcr2 attenuates suppression of T cell proliferation in co-culture with neutrophils from the metastatic niche of tumor-bearing mice. T cell proliferation is unaffected in co-culture with healthy wild type or Cxcr2$^{fl/fl}$ neutrophils. We currently are running orthotopic intrasplenic models to assess the importance of loss of neutrophil-specific Cxcr2 in generation of metastases *in vivo* in CMS4 CRC.

Conclusions: We speculate that ablation of metastasis specific neutrophil subsets in CMS4 CRC in combination with other therapies, may alter the immunosuppressive nature of the immune microenvironment and allow for reduction in tumor burden in metastatic disease.

#6807 Cancer suppressive mechanism of IL-6 secreted by cancer-related fibroblasts in biliary tract cancer.

K. Kimura, R. Tanaka, S. Eguchi, K. Hatta, M. Kinoshita, J. Tauchi, H. Shinkawa, K. Nishio, G. Ohira, T. Ishizawa;
Osaka Metropolitan University, Osaka, Japan

Background and aims: Cancer-associated fibroblasts (CAFs) are a major component of the tumor microenvironment and can exhibit cancer-promoting functions; however, recent studies indicate that CAFs can also inhibit cancer growth and progression. In this study, we identified CAFs that act in an inhibitory manner in biliary tract cancer and elucidated their mechanisms.
Methods: Three biliary tract cancer cell lines and CAFs isolated from resected specimens from four types of biliary tract cancer were used to evaluate the proliferative potential of cancer cells. Potential suppressors that inhibited the growth of cancer cells were identified using protein arrays from CAFs. We determined the effects of these suppressors on cancer cells.
Results: Among the biliary tract cancer CAFs, we identified CAFs that inhibited cancer growth. Protein arrays of conditioned medium from CAFs revealed that Interleukin-6 (IL-6) was one such growth inhibitor. Treatment of biliary tract cancer cell lines with IL-6 significantly reduced their proliferative potential. SOCS3 expression levels increased and STAT3 expression level decreased, suggesting that SOCS3, a downstream signal of IL-6, may be involved.
Conclusion: Inhibitory CAFs are present among biliary tract cancer CAFs and IL-6 production by CAFs may inhibit the growth of biliary tract cancer cells.

#6808 Investigating the role of CXCR3+ monocytes on CAR T cell function.

C. Ong[1], S. Kaczanowska[2], W. Ju[2], J. Cronk[2], S. Ramakrishna[3], R. Kaplan[2];
[1]Kirk Kerkorian School of Medicine at UNLV, Las Vegas, NV, [2]National Cancer Institute, Bethesda, MD, [3]Stanford Cancer Institute, Palo Alto, CA

Chimeric antigen receptor T cells (CAR-Ts) are an emerging immunotherapy that have remarkable efficacy against leukemias and lymphomas but limited success against solid tumors. We conducted a phase I clinical trial (NCT 02107963) of GD2 CAR-T (GD2-CAR.OX40.28.z.ICD9) administration to children and young adults with neuroblastoma and, for the first time, osteosarcoma. While all patients progressed and were switched to alternative therapy, we observed a significant association between good CAR-T expanders and expression of C-X-C Motif Chemokine receptor 3 (CXCR3) on monocytes detected in pretreatment apheresis. This study seeks to uncover the possible interactions between CXCR3 and CAR-Ts that may alter CAR-T function and ultimately lead to better CAR-T expansion. We hypothesize that CXCR3+ monocytes induce functional change in CAR-Ts resulting in improved expansion.

To recapitulate the interaction between tumor, CAR-Ts and monocytes, we took 143Bs (osteosarcoma cell line) and GD2 CAR-Ts and co cultured them with THP-1s (a monocytic leukemia cell line) that were either untransduced (UTD) or transduced via lentivirus to express CXCR3 (CXCR3+). The ratio of UTD or CXCR3+ THP-1s to CAR-Ts and 143Bs was varied between co cultures. Enzyme-linked immunoassay (ELISA) for interferon gamma (IFNγ) expression was run as a proxy measurement for CAR-T cell activity. Flow cytometry was used to assess for expression of activation and exhaustion markers. Differences between UTD and CXCR3+ co cultures were evaluated for statistical significance via unpaired t-test.

We observed that CXCR3 was elevated on GD2 CAR-Ts co cultured with CXCR3+ monocytes. This pattern was seen most prominently in CD4+ CAR-Ts, but also subtly in CD8+ T-cells. Exhaustion markers CD39 and LAG3 were elevated in CAR-Ts co cultured with CXCR3+ monocytes. Additionally, CAR-Ts co cultured with CXCR3+ monocytes displayed greater activity via elevated IFNγ expression.

We conclude that GD-2 CAR-T cells co cultured with CXCR3+ monocytes express elevated exhaustion markers due to possible increased activity when in the presence of CXCR3+ monocytes. Additionally, we suspect that elevated CXCR3 expression on CAR-Ts co cultured with CXCR3+ monocytes may be helping CAR-Ts better target tumor cells, thus leading to improved expansion. If CXCR3 can improve CAR-T cell function, this could lead to better optimization of CAR-Ts against solid tumors and create a viable treatment option for neuroblastoma and osteosarcoma patients.

#6809 Tumor-associated macrophages promote bladder cancer cell migration and invasion through activation of CCL20-CCR6 axis.

R. Nakagawa, I. Kouji, R. Toriumi, S. Aoyama, T. Kamjima, H. Kano, T. Makino, R. Naito, H. Yaegashi, T. Nohara, H. Nakata, A. Mizokami; Kanazawa University, Kanazawa, Japan

We focused on Tumor-Associated Macrophages (TAM) and explored its effects on bladder cancer (BC). Co-culturing PMA-treated THP-1 with BC cell lines (UMUC3 and T24) induced THP-1 to develop suppressed CD68 and increased CD206 expression which differentiated into M2-like macrophages. Co-culture of BC with TAM of this M2-like macrophage enhanced the migration and invasive activities of BC, as well as the expression of EMT marker. Human cytokine antibody array of conditioned medium from the co-culture of BC and TAM showed high CCL20, CCL2 and CXCL7. qPCR revealed that these chemokines were mainly derived from TAMs, not BC. Only CCL20 enhanced the migration and invasion of BC and the expression of EMT markers when each of these three recombinant chemokines was administered to BC. Furthermore, inhibiting CCR6, a receptor specific for CCL20, suppressed migration and invasion as expected. In BC, TAMs promote progression and metastasis by secreting CCL20, and inhibition of CCR6 may be one potential therapeutic approach to suppress BC activity.

#6810 Macrophage secreted CCL9/CCL5 induces CCR1-mediated ovarian cancer metastasis to the omentum in the absence of CCL6.

Supreeti Tallapragada, Justine Chan, Venkatesh Krishnan, Oliver Dorigo

Department of Obstetrics and Gynaecology, Stanford University, Stanford, CA

The tumor-microenvironment (TME) of the omentum plays an important role in providing a pre-metastatic niche for high-grade serous ovarian cancer (HGSC-OvCa) progression. Omentum, a layer of fatty adipose tissue within the peritoneal cavity, is the preferred primary metastatic site for OvCa. Omentum is a well-vascularized fatty tissue containing wide-spread immune clusters (milky spots). Milky spots in the omentum are primarily composed of B cells, T cells, macrophages, NK cells, and dendritic cells. Previous studies from our laboratory have highlighted the importance of CCL6 secreted by omental macrophages as a key chemokine in providing a pre-metastatic niche by activating the CCR1 axis on the cancer cells required for OvCa invasion. We engineered and characterized a CCL6-depleted *in vivo* mouse model using CRISPR/Cas9 to study the effect on OvCa progression and macrophage biology. We demonstrate that deletion of CCL6 in mice alters characteristics of omental tissue-resident (OM-Macφ) and bone marrow-derived macrophages (BMDM) derived from circulating monocytes. RNA sequencing of OM-Macφ and microarray study of BMDM revealed that CCL6 deletion produces enhanced TGFβ1$^{\pm}$CSF-1$^{\pm}$CCL5$^{\pm}$ expression in OM-Macφ and an increase in TGFβ1$^{\pm}$CSF-1$^{\pm}$CCL9$^{\pm}$ in BMDM. This acts as a rescue mechanism to maintain activation of their shared CCR1 receptor with a pro-M2 stimulation profile. Deep multiplexed imaging of the omentum tissue by CODEX showed that CCL6 deletion alters the architecture of milky spots, with enriched macrophage content and reduced B-cell and T-cell-rich neighborhoods. While our previous studies indicated that CCL6 deletion could potentially have an anti-tumoral effect, we found that it does not significantly affect murine ID8 ovarian cancer tumor burden in both short-term (7 days) and long-term *in vivo* studies and provides no added survival advantage. We report that CCL9$^{\pm}$F4/80$^{\pm}$ macrophages accumulate in the omentum post-tumor infiltration in the CCL6-KO model, and neutralizing CCL9 in the CCL6-KO BMDM macrophage-derived conditioned media significantly reduces migration of ID8 cancer cells *in vitro*. Furthermore, we demonstrate that murine CCL9 and its analog, human CCL15, promote the epithelial-mesenchymal transition (EMT) of mouse ID8 and human A2780 OvCa cells. Moreover, our findings indicate that human CCL15 is a prognostic biomarker for reduced survival in OvCa patient cohorts (Stages I&II and Stage III&IV). Further classification of HGSC-OV patients (n=375) from TCGA-OV based on CCL15 and CCR1-high expression correlated with a higher expression of TGFβ1, CCL5, and a T-cell exhaustion signature in the TME. Taken together, given the apparent redundancy of the chemokine network controlling CCR1 signaling, our findings support the strategy of therapeutically blocking the CCR1 receptor to potentially produce a favorable anti-tumor response in HGSC-OvCa patients.

#6811 IL-9 enhances lung tumor growth through intrinsic and ARG1-dependent transcriptomic changes in interstitial macrophages.

A. Cannon, M. H. Kaplan;
Indiana University School of Medicine, Indianapolis, IN

A defining characteristic of cancer is its ability to evade detection by immune cells through the generation of a myeloid cell-dependent immunosuppressive tumor microenvironment. Arginine is utilized by Arginase 1 (ARG1) or nitric oxide synthase in tumor-associated macrophages to respectively elicit pro-tumor or anti-tumor activity. The balance between these enzymes is regulated by extracellular cytokines including Interleukin 9 (IL-9), a pleiotropic cytokine that can be a positive or negative regulator of tumor growth. Our lab identified that IL-9 promotes tumor development in the lung by expanding interstitial macrophage populations and inducing ARG1. Lung tumor growth is attenuated in mice with myeloid cell deficiency of Arg1. Similarly, macrophage-targeting nanoparticles containing *Arg1* siRNA can therapeutically reduce tumor burden and alter macrophage populations in the lung toward an immunostimulatory phenotype. However, an understanding of the mechanism by which IL-9R/ARG1+ interstitial macrophages drive tumor progression remains incomplete. Here, using a B16F10 lung metastasis model in mixed-bone marrow chimeric mice, we demonstrate that IL-9-responsive interstitial macrophages are intrinsically altered at the transcriptomic level toward an ARG1-dependent immunosuppressive phenotype. Furthermore, our research shows that the absence of IL-9 signaling or ARG1 expression in macrophages has a notable impact on the levels of arginine and its metabolites in the lung tissue and bronchoalveolar lavage fluid of tumor-bearing mice. These alterations subsequently lead to an enhanced anti-tumoral immune response, reflected by changes in Interferon-gamma expression in both lung macrophages and T cells. Thus, our work suggests that the IL-9R/ARG1/interstitial macrophage axis promotes lung tumor development by altering intrinsic arginine metabolism and reprogramming immune cell populations toward an immunosuppressive phenotype.

#6812 Durable control of brain tumors by glioma inhibitory macrophages and IL33.

S. V. Menon[1], X. Lun[2], P. Zeng[1], J. Zhang[1], B. Ahn[2], H. Yu[1], A. Poole[2], N. Dang[2], K. Osz[2], J. A. Chan[2], D. F. Quail[3], S. M. Robbins[1], D. L. Senger[1];
[1]Lady Davis Institute at the Jewish General Hospital, Montreal, QC, Canada, [2]Arnie Charbonneau Cancer Institute, Calgary, AB, Canada, [3]Rosalind and Morris Goodman Cancer Institute, Montreal, QC, Canada

Glioblastoma is the most common and deadly form of brain cancer. Even with aggressive treatment including surgery, chemotherapy, and radiotherapy, survival outcomes for newly diagnosed glioblastoma patients remains less than two years. Novel high throughput omics technologies have expanded our understanding of the role of innate immune system in brain tumors, that are generally believed to drive glioma progression and enable evasion of the adaptive immune system. However, targeting of this axis in the clinic remains an unmet opportunity. Previously, we discovered that the dual-function (secreted and nuclear) cytokine IL-33 is a crucial regulator of the inflammatory microenvironment that promotes glioma tumorigenesis through phenotypic and functional changes in the innate immune cell repertoire. Strikingly, when IL-33 is prevented from entering the nucleus, by deletion of its nuclear localization sequence (ΔNLS IL-33), but is still secreted, *in vivo* tumor growth is dramatically inhibited resulting in prolonged long-term survival. Using multiplex immunohistochemistry and spatial transcriptomics with temporal resolution across different stages of tumor progression, we identified a population of glioma-inhibitory macrophages (GIMs) unique to this suppressive environment. Assessment of GIMs in xenografts generated from patient brain tumor initiating cells found an enriched presence of these cells in xenografts with long-term survival (greater than 300 days) versus short-term survival (less than 100 days). The ability of GIMs to inhibit glioma progression was demonstrated when tumors established using a combination of ΔNLS IL-33 expressing cancer cells together with highly tumorigenic cells resulted in a growth inhibitory environment that significantly extended survival. A deeper molecular characterization of this phenotype and development of clinical strategies are currently underway.

#6813 Immunosuppressive monocytes suppress CART19 functions through modulation of the IL-1 pathway.

K. Yun, R. Sakemura, T. Huynh, C. Manriquez Roman, O. Sirpilla, C. Stewart, J. Girsch, E. Ogbodo, I. Can, J. Feigin, L. Mai, H. Xia, B. Kimball, M. Rodriguez, L. Kankeu Fonkoua, M. Hefazi, M. Ruff, E. Siegler, S. Kenderian;
Mayo Clinic, Rochester, MN

CD19-directed chimeric antigen receptor T (CART19) cell therapy has shown remarkable outcomes in B cell malignancies and was FDA approved in multiple indications, but durable remissions are limited to ~40%. Inhibitory myeloid cells in the tumor microenvironment have been found to suppress T cell expansion and contribute to CART19 failure. Here, we studied interactions between monocytes, CART19, and tumor cells to understand the impact of monocytes on CART19 effector functions. First, CD28-costimulated CART19 (CART19-28ζ) generated in the lab from healthy donors were cocultured with JeKo-1, a $CD19^{\pm}$ mantle cell lymphoma cell line, and freshly isolated monocytes or *ex vivo* differentiated M2-like macrophages. M2-like macrophages were generated by incubating fresh monocytes with rhGM-CSF followed by coculturing with JeKo-1. CART19 antigen-specific proliferation was significantly inhibited by M2-like macrophages but not fresh monocytes (*JeKo-1+CART19 vs JeKo-1+M2+CART19, p=0.00503*). Transwell assays indicated that suppression from M2-like macrophages was not contact-dependent. IL-1 receptor antagonist (IL-1ra) was significantly elevated in M2-like macrophage coculture supernatant (*JeKo-1+Mono+CART19 vs JeKo-1+M2+CART19, p=0.0292*) and intracellularly in M2-like macrophages after coculture (*90%+)*. We therefore hypothesized that M2-like macrophages inhibit CART19 by secreting IL-1ra, which blocks IL-1 signaling in CART19. We interrogated the role of IL-1ra in CART19. JeKo-1 was cocultured with CART19, supplemented with rhIL-1β only, IL-1β + IL-1ra, or IL-1β +IL-1ra + IL-1ra neutralizing antibody (neuAb). CART19 antigen-specific proliferation was improved by IL-1β (*PBS vs IL-1β, p<0.0001*). IL-1ra inhibited IL-1β-dependent CART19 proliferation (*IL-1β vs IL-1β+IL1ra p=0.0006*), which was restored by IL-1ra neutralization (*IL-1β+IL-1ra vs IL-1β+IL-1ra+IL-1ra neuAb, p=0.0215*). Additionally, expression of IL-1RI, the receptor of IL-1β and IL-1ra, was measured on T cells after coculturing CART19, JeKo-1, and M2-like macrophages. M2-like macrophages downregulated IL-1RI expression on CART cells, which is a potential mechanism of blocking CART response to IL-1β, resulting in further suppression of CART proliferation (*JeKo-1+M2+CART19 vs JeKo-1+CART19, p=0.001*). Next, we assessed the impact of IL-1ra on CART cell functions in the presence of M2-like macrophage in a mantle cell lymphoma xenograft model. NOD-SCID-$\gamma^{-/-}$ (NSG) mice were subcutaneously injected with human macrophages and $luciferase^{\pm}$ JeKo-1 cells. Upon tumor engraftment by bioluminescent imaging, mice were randomized to treatment with CART19 + IL-1ra neuAb or control IgG for 3 weeks. CART19 + IL-1ra neuAb led to improved antitumor activity (*IL-1ra neuAb vs control IgG, p=0.0033*). Overall, our study revealed a role of IL-1ra in macrophage-induced CART inhibition mediated by blocking IL-1β signaling through IL-1RI.

#6814 E2F1-induced autocrine IL-6 inflammatory loop mediates cancer-immune cell crosstalk that regulates metastatic properties in melanoma.

P. Dhar[1], K. P. Singh[2], S. K. Gupta[2], D. Peringot[1], A. Spitschak[1], **B. M. Putzer**[1];
[1]Rostock University Medical Center, Rostock, Germany, [2]University of Rostock, Rostock, Germany

Melanoma is a cancer that is metastatic, drug-refractory and fatal if managed late or inadequately. The transcription factor E2F1 is a key player in melanoma pathology, promoting metastatic traits like EMT, neoangiogenesis, chemoresistance and evasion of immune surveillance. Particularly, high levels of E2F1 trigger tumor progression by developing protein-protein interactions (PPI) with coregulators that enhance its potential to activate a prometastatic gene regulatory network (GRN). We aimed to investigate the extent to which E2F1-expressing melanoma cells influence the immune response.
Methods: We combined transcriptomic approaches with bioinformatics and structural modeling to search for target genes involved in E2F1-activated immunomodulatory and prometastatic GRNs in aggressive melanoma. Immunoprecipitation and ChIP were performed to verify both PPI and protein-DNA interactions. Functional analyses, including qRT-PCR, immunoblotting and luciferase assays, were performed to verify expression and regulation of downstream targets. Additionally, we established a melanoma-immune cell coculture system with patient-derived CD4+ and CD8+ T cells. Cytokine arrays and ELISA were used for measurement of cytokine secretion to analyze the E2F1-induced tumor-immuno-crosstalk.
Results: We identified an E2F1-dependent GRN with IL-6 as a central factor mediating EMT and immune regulation. Mechanistically, E2F1-induced activation and secretion of IL-6 leads to an autocrine inflammatory forward-feedback loop, which in turn further promotes invasiveness and EMT marker expression in melanoma cells. Interestingly, IL6 activated STAT3 associates with E2F1 in a structure-dependent manner, forming a complex that enhances IL-6 expression by binding to a composite E2F1:STAT3-responsive promoter element. Moreover, we observed that the E2F1-IL6 axis dispenses immunomodulatory effects on surrounding CD4+ and CD8+ T cells, further stimulating IL-6 release, but also leading to secretion of IL-10 into the TME. Although IL-10 has an immunosuppressive function, it also showed anti-metastatic properties in melanoma cells. Thus, in contrast to IL-6, IL-10 decreased cell motility and reduced the expression of Vim, Slug, and Snai1, while simultaneous knockdown of E2F1 increased these effects. The findings are supported by clinical data sets showing that melanoma patients who have high levels of *E2F1* and *IL-6* and low *IL-10* exhibit poor survival.
Conclusion: Our results unveil a novel gene regulatory program by which E2F1-associated IL-6 release induces the formation of an E2F1:STAT3 complex, resulting in a forward-feedback loop that promotes cancer invasion and regulates T cells response through intercellular cytokine signaling in the tumor microenvironment.

#6816 Prevention of cancer cachexia by inhibition of soluble epoxide hydrolase.

R. L. Bayer[1], S. Virani[1], M. Gillespie[1], J. Capuano[1], K. Smith[1], K. Quinlivan[1], K. Vasquez[1], J. Yang[2], H. Yang[2], N. Mitsiades[3], B. D. Hammock[3], D. Panigrahy[1]; [1]Center for Vascular Biology Research, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]College of Food Science and Nutritional Engineering, China Agricultural University, Beijing, China, [3]Department of Hematology and Oncology, and UCD Comprehensive Cancer Center, University of California, Davis, CA

Background: Cancer cachexia is a devastating syndrome characterized by progressive muscle wasting and hyperinflammation. The underlying mechanisms remain poorly understood with no treatment options available. Cachexia is driven by systemic inflammation, pro-inflammatory cytokines, and apoptotic cell death (debris). The resolution of inflammation as an active biochemical process is regulated by novel pro-resolving lipid mediators. Arachidonic acid-derived epoxyeicosatrienoic acids (EETs) are lipid mediators stimulating inflammation resolution. EETs are rapidly metabolized by the enzyme soluble epoxide hydrolase (sEH). sEH is a critical cause of inflammation and a biomarker in several chronic inflammatory diseases. sEH inhibitors promote tissue regeneration and counter-regulate pro-inflammatory cytokines. We hypothesized that pharmacological inhibition of the sEH may prevent cachexia.
Methods: We investigated murine cancer cachexia models using genetically engineered pancreatic (KPC) and prostate (TRAMP C1) tumor cell lines, and “TRAMP” mice (transgenic adenocarcinoma of the mouse prostate). We performed LC-MS/MS-based profiling of bioactive lipids in plasma from KPC and colon cancer (CT26)-induced cachectic mice.
Results: KPC cells injected intraperitoneally induced 19.7% and 54.1% reduction in muscle weight in the tibialis anterior and soleus, respectively, in immunocompetent C57BL/6 mice compared to non-tumor bearing (NTB) mice. LC-MS/MS revealed KPC and CT26 cachexia induced a pro-inflammatory eicosanoid-driven cytokine storm. The human sEH inhibitor EC5026 delayed the onset of cachexia, leading to sustained survival over 250 days post-injection in the KPC model (n=15 mice/group). sEH expression was increased in the gastrocnemius of KPC mice by day 22 post-tumor cell injection vs. NTB. EC5026 counter-regulated sEH expression compared to vehicle-treated. In the TRAMP model, 5/5 of mice treated with EC5026 survived 230 days post-treatment compared to no survival of vehicle-treated mice (n=5). The transplanted KPC and TRAMP showed reduced CD4+ and CD8+ T lymphocytes and B lymphocytes in the tibialis anterior and gastrocnemius vs. NTB after flow cytometry analysis. EC5026 stimulated a general increase in CD3+ T lymphocytes and counter-regulated an eicosanoid-driven cytokine storm as shown by cytokine assays. EC5026 treatment increased tibialis anterior and gastrocnemius muscle weights and body weights compared to vehicle-treated KPC and TRAMP mice.
Conclusions: sEH inhibition may be a novel therapeutic approach to cachexia by targeting the immune response via stimulation of resolution of inflammation without toxicity or immunosuppression. Since sEH inhibitors have proven safe and effective in clinical trials for controlling multiple inflammatory diseases, this study provides a basis for the rapid clinical translation of sEH inhibitors to prevent/reverse cachexia in cancer patients.

#6817 Control of breast cancer via pro-resolving mediators.

S. A. Virani[1], M. Gillespie[1], H. Yang[2], D. R. Bielenberg[3], M. W. Kieran[4], S. Huang[5], C. N. Serhan[6], D. Panigrahy[1];

[1]Department of Pathology and Center for Vascular Biology Research, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, [2]College of Food Science and Nutritional Engineering, China Agricultural University, Beijing, China, [3]Vascular Biology Program, Boston Children's Hospital, Boston, MA, [4]Division of Pediatric Oncology, Dana-Farber Cancer Institute, Harvard Medical School; Department of Pediatric Hematology/Oncology, Boston Children's Hospital, Harvard Medical School, Boston, MA, [5]Institute of Systems Biology, Seattle, WA, [6]Center for Experimental Therapeutics and Reperfusion Injury, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

Tumor recurrence is the principal cause of mortality in breast cancer, yet the underlying mechanisms are not well understood. Anti-estrogen therapy, including tamoxifen, reduces tumor burden by inducing apoptosis and necrosis of cancerous tissue. The resulting cellular debris may stimulate tumor growth by disrupting inflammation resolution and creating pro-inflammatory and pro-tumorigenic microenvironments. Compared to estrogen receptor (ER)-positive breast cancer, ER-negative behaves aggressively, and patients have a poor prognosis due to the lack of treatment options. Here, we demonstrate that breast tumor cells killed by cytotoxic anti-estrogen therapy or chemotherapy ("tumor cell debris") stimulate primary tumor growth when co-injected with a subthreshold (nontumorigenic) inoculum of tumor cells by triggering a macrophage-derived pro-inflammatory and pro-angiogenic "cytokine storm." Thus, tumor cell debris is a critical risk factor for aggressive breast cancer growth. To assess whether stimulating the clearance of debris would impact breast cancer progression *in vivo*, we utilized maresin 1 (MaR1), maresin conjugates in tissue regeneration (MCTR1, MCTR2) and protectin conjugates in tissue regeneration (PCTRs), which are specialized pro-resolving lipid autacoid mediators (SPMs). We treated established models of ER-positive (EO771) and negative (4T1) breast cancer. Each maresin sharply reduced tumor growth in debris-stimulated and spontaneous (e.g. MMTV-PyMT) breast cancer models at nanogram concentrations without toxicity. Notably, PCTR1 inhibited orthotopic triple-negative (4T1) growth and proliferation compared to chemotherapy (paclitaxel) or immunotherapy (anti-cytotoxic T-lymphocyte-associated protein 4, CTLA4). Similarly, PCTR1 alone or in combination with chemotherapy (paclitaxel) reduced gene expression and protein levels of pro-angiogenic factor CXCL12/SDF1 in the ER-negative (4T1) tumor microenvironment. In ER-positive (EO771), a triple combination of PCTR1, chemotherapy (paclitaxel), and immunotherapy (anti-CTLA4) treatment potentiated the immune checkpoint blockade. Maresins also stimulated macrophage phagocytosis of therapy-generated breast tumor cell debris, inhibited tumor angiogenesis, and dampened a therapy-induced cytokine storm, including TNF-α, MIP-2/CXCL2, CCL2/MCP-1, IL- 1ra/IL-1F3, and G-CSF. Expression of SPM receptors (e.g. resolvin D1 (RvD1) receptor ALX/FPR2, resolvin D2 (RvD2) receptor GPR18, maresin 1 (MaR1) receptor LGR6, and resolvin E1 (RvE1) receptor ChemR23) were specifically identified in breast cancer tissue. Taken together, the maresin and protectin pathway mediators may represent a new therapeutic approach to stimulate the resolution of inflammation in breast cancer.

#6818 Obesity-mediated perineural invasion promotes PDAC tumorigenesis.

S. S. Mayengbam, A. Alam, S. Senchanthisai, I. Bektas, P. Dey;
Roswell Park Comprehensive Cancer Center, Buffalo, NY

Obesity is a modifiable host factor that has been reported to increase the risk of pancreatic ductal adenocarcinoma (PDAC) by ~60% and the mortality by two-fold, however, the exact mechanisms by which obesity enhances PDAC aggressiveness is incompletely understood. Given that nearly 74% of U.S. adults are overweight or obese (US Center for Disease Control), resolving the complex association between obesity and PDAC may unveil new targets for prevention and/or intervention to decrease incidence and improve outcomes. The prevailing notion is that obesity-induced tumor *in situ* factors (i.e., oxidative, hypoxic, nutrient, and biochemical) play crucial roles in enhancing cancer cell fitness and survival. However, these concepts have yet to lead to the identification of any actionable target in patients, with obesity-related cancer in general and PDAC in particular. Prior studies and our preliminary data show the presence of a distinctive tumor immune profile in PDAC models under conditions of obesity, which encompasses immune suppressive myeloid and type 2 immune cells, namely M2-like tumor-associated macrophages (TAMs), and myeloid-derived suppressor cells (MDSCs), that inhibit effector $CD8^{+}$ T cell expansion and function enabling PDAC progression. However, the genesis of this ‘type 2 immune cell’ dominant tumor-immune microenvironment (TIME) of obesity-driven PDAC remains to be fully understood. This led us to take a holistic approach utilizing multiple genetically engineered mouse models (GEMMs), pharmacological inhibitors, transcriptomic analysis (RNA-seq, spatial transcriptomic, and scRNA-seq), fresh PDAC patient samples, and imaging technologies (confocal microscopy) to understand the molecular mechanisms. Our novel mechanistic study using some of the above-mentioned tools shows that obesity-driven PDAC has significantly higher perineural invasion (PNI) that enhances PDAC progression. We found that sympathetic nerve terminals (of the PNI) via neurotransmitter release control the expression of integral cytokines that cause a dramatic remodeling of the TIME. Specifically, the PNI-mediated neuro-adrenergic signaling activates β2-adrenergic receptor (β2-AR) on PDAC cells, leading to increased tumor cell production/proliferation and secretion of the ‘alarmins’ IL-33 and IL-1β. Importantly, we showed that mitigation of adrenergic signaling using two separate approaches: (i) pharmacological antagonists of β2-ARs (β-blockers), and (ii) the use of a thermoneutral model leads to substantial abrogation of obesity-mediated tumor progression. These, and other key data raise the provocative question that reducing adrenergic signaling-dependent IL-33 expression and release favor a pro-inflammatory TIME and significantly increase patient survival in obesity-driven PDAC.

#6819 Exploring the impact of *IDH1*-mutations on antitumor immunity in intrahepatic cholangiocarcinoma.

E. Kartalia, J. M. Leatherman, J. W. Lee, K. Yoshima, **D. J. Zabransky**, M. Yarchoan;
Johns Hopkins University, Baltimore, MD

Intrahepatic cholangiocarcinoma (CCA) is an aggressive biliary tract cancer that carries unfavorable prognosis. 10-20% of intrahepatic CCAs harbor a mutation in *IDH1* that can be targeted with mutant IDH1-specific inhibitors. However, objective and durable responses to treatment with mutant IDH1 inhibitors are rare in CCA. Mutant IDH1 has neomorphic enzymatic activity that produces the oncometabolite D-2-hydroxyglutarate (D-2-HG). D-2-HG promotes biliary tumor formation through cancer cell-intrinsic mechanisms but is also a paracrine factor in the tumor microenvironment (TME). Our group and others have identified that *IDH1*-mutant CCAs are not responsive to immunotherapy treatment approaches in part due to decreased CD8+ T cell infiltration and an increase in immunosuppressive macrophage cells in the TME. To better understand the immunosuppressive features of the *IDH1*-mutant CCA TME, we generated an isogenic cell line panel of *IDH1*-mutant (MUT) and *IDH1*-wild type (WT) mouse cholangiocarcinoma cells in the SB1 cell line background through a CRISPR homology directed repair approach. Compared to *IDH1*-WT cells, *IDH1*-MUT cells produce high levels of D-2-HG and both cell line panels readily form tumors in immunocompetent C57BL/6 mice. Tumors formed from *IDH1*-mut cells have reduced CD8+ T cell infiltration compared to *IDH1*-WT tumors, a finding that correlates with analysis of human CCA samples. Using cytometry by time of flight (CyTOF), we identified that CD8+ T cells in *IDH1*-MUT tumors have decreased expression of key regulators of the antitumor immune response including EOMES, TBET, and GZMB compared to those isolated from *IDH1*-WT tumors. Analysis of secreted factors from these *IDH1*-MUT and *IDH1*-WT cells identified that *IDH1*-MUT cells release increased levels of CCL2, a chemokine shown to diminish the antitumor immune response across multiple cancer types, compared to *IDH1*-WT cells. Further, IDH*1*-MUT tumors grown in syngeneic, immunocompetent mice have increased CCL2 staining by IHC compared to *IDH1*-WT tumors. CCL2 expression is also increased in a preliminary analysis of *IDH1*-mutant human CCA primary tumors. Treatment of mice harboring orthotopic liver tumors formed from *IDH1*-MUT cells with a CCL2 neutralizing antibody resulted in decreased tumor size compared to isotype control. Together, our data suggest that CCL2 is a mediator of immunosuppression in the *IDH1*-mutant CCA TME and that modulation of CCL2 activity may improve outcomes in this rare disease subtype. Further work to understand the mechanisms through which *IDH1* mutations regulate CCL2 levels in these tumors is underway.

TUMOR BIOLOGY: Gene Expression Regulation in the Tumor Microenvironment
Poster Session

#6824 Secretion of MAGE-A3 and MAGE-A4 in cell lines and lung cancer.

Bailey Gilmore[1], Dehe Kong[1], Rachel Gonzalez[1], Jina Yom[1], Andy Han[1], Tianli Qu[1], Alex Strom[1], Xiaoxiao Zhao[1], Eden Zewdu[1], Hailey Guo[1], Zhaoying Guo[1], Ranran Zhang[2], Xiaomin Hu[3], Qi Ren[3], Xuan Liu[1], Wei Fu[1]

[1]OriGene Technologies, Inc., Rockville, MD,[2]Origene Wuxi Biotechnology Co., Wuxi, China,[3]OriGene Wuxi Biotechnology Co., Wuxi, China

Melanoma-associated antigen gene A (MAGE-A) family of proteins have previously been shown to express in a variety of tumors, having different roles in cancer pathogenesis. MAGE-A3 and MAGE-A4 have both been shown to inhibit the p53 pathway which leads increased cell growth by stopping apoptosis. Both of these proteins have been associated with cancer progression and poor prognosis. In our studies, we have evaluated multiple MAGE-A3 and MAGE-A4 antibodies using CytoSections. While previous research had only pointed to these proteins being intracellular, our overexpression studies in the development of CytoSections indicated that some MAGE-A proteins were secreted. In this study, ELISA binding assays corroborated that MAGE-A3 and MAGE-A4 were secreted from cells overexpressing these proteins, and serum MAGE-A4 was detected in 24% of lung cancer patients. Flow cytometry data was then collected to see that exogenous MAGE-A proteins were binding to cells in a pattern consistent with secretion data from IHC experiments. Variants of MAGE-A4, differing by only a handful of amino acids, showed very different levels of secretion from one another. MAGE-A3 and MAGE-A6 share 95% homology and were also extremely different in secretion shown between IHC, flow cytometry, and ELISA. This study validates that certain members of the MAGE-A family are secreted from cells.

#6825 Epigenetic dysregulation in well-differentiated pancreatic neuroendocrine tumor (PNET): An immunohistochemistry (IHC) analysis.

Z. Saleh, Y. Ghanem, H. Joshi, M. C. Moccia, H. Toma, Y. Li, U. Joneja, T. Gao, Y. Hong;
Cooper Univ. Hospital, Camden, NJ

Epigenetic dysregulation through DNA Methyltransferase 1 (DNMT1) is integral to pancreatic neuroendocrine tumorigenesis. We aim to investigate the interplay between epigenetic modifiers and pathogenetic markers in the PNET microenvironment. 12 paraffin-embedded PNET specimens and 12 benign adjacent tissue specimens, used as controls, were obtained from Cooper University Hospital Pathology Department (IRB 23-130). IHC was performed using epigenetic markers, including DNMT1, DNMT3A, DNMT3B, and 5-Hydroxymethylcytosine (5-HMC), and pathogenic markers, including Multiple Endocrine Neoplasia 1 (MEN1), Protein-Tyrosine Phosphatase (PTEN), and Ras Association Domain Family 1 (RASSF1). Image J software was utilized for IHC scoring under the guidance of a board-certified pathologist. DNMT1 was upregulated in PNET tumor specimens with a mean density score of 72.02 +/- 31 versus 16.02 +/- 17 in adjacent benign tissue ($p<.001$). Grade 2 tumors displayed increased DNMT1 expression compared to Grade 1 tumors with a mean score of 37 +/-21 versus 71 +/- 23 ($p<.05$). Decreased expression of 5-HMC was noted in tumor specimens in comparison to benign tissue with a mean score of 3.92 +/- 5.05 versus 19.37 +/- 5.05 ($p<.05$). Loss of 5-HMC was observed in higher tumor grades with a mean score of .79 +/- 2 versus 8.2+/-2 ($p<.01$). DNMT3B was upregulated in PNET tumor specimens with a mean score of 13.16 +/- 3.94 versus 7.02+/- 2.553 ($p<.01$) in adjacent benign tissue and was positively correlated to DNMT1 expression. DNMT3A was not found to have a difference in expression between tumor and benign tissue. MEN1 was downregulated in PNET, with 45% of tumor specimens displaying loss of MEN1 expression. Mean MEN1 density in tumor tissue was 4.47 +/- 5.95 versus 11.41 +/- 3.53 in adjacent benign ($p<.01$). Increased expression of DNMT1 found to negatively correlate with MEN1 expression ($R^2=.23$). Loss of RASSF1 expression was present in 70% of tumor specimens with a mean score of 1.32 +/- 1.99 versus 9.50+/- 6.89 ($p<.001$) in adjacent benign tissue. RASSF1 expression correlated negatively with DNMT1 ($R^2=.21$). PTEN expression showed intratumoral homogeneity to benign tissue, and its expression was not correlated with any epigenetic markers. Our work provides a framework of epigenetic regulators involved in the pathobiology of PNET, and can refine prognostic evaluation while providing therapeutic benefits for patients with PNET.

#6826 Comparative analysis of a predictive transcriptomic model and functional gene expression signatures (FGES) for tertiary lymphoid structure (TLS) detection in lung adenocarcinoma (LUAD).

N. Lukashevich, D. Dymov, A. Sarachakov, S. Kust, A. Love, I. Valiev, D. Ivchenkov, A. Bagaev, V. Svekolkin, N. Kotlov, V. Kushnarev; BostonGene, Waltham, MA

Background: TLS are recognized as significant biomarkers for patient prognosis and therapy selection. In current clinical practice, TLS are often detected by manual assessment of H&E slides, which has been associated with reproducibility issues. Here, we developed a transcriptomic model using TLS density to stratify LUAD patients into TLS-high and -low groups and compared it with 5 published TLS FGES to assess the predictive value for patient outcomes.

Design: A regression model to predict TLS density (units(u)/mm²) was created using RNA expression data and histological mapping of 415 TCGA-LUAD samples. Features were chosen based on differential gene expression analysis of sample groups with low (<Q1, 0.26 u/mm²) and high (>Q3, 2.04 u/mm²) TLS density. The model was trained on 269 samples and independently validated on 146 TCGA and 9 internal samples. The RNA model and five previously reported TLS FGES were compared by Wilcoxon paired test to Spearman's ρ and F1-scores from bootstrapped validation set. The resulting predictions stratified immunotherapy-treated samples from SU2C-MARK (n=58) and GSE182328 (n=28) into TLS-high and TLS-low groups by Q2 threshold for TLS density (0.78 u/mm²) for further univariate (Kaplan-Meier) and multivariate (Cox model, adjusted for age and sex) analyses for overall survival (OS) with log-rank tests. P-values were adjusted with Bonferroni correction, and 95% confidence intervals (CIs) were provided.

Results: Statistically significant upregulated genes in samples with high TLS density included FDCSP, MS4A1, and CXCL13 (logFC ≥ 0.95, FDR<0.01). The transcriptomic model showed confident superiority in correlation with TLS density compared to the best FGES in TCGA samples (ρ=0.53±0.03 vs 0.41±0.03, p<0.001). The TLS model also outperformed the highest performing FGES when stratifying TCGA samples into TLS-high and TLS-low groups (F1=0.73±0.02 vs 0.69±0.02, p<0.005). In the internal cohort, the model demonstrated robust performance (F1=0.76±0.05, ρ=0.81±0.04) and outperformed all FGES except one (FGES F1=0.78±0.05, ρ=0.86±0.05). The TLS-high group defined by the TLS RNA model had a significantly better prognosis on immunotherapy cohorts (p=0.01; 1 year OS 49% for TLS-low vs 70% for TLS-high), whereas no discernible difference in OS was identified for the 5 TLS FGES. The TLS model had a log hazard ratio (logHR) of -3.11 (CI:-5.31,-0.91; p<0.05, Harrell's C-index=0.64), indicative of a stronger association with OS than of the TLS FGES (logHR=-2.11; CI:-4.1,-0.08; p=ns; C-index=0.59).

Conclusions: Comparative analysis of the proposed transcriptomic model for TLS detection in LUAD samples demonstrated improved performance metrics and prognostic value compared to previously reported TLS FGES, affirming its potential for guiding therapeutic decision-making.

#6827 Myocardin and myocardin-related transcription factor as potential drivers of the myofibroblastic cancer-associated fibroblast phenotype in colorectal cancer.

A. B. Cornelio, K. A. Johnson, Y. Gadalla, S. Nath, C. A. Pasch, W. Zhang, K. A. Matkowskyj, D. A. Deming;
University of Wisconsin - Madison, Madison, WI

Background: Cancer-associated fibroblasts (CAFs) play a key role in modifying the tumor microenvironment (TME) and could be a future target for treatment. CAFs are typically categorized based on function: myofibroblastic CAFs (myCAFs) amplify extracellular matrix production that blocks therapy and immune cell infiltration while inflammatory CAFs (iCAFs) produce immuno-suppressive cytokines and chemokines. Here we sought to better understand the role and mechanisms of myCAFs in altering the TME by identifying their unique markers and potential drivers.
Methods: Z-scores of ACTA2/TAGLN or ICAM1/PDPN were used to create datasets high in myCAF and iCAF markers, respectively, from TCGA data. A gene set enrichment analysis (GSEA) was performed on the resulting differential expression. Samples of patients were collected to create a cohort of colorectal cancers that were stained via immunohistochemistry (IHC) for alpha-smooth muscle actin (αSMA), transgelin (TAGLN), myocardin (MYOCD) and myocardin-related transcription factor A (MRTFA). Slides were evaluated for collagen using Masson's trichrome stain. MYOCD and MRTFA nuclear expression was expressed as positively stained nuclei per high powered field (HPF; 400x). TAGLN, αSMA, and collagen were scored on a scale of 0-3+.
Results: Of the 592 TCGA patients compiled across all disease stages, 23 (median age 63) formed the myCAF-high group (7 males, 16 females). Within this group, GSEA indicated an upregulation of myogenesis ($q < 0.001$) with the following genes positively associated with myCAF markers: MYLK ($q < 0.001$, log2 fold change [FC] 1.52), DES ($q < 0.001$, 5.32), and MYH11 ($q < 0.001$, 3.57). The following were also upregulated in the myCAF high cohort: CNN1 ($q < 0.001$, 2.95) and MYOCD ($q < 0.001$, 2.27). These genes are targets of MYOCD and MRTFA transcription factors potentially driving the myCAF phenotype. To assess this potential relationship, we evaluated 306 tumor samples from 153 patients with CRC. The cohort consisted of 56 female patients and 97 male patients aged 13-90 years old across all disease stages. High amounts of nuclear MRTFA were associated with high scores for myCAF markers aSMA (average score 1.54 when MRTFA+ nuclei < 5 per HPF vs 2.06 when MRTFA + nuclei > 5 per HPF, $p<0.001$, Wilcoxon Rank Sum Test), TAGLN (1.37 vs 1.62, $p = 0.043$), and collagen (1.73 vs 2.10, $p = 0.009$). Likewise, for MYOCD, αSMA (1.79 vs 2.14, $p = 0.001$) and collagen (1.87 vs 2.15, $p = 0.017$) were positively correlated.
Conclusions: Increased nuclear expression of MYOCD and MRTFA in stromal cells of CRC are positively correlated with myCAF gene expression, supporting our initial hypothesis of these being drivers of the phenotype. Our findings now motivate further analysis as to whether the inhibition of these transcription factors could lead to a reduction in the immune regulatory myCAF phenotype.

#6829 Identification of immune suppressive features in tumor-associated endothelial cells (TECs) in EGFR-mutant non-small cell lung cancer via single-cell RNA sequencing.

S.-J. Choi[1], J. Lee[2], K.-H. Pyo[3], G.-T. Lee[1], Y. Park[3], Y. Lee[4], M. Yun[3], K. Lim[5], J. Lee[1], M. Hong[2], S. Lim[2], B. Cho[2];

[1]Dept. of Research Support, Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [5]JEUK Institute for Cancer Research, JEUK Co., Ltd., Gumi, Korea, Republic of

Introduction: Within the tumor microenvironment (TME), tumor-associated endothelial cells (TECs) exhibit distinct features from normal cells, and diverse phenotypes of TECs result in intratumoral heterogeneity. Here, we aimed to characterize the phenotypes of the TECs of non-small cell lung cancer (NSCLC), identify distinct features that are pivotal in tumor progression, and discover potential therapeutic applications.

Methods: We performed single-cell RNA sequencing (scRNA-seq) from 128 NSCLC patients to include I (N=52), II (N=18), III (N=21), and IV (N=14), and compared them with normal cells (N=24). Epidermal growth factor receptor (*EGFR*)-mutant accounted for 69 samples. *EGFR*-wild (N=35) was further classified as programmed death-ligand 1 (PD-L1) high (N=14) and low (N=21) with PD-L1 high defined as tumor proportion score > 50%.

Results: Twelve distinct EC types were characterized based on clinical information, including *EGFR* mutations and PD-L1 expression. We classified our subset as normal cells and tumor-enriched ECs, which were further classified as *EGFR*-wild or mutant ECs. Compared to normal cells, phenotypes such as activated post-capillary veins (APCVs), tip ECs, and endothelial mesenchymal transition (endoMT) ECs were predominantly observed in all tumor-enriched ECs. In *EGFR*-mutant ECs, ribosomal ECs, and vascular mimicry (VM) ECs were primarily enriched. Trajectory analysis showed that endoMT and VM ECs had lineage tracing of fibroblasts and epithelial cells, respectively. By clinical stage, APCVs, tip ECs, endoMT, and VM ECs were more enriched at advanced stages. PD-L1-high subset had higher expression of adhesion molecules, APCVs, and median transmigration score than other phenotypes. Also, high endothelial venules (HEVs) mediating lymphocyte trafficking to lymphoid organs were enriched in high PD-L1 subset. In the APCVs of *EGFR*-mutant group, there were interactions related to immune cell suppression and interactions of chemokines/chemokine receptors involved in recruitment.

Conclusion: Our findings reveal distinct phenotypes of ECs, including the enrichment of APCVs, tip ECs, and endoMT ECs in all tumor-enriched EC populations, as well as VM ECs in *EGFR*-mutant ECs. APCVs, which is abundant high PD-L1 subset, play a crucial role in the transmigration progress of immune cells across vascular endothelium. In *EGFR*-mutant NSCLC, dysfunctional immune cells are recruited into the tumor, along with relatively low transmigration, resulting in poor tumor-killing effect.

#6830 Xenium *in situ* analysis and reproducibility study of multiple carcinomas for clinical studies.

E. Cheung, B. Zhang, L. Zhang, T. Lu, R. Gakhar, **V. Sundaram**;
BioChain Institute, Inc., Newark, CA

10x Genomics' Xenium is the newest in situ spatial transcriptomics platform offering sub-cellular resolution in frozen and FFPE tissue sections for a deeper study of cellular mechanisms and interactions. Mapping RNA targets at high specificity with fully customizable assays and quick workflow, it uses rolling circle amplification and interpretation-ready data is available immediately after the run. At BioChain Institute, Inc. (BioChain), we are conducting validation studies for reproducibility of results with the Xenium platform using BioChain's oncology biospecimen.FFPE tissues from BioChain's repository were screened by our pathologist for tumor content above 30%. Four carcinoma tissues from Breast, Colon, Lung, and Kidney with high DV200 scores were selected. An array was constructed with these tissues to fit the Xenium slide's imageable area. Two serial sections were used for the Xenium run per 10x Genomics' protocol. The Off-the-shelf Human Multi-Tissue and Cancer Panel was used for targeting 377 genes. H&E staining and imaging was performed, and the image was integrated with the data on the Xenium platform. The results were found to be reproducible between two different operators. For example, in the breast section, over 96,000 cells were detected and median transcripts per cell were 70 in both the runs. There were 20 clusters representing different cell types/ states, 99% transcripts were within cells, and ~85% of the transcripts were found to be high quality. Furthermore, we are analyzing the expression of unique tumor type and immune transcripts to map the heterogeneity of the tissues, as well as sensitivity, and standard deviation between the runs. The Xenium platform is a powerful tool for the sub-cellular spatial transcriptomics study of tissues with targeted gene panels. However, one of the four tissues used here failed to show enough transcripts. Further investigation is underway to examine the issue and conclude best practices thereafter. Our future studies will include accuracy and concordance validation with Xenium run on different days and Visium whole transcriptome assay post- Xenium.

#6831 Single-cell-based epigenetic and transcriptomic analysis in the KPC pancreatic cancer mouse model revealed dynamiccharacteristic subtypes of cancer-associated fibroblasts.

K. Sasaki[1], K. Shinjo[2], X. Wang[2], K. Kumegawa[3], R. Raruyama[3], S. Mii[2], Y. Murofushi[2], M. Suzuki[2], A. Enomoto[2], Y. Kondo[2];
[1]Nagoya University, Nagoya, Japan, [2]Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]Japanese Foundation for Cancer Research, Tokyo, Japan

Pancreatic cancer features robust fibrosis, with 40-80% fibrotic tissue and a dense stroma, highlighting the crucial need to grasp cellular interactions in the cancer microenvironment.
In this study, we used single-cell RNA sequencing (scRNA-seq) to analyze pancreatic tissues from 60-day-old normal mouse (n=1) (GSE125588) and KPC (LSL-KrasG12D/+; LSL-Trp53R172H/+; Pdx-1-Cre) cancer model with tumor diameter of 1-2 cm (n=2) (GSE129455). By examining fibroblast clusters, we identified distinct subtypes of cancer-associated fibroblasts (CAFs), and revealed four clusters: normal fibroblasts cluster, inflammatory CAFs (iCAFs) cluster marked by increased expression of IL6 and other cytokines, myofibroblast CAFs (myCAFs) cluster solely in the KPC model, and antigen-presenting CAFs (apCAFs) cluster expressing Mesothelin. We found that expression pattern of iCAFs in the KPC appeared similar to normal cells than myCAFs, suggesting a potential role in inhibiting cancer. it is reported that mesothelial cells might transition to apCAFs under the influence of IL6 and TGFβ due to tissue damage and inflammatory effects. This transition was visualized in our apCAF cluster, suggesting a potential pathway for the transformation of mesothelial cells into apCAFs.
Next, in order to analyze epigenetic profiles of fibroblasts, we conducted single-cell Assay for Transposase-Accessible Chromatin with high-throughput sequencing (scATAC-seq) using 90-day-old KPC mice (n=2) and a wild-type mouse (n=1).scATAC-seq showed that there are mainly two clusters of fibroblasts, one cluster corresponded to myCAF, enriched with PDPN, while the other represented iCAF cluster, enriched with COL1A2. These data suggest that in terms of the epigenetic state, myCAF contain several different CAFs and have the potential to differentiate into either myCAFs or other type of based on certain stimulation. Ultimately, CAF differentiated into three distinct subtypes as revealed by scRNA-seq. This highlights that despite similar epigenetic states, various transcription factors characterize the functionality of these fibroblast subtypes. Further exploration of the underlying mechanism that lead to different CAF subtypes might help in controlling the microenvironment of pancreatic cancer.

#6832 Gender specific role of LMTK3 in neuronal-tumor microenvironment crosstalk in CRC.

L. Torres-Gonzalez[1], S. Soni[1], Y. Yang[2], G. Smbatyan[1], J. Lo[1], P. Mittal[1], F. Battaglin[1], I. K. Singh[3], P. Jayachandran[1], S. Algaze[1], A. Wong[1], K. Ashouri[1], W. Zhang[1], G. Giamas[4], J. Millstein[2], H.-J. Lenz[1];

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, [3]Deshbandhu College & Delhi School of Public Health, Institute of Eminence, University of Delhi, New Delhi, India, [4]School of Life Sciences, University of Sussex, Falmer, Brighton, United Kingdom

Background: Lemur tail kinase 3 (LMTK3) is a serine/threonine protein kinase with roles in multiple cellular pathways, including Wnt signaling, KIT modulation, and the estrogen receptor pathway; identifying it as a potential target in various cancers. LMTK3 is highly expressed within the central nervous system (CNS) and has been demonstrated to influence neuronal signaling. This study aimed to investigate the potential connection between LMTK3 and neuronal signaling pathways in colorectal cancer (CRC).

Methods: Using the Cre/loxP system, we generated a C57BL/6 mouse strain that lacks the expression of LMTK3. $1x10^6$ MC38 cells were subcutaneously implanted into 8 weeks old male and female wildtype (WT) and knockout (KO) mice. Tumor growth was measured until endpoint was reached. Tumors were then processed for RNA sequencing. Differentially expressed genes (DEGs) for each comparison group: WT Female vs WT Male, WT Female vs KO Female, WT Male vs KO Male, and KO Female vs KO Male were analyzed. Ingenuity pathway analysis (IPA) was done for identification of upstream regulators involved and affected cellular pathways. Expression levels of DEGs for glutamate receptor subunits were validated using qRT-PCR.

Results: Both male and female LMTK3 KO mice showed highly significant ($p<0.01$) reduced tumor size when compared to WT mice of the same sex. Additionally, the KO female tumors were significantly ($p<0.05$) smaller when compared to the KO males. RNA sequencing revealed 761 DEGs in KO and WT female and 133 DEGs in KO female and male cohort comparisons ($q<0.05$). IPA results showed significant ($p<0.01$, Z-score<-2) alterations in pathways including glutaminergic receptor signaling, neurovascular coupling, CREB signaling in neurons, and synaptic long-term depression in the WT vs KO female tumor cohort comparison. Within these pathways DEGs: CACNA1E, CACNA2DA, CACNG2, GRIA1, GRIA2, GRIN1, and GRIN2B, were downregulated in KO females. Upstream regulator analysis identified transcription regulators such as OTX2 and NEUROD1 as well as beta-estradiol to be significantly inhibited ($p<0.01$, Z-score<-2) in KO females. qRT-PCR analysis showed significant ($p<0.05$) decreased expression in GRIA1, GRIN1, and GRIN2B as well as GRIN2A and GRIN2C in KO females when compared to WT females or KO males, validating RNA seq results.

Conclusions: These results showed the involvement of LMTK3 in the gut-brain axis and its effect on CRC tumor growth. Downregulation of multiple neuronal pathways and genes suggest that LMTK3 may influence neuron signaling and neurotransmitter release to produce stimulatory or inhibitory effects within the tumor environment. The concurrent inhibition of beta-estradiol in LMTK3 KO tumors allude to possible sex differences the kinase's effect on the observed tumor growth. Further studies are needed to confirm the mechanism of interaction of LMTK3 within these pathways.

#6833 Microenvironment-specific transcriptomic changes in osteosarcoma metastasis.

Shimara Gunawardana-Zeigler[1], Dan Peng[2], Patrick Cahan[2], David Loeb[1]

[1]Developmental and Molecular Biology/Pediatrics, Albert Einstein College of Medicine, Bronx, NY,[2]Biomedical Engineering, Johns Hopkins University School of Medicine, Baltimore, MD

Osteosarcoma (OS) is the most common primary malignancy of bone in children and adolescents. While conventional chemotherapy has improved 5-year survival rates for localized disease to 70%, metastatic disease remains at 20-30%. Failure of modern treatment options to improve survival reflects the failure of agents that appear promising in preclinical models to demonstrate clinical efficacy in human patients. We hypothesize that this is because most preclinical testing is performed on tumors implanted subcutaneously in immune deficient mice. Our previous work has shown that tumors implanted subcutaneously do not metastasize, whereas genetically identical tumors implanted orthotopically (in the tibia) metastasize to lungs and bones. Thus, to better understand non-genetic drivers of metastasis, we implanted patient-derived xenografts (PDXs) either orthotopically or subcutaneously into NSG mice. Once tumors reached 1.5cm, tumors were extracted along with distant metastases and analyzed by single-cell RNA sequencing. Transcriptomic analysis reveals 1) that fragments of the same tumor implanted subcutaneously have a vastly different transcriptome than fragments implanted orthotopically, 2) the transcriptome of distant metastases is dramatically different from the transcriptome of the primary tumor, and 3) the gene expression profile of metastases is different in different metastatic sites. In all 3 of these circumstances, these differences reflect differences in differentiation status, signaling pathway activation, and immune cell infiltrate. Thus, we conclude that the environment in which a tumor grows significantly alters its gene expression and phenotype. Our study highlights the need for careful consideration of the tumor microenvironment when designing pre-clinical studies to ensure accurate representation of human osteosarcoma and may help to explain the dismal record of translating novel agents from preclinical studies into standard therapy.

#6834 Periostin involvement in cellular senescence in ovarian cancer.

J. Feng, E. Nguyen, J. Reyes, Z. Huang;
Duke University Medical Center, Durham, NC

Purpose: Despite improvements in care and advancements in the understanding of ovarian cancer (OC) pathobiology and genetics, survival rates remain disappointingly low compared to other types of cancer. This is due to a lack of diagnosis strategies, high recurrence rates, and the development of chemo-resistant diseases, which require synergy between cancer cells and the tumor microenvironment (TME). We have demonstrated the functional importance of a TME gene, periostin (POSTN), in OC and recurrent OC, using in vitro and in vivo models. Our objectives were to identify differentially expressed genes by POSTN expression in the TME that contribute to the progression of ovarian cancers.

Procedures: Gene expression data was generated from an ovarian cancer cell line, HEYA8, cultured in a high POSTN conditioned 3D cell culture environment, using the NovaSeq 6000 system to generate RNA-seq data. The data was analyzed to determine the genes expressed at different levels between the HEYA8 cells grown with or without POSTN-high conditioned medium (CM). The gene functional annotation and KEGG pathway enrichment were further analyzed from 10,115 significant differentially expressed genes between the HEYA8 cells grown in high levels of POSTN ($CM^{POSTNhigh}$) or low levels of POSTN (CM^{CTL}) culture conditions, using DAVID bioinformatics.

Results: Using a cell culture and co-culture model, we found that OC cells cultured under conditioned media containing $CM^{POSTNhigh}$ exhibited faster cell migration, more invasiveness ($p=0.006$), more chemo-resistance ($p<0.05$), and increased resistance to paclitaxel-induced apoptosis, compared to OC cells cultured with control medium (CM^{CTL}). OC cell lines cultured with $CM^{POSTNhigh}$ showed increased side population cells relative to CM^{CTL} -cultured cells, suggesting POSTN plays important roles in cancer stem cell enrichment. POSTN-transfected 3T3-L1 cells exhibited more intracellular and extracellular lipids and were linked to increased cancer cell expression of the oncogene fatty acid synthetase. In correspondence to the functions of POSTN in OC cells, the pathways identified to be significantly impacted by POSTN expression included, but were not limited to, the cell cycle, apoptosis, p53 signaling, MAPK signaling, and PI3K-Akt signaling pathways. Interestingly, we also found cellular senescence pathways was one of the most significantly impacted by POSTN suggesting that POSTN may play roles in ovarian cancer via the regulation of cellular senescence, which has not yet been explored.

Conclusions: These data emphasize the importance of TME factors in tumor progression and prognosis via various ways in ovarian cancer, establishing promising potential therapeutic targets of OC.

#6835 Profiling of new prostate cancer vulnerabilities through single-nucleus RNAseq implicates the CAF-specific TGF-β pathway in tumor progression.

A. P. Alloy[1], S. Chamling Rai[2], B. O'Brien[2], A. Lyubetskaya[2], A. Amzallag[2], B. Chen[2], A. Lako[2];
[1]Bristol Myers Squibb, Summit, NJ, [2]Bristol Myers Squibb, Cambridge, MA

Background: Transcriptomic profiles of primary high grade prostate cancer (hgPCa) have been extensively studied and prognostic gene expression signatures to classify patients for risk have been identified. However, such studies have employed bulk genomic techniques that blur the contributions of the different cell types. Indeed, tumor microenvironment (TME) cells can significantly contribute to these transcriptomic signatures thereby confounding the lineage of potential therapeutic targets. These challenges underscore the potential of single-nucleus (sn)RNAseq to elucidate new PCa vulnerabilities. We set out to assess whether the TME, particularly cancer-associated fibroblasts (CAFs) drive poor outcome in PCa.
Methods: We obtained 15 treatment-naïve frozen primary high risk PCa tissue samples, mostly Gleason >=8. A PCa nuclei dissociation protocol was adapted for single nucleus snRNAseq (10X Genomics). Sample profiling included all cell populations in the tissue including tumor and TME. Output was analyzed using Seurat (v.4.1.1), corrected for ambient RNA expression with CellBender (v.0.3.1) and detected and removed doublets with Scds (v.3.9). Tumor cells were distinguished from normal epithelium cells by a combination of inferCNV (v.1.12.0) and supervised learning with random forests classification.
Results: Through snRNAseq, we show that CAFs, and not tumor cells, entirely drive the expression of previously validated poor prognostic signatures (Mortensen, 2015). Our analysis revealed that the TGFβ pathway expression, TGF-β1 in particular, is upregulated in CAFs rather than PCa cells. This pathway, along with poor prognosis signatures are selectively elevated in CAFs from patients with Gleason high compared to low, implicating the TGFb axis as a PCa vulnerability. We also derived a snRNAseq CAF signature that differentiates non-responders to immune checkpoint therapy in mCRPC (Nivolumab+Ipilimumab). Furthermore, cluster profiling of tumor nuclei revealed that hgPCa harbors high heterogeneity with distinct niches of hgPC, mCRPC or neuroendocrine phenotypes for each patient.
Conclusions: Through snRNAseq we show that CAFs are the main contributors to prior bulk RNAseq classifiers of poor response, resulting in a refined CAF signature that allows for direct investigation of the contribution of CAFs in other patient segments (mCRPC). Our findings point to a hgPCa patient segment with high CAF representation that may benefit from the addition of a CAF targeting agent (ie.TGFbi) to androgen deprivation therapy. This data has the potential to help refine our prognostic classifiers for patient selection and clinical applicability. Further study of the reported tumor heterogeneity will inform rational combination therapies to tackle resistance mechanisms.

#6836 Single-cell RNA sequencing of FUS::DDIT3 myxoid/round cell liposarcoma delineates mechanisms of oncogenic progression and immune escape.

R. Gularte-Merida, **E. Seffar**, G. Li, Y.-M. Kim, N. Agaram, N. Socci, F. Sanchez-Vega, N. Schultz, S. Singer;
Memorial Sloan Kettering Cancer Center, New York, NY

Myxoid/Round Cell Liposarcoma (MRCL) is an understudied soft tissue sarcoma that typically affects young adults and accounts for 30% of all liposarcomas. MRCL is characterized by oncogenic DDIT3 fusions, with FUS::DDIT3 being present in over 90% of cases. However, the cellular origins and oncogenic mechanisms of MRCL remain incompletely defined. Here we report oncogene transcription, and tumor-immune interactions in a cohort of 5 patient tumors with matched normal tissue for which we sequenced the transcriptomes of approximately 45,000 single cells using 10X Genomics, and full-length transcripts in approximately 20,000 single cells via Oxford Nanopore in 2 of these patients.

Our results reveal two distinct cancer cell populations: Early Cancer Cells (ECC) and Advanced Cancer Cells (ACC). These cells appear to derive from adipose stem progenitor cells (ASPC) and fall along an ASPC→ECC→ACC pseudo-time axis. Along this axis, a distinct pattern emerges where oncogenes tend to be upregulated and tumor suppressor genes (TSG) tend to be downregulated and these appear to be mutually exclusive. Comparing ECC to ASPC we see increased expression of HIPPO and PI3K pathway oncogenes, FGFR2 and IGF1R RTKs, and downregulation of the TSG CDKN2A and CDKN1A. ACC show upregulation of hedgehog, ErbB, WNT, HIPPO, PI3K, and MAPK signaling pathways compared to ECC. Full-length transcript sequencing at the single-cell level shows a consistent expression of the FUS::DDIT3 fusion transcript in both ECC and ACC populations, confirming that these populations are cancer cells. Furthermore, MRCL displays several immune escape mechanisms, including poor immune infiltration and a marked decline of HLA Class I expression along the pseudo-time axis from ECC to ACC, suggesting a complex interplay between oncogenic signaling and immune evasion.

These results suggest that MRCL likely originates from ASPC and expression of FUS:DDIT3 oncoprotein induces early HIPPO, PI3K, FGFR2, and insulin signaling pathway expression in ECC with further hedgehog, ErbB, MAPK, and WNT pathway activation in ACC. This progressive activation in oncogenic signaling is associated with immune evasion. This is the first single-cell RNA seq analysis to detect the presence of the FUS::DDIT3 fusion in ECC and ACC significantly advancing our understanding of the mechanisms of MRCL oncogenesis, immune escape, and identifies potential novel therapeutic targets.

#6837 Prolonged effects of hypoxia in luminal breast cancer cells.

A. Moriarty[1], O. Iriondo[2], Y. Amzaleg[2], R. Klotz[1], M. Yu[1];
[1]University of Maryland School of Medicine, Baltimore, MD, [2]USC Keck School of Medicine, Los Angeles, CA

Metastasis is the main cause of tumor-related mortality in breast cancer patients. Improving our understanding of the metastatic cascade is imperative to improve patient outcomes. Prior research indicates cancer cells with increased metastatic potential have acquired adaptive properties induced by factors in the tumor microenvironment (TME), including hypoxia. However, previous hypoxia research has primarily focused on signaling changes that occur when cancer cells are in the hypoxic TME and does not account for long-term changes that may occur once cancer cells re-enter normoxia, such as when they metastasize. Our research in patient-derived circulating tumor cell (CTCs) lines and breast cancer cell lines indicates that certain transcriptional changes are maintained after cells leave hypoxia, and that these post-hypoxic cells maintain a higher metastatic potential compared to cells not exposed to hypoxia. Taking an un-biased approach to define changes in hypoxia-exposed breast cancer cells upon reoxygenation, we performed bulk RNA-Seq on post-hypoxic luminal breast cancer cell lines compared to normoxic controls cultured either in adherent or suspension conditions, the latter to mimic the physiological context of CTCs. We found that a subset of genes that were differentially expressed in hypoxic conditions were maintained as up- or down-regulated after cells were reoxygenated, indicating a “hypoxic memory”. Additionally, a subset of differentially expressed genes were unique to the post-hypoxic cells, demonstrating both prolonged and novel gene expression changes induced by hypoxia exposure. We also performed functional assays and observed that this post-hypoxic state is associated with a more aggressive phenotype. Current research in our lab is on-going to understand the epigenetic changes that may be responsible for this hypoxic memory. Overall, this research will improve our understanding of the prolonged consequences of hypoxia on CTC biology and metastasis.

#6838 Adipose tissue features in breast cancer patients: Impact and modifications induced by tumor according to body mass index.

S. Romero-Cordoba[1], R. Agresti[2], V. Regondi[2], G. Trecate[2], F. Bianchi[3], L. Sfondrini[3], S. M. Pupa[2], E. Tagliabue[2], **T. Triulzi**[2];
[1]Instituto de Investigaciones Biomedicas, Universidad Nacional Autonoma de Mexico, Mexico city, Mexico, [2]Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy, [3]Universita degli Studi di Milano, Milano, Italy

Adipose tissue (AT) is emerging as a contributing factor to cancer development and progression, especially in obesity. However, the mechanisms underlying this association are not yet fully understood. Based on the described *in vitro* interplay between cancer cells and adipocytes that induces adipocyte dedifferentiation and the acquisition of an inflammatory phenotype, it is conceivable that tumor-adipocyte crosstalk promotes cancer progression even in normal weight patients (pts). To study tumor-induced AT alterations, we performed a transcriptomic analysis of matched adjacent and distant tumor AT samples from 41 breast cancer (BC) pts (78% Luminal B, 12% HER2+, 7% TNBC) undergoing mastectomy. Comparison of the gene expression landscape of BC-adjacent *vs* distant ATs derived from normal weight pts (BMI<25, n=28) identified 723 differentially expressed genes (FDR<10%). Metabolic signaling processes were over-represented in genes resulted downmodulated in the BC-adjacent AT, while those upmodulated were mainly classified into proliferation, migration and inflammatory response, cell programs associated with dedifferentiated adipocytes *in vitro*. Accordingly, BC-adjacent ATs were found to be enriched (NES=1.78, p<0.0001) in a set of genes unique of *in vitro* dedifferentiated adipocytes compared to mature adipocytes. In overweight/obese pts, no differentially expressed genes were found between BC-adjacent and -distant ATs, although gene sets composed of modulated genes in normal weight pts were found to be significantly enriched (NES=1.50, p<0.0001; NES=-1.52, p=0.0025). In addition, a significant enrichment of altered BC-adjacent AT genes and inflammatory response process was observed (NES=1.49, p=0.0029; NES=1.62, p=0.011) in the BC-distal AT of overweight/obese *vs* normal weight pts, indicating that AT is already altered and inflamed independently of the presence of the tumor in overweight/obese women. To further analyze AT heterogeneity, we performed an unsupervised clustering of all AT samples using the K-means algorithm. Five stable clusters were identified, which were independent of sampling site. Indeed, the matched AT samples derived from 70% of the pts were assigned to the same cluster, with a significant grouping of overweight/obese pts in clusters K1 and K2 (p=0.0217). BC-adjacent AT samples from the remaining pts clustered significantly (p=0.030) in the other 3 clusters, especially in K5, which had the highest CAA score, a signature reflecting adipocyte dedifferentiation. Consistent with the association with obesity, K1/K2 pts had significantly higher circulating PCR, cholesterol, triglycerides and insulin and recurrence rate. Overall these data suggest that BC cells induce adipocyte modifications in normal weight pts and that obesity-associated BC aggressiveness is related to intrinsic characteristics of adipose tissue.(Supported by AIRC)

#6839 Comprehensive transcriptomic analysis of acquired resistance after immune-checkpoint inhibitors in non-small cell lung cancer.

C. Joe, Y. Bang, S. Park, H. Jung, J.-M. Sun, Y.-L. Choi, J. Ahn, M.-J. Ahn, S.-H. Lee;
Samsung Medical Center, Seoul, Korea, Republic of

Background: Treatment of lung cancer has changed dramatically with the use of immune checkpoint inhibitors (ICI). Nevertheless, most patients underwent drug resistance even though they initially showed a response to ICI, and there is an unmet need to delineate the mechanism.
Method: We analyzed RNA sequencing data of paired pre- and post-ICI samples from 31 NSCLC patients. Among them, we identified 17 patients who underwent acquired resistance (AR) who initially showed partial or complete response or stable disease lasting more than six months, and the remaining 14 patients who showed primary resistance (PR) to ICI. The analysis was performed using a tumor microenvironment (TME) classifier, classifying immune-enriched [IE], immune-enriched and fibrotic [IE/F], fibrotic [F] and immune-desert [D] subtype, and CIBERSORTx, the immune cell deconvolutional analysis tool.
Results: Most patients with AR were initially classified as IE or IE/F subtypes (N=12, 70.6%), but six out of 14 with PR (42.8%) showed IE or IE/F subtypes. Among 12 patients with initial IE or IE/F subtypes, seven (58.3%) patients turned into the D subtype after AR to ICI. Most patients initially classified as D or F subtypes (N=5, 29.4%) maintained their subtypes (N=4, 80%) after AR.When assessing the pre-ICI samples, memory B cell was enriched, and M2 macrophage and regulatory T cell were depleted in AR patients compared to PR. The memory B cell and resting memory CD4+T cell decreased, and M2 macrophage increased after AR to ICI. These immune cell composition changes were not observed in PR patients.
Conclusions: We observed differences in TME phenotype and immune cell composition before ICI between AR & PR patients. The TME change from immune-enriched to desert and cell composition change of increased M2 macrophages and decreased memory B and resting CD4+ T cells after AR to ICI could be significant mechanisms of AR to ICI.

#6840 Automated preparation of single nuclei from FFPE samples for snRNA-Seq.

S. Jovanovich[1], N. Pereira[1], D. Meyer[1], C. Snopkowski[2], I. Masilionis[2], B. Meskauskaitė[2], M. Takizawa[2], Z. Abou-Mrad[2], K. Yu[2], V. Tabar[2], K. Luckett[2], K. Ganesh[2], N. Khan[1], R. Chaligne[2];

[1]S2 Genomics, inc., Livermore, CA, [2]Memorial Sloan Kettering Cancer Center, New York, NY

S2 Genomics developed the Singulator™ 100 and 200 Systems to automate the processing of fresh, frozen, or OCT tissues into single cell or single nuclei suspensions using disposable cartridges, reagents, and customizable protocols. The systems have been used to prepare cells or nuclei from a wide range of tissues and organisms, including human, mouse, chicken, insects, snails, zebrafish, and plants.

Formalin-fixed, paraffin-embedded (FFPE) tissues are the preferred format for pathologists and as many as one billion FFPE slides are in repositories. FFPE tissue samples have traditionally been difficult to study with molecular techniques due to the chemical modifications caused by the formalin fixation, which can lead to degradation and sequestration of RNA and DNA. Recent advances in single cell/nuclei RNA-Seq library preparation technology have made it possible to overcome these challenges and generate high-quality single cell or nuclei genomic data from FFPE samples. Protocols have been released for processing previously deparaffinized and rehydrated FFPE samples on the Singulator 100 or 200 into single nuclei.

We now report the development of a fully automated workflow for the deparaffinization and rehydration of FFPE tissues in about 40 min, with an optional enzymatic treatment of 45 min, and processing of FFPE tissues into singulated cells or nuclei on prototype Singulator 200 systems. Data will be presented for the optimization of process parameters for cell or nuclei recovery and RNA quality for six tissues. Finally, single nuclei sequencing data will be presented for snRNA-Seq libraries from healthy and cancerous human FFPE samples including glioblastomas and colorectal cancer. These data demonstrate the successful recovery of genomic materials from FFPE samples using an automated sample preparation system for single cell/nuclei transcriptomics.

#6841 Mutation specific mechanisms of resistance to oncogenic KRAS inhibition.

I. Barravecchia, E. Lasse-Opsahl, S. Cavanaugh, L. Rober, R. Baliira, M. Robotti, R. Hinshaw, J. M. Lee, Y. Zhang, M. Pasca di Magliano, S. Galban; University of Michigan, Ann Arbor, MI

Mechanisms of resistance to inhibitors against mutant KRAS are linked to the remodeling of the tumor microenvironment (TME). Understanding this remodeling process during intervention and tumor recurrence will likely guide the development of future therapeutic treatment paradigms with long-term responses. 56% of never-smokers with non-small cell lung cancer have $KRAS^{G12D}$ mutant cancer and respond little to immune checkpoint therapy (ICI) compared to smokers, who often have mutations in $KRAS^{G12C}$. Our analysis of the TME in a unique $Kras^{G12D}$ inducible and reversible mouse model of NSCLC using single cell RNA sequencing data shows $Kras^{G12D}$-dependent control of the TME, particularly of the expression of PDL1 in a subset of myeloid cells. PDL1 expression was found to be $Kras^{G12D}$ dependent as it was reduced significantly when $Kras^{G12D}$ was turned ON in mouse lungs. Interestingly, when $Kras^{G12D}$ was turned OFF, the expression of PDL1 increased, indicating mechanisms of resistance. Furthermore, the cytokine expression and secretion of IL6, a known regulator of PDL1 expression, increased in lung tissue and lung cancer cells derived from this model upon genetic and chemical (MRTX1133) Kras inhibition. Moreover, the mechanisms of resistance to oncogenic Kras inhibition appear to be mutant specific. Transcriptome and secretome analyses in human and murine $Kras^{G12D}$ or $Kras^{G12C}$ mutant lung cancer cells show distinct cytokine regulation upon KRAS inhibition. Identification of mechanisms of resistance like the induction of PDL1 expression upon KrasG12D inhibition may provide a strong rationale for co-treatment of KRAS inhibitors with ICI for KrasG12D never-smokers with NSCLC.

#6842 The effect of intra-tumoral *Candida albicans* on host gene expression.

A. Loncar[1], D. Grencewicz III[2], R. Hoyd[3], A. Pallerla[1], N. Williams[3], M. Benej[3], Y. Mehra[3], S. Jahanbakhshi[3], M. Anderson[4], N. Denko[3], D. Spakowicz[2]; [1]The Ohio State University, Columbus, OH, [2]The Ohio State University College Of Medicine, Columbus, OH, [3]The Ohio State University Comprehensive Cancer Center, Columbus, OH, [4]University Of Wisconsin - Madison, Madison, WI

The gut and tumor microbiome have been shown to affect tumorigenesis, tumor immune infiltration, and response to traditional cancer therapeutics such as radiation therapy. Further, specific microbe-cancer relationships have been established. One such microbe is *Candida albicans,* which has been identified within several gastrointestinal cancers and is associated with an increased risk of metastases and decreased overall survival. By completing RNA-sequencing on murine rectal tumors colonized with *C. albicans*, we can better understand whether intratumoral changes in gene expression exist based on colonization of specific microbes. This study utilizes gut-to-tumor translocation and whole transcriptome analysis for a discovery-based approach to identify the effects of *C. albicans* on the host tumor.

We established a rectal tumor model with C57BL/6 mice using MC38 rectal cancer cells subcutaneously injected on the right flank, local radiation to the tumor (standard-of-care for rectal cancer), and gavage with either *C. albicans* (*Ca*) or PBS. Fungal presence within tumors was validated by staining with calcofluor white and subsequently, tumors were sent for bulk RNA-sequencing to determine differences in gene expression using DeSeq2 and a gene set enrichment analysis (GSEA).

In unsupervised analysis of gene expression differences between PBS-gavaged and *Ca*-gavaged with bulk RNA sequencing, tumors gavaged with *C. albicans* possessed unique gene expression and pathway analysis when compared to PBS-gavaged mice. Global differential gene expression showed 1,947 genes upregulated in *Ca* gavage and 593 genes upregulated in the PBS gavage ($p < 0.05$). *C. albicans* colonized tumors showed decreased expression in gene pathways relating to immune activation (interferon alpha response, IL-6 and *STAT3* signaling), *p53* expression, DNA repair, oxidative phosphorylation, *NOTCH* signaling, and apoptosis. We subsequently used a network-based approach to identify the most important genes driving the differences in the tumors, calculating the degree, closeness, and betweenness centralities.

Several microbes have been regarded as potential contributors to decreased treatment response and survival in rectal cancer. In the case of tumors colonized with *C. albicans,* bulk RNA-sequencing indicates down regulation of gene pathways related to cell proliferation, immune activation, and DNA maintenance. Down regulation of gene pathways related to cell cycle control and arrest suggests that intratumoral colonization of *C. albicans* may causally affect tumorigenesis. Decreases in immune signaling in tumors suggest a potentially causal role of *C. albicans* immune suppression. These results highlight initial steps to understand how intratumoral *C. albicans* may be affecting rectal cancer progression and treatment response and serve as a technique to allow better insight to individual microbial impact on tumors.

#6843 Comprehensive multi-omics approaches for identification of genetic alterations in head and neck squamous cell carcinoma.

Kirsteen Maclean, Qinqin Zha, Lakshmi Chandramohan, Anna Juncker-Jensen

NeoGenomics, Aliso Viejo, CA

Background: Head and neck squamous cell carcinoma (HNSCC) is one of the most difficult and challenging malignancies, with a high level of heterogeneity and a wide range of treatment responses, regardless of the clinical stage. Oral squamous cell carcinoma (OSCC) is the most common head and neck cancer and accounts for over 90% of cancers that develop in the mucosal epithelium of the oral cavity. Additional carcinogenic risk factors, including tobacco, alcohol, and HPV infection are also associated with the pathogenesis of oral carcinogenesis. Unfortunately, today the failure of standard treatment modalities such as surgery, radiotherapy, and chemotherapy underscore the need for comprehensive genomic profiling to provide a better picture of the genetic alterations and gain an improved understanding of the complex signaling networks involved in the development of potential treatment resistance as well as the identification of novel biomarkers that discriminate between smokers and non-smokers.

Methods: A retrospective analysis was performed on biopsied Formalin-Fixed Paraffin-Embedded (FFPE) samples from OSCC patients with and without a history of smoking and treated +/- chemotherapy. Patient samples representing matched normal tissue to serve as controls were compared to tumor squamous cell carcinoma samples and profiled using a single assay panel that includes 517 genes by both DNA and RNA NGS, microsatellite instability (MSI), and tumor mutational burden (TMB). Further analysis was also performed using the NanoString nCounter® PanCancer Immune Profiling Panel (PCIP), 770-comprehensive gene expression panel

Results: The Neo Comprehensive™ Solid Tumor pan cancer assay enabled simultaneously analysis of both DNA and RNA in one integrated workflow with an accompanying Dragen™ bioinformatics analysis platform and provided comprehensive genomic profiling of sequence and structural variants, as well as genomic signatures such as TMB and MSI in OSCC patients. Utility of the NanoString PCIP highlighted immune-relevant gene expression changes within the different sample cohorts. The detailed molecular information highlighted by our study emphasizes the need for improved patient classification based on smoking status in the management of OSCC and also in establishing potential therapeutic options based on the many altered cell signaling pathways that we identified. By combining a multi-omics approach with expression data for immune-related genes and associated overall survival data, we provide an effective strategy and workflow for the identification of prognostic biomarkers in OSCC.

#6844 Discovery of a novel sialic acid O-acetyltransferase in colon tissue.

B. Lee[1], A. Cook[1], M. Zeineldin[1], S. Sur[1], L. Dobbyn[1], M. Popoli[1], S. Khalili[2], B. Vogelstein[1], N. Papadopoulos[1], S. Zhou[1], C. Bettegowda[1], P. Buckhaults[2], T. Larman[1], K. Gabrielson[1], K. W. Kinzler[1], N. Wyhs[1];

[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of South Carolina, Columbia, SC

Sialic acids have critical functions relating to host-pathogenic interactions and the immune microenvironment. Subsequent post-translational O-acetyl modifications add an extra layer of control by modulating many of these interactions in both normal and transformed colorectal cells. The processes through which this modification is added to sialic acids are not completely understood. To date only one gene, *CASD1*, has been identified to encode a sialic acid O-acetyltransferase in human cells. We used whole-genome sequencing on normal human colon tissue to identify a haplotype strongly associated with colorectal sialic acid O-acetylation, as determined by histopathological mPAS staining. Only SNP's of a single candidate gene within the haplotype correlated perfectly in a 91-sample validation set. CRISPR-Cas9 editing of this gene in 2D cell line and 3D normal colon organoid models yielded changes to modified sialic acid levels. These findings suggest that this candidate gene functions as a novel sialic acid O-acetyltransferase in colorectal tissue and could have implications as a diagnostic tool for patients with inflammatory diseases of the bowel or as an indicator for therapeutic targets in cancer.

#6845 MAGEA3 expression and secretion in MMR-MSH6 and MMR-PMS2 microsatellite-stable colorectal cancer.

J. Yom, R. Gonzalez, B. Gilmore, Z. Guo, A. Han, E. Zewdu, D. Kong, T. Qu, H. Guo, A. Strom, Z. Zhao, X. Hu, Q. Ren, Y. Ma, R. Zhang, Z. Wu, X. Liu, W. Fu; OriGene Technologies, Inc., Rockville, MD

Despite the breakthrough of PD-1/PD-L1 blockade therapy in the recent years, mixed responses have been shown across multiple tumor types, including in colorectal cancer (CRC), the second leading cause of death worldwide. This immunotherapy has proven to be successful for a subtype of CRC that carries mismatch repair deficiency (dMMR) and high microsatellite instability (MSI-H), despite a lack of response by microsatellite-stable CRC. For these types of non-responsive cancers, new immunotherapy targets are currently being investigated for alternative therapy such as the MAGE-A cancer testis antigen family whose expression is restricted to germline cells in normal tissue but is overexpressed in many cancer cells. In this study, we examine the relationship between MAGEA3 and MMR proteins MSH6 and PMS2. Immunohistochemical staining of CRC tissues demonstrated co-expression between MAGEA3 with both MSH6 and PMS2. Immune cells were observed to express MAGEA3 in CRC as well. To investigate the possibility of secreted MAGEA3 from tumor cells, we performed western blot analysis of CRC cell lines, ELISA, and binding assay on cell lines and the positive results suggest that MAGEA3 protein is secreted. The results suggest that MAGE-A3 may be a promising target for microsatellite-stable colorectal cancer immunotherapy.

#6846 Tumor cell metaplastic programs and failure of T cell remodeling drive resistance and progression to frontline chemoimmunotherapy in advanced gastric cancer.

Samuel J. Wright[1], Minae An[2], Byung Hoon Min[3], You Jeong Heo[4], Milan Parikh[1], Lynn Bi[1], Hyuk Lee[3], Taejun Kim[3], Song-Yi Lee[5], Jeonghyeon Moon[6], Ryan J. Park[1], Matthew R. Strickland[7], Woong Yang Park[8], Won Ki Kang[5], Kyoung-Mee Kim[9], Seung Tae Kim[5], Arnav Mehta[1], Samuel J. Klempner[7], Jeeyun Lee[5]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]Experimental Therapeutics Development Center, Samsung Medical Center, Seoul, Korea, Republic of,[3]Department of Gastroenterology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[4]Neocella, Inc., Irvine, CA,[5]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[6]Departments of Neurology and Immunology, Yale School of Medicine, New Haven, CT,[7]Department of Medicine, Division of Hematology-Oncology, Massachusetts General Hospital, Boston, MA,[8]Geninus Inc, Seoul, Korea, Republic of,[9]Department of Pathology and Translational Genomics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Adding aPD1 to 5-FU/platinum in advanced gastroesophageal adenocarcinomas (GEA) has yielded modest and heterogeneous results. Understanding cooperativity between these two treatment modalities will inform novel combination treatments for GEA. Towards this end, we conducted a trial (n = 47) sequentially adding pembrolizumab to 5-FU/platinum in previously untreated advanced GEA. Using serial biopsy of the primary tumor at baseline, after one cycle of 5-FU/platinum, and after the addition of pembrolizumab we transcriptionally profiled 358,067 single cells and obtained TCR-sequences from single tumor-resident T cells. Stratifying patients into slow- (> 6 months) and fast-progressing (< 6 months) groups based on progression-free survival allowed us to quantify differences in immune, stromal and epithelial subpopulations across treatment time points. Using topic modeling with consensus non-negative matrix factorization (cNMF), we identified gene expression programs in each population at each time point and developed a methodology to verify the stability of those programs across the cohort using cross-validation. Faster clinical progression featured decreased M1-like macrophage repolarization and increased MUC5A and MSLN containing metaplasia programs in tumor cells. We next selected features from cell state gene programs and identified trajectories of tumor cells across a spectrum of treatment sensitive and resistant states. We identified several factors that correlated with these trajectories and regulons that may be influencing them. After pembrolizumab we observed slower progression was associated with further increased CD8 T cell infiltration with increased CXCL13+ T cells. We next calculated covarying programs between patient samples at each time point and performed permutation testing to identify which programs (and respective cell types they were expressed in) were significantly correlated to infer the presence of multicellular tumor communities. We found that the tumor cell interferon program co-varied with the CXCL13 T cell program, and the emergence of a covarying module with tumor-reactive CXCL13 program expression happens as early as after the first dose of chemotherapy. To better understand the behavior of tumor reactive T cells within the tumor microenvironment, we leveraged TCR-sequencing data to study T cell clonality and diversity across treatment time points and between fast and slow progressors. Our data provide an invaluable resource to dissect chemoimmunotherapy response in tumor cells, understand T cell behavior and propose strategies to drive anti-tumor immune hub formation to expand the portion of patients benefiting from immunotherapy approaches.

#6847 IGF2BP3 promotes esophageal squamous cell carcinoma progressions via Wnt/CTNNB1 pathway.

Z. Tian[1], Y. Zhou[1], Y. Ding[1], Z. Wu[2], **X. Zhao**[1];

[1]The Second Hospital of Shandong University, Jinhua Shi, China, [2]The Second Hospital of Shandong University, Jinan, China

The M6A RNA modification plays a crucial role in the progression of tumors. Simultaneously, IGF2BP3 is primarily expressed in the tumor cells of squamous cell carcinoma, rather than in stromal cells, including esophageal squamous cell carcinoma (ESCC), a subtype mainly prevalent in East Asia. However, the mechanism of IGF2BP3 in the progression of esophageal squamous cell carcinoma and its role in the tumor microenvironment (TME) remain unknown and require further exploration. Our research reveals that IGF2BP3 not only plays a significant oncogenic role in tumor cells, including the activation of the Wnt pathway, PI3K-AKT pathway, and MAPK pathway, but also, the high expression of IGF2BP3 is positively correlated with the enrichment of M2 macrophages in ESCC tissues, in the TME, IGF2BP3 promotes the infiltration of M2 macrophages, ultimately facilitating the progression of ESCC. Mechanistically, IGF2BP3 enhances the translation of USP36 mRNA by directly binding to its mRNA, rather than increasing the stability of mRNA. The IGF2BP3-mediated USP36 protein elevation enhances the binding capacity with CTNNB1 protein, reducing its degradation through the ubiquitin-proteasome pathway, and following improved the Wnt/CTNNB1 pathway activating. Ultimate, IGF2BP3 aggravated the malignancy of the tumor. Additionally, the activation of the Wnt pathway promotes TGFB1 transcription and secretion, subsequently activating the polarization of M2 macrophages, infuriating the formation of the tumor immune-suppressive microenvironment, ultimately promoting the progression of esophageal squamous cell carcinoma. Our findings strongly emphasize the oncogenic role of IGF2BP3 in the progression of ESCC both in vitro and in
vivo, providing new insights and perspectives for the treatment of esophageal squamous cell carcinoma.

#6848 Analysis of the bone microenvironment cells by single cell transcriptomics reveals altered features in multiple myeloma patients compared to pre-malignant monoclonal gammopathies.

P. Storti[1], T. Torelli[2], C. Manferdini[3], D. Toscani[1], A. Guidi[2], R. Vescovini[1], N. Iannozzi[1], B. Dalla Palma[4], M. Scita[4], F. Librale[4], S. Ricci[4], V. Raimondi[1], O. Lungu[1], G. Todaro[4], G. Sammarelli[4], E. Aleo[5], G. Lisignoli[3], L. Agnelli[2], N. Giuliani[1];

[1]University of Parma, Parma, Italy, [2]IRCCS Istituto Nazionale Tumori, Milano, Italy, [3]IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy, [4]Azienda Ospedaliero-Universitaria di Parma, Parma, Italy, [5]IGA Technology Services, Udine, Italy

Multiple myeloma (MM) is a malignant plasma cell dyscrasia that can be preceded by monoclonal gammopathy of undetermined significance (MGUS) and smoldering MM (SMM). How the bone microenvironment (BME) changes and contributes to tumoral progression in MM remains unresolved. Published data on BME are mainly produced *in vitro* and few data are on MGUS/SMM patients. Up to date, no single-cell RNA sequencing database of the BME cells has been described in MM. The aim of this project was to characterize for the first time at single cell level, the BME in patients with newly diagnosed MM (MMD) and MGUS/SMM to identify alterations involved in tumoral progression. From 15 bone biopsies of MMD, MGUS and SMM patients, we depleted CD235a+, CD45+, CD31+, and CD138+ cells to enrich the rare BME non-hemopoietic cells. The CD45-CD31-CD235a-CD138- cells were analyzed by scRNAseq. Data were generated on Chromium 10X Genomics. Cellranger and Seurat pipeline in R software has been used. Cell identities were assigned by manual curation. The trajectory analysis has been made by Monocle3. Decouple R and FindMarkers were used to compare pathways, and differential gene expression (DGE) of the samples throughout the different conditions. A total of 35723 cells were profiled. We identified 13 BME cell type clusters: 7 mesenchymal stromal cells (MSCs) clusters (proliferating MSC, MSC DDK-OPG-, MSC DKK+, MSC RUNX2-, MSC OPG+, MSC Osteogenic, Perivascular MSC) and 6 osteoblasts (OBs) clusters (OB precursor, OB precursor LEPR+, OB BGLAP+, OB SPP1+, OB NFkB+, OB late). Psdeudotime analyses highlighted a complex trajectory of differentiation from more immature cell clusters (proliferating MSC) to late OB cluster, confirming the ability of the dataset to snapshot the *in vivo* complexity of BME and we highlighted an alteration of the MSCs clusters trajectories starting in SMM samples till a disruption in MM. Pathway analyses, in MMD compared to MGUS/SMM, revealed an upregulation of VEGF and PI3K activity in proliferating MSC, perivascular MSC and OB clusters. TRAIL pathway activity, known to suppress MM cell proliferation, was upregulated in MSC osteogenic and OB BGLAP+ in MGUS. Finally, DGE analyses revealed the modulation of different genes, many not yet described in MM. MGUS MSCs clusters showed an upregulation of *FBLN1, SERPNF1* and MMD MSCs clusters dramatically downregulated *WISP2* and upregulated *SRGN*, involved in MM cell proliferation. Interestingly, in SMM samples, we reported an upregulation of genes involved both in the promotion of osteoblastogenesis (*SCARA3, SPON2*) and inhibition (*GREM1*), likely underling the attempt to contrast the establishment of altered BME, characteristic of MM. Our approach is able to dissect the complex organization of the BME and to highlight at single cells level the alterations of the BME in patients with MM compared to MGUS and SMM.

#6849 Characterizing a discernible stromal fibroblastic gene signature in the shift from high-grade prostatic intraepithelial neoplasia to aggressive prostate cancer.

Mohammad K. Alexanderani, Lucio Queiroz, Mohamed Omar, Claudio Zanettini, Hubert Pakula, Luigi Marchionni, Massimo Loda

Weill Cornell Medicine, New York, NY

Background: High-grade prostatic intraepithelial neoplasia (HGPIN) is a preneoplastic lesion that precedes the development of both indolent and aggressive variants of prostate cancer (PCa). However, the specific stromal molecular mechanisms underlying the progression of HGPIN and their contribution to epithelial cancer cell motility and invasiveness remain poorly understood. This study aims to elucidate the driver genomic alterations involved in shaping the perineoplastic stroma of HGPIN, with the goal of unraveling their role in promoting cancer invasion, and metastasis.

Methods: We performed gene expression profiling on laser capture microdissected perineoplastic stroma of HGPIN and PCa in tissue samples from 25 PCa cases, including 12 low-grade (Gleason 6) and 13 high-grade (Gleason >/= 8) cases. We used the standard moderated t-test from the Bioconductor limma package to assess the statistical significance of differential gene expression between perineoplastic stroma high grade PCa and perineoplastic stroma HGPIN, as well as between perineoplastic stroma low grade PCa and HGPIN. The -log10 *p*-values represents the level of statistical significance for each gene, while the log2 fold change represents the magnitude of gene expression difference between the two comparison groups. Additionally, we computed Gene Set Enrichment Analysis (GSEA) scores using the Bioconductor package and discerned the leading-edge genes among the pathways. This study is supported by the NIH-NCI-T32 program for next-generation pathologists at our institution.

Results: In the gene expression analysis comparing High Grade PCa and HGPIN, several genes, including ***POSTN, BGN, GREM1****, C1QA, THBS4, COL1A1, COL1A2, SFRP4, RNU6-847P, FCGR2P, and TOMM22,* exhibited the highest level of both biological and statistical significance. GSEA revealed that the multi-invasive pathway had the highest enrichment score (>2). Notably, the top overexpressed genes in this pathway exhibited a fibroblastic signature (in bold), including ***POSTN, BGN,*** **GREM1**, **FBN1,** *COL1A2,* **COL3A1, COL5A2**, *ASPN,* **SPARC**, *VCAN, COMP,* **INHBA**, *THBS2, and SFRP4.* The presence of this signature indicates the invasiveness of the disease. Importantly, these genes were not associated with the progression to low grade PCa, indicating their exclusive association with the aggressive variant.

Conclusion: To our knowledge, this study is the first to explore the stroma's role in HGPIN-to-aggressive PCa progression. It highlights a key stromal pathway enriched with fibroblastic gene signature. These findings offer potential biomarkers for targeted therapies and improved care through HGPIN patient stratification.

#6850 Unraveling molecular factors contributing to metallomic dyshomeostasis induced by triple-negative breast cancer using single-cell RNA sequencing.

N. R. Hum[1], J. M. Rolison[1], N. F. Leon[1], A. Navid[1], A. Sebastian[1], J. Wimpenny[1], G. Loots[2];
[1]Lawrence Livermore National Laboratory, Livermore, CA, [2]University of California, Davis, Davis, CA

Triple-negative breast cancer (TNBC) comprises 20% of breast cancer cases and exhibits an aggressive phenotype with increased metastasis; these patients have limited treatment options, poorer prognosis and higher mortality than other breast cancers (BC). Metallomics is a relatively new discipline that studies the abundance of metal ions in biological samples. Metallomic analysis has identified differences in BC patients in elements such as iron (Fe) and zinc (Zn) but it is unclear if these reflect metabolic changes in the tumor. In this study, we conducted metallomic profiling to characterize 55 trace elements in the circulation and in the tumor microenvironment of orthotopic mammary fat pad tumors from two isogenic BC cell lines (highly metastatic 4T1; nonmetastatic 67NR). We complemented this analysis with single-cell RNA sequencing of the tumor to determine if complementary changes occur in molecules known to utilize metals as co-factors or transporters and identify drivers of metal metabolism in different tumors. We performed analysis on systemic metal elements by examining whole blood (including blood cells and platelets) and plasma separately. Tumor samples were assessed at the whole tissue level, and we also profiled separated immune or non-immune cells from the tumor. Li, Na, Mg, P, S, K, Ca, Fe, Cu, Zn, Rb were detectable within 100ul of input of whole blood or plasma. Metallomic analysis of the tumor and associated cell populations detected differential levels of Na, Mg, P, S, K Ca, Fe, Zn, and Rb from an average of 200mg of tissue or 2 million cells. Based on scRNAseq analysis, 67NR tumors were composed of greater proportions of cancer cells relative to the 4T1 tumors (79.1% vs 58.8% of tumor cells respectively) and endothelial cells (2.5% vs 1.8%). 4T1 tumors contained an increased abundance of cancer-associated fibroblasts (5.6% vs 2.1%) as well as immune infiltration (33.8% vs 16.3%). Fibroblasts and macrophage populations also showed elevated metal transporter expression levels based on gene expression relative to other tumor residing cell types yet minor differences induced by cancer type. Cancer cells express high levels of metal transport genes (Zn, Ca, Co, Na, Mg, Fe). 67NR cancer cells exhibited increased gene expression of many metal-transporting proteins including numerous solute carrier (*SLC*) group of membrane transport proteins such as *Slc41a2* when compared to the more aggressive 4T1 cells. This study underscores the potential of linking metallomic profiling to tumor composition and cancer behaviors, offering a pathway for identifying novel biomarkers to differentiate aggressive and non-aggressive forms of breast cancer.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

#6851 The genomic, transcriptomic, and immunologic landscape of TEM8 (*ANTXR1*) in neuroendocrine neoplasms (NENs).

S. A. Kareff[1], H. Krause[2], A. Elliott[2], P. Hosein[1], E. Lou[3], H. Soares[4], M. Oberley[2], A. Chauhan[1];
[1]University of Miami, Miami, FL, [2]Caris Life Sciences, Phoenix, AZ, [3]University of Minnesota, Minneapolis, MN, [4]University of Utah, Salt Lake City, UT

Introduction: TEM8 (coded by *ANTXR1*) is overexpressed in malignant tissues, with oncolytic viruses such as SVV-01 uniquely binding to this receptor on tumor-associated angiogenic endothelial cells, pericytes, fibroblasts, and immune inflammatory cells. Recent pre-clinical data suggest that TEM8-targeting therapies may convert immunologically “cold” tumor microenvironments (TME) into “hot” milieu more amenable to treatment with immune checkpoint inhibitors (ICIs).
Methods: NextGen sequencing of DNA (592 genes or WES) and RNA (WTS) was performed on neuroendocrine neoplasms (NENs; *N* = 1724), excluding small-cell lung cancer, submitted to Caris Life Sciences (Phoenix, AZ). Mutations were defined as pathogenic SNVs/indels. *ANTXR1* expression was divided by *ANTXR1*-expression quartiles (transcripts per million [TPM];Q4:^{H};Q1:^{L}). PD-L1 expression (SP142; Positive (+): ≥2+,≥%5) was assessed by IHC. High tumor mutational burden (TMB-H) was defined as ≥10 mutations per MB. Cell infiltration in the TME was estimated by QuantiSEQ. Gene expression profiles were analyzed for transcriptional signatures predictive of response to immunotherapy (T cell-inflamed) and MAPK pathway activation score (MPAS). Overall survival (OS) data was obtained from insurance claims, and Kaplan-Meier estimates were calculated for molecularly defined subpopulations of patients. Mann-Whitney U and X^2/Fisher-Exact tests were applied where appropriate, with *p*-values adjusted for multiple comparisons ($p<0.05$).
Results: NENs from the adrenal gland had the highest median *ANTXR1* expression (50 TPM), followed by those from the colon and rectum (43.5), genitourinary organs (43.3), and small bowel (excluding appendix) (39.2). The lowest median *ANTXR1* expression was observed in NENs from the pancreas (31.5). No pathogenic mutations were significantly associated with *ANTXR1*^{H} vs ^{L} tumors ($p>0.05$ for all), along with no differences in the prevalence of TMB-H (8.6% vs 12.6%, $p=1$) or PD-L1+ (5.8%: vs 3.1%, $p=1$). A greater proportion of B cells (5.34 % vs 3.78%, $p<0.001$), M1 (1.46% vs 0.15%, $p<0.001$) and M2 macrophages (3.92% vs 2.67%, $p<0.001$), and T-regulatory cells (1.77% vs 1.08%, $p<0.001$) was observed in ANTXR1^{H} TMEs, which were more frequently classified as T cell-inflamed compared to *ANTXR1*^{L} (42% vs 8%, $p<0.001$). *ANTXR1*^{H} tumors also had higher MPAS compared to *ANTXR1*^{L} (1.16 vs -1.61 arbitrary units, $p<0.001$). There was no significant difference in median OS between *ANTXR1*^{H} vs ^{L} tumors (18.8 mo. vs 21.2 months, Hazard Ratio:1.18, $p=0.114$).
Conclusion: The increased immune cell infiltrate and prevalence of T-cell inflamed status among *ANTXR1*^{H} NENs suggests these tumors might be more responsive to treatment with ICIs. As trials incorporating intratumoral injections of SVV-01 in combination with ICIs are underway, further investigation of clinical and molecular associations with *ANTXR1* expression in NENs is warranted.

#6852 Immune microenvironment profiling of pregnancy associated breast cancer: A transcriptomic and multiplex immunohistochemical analyses.

I.-C. Chen[1], C.-H. Chen[2], C.-L. Hsu[3], T.-P. Lu[2], Y.-S. Lu[3], C.-H. Lin[1];

[1]National Taiwan University Cancer Center (NTUCC), Taipei, Taiwan, [2]National Taiwan University, Taipei, Taiwan, [3]National Taiwan University Hospital, Taipei, Taiwan

Background: Pregnancy-associated breast cancer (PABC) is BC diagnosed during pregnancy or within 2 years after pregnancy. Although PABC is a rare subgroup of BC, the outcome of PABC is worse than BC developed in the same age group unrelated to pregnancy. The proliferation and involution of mammary gland during and after pregnancy create a unique immune microenvironment in the breast. Comprehensive profiling of the tumor immune microenvironment in PABC is important but lacking.

Methods: We retrospectively identified PABC patients from electronic medical records and their tumor blocks from pathology department in our institution. Age- and stage-matched BC patients were selected as control group. NanoString Breast Cancer 360 Gene Expression panel and Opal Polaris 7 color immunohistochemical (IHC) were utilized to profile PABC from transcriptome and protein levels.

Result: PABC (N=26), BC developed 2 years (BC>2Y, N=54) after pregnancy, and matched non-pregnant BC patients (NPBC, N=27) were included in the final analysis respectively. Samples from BC>2Y (remote influence from pregnancy) and NPBC (pregnancy did not contribute to BC) both served as control groups for PABC patients in our study. PAM50 subtyping categorized patients into luminal A(N=42), luminal B(N=26), basal(N=12), and HER2 (N=25) enriched subgroups. In multiplex IHC analysis, CD4+ cells, CD8+ cells, CD20+ cells, and CD68+/CD163+ (M2) cells were all statistically higher in the tumor samples from PABC and BC>2Y than from NPBC. This suggests a potential contribution of pregnancy in the immune microenvironment. In the luminal A subgroup, CD8+ cells, CD20+ cells, and CD68+/CD163+ cells remain statistically higher in the PABC than in the NPBC samples. In NanoString BC360 transcriptomic profiling, immune cell abundance was evaluated from representative gene signatures. Mast cells were significantly lower in the PABC group than in the NPBC group. Cytotoxic T cells are significantly higher both in the PABC and BC>2Y groups than in the NPBC group.

Conclusion: We are the first study to profile immune microenvironment using both transcriptomic and IHC methods. Our study is also unique in using NPBC and BC>2Y patients as control groups for PABC patients. CD8+ T cells are statistically higher in PABC patients than in NPBC patients using either transcriptomic profiling or multiplex IHC analysis. M2 macrophages, which promote tumor growth, are abundant in all the PABC and the luminal A PABC samples.

#6853 Spatial proteomic and transcriptomic characterization of the inflammatory landscape of formalin fixed paraffin embedded Barrett's esophagus tissues.

Q. Ain[1], N. Frei[2], A. M. Khoshiwal[2], P. Stougie[2], R. Odze[3], S. Camilleri-Broet[4], L. Ferri[4], L. C. Duits[2], J. Bergman[2], M. D. Stachler[1];
[1]UCSF - University of California San Francisco, San Francisco, CA, [2]University of Amsterdam, Amsterdam, Netherlands, [3]Tufts University, Boston, MA, [4]McGill University, Montreal, QC, Canada

Esophageal adenocarcinoma (EAC), a significant cause of morbidity and mortality, develops from its metaplastic precursor lesion termed Barrett's esophagus (BE). BE progresses to EAC within an inflammation rich environment, however a detailed understanding of the types of inflammatory cells present, how that population changes over time or diagnosis, and the related immunomodulatory pathways that may mediate BEs progression is still understudied. Traditional immunohistochemistry is often inadequate to provide detailed information about a broad number of cells, local cellular proportions, and cellular heterogeneity; while bulk or single cell RNA sequencing lose the spatial context and relationships between the stroma and epithelium. Utilizing modern multiplex profiling technologies such as Nanostring's GeoMx digital Profiler (DSP) aid in identifying both cellular composition and distribution of cells within the epithelium and stroma. Therefore, our aim of this study was to determine the suitability of the DSP platform for analyzing formalin fixed paraffin embedded (FFPE) endoscopic samples of BE and determine any differences between non-dysplastic BE (NDBE) samples from patients who eventually progressed (progressors) compared to those who did not (non-progressors), with the goal to gain deeper insights about cellular composition and spatial distribution of immune cells that may dictate progression of BE. Our secondary goal was to investigate the relationship of these cells to the BE epithelial cells through understanding the immune signaling and regulatory pathways. Our pilot study utilizing a 49-plex antibody panel on 7 NDBE samples from progressors and 8 NDBE samples from non-progressors showed good quality metrics and deciphered an immune rich microenvironment in BE with several immune markers including CD66b (neutrophils), CD14 (monocytes), CD68 (macrophages) and CD56 (NK cells) being overexpressed in the stroma of progressors compared with non-progressors, corrected p value less than 0.05. The myeloid activation marker CD80 was overexpressed in the BE epithelial cells of progressors. To determine how spatial transcriptomic profiling performed in FFPE endoscopic samples, 1,812 transcripts within 48 regions of interest of four BE, HGD, and EAC samples was interrogated. Only 36 (2%) probes fell below the limit of detection quality threshold. Thus, our pilot results show that robust proteomic and transcriptomic profiling can be obtained from endoscopic BE biopsies using this system. Based on these results, we systematically interrogated the immune cell makeup and distribution as well as their related inflammatory and immunoregulatory pathways in 40 NDBE biopsies (20 progressors and 20 with stable non-progressing disease) within discrete compartments (stroma and epithelium) through spatial whole transcriptome profiling.

TUMOR BIOLOGY: Immune Cells in the Tumor Microenvironment 2
Poster Session

#6857 Evolution of myeloid-mediated mechanisms of immunotherapy resistance at single-cell resolution with prostate cancer progression.

A. Lyu[1], Z. Fan[1], D. Luong[1], A. Setayesh[1], A. Starzinski[1], L. Valderrabano[2], E. Van Allen[2], L. Fong[1];
[1]UCSF - University of California San Francisco, San Francisco, CA, [2]Dana-Farber Cancer Institute, Boston, MA

Background: Patients with metastatic castration-resistant prostate cancer (mCRPC) are largely refractory to immune checkpoint inhibitors (ICIs). This resistance is, in part, attributed to the presence of immunosuppressive myeloid cells in tumors. However, attempts to target these cells broadly, such as CSF1R antagonism, have thus far failed clinically primarily due to their heterogeneous nature. Thus, we hypothesized that a more comprehensive understanding of immunosuppressive myeloid subsets and their molecular mechanisms at the single-cell level is critical to enhance the effectiveness of immunotherapy.
Methods: We performed single-cell profiling of patient biopsies with either localized, metastatic hormone-sensitive prostate cancer, or mCRPC. We then reverse translated these findings in a syngeneic mouse model of CRPC, where we performed multi-omic single-cell assessment and conducted studies to assess tumor efficacy and gain mechanistic insights.

Results: We identified a specific subset of tumor-associated macrophages with elevated hypoxia signatures, including higher *SPP1* transcript levels (*SPP1*^{hi}-TAMs). These macrophages become significantly more abundant as the disease advances, expressing elevated immunosuppressive molecular programs. Notably, *CSF1R* transcripts were significantly reduced in *SPP1*^{hi}-TAMs, suggesting their potential role in the clinical ineffectiveness of CSF1R blockade. In a syngeneic mouse CRPC model, we identified an analogous macrophage subset through single-cell profiling and flow cytometry. These macrophages possess the ability to suppress T cell activity in co-culture. Consistent with these findings, adoptive transfer of *Spp1*^{hi}-TAMs into CRPC promoted ICI resistance and worsened survival in vivo. Importantly, these macrophages proved resistant to anti-CSF1R treatment, underscoring the need to target their immunosuppressive signals as a potential therapeutic approach. Pathway analysis revealed enrichment of gene signatures associated with adenosine signaling in *SPP1*^{hi}-TAMs both in patients and in mice, implicating this pathway as their immunosuppressive mechanism. Indeed, blocking adenosine signaling using antibodies or pharmacologic inhibitors resulted in a significant reduction in T cell suppression mediated by *Spp1*^{hi}-TAMs in culture. Furthermore, pharmacologic blockade of adenosine receptors in vivo significantly decreased tumor growth and enhanced the responsiveness of tumor cells to ICI therapies.

Conclusions: Our studies demonstrate that *SPP1*^{hi}-TAMs become prevalent as the disease progresses. They are resistant to CSF1R blockade and play a key role in mediating immunotherapeutic resistance in vivo by activating adenosine signaling pathways. These findings highlight the potential of the associated signals as promising targets for therapeutic intervention.

#6858 PPARδ and type 1 interferon collaboratively regulate CIITA-MHCII pathway: Unveiling novel mechanisms of tumor Tregs.

Q. Yang, Y. Liang, Y. Zheng;
Salk Institute For Biological Studies, San Diego, CA

Regulatory T cells (Tregs) play an essential role in suppressing anti-tumor immunity, often resulting in unfavorable clinical outcomes across numerous cancers. However, systemic Treg depletion, while augmenting anti-tumor responses, also triggers detrimental autoimmune disorders. Thus, dissecting the mechanisms by which Tregs navigate and exert their functions within the tumor microenvironment (TME) is pivotal for devising innovative Treg-centric cancer therapies. Our study highlights the role of peroxisome proliferator-activated receptor β/δ (PPARδ), a nuclear hormone receptor involved in fatty acid metabolism. Remarkably, PPARδ ablation in Tregs escalated tumor growth and augmented the immunosuppressive characteristics of the TME. This absence of PPARδ spurred an increased expression of genes central to antigen presentation, notably CIITA and MHCII. Our results showcase a novel association where the absence of CIITA in PPARδ-deficient Tregs bolsters anti-tumor responses, casting CIITA as a pivotal downstream regulator of PPARδ within Tregs. In vitro assays demonstrated that elevated CIITA levels enhance the suppressive capacity of Tregs, facilitated by an antigen-independent interaction between Treg-MHCII and Tconv-TCR/CD4/Lag3. A significant revelation was the role of type 1 interferon as a TME signal that promotes the genesis of MHCII^{+} Tregs; this process is accentuated by PPARδ deficiency. In conclusion, the co-regulation between TME cues and PPARδ signaling shapes the adaptive and suppressive roles of Treg cells through the CIITA-MHCII pathway. Strategically targeting the potent MHCII^{+} Treg population could open a new avenue for cancer therapies by boosting anti-tumor defenses while curbing autoimmune threats.

#6859 A novel immune checkpoint CD97/CD55 in the initiation and progression of papillary thyroid cancer by scRNA-seq.

Xuan Qin[1], Jia Li[2], Dapeng Li[1], Xing Wan[1], Xianhui Ruan[1], Yimeng Liu[1], Weijing Hao[1], Kejia Xu[2], Yi Shi[2], Yongjun Piao[2], Xiangqian Zheng[1]

[1]Department of Thyroid and Neck Oncology, Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China,[2]The School of Medicine, Nankai University, Tianjin, China

Thyroid cancer (TC), as the most common endocrine malignancy, has exhibited a significant increasing trend in incidence in China and globally, with papillary thyroid cancer (PTC) being the most common pathological type. However, the molecular mechanisms driving the initiation and progression of TC remains scarce, posing a bottleneck problem for the precise diagnosis and treatment. Tumors, as a complex heterogeneous composite consisting of tumor cells, immune cells, and stromal cells, have long been considered to play a key role in driving tumor occurrence and malignant progression through the proportion, spatial distribution, and interaction of tumor cells and immune cells in the tumor immune microenvironment(TIME).We performed single-cell RNA sequencing (scRNA-seq) on 16 clinical samples, including normal thyroid tissue, benign nodules, PTC, and PTC with cervical lymph node metastasis(LNM), delineating the cell atlas of the tumor microenvironment (TME) at various stages from normal thyroid to PTC development. Among these, we discovered a previously undefined $TNFSF9^{high}CD8^{\pm}$ T cell subset with a distinct transcriptional profile from classical exhausted T cells, which was highly enriched in PTC tumor tissues. Further cell interaction analysis revealed that the highly expressed CD97 receptor on these $CD8^{\pm}$ T cells binds to the highly expressed CD55 molecule on PTC tumor cells, promoting the exhaustion of $CD8^{\pm}$ T cells, suggesting that CD97/CD55 may be a key new immune checkpoint (IC) inducing $CD8^{\pm}$ T cell exhaustion and promoting immune escape of PTC tumor cells. We validated the co-localization of CD97/CD55-mediated $CD8^{\pm}$ T cell and tumor cell interactions in PTC patient specimens and spontaneous tumor samples from a mouse PTC model using multiplex immunofluorescence (mIHC). Flow cytometry analysis of the proportion of $CD97^{\pm}$ $CD8^{\pm}$ T cells in patient and mouse specimens revealed a significant increase in the proportion of $CD97^{\pm}$ $CD8^{\pm}$ T cells in PTC tumor tissues. Co-culture experiments of activated and expanded $CD8^{\pm}$ T cells from peripheral blood mononuclear cells(PBMC) of PTC patients with PTC tumor cells showed that CD55 overexpressing tumor cells inhibited the secretion of cytotoxic cytokines IFN-γ and IL-2 by activated $CD8^{\pm}$ T cells through the CD97/CD55 IC signal, thereby weakening the cytotoxity on PTC tumor cells. In summary, the IC regulatory signal formed by the highly expressed CD55 molecule on the surface of PTC tumors and the CD97 receptor on the surface of PTC-specific inhibitory $TNFSF9^{high}CD8^{\pm}$ T cells can reshape the TIME, promoting the formation of an immunosuppressive microenvironment, which may represent a novel molecular mechanism promoting immune escape of tumor cells during PTC initiation and progression.

#6860 Fluorescent tracking reveals that radiation therapy influences the migration and plasticity of Tregs within the tumor microenvironment.

D. J. Friedman[1], T. Blair[1], G. Kramer[1], A. Kaur[1], J. Baird[1], A. Alice[1], M. Potuznik[1], M. R. Crittenden[2], M. J. Gough[1];
[1]Earle A. Chiles Research Institute, Portland, OR, [2]The Oregon Clinic, Portland, OR

Radiation therapy (RT) has long been a cornerstone in cancer treatment, yet the mechanisms underlying its impact on the immune system remain incompletely understood. RT is recognized for its ability to induce DNA damage within cancer cells, leading to cancer cell death. For those cancer cells that do not die as a result of radiation, tumor infiltration by immune cells is closely associated with treatment outcomes. T cell infiltration is a dynamic process, with subsets taking up residence in the tumor while the majority recirculate through lymph nodes into the peripheral blood. T regulatory cells (Tregs) have been recognized as potent suppressors of anti-tumor immune responses, dampening immune-mediated clearance of cancer cells. While RT can initially contribute to an improved anti-tumor immune response, this beneficial effect is often counterbalanced by the presence of suppressive Tregs. Tregs can infiltrate the tumor microenvironment, ultimately impeding and overwhelming the immune response generated by RT. Our objective was to gain insights into the migratory patterns of Tregs to and from tumor sites and to elucidate how RT influences the dynamics of Treg recirculation. Utilizing the established photoconvertible Kaede mouse model we can track photoconverted cells following RT. Following photoconversion, photoconverted T cells were observable within the tumor and subsequently moved to the TdLN and on to other NdLN at later time points. In the TdLN of mice bearing MC38, Moc1, and Moc2 tumors, Tregs represented a significantly higher proportion of photoconverted cells compared to non-Treg CD4 or CD8 T cells. To validate their active departure from the tumor site, mice underwent FTY720 treatment, resulting in a reduction in both photoconverted Treg and non-Treg migration to the TdLN. When RT was administered to the tumor, there was a decrease in photoconverted Treg and non-Treg CD4 T cells within the TdLN, consistent with the expected cytotoxic effects on the irradiated tumor upstream. To focus on recruitment back from the TdLN, mice were analyzed after photoconversion of the TdLN. This revealed that a majority of TdLN Tregs exhibited a preference for relocating to the tumor, with only a minority migrating to the NdLN. The newly entered Tregs were analyzed in the tumor, at D1 and D3 post RT, and we found that these Tregs exhibited increased expression of CCR8, CD69, KLRG1 and Ly6C as compared to those in non-irradiated tumors, suggesting that these are recent entrants with limited suppressive capacity. These findings illuminate the intricate dynamics between RT, Tregs, and the use of site-specific photoconversion to track immune cell movement and changes over time to understand treatment responses. Our ongoing studies focus on the interplay between the Treg and the tumor environment that dictates the success of CD8 T cell mediated control of residual cancer cells following RT.

#6861 PIK3CA activating mutation promotes an immune suppressive microenvironment in squamous cell carcinoma.

B. T. Nicholson, W. Guo, Y. Miao;
University of Chicago, Chicago, IL

Head and neck squamous cell carcinoma (HNSCC) is a leader in cancer incidence worldwide. Recently, immunotherapies such as immune checkpoint blockade (ICB) have offered great promise in treating many solid tumors, including HNSCCs, that are refractory to chemotherapy and radiation. Challengingly, HNSCC patients often relapse following ICB treatment due to the lack of a thorough understanding of the mechanisms underlying cancer immune evasion. These disparities in patient outcomes strongly suggest the existence of genetic variations that underlie their distinct responses to ICB. Although the specific oncogenic mutations responsible for driving relapse in SCC patients remain unclear, it is imperative to grasp the mechanisms of cancer immune evasion in individuals with specific genetic profiles to enhance the precision of immunotherapy. Cancer immune evasion has emerged as a hallmark of cancer and is facilitated by a highly complex tumor microenvironment (TME). We aim to understand the genetic basis shaping the immune suppressive TME and hypothesize that oncogenic driver mutations play a dominant role in preventing the immune clearance of transformed cells by reprogramming the immune landscape in the tumors. To determine the critical genetic signatures enriched in SCC patients that can impact anti-tumor immunity, we analyzed TCGA data which revealed a strong negative correlation between *PIK3CA* level and CD8 T cell signatures. We have identified that activating mutations in the *PIK3CA* gene, found in 20% of HNSCCs, promote rapid tumor relapse after initial response to anti-PD-L1 and anti-CTLA-4 ICB treatments. Utilizing single-cell analysis, quantitative immune profiling, and multiplexed imaging, our lab showed that tumor-initiating cells (TICs) in SCCs can have an intricate dialogue with myeloid-derived suppressor cells (MDSCs) where TICs secrete factors to enhance MDSC recruitment and suppressive function on cytotoxic T cells. Additionally, our data supports that the tumor interstitial fluid (TIF) of *PIK3CA* mutant SCC tumors can enhance the suppressive activity of MDSCs on cytotoxic T cells. These results suggest that the acquisition of *PIK3CA* mutation may trigger TICs to release additional factors to further modify MDSC activities. A critical method by which MDSCs suppress T cells is through the production and respiratory burst of reactive oxygen species (ROS). RNA sequencing revealed that *PIK3CA* mutant SCCs have multiple mechanisms of increasing ROS in the TME and specifically in MDSCs, while simultaneously upregulating lipid metabolism genes, such as SCD1, to protect itself from MDSC-derived ROS. This study reveals a potential strategy for targeting *PIK3CA* mutant SCCs as a promising precision immunotherapy to enhance the efficacy of ICB treatments.

#6862 Loss of STAT1 promotes an immunosuppressive tumor microenvironment in KRAS-driven lung adenocarcinoma.

C. Trenk[1], M. Beres[1], K. Deszo[2], J. Horvath[1], M. Homolya[1], A. C. Luca[1], R. Eferl[1], H. P. Moll[1], E. Casanova[1];
[1]Medical University of Vienna, Wien, Austria, [2]Semmelweis University, Budapest, Hungary

Introduction: Lung cancer is the leading cause of death worldwide. One third of lung adenocarcinomas (LUADs), the most abundant form of lung cancer, harbors activating mutations in KRAS. Since human KRAS-mutant LUAD is correlated to an inflammatory phenotype, we hypothesized that the JAK-STAT pathway plays a crucial role in disease progression. Indeed, preliminary data demonstrated that human KRAS-mutant LUADs are associated with activation of the JAK-STAT signaling pathway, including upregulation of STAT1 expression. Therefore, we aimed to elucidate the tumorigenic functions of STAT1 in KRAS-mutant LUAD.
Methods: To analyze the functions of STAT1 in KRAS-driven LUAD, we used C57BL/6 mice, which were genetically engineered in order to develop KRAS-driven autochthonous LUAD deficient for P53. Tumors additionally expressed ovalbumin (OVA) which acts as a neoantigen to induce immune infiltration (KPO mice). In this immunogenic mouse model, STAT1 was deleted in the tumors (KPOS mice) and overall survival was assessed by Kaplan Meier analysis. Tumor burden and infiltration was analyzed in lungs via H&E, IHC, and IF staining 6 weeks after tumor induction. An inflammatory cytokine antibody array was performed with lung fluid and single cell sequencing with cells isolated from lungs at 10 weeks.
Results and discussion: Expression of OVA in tumor cells increased infiltration by T cells and prolonged survival suggesting neoantigen presentation in this mouse model. When STAT1 was deleted in OVA expressing tumors the survival was significantly decreased. Further, tumor burden as well as tumor size and grades were increased in KPOS lungs. Interestingly, infiltration of CD4 T cells was diminished upon loss of STAT1 while the percentage of CD8 T cells in tumors did not change suggesting an immunosuppressive tumor microenvironment. Indeed, M2 macrophages were increased in tumors lacking STAT1 and less proliferating immune cells were found indicating immune cell inhibition. This was further supported by the increase of CCL9 in KPOS lungs which might induce macrophage recruitment and further T cell inhibition. Finally, scRNAseq analysis revealed that KPOS lungs were composed of distinct immune cell populations as well as states.
Conclusion: This data suggests that loss of STAT1 in tumor cells promotes secretion of CCL9 that drives recruitment of immunosuppressive macrophages to the tumor microenvironment. As a result, T helper cells are excluded from tumors and cytotoxic T cells are inhibited or exhausted. Further experiments will delineate the immune cell states and the mechanisms leading to this interesting phenotype.

#6864 Tumor suppressor function of the ubiquitin ligase Siah1a in melanoma is mediated by myeloid derived suppressor cells.

M. Scortegagna, Y. Du, y. Feng, Z. Ronai;
Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA

Growing evidence supports the important role of myeloid-derived suppressor cells (MDSC) in melanoma progression and response to therapy. MDSC contributes to a pro-tumorigenic phenotype, yet the mechanistic basis for the immune suppressor properties acquired by MDSC remains largely unknown. Mammals have two homologous Siah genes, *Siah1 (Siah1a and Siah1b* in mice*)* and *Siah2*. In the context of melanoma, the ubiquitin ligases *Siah1a* and Siah2 have melanoma-intrinsic and -extrinsic (immune) functions. Correspondingly, ablation of Siah1a/2 in melanoma or its microenvironment attenuates melanoma development in a number of mouse melanoma models. Given that number of macrophage clusters infiltrated into melanoma when grown in Siah2 KO mice, we set to assess macrophage function in melanoma. Selective ablation of Siah1a or Siah2 in macrophages, using *Lyz2*^{Cre}, revealed that Siah1a but not Siah2 elicits a tumor suppressor function in melanoma. Inoculation of mouse melanoma Yummer1.7 cells (*Braf* mutated and *Pten* deleted) in mice lacking *Siah1a* in macrophages, resulted in bigger melanoma tumors compared to melanoma grown in either WT or mice in which macrophages were ablated of Siah2. FACS analysis of melanoma tumors grown in mice harboring Siah1a mutant macrophages revealed a significant increase in MDSC, which coincided with a decrease in CD4$^{\pm}$ and CD8$^{\pm}$ cells, compared with WT mice. These observations suggest that a lack of *Siah1a* in macrophages leads to an expansion of MDSC that affects surrounding immune cells, including T cells. RNA-seq analysis of MDSC that were differentiated *in vitro* from bone marrow cells of WT or Siah1a ablated macrophage mice revealed increased expression of genes involved in proliferation and alternative macrophage activation in MDSC lacking Siah1a when compared to the WT genotype. Mapping mechanisms underlying Siah1a tumor suppressor function is expected to reveal novel regulatory cues in melanoma control by the MDSC population while mapping novel means for stratifications of melanoma to therapy, and possibly new means for therapy of this tumor type.

#6865 Single cell analysis of melanoma reveals a prognostic myeloid cell associated with survival in melanoma with brain metastases.

M. Ahmad, L. Heo, R. V. Nair, S. Sharma, A. Kirane;
Stanford University School of Medicine, Stanford, CA

INTRODUCTION: The interface of the innate and adaptive immune system are a critical factor in tumor behavior and responses to immunotherapy with myeloid cell behavior varying widely between various biogeographies. We sought to elucidate myeloid sub-type differences to characterize biology and support therapeutic strategies.

METHODS: scRNA-seq of primary skin, acral, and metastatic melanoma were combined from 6 datasets with 126 patients for analysis. After integration, cells were analyzed with scCCESS, which uses an artificial neural network to reduce data and optimize k for k-means clusters. Myeloid clusters with analyzed with Recursive Partitioning Analysis (RPA), differential expressed gene (DEG) analysis, and pseudobulk comparison of RPA groups by gene expression.

RESULTS: 102,971 single cells from 126 patients were analyzed to generate a cluster of 15,303 myeloid cells further subjected to clustering generating 6 cell types. RPA analysis of 6 myeloid populations in 46 patients with melanoma brain metastases generated 3 nodes with differing median survival months (17 vs 41 vs 57, p=0.01). There was a trend towards more adjuvant immunotherapy (p=0.057) and targeted therapy (p=0.019) in the worst surviving group. Myeloid type 1 cells showed increased expression of CLEC10A and AXL genes compared to all other cells (adj p = 0.000). Pseudobulk comparison of patient groups of genes showed CLEC10A was significant between all groups (p<0.05).

CONCLUSIONS: Although there were no significant differences in neoadjuvant treatment, increased infiltration of CLEC10A myeloid cells showed improved survival in melanoma brain metastases. Targets of current therapies, such as AXL tyrosine kinase, have heterogenous presence across multiple cell types beyond tumors that may impact wide response variances, further study of these populations will have significant impact in both biomarker and therapeutics development.

#6866 Investigating the role of Epha2 in breast cancer-mediated myeloid cell expansion and function.

D. Parker, V. Ngwa, J. Chen, J. Rhoades;
Vanderbilt University, Nashville, TN

Bone metastases are present in over 70% of metastatic breast cancer patients, and current therapy reduces osteolysis in tumor-induced bone disease (TIBD) but does not improve overall survival. Frequently, TIBD is characterized by an increase in osteoclast proliferation and bone-resorbing activity, and patients often experience pain and pathologic fractures. Increased bone resorption releases growth factors that aid in the progression of tumor growth causing the 'vicious cycle'. Additionally, bone metastatic patients are often resistant to first- and second-line therapies highlighting an importance for research in this area. The receptor tyrosine kinase, Ephrin-type-A 2 receptor (EphA2), participates in both forward and reverse signaling during receptor/ligand engagement and participates in many physiological and pathological processes, including bone homeostasis, immunity, and cancer. Interestingly, EphA2 is highly expressed in bone metastases, and previous evidence suggests that EphA2 can promote TIBD and reduce anti-tumor immunity. We therefore hypothesize that *increased expression of EphA2 in breast cancer cells at the site of bone metastasis promotes expansion of myeloid cells, leading to TIBD*. Previous data shows a reduction in osteoclast number and bone lesions following EphA2 knockout. However, the mechanism by which EphA2 mediates the expansion of osteoclasts is not well understood. In agreement with previous work, our data shows that EphA2 deletion in murine breast cancer (BC) cell line, 4T1, reduces bone lesion area and number and the presence of bone metastasis-associated macrophages. Additionally, we observed a significant reduction in $Ly6C^{hi}$ cells. To assess the effects of EphA2 deletion on the behavior of 4T1 cells, we conducted a wound healing assay and observed a decrease in wound healing capacity in 4T1 cells following EphA2 deletion. This suggests that EphA2 expression in 4T1 cells may increase their metastatic potential. We will repeat these studies and incorporate factors from the bone marrow. Our future studies will investigate the role of EphA2 signaling and reverse signaling in BC cell lines, myeloid progenitor cells, osteoclasts, and bone metastasis-associated macrophages. We will utilize murine and human BC cell lines to elucidate the effects of EphA2 deletion in BC on immune cell populations, bone metastasis, and tumor progression. Additionally, we will investigate how EphA2 reverse signaling impacts osteoclasts' ability to modulate immune cells. We aim to reduce TIBD and tumor burden by reducing the expansion of osteoclasts and shifting the immune cells to an anti-tumorigenic phenotype. Our studies will provide additional insight into the underlying mechanisms of the vicious cycle which will offer new treatment strategies for patients with osteolytic breast cancer.

#6867 TWEAK-Fn14 signaling in glioblastoma-associated myeloid cells promotes tumor invasion via CCL5-CCR5 axis.

A. Beniwal[1], M. Dufault[2], P. Kanvinde[3], D. Nascari[1], R. Eghlimi[1], A. Malla[4], D. Hambardzumyan[5], H. Borges da Silva[6], G. Woodworth[3], J. Winkles[3], N. Tran[6]; [1]Mayo Clinic College of Medicine and Science, Scottsdale, AZ, [2]Midwestern University College of Osteopathic Medicine, Glendale, AZ, [3]University of Maryland School of Medicine, Baltimore, MD, [4]University of Maryland, Baltimore, MD, [5]Mount Sinai School of Medicine in New York City, New York, NY, [6]Mayo Clinic Arizona, Scottsdale, AZ

Glioblastoma remains difficult to treat with immunotherapy due to the immunosuppressive tumor microenvironment and the ability of glioma cells to invade diffusely into normal brain parenchyma. While it is known that glioblastoma-associated myeloid cells (GAMs) comprise a large proportion of the tumor microenvironment and can suppress adaptive and innate immune responses through various mechanisms, detailed mapping of myeloid lineages in glioblastoma is still missing. Further characterization of pro-tumoral myeloid-lineages in glioblastoma is important for identifying myeloid-based drug targets that may synergize with T cell-based therapies and produce a more meaningful anti-tumor immune response. Towards this end, we examined numerous scRNAseq datasets derived from glioblastoma patients and identified expression of TNFRSF12A, the gene encoding the TNF- family receptor, Fn14, in a subset of GAMs enriched for expression of cytokines such as CCL3, CCL5, IL-6, and IL-8. This result is intriguing since TWEAK (TNFSF12), the ligand for Fn14, is abundantly expressed within numerous patient-derived glioblastoma cell lines, namely GBM6, GBM8, GBM22, and GBM39. To validate Fn14 protein expression in GAMs, we isolated murine bone-marrow derived macrophages and treated them with glioma-conditioned media, which induced Fn14 gene expression. We then conducted *in vitro* experiments utilizing the human microglia line HMC3, the murine microglia line SIM-A9, and primary murine bone-marrow-derived macrophages to assess the effects of Fn14 activation in myeloid cells. We found that treatment of Fn14+ myeloid cells with TWEAK ligand upregulates CCL3, CCL5, IL-6, and IL-8 expression. We tested the conditioned media generated from TWEAK-treated Fn14+ myeloid cell lines and found that it promotes glioblastoma invasion in a CCL5-dependent manner. This aligns with previous reports demonstrating the CCL5-CCR5 signaling in glioma cells promotes invasion through calcium-dependent matrix metalloproteinase 2. To assess the spatial distribution of this myeloid subpopulation, we performed RNAscope hybridization against AIF1, TMEM119, CCR5, CCL5, and Fn14 transcripts on sections of murine gliomas generated using the RCAS/tv-a model of human glioblastoma. We found an abundance of Fn14+ plus AIF1+ as well as Fn14+plus TMEM119+ myeloid cells throughout the tumor core and rim of murine tumors and identified CCL5 expression in pseudo-palisades bordering necrotic regions. Our results to date suggest that Fn14 expression in GAMs can promote the invasion of tumor cells into normal brain parenchyma by release of CCL5. Currently, we are utilizing orthotopic patient-derived xenograft models co-implanted with Fn14+/- myeloid cells to test the hypothesis that TWEAK-Fn14 signaling in GAMs provides strong pro-tumoral signals in the glioblastoma microenvironment.

#6868 Exploring myeloid landscapes according to EGFR mutated NSCLC tumor microenvironment.

E. Lee[1], J. Ahn[1], Y. Lee[1], M. Kim[2], S. Oh[1], Y. Park[1], S.-J. Choi[1], J. Lee[1], K. Lim[2], K.-H. Pyo[1], J. Kim[3], J. Lee[1], M. Hong[1], S. Lim[1], M. Yun[3], B. Cho[1];
[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]JEUK Institute for Cancer Research, JEUK Co., Ltd.., Gumi, Korea, Republic of, [3]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: Although the use of immune checkpoint inhibitors (ICIs) has improved the survival rate of some patients, EGFR mutant (MT) NSCLC patients exhibit a poor response to ICIs compared to EGFR wild-type (WT) patients. It has been demonstrated that EGFR MT NSCLC cells contribute to immunosuppressive tumor microenvironments (TMEs) by secreting inhibitory cytokines and metabolites and recruiting pro-tumor immunogenic cells, thereby diminishing ICI efficacy. In particular, myeloid cells represent a major component of the TME and are involved in regulating tumor progression and metastasis, indicating anti- and pro-inflammatory heterogeneous functions. While single-cell based analyses have been conducted in various cell types, studies on the diversity of myeloid cells between EGFR WT and EGFR MT NSCLCs are insufficient. Therefore, we explored to reveal the presence of multifaceted myeloid cell populations and to modulate its functions to augment ICI response in NSCLC patients with EGFR MT using single-cell RNA analysis.
Methods: Using the 10x Genomics Chromium system, we have generated single-cell RNA expression of a total of 904,174 cells from primary lung tissues of 95 patients with EGFR-WT (n=35), EGFR-MT TKI naïve (n=55), TKI post (n=5) and matched normal (n=22). Nine distinct cell lineages were annotated with canonical marker gene expression, focusing particularly on the myeloid (n=212,673 cells).
Results: We characterized 22 transcriptional states of myeloid cells: 4 clusters of alveolar macrophages (AMs; *PPARG*$^{+}$), 4 clusters of interstitial macrophages (IMs; *SPP1*$^{+}$, *FOLR2*$^{+}$, *CCL2*$^{+}$), 4 clusters of conventional DCs (cDCs; *CLEC9A*$^{+}$, *CD1C*$^{+}$, *LAMP3*$^{+}$), 2 clusters of mast cells (*KIT*$^{+}$), 1 cluster of plasmacytoid DCs (pDCs; *LILRA4*$^{+}$), proliferating cells (*MKI67*$^{+}$), monocytes (*FCN1*$^{+}$), neutrophil like cells (*CSF3R*$^{+}$) and 4 other unidentified clusters. In tumor tissues, IMs constituted a significantly higher proportion compared to normal tissues ($p<0.001$), with EGFR-WT and EGFR-MT IMs exhibiting distinct characteristics. EGFR-WT IMs had a high proportion of cluster expressing *FOLR2*, a marker of tissue resident macrophages associated with CD8 T cell infiltration and activation. On the other hand, a major component of IMs from EGFR-MT was a cluster expressing *SPP1* and its regulator *MIF*. SPP1 is well known to be involved in cancer cell progression, epithelial-mesenchymal transition, autophagy, and epigenetic alterations. The abundance of SPP1 IMs in the EGFR-MT TME refers to the formation of an immunosuppressive TME, potentially compromising the effectiveness of ICIs.
Conclusions: We found that EGFR-MT TME comprised a high proportion of immunosuppressive IM cluster expressing SPP1, implying that it contributes to an immunosuppressive TME. Our findings suggest the possibility of developing strategies to enhance ICI responses by targeting SPP1-induced immunosuppressive TME in EGFR-mutant NSCLC patients.

#6870 Immunological aging in triple negative breast cancer leads to a chronic interferon phenotype and immune cell exhaustion that impedes response to therapy.

M. Spasic[1], A. Parsons[1], G. Goreczny[1], Q. Guo[1], A. Recko[2], E. Mittendorf[3], P. van Galen[1], S. McAllister[1];

[1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA, [2]Dana Farber Cancer Institute, Boston, MA, [3]Brigham and Women's Hospital, Dana Farber Cancer Institute, Boston, MA

Age is the biggest risk factor for developing most forms of cancer, and understanding how age impacts cancer progression is critical to improving responses to therapy. As we age immune function declines suggesting that therapeutic responses, particularly to immunotherapies, will also change with age. Early clinical trial data suggests that there are age-associated responses to immunotherapies. Clinical trials, however, are not designed to reflect patient chronological and immunological ages - over 50% of breast cancer patients are over the age of 60, yet less than 25% of patients in clinical trials are in this age range. Here, we utilize a preclinical mouse model of immunological aging to understand how aging impacts immune responses to triple-negative breast cancer (TNBC). Immunologically young (8 weeks old) and aged (~12 months old) FVB mice were orthotopically injected with syngeneic Met1 TNBC cells. We previously established that this preclinical model mimics human immunological aging and enables us to better understand how age impacts disease progression and therapeutic responses. Once tumors became palpable, mice were treated with paclitaxel or vehicle control and/or anti-PDL1 to mimic first-line therapeutic strategies. Tumors grew significantly faster in young control mice compared to aged, but young mice had a more robust response to therapy. Notably, only young mice had a significant benefit of combo therapy (paclitaxel + anti-PDL1) over monotherapy alone. Tumors in aged mice had significantly more infiltration of CD8+ cytotoxic T cells and FOXP3+ inhibitory T-regulatory cells compared to young control mice, yet only tumors in young mice exhibited an increase in T cell infiltration with chemo or immunotherapy. Depletion of either CD8+ or CD4+ T cells in immune-competent FVB mice both led to a complete loss of age-associated differences in tumor growth. RNA sequencing analysis indicated that the infiltrating T cells in aged mice may be exhausted due to a chronic interferon phenotype, as indicated by enrichments of interferon alpha, interferon gamma, and IL2 signaling pathways, as well as expression of RIPK1, TNFa, and the immune exhaustion markers PD1, CTLA4, TIM3, and LAG3. Analysis of published single cell RNAseq data indicated the same interferon response pathways enriched with age in human TNBC, particularly in the T cell compartment.

Our findings show that the aging immune microenvironment significantly impacts tumor progression and that a chronic interferon phenotype with age may lead to T cell exhaustion and impaired therapeutic responses. This work suggests that targeting interferon signaling may lead to improved therapeutic responses. Together these findings demonstrate how immunological aging can impact disease progression and response to therapy and highlight the importance of developing age-stratified treatment strategies.

#6871 Tumor-infiltrating mregDC restrains anti-tumor immunity to promote cancer relapse in HCC.

Z. Zhang[1], J. Zhou[1], J. Fan[1], Y. Zhong[2], L. Wu[2], Y. Sun[1];
[1]Zhongshan Hospital Fudan University, Shanghai, China, [2]BGI Research, Shenzhen, China

Background and aims: Cancer relapse is one of the major causes of mortality in patients after curative resection of primary tumors. Furthermore, significant proportion of patients with recurrent tumor lack of effective treatments, thus novel therapeutic strategies are urgently needed. Although there have been several single-cell studies of primary tumor, functional roles and mechanism of tumor-infiltrating immune cells, especially those of myeloid cells in tumor relapse have remained to be elucidated.
Methods: We analyzed the RNA profile of 16498 cells from 12 primary and 6 early-relapse HCC cases. Digital pathology, multiplex immunofluorescent staining and digital spatial profiling (DSP) of paired primary and relapsed tumors from 41 HCC patients were also performed as our validation set. The molecular mechanisms associated with DCs was further tested through ex vivo and in vivo experiments.
Results: We performed single-cell clustering and visualized 3 DC clusters (cDC1, cDC2, and DC3). Compared with the other two subsets, the enrichment of DC3 in relapsed HCC was correlated with a higher second recurrence rate. Deeper inspections of the signature genes indicated this subset as 'mregDC', a DC subset enriched in maturation and regulatory molecules. Our results demonstrated that mregDC recruited $CD161^{\pm}CD8^{\pm}$ T cells that had an innate-like, low-cytotoxic, and low-clonal-expansion phenotype. $CD161^{\pm}CD8^{\pm}$ T cells secreted large amounts of TNF to activate non-canonical NF-κB pathway via tumor necrosis factor receptor 2 (TNFR2) and promoted the differentiation of immature DC into mregDC. This positive feedback loop between mregDC and $CD161^{\pm}CD8^{\pm}$ T cells shaped a dysfunctional anti-tumor immunity, facilitating cancer relapse in HCC. *In vivo* assay further indicated that therapy combining anti-TNFR2 and PD-L1 antibodies significantly inhibited HCC tumor growth via impeding the infiltration of mregDC compared with anti-PD-L1 monotherapy. We also found mregDC recruited $FCN1^{\pm}$ monocyte, a MDSC-like cell population to create an immunosuppressive niche of relapsed HCC.
Conclusions: We identified this population of mregDC with immunomodulatory function in recurrent HCC and demonstrated the role of these special DCs in shaping the immunosuppressive microenvironment of recurrent tumors. Our study suggests that mregDC may be a new target for the treatment of recurrent HCC in the future.

#6872 A spatio-temporal approach to mapping the dynamics of cutaneous squamous cell carcinoma progression and immunotherapy response: A journey through TiME.

N. Jhaveri[1], B. Ben Cheikh[1], D. Klymyshyn[1], N. Ma[1], A. Pratapa[1], J. Monkman[2], N. Nelson[3], A. Kulasinghe[2];
[1]Akoya Biosciences, Menlo Park, CA, [2]Frazer Institute, University of Queensland, Brisbane, Australia, [3]Abcam, Cambridge, United Kingdom

Background: Cutaneous squamous cell carcinoma (cSCC), arising from proliferation of malignant epidermal keratinocytes, is the second most common non-melanoma skin cancer. cSCC accounts for 75% of all skin cancer related deaths excluding melanoma, and metastatic and immunotherapy-resistant cases pose an emerging global threat. Tumor development is a gradual process characterized by high mutational burden and an immunosuppressive tumor immune microenvironment (TiME); therefore, identifying the underlying changes across the spatial and temporal landscape of these tumors will be crucial to understanding the key cellular and molecular drivers of disease progression and response.
Methods: In this longitudinal study, we used a single-cell, whole-slide approach to mapping key proteins of immune lineage, tissue architecture, cellular metabolism, and stress to study the spatial landscape of cSCC at baseline (pre-treatment) and multiple time points over the course of immunotherapy with the aim to develop a temporal atlas of the tumor. An ultra-high plex antibody panel encompassing over 50 major determinants in the tumor microenvironment was employed on the PhenoCycler®-Fusion spatial biology platform. Deep bioinformatic analyses was performed to identify cellular phenotypes, spatial neighborhoods, heterogenous functional states and cellular interactions by spatial proximity determinations.
Results: Previous studies in our laboratory have identified unique phenotypes correlating with response and resistance to immunotherapies in pre-treatment cSCC biopsies. Our results expand on these findings with temporal data tracking the dynamic changes in the TiME over the course of immune checkpoint inhibitor therapy. Apart from differences in immune cell composition and spatial localization patterns, we also saw differences in macrophage polarization and expression of metabolic markers in the responder and non-responder cohorts.
Conclusions: Overall, ultrahigh-plex spatio-temporal monitoring of cSCC revealed distinct signatures of response and resistance and identified key features in the TiME that reveal deeper insights into the pathobiology of the tumor. Our discovery-based approach identifies novel biomarkers for patient stratification and therapeutic modulation.

#6873 Prognostic impact of squamous cell carcinoma antigen as a mediator of anti-inflammatory macrophage polarization in tumor microenvironment.

L. Chen, V. Shi, E. Liu, J. Yang, A. Singh, M. Inkman, J. Zhang, J. Schwarz, S. Markovina;
Washington University School of Medicine in St. Louis, St. Louis, MO

Squamous cell carcinoma antigen 1 (SCCA1) is a potential biomarker and prognostic indicator for many epithelial cancers including cervix, head and neck, breast, and lung. Cancer patients with high serum levels of SCCA commonly experience treatment resistance and recurrence. We analyze SCCA expression in correlation with tumor microenvironment from 66 human cervical tumor biopsies and find that high serum SCCA is associated with increased macrophage infiltration in tumors and poor overall survival. In a single cell RNAseq analysis of 8 cervical tumors, patients with high SCCA1 show increased immunosuppressive genes (C1QA, C1QC, APOE) and reduced MHC molecules (HLA-DR, HLA-DQA1) in their tumor associated macrophages (TAMs), corresponding to decreased expression of T-cell cytotoxic-associated genes (IFNG, GZMB, PRF1). Thus, we aim to understand the impact of elevated SCCA1 on macrophages and its role in shaping the immune response. Co-culture of peritoneal macrophages isolated from SCCA1-treated mice with T cells from syngeneic wild-type mice, showed significant suppression in T cell proliferation. Downregulation of antigen presentation molecules was also observed SCCA1-treated macrophages and resulted in impaired ability to induce T cell activation by peptide-pulsed macrophages. Compared with treatment-naïve mice, SCCA1-treated macrophages showed increased anti-inflammatory cytokine CCL22, IL10 and immunosuppression regulators ARG1, PD-L1 expression. Moreover, human monocyte-derived M2 macrophages treated with SCCA1 during the differentiation process demonstrated inhibition toward CD3/28-induced T cell proliferation, accompanied by enhanced expression of cytokines, IL10 and CCL18. We further found that targeting SCCA1 by small interfering RNA knockdown significantly reduced tumor growth and macrophage infiltration, resulting in improved T-cell antitumor immunity. Lastly, analysis of cervical cancer patients with chemoradiation therapy showed that patients with high SCCA are associated with increased exhaustion (LAG3, CTLA4) and decreased antitumor gene signature (GZMB, IFNG) during treatment. In summary, SCCA expression promotes immunosuppressive macrophage polarization and function, contributing to T cell exhaustion phenotype and poor treatment response.

#6875 PIM kinases alter the prostate tumor immune microenvironment.

A. N. Clements[1], K. Sutterby[1], S. Kumar Deshmukh[2], S. Wu[2], J. Xiu[2], A. Farrell[2], M. Radovich[2], C. Nabhan[2], E. I. Heath[3], R. R. McKay[4], A. Recio-Boiles[1], N. A. Warfel[1];

[1]University of Arizona Cancer Center, Tucson, AZ, [2]Caris Life Sciences, Phoenix, AZ, [3]Wayne State University, Detroit, MI, [4]University of California, San Diego, CA

Prostate cancer is the second leading cause of cancer-related deaths in American men. While prostate cancer patients typically respond to androgen-deprivation therapy, androgen receptor signaling inhibitor (ARSI), and/or taxane chemotherapy, patients inevitably develop resistance, and the disease progresses to an untreatable and lethal form known as castrate resistant prostate cancer (CRPC). Immunotherapy has changed the treatment paradigm for many types of cancer; however, immune checkpoint inhibitors have not shown clinical benefits in CRPC. Clinical and preclinical evidence indicates that this lack of efficacy can largely be attributed to the immunosuppressive tumor microenvironment. Tumor associated macrophages (TAMs) secrete factors that promote tumor progression and suppress antitumor immunity, making them a promising therapeutic target. The Proviral Integration site for Moloney murine leukemia virus (PIM) kinases are serine/threonine kinases that are overexpressed in prostate cancer. PIM regulates many signaling pathways that promote cell proliferation and survival. However, how PIM kinase alters the prostate tumor immune microenvironment and impacts immunotherapy resistance is not well understood. We analyzed primary prostate and metastatic lymph node samples from treatment-naive metastatic hormone-sensitive prostate cancer patients. Prostate cancer samples with PIM1/PIM2/PIM3-high and -low expression were classified by top and bottom quartile, respectively. PIM high tumors had higher expression of immunostimulatory genes (*IL1β*, *TNF*, and *TNFSF13*), increased infiltration of M2 macrophages, B cells, and NK Cells, and a higher T cell inflamed score compared to PIM-low tumors. Our results demonstrate that PIM overexpressing prostate tumors display increased inflammation and infiltration of immunosuppressive immune cells, including M2 macrophages. Due to the changes observed in inflammation, we hypothesized that PIM kinase may regulate macrophage inflammatory signaling. We treated bone marrow derived macrophages with a PIM kinase inhibitor and showed that PIM inhibition suppresses inflammasome signaling and the release of the pro-inflammatory cytokine, IL-1β. Chronic inflammation can lead to the recruitment of TAMs, further promoting resistance to immune checkpoint inhibitors. Utilizing a syngeneic mouse model of prostate cancer, we demonstrated that PIM inhibition in combination with immune checkpoint blockade synergistically decreased tumor growth. Furthermore, immunoprofiling demonstrated that combination treatment enhances T cell activity. Overall, our results suggest that PIM kinase plays an important role in regulating the prostate tumor immune microenvironment and that PIM kinase may be a potential target to enhance the efficacy of immunotherapy for the treatment of prostate cancer.

#6876 Cyclic immunofluorescent analysis of the tumor microenvironment across human brain cancer subtypes.

D. Fails, M. Spencer;
Fortis Life Sciences, LLC, Montgomery, TX

Introduction: The tumor microenvironment (TME) has been the focus of a myriad of studies over the last decade and advancements in the field of cancer research have grown as a result. Improvements in the number of biomarkers that can be screened has increased across a variety of methods and the field of spatial profiling has largely adapted to keep pace with this. However, many challenges persist: 1) tissue microarrays can be limited by tumor heterogeneity and 2) newer technology can be cost-prohibitive. Brain tumors are of significant importance, especially those of glial origin, as they swiftly progress and result in a high fatality rate. As such, the need for more diverse therapeutic approaches is growing with many already pioneering new IHC-based strategies. The aim of this study was to address both challenges addressed above in the neurobiology space.

Methods: Biomarkers of importance in brain cancer tissues were identified and three distinct panels were designed. The first panel consisted of CD68, CTLA-4, p16ink4A, p14ARF, and p53. The second included PDPN, Calretinin, MAGE-D2, PTEN, and Vimentin. The third panel included IDH2, BRAF, GFAP, VEGF, and BOP1. Staining was achieved using Bethyl Laboratories IHC-validated primary and secondary antibodies and Akoya Opal™ Polaris 7-color IHC kit fluorophores (Akoya Biosciences [NEL861001KT]). Optimization was achieved using FFPE tissue microarrays containing normal neural tissue and brain cancer subtypes. The final optimized order was then tested on whole serial sections of meningioma, astrocytoma, and glioblastoma in six-color mIF. Images were generated using the PhenoImager HT® and subsequently merged and analyzed by Pathomics.

Results: Phenotyping and total cell counts for each marker were identified for each serially stained tissue set. Expression levels of MAGE-D2 and BRAF were high across malignant tissues of variable gradations. Conversely, in tissues with high expression of MAGE-D2, p53 levels in these samples were lower. This is consistent with findings that suggested that MAGE-D2 is a potential dissociator of p53 by impairing transcriptional activity. Macrophage expression appeared to correlate with CTLA4 and overall tumor infiltration.

Conclusions: Utilizing several unique biomarkers to understand the spatial relationships and phenotypes within the tumor microenvironment is becoming a more common practice among researchers. In using this method of serially staining tissue sections and merging the resulting images, more researchers will have access to spatial information which may have been cost-prohibitive otherwise. Additionally, in utilizing whole sections of difficult-to-treat cancerous tissue rather than microarrays, phenotypic information is available across the entire tumor microenvironment enabling a more comprehensive assessment of the TME.

#6877 Progesterone promotes immunosuppression in the murine mammary gland by causing T cell death.

A. Heard[1], L. R. Werner[1], E. I. Chowanec[1], H. Saunders[1], J. Tinoco[1], Z. C. Hartman[2], C. R. Hagan[1];
[1]University of Kansas Medical Center, Kansas City, KS, [2]Duke University, Durham, NC

Breast Cancer is the most common cancer diagnosed in women in the United States. Second only to lung cancer, breast cancer results in the greatest number of cancer deaths for women. Hormone receptor positive (HR+) breast cancers - cancers expressing the nuclear receptors for steroid hormones estrogen and progesterone, termed the estrogen receptor (ER) and progesterone receptor (PR) - make up the largest proportion of diagnosed breast cancers by a significant margin. So, although the HR+ subtype is less aggressive compared to others, it continues to be the largest contributor to breast cancer mortality. Treatment consists of anti-endocrine therapies, largely targeting ER/estrogen, the established drivers of breast cancer growth. Most women respond well to these therapies, but for women who do not, there are few alternative options. With the advent of immunotherapy and its successes in treating and controlling certain tumor types, many were hopeful that it could be employed for breast cancer as well. However, breast cancers, especially HR+ breast cancers, are considered “immune cold.” They lack high proportions of tumor-infiltrating lymphocytes (TILs), have low neoantigen production, and high percentages of immunosuppressive cells. A contributing factor could be the hormones present in the tumor microenvironment. The accepted paradigm is that lifetime exposure to estrogens drives the development of HR+ breast cancer, but both estrogen and progesterone are part of the normal menstrual cycle. Prior work from our lab has uncovered a novel immune-modulatory role for progesterone, pivotal to promoting the growth of PR-positive mammary tumors. Recent preliminary data from our lab show that progesterone treatment conveys immune protection against T cell killing in a co-culture with E0771 mammary gland tumor cells. However, when activated in monoculture, T cells exposed to increasing concentrations of progesterone have no differing expression of cell surface activation or exhaustion markers, implying that progesterone is not eliciting this effect by interfering with the T cell activation cascade nor is it inducing premature exhaustion. Interestingly, progesterone treatment instead leads to a concentration-dependent increase in T cell death compared to the untreated control. In vivo, these results are supported as progesterone treatment decreases the amount of total CD3+ T cells, and specifically the cytotoxic CD8+ subset, in the mammary glands of mice. These results suggest that progesterone could modulate the breast and tumor microenvironment, providing tumor cells with protection from immunosurveillance and contributing to HR+ breast cancer development. These data also argue for the use of anti-progestins to be added to the HR+ breast cancer treatment regimen to boost anti-tumor immune activity.

#6878 Images to insights: Transforming TME characterization into actionable spatial metrics with AI-powered multiplex immunofluorescence.

M. Naderi, L. Krstic, D. Cikic, K. Ruf, I. Mihajlovic, S. Todorovic, C. Weston;
Reveal Biosciences Inc., San Diego, CA

Background: Precise and actionable assessment of cellular mechanisms and interactions within the tumor microenvironment (TME) is critical for advancing clinical trials, preclinical research, and informed decision-making in immuno-oncology. Multiplex immunofluorescence (mIF) assays have emerged as pivotal tools that can enable comprehensive visualization of protein expression and cellular interactions within the TME. Integration of advanced digital analysis tools and mIF assays, can revolutionize our ability to interpret the TME and usher these assays into high-throughput clinical settings.
Methods: In this study, we processed tumor samples utilizing Akoya's PhenoCode Signature Immune Profile Human Protein Panel, which includes immune profiling markers CD8, CD68, CD3, CD20 and tumor marker PanCK. Following the Akoya Opal staining protocol, formalin-fixed paraffin-embedded (FFPE) samples were stained and scanned using the PhenoImager HT scanner. The images were then analyzed using Reveal's AI-mIF digital assay on the ImageDx platform to generate contextual and spatial biomarker data. A deep learning-based cell segmentation model based on MaskRCNN architecture, signal preprocessing for noise and autofluorescence, and dynamic intensity normalization were used. Phenotype classification was precisely executed using dynamic thresholding or neural network classifiers as needed. Results were validated by establishing concordance with pathologist readouts.
Results: The application of our methodology yielded highly concordant results when compared with manual counts, demonstrating the efficacy of our approach. The R2 correlation coefficient across all markers passed the minimum criteria of R2>0.85 with regression slopes between 0.7-1.3, indicating a robust alignment with traditional pathologist assessments. We showcase stratifying samples Desert, Excluded, or Inflamed phenotypes and other quantitative and spatial results such as interactions of immune cells and tumor within 30-um neighborhoods, and their dispersion and arrangement in the TME.
Conclusion: The integration of Reveal Biosciences' ImageDx platform and RevealAI-mIF provides an ecosystem to host, visualize, and analyze Akoya's immune profiling images. This collaborative effort has enabled the transformation of complex multiplex imaging data into distinct spatial phenomic endpoints, thereby introducing the potential to significantly advance biomarker discovery and contribution to translational and clinical research in the field of immuno-oncology.

#6879 Development of a rapid multiplex immunohistochemistry for characterizing tumor-immune microenvironment.

A. Kimura, T. Tsujikawa, H. Morimoto, J. Mitsuda, S. Saburi, S. Mukudai, H. Nagao, N. Sakurai, N. Murakami, A. Miyagawa-Hayashino, H. Ogi, S. Shibata, E. Konishi, K. Itoh, S. Hirano;
Kyoto Prefectural University of Medicine, Kyoto, Japan

Intratumoral immune profiles have been related to prognosis and therapeutic efficacy; this could result in personalized treatment based on biomarkers. Although techniques for multifactorial evaluation of different tumor-immune microenvironments have been established, their practical implementation in clinical settings still requires further improvement, where the time required for testing needs to be reduced and the technology needs to be clinically validated. To develop a multiplex, quantitative, and rapid tissue evaluation method based on clinically established standard immunohistochemistry (IHC), we attempted to develop 6-marker rapid multiplex IHC based on our previously reported 14-marker multiplex IHC via the reduction of the number of labels and speeding up the staining procedure (Tsujikawa et al. Cell Reports, 2017). First, we confirmed whether immunological features that were found to be associated with prognosis in 14-marker multiplex IHC analyses could be identified with fewer labels. Quantitative results by selected six markers exhibited significant correlation with those by 14 markers in terms of immune classifications based on the balance of lymphoid and myeloid cells. Next, we developed a rapid staining protocol by optimizing the reaction temperature, chromogen, and washing time, allowing the completion of 6-marker analysis in 5 hours and 49 minutes as opposed to several days required for the conventional multiplex IHC. By using six markers, validation in benign tonsil tissue and head and neck cancer tissue exhibited significant correlation between rapid and standard multiplex IHC in terms of staining intensities, densities of T cells, macrophages, lymphoid/myeloid immune cells ratios, and spatial profiles of intratumoral immune infiltrates. This method may enable a quantitative assessment of tumor-immune microenvironment on a clinically feasible time scale, which promote the development of tissue biomarker-guided therapeutic strategies.

#6880 Immune infiltration in inflammatory and myofibroblastic cancer-associated fibroblast high microenvironments of colorectal cancer.

Y. Gadalla, K. A. Johnson, S. Nath, C. A. Pasch, D. A. Deming;
University of Wisconsin Madison, Madison, WI

Background: Cancer-associated fibroblasts are major modulators of the tumor microenvironment (TME) and play a large role in the immune system's response to tumors. The direct effect that myofibroblastic CAFs (myCAFs) and inflammatory CAFs (iCAFs) have on immune infiltration is not well studied in colorectal cancer (CRC). Here we investigate the effects that myCAFs and iCAFs have on immune infiltration in human CRCs.
Methods: The Cancer Genome Atlas (TCGA) Colorectal Adenocarcinoma PanCancer Atlas dataset was accessed via cBioPortal. Cancers were separated into myCAF prominent (MP) by high gene expression (Z-score > 1) of *ACTA2* and *TAGLN* and iCAF prominent (IP) by expression of *PDPN* and *ICAM1*. Gene Set Enrichment Analysis (GSEA) was performed on differential expression results comparing these groups. Additionally, bulk RNA sequencing results were analyzed for immune cell subsets using Cibersortx. Statistical analysis was completed in R.
Results: Of 592 cancer samples, 24 were MP and 9 IP. There was no significant difference in age (MP median age 63, IP median age 70, q = 0.6) nor sex (MP 17 female/7 male; IP 4 female/5 male, q=0.9). MP have 1/24 profiled patients with MSIsensor score >=3.5 and 2/24 patients with MSI MANTIS score > 0.4; IP have 3/9 profiled patients with MSIsensor score >=3.5 and 3/9 patients with MSI MANTIS score >0.4. IP cancers were enriched for gene sets associated with enhanced immune cell infiltration (Inflammatory Response, Interferon Gamma Response, Allograft rejection, TNFA signaling via NFKB, IL6 JAK STAT3 signaling, Interferon Alpha Response, Complement, IL2 STAT5 signaling and Apoptosis, all q< 0.001). MP cancers were enriched in the KRAS signaling Down gene set (q=.009). IP cancers had a higher proportion of infiltrating immune cells than MP cancers by CibersortX analysis (iCAF median = 2.829, myCAF median= 2.284, p < 0.01). IP cancers had higher CD4 memory cells (p <0.001, iCAF median = 0.455, myCAF mean = 0.318), NK resting cells (p<0.001, 0.228, 0.103), M1-like macrophages (p <0.01, 0.1977,0.107), and neutrophils (p<0.01, 0.0298, 0). MP cancers had a higher number of NK activated cells (p = 0.04, iCAF median = 0, myCAF median = 0). M1-like macrophage gene markers were higher expressed in IP cancers compared to MP cancers, though not significantly (*NOS2* log2FC = 0.66, q = 0.652; *IL1A* 3.25, 0.0375; *IL23A* 1.34, 0.151; *IL26* 1.31, 0.32). Additionally, IP cancers tended to express markers for activated CD8+ T cells, though only *IFNG* was significant (*GZMB*, log2FC = 0.97, q = 0.337; *IFNG*, 2.16, q<0.001; *PRF1*, 1.12, q=0.198).
Conclusion: These analyses indicate that iCAFs play the major role in modulating the immune infiltration of cancers. These data highlight the need for further research into the mechanisms by which different CAF subtypes alter the immune microenvironment.

#6881 Investigating the role of post-transplant bone marrow immune dysregulation in multiple myeloma.

J. T. Wang, M. Fiala, K. Sato, J. Fortier, R. Vij, L. Ding;
Washington University in St. Louis, Saint Louis, MO

Multiple myeloma (MM) is a cancer of bone marrow plasma cells (BMPCs), which to date remains incurable. Standard of care for qualifying patients involves high-dose chemotherapy followed by autologous stem cell transplant (ASCT), after which minimal residual disease (MRD) testing is used to assess the degree of tumor clearance. Though strongly associated with better survival, MRD-negativity is an imperfect predictor for patient outcomes and fails to account for the pro-tumorigenic BM dysregulation often found in MM patients. As the post-transplant BM milieu in MM is not well understood, we conducted 3' single-cell RNA sequencing (scRNAseq) of 49 newly diagnosed (NDMM) and 79 day-100 post-ASCT whole-BM aspirates to investigate how immunosuppressive microenvironmental signatures may persist or develop following ASCT to influence patient outcomes. 68 of 79 post-ASCT samples come from uniformly-treated clinical trial enrollees with progression-free survival (PFS) ranging from 10 months to over 7 years, with both MRD- and MRD+ cases at either PFS extreme. We observe that although post-ASCT samples have uniformly lower PC count than NDMM samples, only erythroblasts and B cells appear relatively depleted in NDMM samples to compensate for higher PC proportions. T/NK cells and myeloid lineages, though similar in percentage across samples, exhibit clear subtype bias between the two timepoints. Post-ASCT samples are significantly enriched for GZMH+ CD8+ T and NK cells, HIF1A+ hypoxia-responsive monocytes, and depleted for S100A8/9-high CD14+ monocytes. NDMM samples are also enriched for SPINK2+, CDK6+, and AVP+ neutrophils, which are rare in post-ASCT samples. Notably, higher HIF1A expression in myeloid cells post-ASCT is further associated with longer PFS. Regardless of MRD status, NFKBIA, FOS, and GNLY upregulation and GZMK downregulation in post-ASCT T cells are associated with worse PFS. Conversely, enrichment of CD16+ IFN-responsive monocytes and depletion of ARG1+/FUT4+/CEACAM8+ myeloid-derived suppressor cells (MDSCs) are associated with longer PFS. Beyond such general trends, we observe MRD-dependent PFS-association of several CD8+ T cell subsets. Overall, this study enhances our understanding of how post-transplant BM repopulation and immune interaction may impact treatment response in MM.

#6882 Exploring aryl hydrocarbon receptor expression and distribution in the tumor microenvironment, with a focus on immune cells, in various solid cancer types.

D. Kim[1], **C. Lee**[2], Y. Han[2], S. Park[2], H. Han[2], K. Na[2], M. Kim[2], S. Yang[2], S. Baek[2], Y. Kim[2], J. Hwang[2], S. Lee[1], S.-s. Kang[3], T. Han[4], H. Doh[4], J. Cho[4], D. Kim[4], D. Cha[4], M. Hong[5], S. Lim[5], J. Lee[5], J. Kim[2], K.-H. Pyo[6], B. Cho[5];

[1]Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]JEUK Institute for Cancer Research, Gumi, Korea, Republic of, [4]Dong-A ST Research Institute, Yongin-si, Korea, Republic of, [5]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of, [6]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: The aryl hydrocarbon receptor (AhR) is a transcription factor that performs various biological functions upon ligand activation. While there have been extensive studies and development of AhR-targeting anticancer therapies, including active clinical trials, research on the expression of AhR, a key biomarker, in the TME remain limited. Herein, we evaluated the nuclear and cytosolic AhR expression across five solid cancer types: head and neck squamous cell carcinoma (HNSCC), bladder cancer, colorectal cancer, esophageal cancer, and non-small cell lung cancer (NSCLC).

Methods: Multiplexed immunohistochemistry (mIHC) and image cytometry were employed to investigate the AhR expression and distribution in 513 patient samples, of which 292 were from patients with one of five solid cancer types. For quantification of AhR expression levels, FCS files were generated, and the resulting data was analyzed using the R program.

Results: AhR expression was predominantly high in cancer cells, followed by T cells and macrophages across all cancer types. All 513 patient samples were categorized into three clusters based on distinct expression and localization patterns of AhR. Cluster 1 exhibited high AhR expression in the cancer cell nucleus, whereas cluster 3 showed the lowest. AhR expression in the stromal macrophage nucleus was the most pronounced in cluster 2. In cluster 1, NSCLC was entirely absent, with esophageal cancer representing the largest proportion. In contrast, cluster 2 was notably different from cluster 1, with a 5% prevalence of NSCLC and a relatively higher proportion of HNSCC and colorectal cancer. The AhR expression in macrophages within cluster 2 was noticeably higher than in cluster 1. Cluster 3, which had the highest NSCLC proportion, generally displayed low AhR expression compared to other clusters, but also exhibited AhR expression in regulatory T cells (Tregs), a pattern which was not observed in other cancer types. Notably, a positive correlation was observed between the nuclear and cytosolic expressions of AhR, suggesting that AhR expression as a biomarker is independent of its subcellular localization. Furthermore, there was no clear correlation between AhR expression levels and cancer stage, grade, and metastatic status.

Conclusion: We elucidated the expression profile of AhR within the TME across five cancer types, then classified the patient samples into three clusters based on their distinct AhR expression patterns. By demonstrating different expression patterns of AhR in cancer cells and immune cells, our findings are anticipated to provide a fundamental basis for clinical and immunological research on AhR-targeting therapies.

#6883 Investigation of tumor-immune interactions in pediatric sarcomas using single-cell multi-omics.

Zhan Zhang[1], Kyung Jin Ahn[2], Changya Chen[2], Rumeysa Biyik Sit[2], Hesham Mohei[3], Brian Lockhart[4], Malay Haldar[3], Kathrin Bernt[2], Vinodh Pillai[3], Kai Tan[2]

[1]Department of Bioengineering, University of Pennsylvania, Philadelphia, PA,[2]Division of Oncology and Center for Childhood Cancer Research, Children's Hospital of Philadelphia, Philadelphia, PA,[3]Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA,[4]Department of Pathology and Laboratory Medicine, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Pediatric sarcoma represents the second most common solid tumor in children. Despite advances in multimodal therapies, one-third of sarcoma patients do not survive the disease. Over the past few decades, the development of novel therapeutic strategies for sarcoma has been impeded by an insufficient understanding of the tumor microenvironment (TME). In particular, the potential of immunotherapy remains constrained by the gap of knowledge about the molecular and functional phenotypes of the immune cells in the sarcoma TME.
Methods: To address this knowledge gap, we collected treatment-naïve tumor samples from 32 patients with five pediatric sarcoma subtypes. We employed a single-nuclei RNA+ATAC-Seq multi-omics assay to comprehensively characterize the transcriptomic and epigenomic heterogeneity of tumor and immune cells within the sarcoma TME.
Results: Our analysis revealed that tumor-associated macrophages (TAMs) were the most abundant immune cell type in the sarcoma TME. We identified seven distinct TAM subpopulations, each exhibiting unique gene expression and chromatin accessibility patterns. Among these, TAM subsets with higher expression of *SPP1* and *C1QC* genes displayed the strongest immunosuppressive potential. Transcriptional regulatory network (TRN) analysis identified transcription factors that were most likely to drive the phenotypes of SPP1+ and C1QC+ TAMs, including ELF2, JUND and RUNX1. Through cell-cell communication analysis, we discovered that SPP1+ TAMs interact with T cells via SPP1-CD44 signaling, while C1QC+ TAMs interact with NK cells through HLA-E-KLRC1 signaling, suggesting the potential involvement of these signaling pathways in TAM-mediated suppression of these cytotoxic lymphocytes. We prioritized ligand-receptor gene pairs, such as SEMA3D-NRP1 and LTBP3-ITGB5, which likely mediate the interaction between malignant sarcoma cells and SPP1+/C1QC+ TAMs based on their dominance across sarcoma subtypes and association with poorer clinical outcomes. On the other hand, our analysis revealed that sarcoma subtype-specific interactions between TAMs and malignant cells are common, highlighting the heterogeneity of signaling events across sarcoma subtypes.
Conclusion and Significance: Our study presents a comprehensive single-cell multi-omics characterization of pediatric sarcomas and sheds light on its tumor microenvironment. By identifying unique markers for immunosuppressive TAM subpopulations and elucidating intercellular interactions promoting tumor development, this study proposes potential therapeutic targets for sarcoma treatment based on the role of TAMs in sarcoma TME.

#6884 Evaluating tumor-infiltrating immune cells helps predicting prognosis in biliary tract cancer.

Kousuke Hatta, Ryota Tanaka, Kenjiro Kimura, Shinpei Eguchi, Go Ohira, Hiroji Shinkawa, Kohei Nishio, Masahiko Kinoshita, Shigeaki Kurihara, Shuhei Kushiyama, Takahito Kawaguchi, Naoki Tani, Koichi Nakanishi, Mizuki Yoshida, Takeaki Ishizawa

Osaka Metropolitan University, Osaka-shi, Japan

Background: The tumor microenvironment (TME) is composed of not only cancer cells but also an extracellular matrix and many types of non-cancerous cells, including fibroblasts and immune cells. In recent years, infiltrating immune cells in TME are known as a predictor of chemotherapy and immunotherapy effectiveness. The purpose of this study is to evaluate infiltrations of lymphocytes and macrophages in biliary tract cancers (BTCs).

Methods: Clinical data and tissues were obtained from 130 patients who underwent surgical treatment for BTCs (intrahepatic, perihilar, and distal bile duct cancer, gallbladder cancer, and ampullary cancer) at our institution between 2001 and 2017.The immunohistochemical evaluation was performed to evaluate the number of CD8+ T cells, CD4+ T cells and FOXP3+ T cells and CD68+ Macrophages around the tumor cells. We defined Immunoscore based on the status of infiltrating immune cells. With CD8-high, CD4-high, and FOXP3-high TILs and CD68-low TAMs as one factor, the number of factors was counted in each case, and Immunoscore was assigned a score of 5 stages, from 0 to 4. It was high for the score of 3-4 and low for the score of 0-2. Also, to evaluate the correlation with TME and systemic inflammatory reaction, we examined blood inflammatory biomarker from peripheral blood samples.

Results: A total of 59 cases had high Immunoscore and 71 cases had low Immunoscore. Patients with high Immunoscore showed significantly superior overall survival (OS) and recurrence free survival (RFS) than those with low Immunoscore (median OS 60.8 vs. 26.4 months, $p = 0.001$; median RFS not reached vs. 17.2 months, $p < 0.001$). For OS, low Immunoscore, positive lymph node metastasis, presence of distant metastasis, and high serum CA19-9 level were independent poor prognostic factors (hazards ratio 2.05, 3.48, 1.7, and 2.05; $p = 0.01$, $p = 0.005$, $p = 0.05$, and $p = 0.01$, respectively). For RFS, low Immunoscore, T classification of pT3-4, and presence of distant metastasis were independent poor prognostic factors with hazards ratio of 2.41 ($p = 0.001$), 2.16 ($p = 0.005$), and 3.58 ($p = 0.005$), respectively. Patients with high preoperative Neutrophil-to-lymphocyte ratio (NLR) had a significantly lower average number of $CD8^{\pm}$ T cells as compared to patients with low NLR ($p = 0.02$). Preoperative NLR was associated with infiltrating $CD8^{\pm}$ T cells in TME.

Conclusions: High Immunoscore group had significantly longer OS and RFS and was an independent good prognostic factor. Also, infiltrating $CD8^{\pm}$ T cells in TME correlated preoperative NLR. Our findings indicated that in biliary tract cancer, the evaluation of infiltrating immune cells in TME was useful to predict patient prognosis, and preoperative NLR may predict the tumor infiltrating $CD8^{\pm}$ T cells.

#6885 Investigating a novel role of DCLK1 isoforms in colitis and colitis associated colon cancer.

K. A. Yusuf, B. C. Roy, S. Anant, S. Umar;
University of Kansas Medical Center, Kansas City, KS

Chronic intestinal inflammation in patients diagnosed with inflammatory bowel disease (IBD) significantly increases their risk of colorectal cancer (CRC). Despite the rising global frequency of IBD, the precise mechanisms that regulate the transition from IBD to colon cancer are poorly understood. Doublecortin-like kinase 1 (DCLK1) is a protein with two major isoforms, DCLK1-L and DCLK1-S. Previous studies have shown that hypermethylation of the DCLK-1α promoter encoding DCLK1-L, particularly in colorectal cancer, allows switching to the DCLK1-S isoform that confers an invasive tumor phenotype. The DCLK1-L is a tuft cell marker that protects against colitis by sensing and eliminating gut pathogenic infection through various mechanisms. On the contrary, the role of DCLK1-S in colitis and colitis-associated cancer has not been thoroughly investigated. Studies from our lab have identified a marked elevation of DCLK1-S in tissue samples of IBD patients. We also recently discovered that DCLK1-S is predominantly expressed in Ly6G+; MHCII- neutrophils, which coincide with elevated levels of inflammation and tissue damage in the colon. To further understand the role of DCLK1 isoforms in driving the progression of colitis to colon cancer, we bred *Dclk1*$^{fl/fl}$ mice with *MRP8-Cre-ires/GFP* mice to generate *Dclk1*$^{fl/fl}$*;MRP8-Cre+/-* that eliminates DCLK1-L upon tamoxifen injection resulting in sustained expression of DCLK1-S in the granulocytes especially neutrophils. When infected with *Citrobacter rodentium* (CR), *MRP8;Dclk1*$^{-/-}$ mice compared to *MRP8;Dclk1*$^{+/-}$ or WT mice developed more severe colitis. We have also discovered a novel interaction between DCLK1-S and MMP13 in an unbiased docking study that correlated with significant co-localization of DCLK1-S with MMP13 in the colons of CR-infected mice. Employing a knock-in mice over-expressing the DCLK1-S +19 under the CAG promoter, the DCLK1-MMP13 co-localization correlated with severe ulceration and colitis with loss of crypts and immune cell infiltration including Ly6G+ neutrophils. Studies are underway to see if the severity of colitis in *MRP8;Dclk1*$^{-/-}$ mice translates into enhanced tumorigenesis and to see if potential interaction between DCLK1-S and MMP13 could provide a plausible mechanism of colitis progression to colon cancer through ECM remodeling and tissue damage.

#6886 Orion™: 17-plex single-step stain and imaging of normal lung section adjacent to non-small cell lung carcinoma.

S. Larkin, T. George, E. Kaldjian;
RareCyte, Inc., SEATTLE, WA

Background: The ability to image tissue microenvironments (TME) at high-plex over a whole slide without requiring multiple staining steps allows for unprecedented ability to study tissue architecture and molecular mechanisms of immune and disease processes. Here we investigate a sample of normal lung section adjacent to non-small cell lung carcinoma using whole slide, single-step stain and imaging at single-cell resolution.
Methods: These images profiled a whole slide tissue section of normal lung section adjacent to non-small cell lung carcinoma, stained with a 17-plex immuno-oncology biomarker panel. In this profile, we designed a high-plex panel of 17 biomarkers where the tissue autofluorescence was imaged and isolated as an additional fluorescence channel. All markers were stained in a single staining procedure and imaged in a single scan. Whole slide spatial staining and imaging was conducted on the Orion spatial biology platform. The full protocol is quick and simple, using standard histology tools: •Mount sections on glass slides•De-paraffinize and perform antigen retrieval•Quench autofluorescence•Stain slides with a panel of ArgoFluor™ conjugated antibodies•Coverslip with ArgoFluor Mounting Medium and cure overnight•Image whole slides at 20X magnification using the Orion instrument•Process to ome.TIFF and analyze.
Results: Data revealed intact normal lung alveolar architecture, with scattered immune cell infiltrates. Multiplexed imaging revealed epithelial cells, which make up alveoli, and endothelial vasculature as well as immune cells infiltrates in the alveolar space. Various immune cell populations were observed to be present (T cells, B cells, macrophages) and immune cell activation could be distinguished using PCNA and/or Ki-67 markers. Various T cell subsets could also be identified among the infiltrate using markers for CD4, CD8 and T-regulatory marker FOXP3. Through the use of multiplex staining, immune cell activity could also be characterized with respect to bronchiolar, artery, and capillary tissue architecture.
Conclusions: High-quality subcellular imaging of TME can lead to greater spatial investigation and more in-depth understanding of immune function in normal and diseased tissue. Here, multiplexed imaging identified distinct immune cell collections among cancer-adjacent normal lung tissue, providing validation of instrumentation and methods to obtain benchmarks for spatial quantitation of immune cells in control regions adjacent to cancer tissue.

TUMOR BIOLOGY: Preclinical Studies of Cancer
Poster Session

#6890 2D Tumor cell culture based Ex vivo drug sensitivity screening platform for South African patient samples (leukemia, multiple myeloma, ovarian and uterine cancer) demonstrate potential for targeted cancer therapies.

M. Takundwa[1], V. Kenmogne[2], T. Malise[2], B. Monchusi[1], P. Dube[1], E. Nweke[2], J. Fabian[3], H. Maher[3], J. du Toit[3], V. Philip-Cherian[4], P. Fru[2], A. Sajo[5], A. Mouton[5], M. C. van Aardt[5], C. Visser[5], G. Dreyer[5], D. Govindaraj[1];

[1]CSIR South Africa, Pretoria, South Africa, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]Wits Donald Gordon Medical Centre, Johannesburg, South Africa, [4]Chris Hani Baragwanath Academic Hospital, Johannesburg, South Africa, [5]University of Pretoria, Pretoria, South Africa

Resistance to standard chemotherapy is a major challenge with Leukemia (Leuk), Multiple Myeloma (MM), Ovarian Cancer (OvCa) and Uterine Cancer (UtCa) treatments, which ultimately leads to relapse. Our study objective is to establish a robust drug sensitivity screening platform that can identify drugs and drug combinations that are effective in precision medicine for individual South African patient samples (Leuk, MM, OvCa and UtCa). Given that resistance to chemotherapy treatment accounts for high mortality and morbidity, we focus on the hypothesis that several drug combinations will be required for patients to achieve better response for drug regimens beyond first line of chemotherapy. Therefore, our defined objectives were to 1) establish 2D ex vivo tumour cell culturing using South African patient samples; 2) develop a drug sensitivity screening platform through which selected single and drug combinations will be identified; 3) to provide South African cancer (OvCa, Ut Ca, CLL, MM) patients with individualized treatment options with effective drug combinations for targeted therapies. Through collaboration with, Steve Biko Hospital Pretoria, Chris Hani Baragwanath Hospital and Wits Donald Gordon Medical Centre, Johannesburg, South Africa, we performed 100 patient sample collections including Acute myeloid leukaemia (AML) (n=7), Chronic lymphocytic leukaemia (CLL) (n=4), Chronic myeloid leukaemia (CML) (n= 30), MM (n=40), OvCa (n=10), UtCa (n=4) and healthy donors (n=5). Culture setting for all patient-derived tumor cells were established through the 2D cancer cell culturing in 96 well plates. This was followed by functional drug sensitivity testing using a panel of FDA approved chemotherapy drugs. The average turnaround time from biopsy to drug sensitivity test results is currently at 14 days. We have completed ex vivo drug sensitivity screening to perform analysis on patient samples (n=80) using 30 drugs with a concentration range of 1-1000 nm. Our preliminary drug sensitivity screening studies show good response to proteosome inhibitors, melphalan, doxorubicin and kinase inhibitors. We have established a wound healing assay for OvCa and UtCa samples and demonstrated sustained cell growth for the period of 2 weeks with tumor cells growing faster than twin normal tissue. We are now at stage of performing drug sensitivity screening for OvCa and UtCa patient samples for both twin normal and tumor tissues. We have established a drug sensitivity screening platform and wound healing assay with primary patient derived cells that utilizes South African Patient samples to select effective drugs for monotherapy and also drug combinations.

#6891 Establishment and characterization of a panel of naïve and pretreated small cell lung cancer (SCLC) XPDX models.

G. Huelgas Morales[1], P. Forofontov[1], J. Flores[1], A. Simonson[1], A. Diaz III[1], J. Lund[1], N. Banos[1], K. Papadopoulos[2], D. Rasco[2], A. Patnaik[2], A. Abedi[3], N. Puente[3], E. Calvo[4], V. Moreno[4], R. Drengler[5], L. Smith[5], M. Wick[1];

[1]XenoSTART, San Antonio, TX, [2]START San Antonio, San Antonio, TX, [3]Texas IPS, San Antonio, TX, [4]START Madrid, Madrid, Spain, [5]STOH, San Antonio, TX

SCLC is an aggressive cancer of neuroendocrine origin, accounting for approximately 15% of all lung cancer cases. While the incidence of SCLC in the US has declined over past decades due to changes in smoking habits, this disease provides a poor prognosis and few effective treatment options for advanced disease. To better identify useful therapies for SCLC, we established and characterized a panel of 18 XPDX models representing primary and metastatic disease from either naïve or clinically treated patients and tested sensitivities towards chemotherapies and targeted agents. 18 models were established in immune-deficient mice including 8 from newly diagnosed patients (2 from lung primary), and 10 from recurrent disease (3 from lung primary). Models were IHC stained for Nectin-4, Trop2 protein and ERBB2 and profiled using WES and RNA_{seq}. For in vivo studies, models were evaluated against several chemotherapies including cisplatin, etoposide, topotecan, and temozolomide, as well as ADC agents trastuzumab deruxtecan (T-DXd), enfortumab vedotin (EV), and sacituzumab govitecan (SG). Targeted therapies toward CDK4/6, $KRAS^{G12C}$, and PARP were evaluated in some models. Endpoints in all studies included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion; a %T/C of ≤ 20% versus control was considered sensitive. Tumor regression (%T/C<0%) versus Day 0 tumor volume was also reported. Less than 10% of models stained positive for Nectin-4, Trop-2 or ERBB2. Molecular characterization revealed RB1 frameshifts or deletions in most models, KRAS/NRAS point mutations in 3 models, and 2 gene fusions SEPTIN7P2-PSPH and TVP23C-CDRT4. In vivo studies reported differential responses to chemotherapies with the most sensitive models established from treatment-naïve patients. Temozolomide was active in several studies including tumor regressions in both naïve and pretreated models. ADCs also reported differential activity toward the tested panel. We have established and characterized a panel of SCLC XPDX models and benchmarked them against various cancer therapies. This panel can be utilized as a valuable tool in developing novel therapies for SCLC patients.

#6892 Murine *ex vivo* platform: A powerful tool for biomarker assessment and high throughput screening of translationally relevant *in vivo* tumor models for PD and efficacy studies.

S. Bachawal, J. Leung, R. Mandawe, M. Garza, K. ly, O. Stefanson, J. Lohre, D. Kamali, N. Doan, B. King, E. Kim, G. Hegde, X. Liao, S. Liu, J. Kim, A. Mikels Vigdal, A. Mukhopadhyay;
Bristol Myers Squibb, Redwood City, CA

Ex vivo model systems using tumor biopsies from patients are often utilized to develop predictive biomarkers. However, these readouts are often proximal and do not inform on downstream mechanisms (distal pharmacodynamics) and their relationship to anti-tumor efficacy. *In vivo* murine models represent a powerful tool to bridge this gap. However, selection of an appropriate translationally relevant murine model can often be a time-consuming process given that the complexity of the tumor microenvironment (TME). Additionally, *in vivo* models are generally not amenable to high throughput screening. Here, we demonstrate that *ex vivo* mouse tumor platforms can be used for rapid screening of treatment responsive and translationally relevant tumor models. These models can be used to interrogate the impact of a therapeutic on anti-tumor efficacy in a long-term *in vivo* study, thus allowing for the establishment of biomarker/response relationships in a rational and rapid manner. To operationalize this platform, *ex vivo* cultures of dissociated tumor cells (DTC) or tumor tissue slices (histoculture) were first optimized for maximum viability and/or preservation of tissue architecture. To allow for high throughput screening, feasibility of freezing DTCs or tumor chunks prior to sectioning was also explored. Finally, both e*x vivo* tumor cultures and *in vivo* tumors were treated with a Innate agonist as a proof of concept to demonstrate functional equivalency. In conclusion, this work provides a novel way of screening responsive, translationally relevant murine tumor models in a high throughput and cost-effective manner. These efforts have the potential benefits of saving time and animal usage, while also maximizing the probability of successfully evaluating a therapeutic's benefit.

#6894 Modeling the spectrum of vascular changes occurring in healthy and early malignant cancers on a chip.

C. Franca[1], A. Athirasala[1], E. Dimitriadis[2], J. Bays[3], K. Yamada[2], C. Chen[3], L. E. Bertassoni[1];
[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]NIDCR, NIH Cell Biology Section, Bethesda, MD, [3]Boston University, Boston, MA

The transition of a healthy tissue to a pre-malignant and subsequent malignant stage is typically characterized by a marked increase in extracellular fibrosis and collagen density. Such changes coincide with a significant increase in tissue stiffness as the tumor progresses. Despite the large body of work on endothelial cell changes in tumoral angiogenesis, little is known about the dynamic interactions of endothelial cells, perivascular cells, and the extracellular matrix in early-to-late cancers. Appreciating such interactions is crucial for understanding tumorigenesis and early tumor progression. To model the spectrum of vascular changes occurring on pre-tumoral and tumoral ecosystems, we developed an organ-on-a-chip model of biomimetic pericyte-supported capillaries with collagen having increasingly higher density, stiffness and discrete fibril microarchitectures. Briefly, 160-um channels were engineered using type I collagen that underwent fibrillogenesis at different temperatures (4, 16, 21, and 37oC). Thus, the microarchitecture and stiffness would vary from a soft reticular network (healthy/pre-cancerous vascular capillaries) to a stiff fibrillar mesh (fibrotic/tumoral vascular capillaries). We then seeded human umbilical vein endothelial cells (HUVECs) and mesenchymal stem cells (MSCs) in the collagen channels. After 48h, samples were fixed and stained for actin (cytoskeleton), NG2 (pericyte differentiation), and CD31 (endothelial cell junction), laminin, and cell anchorage system, imaged with a confocal microscope and analyzed with Imaris. In addition, we used a Nanostring panel with 770 genes related to the tumor microenvironment in healthy and fibrosis. Vascular capillaries engineered in contact with softer reticular collagen, consistent with a healthy ECM, showed more pericyte differentiation ($p<0.05$), inter-endothelial cell junctions ($p<0.05$), and effective barrier function. In contrast, stiffer fibrillar collagen, which is consistent with the characteristics of the fibrotic malignant extracellular microenvironment, was associated with cell migration outward the vessel, leakiness, and higher RNA expression of interleukin 8 (IL8), TP53, transforming growth factor beta, vimentin, and collagen III genes, thus suggesting a system that compatible with the spectrum of tumoral vasculature changes in cancer and pre-cancer lesions. When vessels were engineered without MSCs, those differences were drastically minimized, To further understand the mechanisms, HUVEC-perivascular cell adhesion was disrupted using silencing RNA for NOTCH3. Upon silencing NOTCH3, the morphology and function of vasculature were reestablished, pointing to a major role of perivascular cells in vascular changes in early tumors.

#6895 Application of MiniPDX® in clinical indication identification and anti-tumor drug development.

B. Xie, H. Chen, S. Zhao, L. Li, S. Xi, Y. Di, Y. Liu, X. Chen, X. Gu, Z. Bi, K. Hu, L. Van, J. Caggiula, C. Tang, **D. Wen**;
Shanghai LIDE Biotech Co., Ltd., Shanghai, China

MiniPDX® (Mini-patient-derived xenograft) is a novel, rapid (7~10days), and accurate method for drug sensitivity testing *in vivo*. It was referred as in vivo version of organoid assy. The testing material can be fresh patient tumor samples or tissues from established PDX models. We have systematically evaluated and compared the response rates of MiniPDX® assays and PDX assays pairwise in 26 PDX models across 3 types of cancers to 12 clinically relevant regimens for chemical and targeting drugs. The results demonstrate a high correlation between drug responses of the two assays, with sensitivity of 80% and specificity of 93%. More and more studies showed that MiniPDX® drug sensitivity test results were consistent with clinical responses in most patients, which indicated MiniPDX® models have great potential in guiding personalized medicine. LIDE has successfully conducted over 3,000 MiniPDX® tests for clinical precision medicine, covering more than 50 indications. The application of MiniPDX® extends beyond therapeutic selection, facilitating the prioritization of approved pharmacological interventions and informing the discovery pipeline for novel agents. Importantly, the MiniPDX® Mouse Trial using fresh tumor samples generated from the clinic is beneficial for determination of potential clinical indications. Only thousands of fresh cells leftover from MiniPDX® preparation are sufficient to get genomic and transcription data by OncoVee ® K-cell technology. The combination of MiniPDX® assay and omics data would be very useful for determination of potential biomarkers to distinguish responders and non-responders in population with certain indication(s) and leveraged for patient stratification and selection criteria in clinical trial design. In addition, we have developed a new version of MiniPDX® assay for immunotherapy (IO-FIVE, Immuno-Oncology Fast In Vivo Efficacy test) by using fresh patient cancer cells with autologous immune cells to maximally mimic human tumor microenvironment before seeding in immune-deficient mice. This assay allows for the tracking of cellular viability and phenotype pre- and post-treatment, thus providing a robust metric of in vivo immunotherapeutic efficacy within a fortnight.

#6896 Biomimetic hydrogels at physiological stiffness reprogram patient derived melanoma cells.

Y. L. Liu[1], J. Gleba[2], C. Kopecky[1], M. Pawlush[2], J. A. Copland[2], K. A. Kilian[1];

[1]UNSW Sydney, Kensington, Australia, [2]Mayo Clinic, Jacksonville, FL

Melanoma is a uniquely difficult cancer to treat due to complex tumor heterogeneity and resistance, where upon dissemination, survival drops to less than 17%. Drug resistance has arisen for the current standard of care and combinatorial therapies, expediting the need for new efficacious agents. The lack of physiologically relevant preclinical models has impeded the development of these therapeutics.

Potential melanoma drugs are typically assayed using cell lines on tissue culture plastic, then tested for *in vivo* efficacy and side effects in animals. This paradigm is inherently unsuitable for the generation of effective therapies as typical cell culture platforms fail to replicate the complex microenvironments known to play critical roles in tumor pathology and rodent models are prohibitively expensive for optimizing novel and combination therapies. Thus, our goal is to synthesize tissue-engineered melanoma models using biomimetic polymers that recapitulate patient tumor characteristics to assess combination and novel therapies that attenuate resistance and disrupt metastatic processes.

In this study, patient melanoma cells, which were unable to recapitulate drug responses on traditional cell culture platforms, were cultured in a controlled spatial and temporal manner on polyacrylamide hydrogels. The hydrogel scaffolds feature stiffnesses spanning that of physiological tissue, with microcontact printed human fibronectin for biomimetic protein presentation to create a microtumor array. Cells cultured on the hydrogel showed a 2.5-fold increase in expression of the cancer stem cell biomarkers, CD271 and ABCB5, which play a key role in melanoma survival and recurrence, compared to cells cultured on plastic or glass substrates. Further study identified BRAF mutant, drug resistant patient cells, regained resistance to standard of care targeted therapies, trametinib and dabrafenib. Through hydrogel microarrays featuring physiological similarities, the technology has enabled the exploration of heterogeneous cell populations with novel and combinatorial therapeutics.

#6897 Defining critical features for successful preclinical use of glioblastoma patient-derived xenografts (PDX) models for therapeutic assessment and clinical trial development.

D. M. Burgenske, A. C. Mladek, K. K. Bakken, Z. Hu, B. L. Carlson, P. A. Decker, J. E. Eckel-Passow, J. N. Sarkaria;
Mayo Clinic, Rochester, MN

Mayo Clinic has developed 111 GBM PDXs from newly diagnosed (72 PDX) and recurrent (39 PDX) patients. This large collection of PDXs provides a broad representation of genetic heterogeneity seen in patients. GBM PDXs that perform well in both *in vitro* and *in vivo* settings can be extensively utilized in the preclinical setting for downstream analysis. Based on 20 years of experience, we have defined the attributes that best enable preclinical use of our GBM PDX models. Among them are short-term *in vitro* culturing performance, large scale genomic evaluation data, benchmarked responses to standards of care, and median time to moribund for untreated orthotopic tumors. PDXs with prolonged survival timelines delay study readouts and, in some situations, confound efficacy results due to age-related animal decline. Setting median survival thresholds as part of the upfront experimental design allows for more timely study readouts that are unaffected by these confounding variables. Our preferred cutoff for the Mayo GBM PDX collection is 70 days median survival (n=64). Using this 64 PDX line panel, regimens expected to double survival would produce results within 4-5 months. This timeframe is well within the range of robust health for athymic nude mice. This 64-line collection features both newly diagnosed (nGBM; n=42) and recurrent (rGBM; n=22) tumors. MGMT promoter methylation status was determined by qMS-PCR (25 methylated, 37 unmethylated, 2 indeterminate). Available WES (n=62) and RNAseq (n=42) data, along with our tissue microarray (n=42), are critical resources for biomarker-based evaluations aimed at defining patient populations that are most likely to benefit from a given therapeutic. From these data, the molecular subtypes available include 26 classical, 14 proneural, and 3 mesenchymal. Twenty-seven of these 64 PDX models have also been successfully cultured from fresh as well as cryopreserved cell stocks to further expand their experimental value. Correlative clinical data including diagnosis and treatments are also available (n=61). Current standards of care for GBM include radiation, temozolomide, and bevacizumab. Defining sensitivity to these therapies is an important first step for evaluating the integration of novel therapeutics with these standards. Since the creation of our GBM PDX collection, efficacy of these therapies has been evaluated as follows: RT 26 PDXs, TMZ 20 PDXs, and Avastin 23 PDXs. The Mayo Clinic GBM PDX collection provides an important platform for preclinical evaluation of novel therapeutics. Through careful selection of PDX lines with favorable growth characteristics and known genetic features, researchers can select the most relevant models for their study. This approach will enable more meaningful preclinical work in the hopes of providing more tangible clinical benefits for GBM patients.

#6898 Cholangiocarcinoma patient-derived models in the NCI Patient-Derived Models Repository.

Y. A. Evrard[1], C. R. Timme[1], B. Das[1], G. Bliss[1], C. Bonomi[1], C. Border[1], T.-C. Chang[1], A. Chen[2], L. Chen[1], M. A. Crespo-Eugeni[3], K. Cooper[1], N. Czarra[1], I. Czernia[1], K. Dougherty[1], M. Gibson[1], T. Grinnage-Pulley[3], S. Jiwani[1], K. Kalmbach[1], C. A. Karlovich[1], C. McGlynn[1], M. Mullendore[1], M. Murphy[1], R. Pauly[1], K. Plater[1], J. Steed[1], L. Stockwin[1], S. Uzelac[1], P.-F. Wu[1], D. L. Newton[1], P. Williams[1], M. G. Hollingshead[3], J. H. Doroshow[2];
[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]National Cancer Institute, Bethesda, MD, [3]National Cancer Institute, Frederick, MD

Cholangiocarcinoma (CHOL) is an aggressive rare malignancy arising in the biliary tract with a 5-year relative survival rate of 10% and a 60-70% recurrence rate following surgical intervention. Advances in treatment strategies are hampered by the lack of well annotated and characterized preclinical models. The National Cancer Institute's Patient-Derived Models Repository (NCI PDMR; https://pdmr.cancer.gov) has developed a national repository of Patient-Derived Models (PDMs) comprised of patient-derived xenografts (PDXs), in vitro patient-derived tumor cell cultures (PDCs) and cancer associated fibroblasts (CAFs) as well as patient-derived organoids (PDOrg). These PDMs are clinically annotated with molecular information available in an easily accessible database for the extramural community. To date, 94 patient CHOL tumor specimens (resections, biopsies, rapid autopsy) have been received from 55 unique patients with an overall PDX take rate of 36.3% (80 assessable specimens). There are currently 15 CHOL PDX models available for the research community to request with 14 more in final QC. Nine of the 15 public PDX models were generated from unique lesions in two rapid autopsy patients and while histo-morphologically consistent, some genomic heterogeneity is observed between the unique anatomical locations likely due to tumor evolution during metastasis. In addition, 27 in vitro PDOrgs, PDCs, and CAFs have been generated from patient or PDX material matched to most of the existing PDX models to allow for comparative translation research. The genetic landscape of the CHOL PDXs includes oncogenic drivers in *NRAS, IDH1, ERBB2, TP53*, *KRAS and FGFR2* fusions; OncoKB likely oncogenic variants including *ARID1A, AXIN1* and *BAP1*; and *CDKN2A* deep deletions representing most of the common alterations in CHOL. Early passage preclinical PDX and in vitro models for CHOL, and many other cancer types, with translational relevant features along with associated NextGen sequencing and patient treatment history are available from the NCI PDMR. Availability of preclinical models that can be used to study these cancers and improve preclinical drug screening is of high importance to better understand the biology of these cancers and prioritize novel therapeutics from bench to clinic. Funded by NCI Contract No. HHSN261200800001E

#6899 Enfortumab vedotin (EV): Efficacy comparison with trastuzumab deruxtecan (T-DXd) and sacituzumab govitecan (SG) and its potential for combination benefit in bladder cancer XPDX models.

J. Flores[1], H. Sessions[1], A. Simonson[1], N. Banos[1], T. Rouzbahani[1], A. Diaz III[1], J. Lund[1], E. Calvo[2], V. Moreno[2], K. Papadopoulos[3], D. Rasco[3], A. Patnaik[3], S. Ulmer[4], L. Rodriguez[4], M. Wick[1];

[1]XenoSTART, San Antonio, TX, [2]START Madrid, Madrid, Spain, [3]START San Antonio, San Antonio, TX, [4]STOH, San Antonio, TX

EV is a Nectin-4 targeting antibody-drug conjugate (ADC) with an MMAE payload, recently approved for bladder cancer treatment. We established and characterized 18 bladder XPDX models representing primary and metastatic disease from naïve or clinically treated patients, some with actionable mutations. To better understand the potential additive benefit of EV in bladder cancer, we evaluated the ADC alone and in combination with agents targeting ERBB2, PIK3CA or FGFR3. In addition, we tested EV alone in ST5420B, a model established from a patient who progressed on EV after five cycles, as well as ST975B, a model which harbors a novel NECTIN4 fusion. 18 bladder XPDX models were established in immune-deficient mice, including 5 from newly diagnosed patients (2 from primary site), and 13 from recurrent disease (2 from primary site). Nectin-4, Trop2 protein and ERBB2 receptor expression was tested, and models profiled using WES and RNA_{seq}. For in vivo studies, all models were evaluated against cisplatin, T-DXd, SG, and EV. Models with actionable mutations were tested with alpelisib, erdafitinib, and neratinib alone and in combination with EV. Endpoints in all studies included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion; a %T/C of ≤ 20% versus control was considered sensitive. Tumor regression (%T/C<0%) versus Day 0 tumor volume was also reported. Most models stained positive for Nectin-4 and Trop-2. FGFR3 variants were found in five models and ERBB2 mutations in two while several models reported PIK3CA variants; deletions in RB1 and CDKN2A were common. In vivo studies reported differential responses to cisplatin with the most sensitive models established from treatment-naïve patients. EV and SG tested alone reported activity in several models; EV added benefit in some combination treatments. We have characterized a panel of bladder XPDX models and benchmarked them against T-DXd, EV and SG alone and EV in combination with targeted therapies. This data is a valuable tool in further developing EV and identifying novel therapies for bladder cancer.

#6900 Patient-derived xenografts from circulating cancer stem cells and their potential utility in personalized medicine of pancreatic cancer.

M. Pizon[1], D. Schott[1], A. Ettner-Sittner[2], B. J. Wagner[3], K. Pachmann[4], T. Aung[5], C. Hackl[3], S. Haerteis[2];

[1]Special Immunology Research and Development, Bayreuth, Germany, [2]Institute for Molecular and Cellular Anatomy, University of Regensburg, Regensburg, Germany, [3]Department of Surgery, University Hospital Regensburg, Regensburg, Germany, [4]Laboratory Dr. Pachmann, Bayreuth, Germany, [5]Faculty of Applied Healthcare Science, Deggendorf Institute of Technology, Deggendorf, Germany

Background: Pancreatic cancer carries a poor prognosis in the majority of patients, with an overall 5-year survival rate of less than 10%. Therefore, the development of new therapies and preclinical models is crucial and urgently needed. Circulating cancer stem cells (cCSCs) are a subset of circulating cancer cells that have stem cell-like properties and play a significant role in tumor progression, metastasis, and treatment resistance. Patient-derived xenografts (PDX) reflect the genotypic and phenotypic landscape of patients' cancers and are useful for drug screening, biomarker development, and preclinical evaluation of personalized medicine strategies. In this study, we describe a fast, simple, and cost effective method to generate PDX on Chorioallantoic Membrane (CAM) from circulating cancer stem cells.

Methods: In this study, primary cultures from circulating cancer stem cells were established using sphere-forming assays from 30 patients with newly diagnosed pancreatic cancer. Subsequently, tumorspheres were transplanted onto the CAM membrane of fertilized chicken eggs to form patient- derived xenografts.

Results: For the identification of cCSCs from peripheral blood of pancreatic cancer patients, an innovative *in vitro* sphere-forming assay was established. The number of tumorspheres was correlated with clinicopathological parameters like tumor size, lymph node involvement and grading status of the primary tumor. Implantation of tumorspheres onto the CAM was successful in ~90 % of the applied samples. The histological analysis suggests that the PDX tumors were morphologically and pathologically identical to primary tumor tissue.

Conclusions: The number of tumorspheres was associated with clinicopathological parameters. Further follow-up is needed to evaluate the prognostic significance of tumorsphere detection in pancreatic cancer. Generation of PDX from cCSCs on CAM has a high success rate and may become an integral part of the drug development arena, including drug screening and biomarker development.

#6901 Paired colorectal and pancreatic cancer patient-derived tumor and organoids biobank.

J. Wang[1], W.-H. Ma[1], Y.-C. Lo[1], H.-C. Hsieh[1], L.-J. Hsiao[1], Y.-P. Bau[1], N.-C. Yang[2], S.-J. Tsai[3], Y.-S. Shan[4], T.-Y. Chen[2], Y.-L. Chen[2], P.-J. Chiang[1], T.-L. Chen[1], H.-P. Chang[1], H.-J. Chin[2];

[1]National Laboratory Animal Center, NarLabs, Tainan, Taiwan, [2]National Laboratory Animal Center, NarLabs, Taipei, Taiwan, [3]Institute of Basic Medical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan, [4]National Cheng Kung University Hospital, Tainan, Taiwan

Patient-derived xenograft (PDX) models constitute a crucial tool in precision cancer medicine owing to their high accuracy in predicting the response to therapeutic drugs among patients in clinical settings. Our center has established a biobank that collects more than 80 colorectal cancer and 25 pancreatic cancer PDX tissues, along with essential information about patients' tumors and PDX models. However, cost-intensive and time-consuming limit the usage of PDX model in high throughput screening during drug development. To overcome this hurdle, we are generating a PDX-match paired organoid (PDXO) biobank by using emerging three-dimensional culture techniques. Before large-scaled expansion, the concordance between PDX tissues and PDXOs of partial specimens was evaluated firstly using short-tandem repeat (STR) analysis, immunohistochemistry (IHC) and H&E staining. Data of STR analysis performed by using AmpFLSTR Identifiler PLUS PCR Amplification Kit demonstrated that PDX tissues and PDXOs have identical DNA fingerprinting. IHC and H&E staining revealed PDX tissues and PDXOs have highly similar organ-specific markers expression (e.g., Cytokeratin 20, Caudal Type Homeobox 2, and Pan Cytokeratin) and histological morphology. Even after passing to at least five generations, passed PDXOs maintained high fidelity to their original state, as confirmed by whole-exome sequencing (WES) and STR analysis across passages. The WES analysis for passage 0 (P0) and passage 5 (P5) of PDXOs from different PDX tissues revealed there is more than 95% intersection between P0 and P5 PDXOs with the same missense mutation gene. The results of STR analysis showed that P0 and P5 PDXOs have identical STR profile. To evaluate the capability of PDXOs in clinical response prediction, several effective and ineffective drugs (e.g., oxapliplatin, 5-FU, gemcitabine) were tested. The results of drug testing indicated that PDXOs can be used to accurately predict the response to therapeutic drugs as PDX model but more efficient than PDX model. Therefore, PDXO biobank can serve as a valuable resource for high throughput *in vitro* drug screening prior *in vivo* efficacy confirmation using PDX models.

#6902 Development of a stable luciferase expressing PDX-derived cell line for translational *in vitro* and *in vivo* testing.

S. Cold[1], R. N. Boge[2], E. Papin[2], I. T. Michler[1], L. K. Kristensen[2], T. B. Engel[2], A. Kjaer[1], C. H. Nielsen[2], S. Gnosa[2];
[1]University of Copenhagen and Minerva Imaging, Copenhagen, Denmark, [2]Minerva Imaging, Copenhagen, Denmark

Despite much effort invested in developing novel cancer therapies, more than 90% of clinical studies fail due to toxicity or lack of efficacy in patients. This can mainly be ascribed to lack of relevant and translational preclinical models. A common model used in preclinical studies is the xenograft model using immortalized cancer cells. Cell line-based models are cost efficient and can be genetically manipulated but are often criticized for lacking translational value. A murine model with higher clinical relevance is the patient derived xenografts (PDX) model established by implanting patients' tumor tissue onto immunodeficient mice. Knowledge of patient therapy response, mutational status and tumor heterogeneity makes it a relevant model. However, PDX models are costly, not applicable for *in vitro* assays or subjective to genetic manipulation. To more closely mimic *in vivo* tumors we have established a PDX-derived cell line (PDXc) and characterized it extensively in a head-to-head comparison to the parental PDX model. Cells were isolated from a subcutaneous (SC) glioblastoma (GBM) PDX tumor (ST146), processed into single cells and cultivated *in vitro*. Once the PDXc were stable over several passages the cells were re-implanted into mice. Tumor take and growth rate were evaluated against the parental PDX model and common characteristics of the model such as EFGR and Vimentin expression were determined by IHC. We furthermore generated a stable Luciferase expressing PDXc using 3rd generation lentiviral particles and implanted the cells in an intracranial (IC) model of GBM. Tumor growth was evaluated using bioluminescence imaging (BLI) and MRI. Upon multiple passages and freeze cycles the cell line (ST146c) exhibited a stable in vitro doubling time (2.6 ± 0.2 days) with a morphology like other GBM cell lines with formation of neurospheres. STR analysis confirmed a genetic identical profile to ST146.

ST146c implanted into mice had similar tumor take and growth rates to the parental PDX when injected IC (>90%, T_d=3 d) and SC (>75%, T_d=6 d). We also showed that ST146c had more homogeneous tumor growth. *Ex vivo* analysis showed similar expressions of EGFR (-), Vimentin (+++) and Ki67 (++) between the models. The BLI signal obtained from luciferase expressing ST146c implanted orthotopically was correlated to tumor volume obtained by MRI. We developed a PDX cell line that preserved critical *in vitro* and *in vivo* characteristics of the PDX model such as doubling time, tumor take rate and marker expression making it feasible to use the PDXc model in future preclinical studies. This will allow *in vitro* screens with patient derived tumor cells. Furthermore, the expression of luciferase in the PDXc enables intracranial and metastatic implantation with tumor monitoring using BLI. This platform consisting of *in vitro* and *in vivo* PDX models could be used as a predictive translational platform for testing new cancer therapies.

#6903 Treatment efficacy of transcatheter hepatic arterial infusion chemotherapy with cisplatin in a severe immunodeficient rat model with patient-derived primary pancreatic ductal adenocarcinoma xenografted into the liver.

K. Kageyama[1], A. Yamamoto[1], M. Ozaki[1], K. Kimura[1], S. Eguchi[1], R. Tanaka[1], M. Terai[2], T. Sato[2], Y. Miki[1];

[1]Osaka Metropolitan University, Osaka, Japan, [2]Thomas Jefferson University, Philadelphia, PA

Purpose: Liver metastases of pancreatic ductal adenocarcinoma (PDAC) is a highly fatal disease; most patients die within 5 years. There is a critical need to identify appropriate anticancer treatments for these patients. A patient-derived tumor xenograft (PDX) model in severe immunodeficient rat with primary PDAC xenografted into the liver is suitable for evaluating transcatheter hepatic arterial infusion chemotherapy.

Materials and Methods: The purpose of this study was to develop a severe immunodeficient rat model with patient-derived primary PDAC xenografted into the liver, and to assess the treatment efficacy of hepatic arterial infusion chemotherapy with cisplatin in this model. Three patient-derived tumors of PDAC were transplanted into the liver of 21 rats each, totaling 63 rats. Four weeks after transplantation, the 21 rats were randomly assigned into three treatment groups of seven rats each: hepatic arterial infusion, systemic venous infusion, and control group. Tumor volumes were evaluated on CT twice at pre-treatment and 4-weeks post-treatment. Following euthanasia of the rats, resected tumor specimens were pathologically analyzed.

Results: The liver-implanted PDAC PDX rat model was established in all 63 rats. hepatic arterial infusion chemotherapy and systemic venous infusion chemotherapy with cisplatin were able to be performed in the assigned rats. The hepatic arterial infusion group significantly inhibited tumor growth and reduced Ki67 expression, indicating lower cell proliferation, compared to the control group in three PDX tumors.

Conclusion: A rat-based preclinical platform was established by liver-implanted PDAC PDX rat model. Arterial cisplatin infusion chemotherapy would be one of potential therapies for PDAC liver metastases.

#6904 Model-derived progression-free survival (mPFS): A better metric for patient-derived xenograft studies?.

A. Chen[1], M. Stoddard[2], **L. Yuan**[2], D. Van Egeren[3], A. Chakravarty[2], D. Bottino[4];

[1]Columbia University, New York, NY, [2]Fractal Therapeutics, Inc., Lexington, MA, [3]Stanford University, Palo Alto, CA, [4]Takeda Pharmaceuticals, Cambridge, MA

Patient-derived xenografts (PDX) are a powerful assay system for translational prediction of therapeutic potential for experimental therapeutics. The primary readout from PDX models is tumor shrinkage, measured by the ratio of treated/control tumor volume. This readout corresponds loosely to the Objective Response Rate (ORR) metric used in clinical trials, in that it is a readout of drug effect on the sensitive subclones within a tumor. In prior work, we have shown that there is a paradoxical relationship between short-term tumor response and progression-free survival (PFS). While ORR is the primary measure utilized in the Phase II to III transition in clinical development, approval hinges on survival metrics, and the disconnect between ORR and PFS creates a potential risk of late-stage failures for experimental anticancer therapeutics. Thus, it is of interest to understand whether there are alternative approaches to analyzing PDX data that can enable the assessment of therapeutic potential in terms of a projected PFS. In this simulation study, we will examine the accuracy of progression-free survival (PFS) estimates obtained directly from observation during a PDX study and compare their accuracy with the accuracy of PFS estimates derived using a mathematical model-based approach that relies on a kinetic model of tumor subclone growth (model-based PFS, or mPFS) fitted directly to PDX tumor growth and rebound kinetics under treatment. We generated our test dataset using a mathematical model of tumor kinetic growth to simulate xenograft data using fitted parameters derived from literature, adding in experimental error consistent with prior experimental measurement-derived variability. We used the simulated raw data to calculate an observed PFS as well as mPFS derived from fitting the tumor clonal kinetic model to the raw data in a blinded fashion. Our results show that the empirical PFS from PDX models is subject to overestimation, as a function of the observation time interval. On the other hand, mPFS is significantly less biased and more accurate, but is subject to some logistical constraints on sampling. Our work demonstrates the practical translational utility of a novel analysis method (mPFS) in deriving estimates of progression-free survival from PDX model data.

#6905 A multi-targeted approach to evaluate therapeutic selection and efficacy in preclinical GBM models.

E. Eastwood, B. Carapia, J. Rodriguez, K. Buck, D. Gorospe, E. Valencia, B. Corcoran, R. Pippa, Y.-H. Chien, W. Andrews, L. Do, **J. K. Nakashima**, J. Sperry; Certis Oncology Solutions, San Diego, CA

Glioblastoma (GBM) is a devastating primary brain cancer with approximately 10,000 new US diagnoses annually. The current standard of care (SOC) for GBM includes surgical resection followed by radiation therapy (RT) and temozolomide (TMZ), however, there is near universal recurrence and development of resistance after treatment. Relapse in disease is tightly linked with dynamic changes in gene expression during tumor evolution, highlighting the need for stronger preclinical GBM models. Here, we report developing a pair of patient-derived xenograft (PDX) models from surgical resections obtained from initial GBM incidence in a patient (BarneyOI™ Cancer Model CRT00433) and subsequent recurrence following treatment (BarneyOI Cancer Model CRT00435) to study disease progression and novel treatment strategies. Recent studies have suggested the utilization of combination therapy approaches for GBM patients to address TMZ resistance. To this end, Certis has developed a personalized, AI-based approach to predict and test combination therapies in preclinical cancer models. Accuracy of the predicted sensitivities to treatment was evaluated *in vivo* using both subcutaneous (SC) and orthotopic (OT) mouse models. Luciferase-tagged CRT00433 and CRT00435 spheroid cell lines were transduced with firefly luciferase and implanted intracranially by stereotactic surgery for OT monitoring. Optical bioluminescence imaging (BLI) and murine-scale MRI from Aspect Imaging were used to assess therapeutic response of AI-predicted combination therapies and SOC treatment.

#6906 Engineered bacteria launch and control an oncolytic virus.

J. Pabon[1], Z. Singer[1], H. Huang[1], C. Rice[2], T. Danino[1];
[1]Columbia University, New York, NY, [2]The Rockefeller University, New York, NY

The ability of bacteria and viruses to selectively replicate in tumors has led to synthetic engineering of new microbial therapies. In our system, Salmonella has been programmed to produce Senecavirus A (SVA)-RNA and launch an SVA infection in bacterially-infected cancer cells. Utilizing time-lapse microscopy, we visualize S. typhimurium invasions into cancer cells and their subsequent delivery of multiple picornaviral species. S.-typhimurium-viral-RNA launch in vitro identified a small-cell-lung cancer cell line, H446, as a promising candidate for S.-typhimurium-SVA launch. This viral RNA-carrying Salmonella strain confers complete tumor regression in vivo. Finally, we integrate into this strain a protease-dependent mechanism to confer SVA-infection spatial localization. This work, to the best of our knowledge, is the first instance of bacteria delivering full-length viral RNAs for therapeutic oncolytic purposes.

#6907 Micro-implantation of patient tumor samples into the avian embryo, a fast and reliable alternative in vivo technology for preclinical studies on melanoma and follicular lymphoma.

C. Costechareyre, Sr.[1], L. Jarrosson, Sr.[1], M. Lacourrege, Sr.[1], **R. Teinturier, Sr.**[1], J. Caramel, Sr.[2], M. Zala, Sr.[3], S. Dalle, Sr.[3], P. Sujobert, Sr.[3], C. Delloye-Bourgeois, Sr.[1], F. Berget, Sr.[1], V. Castellani, Sr.[1];

[1]ONCOFACTORY, Lyon, France, [2]Centre de recherche en Cancerologie de Lyon (CRCL), Lyon, France, [3]CHU Lyon Sud, Lyon, France

Despite recent efforts to develop reliable and predictive patient-derived cancer models, drug attrition rates in oncology remain high. Moreover, conventional models such as patient-derived xenograft (PDX) mouse models face major cost and time limitations, not supporting real-time clinical decision making. To overcome such limitation, ONCOFACTORY developed a proprietary PDX platform enabling the engraftment of small size tumor biopsy samples within targeted tissue of the avian embryo at early stage of development, to conduct preclinical proof of efficacy studies and provide PDX clinical trial solution helping with patient's selection prior to clinical phase II/III. On one hand, we performed prospective co-clinical trial aiming to evaluate the utility of the AVI-PDX™ model in predicting the response to standard therapy, consisting of BRAF and MEK inhibitors, for patient with metastatic melanoma harboring BRAF mutations. Skin biopsy samples were implanted into specific tissue driving tumor formation under the skin of avian embryos. On the other hand, we conducted a retrospective cohort study with 20 follicular lymphoma (FL) patient samples divided into "partial" and "complete" responders to the standard immuno-chemotherapy RCHOP regimen to establish FL AVI-PDX™, and examine sensitivity to RCHOP in ovo. Twenty-four hours post-implantation, avian melanoma and FL replicas were respectively exposed to BRAFi/MEKi or RCHOP and their vehicles, over 24h. Then, embryos were harvested, and tumor response was examined by measuring tumor volume using light sheet microscopy. Alongside, in independent series of avian embryos implanted with FL samples, tumors were harvested for single-cell transcriptomic analyses to explore mechanism of response to RCHOP. For melanoma, we provide the proof of concept that the AVI-PDX™ reliably predict sensitivity or resistance to BRAF and MEK inhibitors within days, matching patient clinical outcome observed in clinic. For FL, we showed that the FL-AVI-PDX™ efficiently captures clinical response to RCHOP in a heterogenous cohort of patients, enabling to discriminate partial and complete responder within short-time frame. Next, we identified a robust genetic signature reflecting exposure of tumoral cells to RCHOP and showed that drug-mediated targeting of one of these genes with a chemotherapy resulted in strong potentiation of RCHOP. Thus, we provide evidence of the high predictive power of the AVI-PDX™ models allowing fast and reproducible generation of tumors replicas from small size patient tumor samples. This places the AVI-PDX™ as a valuable tool for clinical research to rationalize patient inclusion in clinical trials but also for the design of personalized medicine assays.

#6908 Integrating PDX GBM *in vivo* models with patient history and whole exome sequencing: Advancing relevance and precision in preclinical studies.

E. E. Trachet, P. M. Gonzales, S. Gately;
Translational Drug Development (TD2), Scottsdale, AZ

Glioblastoma poses a significant challenge in oncology, necessitating improved translational models that faithfully replicate the intricate tumor microenvironment. Patient-derived xenograft (PDX) models, are key in glioblastoma multiforme (GBM) preclinical research. PDX models (orthotopic and subcutaneous) provide a more clinically relevant representation compared to CDX xenografts. Analyzing PDX tumors in their native environment allows for a nuanced understanding of GBM biology, tumor-stroma interactions, and treatment responses. This abstract explores the rationale and advantages of utilizing PDX GBM *in vivo* models coupled with patient diagnosis and treatment history, empowered by tumor whole exome sequencing (WES), to enhance the relevance of preclinical studies in evaluating GBM-specific treatments. TD2 has access to over 100 GBM PDX tumors models with fully annotated patient details and treatment history. Moreover, 68 of these PDXs also have WES data, that allows most appropriate model selection to ensure alignment with the therapeutic development strategy. Below is a detailed analysis of two GBM PDX models, GBM6 and GBM46, using patient history and WES data to define criteria for success in assessing novel preclinical therapeutic agents. GBM6, was obtained prior to treatment from a 65-year-old man with glioblastoma multiforme, that contains 642 mutations, including EGFR VIII amplification. GBM46, was obtained from a 55-year-old man with prior treatment, contained 646 mutations, including RAS pathway alterations and EGFR (MET and FLT3) amplification. When grown subcutaneously the anti-tumor activity of cetuximab against GBM6 and GBM46 resulted in 41% and 48% growth inhibition, respectively. Traditional treatments have also been evaluated in the orthotopic setting, with temozolomide (TMZ) showing a nominal improvement in lifespan (11%) as expected for the unmethylated MGMT found in the GBM6 model. By contrast, GBM46 from a patient with prior treatment with TMZ, OSI-774, radiation, and BCNU, exhibited a 58% increase in overall lifespan when treated with TMZ alone. Orthotopic PDX GBM models preserve many molecular characteristics, enabling the study of intrinsic GBM mutations for developing novel therapeutic strategies. While orthotopic models better capture GBM's dynamic nature, traditional xenograft systems remain valuable as rapid screening tools. Models with defined clinical treatment history and WES data allows for testing new agents in models that more closely resemble the clinical development path for a given new agent and aids in deciphering factors influencing therapeutic resistance. These models have the potential to reshape preclinical research paradigms, accelerating the translation of promising therapeutic agents increasing the likelihood of clinical benefit for patients with glioblastoma multiforme.

#6909 KRAS^{G12C} inhibitor resistance in patient-derived non-small cell lung cancer models.

Joshua C. Rosen[1], Nhu-An Pham[1], Quan Li[1], Pinjiang Cao[1], Katrina Hueniken[1], Takamasa Koga[1], Nikolina Radulovich[1], Alex Koers[2], Michael Niedbala[3], Sarah Ross[2], Adrian Sacher[1], Ming-Sound Tsao[1]

[1]University Health Network, Toronto, ON, Canada,[2]AstraZeneca, Cambridge, United Kingdom,[3]AstraZeneca, Waltham, MA

Introduction: One quarter of lung adenocarcinomas (LUAD) harbor *KRAS*-mutations, with *KRAS*^{G12C} accounting for the majority (40%). GDP-KRAS^{G12C} inhibitors (G12Ci) have been developed for this patient cohort, and two of these are approved for clinical use in the US. While response rates to G12Ci tested in clinical trials have been between 35-50%, studies have identified mechanisms of adaptive resistance to these novel agents, limiting their use as monotherapies. However, primary (intrinsic) resistance to these compounds has not been explored extensively. We leveraged our patient-derived xenograft (PDX) and xenograft-derived organoid (XDO) development programs to study primary resistance to the novel G12Ci, AZD4625.

Methods: Twelve *KRAS*^{G12C} PDX models were established which recapitulated patient tumor histology, and genomic, transcriptomic, and methylome profiles. From these 12 PDX, six long-term (passage >10) XDO were generated. PDX were treated with AZD4625 chronically for four weeks as well as in an acute dosing pharmacodynamic study, where tumors were harvested for further analysis.

Results: The AZD4625 drug screen in our PDX models reproduced the G12Ci response rate observed in clinical trials. Four of twelve tumor models reduced in size on treatment, while the remainder were considered resistant as these tumors increased in size on treatment. Sensitive tumors became necrotic while those resistant remained proliferative. XDO models recapitulated their originating PDX genomic alterations, histology, as well as responses to AZD4625. During the acute pharmacodynamic screen in our PDX models, we observed a decrease in pERK1/2 and pS6 protein expression in sensitive but not resistant models, despite acute *DUSP6* gene expression decreases in every model. Global proteomic analysis highlighted differences between each model.

Conclusion: PDX and XDO are useful models to study resistance to this novel class of inhibitor, with the *KRAS*^{G12C} NSCLC PDX models exhibiting a treatment response rate that is similar to those observed in clinical trials. Global proteomics suggests uniqueness of each model in our cohort, hinting that a universal combination of specific targeted agents to treat *KRAS*^{G12C} LUAD tumors may be insufficient.

#6910 CancerModels.org: An open global cancer research platform for patient-derived cancer models.

Z. Perova[1], M. Martinez[1], T. Mandloi[1], M. Rios Almanza[1], S. Neuhauser[2], D. Degley[2], D. Krupke[2], C. Bult[2], H. Parkinson[1];
[1]European Bioinformatics Institute, Hinxton, United Kingdom, [2]The Jackson Laboratory, Bar Harbour, ME

CancerModels.Org (www.cancermodels.org) is a research platform that standardises, harmonizes and integrates the complex and diverse data associated with Patient-Derived Cancer Models (PDCMs) for the cancer community. The portal publishes over 7500 models - covering patient-derived xenografts (PDX), organoids and cell lines - across 13 cancer types, including rare pediatric PDX models and models from minority ethnic backgrounds. A total of over 90 million data points are made available across a variety of data types, such as clinical metadata, molecular data and treatment-based information, which makes CancerModels.Org the largest free-to-consumer and open-access resource of this kind.

Over the course of the last twelve months, the platform has been enhanced with new functionality and an updated user interface to cater for a more varied set of use cases. Users can now search for models of interest by exploring molecular data summaries for models of specific cancer types, as well as by using the intuitive search and faceted filtering options of the web interface. The data is also accessible via REST API, hence enabling offline analyses. The underpinning data model was augmented with additional dimensions and covers gene expression, gene mutation, copy number alteration, biomarkers, patient treatment and drug dosing studies. For an improved prioritization of PDCMs we performed knowledge enrichment by linking to external resources, such as publication platforms, cancer-specific annotation tools (COSMIC, CIViC, OncoMX, OpenCRAVAT, ClinGen), and raw data archives (ENA, EGA, GEO, dbGAP). More recently, we added immune-related features of tumors (HLA, MSI, TMB) and image data (also accessible via EMBL-EBI's BioImage archive). Finally, to streamline model and data submission, we made available a Metadata dictionary and a Metadata validation service.

Future work will focus on the curation of rare models with rich accessible metadata and data, new data visualizations, integration of new data types and resources, as well as devising a model quality rating using user feedback. These developments will maximize utility and improve reusability of models and data, and reduce barriers to model and data sharing.

CancerModels.Org is deeply integrated into the general patient-derived cancer models landscape, underpinning or contributing to the data and/or software infrastructure of some of the long-running consortia, such as EUROPDX and PDXNet. The resource is freely available under an Apache 2.0 license (https://github.com/PDCMFinder).

#6911 Expanding reported molecular characteristics for the NCI Patient-Derived Models Repository.

C. R. Timme[1], Y. A. Evrard[1], B. Das[1], T.-C. Chang[1], A. Chen[2], L. Chen[1], M. A. Crespo-Eugeni[3], S. Jiwani[1], C. A. Karlovich[1], R. Pauly[1], P.-F. Wu[1], D. L. Newton[1], P. Williams[1], M. G. Hollingshead[3], J. H. Doroshow[2];

[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]National Cancer Institute, Bethesda, MD, [3]National Cancer Institute, Frederick, MD

The National Cancer Institute's Patient-Derived Models Repository (NCI PDMR; https://pdmr.cancer.gov) has developed a national repository of Patient-Derived Models (PDMs) comprised of patient-derived xenografts (PDXs), in vitro patient-derived tumor cell cultures (PDCs) and cancer associated fibroblasts (CAFs) as well as patient-derived organoids (PDOrg). These PDMs are clinically annotated with molecular information available in an easily accessible database for the extramural community. To ensure the data and models remains pertinent to current translational efforts, NCI actively reviews and adds new molecular features to the public database for researchers to use. While these data could be obtained through analysis of the available NextGen sequencing files in the PDMR database, many laboratories do not have the bioinformatics support to run these assessments for models that are of research interest. Therefore, new pipelines for an array of additional model and molecular characteristics present in PDX, PDOrg, and PDC models have been validated and are reported in the public database in a searchable format. Current model characteristics include addition of OncoTree Codes as a second histologic classifier, use of the PDXNet Consortium's inferred ancestry caller to better represent Native/Latin American populations, human leukocyte antigen (HLA) typing, molecular classification of tumors (e.g. CMS subtyping of colorectal adenocarcinoma, PAM50 signature based subtyping of breast carcinoma), microsatellite instability (MSI) assessment, and identification of clinically relevant fusions. SOPs for the pipelines used are available on the public website to allow for independent validation and use by other laboratories. Funded by NCI Contract No. HHSN261200800001E

#6912 Pretreatment multiomics in conjunction with preclinical trials on patient-derived xenograft models of cholangiocarcinoma can identify chemotherapy response signatures.

A. M. Abdelrahman[1], D. M. Carlson[1], E. Jessen[1], D.-G. Mun[1], I. Lynch[2], A. Fogliati[3], S. Adjei Antwi[1], A. Abeynayake[1], A. Pandey[1], M. J. Truty[1], G. J. Gores[1], R. L. Smoot[1];

[1]Mayo Clinic, Rochester, MN, [2]University of Iowa Roy J. and Lucille A. Carver College of Medicine, Iowa City, IA, [3]University of Milano-Bicocca, Monza, Italy

Background Cholangiocarcinoma (CCA) is a heterogeneous malignancy. Platinum-based chemotherapy (Gemcitabine and Cisplatin) has been the standard treatment for over a decade and is the base for the current immunotherapy combinations. Response rates are typically between 20-30%. Herein, we present outcomes of preclinical efficacy trials on CCA PDX models in correlation with baseline multiomics profiling of CCA patient-derived xenograft (PDX) models to identify molecular features associated with response. **Methods** Tumor samples from twenty-eight CCA PDX were used to isolate RNA and protein to be included in multiomics analysis (Phosphoproteomics, Proteomics, and Transcriptomics). A subset of PDX models were treated with various doses of Gemcitabine and Cisplatin. The Median Efficacy Index (MEI) was calculated as the ratio of the difference in median of delta in tumor volume at the last day of the study between the treatment and the control arms divided by the median of delta in tumor volume of the control at the last day of the treatment (positive= growth, negative=inhibition, and 0=no efficacy). A Hierarchical All-Against-All algorithm was utilized to compare multiomics features to the MEI and pathway analysis completed for identified molecular features. **Results** After conducting preclinical efficacy trials, the five tested CCA PDX models were classified into sensitive, moderately sensitive, and resistant models based on the MEI on each treatment arm. The top up-regulated genes were identified for Gemcitabine response (SRPK2, GLK2, and RIOK2) and Cisplatin response (NTRK1, PRPF4B, and SRPK2). The top up-regulated genes related to Gemcitabine resistance were NTRK1, PIP5K1C, and CSNK2A2, while those related to Cisplatin resistance were SRPK1, PRPF4B, and CSNK2A1. **Conclusion** Cholangiocarcinoma multiomics signatures can predict therapeutic response to standard-of-care chemotherapy in preclinical models. Novel mechanisms of Gemcitabine and Cisplatin resistance were identified related to NTRK1, SRPK1 and SRPK2. Resistant signatures will be challenged with the appropriate targeted therapies on the resistant CCA PDX models.

#6913 A preclinical platform of prostate cancer PDX and derived cellular models as a tool for pharmacological screening and functional studies.

E. Indersie[1], L. Sinayen[1], L. Bigot[2], K. Mevel[1], A. Gorse[1], M. Tavernier[1], E. Le Ven[1], L. Friboulet[2], F. Farace[2], E. Morgado[3], L. Pouyet[3], Y. Loriot[2], F. Romagne[3], **O. Deas**[1];

[1]Janvier Group, Evry-Courcouronnes, France, [2]Gustave Roussy, Villejuif, France, [3]Janvier Group, Marseille, France

Prostate Cancer (PCa) is the most frequently diagnosed cancer in men and remains one of the leading causes of cancer death worldwide. Despite undeniable progress in understanding the biology and genetics of this highly heterogenous and complex disease, the development of effective therapies is hampered by the lack of relevant experimental models recapitulating its diversity. To tackle this issue, over the last years, we have generated and characterized at the molecular and pharmacology level a collection of prostate cancer patient-derived xenografts (PDX) that accurately reproduce PCa histological and molecular heterogeneity. Although the development of these PCa PDX has been challenging, we are now able to offer a preclinical platform of 11 fully characterized PCa PDX models and *in vitro* cellular counterparts for preclinical evaluation of novel treatment modalities. Our platform consists of a collection of 4 androgen receptor high (ARPC), 2 androgen receptor low (ARLPC), 1 amphicrine prostate carcinoma (AMPC) and 4 castration-resistant neuroendocrine prostate cancer (CRPC-NE) PDX models and 6 cellular models derived from these PDX (PDXDC). Most of these PDX models were obtained by transplantation of post-surgery tumor specimens either by grafting of tumor fragments in the interscapular region of nude mice or in the subrenal capsule of NOD scid gamma mice. One model is a CTC-derived eXplant established using circulating tumor cells (CTCs) obtained by diagnostic leukapheresis injected into the fat pad of NOD scid gamma mice. PDXDC were obtained from dissociated PDX tumors cultured under various media and matrix conditions. They were characterized by comparison with the parental PDX by Short Tandem Repeat (STR) profiling before performing a master bank. All models (PDX and PDXDC) were characterized at molecular level by whole exome and RNA sequencing. PDX were characterized pharmacologically for response to standards of care, physical castration and response to the androgen receptor inhibitor enzalutamide. *In vitro* drug sensitivity of PDXDC was compared with their parental PDX *in vivo* drug response. This unique PDX panel reflects the molecular heterogeneity of prostate cancer and reproduces the molecular and drug response profile of human tumors. Associated to *in vitro* cell derivatives, our collection provides a powerful preclinical platform for translational research to identify mechanisms underlying acquired resistance to current therapies and develop novel treatment strategies against PCa and CRPC.

#6914 Genomic landscape and stability of preclinical models in NCI's patient-derived models repository.

T.-C. Chang[1], B. Das[1], L. Chen[1], P. I. Wu[1], Y. A. Evrard[2], R. Pauly[1], D. L. Newton[2], S. Jiwani[1], S. Y. Alcoser[3], L. H. Stockwin[2], C. E. Camalier[1], T. Forbes[1], N. Nair[1], A. Chapman[1], L. Dutko[1], M. Mullendore[2], T. Grinnage-Pulley[3], K. Klarmann[3], S. B. Miller[4], C. A. Karlovich[1], A. P. Chen[4], P. M. Williams[1], M. G. Hollingshead[3], J. H. Doroshow[4];

[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]Advanced Development Research Directorate, Frederick, MD, [3]Developmental Therapeutics Program, Frederick, MD, [4]National Cancer Institute, Bethesda, MD

Background: Patient-derived xenograft (PDX) models serve as a powerful tool for cancer translational research. However, it is unclear to what extent PDX models reflect the genomic intratumoral heterogeneity and genomic aberrations present within the original tumor sample. The National Cancer Institute (NCI) has developed a Patient-Derived Models Repository (PDMR; https://pdmr.cancer.gov/) consisting of PDX, organoids (PDOrg), and tumor cell cultures (PDC) from patients with diverse cancer histologies. We have conducted an in-depth investigation into the genomic stability of PDXs at early passaging and tumor heterogeneity in a large set of preclinical models including rare cancers.

Methods: Tumor specimens were used to establish 1114 models from 1034 patients. For whole exome sequencing (WES) and RNASeq analysis, 1059 models with at least 1 PDX sample and 55 models with only a PDC or PDOrg were used. Analyzed specimens represent the original patient specimens, PDX passages P0, P1, P2, and P3+ and in vitro models. 80% of the PDX specimens were within passages P0 to P2.

Results: Genomic stability in PDMR models was maintained through early passages (P0 - P2) and across independent lineages in PDMR models based on the following observations: 1) variant allele frequencies (VAF) of somatic driver mutations showed no major deviations (exceeding ±10%) when using the stromal fraction corrected VAF from originator data over PDX passages; 2) the median change in the fraction of genome impacted by copy number alterations (CNA) from the originator specimens through passages P0 - P2 was statistically inconsequential, although there was a significant increase in CNA fraction, from 5.3% at P0 initially to 18% by P3; 3) gene expression profiles of specimens within a given PDX model formed clusters in principal component analysis (PCA) plots and showed high correlation (>99.5% models with a Spearman coefficient of >= 0.8). The majority of the PDC and PDOrg specimens exhibited similar findings when compared to the original tumor samples. Furthermore, the positive percent agreement (PPA) was performed to measure the similarity between the patient's tumor and all available derived PDX specimens, with a median PPA over 90%, indicating a high level of retained heterogeneity within the PDX models. Lastly, 69% of models in NCI PDMR had predictive biomarkers, ranging from OncoKB level of evidence 1-4, which could be used to evaluate targeted therapeutics in preclinical studies.

Conclusion: The NCI PDMR has a large and histologically diverse cancer representation. In this analysis, the PDXs exhibited genomic stability within early passages and preserved the majority of tumor heterogeneity observed in the patient specimens. NCI PDMR thus represents a valuable resource for researchers interested in preclinical drug screening or other investigations.

#6915 Integrated proteogenomic analysis for the NCI patient-derived cancer model repository.

Peter I. Wu[1], Li Chen[2], Yuri Kotliarov[3], Jianwen Fang[3], Yingdong Zhao[3], Yvonne Evrard[4], Lijun Chen[5], Shahanawaz Jiwani[1], Biswajit Das[1], Chris A. Karlovich[1], Hui Zhang[5], Lisa McShane[3], Melinda G. Hollingshead[6], Mickey Williams[1], James H. Doroshow[3]

[1]Molecular Characterization Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD,[4]Advanced Development Research Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD,[5]Department of Pathology, The John Hopkins Medical Institutions, Baltimore, MD,[6]Biological Testing Branch, Developmental Therapeutics Program, National Cancer Institute at Frederick, Frederick, MD

Background

Studying protein expression involved in cancer from patient-derived xenografts (PDX) enhances understanding of tumorigenesis and may shed light on patient therapeutic decisions. Recently, mass spectrometry-based proteomics sequencing techniques have enabled the acquisition of high-throughput PDX protein/phosphoprotein expression profiles and paved a way for investigating oncogenic signaling pathways and their interactions in different tumor histologies. Integrated analysis of these proteomic data with existing biomarkers derived from whole exome and RNAseq data will provide the community with a rich resource for translational research.

Materials and methods

iTRAQ-based proteomics/phospho-proteomics data, with 11 Tandem Mass Tag (TMT) channels, were processed and median-normalized at gene level. The gene expression data were derived from tximport and DESeq2 from of RNA-Seq. In addition, whole exome sequencing (WES) data were used to compute mutations and copy number profiles. For data visualization, the R Bioconductor package ComplexHeatmap was used extensively.

Results

PDX proteomics/phospho-proteomics data were analyzed alongside with gene expression, copy number and mutational profiles for several cancer types, revealing vivid molecular regulation for many cancer-related pathways. A moderate yet significant Spearman correlation coefficient of over 0.45 and 0.5 was observed between proteomics and RNA-Seq data at gene and pathway level, respectively. The PDX protein and gene expression pattern from common cancer regulatory pathways of bladder (BLCA, n=32 models), colon (COAD, n=82), lung (NSCLC, n=32), pancreatic (PAAD, n=52), metastatic breast cancer (CSNOS) (n=16) and other histologies were aggregated and discussed at the model level. EGFR, MET and cell-cycle genes CDKN2A and CDKN2B exhibited significant positive correlation among copy number, gene expression and protein expression profiles. Protein and gene expression profiles of PAM50 genes were shown for CSNOS samples, to further sub-classify or correct misclassification. Further analysis using proteomics/phospho-proteomics data with CNA identified several trans-regulatory events. Lastly, we identified RTN1 as a potential biomarker, exhibiting lower expression in sensitive rare-tumor PDX models prior to Axitinib and Vandetanib treatment.

Conclusions

With the multi-omics datasets comprising proteomics/phospho-proteomics, RNA-Seq and WES datasets from the NCI Patient Derived Models Repository cohort, we were able to query some important cancer biological processes at a higher resolution. In addition, we revealed gene- and pathway-level regulatory differences from various histologies. Overall, the multi-omics data from PDX models showed promising recapitulation of original tumor activity and should continue to serve as an amenable and scalable drug screening platform for pre-clinical trials.

#6916 InnoPanel™and InnoPedia™: resources of engineered cell lines and xenografts for drug discovery.

Kyinno Biotechnology Co., Ltd, Beijing, China

The Development of precision medicine relies on well-characterized experimental models that carry naive, induced, or engineered genomic and epigenetic features targetable by certain treatments. Patient-derived xenografts (PDX) and cell lines can serve as such in vivo and in vitro models by harboring abnormalities such as somatic and driver mutations, dysregulated gene expression and silencing, microsatellite instability, gene fusions, copy number amplification and loss of heterozygosity. In addition, cell lines can also be engineered to introduce sometimes rare-occurring abnormalities that the engineered cell line shares an identical genetic background with its parental cell line, thus providing a clearly contrasting pair to evaluate treatment specificity. With the advancement of disease research and drug discovery, existing cell lines can no longer meet the needs of various types of drug discovery. To evaluate drug efficacy more quickly and accurately, Kyinno has constructed and identified more than 4,000 engineered cell lines, including overexpressed cell lines constructed through transposon systems or lentivirus infection, gene-edited cell lines constructed through CRISPR-Cas9 technology, and reporter cell lines targeting multiple signaling pathways and membrane receptors. Besides, InnoPanel™, a panel of over 1000 engineered cell lines was established and characterized to cover a wide range of heavily targeted genes such as CLDN18.1, CLDN18.2, LAG3, OX40, PD-L1, PD-L2, and TIM3. Cell line families were also developed for genes with multiple known driver mutations. All cell lines are annotated with background information, engineering details, functional characterization, and efficacy studies. Furthermore, we developed xenografts for several engineered cell lines and showed that the combination of cell lines and xenografts can accelerate drug development. Additionally, all of this information can be accessed in our free database, InnoPedia™. The database also offers browsing, searching, and analytical capabilities for over 600 commonly used tumor cell lines and thousands of engineered cell lines with essential genomic and pharmacological data, cell line efficacy data for nearly 2000 common anti-tumor drugs, and comprehensive details for over 100 standard antibodies. Our engineered cell lines are now registered in the online cell line database Cellosaurus, which is available on the ExPASy server.

#6917 Ba/F3 AKT engineering cell lines, a useful platform for novel drug discovery.

G. Wang, Y. Tang, J. Xu, Y. Peng, Y. Wang, J. Ning, **F. Hao**;
Kyinno Biotechnology Co., Ltd, Beijing, China

AKT, also known as phosphoinositide 3-kinase (PI3K), plays a key role in various signaling cascades involved in cell growth and division, apoptosis inhibition, and angiogenesis. For AKT, which is at the central node of the PI3K/AKT/mTOR signaling pathway, the loss of PTEN, mutation, or amplification of AKT/PIK3CA can lead to the overactivation of the AKT signaling pathway, resulting in the occurrence and development of tumors. Recent studies have also found that AKT activation is associated with drug resistance in tumor therapy. Therefore, AKT has become a hot target for tumor therapy. The AKT family consists of three highly homologous isoforms, AKT1 (PKBα), AKT2 (PKBβ), and AKT3 (PKBγ), with more than 85% homology in their kinase regions. E17K is the most common and well-characterized activating mutation, accounting for approximately 15% of all AKT mutations. Rare mutations mainly include L52R, Q79K, and D323H. The failures of AKT inhibitors LY2780301 and Bayer's BAY1125976 demonstrate the significant challenges and complexities in developing inhibitors of the AKT pathway. Currently, the most advanced AKT inhibitor globally is AstraZeneca's capivasertib, which is primarily indicated for HR+ breast cancer and triple-negative breast cancer. Our group has generated 21 Ba/F3-AKT engineering cell lines, as useful models for novel drug discovery in vitro and in vivo, almost all clinically significant mutations were included, such as common mutations AKT1/2-E17K as well as rare mutations L52R, Q79K, D323H, and others. The Ba/F3-AKT engineering cell lines can be useful for developing and evaluating next-generation AKT inhibitors and exploring newly acquired resistance mutations in AKT.

#6918 Ba/F3-BCR-ABL engineering cell line panel, a useful platform for novel drug discovery.

G. Wang, Y. Peng, Y. Wang, Y. Tang, J. Xu, J. Ning, **F. Hao**;
Kyinno Biotechnology Co., Ltd, Beijing, China

In the past few years, with the great success of Imatinib, the first kinase inhibitor, Imatinib rapidly became the first-line treatment for CML (Chronic myelogenous leukemia) carrying the BCR-ABL mutation. It opened a new chapter in targeted cancer treatment. Despite the increase in overall survival allowed by imatinib, the onset of drug resistance led scientists to investigate imatinib's fine structural mechanism of action to develop new and more effective compounds against mutated forms of Bcr-Abl. 7 BCR-ABL inhibitors have been approved, they are Imatinib, Dasatinib, Nilotinib, Bosutinib, Ponatinib, Olverembatinib, and Asciminib. However, acquired resistance has been a major challenge in the treatment of CML, and some patients still experience disease progression or even death due to drug resistance. BCR-ABL kinase domain mutations are one of the important mechanisms of acquired resistance, with the T315I mutation being the most common type of drug resistance mutation, accounting for approximately 25% of drug-resistant CML cases. Patients with T315I mutations in CML are resistant to all current first- and second-generation BCR-ABL inhibitors. Asciminib is designed as an allosteric inhibitor combined with an ATP-competitive TKI agent, which may hinder the development of mutation-driven acquired resistance or restore efficacy against highly resistant BCR-ABL mutants. Our group has generated 38 Ba/F3-BCR-ABL engineering cell lines as useful models for novel drug discovery in vitro and in vivo, including wild-type BCR-ABL and inhibitors leading drug resistance mutations, such as T315I, E255, Y253, F317, F359. V299, G250, A337T, V468F, and double mutations. Each cell was validated by cell sequencing and cell efficacy verification using approved BCR-ABL inhibitors. The Ba/F3-BCR-ABL engineering cell line panel can be useful for developing and evaluating next-generation BCR-ABL inhibitors and exploring newly acquired resistance mutations in BCR-ABL.

#6919 Cell line panel with HIBIT-tagged endogenous proteins to accelerate PROTAC drug discovery.

Y. Zhai[1], J. Ma[2], Y. Wang[1], M. Liang[1], Y. Peng[1], J. Ning[1], **F. Hao**[1];
[1]Kyinno Biotechnology Co., Ltd, Beijing, China, [2]Beijing National Day School, Beijing, China

Small molecular drugs have been an important part of disease treatment, but there are also some problems along with time and intrinsic disadvantages of small molecular drugs. In recent years, the emergence of proteolysis targeting chimeras (PROTACs) is expected to overcome some defeats of traditional small molecules. PROTACs, also known as hetero-bifunctional compounds, are a new kind of therapeutic, that consists of a specific ligand to bind the target protein, a suitable linker, and an E3 ubiquitin ligase substrate. After binding to target proteins, PROTACs recruit E3 ligase and induce degradation of target proteins through the ubiquitin-proteasome system. Therefore, PROTACs are a good choice for some protein targets that have small molecular binding ligands but poor small molecular efficacy, which expands druggable targets. Meanwhile, the protein degradation induced by PROTACs destroys not only the enzymatic but also the non-enzymatic functions of targets, rather than only inhibiting the protein activity, which reduces drug resistance. In this study, in order to detect the degradation of intracellular target proteins by PROTACs, Kyinno has designed and constructed several HiBiT-tagged cell line models for different target proteins and their mutations, including KRA, CDK2, LDHA, and HPK. HiBiT is a small tag with 11 amino acids that don't influence the expression, folding, and localization of target proteins, and luminesces with a detection buffer. All these cell lines with endogenous protein mutations and HiBiT knock-ins are constructed by CRISPR-Cas9 technology and validated by siRNA and PROTACs. Compared with overexpressed exogenous HiBiT-tagged target proteins, endogenous proteins can more accurately and stably reflect the efficacy of PROTACs. Our cell models can be used for high-throughput screening not only for PROTAC drugs but also for molecular glues, lysosome-targeting chimeras (LYTACs), and antibody-based PROTACs (AbTACs).

TUMOR BIOLOGY: Tumor Evolution at Single Cell Resolution
Poster Session

#6923 Deconvolution of breast cancer dissemination and therapy resistance via single-cell transcriptional lineage tracing.

A. Dalmasso[1], A. Cossa[1], G. Bertolini[2], N. Roda[3], I. Servidio[1], F. Tucci[1], S. Pece[1], G. Sozzi[2], P. Pelicci[1],
[1]European Institute of Oncology (IEO), Milano, Italy, [2]Istituto Nazionale dei Tumori IRCCS, Milano, Italy, [3]VIB-KU Leuven Center of Cancer Biology, Leuven, Belgium

Chemotherapy remains the most used systemic treatment option for triple-negative breast cancer (TNBC). Lineage tracing studies demonstrated that treatment does not significantly alter clonal composition of primary tumors (PTs). The specific transcriptional phenotype(s) conferring chemoresistance in PTs and metastasis, however, are still largely undetermined, and have not been analyzed at single-clone resolution.
We first modelled clinically relevant contexts of chemoresistance in our recently published single-cell lineage tracing approach (DOI: 10.1158/0008-5472.CAN-22-2717), using the standard-of-care combination of adriamycin and cyclophosphamide (A+C) in TNBC xenografts. Treatment was administered in neoadjuvant or adjuvant settings, or both together. In all cases, surgical PT resection was followed by metastatic disease. The neoadjuvant treatment resulted into a stable disease, thus resembling a significant fraction of the treated patients.
To investigate clonal and transcriptional dynamics we performed scRNAseq analysis of 12 replicates (3 matched PT-lung replicates for each condition, for a total of 24 samples). Clustering analyses revealed a separation of treatments and tissue of origin. We retrieved a large number of longitudinal clones, including rare clones with high metastatic potential, in all the experimental conditions. A+C did not significantly alter clonal abundances, neither in PTs nor in metastases.
Pseudobulk transcriptional analyses revealed key transcriptional traits associated with chemoresistance. Differential expression on longitudinal clones gave insights about transcriptional features of chemoresistant and pro-metastatic clones under chemotherapy. Integration at single-clone level of cluster analysis, pseudobulk and differential expression revealed cystatin (CST) family genes as highly-enriched in the chemoresistant and pro-metastatic phenotype. We are currently validating the role of CST genes in tumor growth, dissemination and chemoresistance in vivo using a panel of specific shRNAs.
In parallel, using the same experimental model, we successfully deconvoluted the metastatic cascade through a single-cell lineage tracing approach on matched PT-CTC (circulating tumor cells)-lung replicates. scRNAseq analyses of pro-metastatic, circulating and metastatic clones is ongoing.
Our preliminary data showed that all the dominant clones in the metastatic lungs are also found as CTCs in the bloodstream, thus suggesting that all pro-metastatic cells are also capable of surviving in the bloodstream and reinforcing our concept of pro-metastatic clone. This approach led us to gain a complete overview around clonal and transcriptional evolution of breast cancer dissemination.

#6924 Structural variant dynamics in melanoma: Unraveling tumor heterogeneity and evolution.

X. Cui, A. G. Keskus, F. R. Mehrabadi, S. Malikic, M. Kolmogorov, C.-P. Day, G. Merlino, S. Sahinalp;
National Cancer Institute, Bethesda, MD

Melanoma is characterized by significant intratumoral heterogeneity and complex evolutionary dynamics. This diversity in genomic alterations leads to the emergence of various subclonal populations within a single tumor. In our research, we established a new model system composed of 24 single-cell-derived clonal sublines (C1-C24), originating from the M4 melanoma model. This model was developed using a genetically engineered hepatocyte growth factor (HGF)-transgenic mouse. We employed Trisicell (Triple-toolkit for single-cell intratumor heterogeneity inference), a cutting-edge computational tool for scalable analysis of intratumor heterogeneity and evaluation based on single-cell RNA mutations. This enabled us to construct a phylogeny tree, revealing melanoma's intricate branching evolutionary patterns. These patterns show ancestral clones evolving into genetically distinct subclones, which demonstrate varied phenotypic traits such as drug sensitivity or resistance, cellular plasticity, and immunogenicity. In our study, we conducted long-read sequencing on these clonal sublines in the phylogeny and identified structural variants (SVs) using Severus, a tool optimized for phasing in long-read sequencing. The types of SVs we discovered include deletions, insertions, amplifications, translocations, and inversions. We explored their roles in subclonal evolution, particularly focusing on how they disrupt genes and accumulate during melanoma progression. Our initial data from eleven sublines indicated a higher prevalence of ancestral SVs, shared by all sublines, compared to subline-specific SVs, representing later events. Notably, the individual sublines showed a higher rate of gene disruption by SVs, hinting at potential functional selection. Our analysis further revealed that SVs common to all sublines are linked with genes in key cell growth pathways, such as Rap1, Hippo, and calcium signaling pathways. In contrast, subline-specific SVs primarily affect genes involved in neurophysiological pathways, such as glutamatergic synapse and morphine addiction pathways. These findings suggest that different genes, associated with various pathways, are disrupted at distinct stages of melanoma progression, providing insights into the genetic factors that may predispose individual melanocytes to melanomagenesis. This methodology presents a comprehensive tool for characterizing tumor genomes and understanding their relationship with disease progression and therapy resistance. We are continuing our analysis to map SVs across the entire mutation-based phylogeny of all sublines, which will further our understanding of melanoma's genomic landscape.

#6925 Integrative single-cell tracking of genome evolution and tumor cell plasticity in small cell lung cancer (SCLC).

M. Schmiel, L. Kaiser, M. Cartolano, M. Peifer, R. K. Thomas, J. George;
University Hospital of Cologne, Cologne, Germany

SCLC is the deadliest type of lung cancer, which is mostly diagnosed at late stages and accounts for 15% of pulmonary tumors. Even though chemotherapy is initially effective, patients with SCLC relapse quickly and develop resistant tumors. Genome studies revealed a universal loss of TP53 and RB1; recent transcriptional studies categorized SCLC based on the expression of 4 lineage transcription factors (TFs). We aimed to dissect how genomic cues impact transcriptional phenotypes, tumor cell plasticity and the dynamics of tumor and immune cell interactions, to thus decipher molecular mechanisms of phenotypic divergence and therapy resistance in SCLC. We performed genome sequencing and single cell transcriptome profiling of 55 tumors from patients with SCLC, including primary tumors, local and distant metastases and of paired relapsing tumors acquired after chemotherapy. Single cell sequencing was performed with the 10x Genomics platform and yielded > 200.000 cells. Transcriptome profiles at single cell levels revealed co-expression of at least two of the lineage TFs ASCL1, NEUROD1 or POU2F3 in each tumor. Copy number (cn) estimation for transcriptome data pointed to genomic events impacting transcriptional heterogeneity within the tumor. Furthermore, our data pointed to a marked intra- and interpatient, as well as to inter-metastatic heterogeneity. To specifically investigate how underlying genetic alterations affect molecular phenotypes, integrative studies across all patients were performed. This revealed shared transcriptional programs in tumors with amplifications of MYC family members; trajectory inference for cases with low and high-level copy gains of MYCN pointed to distinct transcriptional states. We performed multi-regional and longitudinal studies of matched patient cases to reconstruct the genomic patterns of clonal evolution, and projected genomic subsets to transcriptional profiles at single cell level, thus analyzing the effect of genome diversity on the transcriptional landscape. Additionally, tumor intrinsic profiles of heterogeneity were mapped to single cell data of patient tumors to elucidate the effects on tumor-immune cell interactions.

All together our data points to a concerted regulation of a multitude of lineage factors and transcriptional programs in each SCLC tumor and provides a first comprehensive framework for the study of underlying genetic alterations that shape the transcriptional landscape and phenotypic plasticity in SCLC.

#6926 Tracing clonal evolution and immune evasion in glioblastoma progression.

Davide Ceresa[1], Sebastian A. Garcia Mena[1], Francesca Piaggio[1], Appolloni Irene[2], Daniela Marubbi[2], **Paolo Malatesta**[2]

[1]IRCCS Ospedale Policlinico San Martino, Genoa, Italy, [2]DIMES, University of Genoa, Genoa, Italy

Glioblastoma continues to be a daunting obstacle in oncology research, with its early-stage progression being particularly enigmatic. In a recent published work, we traced the clonal dynamics of glioblastoma evolution by the simultaneous transfer of PDGFB and genetic barcodes into mouse brains. We observed a continuous clonal loss during the acquisition of a malignant phenotype, underlined by the modulation of the levels of c-Myc expression and their functional targets. In this study, we delve deeper into the evolution of glioblastoma by transplanting multiclonal, early-stage glioma cells into multiple immunodeficient NOD-SCID mice. This experimental design allowed us to track the clonal dynamics over serial transplants, revealing how early-stage glioma clones acquire immune-evasive features capable of initiating tertiary tumors in immune-competent hosts. Through barcode sequencing and single-cell RNA sequencing of early-stage gliomas, coupled with bulk RNA sequencing of secondary and tertiary gliomas, we dissected the clonal and transcriptomic landscape of these tumors. We observed that, of the various clones composing primary tumors, just a few of them are predominating in subsequent passages. Furthermore, the clonal composition of secondary tumors derived from the same primary glioma showed partial overlap, indicating a partial predetermination in the development of immune-evasive behavior. Our intra- and inter-clonal transcriptomic analysis across various stages of tumor progression is shedding light on how new functional traits can emerge in gliomas. Further analysis of our data will determine whether it is the result of the expansion of clones already possessing these traits, or if they stem from functional adaptations within the clones themselves. Our insights further reinforce the concept of clonal competition, highlighting the significant influence of immune-system interactions in driving these competitive dynamics.

#6927 A refined view of pancreatic cancer genomic evolution through single-nucleus DNA sequencing.

H. Zhang[1], P. Sashittal[2], E.-R. Karnoub[1], A. Jakatdar[2], S. Umeda[1], N. Lecomte[1], J. Hong[1], K. Mullen[1], A. Hayashi[3], C. A. McIntyre[1], B. J. Raphael[2], C. A. Iacobuzio-Donahue[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Princeton University, Princeton, NJ, [3]Kyorin University, Tokyo, Japan

Numerous next-generation sequencing studies have provided an overview pancreatic ductal adenocarcinoma (PDAC)'s genomic evolution. But how its genome evolves through treatment and metastasis has not been extensively studied due to lack of samples and technical limitation of bulk sequencing on low-tumor purity samples.

Herein we applied targeted single-nucleus DNA sequencing (snDNA-seq) to a cohort of 18 patients, each with >= 2 multiregional/longitudinal samples, totaling 65 samples. These included 5 early-stage resections, 11 stage IV autopsies and 2 biopsy-derived organoids taken pre- and post-treatment. We also developed a set of computational methods for this new datatype to delineate genomic evolution at high resolution.

Despite higher sensitivity than bulk, snDNA-seq did not uncover significant subclonal single-nucleotide variations (SNVs) on our panel targeting 253 select genes for PDAC. But it detected a higher frequency of *CDKN2A* (72% against 30%) and *SMAD4* (56% against 32%) alterations, mostly attributed to chromosomal deletions. Many were subclonal or only affected a few hundred base-pairs of the gene, making them elusive to bulk sequencing.

Except for one case driven by *BRCA2* mutations rather than the canonical *KRAS* oncogene, other patients had mostly linear phylogenies with more SNVs occurring before the most recent common ancestor (MRCA) of clones, for early/late-stage and longitudinal cases alike. This early fixation of drivers and rapid clonal sweep afterwards likely correlates with the particular aggressiveness of PDAC. Metastatic clones almost always fell towards the end of phylogenies and were shared among spatially separated sites, indicating late metastatic dissemination in molecular evolution time. Metastases to the liver and diaphragm appeared to be more genetically evolved than other sites, likely due to harsher selective pressure cast by the metastatic routes/distal microenvironments.

16 of 18 PDACs were observed to converge towards tumor cell-intrinsic TGF-β unresponsiveness by mutating various components of the pathway. Such convergent evolution usually happened at the primary site, indicating a strong selective advantage of the phenotype in the desmoplastic, nutrient-poor pancreas microenvironment. Continuous evolution was seen through treatment and metastasis, driven by seemingly random genome-scale copy number variations (CNVs) and focal amplification/deletions to genes such as *KRAS, CDKN2A, SMAD4, MYC.*

These insights on PDAC's genomic evolution inform more precision medicine efforts to come. Early fixation of driver SNVs sculpts a largely homogeneous disease that could be uniformly targeted. But special care should be taken to obviate resistance mechanisms conferred by continuously evolving CNV events- compared to SNVs, these mechanisms provide faster remodeling of the genome, and thus faster generation of new phenotypes and adaptation.

#6928 Expressed mitochondrial variants capture patterns of tumor evolution at single-cell level.

Andrea Cossa[1], Alberto Dalmasso[1], Andrea Tirelli[1], Zhan Yinxiu[1], Chiara Caprioli[1], Giulia Perticari[2], Pier Giuseppe Pelicci[1]

[1]Istituto Europeo di Oncologia e Centro Cardiologico Fondazione Monzino, Milan, Italy,[2]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands

Single-cell lineage tracing (scLT) has recently emerged as a promising tool to investigate cancer evolution. Among other scLT markers, mitochondrial variants (MT-SNVs) have been successfully used to track clones in a variety of experimental and clinical settings. However, in spite of the dynamic accrual of such genetic mutations, analysis of MT-SNVs variation has often been limited to standard clustering procedures, not exploiting the information associated with these markers at full potential. Here, we benchmarked expressed MT-SNVs-based single-cell phylogenies. To this end, we generate two single-cell multi-omics datasets: i) a benchmarking dataset, with joint profiling of MT-SNVs, gene expression and ground truth (GT) clonal identity (from lentiviral barcodes cells), and ii) a clinical cohort of wild type and mutated SRFS2 Acute Myeloid Leukemia patients, at diagnosis, with joint profiling of MT-SNVs, gene expression and targeted nuclear SNVs. We first leveraged our benchmarking dataset for validation purposes, taking advantage of its different levels of clonal complexities (*in vitro* clonal mixtures vs *in vivo* xenografts) and its longitudinal nature (i.e., matched primary tumor-lung metastasis couples). Supervised analysis detected (GT) clonal-specific mutations rarer than previously shown, but significantly associated with GT clonal labels. The performance of tested feature selection methods varied wildly in terms of GT MT-SNVs recover, with higher False Positive than False Negative Rates. Accurate detection of GT-clones from MT-SNVs correlated with samples clonal complexity, with a substantial number of GT-clones sub-optimally detected in the highest complexity sample generated. Longitudinal analysis of matched primary tumor-metastasis couples revealed remarkable stability of MT-SNVs, corroborating evidence from other studies without longitudinal GT lentiviral clones. We then asked whether expressed MT-SNVs hold enough signal to reconstruct reliable single-cell phylogenies. Transfer Bootstrap (TS) supports of reconstructed trees correlated with clades size, with a significant number of deep clades showing high (>.70) TS values across samples and bootstrapping procedures. Moreover, GT clonal labels significantly clustered across phylogenies, suggesting high phylogenetic signal. Finally, we investigated evolutionary patterns in our clinical cohort. Here, we found independent acquisition of both nuclear- and MT-SNVs by distinct normal and malignant lineages, and characterized patterns of gene expression inheritance along recovered phylogenies. All in all, our data support the emerging role of MT-variants based lineage tracing approaches in cancer evolution studies, highlighting intrinsic limitations and potential of these endogenous markers for retrospective, phylo-phenotypic analysis.

#6929 Inter- and intratumoral *PIK3CA* subclonal diversity in breast cancer contextualized by single-cell multiomics.

J. Zawistowski[1], I. Salas-Gonzalez[1], T. Tate[1], T. Morozova[1], K. Kennedy[1], D. Arvapalli[1], J. Remington[1], J. Marks[2], E. Hwang[2], G. Harton[1], V. Weigman[1], J. A. A. West[1];

[1]BioSkryb Genomics, Durham, NC, [2]Duke University Medical Center, Durham, NC

Rare clonotypes within pre-cancerous tissues can drive progression to cancer. However, the evolution of rare clonotypes in tumors or normal tissue cannot be defined in the absence of single-cell resolution. At this single-cell level, multiomic interrogation across the Central Dogma of Biology provides enhanced power to reconstruct such evolutionary trajectories, defining the mutational profile, cell identify, and receptor expression within each subpopulation. Leveraging a multiomic approach, we aimed to define how different mutations in the same oncogenic driver observed in the same tumor resection associate with copy number variation (CNV) across the genome.

We analyzed individual ductal carcinoma in situ/invasive ductal carcinoma cells using a unified whole-genome and full-transcript RNAseq workflow (ResolveOME™, BioSkryb Genomics) coupled with panel-level extracellular protein information through oligo-conjugated antibodies (BioLegend). We sequenced the exomes and transcriptomes of ResolveOME-amplified single cells from mastectomy samples from twelve patients. At the single nucleotide variant (SNV) level, we identified an allelic series of *PIK3CA* oncogenic driver mutations in the same tumor resection. A single amino acid, in-frame deletion of E109 dominated the sample, followed by H1047R and K111E in decreasing subclonal abundance. A fourth mutation, E345T, not present in the first sample, was detected as the sole *PIK3CA* variant in the second tumor sample. Intriguingly, each respective *PIK3CA* mutation class was associated with a distinct copy number alteration profile revealed by low-coverage whole-genome sequencing: Cells harboring the predominant ΔE109 mutation displayed chromosome 8p,16p, and 17 loss while the less abundant H1047R mutation was in single cells harboring 1q gain, 4q loss, and 22 loss in addition to the 8p and 16q loss present in the ΔE109 cells. *PIK3CA* K111E had a quiescent, 2n copy number profile. The transcriptomic arm of ResolveOME, containing an oligo-conjugated antibody readout of surface protein expression, jointly confirmed the epithelial identity for the cells harboring the oncogenic *PIK3CA* mutations. A subpopulation of cells harboring prototypical breast cancer CNV were typed as non-epithelial with increased stemness characteristics, indicative of the ability to resolve phenotypic cellular states.

These results suggest a tight interrelationship between CNV and SNV influencing the relative rate of clonal expansion. They also provide the opportunity to explore CNV:SNV signature association with loci exclusive of *PIK3CA*, and to exploit the power of multiomic integration for lineage reconstruction and for defining common oncogenic signatures of the evolving tumors.

#6930 Spatial analysis of multi-ancestral tumors to understand how intercellular signaling impacts tumor invasion.

Mary M. Stangis[1], Lingxin Cheng[2], Dawn Albrecht[1], Santina Snow[1], Tessa Wirtz[1], Kristina A. Matkowskyj[3], Huy Q. Dinh[1], Christina Kendziorski[2], Richard B. Halberg[1]

[1]McArdle Laboratory for Cancer Research - Department of Oncology, University of Wisconsin-Madison, Madison, WI,[2]Department of Biostatistics and Medical Informatics, University of Wisconsin-Madison, Madison, WI,[3]Department of Pathology and Laboratory Medicine, University of Wisconsin-Madison, Madison, WI

Colorectal cancer (CRC) persists as a leading cause of cancer-related deaths in the United States. Intratumoral heterogeneity stems from a multi-ancestral origin or clonal divergence and contributes to treatment resistance. Unfortunately, tumors in existing mouse models are largely homogenous, rendering predictions of drug efficacy inaccurate. To investigate whether signaling between distinct neoplastic clones in a tumor and cells in the surrounding microenvironment impacts CRC biology, we performed spatial transcriptomic analysis on samples collected from a transgenic mouse model previously established in the Halberg laboratory. This model (referred to as B6.FCTG3KM) develops three types of tumors: homotypic Adenomatous Polyposis Coli (APC)-deficient tumors that express red fluorescent protein (RFP), homotypic APC-deficient tumors that express constitutively active phosphoinositide 3-kinase (PI3K) and green fluorescent protein (GFP), and heterotypic tumors. Previous characterization of the model clearly demonstrated that heterotypic tumors are significantly more aggressive than either type of homotypic tumor.
Analysis was conducted on four serially sectioned slides containing three tumors and adjacent normal tissue obtained from the colon of a male B6.FCTG3KM mouse using the 10x Genomics Visium CytAssist platform with the mouse whole transcriptome probe set. Collected tumors were staged using traditional histopathology techniques by a board-certified pathologist (Matkowskyj). Immunohistochemistry and immunofluorescence were used to assess β-catenin localization and to re-probe for RFP and GFP expression. Sequencing was performed on the Illumina NovaSeqX platform to an average depth of 255,528,294 reads per sample. Data analysis was performed using the 10x Genomics SpaceRanger and Kendziorski laboratory R/SpatialView packages. A fold-change threshold of 1.5 and an adjusted p-value threshold of 0.05 were used when establishing marker genes for each of the 8 clusters identified. One distinct cluster was identified by marker genes including *Notum, Wif1,* and *Dkk2,* factors previously implicated in CRC tumorigenesis, and corresponded to the center of each region of surface-level dysplastic epithelia. The remainder of the surface-level dysplastic epithelia corresponded to a second cluster, with marker genes including those coding for TRIM family proteins (*Trim5, Trim10, Trim40, Trim12*c), and matrix metalloproteinases (*Mmp12, Mmp9, Mmp10, Mmp13*). A third cluster corresponded to the desmoplastic stroma underlying each neoplasm. Ongoing analyses are underway to identify clonal interactions that alter gene expression and tumor aggressiveness.

#6931 Characterization of cancer evolution landscape based on accurate detection of somatic mutations in single tumor cells.

M. Niu, Y. Zhang, J. Luo, J. C. Sinson, A. M. Thompson, C. Zong;
Baylor College of Medicine, Houston, TX

Accurate detection of somatic mutations in single tumor cells is greatly desired as it allows us to quantify the single-cell mutation burden and construct the mutation-based phylogenetic tree. Here we developed scNanoSeq chemistry and profiled 842 single cells from 21 human breast cancer samples. The majority of the mutation-based phylogenetic trees comprise a characteristic stem evolution followed by the clonal sweep. We observed the subtype-dependent lengths in the stem evolution. To explain this phenomenon, we propose that the differences are related to different reprogramming required for different subtypes of breast cancer. Furthermore, we reason that the time that the tumor-initiating cell took to acquire the critical clonal-sweep-initiating mutation by random chance set the time limit for the reprogramming process. We refer to this model as a reprogramming and critical mutation co-timing (RCMC) subtype model. Next, in the sweeping clone, we observed that tumor cells undergo a branched evolution with rapidly decreasing selection. In the most recent clades, effectively neutral evolution has been reached, resulting in a substantially large number of mutational heterogeneities. Integrative analysis with 522-713X ultra-deep bulk whole genome sequencing (WGS) further validated this evolution mode. Mutation-based phylogenetic trees also allow us to identify the early branched cells in a few samples, whose phylogenetic trees support the gradual evolution of copy number variations (CNVs). Overall, the development of scNanoSeq allows us to unveil novel insights into breast cancer evolution.

#6932 Single-cell multiomics profiling reveals heterogeneous transcriptional programs and microenvironment in desmoplastic small round cell tumors.

C. Henon[1], J. Vibert[2], T. Eychenne[1], N. Gruel[2], L. Colmet-Daage[1], C. Ngo[1], M. Garrido[1], N. Dorvault[1], M. Marques Da Costa[1], A. Marchais[1], A. Kawachi[1], M. Lenormand[1], C. Astier[1], R. Chabanon[1], B. Verret[1], R. Bahleda[1], A. Le Cesne[1], F. Mechta-Grigoriou[2], C. Honore[1], M. Faron[1], O. Delattre[2], J. Waterfall[2], S. Watson[2], S. Postel-Vinay[1];

[1]Gustave Roussy, Villejuif, France, [2]Institut Curie, Paris, France

Background: Desmoplastic Small Round Cell Tumor (DSRCT) is a rare, aggressive sarcoma primarily affecting young males. Despite being driven by the unique oncogenic transcription factor (TF) EWSR1-WT1, and a monotonous morphology, DSRCT cells display a polyphenotypic differentiation of unknown etiology.
Methods: To explore DSRCT heterogeneity, we characterized a series of patient samples by single-cell, spatial, and bulk multi-omics. We integrated patients' data with bulk RNA-sequencing, ChIP-sequencing, and ATAC-sequencing data generated in a DSRCT cell line model upon EWSR1-WT1 transcriptional silencing.
Results: Single-cell RNA-sequencing (scRNA-seq) on 11 patient samples identified recurrent subpopulations of DSRCT tumor cells, including lineage-, metabolism-, and pseudostate-related clusters. These subpopulations showed overlapping gene modules and lacked copy number variation diversity, suggesting transcriptional plasticity as a potential source of tumor heterogeneity. We first investigated whether cell-intrinsic mechanisms may drive DSRCT intra-tumor heterogeneity. Using an in-house-developed assay, we found limited variability in *EWSR1-WT1* transcript expression. Preclinical modeling defined an EWSR1-WT1 regulon, used as a surrogate for EWSR1-WT1 TF activity. Integration with scRNA-seq data showed that high EWSR1-WT1 activity was associated with lineage-related states, while glycolytic and profibrotic states correlated with low EWSR1-WT1 activity. Single-cell ATAC-seq with scRNA-seq (Multiome) on one patient sample identified TF motifs related to developmental processes - e.g., SOX, FOX, and GATA - as the most differentially enriched across clusters. Interestingly, EGR1 regulon activity showed an inverse correlation with EWSR1-WT1 and Androgen Receptor regulons' activity, in line with preclinical data, where ATAC-seq showed increased accessibility of *EGR1* upon EWSR1-WT1 silencing. We next investigated cell-extrinsic factors by spatial transcriptomics in six patient samples. Glycolytic and profibrotic subpopulations localized within hypoxic niches at the tumor periphery, in direct proximity to cancer-associated fibroblasts (CAFs), which promoted tumor growth *in vitro*, as assessed in DSRCT cells/CAFs co-culture assays. Finally focusing on inter-tumor heterogeneity, the prognostic evaluation of scRNA-seq-derived signatures revealed that a tumor cell epithelial signature correlated with improved patient survival in a cohort of 29 DSRCT samples profiled with bulk RNA-sequencing.
Conclusion: DSRCT heterogeneity is driven by combined cell-intrinsic and -extrinsic mechanisms, including EWSR1-WT1 DNA-binding activity and interaction with CAFs. Gene signatures associated with specific DSRCT subpopulations correlated with prognosis, highlighting the clinical relevance of our findings.

#6933 Decoding the archetypes and eco-hubs of triple-negative breast cancer in responses to chemotherapy.

Y. Yan[1], Y. Lin[1], T. Kumar[1], S. Bai[1], J. Li[1], T. Tran[1], M. Hu[1], E. Ravenberg[1], M. Rauch[1], A. Clayborn[1], A. Thompson[2], B. Lim[2], L. Huo[1], S. Moulder[1], C. Yam[1], N. Navin[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor Medical College, Houston, TX

Triple-negative breast cancer (TNBC) is a highly aggressive type of breast cancer commonly treated with neoadjuvant chemotherapy (NAC). While about 50% of patients achieve a pathological complete response (pCR), the remainder often develop resistance and metastasis, leading poor survivals. Currently, the factors linking pre-treatment cancer cells and the tumor microenvironment (TME) to NAC response are unclear. To investigate this question, we conducted single-cell RNA sequencing on fresh pre-treatment core biopsy samples collected from patients in the ARTEMIS clinical trial. We identified 13 gene expression meta-programs of cancer cells and about 50 cell states of immune and stromal cell types. Based on the cancer cells alone, we identified four TNBC archetypes at patient-level: luminal secretory-associated (LSA), basal-associated (BA), immunoreactive (IR), and luminal androgen receptor (LAR). Notably, the archetype BA and IR were associated with non-pCR and pCR, respectively. Additionally, we found the TNBC ecosystem was composed of eight eco-hubs, reflecting the co-occurrence patterns of cancer and TME cell states. These eco-hubs revealed different cell community across archetypes and NAC outcomes. For example, an eco-hub with a co-occurrence of interferon response-related cancer cells and immune cells was prevalent in the archetype IR and pCR patients. To facilitate a clinical application, we further developed a 13-gene-based machine learning model to predict NAC response. In summary, these results provide new insights into the cellular determinants of TNBC biology and chemotherapeutic response.

#6934 Integrating deep learning morphology profiling, cell sorting, and scRNASeq reveals sample diversity and enriched sub-populations.

A. Jovic, C. Corona, K. Saini, T. Pham, R. Carelli, **V. Lu**, S. Zhang, S. C. Boutet, M. Masaeli;
Deepcell Inc., Menlo Park, CA

Advances in single cell technologies have ushered in a new multi-omics era that has provided more granular information on cell types and functions at unprecedented resolution. Morpholomics (the information encoded by cell morphology) has traditionally been used as a readout of cell identity, state, and function; but scalability, interpretation, and sorting based on morphology has remained challenging. The Deepcell® platform, REM-I, performs high-dimensional morphology analysis of unlabeled, single cells using deep-learning on high-resolution bright-field images captured in microfluidic flow to profile and sort target cells in real-time and at scale. Morphology analysis of single cells is achieved by a self-supervised deep learning foundation model, 'Human Foundation Model' (HFM), which combines deep learning features with morphometrics. HFM determines cell identities using morphological features associated with distinct processes characterized by granules, vesicles, cell size, pigmentation. and others. To demonstrate the ability of HFM modeling to distinguish and characterize a diversity of cell types representative of tumor microenvironments, we processed various sample types on the REM-I platform. Human melanoma, immune cells, stromal cells, and dissociated biopsies were combined to recapitulate heterogeneous tumor samples. HFM analysis enabled morphology-based exploration of the resulting bright-field images, revealing the presence of various morphologically distinct populations within each sample. Tumor cells were morphologically distinct and clustered separately from non-tumor cells. Immune cells exhibited subtle but separable morphologies, including T cells of distinct activation states. To demonstrate the morphology-based sorting capabilities of REM-I, we applied it to a 'reference sample' consisting of several fixed cell lines, at proportions ranging from 1% to >90%. Using only brightfield images of single cells analyzed through HFM, we used the platform to enrich each cell line from the 'reference sample' with high yield and purity, and identified cell types constituting a small percentage (~1%) of the total population. We next showed that unlabeled cells enriched on REM-I that are characterized as unperturbed and viable are amenable to downstream molecular analyses. These cell populations were sorted and the retrieved live cells were analyzed by scRNA-Seq (10x Chromium), demonstrating enrichment of various cell types of the tumor microenvironment in each cell population relative to the pre-sorted sample. These results illustrate: 1) the ability to perform downstream molecular analyses on sorted cells from REM-I, 2) the platform can be used to parse the tumor microenvironment, and 3) the link between morphology, cell identity, and molecular signatures.

#6935 Non-genetic routes of lung cancer evolution.

G. Ciriello, D. Tavernari, M. Varrone;
UNIL University of Lausanne, Lausanne, Switzerland

Cancer cell plasticity underlies the progression of several solid tumors. In lung adenocarcinoma, morphological changes characterizing the transition from indolent to aggressive disease exhibit profound epigenetic and transcriptional reprogramming[1]. However, the extent, features, and drivers of cancer cell plasticity in the progression of human lung adenocarcinoma is still largely unexplored. Here, we assembled and analyzed a meta-cohort of 119 human lung tumors analyzed by single-cell RNA-sequencing, for a total of ~730,000 cells. Cancer cell heterogeneity was the result of differential activation of 17 transcriptional programs associated with common cancer phenotypes, such as proliferation, cell migration, and response to hypoxia, as well as alveolar lineage identity (AT2). In particular, AT2-specific expression of MHC-II was down-regulated with the progression of the disease and markedly reduced in *KEAP1* and/or *STK11* mutated samples, providing a rationale for the association between these mutations and immunotherapy resistance. Co-activation of transcriptional programs clustered tumor cells in 4 major cell states, which emerged with the progression of the disease. To explore spatial distribution of different cancer cell states, we generated and analyzed multiple spatial transcriptomics and proteomics lung adenocarcinoma cohorts. To this purpose we developed a new algorithm called CellCharter[2]. CellCharter identified distinct cancer-enriched niches within individual samples, corresponding to the cancer cell states that we discovered in the scRNA-seq cohort and exhibited specific interactions with the tumor microenvironment (TME). In particular, we identified a cancer cell state characterized by response-to-hypoxia and migratory phenotypes, which spatially segregated from highly proliferative cancer cell niches and formed specific interactions with tumor associated neutrophils. This cell state was enriched in advanced primary samples, it uniquely characterized metastatic samples, and was an independent marker of poor prognosis across multiple independent datasets. Overall, our work uncovered cell plasticity trajectories associated with the progression of lung adenocarcinoma and shed new light into the tumor-TME interactions at their origin.

#6937 High throughput single cell simultaneous DNA and RNA sequencing identified cell-of-origin of breast cancer.

K. Wang[1], R. Ye[1], S. Bai[1], Z. Xiao[1], L. Yang[1], J. Li[1], Y. Lin[1], E. Sei[1], S. Lin[1], A. Thompson[2], S. Krishnamurthy[1], N. Navin[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Understanding the relationship between genotype and phenotype in breast cancer cells has been challenging at single cell resolution, mainly because existing high-throughput methods are limited to measuring a single modality and data must be integrated indirectly via computational methods. To address this challenge, we developed wellDR-seq, a high-throughput single cell method that can simultaneously measure the single cell whole genome and transcriptome directly from thousands of single cells in parallel. Using this method, we profiled 17,427 single cells in 6 different ER+ breast cancer patients with either premalignant disease (Ductal-carcinoma-in-situ) or invasive ductal carcinoma (IDC). From these data we identified the epithelial cell-of-origin in 3 cases, showing that ER+ breast cancer cells originated from Luminal Hormone Responsive (LumHR) in the normal breast tissues. We also found that autosomal somatic copy number aberrations were exclusively present in LumSec (< 2%) and LumHR epithelial cells, while chrX gain or loss also occurred in stromal cells (eg fibroblast and endothelial) but a low frequency (<2%) in our datasets. Additionally, our data show the impact of subclonal copy number profiles on gene expression programs, which reflects both gene dosage effects in CNA regions and more complex deregulation in copy-neutral regions. wellDR-seq offers a powerful tool for large-scale single cell genome and transcriptome simultaneous sequencing across different clinical samples, opens new avenue to investigate genotype and phenotypes interactions, identify tumor cells origins, reveal somatic copy number and mutation events, quantify the gene dosage effect and discerning differential genes expression between tumor subclones.

#6938 Identification of distinct tumor-TME ecomodules in glioma from neurofibromatosis type 1.

L. Garofano[1], F. D'Angelo[1], M. Oh[1], M. Ceccarelli[1], F. Bielle[2], M. Sanson[2], A. Lasorella[1], A. Iavarone[1];
[1]University of Miami Miller School of Medicine, Miami, FL, [2]Pitie Salpetriere Hospital, Paris, France

Neurofibromatosis type 1 (NF-1) is the most common cancer predisposition syndrome in which 15-20% of affected individuals develop glioma. Large scale DNA and RNA bulk profiling showed the molecular complexity of NF-1 glioma with the tumor cellular ecosystem constituted by multiple malignant phenotypes and heterogenous immune microenvironment. However, the composition and function of infiltrating cells was hidden in the bulk tumor, and the extended granularity of NF-1 glioma tumor microenvironment (TME) remained still unexplored. Here, we collected glioma samples from 46 NF-1 patients including 22 high-grade (HGG) and 24 low-grade (LGG) tumors, and we analyzed their gene expression by single nuclei RNA sequencing. A total of 239,044 single cells were classified into tumor and non-tumor components by integrating multiple computational approaches (including genomic copy number inference, gene signature enrichment, and clustering). We defined the pattern of intra-tumor heterogeneity of NF-1 glioma cells using non-negative matrix factorization and derived 7 malignant meta-programs (MPs) that we respectively defined as Neuronal-like, EMT, Astrocyte-like, Dividing Radial Glia-like, Ependymal-like, Immune, and Glycolytic/Hypoxic-like. These MPs recapitulated normal brain cell subtypes, thereby reflecting broad cell plasticity. The non-tumor cell compartment (121,364 cells, 51%) was dissected for the characterization of the cell types that populate the TME of NF-1 glioma. We identified different subpopulations exhibiting specific immune functions within myeloid and lymphoid components. Different glioma ecomodules were highlighted by comparing the relative composition of the TME across the tumors. Recruitment and activation of cytotoxic $CD8^{+}$ T cells and natural killers by an active crosstalk with dendritic and pro-inflammatory myeloid cells defined an immune-supportive phenotype that could mediate a potential anti-tumor response in low-grade NF-1 glioma (LGG immune high). Conversely, regulatory T cell infiltration and effector T cell exhaustion induced immune suppression in a low-grade glioma immune dysfunctional ecomodule. The absence of lymphocytes characterized a large set of cold tumors, mostly including high-grade glioma. Together, the complex interplay of tumor cell states with different TME compartments elucidated the existence of separate ecomodules in NF-1 glioma, with the LGG immune high TME associated with Neuronal-like and the LGG immune dysfunctional with Ependymal-like tumor cells. The Ependymal-like state also exhibits maximal association with brain-specific normal cells, including oligodendrocytes, neurons and astrocytes, whereas the HGG are enriched with Dividing Radial Glia- and Glycolytic/Hypoxic-like tumor cell states. The elucidation of different ecomodules provides novel insights for the application of targeted therapies in NF-1 glioma patients.

#6939 Residual disease after HER2 inhibition is driven by a primary tumor subpopulation expressing an *ERBB2*-low associated transcriptional program.

S. K. Kabraji[1], W. Wang[2], Y. Zhang[1], J. Bergholz[2], T. Jiang[2], V. Kurisetty[1], M. Homsi[1], J. Wang[1], J. Zhao[2];
[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Dana Farber Cancer Institute, Boston, MA

Background: In HER2+ breast cancer (BC), residual disease (RD) after neoadjuvant HER2 inhibition is associated with increased risk of recurrence. However, the genetic and non-genetic resistance mechanisms underlying RD remain incompletely characterized. Here we used single nuclei (sn) RNA and DNA sequencing to profile genetic and transcriptional changes in growing, residual, and recurrent tumors from an inducible mouse tumor model of HER2+ breast cancer.
Methods: We used mammary tumors / tumor bed (n=2-3/time point) from female *MMTV-rtTA; TetO-ERBB2* mice at 9 weeks DoxOn (HER2on), 7 days DoxOff (HER2off) and 12-21 weeks Doxoff (recurrent). Samples were snap frozen and single nuclei isolation was performed. snRNAseq was performed using 10X 5' v2 kits for library preparation and sequencing. snDNAseq was performed using a custom amplicon panel targeting the mouse genome and human *ERBB2* locus via the MissionBio Tapestri platform.
Results: For snRNAseq analysis, tumor cell clusters were identified by *Epcam* and *ERBB2* gene expression. Tumor cells were further subclustered into 18 unique clusters that separated by *ERBB2* expression. Seven subclusters of HER2on tumor cells were characterized by low *ERRB2* expression: 1.38 vs 2.94 (median normalized log counts) in HER2on-*ERBB2*high cells. Top 5 differentially expressed genes (DEG) per condition (log2 fold change >1.5, adjusted p value < 0.05) were: HER2on: *Erbb2, Csn3, Lcn2, Csn2, Wfdc18*; HER2on-*ERBB2*high: *Csn3, Igfbp5, Csn2, Lcn2, Trf*; HER2on-*ERBB2*low: *Lars2, Gm47283, Cmss1, Gm42418, Neat1*; HER2off: *Lars2, Hexb, Cmss1, Gphn, Gm42418*; Recurrent: *Capza2, Vim, Lgals1, Crabp1, S100a6*. HER2on-*ERBB2*low cells were more closely related in transcriptional space to HER2off residual tumor cells than HER2on-*ERBB2*high tumor cells. Trajectory analysis suggested that HER2off RD evolved from HER2on-*ERRB2*low cells and formed the basis of recurrent disease. To determine clonal evolution over time, we used common top 10 DEGs between HER2on vs HER2off vs HER2low snRNAseq data and intersected that set with significantly enriched single nucleotide variants (SNVs) from our snDNAseq data. We identified 16 clones containing at least 1 SNV at >1% frequency across all samples. We observed clonal persistence, relative enrichment and extinguishment between HER2on, HER2off and recurrent samples but without clonal dominance.
Conclusion: Time-series analysis of genetic and transcriptional evolution in a mouse model of HER2+ BC RD suggests that a tumor cell subpopulation characterized by an *ERBB2*low-associated transcriptional program drives RD after HER2 inhibition.

#6940 The transcriptional and epigenetic regulation of epithelial-mesenchymal plasticity in patient-derived pancreatic cancer cell lines.

D. Yeramosu[1], L. Bi[1], A. Collins[1], M. Bogaev[1], M. Jankowiak[1], A. Al'Khafaji[1], M. Parikh[1], M. Babadi[1], A. Bloemendal[1], S. Nagaraja[2], R. Jones[1], J. Shendure[3], D. T. Ting[4], A. Aguirre[5], N. Hacohen[6], D. Pe'er[7], E. S. Lander[1], A. Mehta[1];

[1]Broad Institute of MIT and Harvard, Cambridge, MA, [2]Harvard Medical School, Boston, MA, [3]University of Washington, Seattle, WA, [4]Mass General Cancer Center, Boston, MA, [5]Dana-Farber Cancer Institute, Boston, MA, [6]Massachusetts General Hospital, Boston, MA, [7]Sloan Kettering Institute, New York, NY

Epithelial-mesenchymal transition (EMT) is a hallmark of pancreatic ductal adenocarcinoma (PDAC) invasion. In general, cellular plasticity is a major contributor to both tumor progression and therapy resistance. The major goals of our study are to 1) directly and quantitatively measure plasticity in PDAC3 cell lines, and 2) identify candidate genes that could alter the plasticity of cancer cells. By understanding the regulation of tumor cell plasticity, we may find ways to perturb cells and prevent the transition towards treatment resistant cell states. A strict definition of plasticity in cancer has yet to be established, however, and is imperative to our understanding of cell state regulation and for identifying vulnerabilities in plastic cells. We argue that in order to prove plasticity occurs within a population of cells, one must either 1) demonstrate that a new cell state has emerged that was previously not present, or 2) trace the lineage of a cell to show it can adopt multiple cell states. For our study, we profile 12 patient-derived PDAC cell lines to find convergent EMT programs and perform lineage tracing on these cell lines using a modified CROP-seq vector, called ClonMapper, to quantitatively measure plasticity. Towards this goal, we perform single-cell RNA-seq (scRNA) and single-cell multiomic measurements of 1000 uniquely barcoded cells expanded over a time course of 2, 3 and 4 weeks. We refer to cells that have the same lineage barcode - originating from the same initial cell - as families. We found that ~50% of families are composed of cells that are epithelial and mesenchymal, thus proving plasticity must exist, as it shows that a given parental cell of unknown state can give rise to progeny that are in multiple states. We then develop mathematical models to show that families have different levels of plasticity, defined by the rates of transition between distinct cell states. We next leverage our barcode-resolution time course data to identify factors at early time points that may influence plasticity at later time points. We show there is differential accessibility of several of these factors across families with different plasticity properties, thus proposing a role for epigenetic regulation of EMT. Importantly, we find that specific factors drive gene regulatory networks important for epithelial and mesenchymal programs, and therefore propose candidates for the modulation of EMT for therapeutic benefit.

#6941 Transcriptomic effects of retinoblastoma progression-related somatic copy number alteration (SCNA).

Kevin Stachelek, David E. Cobrinik

USC - University of Southern California, Los Angeles, CA

Retinoblastoma is a pediatric retinal cancer that initiates in response to biallelic RB1 loss or MYCN amplification in a cone precursor cell of origin. After initial emergence, RB1-/- retinoblastomas progress to more aggressive forms by accumulation of single nucleotide variants (SNVs) and highly recurrent somatic copy number alterations including 1q+, 2p+, 6p+ and 16q- (RB SCNAs), resulting in heterogeneous mixtures of subclonal cell populations. SCNAs are enriched in highly evolved and aggressive tumor subtypes and show prognostic value in retinoblastoma liquid biopsies. However, the transcriptomic effects of retinoblastoma SCNAs are poorly understood. Single cell methods may enable comparison of tumor subclones within emerging retinoblastoma tumors and thereby provide insight into tumor progression.

We retrieved single cell RNA sequencing data for 25 retinoblastoma tumors and inferred SCNAs and subclone phylogenies from scRNAseq information using a recently published tool, Numbat. We identified tumors with clonal variation in RB SCNAs and excluded samples with poor transcriptome quality or excessive additional SCNAs. We proceeded with analysis of 11 tumors with subclonal heterogeneity for an SCNA of interest, including 10 with 1q+, eight with 2p+, four with 6p+, and six with 16q-. After removal of nontumor cells, we defined cell clusters, cluster marker genes, and cell cycle phase gene signatures, and we compared cell state distributions for subclones with an acquired SCNA relative to their immediate antecedents.

These analyses revealed recurrently discriminated transcriptomic clusters corresponding to six discrete cell cycle states (post-mitotic G1, G1, G1/S, S, S/G2, G2/M) and variable cell stress states, including a cluster with hypoxia and heat shock related marker gene expression in all samples. In each tumor, SCNA-defined tumor subclones had a distinct cell state distribution. Tumor subclones with acquired 1q+ were enriched in G2 states and depleted in G1 states. Subclones with 2p+ were enriched in G2 states. Subclones with 6p+ were enriched in S phase states. Subclones with 16q- were diminished in post-mitotic cell states. Tumor clones with 1q+ and 16q- were most strongly enriched for G2 phase cells. Such 1q+/16q- tumor cells were significantly differentially distributed in three tumor replicates. Tumor clones with other RB SCNAs were enriched over diploid clones in proliferating G2 cells without SCNA specific effects.

To identify candidate drivers of SCNA-specific transcriptomic effects we measured RB SCNA clonal variation in gene expression within and across transcriptomic states. We identified recurrently differentially expressed in-segment genes in 1q+, 2p+, 6p+, and 16q- , as well as out-of-segment genes. Finally, we propose molecular mechanisms underlying SCNA recurrence that may enable tumor evolution in retinoblastoma.

#6942 Single cell resolution of intrapatient drug resistance mechanisms in metastatic melanoma.

H. P. Wilson[1], G. L. Mersky[1], J. I. Haj[1], J. Teh[1], P. F. Cheng[2], S. Caksa[1], C. D. Stefanski[1], V. Chua[1], C. Capparelli[1], M. P. Levesque[2], R. Dummer[2], T. J. Purwin[1], A. E. Aplin[1];

[1]Thomas Jefferson University, Philadelphia, PA, [2]University of Zurich Hospital, Zurich, Switzerland

Intrapatient heterogeneity among different metastatic sites contributes to immunotherapy (ICi) and targeted therapy resistance. Determining the evolution of metastatic melanoma lesions that develop within the same patient could help elucidate adaptive mechanisms that drive tumor progression during therapy. To assess how metastatic melanoma persists through immunotherapy and targeted inhibitor treatments, we utilized samples from a single patient who had received anti-CTLA4, BRAFi/MEKi, and BRAFi/MEKi+CDK4/6i treatments during the LOGIC2 clinical trial. Eight short-term cultures were established from different metastatic site biopsies at chronological time points throughout the patient's treatment and subsequent post-mortem resection of the bone, ovary, and brain metastatic sites. While the initial treatment naïve metastatic tumor in the breast was *BRAF*^{V600E} mutant, *NRAS*^{Q61} mutations were acquired after treatment with CDK4/6i in the bone and ovary tumors. Tumors that persist through treatment and colonize distant organs adapt to and rely on organ-specific microenvironments. To assess treatment- and organ-specific adaptations, single-cell RNA sequencing was performed on seven of the short-term cultures to identify subpopulations that persist through each treatment. We analyzed samples and subpopulations of each culture to determine differences in their transcriptional cell states. The regulon transcriptional network of each sample and subpopulation was evaluated to determine site- and treatment-specific transcriptional regulation differences. In addition, we identified the treatment naïve culture is split into two major subpopulations by therapy resistance features which are further made up of six distinct subpopulations with heterogeneous regulatory networks. We determined the longitudinal evolution of subpopulations in response to treatment and organ site to evaluate how the pressure of therapies and the microenvironment influence metastatic progression. We further evaluated site-specific resistance mechanisms and detected increased HER3 expression in the melanoma brain metastasis (MBM) sample. Treatment with Neuregulin 1, a ligand for the HER3 receptor that is abundant in brain tissue, partially rescued the growth of MBM cells and restored MAPK and AKT-mTOR signaling in the presence of BRAFi/MEKi. Targeting the NRG1-HER3 signaling axis could have therapeutic potential in melanoma patients with active brain metastases. Additionally, we evaluated treatment-specific resistance mechanisms and identified high Brevican (BCAN) expression in an early emerging subpopulation that arises after ICi in this patient and in others. BCAN is implicated in both ICi- and cross-resistance. We will functionally investigate whether targeting BCAN sensitizes cells to ICi. Future studies aim to functionally examine novel site- and treatment-specific cross patient targets.

#6943 Evolutionary dynamics under chemotherapy in small cell lung cancer: Insights from patient-derived xenotransplant models.

L. C. Kaiser, M. Schmiel, A. Ruminska, N. Alavinejad, C. Muller, J. Valiulis, M. Peifer, M. Cartolano, R. K. Thomas, J. George;
University of Cologne, Koln, Germany

Introduction: The treatment of patients with small cell lung cancer (SCLC) represents a major medical challenge due to aggressive tumor growth and the poor 5-year overall survival rate of only 5%. SCLC tumors typically are remarkably sensitive to chemotherapy at the beginning; however, the subsequent rapid relapse of therapy-resistant tumors is a severe obstacle. We therefore aimed to decipher the molecular patterns guiding processes of evolutionary adaptation in SCLC as a consequence of therapeutic interventions.

Methods: Over 100 patient-derived xenotransplant models were generated from clinical SCLC specimens capturing a wide range of genetic and molecular features as well as clinical phenotypes with regard to chemotherapy response. We recapitulated chemotherapy response *in vivo* for 32 models, and performed in-depth genome and single-cell transcriptome sequencing to thus dissect genomic evolutionary trajectories and transcriptional plasticity of therapy-naïve and relapsed tumors, which includes the study of multiregional and longitudinal samples.

Results: The response to chemotherapy *in vivo* reflected the clinical response of the patients; however, several models of relapsed patients remained sensitive to treatment. Genomic studies of clonal dynamics indicated selection of subclones as a result of therapeutic pressure. In contrast, chemo-refractory tumors maintained their clonal composition after therapy. In agreement with genomic profiles, single-cell transcriptome data revealed a tremendous shift in expression profiles and composition of subpopulations. Furthermore, subclonal genomic events including copy number alterations were found to shape the transcriptional heterogeneity in tumors.

Conclusion: Here, we demonstrate a comprehensive functional characterization of multi-regional tumor sites and longitudinal specimens acquired from patients with SCLC, in which we elucidate genomic and transcriptional heterogeneity as a consequence of therapy response. Overall, our data points to a complex interplay between sub-clonal genomic changes and transcriptional plasticity shaping therapy response in which pre-existing genomic alterations impact selection under therapy.

#6944 Transcriptional programs underpinning reoccurring cancer cell states, plasticity and tumour phylogenies in clear cell kidney cancer.

O. Lombardi[1], R. Li[1], L. Browning[2], F. Jabbar[1], H. Evans[1], P. J. Ratcliffe[1], D. R. Mole[1];

[1]University of Oxford, Oxford, United Kingdom, [2]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Intratumor heterogeneity (ITH) is a substrate for tumor evolution and confers amenability to stressors and therapies. Sources of ITH include subclonal mutations, microenvironmental factors, and plasticity whereby a cell has the ability to adopt different cell states. Clear cell kidney cancer (ccRCC) has a well-characterized genetic initiating event - VHL inactivation - resulting in activation of HIF-1 and HIF-2 transcription factors. Although VHL inactivation is consistently clonal in nature, ccRCC nonetheless exhibits extensive genetic and morphological ITH. This makes ccRCC an excellent model in which to study ITH.

We performed single cell RNA-seq on multiregional samples from kidney tumors and macroscopically normal kidney tissue. We obtained 55 samples from 16 tumors and used the 10x Genomics platform to obtain gene expression data from ~150,000 single cells, including ~80,000 cancer and normal epithelial cells. We identified three cancer cell states, co-existing in all clear cell kidney cancer tumors analyzed and marked by different gene expression programs: 1) differentiated-like cells marked by proximal tubule cell genes characteristic of the cancer cell of origin; 2) epithelial-mesenchymal transition (EMT)-like cells and 3) injured-like cells. Differentiated markers and EMT markers were associated with good and poor prognosis, respectively, indicating that these cell subpopulations are clinically important. Notably, these cell states are also present in the normal proximal tubule although in different proportions to the tumor samples, which contain more cells in the EMT-like and injured-like states. This suggests that the core features of ITH are inherent to the cell of origin of the cancer, but that the cell state trajectories are dysregulated in the tumor. Furthermore, in tumors these states exist as a continuum, whereby transitional cells in between states appear to exist, suggesting that cancer cells are continually and dynamically transitioning between states.

Lastly, we used chromosomal copy number variation (CNV) patterns to study genetic ITH. We examined the effect of 14q loss, which is associated with ccRCC metastasis, on gene expression. We found that 14q loss is associated with downregulation of HIF-1 transcriptional activity together with a reciprocal increase in HIF-2 activity, MYC activity and oxidative phosphorylation, highlighting potential mechanisms by which 14q loss may driver ccRCC metastasis.

#6945 Dissecting the interplay of cell identity and extrachromosomal DNA in glioblastoma.

B. Taylor, B. Jones, D. Kawauchi, Y. Miyake, R. Vadla, N. Jameson, S. Miki, T. Koga, B. Ren, F. Furnari;
UC San Diego School of Medicine, San Diego, CA

The five-year survival rate of glioblastoma multiforme (GBM) is 5.8%, and its standard of care has not changed since 2005. This stagnation in therapeutic development is due, in part, to its characteristic heterogeneity--*multiforme*--highlighting a *critical need* to understand the biological processes underlying this GBM hallmark. Despite the well-documented individual relationships between extrachromosomal DNA (ecDNA), GBM, and heterogeneity, the interplay between the three is not well understood. The Furnari lab has generated a library of cancer avatars, or human induced pluripotent stem cells (hiPSCs) engineered to harbor cancer driving mutations. Single cell RNA sequencing (scRNA-seq) was used to characterize the longitudinal evolution of the first avatars engineered to have *TP53*$^{-/-}$;*PDGFRA*$^{\Delta 8\text{-}9}$ and *PTEN*$^{-/-}$;*NF1*$^{-/-}$ genotypes. The *TP53*$^{-/-}$;*PDGFRA*$^{\Delta 8\text{-}9}$ avatar acquired ecDNA, while the *PTEN*$^{-/-}$; *NF1*$^{-/-}$ avatar did not. Re-analysis of the scRNA-seq data identified a subpopulation of cells in the *TP53*$^{-/-}$;*PDGFRA*$^{\Delta 8\text{-}9}$ avatar that had high expression of *CDK4* and *PDGFRA*, two genes that are commonly co-amplified, found on ecDNA, and drive cellular states. This subpopulation of cells also had highly expressed genes near the *CDK4* locus indicating a structural variant and possibly ecDNA. This population diverged transcriptionally from other cells and was associated with the OPC-like cellular state, which has been shown to be associated with high levels of *PDGFRA* and, at times, co-expression with *CDK4*. While *TP53*$^{-/-}$;*PDGFRA*$^{\Delta 8\text{-}9}$ tumors contained cells across all four GBM cellular states, *PTEN*$^{-/-}$;*NF1*$^{-/-}$ tumors had a significantly less diverse composition of cellular states suggesting that ecDNA may facilitate cellular state diversity. With the eventual goal to directly test whether ecDNA enables transcriptional state heterogeneity compared to chromosomally inherited amplifications, CRISPR-Cas9 and CRISPR-C were implemented to engineer *EGFRvIII* ecDNA in U87. While inverse PCR confirmed the successful generation of ecDNA in U87, ecDNA was lost following long term *in vitro* cell passaging. Current follow up work aims to identify different intrinsic (oncogene amplified, genetic background, cell type, cell line) and extrinsic (*in vitro* conditions, orthotopic engraftment) contexts that promote the selection and amplification of engineered ecDNA, as it would be would be valuable to have genotypically identical cancer models with different classes of amplifications (i.e., engineered ecDNA vs. lentiviral overexpression, which is chromosomally inherited). Together, these results highlight the potential to use hiPSC-derived models and single cell methods to investigate gliomagenesis and cell identity.

#6946 Unravelling intra-tumor phenotypic heterogeneity in colorectal cancer organoids.

S. J. Fletcher[1], I. Catalano[2], E. Grassi[1], S. Borgato[1], B. Peracino[1], E. Piretto[1], L. Alessandri[1], R. Calogero[1], L. Primo[1], L. Trusolino[1], A. Bertotti[1], A. Puliafito[1]; [1]University of Turin, Torino, Italy, [2]Candiolo Cancer Institute-FPO IRCCS, Torino, Italy

Colorectal cancer (CRC) is one of the most diagnosed cancers worldwide. Though several treatment strategies are available today, around a million people die of this disease each year worldwide. Thus, there is still a pivotal need for new and more effective treatments. Genetic and non-genetic intra-tumor heterogeneity has emerged lately as an intrinsic feature of malignancies and as one of the factors responsible for therapy resistance or tolerance. In particular, the nature and role that phenotypically distinct, yet genetically indistinguishable, subpopulations have on tumor biology is far from being understood. Here we investigate phenotypic heterogeneity in CRC by identifying specific transcriptionally well defined cell subpopulations. We aim at deciphering the interactions between populations in terms of differentiation and plasticity, tumor growth and potentially exposed targetable vulnerabilities. To this end, we used patient-derived metastatic CRC (mCRC) organoids, including KRAS wild type (wt) and mutant (*kras*) models. We performed in total scRNAseq for 7 mCRC samples (4 wt; 3 *kras*) in different growth media: normal growth medium (supplemented with EGF) (n=1); medium without EGF (noEGF) (n=7); or treated with Cetuximab (CTX, a clinically approved monoclonal antibody against EGFR) (n=7). We found that the wt sample grown in EGF presents 2 distinct subpopulations: one with stemness characteristics (LGR5 high) and the other with a more differentiated phenotype (KRT20 high), in agreement with the current bibliography. Interestingly, in EGF deprived cultures new subpopulations appear. In particular, we were able to identify a subpopulation with distinct expression of WNT-related genes (APCDD1, WNT6, WIF1). This subpopulation is also present, and in cases increasing in fraction, when organoids are treated with CTX (in 3 out of 7 samples). Interestingly, a fraction of the WNT positive subpopulation seems to be able to proliferate under CTX treatment (Ki67 positive). We identified the negative regulator of the WNT pathway, APCDD1, as a potential marker to track this subpopulation. We took one wt and one *kras* sample as models to validate these findings by flow cytometry. Furthermore, sorting of APCDD1 positive and negative cells, and further RT-qPCR analysis, confirmed good correlation between antibody staining and gene expression. Moreover, we found that both types of cells are able to re-grow as organoids after re-culturing. This suggests that this WNT-associated subpopulation could be contributing, at least in part, to CTX tolerance or resistance. Our results show promising potential to help unravel basic features of intra-tumor heterogeneity both in basal conditions and upon treatment, and possibly to find new therapeutic targets.

#6947 Exploring the single-cell dynamics of FOXM1 under cell cycle perturbations.

T. Jawwad[1], M. Kamkaew[2], K. Phongkitkarun[1], P. Chusorn[3], S. Sampattavanich[1];
[1]Mahidol University, Bangkok, Thailand, [2]Tufts University, Boston, MA, [3]Roi Et Rajabhat University, Bangkok, Thailand

The cell cycle plays a critical role in maintaining normal cellular functions and preventing abnormal cell growth. The transcription factor FOXM1 has emerged as a crucial regulator of cell cycle progression and has been implicated in various physiological and pathological processes. Notably, FOXM1 overexpression has been observed in numerous cancer types, including liver, prostate, breast, lung, and colon cancer. Despite its significance, our understanding of how FOXM1 dynamic behaves at the single-cell level under different cell cycle perturbations and its link to cell behavior heterogeneity remains limited. Here, we investigated the dynamic behavior of FOXM1 in individual cells exposed to various cell cycle perturbations, focusing on understanding heterogeneity in cell behavior and improving disease treatment. At the single-cell level, our investigation reveals six distinct dynamic features of FOXM1 in response to various therapeutic interventions, each of which corresponds to a unique cell phenotype. Our result further demonstrates that for cells exhibiting a high FOXM1 pattern, targeting aurora kinase and PLK1 may hold promise as a therapeutic approach for cancer suggesting that FOXM1 is a strong biomarker, and its pattern can be predictive of drug response, especially in cases with G1 checkpoint defects like Rb1 loss or p53 deficiency.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Cancer Cell Communication with the Tumor Microenvironment

#6951 The role of estrogen-dependent activation of p38 MAPK signaling pathway in inflammatory breast cancer.

Keyla V. Ramirez[1], Adrian D. Bonilla-Gonzalez[1], Jeisac Guzman-Rivera[2], Esther A. Peterson-Peguero[1]

[1]University of Puerto Rico - Rio Piedras, San Juan, PR,[2]Rutgers University, Newark, NJ

Inflammatory breast cancer (IBC) is a rare and aggressive type of breast cancer in which the lymphatic vessels become blocked by cancer cells in the breast tissue. The five-year survival rate for this type of cancer is around 40%, one of the worst among breast cancer. Most IBCs are estrogen receptor (ER) and progesterone receptor (PR) negative and HER2 positive, with some presenting an amplification of HER2 while others are ER, PR, and HER2 negative, formally known as the triple-negative (TNBC) subtype. However, it has been reported that treatment with 17β-Estradiol (E2) of ER-negative IBC and non-IBC cells can exert rapid non-genomic signaling mediated by ERα-36, GPR30, and/or estrogen receptor beta, activating MAPK pathways involved in oncogenic phenotypes. Previous data generated in our lab showed that when cells were treated with estradiol it led to increased phosphorylation levels of p38. However, the specific role p38 MAPK signaling takes on in IBC is unknown. Thus, this study centers on examining the role of estradiol and p38 regulation in the triple-negative IBC cell line model, SUM149PT. We hypothesize that upon estradiol treatment p38 signaling pathway is activated resulting in the over-expression of pro-inflammatory cytokines which regulate pro-tumorigenic phenotypes including the growth and survival of IBC cells. Inflammatory cytokines can promote pro-oncogenic features by promoting cell proliferation, angiogenesis, and immune suppression. We treated SUM149 IBC cells with 10nM of estradiol and measured the levels of human cytokines using a Human Cytokine Antibody Array. In addition, treatment using SB202190, a potent p38 inhibitor, caused a significant decrease in cell viability of several breast cancer cell lines in a dose-dependent manner. Ongoing studies include assessing the effects of p38 inhibition proliferation, invasion, and migration. In summary, a better characterization of the effect of E2 and p38 activation in ER-negative cell lines may provide great insight into novel targeted therapies for IBC.

#6952 The role of interleukin-11 (IL11) in cancer-associated cachexia (CAC).

K. Drinkwater, A. Meyers, S. Kargari, N. Crisan, **A. Mody**, M. Shim;
Midwestern University - Glendale Campus, Glendale, AZ

Cancer-associated cachexia (CAC), characterized by loss of skeletal muscle and involuntary body weight loss, is responsible for increased chemotherapy toxicity, reduced quality of life, and impaired survival in cancer patients. While interleukin-11 (IL11), one of the IL6 family cytokines, was originally thought to be involved in hematopoiesis, studies increasingly suggest its involvement in tumorigenesis including chemoresistance, metastasis, and survival of cancer cells. However, the precise role of IL11 in CAC has not been determined. Our lab has previously shown that IL11 treatment suppressed the myogenic differentiation of C2C12 myoblasts, suggesting that IL11 may interfere with differentiation and subsequent regeneration of muscle. In this study, we investigated the role of IL11 in cancer-induced muscle wasting using cell culture and mouse models. The mRNA expression of IL11 was highly up-regulated in C26 and Lewis lung carcinoma (LLC) cells, two well-known cachectic mouse cancer cell lines, while its expression was low in a non-cachectic MC38 mouse colon cancer cell line. Knockdown of IL11 in C26 cells using two independent lentiviral shRNAs significantly reduced the mRNA levels of the cytokines involved in CAC including GDF15, LIF, and VEGFA, while the mRNA level of IL6 was not significantly altered. Additionally, IL11 knockdown significantly reduced the mRNA and protein levels of ATF4, CHOP, and TRIB3, suggesting that IL11 may be responsible for the activation of unfolded protein response, an adaptive mechanism for growth, survival, and angiogenesis of cancer. Knockdown of IL11 in C26 and LLC cell lines also significantly reduced the volume of tumors in syngeneic mouse models, while over-expression of IL11 in MC38 cells increased tumor size. Moreover, the knockdown of IL11 in cachectic cancer cells partially prevented the loss of muscle and body weight in tumor-bearing mice, although the amelioration of muscle loss by IL11 knockdown may be associated with the decreased tumor burden. Together, these results indicate that IL11 may contribute to muscle wasting and provide novel insight into the previously unestablished role of IL11 in CAC.

#6953 Wnt2b deficiency exacerbates colitis and leads to increased tumorigenesis in mice.

L. Silva Oliveira[1], A. E. O'Connell[2];

[1]Boston Children's Hospital, Brookline, MA, [2]Boston Children's Hospital, Division of Newborn Medicine, Brookline, MA

Colitis-associated cancer (CAC) is considered the most severe complication of inflammatory bowel disease (IBD). It has been demonstrated that WNT2B deficiency leads to severe intestinal impairment in humans and predisposes to colitis in mice. Evaluating a human cohort from The Cancer Genome Atlas (TCGA), we observed that low expression of WNT2B is associated with poor prognosis of patients with colon cancer. However, the functional roles of WNT2B in CAC development remain unclear, and we hypothesized that WNT2B is involved in the resistance to CAC development during long-term colitis. Thus, we model CAC development using Wnt2b deficient mice subjected to mutagenesis induction with 10 mg/kg Azoxymethane (AOM) and a long-term colitis protocol with three cycles of 2.5% Dextran Sodium Sulfate in the drinking water for three days, followed by a recovery period with autoclaved water. We observed that Wnt2b KO mice had increased susceptibility to colitis and more significant body weight changes than WT mice, especially in the first and second recovery cycles of colitis recovery. The maximum weight loss and disease activity index (DAI) were significantly higher in KO than in WT mice. Interestingly, Wnt2b KO mice developed more tumors, which were more extensive than those observed in WT. Moreover, the histopathological analysis showed that Wnt2b KO had the highest score for ulceration, aberrant crypt foci, and immune cell infiltration. Our data suggest a protective role for WNT2B, conferring resistance to tumor development during colitis. Furthermore, our data provides new insights into the functional roles of Wnt ligands in colon cancer. A better understanding of the factors involved in CAC etiology is critical for improving diagnosis and developing new targeted therapies. We believe WNT2B may emerge as one of these factors and offer novel targets for improved colorectal cancer management.

#6954 Glycine decarboxylase regulates renal carcinoma progression and DNA damage response via interferon stimulated gene factor 3-mediated pathway.

J. Kim, B. Kim, M. Choe, T. Pham, M. Kim, J. Seo, S. Shin;
Keimyung University Dongsan Medical Center, Daegu, Korea, Republic of

Glycine decarboxylase (GLDC) is a mitochondrial enzyme of glycine cleavage system which catalyzes glycine to donate for one-carbon metabolism. It is implicated as a tumor suppressor in hepatocellular carcinoma but as an oncogene in lung cancer. Although GLDC expression in the kidney is second highest next to the liver, the role of GLDC in the kidney remains unclear. Thus, this study was designed to determine the role of GLDC in renal carcinoma. We found markedly increased expressions of GLDC in patients with renal cell carcinoma (RCC) classified as poor-risk group based on the Memorial Sloan Kettering Cancer Center prognostic model. *In vitro* studies revealed that cellular proliferation, colony formation was decreased in GLDC-deficient renal carcinoma cells. Additionally *in vivo* xenograft studies with GLDC-deficient and -overexpressing cells also revealed that tumor sizes were noticeably decreased in GLDC-deficient cell-injected mice while those were increased in GLDC-overexpressing cell-injected mice. Mechanistically, we found GLDC regulates renal carcinoma progression via interferon (IFN) stimulated gene factor 3 (ISGF3)-mediated pathway. Expressions of IRF9 and STAT2 were increased in GLDC-deficient cells while those were decreased in GLDC-overexpressing cells. Upon inducing expression of ISGF3 subunits, GLDC deletion elevated DNA damage, mitotic catastrophe, mitochondrial deficiency induced by chemotherapy. Finally, GLDC knockdown diminished pyrimidine synthesis to impair renal cancer progression. In summary, our finding reveals that GLDC regulates renal carcinoma progression and DNA damage response via ISFG3-medated pathway and lays a scientific foundation that could support a therapeutic strategy that targets GLDC for the treatment of renal carcinoma.

#6955 Activation of ERK pathway by mutant Ras oncoproteins derived from THP-1 cell exosomes.

J. B. Hwang, L. Marquardt, O. Sait, B. Gilliam, Q. Xiao;
MilliporeSigma, St. Louis, MO

The study of exosomes has attracted worldwide research due to its ability to modulate cellular activities, especially in the progression of cancer. Exosomes are membrane vesicles that can deliver lipids, proteins, and nucleic acids from one cell to another through membrane fusion, providing a unique form of cell-to-cell communication. It has been shown that KRAS G12V oncoprotein has been detected inside various pancreatic cancer cell derived exosomes. Our goal for this study was to examine the effect of KRAS G12V oncoprotein, detected inside exosomes isolated from THP-1 cell line supernatant, to activate MAPK pathway in MCF-7 breast cancer and AsPC-1 pancreatic cancer cells. To this end, we developed MILLIPLEX® immunoassays to detect cell signaling proteins as well as the exosome markers (CD9, CD63 and CD81), using Luminex® xMAP® technology which allows multiplex detection of proteins in a small volume of sample. Exosomes were isolated from THP-1 derived cell supernatant, using Qiagen exoEasy Maxi kit according to the kit protocol. KRAS G12V oncoprotein was detected in isolated THP-1 exosomes. As a control, THP-1 exosomes were enriched with exosome markers such as CD9, CD63 and CD81. After 48-hour incubation of AsPC-1 cells with KRAS G12V containing THP-1 exosomes, significant increase in KRAS G12V levels were detected in AsPC-1 cells. More importantly, this increase in KRAS G12V levels corresponded with an increase in phosphorylated ERK signaling, but not JNK, p38, NFκB, Akt, STAT3 and STAT3 pathways. In contrast, 48-hour incubation of MCF-7 cells with KRAS G12V containing THP-1 exosomes had no effect on any signaling pathways. Using MILLIPLEX® multiplex immunoassays, our data supports research findings that exosomes contain mitogenic signaling components that may enhance progression of cancer.

#6956 Role of soluble CD109 in the progression of head and neck squamous cell carcinoma.

Varsha Reddy Durgempudi, Tenzin Kungyal, Anie Philip

Surgery and Division of Plastic Surgery, McGill University, Montreal, QC, Canada

Introduction: About five percent of global cancer deaths are attributed to Head and Neck Squamous Cell Carcinoma (HNSCC), and its annual incidence is predicted to skyrocket by thirty percent by 2030 (according to GLOBOCAN estimates). HNSCC originates from squamous cells in the oral cavity, lips, tongue, larynx, pharynx, and salivary glands. Despite the comparatively easy tumor diagnosis, the number of patients diagnosed at an advanced stage with metastatic spread is substantial. Multiple cell-signaling pathways have been proven to be dysregulated in HNSCC, including the epidermal growth factor receptor (EGFR). Our group has identified CD109, a GPI-anchored membrane-associated protein, as a TGF-β co-receptor that inhibits TGF-β signaling. CD109 expression is upregulated in SCC, and its elevated expression in premalignant lesions is associated with an increased risk of metastatic progression. Recent studies by our team have revealed that CD109 promotes tumor growth *in vivo*, likely by enhancing EGFR signaling. Interestingly, we have also discovered that membrane CD109 (mCD109) is endogenously released from the cell surface; however, the mechanism of action of the released/soluble form of CD109 (sCD109) remains unknown. In the current study, we examined whether sCD109 opposes the mCD109/EGFR-mediated pro-tumorigenic signaling and HNSCC progression.
Research Questions: 1.Does sCD109 regulate EGF-induced EGFR signaling and downstream stem cell marker expression?2.Does sCD109 regulate EGFR expression levels on the HNSCC cell surface?3.Does sCD109 affect the nuclear localization of EGFR?4.Does sCD109 promote EGFR internalization and degradation?
Methodology: HNSCC cells and patient-derived primary cells were treated with/without sCD109 recombinant protein (1nM, 5nM, and 10nM) without and with the EGF induction (10ng/ml for 15 mins) and were analyzed by western blotting, immunofluorescence, and immunocytochemistry. The role of sCD109 in regulating membrane EGFR levels was assessed by flow cytometry and surface protein biotinylation assay.
Results: Our findings demonstrated that sCD109 inhibited EGF-induced phosphorylation of EGFR (Y1068), STAT3, AKT, and ERK. The sCD109 suppressed the stem cell marker expression (Nanog, OCT4, SOX2). Additionally, sCD109 hindered the nuclear localization of activated EGFR. The sCD109 decreased the membrane EGFR expression levels and activated the phosphorylation of EGFR (Y1045), suggesting a role for sCD109 in promoting EGFR degradation.
Conclusion: Our team has previously reported that mCD109 is pro-tumorigenic, and our current findings suggest that sCD109 opposes the pro-tumorigenic effects of mCD109. This study aimed to determine how sCD109 regulates cellular signaling pathways and will provide key insights into the molecular mechanisms underlying the progression of HNSCC, a highly prevalent malignancy.

#6957 Extrachromosomal FGFR2 is delivered in extracellular vesicles in two models of cancer of unknown primary.

I. Salamon[1], G. Storci[2], B. Fontana[3], S. Serravalle[2], G. Gallerani[3], R. Roncarati[4], S. Santi[4], M. Bonafe[3], **M. Ferracin**[3];
[1]University of Bologna, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, [3]University of Bologna, Bologna, Italy, [4]Institute of Molecular Genetics, National Research Council of Italy, Bologna, Italy

The extracellular vesicle (EV) route is essential for cell-to-cell communication. Cancer cells release EVs in the extracellular space, where they can interact with recipient cells inducing regulation of gene expression, activation of specific signaling pathways and tumor microenvironment remodeling. We investigated the EVs released by two cell lines of cancer of unknown primary site (CUP) that we established from patient's tumor cells, namely CUP#55 and CUP#96, as described in https://www.medrxiv.org/content/10.1101/2023.03.12.23287041v1). CUP comprises 3-5% of new cancer cases and presents with metastases of unknown or uncertain origin and no apparent primary tumor. Our CUP cell lines are both characterized by *FGFR2* gene amplification. It has been recognized that tumors use circular extrachromosomal DNA (ecDNA) as a way to increase oncogenic amplification. We hypothesized that FGFR2 amplification in CUP cell lines could be associated with ecDNA generation and that this ecDNA could be loaded as cargo inside EVs. *FGFR2* copy number was quantified using a probe-based droplet digital PCR assay then we identified the different nature of *FGFR2* amplification in the two models using FGFR2 FISH assay: CUP#55 presented a chromosomal homogeneously staining region while CUP#96 displayed double minute chromosomes. *FGFR2* DNA was detectable in the cytoplasm fraction, therefore we isolated extracellular vesicles from culture medium using an ultracentrifugation-based protocol and confirmed the presence of the entire length of *FGFR2* gene inside small and large vesicles. Since ecDNA contributes to cancer genome remodeling also forming chimeric circles, we confirmed the circular nature of a fraction of *FGFR2* ecDNA using the Plasmid-Safe ATP-dependent DNAse test. Finally, we tested the oncogene delivery capability of CUP EVs by administering CUP#96 and CUP#55 small and large vesicles to recipient cell lines. We observed an increase of *FGFR2* DNA at 24 hours upon EV treatments, and its functional transcription in FGFR2 mRNA after 48 hours. In conclusion, we identified a model of oncogene amplification and delivery in two cell lines of cancer of unknown primary, which could explain the high metastatic potential of this cancer type. (The research leading to these results has received funding from AIRC under IG 2021 - ID. 25789 project - P.I. Ferracin Manuela)

#6958 CRIPTO-regulated extracellular vesicles mediate heterotypic cellular crosstalk in triple negative breast cancers.

D. W. Freeman[1], B. L. Gates[1], M. D. Spendlove[2], **B. T. Spike**[1];

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]Huntsman Cancer Institute/BYU, Salt Lake City, UT

Tumor progression involves dynamic interaction between various cell types within the tumor microenvironment. Fibroblasts, which normally participate in wound healing, reciprocally communicate with breast cancer cells to promote tumor cell plasticity and heterogeneity. Gaining insights into the molecular mechanisms underlying this cell-to-cell communication, could unlock novel therapeutic avenues for inhibiting cellular plasticity, breast cancer progression and metastasis. The small GPI-anchored adaptor protein CRIPTO is a key player in this context though important molecular details remain to be elucidated. CRIPTO orchestrates TGF-β pathway signaling as well as growth factor-like signaling pathways that activate c-Src/MEK/AKT, in an autocrine and paracrine manner. CRIPTO is expressed during mammary development, wound healing, and breast cancer but is largely undetectable in homeostatic tissue, making it a promising therapeutic target. Our previous studies have demonstrated that the activity of CRIPTO is contingent upon cellular stress, with pronounced influence within pro-fibrotic, hypoxic domains of tumors. Importantly, we have shown that inhibition of CRIPTO using the soluble recombinant protein antagonist A4Fc effectively impedes the progression of triple negative breast cancer (TNBC) in murine xenograft models. Building upon these findings, we have been dissecting CRIPTO's role in coordinating fibroblast activation and cell-state reprogramming in TNBC. We find that inhibition of CRIPTO with A4Fc suppresses cancer associated fibroblast (CAF) activation and collagen remodeling *in vivo*. Further, by modeling tumor cell:fibroblast crosstalk *in vitro*, we have demonstrated mechanistically that CRIPTO expression in tumor cells mediates subsequent extracellular vesicle (EV) uptake by fibroblasts, as well as fibroblast SMAD pathway activation and priming for reciprocal signaling back to tumor cells to promote transcriptional reprogramming and cellular invasion.The significance of these findings lies in their elucidation of key EV control mechanisms that could be exploited to intervene in essential tumor cell:fibroblast crosstalk or to enhance targeting of therapeutic moieties based on EV architecture and function in cancer and/or normative regenerative processes.

#6959 Acetylcholine potentiates invasion and migration of human pancreatic cancer cells under hypoxia through α7 nAChR-mediated increases in HIF-1α expression.

Yunmi Cho[1], Eun-Taex Oh[2], Ha Gyeong Kim[3], Heon Joo Park[3]

[1]Program in Biomedical Science & Engineering, Inha University College of Medicine, Incheon, Korea, Republic of,[2]Department of Biomedical Sciences, Inha University College of Medicine, Incheon, Korea, Republic of,[3]Department of Microbiology, Inha University College of Medicine, Incheon, Korea, Republic of

The most significant nerve-related problem in clinical pancreatic cancer management is perineural invasion (PNI), characterized as the neoplastic invasion of cancer cells into or surrounding the nerves. It is a characteristic feature of pancreatic ductal adenocarcinoma (PDAC) associated with a poor prognosis, tumor recurrence, and emergent pain. However, why PDAC is associated with a higher incidence of PNI remains unclear. HIF-1 (hypoxia-inducible factor-1) regulates the expression of ~1000 genes involved in angiogenesis, metastasis, tumor growth, chemoresistance and radioresistance, underscoring the growing interest in targeting HIF-1 for cancer control. In the present study, we investigated the molecular mechanisms underlying neurotransmitter acetylcholine (Ach)-potentiated HIF-1α expression and subsequent increase in invasion and migration of human pancreatic cancer cells in hypoxia (2% O_2). The expression of various acetylcholine receptors in six types of pancreatic cancer cell lines (MIA-PaCa-2, PANC-1, HPAF-II, Capan-1, AsPC-1, and BxPC-3 cells) was observed using qPCR, and α7 nAChRs was observed to be expressed in all pancreatic cancer cells. Therefore, we chose MIA-PaCa-2 cells, expressing high levels of α7 nAChRs, and HPAF-II cells, expressing low levels of α7 nAChRs, for loss- and gain-of-function studies, respectively. *In vitro* assays showed that, under hypoxic conditions, Ach caused a concentration-dependent increase in α7 nAChRs-mediated HIF-1α expression, enhancing expression of HIF-1α target genes, and promoting invasion and migration of human pancreatic cancer cells. We further found that Ach increased HIF-1α protein stability in pancreatic cancer cells under hypoxic conditions. This effect was mediated by YAP signaling, as evidenced by the fact that Ach-induced increases in HIF-1α protein stability were blocked by siRNA-mediated knockdown of YAP. Consistent with these findings, an investigation of the relationship between α7 nAChRs and clinicopathological features in pancreatic cancer patients using publicly available datasets showed that high levels of α7 nAChRs are correlated with a poorer prognosis in pancreatic cancer patients. Collectively, these findings identify novel mechanisms by which Ach potentiates invasion and migration of pancreatic cancer cells and provide further evidence that HIF-1α is a potential anticancer target in Ach-associated pancreatic cancer.

#6960 Lysosome inhibition suppress collective cell migration through caveolin-1 mediated E-cadherin stabilization in colon cancer cells.

Y.-C. Ching, H.-C. Chen, Y.-C. Wang, C.-P. Cheng, C.-E. Ku, S.-R. Lee, W.-T. Chao;
Tunghai University, Taichung, Taiwan

In tumor nest growth and collective cell migration, the dynamics of E-cadherin is critical, and been shown to be regulated by cell vesicle traffic system. Caveolin-1 is the vesicle protein to regulate caveolae associated endocytosis, many of the membrane receptors are shown been regulated by caveolin-1 in cancer progression, however, the role is still controversial. This study demonstrated the effect of lysosome inhibition in caveolin-1 mediated E-cadherin turnover in the cell cohort of colon cancer cells. HT-29 colon cancer cells were used in this study, the cells were treated with chloroquine to inhibit lysosome activity. The cell spheroid from HT-29 cells were also collected according to cell adhesion ability. Caveolin-1 and E-cadherin were immuno-stained and revealed by confocal microscopy. In the result of immunostaining, caveolin-1 was showed the co-localization with E-cadherin at cell-cell contacts. When cells were treated with chloroquine, the lysosome inhibitor, the collective cell migration of HT-29 cells were suppressed, and stable caveolin-1 distribution was found accumulated on the cell-cell contacts., meanwhile, chloroquine has no effect on clathrin distribution at either cell-cell contacts or cell leading edge. Furthermore, the distribution of caveolin-1 at cell-cell contacts on cell spheroid that derived from HT-29 cells was decreased. The results of these study suggested lysosome plays important role in mediating caveolin-1 regulated E-cadherin dynamics in collective cell migration, but not in the cell spheroid formation. The results of these study demonstrated chloroquine can be the potential inhibitor for collective cell migration in colon cancer cells through caveolin-1 mediated vesicle transport.

#6961 The cell adhesion molecule ninjurin 2 modulates tumorigenesis, inflammatory response and metabolism via modulating and pyroptosis.

J. Zhang, W. Zhang, X. Chen;
UC Davis, Davis, CA

The nerve injury induced protein 2 (NINJ2) belongs to a family of homophilic adhesion molecules and was initially found to be involved in nerve regeneration. However, the role of NINJ2 in other cellular process are not well studied. Here, by generating a Ninj2-deficient mouse model, we showed that mice deficient in *Ninj2* have a short lifespan and are prone to spontaneous tumors, systemic inflammation and metabolic defects. To better understand the metabolic traits that contributes to these phenotypes, we performed comprehensive carbohydrate and lipid metabolic analyses. Indeed, carbohydrate metabolic analyses indicated that NINJ2-deficiency led to defects in monosaccharide metabolism along with accumulation of multiple disaccharides and sugar alcohols. Similarly, lipidomic analyses indicated that Ninj2 deficiency altered patterns of several lipids including triglycerides, phospholipids and ceramides. To identify a cellular process that associate with these metabolic defects, we examined the role of Ninj2 in pyroptosis, a programmed cell death that links cancer, inflammation and metabolic disorders. Indeed, we found that loss of NINJ2 promotes pyroptosis by activating the NLRP3 inflammasome. Taken together, these data reveal a critical role of NINJ2 in tumorigenesis, inflammatory response, and metabolism via modulating pyroptosis.

#6962 Shed Trop2 drives prostate cancer progression and Trop2 is a novel tissue prognostic biomarker and a candidate urinary marker for prostate cancer.

S. Liu[1], S. Hawley[2], C. Kunder[2], E.-C. Hsu[2], M. Shen[1], M. Aslan[2], F. J. G. Marques[2], C. S. Lee[1], A. Bermudez[2], L. Westphalen[1], H. Auman[2], L. F. Newcomb[3], D. W. Lin[3], P. S. Nelson[4], Z. Feng[4], M. S. Tretiakova[3], L. D. True[3], F. Vakar-Lopez[3], P. R. Carroll[5], J. Simko[5], M. E. Gleave[6], D. A. Troyer[7], J. K. McKenney[8], D. Peehl[5], S. J. Pitteri[2], J. D. Brooks[2], M. A. Liss[9], T. Stoyanova[1];

[1]University of California Los Angeles, Los Angeles, CA, [2]Stanford University, Palo Alto, CA, [3]University of Washington, Seattle, WA, [4]Fred Hutchinson Cancer Center, Seattle, WA, [5]University of California San Francisco, San Francisco, CA, [6]University of British Columbia, British Columbia, BC, Canada, [7]Eastern Virginia Medical School, Norfolk, VA, [8]Cleveland Clinic, Cleveland, OH, [9]University of Texas Health Science Center at San Antonio, San Antonio, TX

Distinguishing indolent from clinically significant localized prostate cancer and treatment of metastatic prostate cancer are two major clinical challenges in prostate cancer. The development of novel predictive biomarkers will help with risk stratification, and influence clinical decision-making between treatment and active surveillance, leading to a decrease in over or under-treatment of patients with prostate cancer. Here, we report that Trop2, an oncogenic transmembrane surface protein, is a prognostic tissue biomarker for clinically significant prostate cancer by utilizing the Canary Prostate Cancer Tissue Microarray (CPCTA) cohort composed of over 1100 patients from a multi-institutional study. We demonstrate that higher Trop2 expression is correlated with worse clinical features and elevated Trop2 expression at radical prostatectomy predicts worse overall survival in men undergoing radical prostatectomy. Additionally, we detected shed Trop2 in urine from men with clinically significant prostate cancer. We further define the functional role of shed Trop2 on metastasis in prostate cancer and identify that shed Trop2 increases cell migration, invasion, metastatic colonization, and spontaneous metastasis *in vitro* and *in vivo*. Proteomic profiling reveals that shed Trop2 modulates a set of proteins associated with invasion, migration, mTOR signaling, and epithelial-to-mesenchymal transition. shed Trop2 binds to EGFR and results in the activation of the EGFR-PI3K-AKT-mTOR pathway in prostate cancer. Our study reveals the new function of shed Trop2 in driving prostate cancer progression and identifies Trop2 as a novel tissue prognostic biomarker and a candidate non-invasive marker for prostate cancer that could be used to optimize treatment decision-making.

#6963 Cysteinyl leukotriene receptors promote melanoma progression and metastasis.

E. Sabu Kattuman, L. Reddy Teegala, S. Darzi, S. Paruchuri;
The University of Toledo, Toledo, OH

Background: Cysteinyl leukotrienes (cys-LTs; LTC_4, LTD_4, LTE_4) are pro-inflammatory mediators mainly produced by hematopoietic cells, which enhance inflammation through their receptors, $CysLT_1R$ and $CysLT_2R$. They play a pivotal role in the development of chronic asthma in humans. Recent association of inflammation with cancer has led to immense interest on the role of cysteinyl leukotrienes in cancer progression and metastasis. However, the exact molecular mechanisms regarding how these inflammatory mediators regulate the tumor proliferation and metastasis remain unexplored. A thorough investigation of these precise molecular mechanisms and identification of the specific receptor/s responsible can aid in understanding the therapeutic potential of these receptors in various cancers like melanoma. Since the inhibitors of these receptors are already FDA approved for the treatment of asthma, our goal is to repurpose these drugs to treat melanoma progression.
Objective: To determine the mechanistic aspects of how CysLTRs regulate melanoma tumor initiation, progression, and metastasis.
Methods: Protein expression by western blotting and ELISA, transcript expression by qPCR, viability, and proliferation by XTT and BrDU, migration using trans-well assay, tumor growth and metastasis were confirmed through *in vivo* experiments.
Results & Conclusion: B16F10 melanoma cells express high $CysLT_1R$ compared to $CysLT_2R$ and produce endogenous cys-LTs that function in an autocrine signaling pattern. Further, cys-LTs mediated the activation of several signaling proteins such as ERK, p38, AKT, and CREB that are important for melanoma survival and proliferation. Moreover, treatment with CysLTR antagonists significantly reduced melanoma cell proliferation, survival, and migration. Accordingly, we observed a significant reduction in the melanoma tumor volume *in vivo* in both *Cysltr1*$^{-/-}$ and *Cysltr2*$^{-/-}$ mice compared to the WT mice. Interestingly, angiogenesis was significantly reduced in *Cysltr2*$^{-/-}$ mice but not in *Cysltr1*$^{-/-}$. Therefore, we speculate that while both receptors play a crucial role in tumor proliferation *in vivo*, $CysLT_2R$ is the main driver of angiogenesis and metastasis. Therefore, targeting both these receptors using their specific antagonists can offer potential therapy for melanoma progression and metastasis.

#6964 Regulation of TGF-β signaling via a novel TβRIII sheddase.

B. M. Greulich[1], J. Pawlak[2], J. Post[2], E. Karas[2], G. Blobe[2];
[1]Mercer University, Macon, GA, [2]Duke University Medical Center, Durham, NC

In a normal cell, TGF-β signaling serves as a tumor suppressor by reducing proliferation and promoting apoptosis. Paradoxically, the function of TGF-β signaling reverses in a cancer cell and begins to promote oncogenic pathways such as proliferation, survival, evasion of the immune system, and epithelial to mesenchymal transition (EMT). This has made TGF-β signaling a very attractive therapeutic target for a wide variety of human carcinomas. As a result, many small molecule inhibitors of TGF-β signaling have been developed, but none have achieved FDA approval for use in human cancers due to the deleterious effects of inhibiting TGF-β responsiveness in normal cells. In effort to overcome this obstacle, we aim to restore the normal biological mechanisms that regulate TGF-β signaling. Specifically, the membrane bound co-receptor TβRIII can be proteolytically cleaved and shed from the membrane, resulting in an extracellular protein capable of binding and sequestering TGF-β ligand. This decoupling of ligand binding from the receptor allows TβRIII to suppress signaling. TβRIII shedding decreases TGF-β mediated oncogenic phenotypes such as migration and metastasis in multiple cancer types. However, this shedding is often lost in cancer. Therefore, restoration of TβRIII shedding could be a viable therapeutic approach for multiple cancer types. One potential mechanism for the loss of shedding is the negative regulation of the protease responsible for shedding (sheddase). However, the identity of the sheddase still remains unknown. Here, our goal is to identify the sheddase and uncover regulatory mechanisms that could be leveraged to restore TβRIII shedding in cancer. To achieve this goal, a library of protease CRISPR knockout viruses was screened to determine which proteases have an effect on shedding. The quantity of TβRIII shed into the cell culture media was measured via ELISA for each of these CRISPR knockout cell lines, and the candidates with the largest reduction of shedding were retained for further investigation. The list of candidates was further screened *in silico* via gene set enrichment analysis of human patient data against a TGF-β signaling gene set signature. Only the candidates demonstrating a negative correlation between sheddase candidate expression and TGF-β signaling activity were studied further. To further validate these candidate sheddases, knockdown and overexpression cell lines were created and characterized. Overexpression of the most promising candidate reduced TGF-β mediated phenotypes such as migration and invasion, while knockdown of this candidate increased the same phenotypes. Knockdown also increased expression of TGF-β and EMT markers. Importantly, these effects of sheddase knockdown were neutralized in the presence of the TGF-β inhibitor galunisertib or when the cells were rescued with exposure to purified soluble TβRIII, indicating the effects are mediated through TβRIII shedding.

#6965 Characterizing the proteome landscape of extracellular vesicles from prostate cancer cell lines by mass spectrometry.

M. L. Ludwig, A. Day, H. E. Bergom, Z. Sychev, A. Horrmann, J. Hwang, J. M. Drake;
University of Minnesota Medical School, Minneapolis, MN

Multiple subtypes of prostate cancer can emerge in advanced stages of disease, such as tumors that maintain androgen receptor features (AR+), those without AR but with neuroendocrine features (AR-/NE+), and those without AR or NE features (AR-/NE-). These latter subtypes are particularly aggressive and incredibly lethal. Extracellular vesicles (EVs) are small particles that are mediators of cell-cell communication and have been nominated as potential biomarkers of disease state. We hypothesized that the proteome of EVs contains information about their originating cell that can distinguish between prostate cancer subtypes. To address this, we isolated EVs from cell lines of differing subtypes – AR+ (LNCaP, LNCaP95, C4-2, 22RV1), AR-/NE+(NCI-H660, EF1, LASCPC-01), and AR-/NE- (PC3, DU145) – and prepared the EV proteome for quantitative, label-free mass spectrometry analysis. This identified 2,000+ proteins in the EVs for each cell line where EVs from similar subtypes clustered together. Interestingly, we also found that EVs contained enough protein information to utilize developed gene signatures for AR or NE activity. EVs isolated from AR-/NE+ cells contained known NE signature proteins such as SYP, CHGA, and UCHL1. EVs from the AR+ cell lines displayed >50% AR activity driven by PSA and STEAP1 proteins in addition to other significant distinguishing protein markers. This supports the potential for using the proteome of tumor-derived EVs to identify novel signature molecular markers besides those already known to the field for developing liquid-based biomarker assays. In addition, our work characterizes the EV surfaceome which is critical for enriching signals from tumor-derived EVs feasible for clinical diagnostics assay development. While PSMA has been a reliable marker for cells reliant on AR signaling, less is known about protein markers in the AR- subset. Our work highlights TROP2 as especially enriched in the EVs from AR-/NE- cell lines, supporting its relevance as a target in patients without treatment options. To evaluate disease outcomes, further clinical studies are needed to develop specific and sensitive tests based on the EV proteome derived from advanced prostate cancer patients.

#6966 STAT3 integration of inflammatory signals and cellular stress promote tumor initiation and progression through the expression of integrin β3.

A. D. Campos, R. Shepard, I. Heumann, J. Lam, S. M. Weis, D. Cheresh;
UCSD Moores Cancer Center and Sanford Consortium for Regenerative Medicine, San Diego, CA

STAT3 represents an oncogene whose transcriptional regulation is known to drive tumor initiation, progression, and drug resistance. Although STAT3 can regulate many genes, it remains unclear which genes are critical for STAT3-mediated cancer progression. Here, we report that inflammatory cytokines and cellular stress induce STAT3 activation leading to tumor initiation and progression, which we show depends on its ability to drive transcription of the β3 integrin gene leading to αvβ3 expression. Specifically, CRISPR KO of either STAT3 or integrin β3 in pancreatic cancer cells, is sufficient to impede their tumor initiating capacity in mice, while ectopic STAT3 or β3 expression in STAT3 KO cells rescues their tumor initiation capacity. Mechanistically, STAT3 activation induces β3 expression based on its ability to engage enhancer regions that modulate β3 gene expression. These findings implicate integrin αvβ3 as a critical downstream effector of STAT3, thereby contributing to its role as a driver of tumor initiation and progression.

#6967 Role of CXCL7 in colon cancer cell proliferation.

H. Aldhowayan, J. F. Nipa, L. Jun, I. Odeniyi, P. L. Jones, R. Jeganathan, E. A. Lipke, M. W. Greene;
Auburn University, Auburn, AL

Chemokine (C-X-C motif) ligand 7 (CXCL7) - a protein product of the *pro platelet basic protein* (*PPBP*) gene - is a potential biomarker for colorectal cancer (CRC) diagnosis. However, its role in CRC progression is not known. Hence, we examined the role of CXCL7 in colon cancer cell proliferation through enhanced aerobic glycolysis. We first examined the effect of CXCL7 on cellular proliferation and glycolytic flux using human colon cancer (HT-29) cells transfected with CXCL7 or an empty vector as a control. Stable CXCL7- and vector-expressing cells were selected using hygromycin B. In addition, we treated HT-29 cells with CXCL7 obtained from the conditioned media (CM) from CXCL7-transfected HEK-293T cells or CM from vector-transfected (control) cells. CXCL7 expression was confirmed by analyzing *PPBP* expression using RT-qPCR, and CXCL7 level in the conditioned media was quantified by ELISA. The specificity of CXCL7 actions were examined using a CXCL7 neutralizing antibody (R&D Systems) and an antagonist (SB225002) to C-X-C motif chemokine receptor 2 (CXCR2). Cancer cell proliferation was assessed by measuring DNA synthesis (EdU incorporation). Glycolytic flux was monitored by measuring glucose uptake using a fluorescent derivative of 2-deoxyglucose (2-NBDG), Seahorse glycolysis stress test analysis, lactate accumulation in the cultured cell's media, and Western blotting for glycolytic enzyme protein expression. To further investigate CXCL7-mediated proliferation, we examined EdU incorporation and colony size in 3D engineered tissues and tumor xenograft growth in nude mice injected with CXCL7- and vector-expressing HT29 cells. The proliferation rate in CXCL7-expressing HT-29 cells and HT-29 cells treated with the CXCL7-CM were significantly higher (1.2-fold and 1.8-fold, respectively) compared to controls ($p<0.01$). Consistently, the proliferation rate in CXCL7-expressing HT-29 3D engineered tissues was significantly enhanced compared to vector-expressing tissues ($p<0.05$). Importantly, blocking the CXCL7/CXCR2 axis using a CXCL7 neutralizing antibody and a CXCR2 inhibitor abrogated CXCL7-stimulated proliferation. Lactate levels were two-fold higher in the culture media from both CXCL7-expressing HT-29 cells and HT-29 cells treated with CXCL7-CM compared to the controls ($p<0.05$). Glucose uptake was also greater in CXCL7-overexpressing cells and CXCL7-CM treated cells compared to vector controls. Data from Seahorse assay and Western blots confirmed that CXCL7-expressing HT-29 cells and HT-29 cells treated with CXCL7-CM have higher glycolytic capacity and increased glycolytic enzymes' protein expression compared to the controls, respectively. In *vivo*, CXCL7-expressing HT-29 xenograft tumor weight and PCNA protein levels were 100% and 60% greater, respectively, than vector-expressing tumors ($p<0.05$). Our study for the first time showed that CXCL7 stimulates colon cancer cell proliferation and enhances aerobic glycolysis.

#6968 Extracellular vesicles as carriers of signaling factors in cancer.

A. Schubert[1], N. Winkler[1], A. Mongkolsittisilp[2], M. Schulz[3], O. Voloshanenko[1], M. Schaffrinski[3], D. Kranz[1], K. Nienhaus[2], D. Jager[4], L. Trumper[3], J. Buntzel[3], C. Binder[3], G. Nienhaus[2], M. Boutros[1];

[1]DKFZ German Cancer Research Center, Heidelberg, Germany, [2]Karlsruhe Institute of Technology, Karlsruhe, Germany, [3]University Medical Center Gottingen, Gottingen, Germany, [4]National Center for Tumor Diseases (NCT), Heidelberg, Germany

Extracellular vesicles (EVs) are small, membrane-bound structures released by cells. They contain various biomolecules and have emerged as mediators of cellular signaling. EVs of various origins can be isolated from body fluids and hold potential as novel biomarkers. However, their clinical implementation as biomarkers is hampered by complex isolation procedures, limited expertise in routine labs, and a lack of mechanistic understanding of signal transfer, particularly *in vivo*.

To better understand how EVs carry oncogenic signaling factors, we performed mechanistic investigations into the role of EVs in WNT signaling as a representative cancer-associated signaling pathway, as well as *ex vivo* validation experiments analyzing patient-derived EVs.

Hydrophobic WNT ligands can use EVs to travel the extracellular space. However, little is known about the quantities of WNT secretion onto different EV fractions and potentially other vehicles. To explore WNT secretory routes and potential functional differences, we generated fluorescently tagged marker constructs of the non-canonical ligand WNT5a, which has context-dependent tumor-suppressing or -promoting functions in cancer. In additional *in vitro* experiments, we tested how the WNT signaling activation state and cancer-specific WNT mutations, such as CRISPR/Cas9-induced APC truncations, quantitatively and qualitatively affect EV shedding in colorectal cancer cell lines. Further functional testing of EV-bound vs. non-EV WNT ligands is ongoing.

For proof-of-concept analyses and to test EVs as biomarkers, we set up the liquid biopsy study *EValuate*. The project aims for cross-entity analysis of EV profiles and correlation of results to cancer presence, stage, and survival. For quality control and before pipeline implementation, we tested various EV isolation methods and compared different sample pre-processing steps.

By combining multidisciplinary expertise in biophysics, molecular biology, and basic and clinical cancer research, we aim to gain a better mechanistic understanding of EV-mediated signal transfer and facilitate the integration of EVs as diagnostic and prognostic biomarkers into clinical studies.

#6969 Determining the role of obesity in breast cancer progression.

A. Perlman, A. Piekny, E. Kuzmin, S. Santosa;
Concordia University, Montreal, QC, Canada

Breast cancer, especially triple negative breast cancer, impacts a large proportion of the female population. Approximately ten to fifteen percent of all breast cancer diagnoses will be triple negative. Triple negative breast cancer lacks receptors that are used as therapeutic targets for other forms of breast cancer and has the poorest prognosis. Notably, the age of onset has also decreased, which correlates with the rise in prevalence of obesity. In addition, past studies revealed that maintaining a high BMI from childhood correlates with higher cancer mortality in adulthood. However, the mechanisms by which obesity contributes to cancer progression are not clear. Adipose tissue from different locations (visceral vs. subcutaneous, abdominal vs. femoral) and from patients with obesity from childhood rather than as adults could have different molecular characteristics. Further, depending on the genetic background, different profiles may be more susceptible to environmental cues that could drive their progression. To address this, we are using conditioned media collected from tissues that reflect these differences and determining how they affect TNBC cell lines with distinct genetic profiles. Preliminary data revealed that adipose tissue from both the abdominal and femoral regions of high BMI individuals caused an increase in the proliferation rate of TNBC cell lines. To determine if the adipocytes vs. other cell types in the adipose tissue drive this growth, we are co-culturing mature adipocytes from these tissues with the TNBC cell lines. Recent studies by other groups showed that adipocyte-derived extracellular vesicles could drive the expression of EMT genes in cancer cells. We will purify EVs from the adipocytes and characterize differences in their molecular signatures for different patients to determine which factors cause the change in TNBC progression and correlate this with different fat depots and/or age of onset. We will also measure the effect of adipose tissue and/or adipocytes on other cancer hallmarks including metastasis (migration and invasion) and changes in metabolism. These studies should reveal how adipocytes confer changes in TNBC progression, and how to consider obesity in different treatment regimes.

#6970 identification of spatially enriched cancer cell- and immune cell-regulatory multi-marker-defined prognostic cancer associated fibroblast subsets of human colon cancer.

L. Huang[1], M. Herrera[1], J. Sjolund[2], V. Chocoloff[1], S. Joost[1], R. M. Tabiev[1], L. W. Leiss[1], C. Strell[3], L. Nunes[3], A. Mezheyeuski[3], D. Edler[1], A. Martling[1], F. Ponten[3], B. Glimelius[3], T. Sjoblom[3], M. Kasper[1], K. Pietras[2], A. Ostman[1];

[1]Karolinska Institutet, Stockholm, Sweden, [2]Lund University, Lund, Sweden, [3]Uppsala University, Uppsala, Sweden

Introduction: Subsets of cancer-associated fibroblasts (CAFs) in colorectal cancer remain poorly characterized preventing their use as biomarkers and drug targets.

Results: Integrated scRNA seq profiling and multiplex staining identified four human CAF subsets These were A1 (PDGFRA+/FAP-/TF), PDGFRA^{high}A2 (PDGFRA+/FAP+/TF-), PDGFRA^{low}A2 (PDGFRA-/FAP+/TF-) and A3 (PDGFRA+/FAP-/TF+) (TF: Tissue Factor).Spatial analyses identified spatial associations indicative of specific functional interactions of fibroblast subsets with cancer cells or immune cells. Explorative analyses in six CRC cases suggested, in general, favorable effects of FAP-negative subsets (A1 and A3) on immune features and cancer cell proliferation, whereas FAP-positive subsets PDGFRA^{high}A2 and PDGFRA^{low}A2 overall showed pro-tumoral associations. To extend findings, niches were quantitated in U-CAN cohort of approximately 200 stage I-IV cases with around 80% stage II/III. Spatial screening generated more than 1600 different multi-marker-defined tissue metrics. Analyses identified a higher average of A1 density in areas surrounding proliferating vs non-proliferating T-cells, and a higher average PDGFRA^{low}A2 peri-T-cell density in the low proliferating T-cell group. Regarding cancer cell proliferation, high proliferating cancer islands showed lower peri-epithelial density of A3 and PDGFRA^{low}A2 cells as compared to low proliferating cancer islands. As for T-cell cancer island infiltration, high peri-cancer island density of A1 and PDGFRA^{high}A2 was associated with high T-cell cancer island infiltration. Additional analyses related CAF metrics to stage and survival. Density of PDGFRA^{low} A2 cells increased with stage (I-III), whereas density of A1 showed an opposite pattern with an inverse association with stage (I-III). Regarding survival associations, these were in general stronger for metrics collected in peripheral regions of tumors. Among prognosis signals related to niches referred to above, it was noted that A1 density in peri-cancer regions was significantly associated with good prognosis. Interestingly, this association was not detected when A1 density was scored in total stroma. Among all metrics, the strongest metrics were A1 density in 20µm A1 expansion areas (good prognosis) and T-reg density in the 10µm A3 expansion areas (bad prognosis) ($P<0.001$; univariate Cox-regression); both in peripheral regions.

Conclusion: Four novel CRC CAF subsets, defined by PDGFRalpha, FAP and TF, was identified by integrated single cell RNA seq analyses and multiplex staining with associated digital image analyses. Non-random spatial distribution of these subsets and compartment-specific prognosis associations are compatible with distinct and different functions of these subsets.

#6971 The impact of lecithin retinol acyltransferase in squamous cell carcinoma: Tissue formation, cell mechanics, and gene transcription.

E. Peterson[1], K.-C. Feng[2], J. Gao[3], M. Rafailovich[2], M. Simon[3];

[1]Renaissance School of Medicine, Stony Brook University, Stony Brook, NY, [2]Department of Materials Science and Chemical Engineering, Stony Brook University, Stony Brook, NY, [3]Department of Oral Biology and Pathology, Stony Brook University, Stony Brook, NY

Squamous cell carcinoma, along with several other cancers, has been found to lack expression of lecithin retinol acyltransferase (LRAT), a protein which catalyzes retinol esterification and thereby mediates retinoic acid biosynthesis. When expression of LRAT was reintroduced in squamous cell carcinoma, the protein promoted cell differentiation in addition to retinoid status normalization—whether this effect was dependent on the known enzymatic activity of LRAT in retinol esterification, versus another function, has not yet been established. Cell elasticity differences have also been reported between squamous cell carcinoma and normal keratinocytes. In this study, the role of LRAT expression and activity was evaluated in human squamous cell carcinoma cell line SCC13. LRAT was integrated into the genome of SCC13 via retroviral transduction, both as wild-type LRAT and LRAT with a cysteine-to-serine mutation at the active site for retinol esterification (C161-S). In these transformed cell lines, LRAT promoted formation of a cohesive sheet of tissue which remained intact after its removal from the tissue culture plastic surface, as evaluated at two weeks post-confluence. SCC13 alone produced tissue which easily fragmented during this scraping assay. In an evaluation of cell elasticity with shear modulation force microscopy, relative cell modulus measurements of pre-confluent SCC13 with LRAT expression were found to be significantly greater and consistent with the cell modulus of human keratinocytes (DO33). These effects persisted with mutation of the retinol esterification active site, suggesting that LRAT possesses an additional function which has yet to be described. Variation in transcription levels of multiple genes—urokinase-type plasminogen activator, plasminogen activator inhibitor 1, tissue inhibitor of metalloproteinases 1, and kallikrein 5—was also found based on LRAT expression and level of confluence. These findings suggest that the presence of LRAT influences tissue formation, cell elasticity, and gene transcription in SCC13.

#6972 Programmed death-ligand 1 (PD-L1) upregulates c-MET phosphorylation via protein tyrosine phosphatase and contributes to the development of *MET* amplification in epidermal growth factor receptor (EGFR) mutant non-small cell lung cancer.

Derek De-Rui Huang[1], Chia-Chi Hsu[2], Wei-Hsun Hsu[3], Bin-Chi Liao[1], James Chih-Hsin Yang[1]

[1]Department of Medical Oncology, National Taiwan University Cancer Center (NTUCC), Taipei City, Taiwan, [2]Department of Medical Education and Research, National Taiwan University Cancer Center (NTUCC), Taipei City, Taiwan, [3]Department of Oncology, National Taiwan University Hospital, Taipei City, Taiwan

High expression of programmed death-ligand 1(PD-L1) is associated with poor survival outcomes in epidermal growth factor receptor (EGFR) mutation non-small cell lung cancer (NSCLC) patients receiving EGFR tyrosine kinase inhibitors (EGFR-TKIs). In this study we aimed to determine how increased PD-L1 affects the signal transduction of EGFR-mutant NSCLC cells. We first established PD-L1 overexpression EGFR mutant NSCLC cells, and discovered that PD-L1 overexpression cells had upregulated c-MET phosphorylation compared with parental cells using receptor tyrosine kinase array study. Subsequently, we demonstrated that knocking out PD-L1 (CD 274) in EGFR mutant NSCLC cells resulted in down-regulation of c-MET phosphorylation. Since protein tyrosine phosphatases (PTP) are known key regulators for c-MET phosphorylation and dephosphorylation, the activity of PTP was assessed. In PD-L1 overexpression EGFR mutant NSCLC cells, the PTP activity was decreased, whereas in PD-L1 knock-out cells, the PTP activity was increased. Additionally, the downregulation of c-MET phosphorylation in PD-L1 knock-out cells could be restored by adding PTP inhibitor (Na_3VO_4). The gene expression analysis showed that PTP expression was down-regulated in PD-L1 overexpression cells, indicating that PD-L1 upregulates c-MET phosphorylation by reducing PTP expression. We further established xenograft animal models using NSCLC cells with strong baseline c-MET phosphorylation to determine the effect of c-MET phosphorylation on osimertinib (a 3rd-generation EGFR-TKI) treatment. We found that tumor cells with strong c-MET phosphorylation were prone to develop MET amplification as acquired resistance under osimertinib, which could be overcome with combination of osimertinib and tepotinib, a c-MET inhibitor. Taken together, our results expand our understanding of PD-L1's role beyond an immune checkpoint in EGFR mutant NSCLC. PD-L1-regulated *MET* alterations could be a crucial mechanism leading to poor treatment outcome of EGFR-TKIs in PD-L1 overexpression EGFR mutant NSCLC.

#6973 Investigates the role of exosomes in dasatinib treated HT29 colon cancer cells.

Hui Min Koo, Yi-Wen Lu, Xiang-Ling Hou, Wei-Ting Chao

Tunghai University, Taichung City, Taiwan

The mortality rate due to metastasis in cancer is as high as 90%. The underlying mechanisms have been studied, however, the process of metastasis is complicated, current therapies still cannot inhibit metastasis efficiently. In recent years, studies have mentioned that extracellular vesicles play an important role in cancer cell metastasis and tumor microenvironment. Extracellular vesicles can be divided into microvesicles, apoptotic bodies and exosomes, which can carry different substances into the tumor microenvironment. Especially exosomes, whose diameter is around 30-160nm, can carry DNA, RNA, miRNA, membrane proteins, lipids and other intracellular molecules into the cell through endocytosis for regulation. The process of metastasis and the drug resistance were also been demonstrated can be regulated by exosomes. At present, the physiological functions of exosomes are not clear. HT29 colon cancer cells previously discovered in our laboratory can have different responses to dasatinib treatment, and cells can be isolated to dasatinib selected cells(DSTS) and resistant cells(DSTR). In this study, the role of exosome upon dasatinib treatment in HT29 cell is investigated. In the experiment, exosomes from HT29, DSTS, and DSTR were isolated by ExoQuick-TC. Transmission electron microscope was used to observe the difference in exosome size. Exosomes from different cells were treated in HT29 cells, and differences at the protein and mRNA levels were observed using western blot and reverse transcription-polymerase chain reaction(RT-PCR). In my results, the diameter of exosomes in DSTS cells was smaller than that in DSTR and HT29 cells. The protein expression levels of Cavoelin-1 and Clathrin in HT29 were also increased in the treatment of exosome that from three types of cells. In addition, the DSTR derived-exosomes can induce the expression of pFAK and Clathrin mRNA in HT29 cells. The preliminary results suggest that DSTR derived-exosomes may affect cell migration. This study provides the clues that through understanding exosomes that secreted from different cells, cancer diagnosis and treatment can be conducted according to their characteristics, so as to reduce the possibility of cell metastasis precisely.

#6974 Spatial exosome analysis reveals the location heterogeneity of exosomal miRNAs in ovarian cancer patients.

A. Yokoi[1], K. Yoshida[1], Y. Yamamoto[2], T. Yasui[3], H. Kajiyama[1];

[1]Nagoya Univ. Graduate School of Medicine, Nagoya, Japan, [2]National Cancer Center Research Institute, Tokyo, Japan, [3]Tokyo Institute of Technology, Tokyo, Japan

Extracellular vesicles (EVs), including exosomes, are recognized as promising functional tools involved in cancer progression. Although evidence of the functions of EV in cancer biology has been accumulating, optimizing EV isolation is still a major challenge. In ovarian cancer, peritoneal dissemination is a crucial prognostic factor due to the lack of effective treatment, and EVs in malignant ascites play a key role for progression. In this study, we invented cellulose nanofiber (CNF) sheets which enable to capture EVs from approximately 10 μL of biofluids and enabled the analysis of the bioactive molecules included in the EVs (*Nature Communications* 2023). By attaching CNF sheets to moistened organs, the EVs in trace amounts of ascites were collected, which was sufficient to perform small RNA sequence analyses. In the ovarian cancer mouse model, CNF sheets enabled the detection of cancer-associated miRNAs from the very early phase when the mice did not have apparent ascites, and the EVs from different locations, such as pelvic walls or liver surfaces, had unique miRNA profiles. To confirm the utility of the CNF sheets in cancer patients, we directly collected the EVs on the organ surfaces by the EV attachment method during surgery under appropriate ethical institutional approval with individual consent. EVs were collected from the pelvic peritoneum, omentum, liver surface, or tumor surface, and the miRNA profiling demonstrated each location formed unique clusters. Notably, several tumor-suppressive miRNAs have been identified in liver surface EVs, such as miR-122-3p, and this is consistent with actual ovarian cancer cell progression, which tends to metastasize to the diaphragm rather than to the liver surface. In addition, the trajectory analysis revealed that the pattern of connection in each site was different between patients with localized and advanced disease. We identified ten miRNAs were high in tumors and in EVs from tumor rupture sites, and the level of each miRNA decreased with distance from the primary tumors. Among ten miRNAs, hsa-miR-200b-3p and hsa-miR-429 were confirmed as highly expressed in tumor tissues compared to adjacent normal tissues or benign tumors, and three miRNAs in serum, urine and saliva decreased post-surgery. In summary, spatial CNF sheet analyses in patient bodies identified location-based heterogeneity in EV-miRNA profiles, and the profiles reflected disease conditions. This new method could provide unveiled biological aspects of EVs, and suggest a clinical strategy contributing to cancer diagnosis, staging evaluation, and therapy planning.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Elucidating Mechanisms of Oncogenic Action
Poster Session

#1457 Decoding the molecular mechanisms related to mutations in the GNAQ/11 and BAP1 genes in ocular melanoma.

Aurelie Fuentes-Rodriguez[1], Andrew Mitchell[2], Joel Rousseau[3], Jacques P. Tremblay[4], Solange Landreville[1]

[1]Department of Ophthalmology, Faculty of Medicine, Universite Laval, Quebec, QC, Canada,[2]Regenerative Medicine Axis, CHU de Quebec, Universite Laval, Quebec, QC, Canada,[3]Department of Molecular Medicine, Faculty of Medicine, Universite Laval, Quebec, QC, Canada,[4]Neuroscience Axis, CHU de Quebec, Universite Laval, Quebec, QC, Canada

Uveal melanoma (UM) is the most frequent intraocular cancer in adults and 50% of patients develop liver metastases for which no treatment is effective. According to *The Cancer Genome Atlas*, 92% of cases are characterized by early mutations in two genes coding for alpha subunits of G protein coupled receptors (GPCR): *G protein subunit alpha q* (*GNAQ*) or *11* (*GNA11*). These mutations are mostly found in the codon Q209 causing a constitutive activation of different signaling pathways linked to cellular proliferation such as MAPK and PKC. Furthermore, a bi-allelic inactivation of the *BRCA1 associated protein-1* (*BAP1*) is found in 83% of metastatic UM and causes a loss of function of this protein. Our hypothesis is that the inactivation of compensatory pathways in the absence of these proteins and the understanding of pathways essential only to mutated cells will pave the way for the identification of better therapeutic candidates specific to UM cancer cells (UMCCs) to prevent metastatic progression and improve treatment options. The research objectives include the identification of compensatory signaling pathways in the absence of *GNAQ/11* and *BAP1* using classical CRISPR/Cas9, the discovery of essential molecular mechanisms for the survival of mutated UMCCs using Prime Editing, and the identification and characterization of novel therapeutic targets using 3D *in vitro* and *in vivo* models. First, the electroporation optimization using an eGFP plasmid demonstrated an efficiency of 40-50% for normal choroidal melanocytes (NCM) and 60-80% for UMCCs Mel285. Subsequent transfection with CRISPR complexes resulted in an average editing efficiency of approximately 20% for *GNAQ/11* and 60% for *BAP1*. Currently, we have successfully established a *GNAQ* knockout (*GNAQ*-KO) Mel285 cell line. The characterization and validation of this cell line were performed through sequencing and Western blotting, confirming the creation of stop codons and the absence of *GNAQ* expression. We observed an overactivation of the ERK1/2 pathway and an upregulation of beta-catenin in the Mel285 *GNAQ*-KO line. Additionally, we noted a decrease in proliferation, adhesion, and migration on collagen I. For Prime editing, we constructed three plasmids with desired mutations. Preliminary tests in HEK293T cells showed an insertion efficiency of 4%, 20%, and 10% for *GNAQ*, *GNA11*, and *BAP1*, respectively, following a single treatment. Finally, *in vitro* testing has been started for inhibitors targeting compensatory pathways involving beta-catenin (WIKI4) and ERK1/2 (ASN007), in combination with the *GNAQ/11* inhibitor (FR900359). These tests are being conducted on various mutant UMCCs for *GNAQ/11*.A better understanding of the altered pathways in our *GNAQ/11* or *BAP1* mutant isogenic cell lines will help to identify new drugs targeting specifically UM cells.

#3020 The tumor suppressive role of methylthioadenosine phosphorylase in melanoma.

J. J. Hsiao[1], P. Andreu-Perez[1], L. V. Kemeny[2], M. Hejna[3], J. Nsengimana[4], J. Allouche[5], A. Al Emran[1], D. Bishop[6], G. B. Jonsson[7], J. Newton-Bishop[6], J. Song[3], D. E. Fisher[1];

[1]Harvard Medical School/Massachusetts General Hospital, Charlestown, MA, [2]Semmelweis University, Budapest, Hungary, [3]University of Illinois, Urbana, IL, [4]Newcastle University, Newcastle upon Tyne, United Kingdom, [5]INSERM U861, I-Stem, Association Francaise contre les Myopathies, Institute for Stem cell Therapy and Exploration of Monogenic diseases, Corbeil-Essonnes, France, [6]Institute of Medical Research, University of Leeds School of Medicine, Leeds, United Kingdom, [7]Lund University, Lund, Sweden

Methylthioadenosine phosphorylase (MTAP) is an enzyme that is expressed in virtually all tissues but lost in many cancers. MTAP deficiency can be due to either deletion of the MTAP gene or methylation of the MTAP promoter. In normal cells, MTAP catalyzes the conversion of methylthioadenosine (MTA), produced during polyamine biosynthesis, to adenine and 5-methylthioribose-1-phosphate, which is subsequently converted to methionine. MTAP deficiency results in intracellular accumulation of MTA. Although recent genome wide association studies (GWAS) have associated the MTAP locus with melanoma risk, the molecular mechanisms linking MTAP loss to increased tumorigenesis are not yet fully understood. In this study, we hypothesized that loss of MTAP and the resulting accumulation of MTA would dysregulate microphthalmia transcription factor (MITF), a master transcriptional regulator of melanocytes that is also an amplified or mutated oncogene in melanoma. We identify a novel signaling mechanism in which MTA accumulation from MTAP deficiency aberrantly induces MITF expression via inhibition of the cAMP phosphodiesterase PDE4D3 in melanocytes. Inhibition of PKA abolishes this MITF induction, suggesting that the PKA pathway is hyperactivated upon MTAP deficiency. Downregulation of MTAP leads to increased proliferation of melanoma cells *in vitro* and increased melanoma tumor growth *in vivo*. We also show that MTAP deficient melanoma cells are more resistant to the BRAF inhibitor vemurafenib and observe MTAP downregulation in BRAF inhibitor resistant melanoma clinical specimens. Furthermore, MTAP downregulation via decreased expression and/or genomic loss corresponds to significantly worse outcomes in early-stage cutaneous melanomas from multiple datasets, thereby identifying a clinically important sub-category of “thin-lethal” tumors.

#6977 ETV6 is an unexplored partner of the Chr.8 q24.3 amplicon-embedded immortalizing oncogene TONSL in tumorigenesis.

A. S. Khatpe, E. Doud, A. Mosely, K. D. Miller, H. Nakshatri;
Indiana University School of Medicine, Indianapolis, IN

Approximately 20% of breast cancers exhibit recurring genomic amplification involving chromosome 8q24.3. In our previous study, we identified the Tonsoku-like DNA repair protein (TONSL) within this amplicon as an immortalizing oncogene of breast epithelial cells, that can promote Estrogen Receptor-positive (ER+) breast adenocarcinomas when combined with other breast cancer-associated oncogenes. Our findings indicated that TONSL-amplified breast cancer cells are dependent on TONSL for tumor growth and exhibited deregulated homologous recombination and cell cycle pathways. High levels of TONSL in primary breast cancers, particularly ER+ breast cancers, were associated with poor outcomes. Although TONSL itself is not druggable, owing to its lack of enzymatic activity, molecules that disrupt the TONSL interactome can be developed. Towards this goal, we performed immunoprecipitation (IP) with TONSL antibody using protein lysates from TONSL-immortalized primary breast epithelial cells and subjected the immunoprecipitates to mass spectrometry. We identified several proteins selectively enriched with the TONSL antibody, the most significant of which was ETS variant transcription factor 6 (ETV6). ETV6 is a modular protein consisting of a C-terminal DNA-binding ETS domain and N-terminal point (PNT) domain and is known to play a role as a transcriptional repressor during embryonic development and hematopoiesis. We confirmed these data by IP followed by western blot analysis of primary breast epithelial cells and TONSL amplified MDA-MB-436. Furthermore, we utilized ClusPro to model the TONSL-ETV6 interaction and predicted that the TONSL's ankyrin repeats docks onto ETV6's PNT in a favorable manner. To investigate the functional significance of this interaction, we evaluated ETV6-regulated genes using RNA-seq. Our analysis revealed that ETV6-regulated genes were downregulated following TONSL knockdown and vice versa. Most ETV6 target genes affected upon TONSL manipulation are involved in Epithelial-Mesenchymal Transition (EMT), particularly TWIST1, SNAI2 and ZEB1. Previous studies have demonstrated a role of ETV6 in limiting EMT by repressing the expression of EMT-associated transcription factors. Our findings revealed that TONSL overexpression in primary breast epithelial cells led to a significant increase in these EMT gene expression, whereas TONSL knockdown in MDA-MB-436 cells resulted in a moderate decrease. These findings suggest that TONSL binds to ETV6 and restricts its ability to bind to the regulatory regions of EMT-associated genes, leading to a transcriptional surge of EMT-associated genes leading to tumor progression. Further studies will contribute to our understanding of the role of the chr.8q24.3 amplicon, specifically the TONSL gene, in initiating/promoting breast tumorigenesis and the development of novel drugs that target the TONSL interactome.

#6979 Uncovering the BRAF interactome to identify novel therapeutic targets for BRAF driven melanoma and lung cancer.

K. T. OToole;
Huntsman Cancer Institute, Salt Lake City, UT

BRAF protein kinases act downstream of RAS-GTP and upstream of MEK>ERK MAP Kinase signaling. Notably, mutational activation of BRAF is a driver of approximately 8% of all cancers, with a particular prevalence in lung cancer, thyroid cancer, and melanoma. Importantly, melanoma is responsible for the largest number of skin cancer deaths per year. Patients whose melanoma is driven by mutationally-activated BRAF account for ~50% of cutaneous melanoma cases. The most common mutational alteration is *BRAF*^{T1799A}, which encodes the BRAF^{V600E} oncoprotein kinase. Combined inhibition of BRAF^{V600E} plus MEK1/2 has been approved for the treatment of BRAF^{V600E}-driven melanoma and lung cancer. Although patients with mutationally-activated BRAF often have a significant response to BRAF^{V600E}-targeted therapeutics, many patients develop lethal drug-resistant disease. The BRAF^{V600E} oncoprotein kinase is proposed to be a monomer, yet many questions remain regarding the biochemistry of these signaling interactions. Thus, we aim to better understand the molecular mechanisms driving BRAF^{V600E}-mediated melanoma and lung cancer cell growth. Preliminary data using gel filtration chromatography and immunoblotting analysis indicates that BRAF^{V600E} is detected in a large multiprotein complex. Interestingly, the addition of a BRAF^{V600E} inhibitor, vemurafenib, shifted the elution of complexes with BRAF^{V600E} into lower molecular weight fractions. Based on these preliminary results, we characterized the components of these complexes to advance our understanding of how mutationally activated BRAF exists in melanoma cells; and thus, provide future insight into how we can better therapeutically target BRAF^{V600E}. Moreover, in order to further elucidate BRAF interactions, we employed a novel form of proximity labeling, TurboID, to unbiasedly identify novel BRAF interactors and better understand how drug treatments change the BRAF interactome. The top ten statistically significant interactors are being investigated to understand how BRAF complexes are formed within the cell, how the complexes are influenced by drug treatments, and how important the individual components are in the formation of complexes with BRAF. Here, we investigate an interaction between BRAF^{V600E} and the tumor suppressor, TP53. Moreover, elucidating the molecular architecture of BRAF^{V600E} signaling complexes could highlight new therapeutic options for patients who display either primary or acquired resistance to inhibitors of BRAF^{V600E} signaling.

#6980 GOLGA7 is essential for NRAS trafficking from the Golgi to the plasma membrane but not for its palmitoylation.

C. Liu[1], B. Jiao[1], P. Wang[1], B. Zhang[1], J. Gao[1], D. Li[1], X. Xie[1], Y. Yao[1], L. Yan[1], Z. Qin[2], P. Liu[1], **R. Ren**[1];

[1]Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Soochow University, Suzhou, China

RAS GTPases play a crucial role as oncogenic drivers in multiple cancer types. Targeting their localization to the plasma membrane (PM) is a promising strategy for cancer therapy, as RAS signaling requires PM localization. While KRAS traffics through a Golgi-independent route, palmitoylated RAS isoforms are transported to PM from the Golgi via a secretory pathway that is not yet fully understood. GOLGA7 is a Golgi-resident protein known as an accessory protein stabilizing the palmitoyltransferase ZDHHC9 for the palmitoylation of NRAS and HRAS. In this study, we found that among all four RAS isoforms, NRAS uniquely requires GOLGA7 for its association with the PM. Interestingly, the mislocalization of NRAS is achieved without detectable changes in its palmitoylation level in GOLGA7 deficient cells. We further observed that loss of GOLGA7 inhibit the anterograde trafficking of GFP-$NRAS^{G12D}$ proteins and result in the accumulation of NRAS in the cis compartment of the Golgi apparatus. Moreover, targeting GOLGA7 suppresses cell proliferation by downregulating RAS signaling in a variety of NRAS-mutant cancer cells. Finally, GOLGA7 depletion attenuated the oncogenic transformation induced by $NRAS^{G12D}$ in mice. These findings reveal a specific intracellular trafficking route mediated by GOLGA7 and have identified GOLGA7 as a potential therapeutic target for NRAS-driven cancers.

#6981 p38-mediated EZH2 phosphorylation at T367 regulates HER2 pathway in triple negative breast cancer.

M. E. Gonzalez, A. Eido, C. G. Kleer;
Rogel Cancer Center, Ann Arbor, MI

Background: Triple negative breast carcinomas (TNBC) are highly aggressive tumors with limited effective treatments. Clinical studies showed that targeting low HER2 levels in TNBC with anti-HER2 agents has survival benefit. Enhancer of Zeste Homolog 2 (EZH2) is a lysine methyltransferase component of the Polycomb Repressive Complex2 that regulates differentiation genes in normal and neoplastic cells. EZH2 phosphorylation at T416 was shown to maintain the TNBC phenotype. We have reported that p38-induced EZH2-T367 phosphorylation enhances metastasis and that high pEZH2-T367 expression is significantly associated with human TNBC tumors compared to other breast cancer subtypes. In this study we tested the hypothesis that pEZH2-T367 may regulate the HER2 pathway in TNBC and that inhibition of pEZH2-T367 may upregulate HER2 signaling, with clinical implications.

Methods: MDA-MB-231 (mesenchymal-like TNBC) and CCN6KO cells derived from MMTV-Cre;$Ccn6^{fl/fl}$ (CCN6KO) TNBC mouse model generated in our lab were transduced with vector or EZH2 shRNA knockdown (KD). MDA-MB-231 EZH2 KD cells were rescued with lentivirus containing EZH2-wild-type (WT) or T367A phosphorylation-deficient mutant. Gene and protein expression was analyzed by RNA sequencing, q-RT-PCR, immunoblot and immunohistochemistry. Vector and EZH2-KD rescue MDA-MB-231 cells were treated with anti-HER2 (trastuzumab or pertuzumab 100 ug/ml) followed by Hoestch proliferation assays. TNBC cells were treated with vehicle, EZH2 inhibitor (EPZ-6438, 20uM), p38 inhibitor (p38i, SB202190, 20uM), EPZ+p38i, anti-HER2 (100 ug/ml), and EPZ+p38i+anti-HER2, followed by Hoestch cell proliferation assays.

Results: EZH2-T367A deregulates the expression of a 94-gene network of HER2 pathway genes including EREG, SERPINB5, MERTK, IL6R, SOCS3, and FASCN1 compared to EZH2-WT. EZH2-T367A increased protein levels of HER2, EREG, and PP2AB, a major HER2 regulator and was sufficient to sensitize TNBC cells to the anti-proliferative effects of anti-HER2. Supporting the role of pEZH2-T367, we found that the combination of p38i and EPZ significantly sensitizes TNBC cells to anti-HER2 therapies.

Conclusions: We demonstrate that T367 phosphorylation mediates the effect of EZH2 on HER2 signaling in TNBC. Our data support a role for pEZH2-T367 in maintaining the HER2-negative phenotype in and suggest that blocking this phosphorylation event may render TNBC tumors amenable to anti-HER2 treatment strategies.

#6982 The roles of NDRG1 in HCC progression and its clinical significance.

J. Lu[1], L. Tian[1], Y.-M. Tsui[1], X. Wong[2], Q. Zhang[1], D.-H. Ho[1], I.-L. Ng[1];

[1]The University of Hong Kong, Pokfulam, Hong Kong, [2]China Medical University, Shenyang, China

Background: Hepatocellular carcinoma (HCC) is prevalent globally and the third leading cause of cancer-related mortality. N-myc downstream regulated 1 (NDRG1) was found to be tumor promoting in some cancers while suppressive in others. The expression of NDRG1 is induced by stress signals such as DNA damage and hypoxia. In HCC, it has been found to promote proliferation and metastasis. Contradictory results, however, were also suggested on the functions of NDRG1.

Methods: Our own HCC cohort and multiple publicly available databases were examined for NDRG1 expression and clinicopathologic correlation. NDRG1 expression under hypoxic conditions was investigated. Various functional assays were performed for NDRG1-knockdown HCC cell lines Huh-7 and PLC/PRF/5.

Results: With RT-qPCR analysis on our 102 pairs of patients' HCC tumor and corresponding non-tumorous liver samples, we found NDRG1 to be upregulated in HCC tumors. Similarly, RNA-sequencing analysis comparing 41 pairs of samples confirmed NDRG1 enrichment in HCC tumors. The upregulation was significantly and positively correlated with the absence of tumor encapsulation and cellular differentiation. These were further supported by TCGA and ICGC databases, in which upregulation of NDRG1 was significantly correlated with poor HCC patient overall survival. Interestingly, in the TCGA database, only 17% of the HCC cases were inferred to have copy number amplification of NDRG1 gene while NDRG1 mutations were rarely found. As hypoxia is a major tumor microenvironmental factor in HCC, we investigated NDRG1's expression level in HCC cells under hypoxic or normoxic conditions and found significant increase in NDRG1 expression under hypoxic environment. We further found that NDRG1 knockdown inhibited cell proliferation, self-renewal ability, and migration. RT-qPCR analysis found lower LGR5 and SOX2 expression upon NDRG1 knockdown. This is in line with the positive correlation between NDRG1 and various cancer stemness-related gene expression, including LGR5, CD24, MYC, SOX2, and NOTCH1, in TCGA database. Lastly, in the resected HCC tumors on which spatial transcriptomics using Visium 10X and single-cell RNA-sequencing using Chromium 10X were performed, we found NDRG1 enrichment in both tumors cells and cancer associated fibroblasts (CAFs).

Conclusion: NDRG1 was found to be significantly upregulated in HCC cells in our in-house cohort and publicly available databases. NDRG1 consistently promotes various oncogenic features of HCC cells, including proliferation, self-renewal ability, and migration. In addition, NDRG1 was found to be enriched in both the HCC cells and CAFs.

#6984 Investigating the function of the OSM-OSMR axis in pancreatic ductal adenocarcinoma (PDAC)..

Y. Sui, T. Hunter;
The Salk Institute For Biological Studies San Diego California, La Jolla, CA

Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal forms of cancer, characterized by a low survival rate and a significant global mortality impact. The interaction between PDAC and the immune system is complex and plays a crucial role in the progression of the disease. PDAC creates an immunosuppressive tumor microenvironment, which hampers the ability of immune cells to effectively infiltrate the tumor and mount an anti-cancer immune response. Additionally, there is an imbalance of cytokines, with an overabundance of immunosuppressive factors and a deficiency in pro-inflammatory cytokines. This hostile immunological landscape contributes to the aggressive nature of PDAC and hinders the success of immunotherapies and adjuvant treatments. One cytokine of particular interest is oncostatin M (OSM), a member of the interleukin-6 (IL-6) family. OSM has been implicated in the regulation of cancer and has been associated with poor overall survival in pancreatic cancer and other malignancies. Similar to other cytokines, OSM is secreted by immune cells and acts as a regulator of the inflammatory microenvironment surrounding the tumor. The levels of OSM in this milieu can potentially influence cancer development and regulation through multiple mechanisms. Despite the growing understanding of cytokines in cancer, research on the role of OSM in PDAC is still limited and requires further investigation to identify potential therapeutic targets. Therefore, there is a critical need to delve deeper into the functions of OSM and its receptor, oncostatin M receptor (OSMR), in the initiation and progression of pancreatic cancer. **As such, our goal is to examine the functions of OSM and its receptor (OSMR) in initiating and advancing pancreatic cancer to better comprehend the role of the OSM-OSMR axis in PDAC, both *in vivo* and *in vitro*.**

#6985 The oncogenic functions and action mechanism of UTP14A, a subunit required for 18S rRNA synthesis, in head and neck cancer.

L.-W. Wu[1], C.-N. Chang[1], P. K. Biswas[1], S.-T. Tsai[2];

[1]National Cheng Kung University, Tainan, Taiwan, [2]National Cheng Kung University Hospital, Tainan, Taiwan

Head and neck cancer (HNC) is the sixth common malignancy in the world and > 90% of HNC cases are squamous cell carcinoma in origin. Oral cancer is one major HNC subtype. Despite the recent advancements in cancer diagnostics and therapeutics, the 5-yr survival rate of advanced HNC patients remains <50%. Ribosomes are the cellular factories responsible for making proteins. The hyper-activation of ribosome biogenesis initiated by oncogene gain or tumor suppressor gene loss plays a critical role in cancer initiation and progression. Ribosome biogenesis is a complex and energy intensive process that involves hundreds of factors. UTP14A gene encodes a member of the uridine triphosphate 14 family and is an essential component of a large ribonucleoprotein complex bound to the U3 small nucleolar RNA. Previous studies have demonstrated that UTP14A plays a key role in the synthesis of ribosomes and 18S rRNA, and is overexpressed in several malignancies. However, the biological functions and underlying mechanisms of UTP14A in HNC remain elusive. We found not only the increase of UTP14A mRNA expression in TCGA-HNC database but also its negative impact on patient clinical outcome. UTP14A depletion significantly impaired HNC cell proliferation, migration and invasion in vitro. Ectopic overexpression had the opposite effect, suggesting an oncogenic role for UTP14A in HNC. Through gene set enrichment analysis of pairwise RNA sequencing results, several genes involved in the process of epithelial mesenchymal transition (EMT) were potentially associated with manipulated UTP14A expression. We also detected a concordant change of lipid droplet numbers and its surface marker expression in UTP14A-manipulated cells, respectively, by BODIPY staining and immunhistochemical staining. Western blot analysis validated a positive relationship of EMT markers and COX-2, a potential mediator of lipid metabolism and EMT, with altered UTP14A expression. The involvement of COX2 in UTP14A mediation was confirmed by using both pharmacological inhibition and genetic manipulation. We also identified p38 as a central downstream effector but acting upstream from COX-2 in UTP14A mediation in oral cancer cells. We believe that our study of UTP14A-mediated oncogenic signaling axis can potentially be harnessed as a novel therapeutic target against HNC although more mechanistic studies may be needed.

#6986 Oncogenic CARD11 enhances marginal zone B cell survival by potentiating the non-canonical NF-κB pathway.

A. Ghosh, J. Pomerantz;
Johns Hopkins University School of Medicine, Baltimore, MD

Dysregulation of antigen receptor-mediated signaling contributes to the oncogenesis of lymphoid malignancies. The activated B cell-like (ABC) subtype of Diffuse Large B cell Lymphoma (DLBCL) is characterized by receptor-independent constitutive activation of the canonical nuclear factor-kappaB (NF-κB) pathway, which is essential for the proliferation and survival of tumor cells. Caspase recruitment domain-containing protein 11 (CARD11) is a scaffolding protein that regulates B and T cell receptor signaling to canonical NF-κB activation downstream for adaptive immune response. Oncogenic gain-of-function (GOF) CARD11 mutations bypass normal pathway regulation and result in a hyperactive CARD11 that signals constitutively. Although present in ~10% of human ABC-DLBCL biopsies, we do not have a complete mechanistic understanding of how CARD11 GOF mutations drive abnormal B cell proliferation to cause lymphoma. We generated a mouse expressing the DLBCL-associated GOF mutation C49Y from the endogenous CARD11 locus. GOF CARD11 was sufficient to specifically drive B cell expansion in the mice with no significant effect on $CD4^{\pm}$ or $CD8^{\pm}$ T cells or NK cells. Quantification of splenic lymphocytes revealed that $CARD11^{C49Y/C49Y}$ mice had ~5-fold more splenic B cells when compared to $CARD11^{+/+}$ mice and ~13-fold more marginal zone (MZ) B cells. $CARD11^{C49Y/C49Y}$ MZ B cells proliferated and survived much better than $CARD11^{+/+}$ following stimulation with αIgM and importantly exhibited significant survivability prior to stimulation. Bulk mRNA sequencing revealed genes uniquely dysregulated in $CARD11^{C49Y/C49Y}$ MZ B cells including those associated with non-canonical NF-κB pathway signaling. $CARD11^{C49Y/C49Y}$ MZ B cells exhibited elevated levels of the p100 precursor NF-kB subunit leading to enhanced production of nuclear p52 following BAFF treatment. $CARD11^{C49Y/C49Y}$ MZ B cells also exhibited elevated levels of TRAF2, TRAF3 and cIAP1/2, components of a complex that degrades the NIK kinase that is responsible in normal cells for inducing p100 processing. Our results reveal an unexpected ability of CARD11 GOF mutants to potentiate the non-canonical NF-κB pathway through p100 accumulation, which likely contributes to the dysregulated B cell expansion observed in DLBCL cases that harbor CARD11 GOF variants.

#6988 TP53RK regulates DNA replication by CDC7-mediated MCM helicase phosphorylation in colorectal cancer.

Y. Choi[1], J.-w. Park[1], J.-k. Kang[1], E.-j. Kim[1], S.-H. Song[1], E. Yi[2], T.-Y. Kim[1];

[1]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of, [2]Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of

Background: We identify TP53 regulating kinase (TP53RK), which showed the highest cell growth inhibition efficiency in six colon cancer cell lines. TP53RK is overexpressed in various cancer types, including multiple myeloma and skin cancer, but the mechanism for its tumorigenesis in colon cancer is unknown. Therefore, this study aims to reveal the tumorigenesis mechanism of TP53RK, which is overexpressed in Colorectal Cancer (CRC), through global and phospho-proteomics.

Method: A total 5 CRC cell lines (HT29, SW480, HCT116, H508 and CaCO2), colon normal fibroblast CRL1459, HCT116 p53 null cell and patient-derived normal organoid were used. Immunoblotting, MTT assay, Colony formation assay, Annexin-V assay and cell cycle analysis were performed for evaluation of TP53RK loss-of-function. With kinase-substrate enrichment analysis with phospho-proteome analysis, MCM2 was found to be a substrate for the kinase regulated by TP53RK.

Results: High-throughput genetic screening approach have been widely applied to the study the gene function and molecular mechanism associated with tumorigenesis. By using genome-wide CRISPR/Cas9 library screening, we identify TP53RK, the first committed negative-selected gene, as a tyrosine kinase in the colorectal cancer(CRC) specific biomarker. Through proteome analysis, we found that depletion of TP53RK can hypo-phosphorylate the DNA helicase complex, MCM2 (minichromosome maintenance protein2). According to previous studies, the phosphorylation of MCM2 is regulated by CDC7 (cell division cycle7), and the abnormal states of CDC7 and MCM2 cause DNA replication disorder. Our results show that TP53RK expression is upregulated in CRC and its depletion results in decreased CDC7 expression and hypo-phosphorylation of the MCM complex. Decreased CDC7 expression due to its instability after TP53RK depletion can lead to DNA replication errors. DNA replication errors can lead cancer cells to apoptosis, suggesting that they may be a strategy for cancer treatment. In summary, we provide TP53RK as a novel prognostic and therapeutic target in CRC.

Conclusion: To recapitulate briefly, our findings suggest that the interaction of TP53RK with CDC7 can regulate CDC7 protein stability and stabilized CDC7 can phosphorylate MCM2 to initiate DNA replication. In other words, because overexpression of TP53RK acts as an oncogene that promotes tumor progression in CRC, depletion of TP53RK can degrade CDC7 and induce colon cancer cells to death or regression.

#6990 RHBDF1 is a potential modulator of EGFR activation and oncogenic biomarker in triple-negative breast cancer.

H. Kim, S. Park, D. Kim, C. Lee, M. Song, H. Ryu;
Seoul National University, Seoul, Korea, Republic of

Recently, our proteomics study on breast cancer (BC) reported a possible association of RHBDF1 with triple-negative breast cancer (TNBC). The overall survival of TNBC patients on METABRIC data set implicated that the RHBDF1 high-expression group has a shorter life expectancy than the RHBDF1 low-expression group. Although many TNBC patients have high expression levels of RHBDF1 and poor prognosis, the mechanism of RHBDF1 in the pathogenesis of TNBC remained unclear. Rhomboid 5 homolog 1 (RHBDF1) is a catalytically inactive pseudoprotease on the Golgi and endoplasmic reticulum membrane. Despite its inactive status of peptidase, it regulates the activity of ADAM17 protease that cleaves the extracellular portion of EGFR ligands such as TGF alpha and EGF. Eventually, RHBDF1 and ADAM17 complex activate the EGFR signaling pathway, thereby increasing cell proliferation, migration, and tumorigenesis. First of all, we recruited the clinical data of the overall survival (OS) and disease-free survival (DFS) in the hospital of Seoul National University (SNUH cohort, n= 203) and compared IHC score 0 or 1 with survival rate. To investigate the underlying biological mechanism of RHBDF1 in TNBC, the effect of knockdown or overexpression of RHBDF1 was observed in TNBC cell lines (MDA-MB-468, HCC1143 and BT20) using siRNA (small interfering RNA) and lentiviral systems. Cell proliferation assay was performed to clarify whether RHBDF1 affects cell growth. Then, we estimated the ability of migration, invasion, and sphere formation to confirm the characteristics of cancer cells including cancer stemness and metastasis. SNUH cohort with TNBC patients showed that the RHBDF1 high-expression group has a poorer disease-free survival (DFS) than the low-expression group ($p<0.05$). In vitro assay, RHBDF1 knockdown inhibited proliferation in MDA-MB-468 and HCC1143. RHBDF1 downregulation also decreased the ability of migration and invasion. We found that RHBDF1 activates specific cell growth signaling pathways and increases cell mobility in TNBC. The sphere formation assay was performed to measure cancer stemness characteristics. As a result, RHBDF1 knockdown TNBC cell lines couldn't form spheres relative to RHBDF1 overexpressed TNBC cell lines. In conclusion, we demonstrated that RHBDF1, a potential triple-negative breast cancer biomarker, is highly amplified in TNBC patients and TNBC cell lines. Its functions of accelerating cell proliferation, metastasis and cancer stemness were unveiled. But we need to study ultimately how RHBDF1 regulates ADAM17 activity at Golgi and endoplasmic reticulum membrane and which transcription factor activates RHBDF1 expression.

#6991 Transcriptomic profiling of human and mouse models highlights YAP pathway hyperactivation as the underlying mechanism of the biological and clinical aggressiveness of Numb-defective bladder cancer.

F. Tucci[1], R. Pennisi[1], M. Filippone[1], R. Bonfanti[1], F. Romeo[1], D. Rigiracciolo[1], S. Freddi[1], F. Sanguedolce[2], G. Renne[1], G. Pruneri[3], G. Vago[4], D. Tosoni[1], S. Pece[1];

[1]European Institute of Oncology IRCCS, Milan, Italy, [2]University of Foggia, Foggia, Italy, [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [4]University of Milan, Milan, Italy

In this study, we identify a previously uncharacterized role for the tumor suppressor, Numb, in bladder tumorigenesis, defining new predictive biomarkers and potentially actionable targets for the treatment of non-muscle-invasive bladder cancers. We conducted a comprehensive IHC analysis of Numb expression leveraging two retrospective longitudinal cohorts comprising 356 post-cystectomy muscle-invasive bladder cancer (MIBC) patients and 77 high-grade non-muscle-invasive (NMIBC) patients with transurethral resections. We found that Numb expression is frequently deregulated in the tumor compared to the adjacent normal urothelium, with Numb^{Low} status correlating with poorer prognosis both in MIBC, associated with advanced stage at diagnosis, vascular invasion, and worse overall survival, and in NMIBC, where a Numb^{Low} status associates with a higher rate of progression to life-threatening MIBC disease. In a transgenic mouse model with targeted deletion of the *Numb* gene in the basal layer of the bladder mucosa, we observed that loss of Numb *per se* is sufficient to drive malignant transformation of the normal urothelium and accelerates tumorigenesis in carcinogen-induced models. Integrative transcriptomic analysis of human and mouse Numb-deficient BC models revealed consistent dysregulation of the YAP1/TAZ1 inhibitory Hippo pathway, identifying YAP1 transcriptional hyperactivation as the most distinguishing trait downstream of NUMB loss. Through genetic and pharmacological functional inhibition studies in relevant mouse and human BC cell line-based models, we provide proof-of-evidence that interfering with YAP pathway activation at multiple upstream levels of the Hippo cascade reverts the aggressive Numb loss-associated tumor phenotypes, in particular growth and invasive/migratory potential, thereby highlighting the YAP pathway as a potential therapeutical vulnerability for the treatment of clinically aggressive Numb-deficient human BC. We also identified a gene signature of early BC depending on loss of Numb that we extensively validated for its potential as a predictor of NMIBC to MIBC progression, arguing for its clinical application as a biomarker for NIMBC patient stratification for targeted anti-YAP signaling treatment to prevent MIBC transition. In summary, our study identifies a previously uncharacterized role of Numb in bladder cancer progression, highlighting its potential as a predictive biomarker of NMIBC to MIBC transition and response to targeted therapies, thereby advancing a framework for precision oncology for NMIBC patients at high risk of progression to life-threatening MIBC disease.

#6992 Profilin 2 (PFN2) promotes the proliferation, migration, invasion and epithelial-to-mesenchymal transition of oral squamous cell carcinoma.

C. Liu[1], L.-H. Lin[1], K.-W. Chang[2], H.-W. Cheng[1];

[1]Mackay Memorial Hospital, Taipei, Taiwan, [2]National Yang Ming Chiao Tung University, Taipei, Taiwan

Background:Oral squamous cell carcinoma (OSCC) stands as a prevalent malignancy worldwide. Profilin 2 (PFN2), an actin-binding protein regulating actin polymerization dynamics and associated with cell motility, has recently gained attention as a significant regulator in various cancers. However, the clinical significance and biological function of PFN2 in OSCC remain debatable. This study aims to elucidate the role of PFN2 in OSCC.
Methods:We assessed PFN2 expression in OSCC and adjacent normal oral mucosa tissues through Q-RT-PCR and immunohistochemistry analysis. Associations between PFN2 expression, clinicopathological features, and OSCC prognosis were analyzed. Cell proliferation, invasion, and migration effects were examined via MTT and Transwell assays. Western blotting assessed the protein expression related to epithelial–mesenchymal transition (EMT). Additionally, we established OSCC xenografts to determine tumorigenicity in vivo using female Nude mice.
Results:PFN2 RNA and protein expression were significantly increased in OSCC compared to normal oral mucosa. PFN2 expression positively correlated with lymphovascular invasion and cervical lymph node metastasis. MTT and Transwell assays demonstrated that PFN2 promoted OSCC cell proliferation, migration, invasion, and endothelial invasion. Downregulation of PFN2 induced an EMT phenotype, including an increase in the expression of the epithelial marker E-cadherin and a decrease in the expression of mesenchymal markers Vimentin, Snail, and Slug in OSCC cells in vitro. Similarly, OSCC cells with reduced PFN2 expression exhibited weaker tumorigenicity in vivo.
Conclusions:Our findings unveil a novel role for PFN2 in promoting OSCC progression and metastasis, suggesting its potential as an early biomarker for high-risk populations. Targeting PFN2 may offer a promising therapeutic strategy for OSCC treatment.

#6993 SLC1A4 is associated with metabolic reprogramming in triple-negative breast cancer.

S. Park, D. Kim, H. Kim, M. Song, H. Ryu;
Seoul National University, Seoul, Korea, Republic of

The solute carrier protein (SLC) family is transporters as integral membrane proteins that transport solutes in an ATP-independent manner. The SLC1 family consists of five high-affinity glutamate transporters and two neutral amino acid transporters, among which SLC1A4 transports the neutral amino acids and is known to participate in various biological processes, including metabolism and tumorigenesis. However, the relationship between SLC1A4 and breast cancer remains unclear. Here, we aimed to verify the role of SLC1A4 in triple-negative breast cancer (TNBC). To reveal the characteristics of SLC1A4 in TNBC cell lines, five cell lines (HCC38/OE, HCC1395/OE, HCC1937/OE, MDA-MB-468/KD, and Hs578T/KD) that regulate gene expression of SLC1A4 were established using a lentiviral system. The two major energy-producing pathways, glycolysis and oxidative phosphorylation, were measured according to SLC1A4 gene expression. In addition, cell proliferation, cell migration, and cell invasion ability were confirmed upon overexpression or knock-down of SLC1A4. To confirm cancer stem cell function according to SLC1A4 gene expression, ALDH activity and sphere formation ability were evaluated. To ensure transcript changes due to SLC1A4 expression, RNA sequencing was performed. Anti-cancer drug (cisplatin, carboplatin, paclitaxel, and doxorubicin) sensitivity was also tested. The result showed that energy production efficiency was significantly reduced in cells where SLC1A4 expression was suppressed. In addition, in cells overexpressing the SLC1A4 gene, the presence of SLC1A4 was confirmed to increase cell proliferation, migration, and invasion ability significantly. Transcriptome analysis results showed notable changes in genes related to signaling receptor binding. Regarding material transport, to investigate whether there was a change in amino acid uptake ability according to SLC1A4 gene expression, no difference was observed. In the drug responses, doxorubicin showed a significant sensitive response in the absence of SLC1A4 gene expression. Taken together, SLC1A4 is a potential oncogene that not only induces rapid proliferation, aggressive invasion, and migration through metabolic reprogramming but also contributes to increasing cancer stem cell capabilities. In addition, it shows the sensitive response to ADR when SLC1A4 is low or absent, so it can be used as a treatment strategy for TNBC.

#6994 MerTK drives proliferation and metastasis activity in triple negative breast cancer.

C. Glitchev[1], M. Iida[1], B. E. Crossman[1], K. L. Kostecki[1], C. A. Kranjac[1], J. M. Adams[1], P. Liu[1], I. Ong[1], D. T. Yang[1], I. Kang[2], R. Salgia[2], D. L. Wheeler[1]; [1]University of Wisconsin-Madison, Madison, WI, [2]City of Hope, Monrovia, CA

Triple negative breast cancer (TNBC) is characterized by the absence of estrogen, progesterone, and HER2 receptors. It exhibits a higher level of aggressiveness compared to other types of breast cancer, with a greater likelihood of recurrence following standard treatments such as surgery, chemotherapy, and radiation. Despite limited FDA-approved targeted therapies for TNBC, there is an ongoing need for additional molecular targeting agents.Our investigation focused on the role of the receptor tyrosine kinase MerTK and its impact on proliferation and invasion/metastatic potential. Immunohistochemistry analysis revealed that approximately 86% (128/148) expressed varying levels of MerTK in human TNBC samples, whereas approximately 50% (23/47) of TNBC patient-derived xenografts (PDX) expressed MerTK. Additionally, three established TNBC cell lines (BT549, MDAMB231, and MDAMB436) exhibited elevated MerTK expression levels.To further explore the role of MerTK in TNBC, we stably overexpressed MerTK in human TNBC cell lines SUM102 and SUM159, which naturally have low MerTK levels. The results demonstrated that MerTK overexpression led to increases in proliferative potential, robust in vivo tumor growth, heightened migration/invasion potential, and increased lung metastasis. NanoString nCounter analysis of MerTK-overexpressing SUM102 cells (SUM102-MerTK) revealed upregulation of several signaling pathways, including PI3k-Akt, PDGF, and Myc, ultimately driving cell cycle progression, reducing apoptosis, and enhancing cell survival in TNBC.Further investigation using a cytokine array showed increased endoglin production in SUM102-MerTK cells compared to vector control cells. This suggested that MerTK might be creating a conducive environment for increased proliferative and metastatic activity via elevated endoglin expression in TNBC. To ascertain the role of endoglin in increase proliferation and/or invasion potential, we knocked out endoglin in SUM102-MerTK cells. While endoglin knockout SUM102-MerTK cells exhibited similar growth to SUM102-MerTK cells, the number of lung metastases was significantly impacted, indicating that MerTK regulates invasion and metastasis through endoglin in TNBC. Collectively, our data suggests that MerTK regulates a unique proliferative signature allowing for robust tumor growth and increased metastatic potential through endoglin regulation. This suggests that targeting MerTK and endoglin simultaneously may be a viable approach for TNBC patients.

#6995 Functional characterization of the novel cell adhesion molecule MPZL3 in ovarian cancer.

Y.-Y. Cheng[1], B. Worley[2], Z. Javed[2], A. T. Elhaw[2], P. W. Tang[2], N. Hempel[1];
[1]University of Pittsburgh, Pittsburgh, PA, [2]Pennsylvania State University, Hershey, PA

Ovarian cancer (OVCA) is the most lethal gynecological malignancy in the United States often detected at advanced stages. OVCA progression involves transcoelomic metastasis, where cells disseminate into the peritoneal fluid, adhere to form multicellular aggregates that promote anchorage-independent survival and facilitate metastatic colonization of the peritoneum. To meet the requirements of each stage of this detachment, aggregation, and re-attachment cycle, OVCA cells have been shown to dynamically regulate the expression of multiple cell adhesion molecules (CAMs) throughout their progression. Moreover, targeting cell-cell adhesion molecules has shown to be an effective method to slow/inhibit the progression of OVCA. In this study, we characterize the novel role of the understudied CAM MPZL3 in OVCA. Myelin protein zero-like 3 (MPZL3) is a transmembrane protein with homology to other immunoglobulin-like (Ig) family of CAMs. While it has been reported that altered Ig-CAM expression plays a role in ovarian cancer, the function of MPZL3 has not been investigated. Interestingly, TCGA data demonstrates that chromosomal loss of the *MPZL3* locus (11q23.3) is frequently detected in several cancer types, including 22% of clear cell and 30% of high grade serous ovarian cancers (HGSOC), implying that loss of genes located in this area has tumorigenic consequences. On the other hand, few studies showed that MPZL3 contains an oncogenic potential in breast and MET-amplified cancer cell lines, suggesting that the role of MPZL3 in cancer is context dependent. To study the function of MPZL3 in OVCA, we used shRNA mediated MPZL3 knockdown in OVCAR4 human HGSOC cells and examined transcriptome-wide effects by RNA-sequencing. The subsequent Gene Set Enrichment Analysis indicated that pathways involved in regulating cell growth, death, adhesion, and epithelial-mesenchymal transition were significantly altered by loss of MPZL3. To validate the candidate pathways, we knocked down or over-expressed MPZL3 in OVCA cells to test its importance in regulating OVCA cell growth, apoptosis, adhesion, and migration. We found that loss of MPZL3 resulted in decreased cell growth with a concomitant resistance to both Cisplatin and Olaparib treatments, both of which are commonly used for treating OVCA. Moreover, we show that knockdown of MPZL3 alters the homotypic adhesive-capacity of OVCA cells. Ongoing studies are underway to further characterize the role played by MPLZ3 in the mentioned contexts. Additionally, to elucidate the underlying molecular mechanism and identify novel interactors of MPZL3, we will conduct co-immunoprecipitation experiments in OVCA cells expressing V5-tagged MPZL3. Understanding the novel role of MPZL3 will provide further insight into OVCA progression, thus generating opportunities of developing new treatments for patients with low MPZL3 expression as an approach for precision cancer medicine.

#6996 A role for the cell adhesion molecule NCAM1 in regulating activity of the receptor tyrosine kinase RET in cancer.

M. H. Hussain[1], B. D. Hyndman[1], F. S. Vizeacoumar[2], M. J. F. Crupi[3], F. J. Vizeacoumar[2], L. M. Mulligan[1];
[1]Queen's University, Kingston, ON, Canada, [2]University of Saskatchewan, Saskatoon, SK, Canada, [3]University of Ottawa, Ottawa, ON, Canada

RET (REarranged during Transfection) is a receptor tyrosine kinase with essential roles in early development; however, genetic alterations lead to aberrant RET activity that contributes to oncogenic processes in several cancers. While some of the mechanisms by which RET mediates these processes are known, the network of proteins facilitating its activity remains largely undiscovered. To address this, we performed a genome-wide synthetic dosage lethal screen which identified NCAM1 (Neural Cell Adhesion Molecule 1) as one potential candidate modulating RET activity. Using an NCAM1 knockdown (KD) in SH-SY5Y neuroblastoma cells, we show that loss of NCAM1 reduces total protein levels of RET with no effect on *RET* transcription. Despite reduced abundance of RET, we show that the mature form of RET has a prolonged half-life in the absence of NCAM1**.** Assessing the functional outcomes of reduced RET protein levels, we observe reduced activation of RET by its extracellular ligand GDNF (Glial cell line-derived neurotrophic factor) and a subsequent reduction in activation of proliferative signaling pathways downstream of RET. As a result, RET-mediated proliferation is diminished in the absence of NCAM1, with reduced viability of NCAM1 KD SH-SY5Y observed in response to GDNF. Together, our data suggest that the synthetic lethal relationship between RET and NCAM1 may arise from a role for NCAM1 in regulating total RET protein available for activation, thereby reducing RET-mediated cell viability and proliferation. Our work has uncovered a role for NCAM1 in modulating RET activity in cancer and validates the use of our synthetic dosage lethal approach in uncovering proteins facilitating oncogenic RET activity.

#6997 Elucidating the tumorigenic properties of alveolar epithelial type 1 cells in EGFR-mediated LUAD tumorigenesis.

Aaron M. Neely[1], Andrea Lanz[2], William Dean Wallace[3], Anthony W. Kim[4], Zea Borok[5], Crystal N. Marconett[1]

[1]Translational Genomics, USC - University of Southern California, Los Angeles, CA,[2]Univeristy of California-Irvine, Irvine, CA,[3]Pathology, USC - University of Southern California, Los Angeles, CA,[4]Thoracic Surgery, USC - University of Southern California, Los Angeles, CA,[5]Medicine`, University of California San Diego, San Diego, CA

Originating from within the distal lung, lung adenocarcinoma (LUAD) is the most common pathologic subtype of non-small cell lung carcinoma (NSCLC) and encompasses an assortment of histologic presentations. Colocalized within the distal alveolar epithelium are two alveolar epithelial cell (AEC) subpopulations: alveolar epithelial type 1 (AT1) and alveolar epithelial type 2 (AT2) cells. We previously demonstrated that signatures unique to each AEC subpopulation were detected in LUAD tumors formed by oncogenic $KRAS^{G12D}$ activation in mice and were associated with disparate survival outcomes, transcriptomic patterning, and histologic presentation. Epithelial growth factor receptor (EGFR) mutations are among the most frequent oncogenic drivers in thoracic oncology. Therefore, we set out to determine if EGFR oncogenic activation resulted in differential LUAD presentation and outcomes based on the cell of origin in which it was activated. To activate EGFR oncogenic mutations in AT1 or AT2 cells, we employed triple transgenic mouse models (AT1: *Gramd2*-CreERT2:*EF1*-LSL-tTA:*TetO*-$EGFR^{del20/T790}$ and AT2: *Sftpc*-CreERT2:*EF1*-LSL-tTA:*TetO*-$EGFR^{del20/T790}$), which allowed for EGFR activation in either *Gramd2*$^{\pm}$ AT1 or *Sftpc*$^{\pm}$ AT2 cells. Longitudinal analysis of hematoxylin and eosin-stained lungs over the course of 20 weeks was performed. Blinded pathology review demonstrated that EGFR oncogenic activation in *Gramd2*$^{\pm}$ AT1 cells resulted in histologically defined LUAD with lepidic properties at early time points and solid adenocarcinoma properties at later time points. This differed from EGFR activation in *Sftpc*$^{\pm}$ AT2 cells, which resulted in pre-carcinogenic atypical adenomatous hyperplasia (AAH) formation that did not progress to adenocarcinoma. While preliminary, our results suggest that cell of origin strongly influences EGFR-mediated lung oncogenesis and concomitant pathology and histologic presentation. This work may advance our understanding while informing patient stratification and treatment strategies for LUAD patients.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Epigenetic Profiling and Technology
Poster Session

#7001 Profiling the CpG methylation patterns of Epstein-Barr virus DNA in lymphoma patients from Ethiopia.

Seifegebriel T. Feleke[1], Kidist Z. Shita[2], Abdulaziz A. Sherif[3], Fisihatsion T. Woldegebriel[3], Christoph Weigel[4], Elshafa H. Ahmed[4], Tamrat A. Zeleke[1], Robert A. Baiocchi[5]

[1]Microbiology, Immunology and Parasitology, Addis Ababa University, Addis Ababa, Ethiopia,[2]Ethiopian Public Health Inistitute, Addis Ababa, Ethiopia,[3]Addis Ababa University, Addis Ababa, Ethiopia,[4]The Ohio State University, Columbus, OH,[5]Internal Medicine, The Ohio State University, Columbus, OH

Introduction: Epstein-Barr virus (EBV) is a tumor virus associated with various malignancies, driven by genetic mutations and epigenetic alterations, including DNA methylation. Abnormal CpG methylation holds promise as a diagnostic and therapeutic biomarker for EBV-associated tumors. However, the understanding of EBV's epigenetic mechanisms remain limited. Determining the methylation profile of EBV is crucial for gaining insights into the pathogenesis of EBV-associated tumors, developing diagnostic biomarkers, and exploring potential therapeutic strategies. Therefore, our study aimed to assess the CpG methylation profile of EBV DNA in lymphoma patients from Ethiopia.
Methods: This study enrolled 115 lymphoma patients from Tikur Anbessa Specialized Hospital in Addis Ababa, Ethiopia. Plasma and formalin-fixed paraffin-embedded blocks were collected from the participants, and isolation of DNA was performed from these samples. The methylation analysis was performed using the methylation-iPLEX assay. iPLEX capture and extension primers were designed to amplify and target EBV CpGs from bisulfite-converted DNA sequences. Ethical approval was also obtained from respected institutions.
Results: Among the 115 participants, 65.2% (n = 75) were male patients. The largest proportion (n = 35, 30.4%) fell within the 41-60 age group. Non-Hodgkin lymphoma (NHL) was diagnosed in 96 patients, while 19 had Hodgkin lymphoma (HL). In the NHL group, the majority (n = 27, 28.1%) were classified as diffuse large cell lymphoma, followed by follicular lymphoma (n = 24, 25%). Out of the different EBV genome methylation sites, we have identified 24 EBV genes to assess the methylation status of the EBV genome. Average methylation levels of these genes were ranged from 45% to 50%. Notably, the HL group exhibited significant heterogeneity in methylation levels, while the CpG methylation status of EBV genes in NHL subtypes demonstrated a consistent pattern. A significant proportion of our samples exhibited methylation loss in the lytic gene BZLF1 and at the origin of replication associated with lytic replication.
Conclusions: This study presents the first data from East Africa, shedding light on the EBV DNA methylation status in a diverse group of lymphoma patients. Further investigations in different locations are necessary to elucidate the impact of EBV DNA methylation on tumor progression.

#7002 RNA m^{6}A modification and lung cancer risk: An epitranscriptome-wide association study.

Y. Yang[1], Y. Chen[2], Y. Qi[2], H. Liu[2], G. Jia[3], J. Ping[3], X.-O. Shu[3], W. Zheng[3], W. Li[2], J. Long[3], Q. Cai[3];
[1]University of Virginia, Charlottesville, VA, [2]West China Hospital, Sichuan University, Chengdu, China, [3]Vanderbilt University Medical Center, Nashville, TN

N^6-Methyladenosine (m^{6}A), the most prevalent epitranscriptomic modification in eukaryotic mRNA, determines the fate of target RNAs. Key m^{6}A regulators have been elucidated to be essential for lung cancer cell proliferation. However, the relationship between individual m^{6}A markers and lung cancer risk remains inadequately explored.

We conducted an epitranscriptome-wide association study (EpiTWAS) to investigate genetically predicted m^{6}A in association with lung cancer risk. Genetic and m^{6}A data of 30 lung, 12 heart, 28 muscle, and 50 brain tissues from 87 donors predominantly of European ancestry were obtained from Genotype-Tissue Expression (GTEx). For each m^{6}A marker, we built a single-tissue model via elastic net, focusing on lung tissue, and a cross-tissue model through the unified test for molecular signatures (UTMOST) approach, capturing genetic influences on m^{6}A shared by lung and other tissues. SPrediXcan was used to apply these models to data of genome-wide association studies (GWAS) among 38,422 lung cancer cases and 677,930 controls of European descent from International Lung Cancer Consortium (ILCCO), UK Biobank, and FinnGen. For m^{6}A markers significantly associated with lung cancer risk at false discovery rate (FDR) <0.05, we assessed the differential expression of proteins encoded by their target mRNAs in lung cancer versus adjacent normal tissues (200 pairs), using data from Clinical Proteomic Tumor Analysis Consortium (CPTAC).

Of the 38,841 high-quality m^{6}A markers in 11,715 genes analyzed, prediction models were built for 6,809 m^{6}A markers in 4,548 genes with performance of R>0.1 (*P*<0.05), ~85.2% (5,801) of which were single-tissue models. Among these, 28 m^{6}A markers in 26 genes were significantly associated with overall lung cancer risk (FDR<0.05). Notably, 12 (~43%) of these markers in 12 loci are >2 megabases away from any of GWAS-identified lung cancer risk variants. When conditioning on nearby GWAS signals, these 12 associations did not change materially, whereas 15 of the remaining 16 associations lost statistical significance. Analyses by lung cancer histology and smoking status revealed no significant heterogeneity among the 28 associations but identified eight additional m^{6}A markers significantly (FDR<0.05) associated with the risk of adenocarcinoma (n=2), squamous cell carcinoma (n=3), and overall lung cancer among ever- (n=2) or never-smokers (n=1). Of the 33 target RNAs of those 36 m^{6}A markers, 30 encode proteins and 22 of these proteins displayed a significant tumor-normal differential expression at fold change >1.5 and FDR<0.05 in CPTAC lung tissue data.

Our study demonstrates the ability of EpiTWAS to decipher GWAS loci and uncover signals potentially missed by GWAS. Our results imply that certain m^{6}A markers may impact lung cancer risk by modulating mRNA translation, underscoring the need for further research to fully unravel the role of m^{6}A in lung cancer etiology.

#7003 Microfluidic platform for DNA methylation profiling towards early detection of ovarian cancer.

C. O'Hersey, Y. Zhao, T. R. Pisanic, T.-L. Wang, I.-M. Shih, T.-H. J. Wang;
Johns Hopkins University, Baltimore, MD

We present a microfluidic platform for molecule-by-molecule detection of heterogeneous epigenetic patterns of rare tumor-derived DNA by highly parallelized digital melt. The platform digitizes DNA molecules in a 4-module, 40,000 1-nL array microfluidic device and observes sequence-dependent fluorescence changes during temperature ramping. The platform is applied to quantify DNA methylation heterogeneity of a biomarker panel within Pap specimens in a small cohort of healthy and ovarian cancer patients, and demonstrates an accuracy of 0.9. DNA hypermethylation of tumor-suppressor genes is an epigenetic phenomena that occurs early in tumorigenesis. Variable methylation patterns are observed in ovarian cancer precursor tissue, and trace amounts of ovarian-tumor-derived DNA can be found in Pap specimens, albeit at low frequencies (<0.01%). This suggests that methylation profiles of DNA extracted from routinely-obtained Pap specimens could contain early cancer biomarkers. However, due to the scarcity of these molecules, current techniques, such as sequencing and digital PCR (dPCR), have technical limitations precluding their ability to profile methylation patterns reliably. Sequencing, although comprehensive, has limited sensitivity, undermining its utility for routine detection of fractions below 0.1%. dPCR achieves high sensitivity, but is limited to known sequences, thus cannot provide comprehensive analysis of molecular heterogeneity.

To overcome these limitations, we developed a technique called digital high resolution melt (dHRM), a thermodynamics-based approach to detecting molecular variability by observing the sequence-specific release of a DNA-intercalating dye under a thermal ramp. dHRM can discriminate methylation patterns on CpG-by-CpG basis and detect methylated epialleles at frequencies as low as 0.00005%. Here, DNA from Pap specimens was loaded on a microfluidic chip that digitizes rare target molecules into individual reaction chambers. A thermal-optical platform was developed to perform parallelized dPCR and dHRM. Methylation patterns of a biomarker panel were analyzed to produce a probability score that the Pap specimen contained tumor-derived DNA. 12 healthy and 12 ovarian cancer Pap specimens were assessed for methylation heterogeneity of 9 genes. Optimal methylation density thresholds were determined, and data above each threshold was combined into a single score for each possible combination of biomarkers. In this small cohort, methylation heterogeneity analysis of just 2 loci produced an area under the receiver-operator characteristics curve (AUC) of 0.9.

This highly sensitive methylation profiling technology demonstrates promising utility towards early cancer detection. Future work aims to expand the testing cohort for ovarian cancer detection and permit further studies on the impact of methylation heterogeneity on early cancer development.

#7004 DNA Methylation analysis of African American colorectal cancers reveal race-specific alterations.

S. Rajpara[1], D. N. Buckley[1], R. Xicola[2], R. Mikaeel[2], M. K. Yagle[3], B. Kerimoglu[3], C. Thorne[3], D. A. Bellomo[3], M. Padi[3], X. Llor[2], N. Ellis[3], B. Salhia[1];
[1]Keck School of Medicine of USC, Los Angeles, CA, [2]Yale School of Medicine, New Haven, CT, [3]University of Arizona, Tucson, AZ

African Americans (AAs) have among the highest incidence and mortality rates of colorectal cancer (CRC) in the US. They present with more right-sided, microsatellite stable (MSS) tumors and are diagnosed at earlier ages than non-Hispanic Whites (NHW). While DNA methylation changes and their significance have been previously described in CRC, much less is known about the unique DNA methylation changes that occur in AA CRCs compared to NHW CRCs. In the current study, we analyzed DNA methylation changes in AA patients and compared those changes to data from NHWs. AA patients diagnosed with a MSS colorectal tumor at the Yale New Health System were included in the study. A pathologist reviewed archival slides, and selected areas from CRCs (n=160) and adjacent normal tissue (n=42) were cored (median age=59; 82 females, 78 males). DNA was bisulfite converted and analysis performed using EPIC arrays. The 450K methylation array from NHW CRCs was also analyzed for 217 CRCs and 20 normal tissues obtained from TCGA (median age=68; 103 females, 114 males). Differentially methylated regions (DMRs) with $|\Delta\beta|>0.1$, FDR corrected p-value <0.05 between tumor and normal tissue were identified using SeSAMe. We identified 4881 DMRs (57% hyper- and 44% hypomethylated) between AA CRC and normal tissue. Of these, 46% were in CpG Islands, 15% in CpG Shores, 4% in CpG shelves, and 36% in open sea. Most DMRs (71%) were in promoter regions, with 18% in gene bodies, 5% in enhancer regions, and 6% in intergenic regions. Next, we performed additional DMR analysis using overlapping probes from both arrays to compare NHW with AA data. We identified 2239 DMRs between AA CRC and normal tissue compared to 4138 in NHW. Of the 2239 AA DMRs, 1419 (66%) were common with NHW DMRs, 790 (34%) were unique to AAs. There were many overlapping pathways and genes; however, the DMRs impacting these pathways differed between AA and NHW CRCs. Hypermethylation of LCK, a tyrosine kinase involved in T-cell receptor signaling, was found in 60% of AA CRCs compared to 5.9% of NHW CRCs. LCK hypermethylation leads to CD4/8 T-cell inactivation and linked to poor outcomes in lung cancer. We observed AA-specific hypermethylation of SSTR1 in 57.2% of AA CRCs compared to 27.6% of NHW CRCs. Somatostasin (SST) suppresses tumor growth by regulating certain factors involved in cell proliferation. Hypermethylation of SSTR1 has been associated with various malignancies including gastric cancer. Lastly, promoter hypermethylation of 3 protocadherin genes was found in 65.1% of AAs compared to 33.1% NHWs. Protocadherins regulate WNT signaling and hypermethylation is associated with poor outcomes in multiple cancers. Taken together, these results show AA-specific CRC methylation changes compared with NHW CRCs. Further work is warranted to investigate the potential functional and clinical implications of these methylation alterations, some of which may represent therapeutic targets and biomarkers.

#7005 Distinct DNA methylation patterns between early-onset and average-onset colorectal cancer patients.

L. Su[1], P.-C. Hsu[2], A. Rathod[1], Y. Liu[1], J. Ferruzzi[3], S. Kazmi[1], E. Huang[1];
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]University of Arkansas for Medical Sciences, Little Rock, AR, [3]University of Texas at Dallas, Dallas, TX

Objective: Early onset colorectal cancer (EO CRC) is rising at an alarming rate. While average onset colorectal cancer (AO CRC) affects patients mostly above 65 years of age, EO CRC affects patients under 50 years of age, disproportionately affecting males from low-income communities and racial/ethnic minorities. Chronic inflammation has been identified as a strong contributor to pathogenesis. We hypothesize that methylation of DNA may serve as a potential mechanism associated with chronic inflammation that contributes to the etiology differentially between EO and AO CRC.
Methods: Formalin-fixed paraffin-embedded (FFPE) tissue specimens from four AO and EO CRC patients each were retrieved from the Tissue Repository. Paraffin curls containing tumor and adjacent normal tissues were generated from appropriate EO and AO CRC patient tissues. The Qiagen GeneRead DNA FFPE genomic DNA kit was then used to extract the DNA from the paraffin curls. Illumina Methylation EPIC v2.0 kit was used to evaluate DNA methylation (DNAm) patterns after the restoration process from deamination in the fixed/embedded sample using the Uracil-N-Glycosylase enzyme. Unreliable and non-specific probes were removed before statistical analysis for differentially methylated CpG sites. Age acceleration for each tissue was calculated by comparing the estimated DNAm age with chronological age using the Horvath approach.
Results: A clear clustering of DNAm patterns by age of onset were observed for both normal and tumor tissues. However, there was no difference when comparing tumor and normal tissues after multiple corrections. Four-way ANCOVA adjusting for race, gender, BMI, and tissue type suggested that age onset was the most significant factor. We also found that age acceleration in EO CRC tissue is greater than in AO CRC. After applying Bonferroni correction, significant differentially methylated regions (DMRs) were found in the promoter and the gene body of *SNTB1, NFATC3, SLC25A24, RABGAP1L, WDSUB1, WWOX, SELB, SLC28A3*, and *PPP6R2* in EO CRC patients when compared to AO CRC. *SNTB1* regulates colorectal cancer progression and stemness, while *NFATC3* has been associated with inflammation and cancer.
Conclusions: The preliminary results from this study showed a significant difference in the DNAm profile of FFPE samples between AO and EO CRC. The finding suggests that epigenetics may play a role in the etiology of CRC, potentially involved in the chronic inflammation pathway. The analysis of a larger patient number is underway to strengthen these findings.

#7006 Identification of endothelial-cell-specific DNA methylation alterations in breast cancer with deconvolution of the tumor microenvironment.

Barbara Karakyriakou, Ze Zhang, Irma Vlasac, Pauline Mochama, Lucas Salas, Brock Christensen

Geisel School of Medicine, Dartmouth College, Hanover, NH

The tumor microenvironment (TME) plays a pivotal role in cancer progression, with tumor endothelial cells (TECs) emerging as key orchestrators of angiogenesis and vascular remodeling. Tumor-associated vasculature can have increased permeability and irregular blood flow, impacting drug delivery and tumor immune response.

Understanding the molecular alterations within TECs may help identify targeted therapies and improve treatment outcomes with existing therapies. We combined TME cell-type deconvolution with modeling to identify cell-specific methylation alterations of TECs in breast cancer.

Genome-scale DNA methylation array data accessed in GEO and GTEx from preinvasive, mixed, and invasive breast cancer tissue (n=609) & normal breast tissue (n=230). We applied HiTIMED, a reference-based cell-type deconvolution algorithm, to estimate endothelial and other cell-type proportions in the TME. Next, we applied CellDMC, a statistical algorithm that identifies cell-specific driven differential methylation, to our cell fraction results, unraveling differentially methylated positions occurring in the endothelial compartment of the angiogenic component of our breast tissue DNA methylation profiles.

We identified 29 TEC driven differentially methylated positions (FDR ≤ 8e-03), including loci within genes in angiogenic pathways regulated by VEGF, endothelial inflammation and activation genes, and tumor-associated vasculature factors in the TME. Our findings suggest that variation in DNA methylation between TECs and normal endothelial cells is crucial to understanding the TME and providing insights into unknown cancer cell behaviors that contribute to tumor growth and metastasis, thus leading to the design of novel efficient therapies that target the malignant vascular component.

Our study demonstrates the power of combining cell-type deconvolution and a modeling framework that identifies cell-specific somatic alterations to unravel the intricate characteristics of TECs in breast cancer. Furthermore, this study highlights the potential of DNA methylation profiling as a robust tool for characterizing TEC heterogeneity and elucidating the molecular basis of angiogenesis beyond breast tissue in the context of diverse cancer types. Our integrative approach holds promise for advancing precision oncology, paving the way for effective and targeted therapies aimed at modulating the tumor vasculature to impede cancer progression in breast cancer and other cancer types.

#7007 5hmc-sequencing identifies candidate genes in Puerto Rican Hispanic/Latino men with aggressive prostate cancer.

M. S. Patel[1], M. Almubarak[1], J. Matta[2], C. Ortiz-Sanchez[2], J. Encarnacion[2], G. Ruiz-Deya[2], J. Dutil[2], J. Dhillon[1], K. Yamoah[1], A. Berglund[1], H. Park[1], L. Wang[1], J. Y. Park[1];

[1]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [2]Ponce Research Institute, Ponce Health Sciences University-School of Medicine, Ponce, Puerto Rico

Introduction: Puerto Rican (PR) Hispanic/Latino (H/L) men are an understudied population which has the highest prostate cancer (PCa) specific mortality when compared with other Hispanic populations. According to the recent PR Cancer Registry data, PCa is the leading cancer type in terms of incidence (38% of all cancer cases) and mortality (16% of all cancer deaths) in PR H/L men. PR H/L men also have significantly higher PCa-specific mortality than non-Hispanic Whites (NHW) and non-Hispanic Blacks (NHB). So far, little is known about higher mortality in PR H/L men. It is believed that epigenetic changes of key genes play a critical role in aggressive tumors. Therefore, our study was aimed to identify key 5-hydroxymethylcytosine (5hmC) changes in PR H/L men with aggressive PCa.

Methods: We prepared sequencing libraries using the enriched 5hmC DNA from 42 prostate tumor and 44 adjacent normal FFPE samples. We performed sequencing on an Illumina NextSeq 500 with 75bp single end. We used DESeq2 package to identify differentially methylated genes (DMGs). We also downloaded additional 5hmC data (Database: EGAS00001004942) of 51 localized PCa and 7 adjacent normal for confirmation analysis. We used Gleason score (GS) as a cut-off to identify DMGs in aggressive PCa patients (GS- 7 (3+4) or less, Non-aggressive; GS- 7 (4+3) and above, Aggressive).

Results: We identified 808 DMGs in tumors compared to adjacent normal tissues (FDR<0.05, log2FC>|0.4|). Pathway analysis of DMGs demonstrated that cell-cycle, cell division, and DNA repair related pathways were most upregulated in tumors. Since 5hmC abundance is highly correlated with gene expression levels, we further investigated 808 DMGs with TCGA prostate cancer gene expression data. This analysis identified 59/73 DMGs (80.1%, (FDR<0.05, delta>|1|) with significant 5hmC and gene expression changes in the same direction. We also performed differential methylation analysis in another dataset and observed that 129 DMGs were common with our results. Finally, we demonstrated 111 DMGs ($p<0.05$) in aggressive tumors (n=7) compared to non-aggressive tumors (n=15). These 111 DMGs include important 5hmC hypomethylated genes (*BCCIP* and *KLK10*) and hypermethylated genes (*COX6C, ARMC2, PVT1*) in aggressive PCa patients.

Conclusions: Our study identifies 59 genes having coordinated epigenetic and transcriptomic changes in PR H/L men and 111 DMGs in aggressive tumors. The coordinated 59 genes include tumor suppressor genes such as *DKK3* and *PRDM8* with downregulated 5hmC and gene expression levels. Also, previous studies reported downregulation of *BCCIP* and *KLK10* and upregulation of *COX6C, ARMC2, PVT1* expression in PCa. The coordinated changes in 5hmC could be critical in aggressive PCa biology, hence in future, these genes will be validated as candidate biomarkers and targets for aggressive PCa among PR H/L men.

#7008 NEBNext® E5hmC-seq™: Direct detection of 5-hydroxymethylcytosine at single base resolution.

G. M. Cammarata, D. J. Evanich, V. Ponnaluri, V. Panchapakesa, A. Erijman, M. A. Campbell, N. Dai, B. W. Langhorst, L. Williams;
New England Biolabs, Inc., Ipswich, MA

DNA methylation is a critical epigenetic regulator of gene expression during development and in diseases such as cancer. The modified cytosines, 5-methylcytosine (5mC) and 5-hydroxymethylcytosine (5hmC), can be detected by sequencing libraries generated using existing methods: NEBNext® EM-seq™ or bisulfite sequencing. However, these methods cannot differentiate between 5mC and 5hmC. Interest in the role of 5hmC in regulating gene expression and as a cancer biomarker has increased, resulting in the need for robust methods for the identification of specific 5hmC sites. Methods currently exist to enable discrimination of 5mC and 5hmC (for example, oxBS-seq and TAB-seq), however these are based on modifications of bisulfite sequencing, and suffer from reduced data quality due to fragmentation and loss of DNA. Here we describe an enzymatic method that enables specific detection of 5hmC, termed NEBNext® Enzymatic 5hmC-seq (E5hmC-seq™). E5hmC-seq libraries were generated for 0.1 ng to 200 ng DNA isolated from human brain and E14 mouse embryonic stem cells. Libraries were prepared using NEBNext® Ultra II™ reagents followed by two enzymatic steps to detect 5hmC. In the first step, 5hmCs are glucosylated, which protects them from subsequent deamination by APOBEC. In contrast, cytosines and 5mCs are deaminated resulting in their conversion to uracil and thymine, respectively. This conversion allows discrimination of 5hmC from cytosine and 5mC. Finally, libraries were PCR amplified using NEBNext® Q5U® and sequenced on the Illumina platform. The E5hmC-seq libraries have similar characteristics to EM-seq libraries, including expected insert sizes due to intact DNA molecules, low duplication rates and minimal GC bias. Moreover, E5hmC-seq libraries were well-correlated between inputs and replicates at higher sequencing depths. Fully hydroxymethylated T4147 phage DNA was used as an internal control, with 98-99% of cytosines identified as 5hmC. 5mC and 5hmC levels were also profiled during E14 cell differentiation for a period of 10 days. Interestingly, 5hmC levels decreased whereas 5mC levels increased particularly during the first five days of differentiation. LC-MS/MS quantification of this same DNA mirrored the changes observed by sequencing. E5hmC-seq libraries provide accurate measurements of 5hmC across a wide input range with expected insert sizes and minimal GC bias. Additionally, subtracting E5hmC-seq data from EM-seq data, which detects both 5mC and 5hmC, enables the precise location of individual 5mC and 5hmC sites. The ability to discriminate between 5mC and 5hmC will allow key insights to be made into the role of cytosine modifications in development and cancer.

#7009 Quantification of DNA methylation using methylation-sensitive restriction enzymes and digital PCR .

Y. Zhao, L. Cambria;
Roche Diagnostics, Wilmington, MA

DNA methylation is a common epigenetic modification, characterized by the presence of the signature 5-methylcytosine without altering the sequence of DNA. The study of DNA methylation in mammals has gained significant attention due to its broad impact on numerous biological processes and its critical role in the onset and progression of many diseases, such as cancer and aging. Consequently, there is a pressing need for a rapid and precise method to assess methylation status. Currently, most approaches for quantifying DNA methylation rely on sodium bisulfite treatment. However, such approaches do not align with the uracil DNA glycosylase PCR system. In this study, we demonstrate the application of methylation-sensitive restriction enzymes (MSRE) and digital PCR to determine the methylation status of the Ras association domain family 1 isoform A (*RASSF1A*) in cancer cell lines. Digital PCR enables the precise detection and absolute quantification without the reliance on reference standards. We developed a multiplex digital PCR assay that includes the target gene RASSF1A, along with two reference genes for the purpose of monitoring digestion completion and correcting DNA input. Each sample of interest was measured both before and after a MSRE digestion. To ensure the quantification accuracy, we employed the commercially available CpGenome human methylated DNA standard with a known concentration from MilliporeSigma, treating it with and without a MSRE, and subsequently performing digital PCR experiments using Roche Digital LightCycler® IVD system with a Universal nanowell plate featuring 28,000 partitions. The expected concentrations lay within the 95% confidence interval, affirming the accurate quantification achieved through digital PCR. Next, we measured the fraction of methylated alleles in various lung cancer and breast cancer cell lines, as well as in healthy human gDNA. The methylation of *RASSF1A* promoter in healthy human gDNA is ~0.7%, while a broad range of methylation levels was observed in cancer cell lines, ranging from ~0.7% to ~100.2%. Notably, the influence of GC bias was identified in this study. To overcome this critical challenge, we optimized the usage of several high GC enhancers. The results demonstrated that the concentration of 5-7.5% DMSO, 7.5% glycerol, and commercially available OneTaq or Q5 GC enhancers from New England Biolabs were effectively incorporated into the Roche digital PCR system, thereby enhancing the accuracy of quantification from 30% to 100%. Together, we demonstrated a remarkable approach for DNA methylation analysis using Roche digital PCR system in combination with MSREs and suitable high GC enhancers. This study suggests a promising rapid, accurate and cost-effective tool to advance research in the field. *Data on file at Roche Diagnostics, Wilmington, MA, USA

#7010 A pan-tissue investigation of epigenetic aging in association with genetic risk for cancer among European descendants.

Y. Chen[1], Y. Qi[1], G. Wang[1], Y. Xie[2], Y. Yang[3], W. Li[1];

[1]West China Hospital, Sichuan University, Cheng Du, China, [2]West China Hospital of Sichuan University, Cheng Du, China, [3]University of Virginia, Charlottesville, VA

Epigenetic age (EA) is recognized as a valuable biomarker of aging. The discrepancy between epigenetic and chronological age (CA), termed epigenetic age acceleration (EAA), has been associated with increased mortality from various age-related diseases, including cancer. However, previous studies primarily focused on the EA in blood cells, resulting in a notable gap in understanding the EA in cancer-relevant tissues and its relationship to cancer development.

To examine if genetic risks for seven distinct cancers are associated with EAA in cancer-relevant tissues and blood cells, we utilized Illumina EPIC-array-based DNA methylation data and whole genome sequencing (WGS)-derived genotype data of 659 normal tissue and 42 whole blood samples from 315 European-ancestry subjects in the Genotype-Tissue Expression (GTEx) project. EA was estimated across 30 female breast, 167 colon, 41 kidney, 163 lung, 118 ovary, 96 prostate, 44 testis, and 42 whole blood samples via seven established epigenetic clocks: HorvathAge, GrimAge, GrimAge2, HannumAge, PhenoAge, Zhang-BLUP-Age, and Zhang-EN-Age. EAA was calculated as the residual of EA regressed on CA. For each participant, a polygenic risk score (PRS) was computed to assess the genetic risk for each cancer, using validated cancer-specific PRSs for European populations from the Polygenic Score Catalogue. Linear regression analysis was performed to evaluate the association between cancer PRS and EAA, adjusting for body mass index, sex (where applicable), cigarette smoking, and WGS platform and library construction protocol.

All EA estimates of cancer-relevant tissues and blood cells exhibited significant correlations with CA (maximum $P=2.44\times10^{-3}$). Among them, GrimAge, known for its strong predictive capacity for mortality, had the most pronounced correlation with CA, with Spearman coefficients ranging from 0.80 in blood cells to 0.98 in breast tissues. A higher prostate cancer PRS was significantly associated with increased EAA in normal prostate tissues measured by PhenoAge (β=2.49; $P=0.01$), Zhang-BLUP-Age (β=1.71; $P=0.02$), HannumAge (β=1.36; $P=0.04$), and GrimAge (β=0.73; $P=0.04$). In addition, a higher PRS for renal cell carcinoma showed a significant association with increased GrimAge acceleration in normal kidney tissues (β=0.82; $P=0.02$). Moreover, breast and lung cancer PRSs were significantly associated with increased EAA in blood cells. Specifically, breast cancer PRS was associated with Zhang-BLUP-Age acceleration (β=0.99; $P=0.04$), while lung cancer PRS showed associations with HannumAge (β=1.78; $P=0.01$) and Zhang-EN-Age acceleration (β=0.94; $P=0.02$).

Our results suggest a potential connection between genetic susceptibility to certain cancers and accelerated aging in relevant tissues and/or blood cells before cancer onset. Future large-scale studies are needed to substantiate and expand upon our findings.

#7011 The DNA methylation landscape across the TCR loci genes in patients with acute myeloid leukemia.

M. Pospiech, J. Beckford, A. M. S. Kumar, M. Tamizharasan, J. Brito, G. Liang, S. Mangul, H. Alachkar;
USC - University of Southern California, Los Angeles, CA

The T-cell receptor (TCR) repertoire is partly shaped by epigenetic modifications, including DNA methylation. Hypomethylating agents like decitabine are used to treat patients with acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). The precise DNA methylation patterns within the TCR loci and their dynamics associated with HMAs treatments remain underexplored. Here, we analyzed methylation patterns across TCR alpha and beta gene loci in T cells from GSE175758 and GSE67170 datasets, comparing patterns between patients with AML and healthy controls. We also investigated the impact of decitabine on the methylation patterns of TCR gene loci in patients with AML and MDS (GSE175758 and GSE80762).The overall levels of methylation between T cells from healthy donors and patients with AML were significantly different within the *TRAV* (0.55 vs 0.42, P < 0.001) and *TRBV* regions (0.70 vs 0.59, P < 0.001) with 46 *TRAV* and 33 *TRBV* sites differentially methylated positions, respectively. However, methylation patterns in HSCs (GSE63409), T cells from healthy donors and patients with AML and those in AML cells were strongly correlated (R > 0.67, range 0.67-0.99, P < 0.001).Because decitabine preferentially acts on leukemic cells and given the high correlation levels between AML cells and T cells across datasets we analyzed the effects of decitabine on TCR DNA methylation patterns in AML cells. In the leukemic cells decitabine treatment led to significant demethylation across 33 and 30 CpG sites within the *TRAV* and *TRBV* genes, respectively. In the pre-treatment AML samples higher methylation beta values were observed in differentially methylated positions (DMPs) compared with non-DMPs (*TRAV*: 0.847 vs 0.407; P < 0.001; *TRBV*: 0.771 vs 0.538; P = 0.049). In samples largely enriched of myeloid leukemic blasts, we found that *TRAV* and *TRBV* loci methylation patterns differ significantly between AML patients with good, moderate, and poor risk patients (P < 0.001). We found TRBV6-1 position 1 and 2 methylation was lower in patients with good risk, compared with intermediate risk (pos1: 0.07 vs 0.13, P=0.04; pos2: 0.1 vs 0.2, P = 0.002) and poor risk (pos 1: 0.07 vs 0.21, P < 0.001; pos 2: 0.1 vs 0.32, P < 0.001) and was lower in patients with intermediate risk compared with poor risk (pos1: 0.13 vs 0.21, p=0.007; pos 2: 0.21 vs 0.32, P = 0.001). The high correlation of TCR DNA methylation patterns between the T cells and the myeloid cells, suggests the need for similar analyses in the context of AML T cells.
The study highlights the presence of a conserved TCR loci methylated signatures which is highly correlated between myeloid leukemic cells and T cells and is associated with clinical outcomes, offering a potential avenue for therapeutic intervention. Hypomethylating agents, such as decitabine, can modulate TCR loci methylation patterns.

#7012 Studying mosaic epimutations at scale.

O. Nikolaienko, P. E. Lonning, S. Knappskog;
K. G. Jebsen Center for Genome-Directed Cancer Therapy, University of Bergen, Bergen, Norway

Mosaic epimutations (i.e., epigenetic gene inactivation) within the *BRCA1* gene promoter occur in 5-8% of healthy individuals and are associated with a significantly elevated risk of breast and ovarian cancer. These epimutations arise prenatally and then serve as an underlying cause of cancer in adulthood, likely accounting for about 20% of triple-negative breast cancers. Similar mosaic epimutations have been detected in some other tumor suppressor genes as well, but the intraindividual and population frequencies of this phenomenon remain unknown. To address this gap, we have developed novel methodology for detection of mosaic epimutations. The experimental technique is a multiplexed, hybridization capture-based, targeted methylation sequencing assay covering gene regulatory areas. It allows cost-effective assessment of epimutations in established and emerging tumor suppressor genes. An accompanying tailored data analysis pipeline is designed to quantify epimutations. The pipeline is sensitive and robust to variance in methylation, sequencing errors and batch effects. We applied this method to a set of samples from healthy young males. Analysis uncovered significant interindividual epimutational heterogeneity and confirmed high sensitivity of the assay and its superiority compared to methylation profiling using microarrays. Here, we present details on the highly sensitive, scalable and robust methodology for analysis of mosaic epimutations together with the results on initial assessment of the prevalence of epimutations in healthy individuals. We anticipate that this method will become widely used for studies of epigenetic gene regulation and related cancer risk.

#7013 Methyl-Micro-C: simultaneous high-resolution characterization of three-dimensional chromatin structure and the DNA methylome.

C. Stevens, L. Gonzalez-Smith, H. Cao, S. K. Rhie;
Keck School of Medicine of USC, Los Angeles, CA

Understanding cancer biology allows for the determination of patient prognosis through biomarkers and predicting treatment sensitivity. For many cancer types, genetic changes have been largely characterized, but the contributions of epigenetic changes, which are also implicated in tumorigenesis, are not yet well understood. Three-dimensional chromatin architecture changes occur throughout tumor development, changing the states and interactions between cis-regulatory elements, overall inducing gene dysregulation. Chromatin structure changes have previously been interrogated using Hi-C, a technique which utilizes restriction enzyme-mediated digestion of chromatin. Although this method is useful, it cannot detect chromatin states of regulatory elements with high sensitivity and resolution due to the use of restriction enzymes that give multi-nucleosome-sized fragments. Micro-C instead uses MNase that preferentially digests accessible regulatory elements, resulting in mono, di, and tri-nucleosome fragments, providing higher-resolution chromatin interaction data, indirectly determining which regulatory elements are active and in proximity to one another. However, spatial proximity of genomic regions are only a piece of the chromatin structure epigenetic story. Partially methylated domains, which are gained or altered throughout tumor development, are reported to co-localize with topologically associating domains, suggesting that they can contribute to chromatin structure alterations. Whole methylome sequencing techniques can be used to determine methylation states of these domains and regulatory regions. Recently, enzyme-mediated methylation sequencing has been shown to induce less DNA damage than the canonical whole-genome bisulfite sequencing, providing a more accurate and comprehensive picture of the DNA methylome. Although DNA methylome data alone can provide information about epigenetic status within genomic regions, overlaying chromatin structure changes at these locations can further corroborate findings. In this way, chromatin structure and DNA methylome data together can provide a more complete picture of cancer epigenetics. However, it is very expensive to sequence at the depth necessary to gain useful information. To address this issue, we developed a technique called Methyl-Micro-C to simultaneously interrogate the DNA methylome while observing chromatin structure in the same sample. Methyl-Micro-C integrates the higher resolution Micro-C method and more comprehensive enzyme-mediated methylation sequencing method together to investigate both the chromatin interactions as well as DNA methylation patterns for the same sample simultaneously. Here, we use Methyl-Micro-C with prostate cancer cells to characterize 3D epigenomic mechanisms that drive prostate carcinogenesis.

#7014 Integrative DNA methylation cancer profiling reveals patterns associated with tumor progression and treatment response.

A. Lahtinen[1], G. Marchi[1], D. Afenteva[1], K. Lavikka[1], S. Holmstrom[1], E. Pollanen[1], G. Micoli[1], I. Maarala[1], Y. Li[1], T. A. Muranen[1], J. Oikkonen[1], S. Hietanen[2], A. Virtanen[3], J. Hynninen[2], A. Hakkinen[4], S. Hautaniemi[1];

[1]University of Helsinki, Helsinki, Finland, [2]University of Turku and Turku University Hospital, Turku, Finland, [3]University of Helsinki and HUS Diagnostic Center, Helsinki University Hospital, Helsinki, Finland, [4]Boston Children's Hospital, Harvard Medical School, Boston, MA

DNA methylation plays a critical role in tumor progression and response to chemotherapy. Frequently dysregulated during tumor development, it is closely intertwined with mixed effects from patient epigenetic background, tissue context, and treatment pressure. Here, we leveraged methylomic and transcriptomic profiling of 400 whole-genome sequencing samples from 125 patients with ovarian high-grade serous carcinoma (HGSC), belonging to the prospective, longitudinal, multi-region DECIDER trial (NCT04846933). This cohort included 120 samples from tubo-ovarian tumors, 209 samples from intra-abdominal metastases, and 71 ascites, representing all major sites of HGSC metastases. We profiled cancer methylome across tissues, patient groups, and various anticancer treatments using decomposition method, which allows separating the effects of tumor microenvironment and treatment, tissue, and patient specific changes, thus, facilitating integration of the heterogeneous collection of samples. First, we systematically examined the tissue-specific carcinogenesis and characterized methylomes of all types of metastases and excess fluid accumulations in the abdominal cavity. In our analyses, the cancer spread from tubo-ovarian sites to metastatic deposits involved gradual loss of DNA methylation and increase in transcriptomic levels, possibly indicating stemness. Specifically, several members of the ATP-binding-cassette (ABC) family of transporters, as well as receptor tyrosine kinases were frequently hypomethylated in bowel and omentum. The methylome of ascites showed most commonality to the tubo-ovarian tumors and peritoneum. Our results confirmed that several well-known tumor-associated genes, such as *PTEN*, *GSK3B*, *ESR1*, *FGFR2*, *TNC*, *BCL6*, *HIF1A*, *NOTCH2* are regulated epigenetically, and this dysregulation stems early from the sites of origin. Next, we built methylomic profiles of patients with various treatment responses. Direct comparisons between good and poor responders revealed pronounced methylation differences, with refractory disease being associated with severely aberrated methylome prior to chemotherapy treatment. Neoadujuvant chemotherapy resulted in very few changes to these epigenetic aberrations and no acquired mechanisms, suggesting that intrinsic methylomes of poor responders accommodate multiple drivers for EMT, hypoxia, and chronic inflammation to resist chemotherapy-induced cell death already prior to treatment. In conclusion, using a large whole-genome sequencing DNA methylation dataset we elucidated the major underlying epigenetic mechanisms of tumorigenesis and platinum resistance, which provide possible drug targets for improving platinum sensitivity. Our multi-omics analyses enabled the identification of aberrated patterns that drive transcriptional changes, shedding light on epigenetic landscape of HGSC.

#7015 Crosstalk between histone and DNA methylation in the development and progression of ALK+ ALCL.

C. Lobello[1], S. Wang[1], S. Rao[1], J. Pawlicki[2], N. Mansoor[1], J. L. Riley[2], R. Nejati[1], W. A. Mariusz[1];
[1]Fox Chase Cancer Center, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA

ALK-positive anaplastic large cell lymphoma (ALK+ ALCL) is a T-cell non-Hodgkin lymphoma characterized by the presence of the fusion oncogene nucleophosmin-anaplastic lymphoma kinase (NPM-ALK). Tumor cells control the expression of key genes in different manners: mutations, translocations or epigenetically. Our group have shown that in this tumor a plethora of genes are silenced by NPM-ALK through DNA methylation. However, recent evidence showed that some of the genes downregulated by DNA methylation might have already been silenced prior to the appearance of DNA methylation. Herein, we investigate the possible role of histone methylation in the silencing of genes and its relationship to DNA methylation. To better understand the possible players in the silencing of genes in ALK+ ALCL we used T-cell transformed with NPM-ALK and recorded over time the changing in gene expression, DNA methylation and histone marks. Using RNAseq comparing transformed cells at different time points, we noticed that downregulated genes in ALK+ ALCL became gradually silenced also in our system. Next, we investigated the DNA methylation (meDNA) on their promoters, and we confirmed a progressive increase of meDNA but clearly slower compared to the silencing of the genes, or if compared to the meDNA status of established ALK+ ALCL cell lines. Finally, we explored the presence of silencing histone marks on the promoter of the silenced genes using qPCR-ChIP. Among the repressive histone marks evaluated, H3K27me3 stood up as possible candidate for the gene silencing. Therefore, we look at the different gene expression changes after the inhibition of either meDNA, using a DNMT1 inhibitor (GSK3685032), or histone methylation, by EZH2 inhibitor (EPZ6438). RNAseq data showed the re-expression of downregulated genes after EZH2 and/or DNMT1 inhibition providing clear insights on their epigenetic regulation. The co-presence of H3K27me3 and meDNA on the promoters of those genes points towards a crosstalk between DNA and histone methylation machineries. Despite it is clear how NPM-ALK regulates DNA methylation, nothing is known about NPM-ALK and EZH2. To investigate their relationship, we treated ALK+ cells with ALK inhibitor, and we observed a decrease of EZH2 expression at protein and mRNA level. STAT3 inhibition, through napabucasin or by STAT3 silencing using Crispr-cas9 technology, resulted, likewise, in the downregulation of EZH2. Moreover, ChIPseq showed STAT3 presence on *EZH2* promoter, further confirming this mechanism. Altogether, those data showed that NPM-ALK regulates *EZH2* expression through STAT3. In conclusion, we provide, not only novel information on the mechanism in the downregulation of genes in ALK+ ALCL, but also new insight on the understanding of the epigenetics machinery and the crosstalk between histone and DNA methylation, for long time considered two mutually exclusive mechanisms, or even antagonist.

#7016 Plastic epigenome in youth: Insights from open chromatin in stem cells.

Y.-Y. Liu[1], C. Takeuchi[1], S. Yamashita[2], T. Ushijima[1];

[1]Hoshi University, School of Pharmacy and Pharmaceutical Sciences, Tokyo, Japan, [2]Maebashi Institute of Technology, Maebashi, Japan

The presence of plasticity in the epigenomes of young individuals is suggested by the aggressive phenotypes observed in cancers among adolescent and young adults (AYAs), including gastric cancers. To demonstrate the presence of this plasticity and identify the underlying epigenomic characteristics in gastric stem cells during youth, we examined organoids established from murine stomach tissue and conducted single-cell RNA-seq and ATAC-seq using murine antrum-pyloric tissues at ages of 3 weeks and 50 weeks, corresponding to human infancy and middle-age adult, respectively.

Organoids established from infant mice showed higher dependence to niche factors, and stronger response to cytokine signals. Ligand-receptor analysis using single-cell RNA-seq data of tissues showed that infant epithelial stem cells and stromal cells had stronger interactions. Both supported the plastic nature of infant gastric epithelial cells.

Single-cell ATAC-seq enabled us to identify epithelial stem cell population in infant and middle-aged mice, and 71 and 118 chromatin peaks were specific to infant and adult stem cells, respectively. Motif enrichment analysis showed an enrichment of binding sites for bZIP family transcription factors in infants, and an enrichment of binding sites of a chromatin remodeling factor and a family of transcription factors in adults. Additionally, comparison between differentiated epithelial cells, marked by the pit cell marker *Muc5ac*, and stem cells, marked by *Lgr5*, showed more pronounced differences: 46,772 peaks specific to pit cells and 39,076 peaks specific to stem cells. Interestingly, regions specific to pit cells were enriched in binding sites of the chromatin remodeling factor and the family of transcription factors, identical to the open regions specific to adult stem cells. This suggested that the chromatin accessibility profile of aged stem cells approaches to that of differentiated cells, leading to a loss of stemness. The single-cell RNA-seq data also revealed an increase in interactions between differentiated epithelial cells and fibroblasts in aged mice, as opposed to infant, suggesting the emergence of aberrant interactions in aged stomach tissue. Collectively, our data suggested that chromatin accessibility of gastric stem cells undergo an epigenomic shift during aging, approaching to the profiles of differentiated cells and losing their plasticity, and that a specific chromatin remodeling factor and a family of transcription factors could be involved in the process.

#7017 Increased epigenetic age acceleration in young adult and early onset colorectal cancer patients post-treatment: A ColoCare Pilot Study.

E. M. Siegel[1], J. K. Kresovich[1], A. M. Bloomer[1], A. Berglund[1], E. Jean-Baptiste[1], G. Trujillo[1], R. Carmella[1], J. Love[1], S. Felder[1], J. Ose[2], B. Gigic[3], C. I. Li[4], J. C. Figueiredo[5], A. T. Toriola[6], C. M. Ulrich[2], D. Shibata[7], L. B. Oswald[1];

[1]Moffitt Cancer Center, Tampa, FL, [2]Huntsman Cancer Institute, Salt Lake City, UT, [3]University Hospital Heidelberg, Heidelberg, Germany, [4]Fred Hutchinson Cancer Center, Seattle, WA, [5]Samuel Oschin Comprehensive Cancer Institute at Cedars-Sinai Medical Center, Los Angeles, CA, [6]Washington University School of Medicine, St. Louis, MO, [7]University of Tennessee Health Science Center, Memphis, TN

Introduction: Advanced biological age relative to chronological age has been observed in individuals with colorectal cancer (CRC), and there is growing evidence that cancer treatments can further accelerate biological aging. However, the influence of age at diagnosis on these relationships has yet to be examined in detail. This pilot study used data from the ColoCare Study to explore pre- and post-treatment differences in age acceleration by chronological age at CRC diagnosis.

Methods: The ColoCare Study is a prospective cohort study of newly-diagnosed CRC patients enrolled across seven U.S. and European sites. Participants in this pilot study were from the ColoCare site in Tampa, Florida who had available pre-treatment blood DNA. Young adult (YA, aged 18-39) and early onset (EO, aged 40-49) participants were matched with average onset (AO, aged 50-64) and late onset (LO, aged >64) participants on stage, sex, race and microsatellite instability status. Genome-wide DNA methylation profiles were assayed on buffy coat DNA using MethylationEPIC v2 BeadChips. PhenoAgeAccel and GrimAgeAccel were calculated on all samples to quantify the difference between DNA methylation-predicted biological age and chronological age (i.e., age acceleration). Linear regression models were used to estimate the associations of age at diagnosis and treatment with PhenoAgeAccel and GrimAgeAccel, adjusted for sex, race, and site (rectal, colon).

Results: The sample (n=60) included n=19 YA, n=15 EO, n=11 AO, and n=15 LO participants with pre-treatment blood DNA. Over half (n=15 YA/EO, n=20 AO/LO) had a paired post-treatment blood sample available. Half of participants were female and had colon tumors, and 76% were diagnosed with stage I-III disease. Pre-treatment, PhenoAgeAccel and GrimAgeAccel were similar across age groups (P > 0.05). In the subset of participants with pre- and post-treatment samples, age acceleration appeared to increase post-treatment (pre- and post-treatment differences, PhenoAgeAccel: 1.44, SD: 5.55, P= 0.13; GrimAgeAccel: 0.92, SD: 2.80, P= 0.06). Increases were largest among YA/EO participants. In adjusted models, the predicted differences in pre-to post-treatment PhenoAgeAccel were 2.89 (95% CI: -0.13, 5.90) in YA/EO and 0.36 (95% CI: -2.25, 2.96) in AO/LO (P-difference= 0.20). The predicted differences in GrimAgeAccel were 1.75 (95% CI: 0.25, 3.25) in YA/EO and 0.30 (95% CI: -1.00, 1.60) in AO/LO (P-difference= 0.15).

Conclusions: In this pilot study of CRC patients, pre-treatment age acceleration did not vary by age at diagnosis. Post-treatment, patients diagnosed at age 49 or younger had larger increases in age acceleration than patients diagnosed at age 50 or older. These findings warrant further investigation in larger samples and to determine if increases in post-treatment age acceleration as associated with patient outcomes and treatment response.

#7018 Application of HiTIMED and cell type adjusted epigenome-wide models identifies driver tumor DNA methylation alterations in multiple cancers.

I. M. Vlasac, Z. Zhang, L. A. Salas, B. C. Christensen;
Dartmouth Geisel School of Medicine, Lebanon, NH

DNA methylation (DNAm) is an epigenetic mark crucial in lineage specification and cellular differentiation, resulting in distinct patterns by cell type. These patterns can serve as biomarkers in deconvolution approaches inferring cell proportions from composite DNAm signals in biospecimens like blood and tumor tissue. Adjusting for cellular heterogeneity is critical to avoid confounding by cell type. The HiTIMED (hierarchical tumor immune microenvironment epigenetic deconvolution) algorithm provides high-resolution tumor microenvironment profiling, up to 17 cell types, including tumor, myeloid, and angiogenic compartments. We analyzed bladder, prostate, and uterine cancers, applying HiTIMED on the tumor (n=1,341) and normal adjacent tissue (n=105), adjusting for age, sex, and cell types. DNAm data from The Cancer Genome Atlas (TCGA) was used, and HiTIMED was applied to deconvolute various cell proportions.
Linear model comparisons to identify significantly differentiated loci with/without cell type adjustment are summarized in Table 1. We demonstrate greater than 99% reduction in both hypermethylated and hypomethylated loci in all cancer types after adjustment for cell type. Our study demonstrates HiTIMED's applicability to deconvolve the tumor microenvironment in multiple cancer types and demonstrates the importance of adjusting for cell type in epigenome-wide association studies to identify differentially methylated loci, offering greater biological insight into the etiology of specific cancer types.

Significant differentially methylated loci in tumor versus normal adjacent tissue, FDR <0.05			
Cancer type	Linear model	Hypermethylated in tumor (logFC >2.0)	Hypomethylated in tumor (logFC < -2.0)
Bladder cancer n = 21, normal adjacent tissue n = 413 tumor	Model 1 (Cancer Status, Age, Sex)	4495	19,936
	Model 2: (Cancer Status, Sex, age, six cell types)	27	39
Prostate adenocarcinoman = 50, normal adjacent tissuen = 499 tumor	Model 1 (Cancer Status, Age)	8988	2207
	Model 2: (Cancer Status, age, six cell types)	2	4
Uterine carcinoman = 34 normal adjacent tissuen = 429 tumor	Model 1 (Cancer Status, Age)	11,698	16,249
	Model 2: (Cancer Status, age, six cell types)	250	8245

#7019 Identifying cell free DNA methylation signatures in cerebrospinal fluids for the early detection of brain metastasis in non-small cell lung cancer.

T. Chen[1], B. T. Lau[1], X. Bai[1], M. H. Gephart[2], H. P. Ji[1];

[1]Stanford University School of Medicine, Stanford, CA, [2]Stanford University, Stanford, CA

Brain metastasis (BM) is major complication for adult cancer patients. Up to 2% of all cancer patients develop BM. Non-small cell lung cancer (NSCLC) contributes up to 55% of all BM. Approximately 15-20% of NSCLC patients show metastases at diagnosis, and approximately half will develop BM during their clinical course. Even after treatments like surgery, radiation and immunotherapy, the prognosis is dismal with median overall survival less than 13 months. No standard screening or early diagnostic testing exists for BM now. There is an urgent need to identify genomic features that predispose towards brain metastasis - these biomarkers could be used for early detection and disease monitoring. The cfDNA methylation and fragmentation patterns provide potential epigenetic biomarkers for detecting cancer. These patterns are specific to cell/tissue origin and cancer types. DNA methylation refers to a chemical modification of a specific carbon with an added methyl group in the cytosine. Hypomethylation in the gene body and hypermethylation in the promoter region lead to cancer development. We hypothesize that there are specific cfDNA methylation and fragmentation signatures in CSF that reflect the epigenetic states of BMs, and cancer predisposition for brain metastasis. We applied a novel single molecule sequencing approach to study CSF cfDNA methylation of BM from NSCLC. Our cohort consisted of ten patients with NSCLC-BM (samples N=14) and eleven healthy controls (N=11). Briefly, extracted cfDNA was obtained from CSF samples. Multiplexed sequencing libraries were prepared following an optimized protocol, and sequenced on PromethION flow cell for 72hr by Oxford nanopore technologies. Data were processed with the onboard base and methylation calling, followed by our bioinformatic pipelines for cfDNA size and methylation analysis. Distinct methylation patterns were found on significant CpG sites (fdr-corrected $p<0.01$) between cancer patients and controls, in both gene-body and promoter region. Biological pathway analysis showed enrichment in essential functions involving PI3K, ERBB2, TNF-α signaling ($p<0.03$), all of which play a role in NSCLC. Enriched mono-nucleosome levels ($p = 1.07e-03$) and differentiated mono-/tri- nucleosome ratios ($p = 1.34e-03$) were found in cancer vs. controls. Overall, our results suggest that a combination of cfDNA methylation and fragmentation can detect NSCLC-BM. This study will benefit BM patients with early detection and better prognosis, and extend our understanding in brain metastases in NSCLC.

#7020 Prognostic implications of microRNA 181a 2 3p expression in association with tumor budding in patients with stage III lung squamous cell carcinoma.

E. Lee[1], **S. Kim**[1], J. Kim[2], M. Lee[3], Y. Ko[4], S. Chun[4];
[1]Seoul St. Mary's Hospital, Seoul, Korea, Republic of, [2]Department of Hospital Pathology, College of Medicine, The Catholic University of Korea,, Seoul, Korea, Republic of, [3]Department of Life Science, Dongguk University-Seoul, Ilsandong-gu, Goyang-si, Korea, Republic of, [4]Division of Oncology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of

Introduction: Tumor budding (Bd) has been known as an independent prognostic factor in various malignancies. MicroRNA (miRNA) are known to play an important role in regulating Bd. However, understanding the relationship between Bd and miRNA in Lung Squamous cell carcinoma (LUSC) remains limited.
Methods: 115 LUSC patients who underwent curative resection were included in the discovery cohort. Bd was verified through immunohistochemical (IHC) stain. Bd was classified according to a three tier system: Bd1 with 0-4 buds, Bd2 with 5-9 buds, and Bd3 with 10 or more buds. MiRNA expression profiles were analyzed through RNA sequencing. Differences in survival outcomes for miRNA, as identified in the discovery cohort, were confirmed using LUSC data of The Cancer Genome Atlas (TCGA) as a validation cohort.
Results: The relationship between Bd2 and the prolongation of recurrence-free survival (RFS) was statistically significant (p=0.0113), whereas Bd1 was correlated with Overall Survival (OS) (p=0.0468). Multivariate analysis indicated that both a high T stage (HR: 5.211, 95% CI: 1.168-23.250, p = 0.031; and HR: 5.107, 95% CI: 1.447-18.030, p < 0.011) and Bd3 (HR: 3.683, 95% CI: 1.370-9.900, p = 0.010; and HR: 1.600, 95% CI: 0.800-3.201, p = 0.018) are independently significant poor prognostic factors for both RFS and OS. MiRNA-181a-2-3p was identified through Differentially Expressed miRNA (DER) analysis. A higher expression of miRNA-181a-2-3p in stage III LUSC of the TCGA dataset was associated with OS (p=0.0463).
Conclusions: Our study demonstrates that the miRNA 181a 2 3p expression is associated with improved OS. This association may be attributed to its inhibitory effect on Bd in advanced stages of LUSC.

#7021 Selecting your epigenomic assay: Comparing ChIP-seq, CUT&RUN, and CUT&Tag.

A. H. Guo, C. R. Comeau, F. Chen;
Cell Signaling Technology, Inc., Danvers, MA

For many years, chromatin immunoprecipitation (ChIP) was the standard assay for studying epigenetic mechanisms. However, two new versatile techniques have recently been developed that are faster, experimentally easier, and more cost-effective than ChIP. Cleavage Under Targets & Release Using Nuclease (CUT&RUN) and Cleavage Under Targets & Tagmentation (CUT&Tag) can be used for understanding protein-DNA interactions within the natural chromatin context of the cell. Both CUT&RUN and CUT&Tag can be combined with Next Generation Sequencing (NGS) to analyze the function of histone modifications and the binding of transcription factors, DNA replication factors, or DNA repair proteins across the genome.

CUT&RUN and CUT&Tag are rapid, robust, and true low cell number methods for the detection of protein-DNA interactions. Unlike ChIP, both assays are free of formaldehyde cross-linking, chromatin fragmentation, and immunoprecipitation. When compared to ChIP, CUT&RUN and CUT&Tag require fewer starting cells (as low as 5,000 – 20,000), are shorter assays (one day from cells to DNA), and generate lower background signal (requiring fewer sequencing reads). At Cell Signaling Technology (CST), we have developed ChIP-seq, CUT&RUN, and CUT&Tag assay kits and validated a broad set of antibodies against histone modifications, transcription factors, and cofactors that are compatible with these kits. This poster will discuss the fundamentals of all three assays and highlight important factors to consider when selecting an assay for your experiment.

Through our antibody validation efforts, we have also generated a unique and extensive archive of ChIP-seq, CUT&RUN, and CUT&Tag NGS data using recombinant, monoclonal antibodies. This allows for the controlled comparison of these three commonly used chromatin profiling techniques. In this poster, I will highlight the similarities and differences between these assays when mapping a variety of histone modifications, transcription factors, and cofactor binding events across multiple sample types.

#7022 Whole genome and reduced representation enzymatic methyl-seq enable cost effective methylomes.

V. Panchapakesa, C. Ponnaluri, D. Evanich, A. Erijman, B. Langhorst, L. Williams;
New England Biolabs, Inc., Ipswich, MA

DNA methylation is an epigenetic regulator of gene expression with important functions in development and diseases such as cancer. Traditionally, sodium bisulfite conversion was used to distinguish 5-methylcytosines (5mC) and 5-hydroxymethylcytosines (5hmC) from cytosines. However, this method damages DNA and introduces significant sequencing bias. NEBNext® Enzymatic Methyl-seq (EM-seq™) is an enzymatic conversion approach that minimizes DNA damage therefore enabling longer insert sizes, lower duplication rates and a more accurate quantification of methylation in DNA samples with inputs ranging from 10 ng to 200 ng. An improved enzymatic conversion method, EM-seq v2, has a more streamlined workflow and an expanded DNA input range of 100 pg to 200 ng. Libraries made using NA12878 genomic DNA show improved yields, consistent global methylation and an even GC bias representation. The increased library yields subsequently reduces sequencing duplications and costs. Sequencing costs are an important consideration when performing whole genome methylome analysis as this often needs high sequencing depth to attain meaningful coverage to accurately call methylation. Reduced representation libraries, a commonly used method to investigate DNA methylation, relies on enrichment of CpGs within libraries digested using MspI. These CpGs are commonly found in regulatory regions. Although lacking comprehensive CpG coverage, for many researchers this method provides enough cost effective CpG methylation coverage for their studies. Reduced Representation EM-seq libraries (RREM-seq) and Reduced Representation Bisulfite libraries (RRBS) were made using 200 ng to 100 pg of NA12878 DNA. EM-seq adaptors were ligated to MspI digested DNA followed by conversion using either EM-seq v2 or sodium bisulfite. Libraries were PCR amplified and sequenced on an Illumina NovaSeq platform. RREM-seq resulted in higher yields and reproducible results regardless of input amounts compared to RRBS libraries. RREM-seq libraries also identified a higher number of CpGs with even coverage facilitating accurate methylation calling. RREM-seq libraries have superior sequencing metrics resulting in robust methylation profiling. Focusing on a subset of the genome generates higher coverage DNA methylation data at a lower DNA sequencing cost.

#7023 Application of exclusive liquid repellency for low input CUT&Tag histone analyses in prostate cancer spheroids.

Z. J. Kauffman, K. Koesser, K. T. Helzer, J. M. Sperger, M. N. Sharifi, C. Li, E. Heninger, X. Hazelberg, C. Gilsdorf, S. G. Zhao, D. S. Juang, D. J. Beebe, J. M. Lang;
University of Wisconsin - Madison, Madison, WI

Introduction/Background: Epigenetic alterations, including histone modifications and DNA methylation, drive treatment resistance and lethal prostate cancer. However, epigenetic assays typically require thousands of cells and are difficult to scale for patient tumor biopsies. While identifying these alterations is possible in cell lines, these analytes are more difficult to follow in clinical settings. Patient-derived organoids have emerged as viable intermediaries to investigate the changing chromatin landscape during the progression toward treatment-emergent prostate cancer. This report seeks to adapt the Cleavage Under Targets and Tagmentation (CUT&Tag) assay for use on a microfluidic technology to eliminate cell loss associated with complex, multi-step epigenetic assays to facilitate analysis of low input prostate cancer spheroids.
Methods: The Oil Immersed Lossless Total Analysis System (OIL-TAS) is an exclusive liquid repellency (ELR) platform that passes magnetic bead-bound analytes through immiscible phases to separate and extract analytes of interest while eliminating traditional centrifugation and wash steps that lead to sample loss. This platform enables adaptation of complex molecular assays such as CUT&Tag for lossless sample manipulation. We focus on the analysis of histone modifications in rare cells utilizing antibodies for H3K27 acetylation and methylation. Comparison of LNCaP prostate cancer cell lines harvested from either 2D cell culture or 3D spheroids was performed to evaluate the sensitivity and specificity of this integrated assay.
Results: The macroscale CUT&Tag assay has been performed with inputs of 25,000 nuclei from LNCaP spheroids with greater yields than similar inputs from 2D LNCaP cell culture. Yield increases have also been seen when performing the assay with inputs <10,000 nuclei in microscale on the OIL-TAS relative to the macroscale. Utilizing the OIL-TAS platform with spheroid inputs will allow for more sensitive investigation of histone modifications.
Conclusions: Integration of 3D, humanized models of tumor growth into the CUT&Tag assay will enable discovery of differential epigenetic regulation within patient-derived organoids or complex co-culture studies. Establishing baseline epigenetic landscapes among these intermediary models will enable a new platform for drug testing. Utilization of the OIL-TAS platform will allow for miniaturization of the assay down to 1,000 cell inputs and enable multiparametric RNA-seq, EM-seq, and CUT&Tag-seq of the same patient samples for longitudinal study.

#7024 Development of quality control methods for reliable NGS measurement of methylation in cfDNA.

J. C. Willey[1], E. L. Crawford[1], D. J. Craig[1], T. M. Morrison[2], H.-J. He[3], J. G. Herman[4];
[1]University of Toledo, Toledo, OH, [2]Accugenomics, Inc., Wilmington, NC, [3]National Institute of Standards and Technology, Gaithersburg, MD, [4]University of Pittsburgh School of Medicine, Pittsburgh, PA

Background and Purpose: Reliable measurement of circulating free genomic DNA (cfDNA) methylation patterns promises a means for cancer early detection as well as treatment response. Use of Next Generation Sequencing (NGS) methods to measure the cfDNA methylome across a large number of potentially methylated CpG sites may enable earlier detection by overcoming stochastic sampling associated with the small specimens obtainable by a blood draw. Wide-spread adoption of these methods for clinical diagnostic applications will be facilitated through improved quality controls that increase reliability. The goal of this study is to assess the performance of the SNAQ-SEQ™ method as a means to establish a limit of detection (LOD) for measurement of methylation at each targeted CpG site. For this purpose, we used test materials that were developed by the National Institute for Standards and Technology (NIST) to mimic methylated cfDNA.

Methods: NIST test materials were formulated by physically shearing cell line gDNA then subjecting it to size separation to mimic a size distribution similar to that observed in cfDNA, then mixing sheared DNA in its “native” state of methylation with sheared DNA that was *in vitro* methylated. Non-sheared NIST test materials also were assessed in these studies. Synthetic spike-in internal standards (IS) were combined with NIST test materials and the combined samples were bisulfite converted, then subjected to PCR-amplicon library preparation. Libraries were sequenced on an Illumina MiSeq instrument and bioinformatic analysis was conducted using the Qiagen CLC Workbench.

Results and Conclusions: In initial testing of an off-the-shelf IS for a region of the SOX2 gene, average methylation (preserved C) across 14 targeted CpG sites was 16.4% (0.5%-50%) in the “native” NIST non-sheared sample. This was consistent with the 11.6% methylation across all of SOX2 measured by the NIST. In contrast, in IS corresponding to the targeted SOX2 region the average preserved C was 0.32% (0.03%-0.5%). Use of synthetic internal standards enabled determination of LOD for each individual methylated site, controlling for all known sources of technical error, including inefficient bisulfite conversion, nucleotide substitution error, and alignment error. Studies are now underway that use the NIST test materials to measure methylation at five targets known to be altered in cfDNA from lung cancer subjects, SOX2, CDO1, TAC1, SOX17, and HOXA7.

#7025 Advancing methylation analysis: TAPS v1.0: A fast, scalable, and non-destructive sequencing method.

A. Garnett[1], J. Haimes[1], C. Marshall[1], T. Sanders[1], S. Vogel[1], M. Ranik[1], E. Casas[1], D. Wendel[1], L. Karamanof[2], B. Faurholme[2], A. de Beer[2], L. French[2], R. Wadsworth[2], E. van der Walt[2], K. Giordia[1], B. Kudlow[1];

[1]Watchmaker Genomics, Inc., Boulder, CO, [2]Watchmaker Genomics, Inc., Cape Town, South Africa

In the pursuit of advancing multi-cancer early detection, the exploration of cell-free DNA (cfDNA) through methylation profiling has emerged as a promising avenue. However, the realization of its full potential is impeded by limitations inherent in conventional methodologies, notably the 'gold standard' bisulfite conversion methods. These approaches pose challenges such as DNA destruction and the generation of low-complexity sequences resulting from the conversion of unmethylated cytosines to thymine. TET Assisted Pyridine-Borane Sequencing (TAPS) holds the potential as a non-destructive, rapid, and scalable alternative for base-level methylation analysis.

In this context, we introduce TET Assisted Pyridine-Borane Sequencing version 1.0 (TAPS v1.0), showcasing advancements to the technology originally introduced by Schuster-Böckler, Song, and their collaborators. TAPS v1.0 transforms 5mC into dihydrouracil (DHU) through a series of oxidation and reduction reactions. Ultimately, DHU is recognized as dU during PCR resulting in C-to-T conversions at 5mC sites, leaving unmethylated cytosines, the majority of cytosines, unchanged. The nondestructive nature of 5mC conversion yields significantly higher library yield and complexity compared to BS-seq. By leveraging Watchmaker's proprietary polymerase evolution platform, a DNA polymerase tolerant to DHU was selected for library amplification post DHU conversion, enabling unimpeded detection of 5mC, particularly in densely packed CpG repeats. Coupled with an optimized End Repair and A-tailing chemistry preceding TAPS v1.0, clinically relevant cfDNA samples of low quality and/or quantity can be analyzed in methylation detection pipelines.

To evaluate the performance of TAPS v1.0, human genomic DNA with control spike-ins featuring varying methylation statuses were employed. TAPS v1.0 exhibited significantly higher final library yield and greater complexity compared to BS-seq. Similar outcomes were observed in clinically relevant cfDNA samples.

#7026 Multi-omic genomic mapping with long read sequencing.

B. J. Venters[1], P. W. Hook[2], V. S. Kumary[1], A. R. Hickman[1], J. T. Anderson[1], A. Vaidya[1], R. J. Ezell[1], J. M. Burg[1], Z.-W. Sun[1], M. W. Cowles[1], W. Timp[2], M.-C. Keogh[1];

[1]EpiCypher, Durham, NC, [2]Johns Hopkins University, Baltimore, MD

Gene transcription is regulated by the complex interplay between histone post-translational modifications (PTMs), chromatin associated proteins (CAPs), and DNA methylation (DNAme). Mapping their genomic locations and examining the relationships between these chromatin elements is a powerful approach to decipher mechanisms of disease, thereby enabling discovery of novel biomarkers and therapeutics. Leading epigenomic mapping technologies (*e.g.,* ChIP-seq, CUT&RUN) rely upon DNA fragmentation to isolate regions of interest for sequencing on short read platforms (*e.g.,* Illumina). This strategy leads to substantial loss of contextual information regarding the surrounding DNA, precluding the identification of multiple co-occurring epigenomic features on a single DNA molecule. By contrast, long-read sequencing (LRS) platforms are capable of sequencing very long reads from a single molecule (typically >10kb), allowing relationships between features on a single molecule to be used to resolve heterogeneity within mixed populations. Here we report a robust multi-omic method that leverages LRS to simultaneously profile histone PTMs (or CAPs), DNAme, and parental haplotype in a single assay. This nondestructive, epigenomic mapping approach leverages a novel DNA methyltransferase fusion protein (pAG-M.EcoGII) to label DNA underneath antibody-targeted chromatin features, thereby marking sites of interest while preserving DNA molecules intact for LRS. Inspired by our work with state-of-the-art immunotethering-based approaches (CUT&RUN / CUT&Tag), nuclei are bound to magnetic beads to streamline and automate sample processing. Next, adenosines nearby antibody-targeted chromatin features are methylated with pAG-M.EcoGII, which are then directly read from genomic DNA using Oxford Nanopore Technologies or Pacific Biosciences LRS platforms. To determine the capabilities and limitations of this assay, we tested multiple chromatin targets in various cell lines. Importantly, this method is highly reproducible across biological replicates, and highly concordant with orthogonal SRS assays (*e.g.,* CUT&RUN). Further, we showed that this method is a true multi-omic approach by simultaneously profiling histone PTMs, native DNAme (5mC), and parental single-nucleotide variants from single DNA molecules within a single reaction. Finally, this workflow preserves chromatin integrity for LRS, revealing heterogeneity (*e.g.,* haplotype or paternal origin) within / between data types and providing access to previously unmappable genomic regions (*e.g.,* centromeres).

#7027 Direct multi-omics for the masses: Linking DNA methylation to chromatin targets via TEM-seq.

K. E. Maier[1], V. U. Sunitha Kumary[1], B. J. Venters[1], A. Hickman[1], A. Vaidya[1], J. Anderson[1], R. Ezell[1], J. M. Burg[1], L. Williams[2], C. Ponnaluri[2], P. Esteve[2], I. Meek[2], Z.-w. Sun[1], M. W. Cowles[1], S. Pradhan[2], M.-C. Keogh[1];

[1]EpiCypher Inc, Durham, NC, [2]New England Biolabs, Ipswich, MA

DNA methylation (DNAme) is an epigenetic mark that includes the modification of cytosine resides (5mC) within CpG islands. In addition to well characterized roles regulating gene expression, imprinting and silencing parasitic DNA elements, the misregulation of DNAme is implicated in multiple diseases. Evidence is emerging that DNAme is not an independent epigenetic mark but rather closely linked to the post translational modification (PTM) of histone proteins. However, examining the relationship between 5mC and PTMs are hampered by the usual approach of independent analyses that cannot establish a direct linkage. Furthermore, the traditional approach to measure 5mC relies upon harsh bisulfite chemical conversation of DNA, which introduces damage and systemic biases. To address these limitations, we developed Targeted Enzymatic Methylation-sequencing (TEM-seq): an ultra-sensitive multi-omic genomic mapping technology that delivers high resolution DNAme profiles at epitope-defined chromatin features. Importantly this assay is capable of directly examining the link between 5mC and histone PTMs and/or chromatin associated proteins (ChAPs). The TEM-seq workflow integrates CUT&RUN for genomic mapping with NEB's enzymatic methyl-seq (EM-seq) for unbiased DNAme analysis. CUT&RUN is a highly sensitive, standards-driven assay that uses antibodies to locally tether protein A/G-micrococcal nuclease (pAG-MNase) to chromatin within intact cells or nuclei, followed by controlled activation of the MNase to cleave nearby DNA. EM-seq then enzymatically converts [5mC/5hmC] to generate single-base resolution, unbiased DNAme profiles from sub-ng samples.

To determine the capabilities and limitations of this novel approach, we tested multiple chromatin targets in various cell lines. We demonstrate that TEM-seq is highly reproducible, specific, and efficient (<10% off-target binding, >90% enzymatic conversion of DNAme, <0.5% conversion of unmethylated DNA). TEM-seq is also highly-sensitive, requiring only five million short-read sequences per assay (10-50x less than whole-genome 5mC-sequencing), demonstrating the disruptive potential of the assay to enable cost-effective approach for targeted DNAme analysis. Finally, we leveraged TEM-seq to gain mechanistic insights to Rett syndrome a neurodegenerative disorder that results from mutations in the 5mC-binding domain of the *MECP2* gene.

#7028 Optimization of DNA extraction methods and DNA methylation array quality from FFPE prostate tumor tissues to identify DNA methylation biomarkers.

Colton Duran Stensrud[1], Leonardo Gonzalez-Smith[1], Claire Stevens[1], Huan Cao[1], Jenaye Mack[2], Olumide Arigbede[3], Daniel Weisenberger[1], Sarah G. Buxbaum[3], Sara M. Falzarano[2], Suhn Rhie[1]

[1]Biochemistry and Molecular Medicine, USC - University of Southern California, Los Angeles, CA,[2]Pathology, Immunology, and Laboratory Medicine, University of Florida, Gainesville, FL,[3]Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL

Prostate cancer is the second leading cause of cancer related deaths among men in the United States. Health disparities in men diagnosed with prostate cancer are observed between patients of African and those of European ancestry. To elucidate molecular mechanisms behind prostate tumorigenesis and racial disparities, researchers have identified genetic alterations such as gene fusions, deletions, and mutations that occur at varying frequencies among different ethnic groups. However, results are inconsistent across studies, suggesting that racial disparities may be multifactorial. Our approach to further understand the mechanisms underlying racial disparities is to compare DNA methylation profiles between cancers from different ethnic groups using formalin-fixed paraffin-embedded (FFPE) prostate cancer tissue samples. For this study, FFPE prostate cancer specimens from 32 Black men and 30 age-matched White men were obtained in the form of tissue sections on glass slides. To profile DNA methylation in these samples, tumor and normal tissue regions (in a subset of cases) were outlined on a hematoxylin & eosin (H&E) reference slide and the respective regions were macro-dissected off the corresponding unstained slides from the same block. The areas of macro-dissected regions were measured using ImageJ, and the number of slides were taken to normalize DNA yield. Next, we compared magnetic bead and column based DNA extraction methods. We evaluated them on their relative DNA yield per tissue size, and identified that the bead-based extraction method had both higher and more consistent DNA yield. In total, we used 95 unique tissue regions to profile global DNA methylation levels using Illumina Epic array. We found that a subset of samples harbored an aberrant DNA methylation pattern. Therefore, we extracted DNA from additional FFPE tissue slides using the bead-based method and repeated the assay with a larger amount of DNA, successfully rescuing the majority of the aberrant samples. Next, we will evaluate associations between DNA methylation levels in different ethnic groups, clinicopathological features, and follow-up data to help identify potential DNA methylation biomarkers and therapeutic targets linked to prostate cancer from different ethnicities.

#7029 Trajectory of DNA methylation in blood up to 18 years prior to lung cancer diagnosis.

Y.-J. Choi[1], **K.-J. Hong**[2], Y.-S. Lee[3], W. Kim[4], Y. Kim[1], S. Jee[5], J. Kim[2];

[1]National Cancer Control Institute, National Cancer Center, Goyang, Korea, Republic of, [2]Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Republic of, [3]Research Institute, National Cancer Center, Goyang, Korea, Republic of, [4]School of Medicine, Kangwon National University, Chuncheon, Korea, Republic of, [5]Institute for Health Promotion, Graduate School of Public Health, Yonsei University, Seoul, Korea, Republic of

Purpose: Lung cancer (LC) has the highest mortality rate in South Korea. As prediction and early detection of lung cancer is pivotal to enhance survival rates, we attempted to investigate the trajectory of DNA methylation (DNAm) several years prior to lung cancer diagnosis by using prediagnostic blood samples.
Methods: From National Cancer Center Health Examinee Cohort, established in 2003, we selected study participants who became diagnosed with LC several years after health examination, thereby collecting prediagnostic samples from 18 years to 1 year prior to LC diagnosis. Normal controls (n=150) were matched with patients (n=150) by sex, age, and the time of sample collection. Epigenome-wide DNAm data were obtained by using Infinium Human MethylationEPIC v2.0 Beadchip. We assumed non-linear relationship between DNAm changes and the time-to-diagnosis and estimated an optimal threshold point of non-linear relationship with a piecewise linear regression analysis at each CpG sites (CpGs). We used the ratio of M-values of patients and matched controls to establish the non-linear model composed of two linear models with a threshold point where the slope changes. Then, we performed functional enrichment analysis by each year prior to LC diagnosis using ReactomePA.
Results: We identified threshold models with a threshold point where the slope changes from zero (from 18 years prior to LC up to the threshold point) to positive or negative (from threshold point to the point of LC diagnosis), which we termed “flat-to-change model”. Out of 790,048 CpGs, we identified a total of 7214 CpGs showing the “flat-to-change model”, of which 944, 789, 480, 413, 687, 542, 516, 1140, 315, 284, 327, 432, 83, 95, 74, 32, and 23 CpGs were found prior to 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, and 17 years before LC diagnosis, respectively. Functional enrichment analysis showed that various pathways were associated at different time point berfore LC diagnosis. CpGs of which DNAm was changed two years before LC diagnosis were associated with telomerase extension by telomerase involving *ANKRD28/TERT/TERF2/PPP6R3/WRAP53*. Transcriptional regulation by TP53 was associated with DNAm changes before both 5 and 14 years of LC diagnosis via *POLR2A*.
Conclusions: We identified the trajectories of DNA methylation up to 18 years prior to LC diagnosis, and found that a greater number of CpG sites showed DNAm changes adjacent to the time point of LC diagnosis. CpG sites associated with specific time point before LC diagnosis may elucidate the mechanisms of tumorigenesis and also have potential for LC prediction markers.

#7030 Reference materials for analysis of DNA methylation in cell-free circulating tumor DNA.

A. Higgs, A. Ryan, J. Ramprakash, D. Ruminski Lowe, Y. Konigshofer, C. Huang, A. Anfora, R. Garlick, B. Anekella;
LGC Clinical Diagnostics, Gaithersburg, MD

Aberrant DNA methylation is associated with many cancers including breast, liver, bone, and colon and has been identified as a biomarker for early cancer screening. Liquid biopsies are beginning to screen for DNA methylation in cancer-derived DNA, but accurate assessment of methylation is not trivial, and methods like bisulfite sequencing can result in biased data. Reference materials for establishing the analytical validity of measurements of CpG methylation are not widely available. In order to prepare such reference materials, genomic DNA (gDNA) was extracted from the well characterized human reference cell line GM24385 and fragmented to a circulating tumor DNA (ctDNA)-like size distribution. This DNA was processed further to prepare CpG-methylated and unmethylated versions. The size distribution was determined by using the Bioanalyzer High Sensitivity DNA Kit (Agilent, Santa Clara, CA). Methylation status in the reference materials was confirmed by both digital PCR (dPCR) and NGS based methods. A digital PCR method was developed to analyze heterozygous single nucleotide polymorphisms (SNPs) using the Bio-Rad QX200™ Droplet Digital PCR (ddPCR) System. To determine methylation levels by NGS, the NEBNext™ Enzymatic Methyl-seq Kit was used (EM-seq). Paired-end sequencing of the libraries was performed on a NextSeq™ 2000 (Illumina, San Diego, CA). Data alignment to hg19 was done with the bwa-meth (Pedersen, BS., et al.) aligner, and assessment of methylation in the aligned data was done with MethylDackel (Ryan, D.). Each reference material had an average peak size of ~160 bp in length, similar to patient cfDNA. By dPCR, the unmethylated reference material had an average of 0.73% DNA methylation, while the methylated reference material had an average of 100.10% DNA methylation. Values can be above 100% by dPCR due to unequal representation of both alleles. By NGS, the unmethylated reference material had an average of 0.93 % CpG methylation, which was similar to the background of 1.13 % and 1.31 % for CHG and CHH methylation, respectively. The methylated reference material had an average of 93.95 % CpG methylation, with a background of 0.69 % and 0.74 % for CHG and CHH methylation, respectively. Because EM-seq relies on enzymatic protection and conversion steps, it may be that these reactions did not allow for full protection and full conversion, which led to values above 0 % for unmethylated and below 100 % for methylated materials. We have developed reference materials for the assessment of DNA methylation in ctDNA. One unmethylated and one methylated reference material was created. These reference materials can be mixed together to the level of methylation required to help aid in assay design, optimization, and validation.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Genomics and Immunooncology

T cell exhaustion resulting from chronic antigen stimulation and an immunosuppressive tumor microenvironment limits the efficacy of T cell therapies in the solid tumor setting. The onset of T cell exhaustion is associated with distinct epigenetic and transcriptional changes. We hypothesized that genetic perturbations which shift T cells away from exhaustion associated states could increase the potency of immunotherapies. To this end, we utilized pooled, *in vitro* CRISPR/Cas9-based screening paired with deep sequencing readouts to characterize perturbation dependent T cell states in the context of chronic antigen stimulation. In order to achieve this, we developed a lentivirus-based workflow to perform CRISPRko, CRISPRi and CRISPRa pooled screens in human CAR T-cells that allowed for assessment of T cell phenotypes mediated by knockout, knockdown or overexpression of a large pool of target genes with single cell transcriptome readout. Subjecting these engineered CAR T-cells to an antigen-specific, cell-based repetitive stimulation assay (RSA) led to the progressive loss of T cell proliferation and effector function enabling *in vitro* modeling of T cell exhaustion. Moreover, characterization of the CAR T-cells by single cell sequencing recapitulated key hallmarks of the transcriptional and epigenetic landscape of T cell exhaustion. We also discovered T cell intrinsic gene perturbations that govern T cell states in the context of chronic antigen stimulation. These results demonstrate the power of pooled CRISPR screening with single cell readouts to identify novel target genes to enhance CAR T-cell therapies.

#7035 Characterization of tissue-resident memory T cells in hepatocellular carcinoma through single-cell multi-omics.

M.-S. Park[1], H. Cho[1], H. Kim[1], W.-Y. Park[2], Y.-H. Paik[3], Y. Yoon[1], W. Kang[3], H.-H. Won[1];

[1]Samsung Advanced Institute of Health Sciences and Technology (SAIHST), Sungkyunkwan University, Seoul, Korea, Republic of, [2]Samsung Genome Institute, Samsung Medical Center, Seoul, Korea, Republic of, [3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

As the fifth leading cause of cancer-related mortality, liver cancer imposes a global burden. Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer, with a five-year overall survival rate of less than 20% for advanced-stage cases. Even the most advanced immunotherapy for HCC has disparate response rates in each patient with HCC, which has led to efforts to unravel the underlying factors in the progression of HCC using bioinformatic approaches. In recent decades, numerous studies have explored T-cell subtypes with tissue-specific residency, suggesting their early protective functions and therapeutic potential within tumor microenvironment (TME). This study aimed to understand inter-individual and intercellular TME through single-cell RNA sequencing (scRNA-seq) and single-cell TCR sequencing (scTCR-seq) in five recurrent/non-recurrent HCC patients. We identified tumor-associated tissue-resident memory T (TA-T_{RM}) cells and investigated the heterogeneous characteristics of two T_{RM} clusters ($CD69^{+}$ and $CD103^{+}$). Whereas $CD69^{+}$ TA-T_{RM} showed high expression of genes associated with immunological activation, $CD103^{+}$ TA-T_{RM} exhibited upregulation of genes related to proliferation capacity. To validate the unique molecular patterns, we analyzed an independent HCC dataset (GSE140228) and observed high concordance of significant core marker genes for TA-T_{RM} clusters between the two datasets. Moreover, we assessed the association of gene expression in TA-T_{RM} cells with overall and recurrence-free survival by conducting survival analysis in two independent large-scale cohorts. The cross-validation approach was applied to estimate risk scores for patients with primary HCC tumors in The Cancer Genome Atlas (TCGA), and the trained model was evaluated using the International Cancer Genome Consortium (ICGC) data. The result of calculating the risk scores clearly indicates that TA-T_{RM} cells are associated with survival in HCC. Therefore, our study characterized two distinct subtypes of TA-TRM cells in HCC, delineated their unique molecular signatures, and established their relevance to survival outcomes. The findings can potentially enhance the understanding of the roles of TA-T_{RM} cells in the context of HCC.

#7036 Integrative biomarker profiling for predicting immunotherapy outcomes in gynecologic cancers.

G. Idumah[1], L. Li[1], H. Mahdi[2], Y. Ni[1];

[1]Cleveland Clinic, Cleveland, OH, [2]University of Pittsburgh Medical Center, Pittsburgh, PA

Immunotherapy with immune checkpoint inhibitors (ICI) has proven effective for various solid tumors, such as those in the lungs, urinary tract, and skin. However, its efficacy in gynecologic (GYN) cancers has been limited, with response rates of 11-17% in recurrent cases. Only a minority of patients with DNA mismatch repair deficiencies exhibit favorable responses to PD-1 inhibitors. The predictability of PD-L1 expression in GYN cancers remains inconsistent. Our research aimed to identify and prioritize biomarkers and mechanisms linked to ICI resistance in GYN oncology, targeting those who could benefit from these treatments.We gathered clinical and pathological data from 49 patients with ovarian, endometrial, and cervical cancers at various stages, all treated with ICI. We performed comprehensive analyses, including transcriptome-based immune cell abundance estimation, signaling pathway enrichment, and correlation with ICI treatment responses and survival outcomes. Our previous work highlighted TGF-β and CD47's roles in immunotherapy resistance, facilitating an immunosuppressive environment within our GYN cancer cohort. Moreover, we conducted a stoichiometry constraint-based genome-scale metabolic model and computed correlation-grouped metabolic activity scores (cgScore) using metabolic enzyme gene expression as constraints. Among 1533 metabolic reactions, pyruvate transport and folate metabolism stood out as the most upregulated in responders versus those who progressed.Upon identifying several promising biomarkers, we used logistic regression classifiers to decipher the predictive value of each. Our model included clinical-demographic (age, BMI, cancer type, stage) and molecular-genomic features (immune marker gene expression, TopTGF-β score, immune cell abundance from transcriptomic deconvolution, and the top 2 cgScores). Analysis divided into training and testing sets highlighted features such as stage, BMI, eosinophils, CD274, CD47, and the pyruvate transport reaction as significant predictors of ICI response. The model achieved an 80% accuracy rate on the test set, confirmed by permutation importance from scikit-learn. We also used a Regularized Cox model to link predictors with progression-free survival, emphasizing the roles of BMI, plasma cells, CD276, pyruvate transport reaction, and folate metabolism. In conclusion, there are immunological and metabolic markers have the potential to serve as predictive indicators for ICI treatment response and survival in GYN cancers. Understanding these predictors can profoundly influence clinical decision-making in immunotherapy, ultimately leading to enhanced patient outcomes and personalized treatment approaches.

#7037 Comprehensive molecular and immune profiling of triple negative invasive lobular carcinoma.

P. Advani[1], S. Deshmukh[2], S. Wu[2], J. Andring[2], J. Xiu[2], J. Leone[3], P. Jayachandran[4], S. Graff[5], M. Oberley[2], G. Sledge[2], A. Chanan-Khan[1];
[1]Mayo Clinic, Jacksonville, FL, [2]Caris Life Sciences, Phoenix, AZ, [3]Dana Farber cancer Institute, Boston, MD, [4]Norris Comprehensive Cancer Center, Los Angeles, CA, [5]Lifespan Cancer Institute, Brown University, RI

Background: Triple-negative invasive lobular carcinoma (TN-ILC) is a rare (0.1-1.4%) breast cancer with prognosis worse than ER positive ILC. Currently there are no targeted therapies or clinical trials specifically for TN-ILC. A comprehensive analysis of the molecular and immune landscape can help identify novel targets and pathways for TN-ILC to improve patient outcomes. Here, we characterized the molecular and immune signature of TN-ILC.
Methods: 11,760 breast cancer samples (Invasive ductal (ID) TNBC, n=364; TN-ILC, n=31) were analyzed (592, NextSeq; WES, NovaSeq), (WTS; NovaSeq) (Caris Life Sciences, Phoenix, AZ). Tumor mutational burden (TMB) totaled somatic mutations per tumor (high ≥10 mt/MB) was tested by NGS. Microsatellite-instability (MSI) was tested by NGS. Immune cell fractions were calculated by deconvolution of WTS. Statistical significance was determined using chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($q < 0.05$).
Results: TN-ILC had higher frequency of *CDH1* (0.83% vs. 66.67%), *ERBB2* (0.84% vs.28.57%), *ARID1A* (1.65% vs. 23.33%), *CBFB* (0.55% vs.16.67%), *AKT1* (2.22% vs.16.13%) and *KMT2C* (3.83% vs.13.79%), but lower frequency of *TP53* (89.7%5 vs. 38.71%) mutations (all $p<0.05$) compared to ID-TNBC. TN-ILC had higher frequency of TMB high (23.3% vs. 5.2%, $p<0.05$) but there was no difference in dMMR/MSI-H (0% vs 1.1%, $p=1$). TN-ILC had higher AR RNA (FC: 14.2), protein expression (80.6% vs. 24.8%) and higher frequency of fusion variant-AR (16.1% vs 4.9%) (all $p < 0.05$) compared to ID-TNBC. Analysis of inferred immune cell infiltrates showed that TN-ILC had higher infiltration of M2 macrophages (5.34% vs. 2.94%) and neutrophils (4.83% vs. 2.65%) but lower infiltration of M1 macrophages (3.46% vs 2.17%) and CD8 T cells (0.58% vs. 0.11%) (all $p<0.05$). TN-ILC had lower T cell inflamed signature (16.1% vs 35.7%, $p<0.05$), decreased immune checkpoint genes (*CD274, CTLA4, FOXP3, LAG3, IDO*, FC: 1.2-2.7, all $p < 0.05$), PD-L1 protein expression (SP142: 30.4% vs. 50.2%, $p=0.06$; 22c3: 15.4% vs. 42.6%, $p = 0.05$) and differential expression of BCL2 family genes (upregulation: *BIK*, FC: 2.2; downregulation: *BAX, BAK1, BID, PMAIP1, MCL1, BCL2A1, BCL2L10*, FC: 1.0-6.3, all $p < 0.05$) compared to ID-TNBC.
Conclusion: These data suggest that TN-ILC had higher frequency of CDH1, ERBB2, AKT1, ARID1A mutations, higher M2 macrophages and neutrophils and lower M1 macrophages and CD8 T cells infiltration and, lower T cell inflamed signature. High TMB and AR expression can translate into use of immunotherapy (ICI) and AR antagonists in these patients. Additonal analysis to determine the optimal biomarker for ICI response in TN-ILC is needed. Results of our study need to be validated in larger studies with survival correlation.

#7039 Leveraging single cell RNA-seq for uncovering immune landscape of hepatocellular carcinoma.

Jian He

School of Medicine, Shanghai Jiao Tong University, Shanghai, China

The immune cell types as well as tumor microenvironment (TME) status may influence prognosis, metastasis, tumor progression, and clinical response to immunotherapies for cancer. Hepatocellular carcinoma (HCC) is a typical highly heterogeneous solid tumor with high morbidity and mortality worldwide, especially in China, however, the immune microenvironment of HCC, especially which caused by cancerogenic substance has not been clarified so far. In this study, we employed single-cell RNA sequencing (scRNA-seq) on diethylnitrosamine (DEN)-induced mouse HCC model to dissect the immune cell dynamics during tumorigenesis. Our findings reveal distinct immune profiles in both precancerous and cancerous lesions, indicating early tumor-associated immunological alterations. Notably, specific T and B cell subpopulations are preferentially enriched in the HCC TME. Furthermore, we identified a subpopulation of naïve B cells with high CD83 expression, correlating with improved prognosis in human HCC. These signature genes were validated in The Cancer Genome Atlas (TCGA) HCC RNA-seq dataset. Moreover, cell interaction analysis revealed that subpopulations of B cells in both mouse and human samples are activated and may potentially contribute to oncogenic processes. In summary, our study provides insights into the dynamic immune microenvironment and cellular networks in HCC pathogenesis, with a specific emphasis on naïve B cells. These findings emphasize the significance of targeting TME in HCC patients to prevent HCC pathological progression, which may give a new perspective on the therapeutics for the HCC.

#7040 Mutations in cytoskeleton genes SPTAN1/SPTBN1 serve as novel predictive markers for immunotherapy against bladder cancer.

B. Y. Kuo;
National Sun Yat-sen University, Kaohsiung, Taiwan

Cancer progression is often driven by somatic mutations. Despite several well-known driver mutations, more evidence has shown that genetic alterations in cytoskeleton organization enhance tumor aggressiveness and promote cancer progression, suggesting their roles as potential drivers. In this study, pan-cancer genetic analyses by using TCGA cohorts, more frequent mutation events were found in cytoskeleton-related genes as compared to total annotated genes, especially in cancers derived from hollow organs. High-dimensional analysis of molecular alterations in cancer (HD-MAC) suggested gene mutations in SPTAN1 and its partner SPTBN1 as potential prognostic biomarkers for clinical outcomes of patients with bladder cancer. Gene knockdown in either SPTAN1 or SPTBN1, mimicking silencing mutations in cancer tissues, caused cell morphology changes, DNA breaks, and alternations in cytokine profiles via activating cGAS-STING mediated interferon signaling. Xenograft tumor models also indicate accelerated tumor growth in SPTAN1- or SPTBN1-silenced cells, suggesting a more advanced cancer type. Based on immune staining in both human and mouse samples, increased CD8+ T cell infiltration was in tumor lesions with mutations or truncations in SPTAN1/SPTBN1 genes. In addition, several known substitution mutations were found as potent neo-antigens based on MHC II binding prediction, which could be utilized as targets for immune checkpoint therapy. This study provides a novel insight into how the cytoskeleton can contribute to cancer progression and find out predictive biological indicators with therapeutic values.

#7041 Tumor-immune interactions and cisplatin resistance in localized muscle-invasive bladder cancer.

F. L. De Carvalho[1], **J. Lee**[1], K. Bi[2], B. Titchen[2], K. Stawiski[2], J. Park[2], A. Garza[2], D. Michaud[1], J. Guerriero[1], E. Mittendorf[1], K. Mouw[2], E. Van Allen[2]; [1]Brigham and Women's Hospital, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA

Background: Cisplatin-based chemotherapy followed by radical cystectomy remains the standard-of-care treatment for patient with localized muscle-invasive bladder cancer (MIBC). Neoadjuvant clinical trials studying the combination of cisplatin-based chemotherapy and immune checkpoint blockade (ICB) in MIBC reported encouraging pathologic complete response rates. However, the molecular mechanisms and cellular programs involved in response and resistance to cisplatin and ICB in MIBC remain incompletely characterized. Our goal is to define cellular transcriptional programs and chromatin accessible regions in cancer cells and infiltrating immune cells associated with response and resistance to neoadjuvant systemic therapy.

Methods: We performed single-cell Multiome ATAC and Gene expression sequencing (simultaneous identification of gene expression and open chromatin regions within the same cell) of tumors that had a complete response – “responders” – and tumors that had no response or progressed – “non-responders” – through neoadjuvant cisplatin-based chemotherapy (n=15). Single cell suspensions were prepared following the 10x Genomics protocol. Cell Ranger ARC was used for sequence alignment, peak calling, and generation of count matrices. Downstream single-cell gene expression analysis was performed with Scanpy and ATAC-seq with Seurat.

Results: We identified two distinct urothelial cell populations in "responders" vs "non-responders" based on single cell gene expression and genome wide chromatin accessibility regions. Cancer cells in “non-responders” preferentially express basal cell gene expression signatures. “Non-responders” were significantly enriched in suppressive tumor-associated macrophages (TAMs). Interestingly, SPP1+ TAMs known to have a pro-tumoral role and promote resistance to ICB were exclusively identified in “non-responders”.

Conclusion: Single cell and genome wide chromatin accessibility regions identify heterogenous urothelial cell populations expressing basal cell markers in tumors resistant to neoadjuvant cisplatin-based chemotherapy. “Non-responders” are significantly enriched with TAMs implicated in resistance to ICB. Future studies will better define the implications of these findings in cancer therapeutics for patients with MIBC.

#7042 Enhancing TCR T cell function in solid tumors through *in vivo* combinatorial screens and single-cell analysis.

Dina Polyak[1], Jessica Fuhriman[1], Josephine Susanto[1], Allyson Merrell[1], Mandi Simon[1], Catherine Oh[1], Andrew Cordazo[1], David DeTomasso[1], Carla Tocchini[1], Vibhavari Sail[1], Eric Cui[1], Jeff Milush[1], Levi Gray-Rupp[1], Brendan Galvin[1], Christopher Murriel[1], Grace Zheng[1], Angela C. Boroughs[1], Pratiksha Thakore[2], Soyoung Oh[2], Jake Freimer[2], Bob Chen[2], Celine Eidenschenk[2], Emily Wheeler[2], Jacob Levine[2], Jan-Christian Huetter[2], Jill Schartner[2], Katie Geiger-Schuller[2], Orit Rozenblatt-Rosen[2], Sascha Rutz[2], Ira Mellman[2], W. Nicholas Haining[1]

[1]Arsenal Biosciences, 329 Oyster Point South San Francisco, CA,[2]Genentech, San Francisco, CA

The therapeutic potential of T cell therapies for treating solid tumors can be limited by intrinsic T cell exhaustion mechanisms and the suppressive tumor microenvironment. To better understand these challenges and identify genetic perturbations to enhance T cell functions, we developed *in vivo* exhaustion models and performed pooled CRISPR/Cas9-based screens with detailed characterization of T cell states through single cell RNA-sequencing (scRNA-seq). *In vivo* Xenograft exhaustion models were developed in the format of T cell receptor (TCR) T cells, with tumor cell lines expressing TCR-specific antigen (NY-ESO-1) respectively. Individual perturbations were introduced into T cells via non-viral editing and pooled before transferred into mice with established tumors of various sizes that provided continuous antigen exposure to drive exhaustion, while providing sufficient number of T cells from tumor and spleen tissues for scRNA-seq. The pooled CRISPR *in vivo* screens in human TCR T cells enabled us to evaluate T cell phenotypes resulting from gain-of-function, loss-of-function, or combinations of these modifications across a wide array of target genes. We identified known and previously uncharacterized combinatorial perturbations that were enriched or depleted and were associated with distinct transcriptional phenotypes over the course of chronic stimulation. This approach allows us to bridge the gaps in our understanding of how T cells can be reprogrammed to overcome exhaustion and function more effectively in the challenging environment of solid tumors.

#7043 Genomic profiling of DLL3-positive and negative CTCs in small cell lung cancer.

Z. Simandi[1], T. Bui[1], A. Ferrarini[2], S. Hepburn[1], R. G. Del Mastro[1];
[1]Menarini Silicon Biosystems Inc., Huntingdon Valley, PA, [2]Menarini Silicon Biosystems SpA, Bologna, Italy

BACKGROUND: Delta-like ligand 3 (DLL3), an atypical Notch family protein implicated in neuroendocrine tumorigenesis, has emerged as a promising therapeutic target in small cell lung cancer (SCLC), prompting numerous clinical trials investigating DLL3-targeted treatments. Exploring DLL3 in circulating tumor cells (CTCs) through liquid biopsy, coupled with comprehensive genomic analysis, presents an invaluable and minimally-invasive avenue for monitoring disease progression. This approach holds the potential to tailor personalized treatment strategies, emphasizing the critical need for in-depth investigations into both DLL3-positive and negative cell genomic compositions.
METHODS: This study examined blood collected in CellSave preservative tubes from stage I (n=17) and stage IV (n=12) SCLC patients, as well as healthy donors (n=10). The CELLSEARCH® platform was employed to count EpCAM-enriched CTCs and evaluate DLL3 protein expression. Subsequently, individual CTCs were isolated based on the presence and absence of DLL3 expression using the DEPArray™ PLUS. The isolated DLL3-negative and positive CTCs were subjected to low-pass sequencing using the Ampli1™ LowPass Kit to uncover genomic aberrations.
RESULTS: CTCs were absent in the healthy control group. In stage I patients, CTCs were identified in 5.8% of blood samples, while in stage IV patients, they were present in 50% of samples, with an average CTC count of 148 in stage IV. Among a total of 2074 detected CTCs, 460 were DLL3-positive, accounting for 6-28% of EpCAM-enriched CTCs in individual patients. Analysis of >300 copy number alteration (CNA) profiles of sorted single cells revealed considerable inter-patient and intra-patient heterogeneity, delineating recurrent clonality and specific genomic alterations in DLL3-negative CTCs. In contrast, DLL3-positive cells showed more stochastic CNA profiles, suggestive of apoptosis-related DNA fragmentation.
CONCLUSIONS: Integrating CellSearch, DEPArray, and low-pass sequencing provides a minimally-invasive approach to compare genomic characteristics in DLL3-positive and negative CTCs from SCLC patients. Extension of this approach to a larger patient cohort and employing machine learning algorithms will facilitate identification of patterns within diverse CNA profiles, improving patient stratification and predicting treatment responses for personalized therapeutic strategies in SCLC.

#7044 Transcriptome and TCR repertoire in human telomerase reverse transcriptase peptide vaccine treated metastatic prostate cancer patients.

R. Natkin[1], J. E. Simensen[2], N. Engedal[2], E. B. Ellingsen[3], M. Westhrin[3], I. Westgaard[3], E. Hovig[2], W. Lilleby[2], M. Nykter[1], A. Urbanucci[1];
[1]Tampere University, Faculty of Medicine and Health Technology, Tampere, Finland, [2]Oslo University Hospital, Institute for Cancer Research, Oslo, Norway, [3]Ultimovacs, Oslo, Norway

Human telomerase reverse transcriptase (hTERT) vaccine has found to be effective for most of the participated de novo metastatic prostate cancer patients in clinical studies. Nevertheless, the molecular mechanisms behind the immune response induced by the hTERT vaccine are not fully elucidated. Among the cohort of 21 patients treated with androgen deprivation therapy, radiotherapy and hTERT vaccine, we used RNA-sequencing and TCR-sequencing (20 and 14 pre-treatment and 20 and 21 post-treatment samples, respectively) to inspect the changes in transcriptome and TCR-repertoire after the hTERT vaccine treatment and differences between patients that had early response and patients that had late or no response. We found multiple hallmarks being shifted after the treatment and being different between early and late responders. Also, a change in activity of multiple gene set signatures was detected after the treatment and activity of part of the gene set signatures predicted survival. Deconvolution of cell type composition from RNA-sequencing data revealed changes in immune cell abundances after the treatment. TCR-sequencing revealed changes in composition and diversity of TCR repertoires after the treatment and these differed between early and late responders. The results of this study will help to predict patients' responses to the cancer vaccine and to further understand the mechanisms behind successful cancer vaccines.

#7045 RNA sequencing approaches enable tissue specific B and T cell gene expression and immune repertoire profiling.

C. Song, E. Janzen, T. Devoe, A. Erijman, G. Naishadham, L. Song, B. W. Langhorst;
New England Biolabs, Inc., Ipswich, MA

The adaptive immune system defends the human body from pathogens through the recognition ability of antigen receptors from B and T cells. Different organs play various immune function roles, and therefore present varied B and T cell gene expression and immune repertoire profiles. Abnormality of these profiles may reflect immunological disorder, presence of neoplastic tissue, or response to infectious agent. High-throughput sequencing technology has facilitated the understanding of gene expression and related cell functions, but in-depth understanding of B and T cell phenotype and clonotype profiling is an emerging application that has yet to take full advantage of sequencing technology for diagnosis and prognosis of disease.

Here, we share results of RNA sequencing of immune system tissues; including B cell and T cell specific gene expression and full-length immune repertoire profiling. Total RNA was extracted from various tissue samples including healthy donor peripheral blood mononuclear cells (PBMC), lymph nodes, bone marrow, spleen, thyroid, thymus and colon, as well as diseased PBMC and colon samples. RNA-seq and Immune-seq libraries were made from these samples and sequenced on Illumina NextSeq2000. Gene expression analysis and immune repertoire profiling from RNA-seq data were performed using edgeR and TRUST4. Immune repertoire sequencing data was processed using pRESTO and IgBlast. We correlated RNA-seq with Immune-seq results for B-cell receptor and T-cell receptor clonotypes. Differential expression and clonotype profiling comparisons were also performed between normal and diseased RNA samples. The effect of reference on immune repertoire detection sensitivity and accuracy was further investigated by comparing IMGT reference and AIRR-C Human IG Reference Sets.

This study has identified tissue specific B/T cell phenotype and clonality patterns that relate to tissue functions and disease progression. RNA-seq enables highly multiplex immunophenotyping which is traditionally performed by flow cytometry. RNA-seq can detect high-abundant clones that correlate with Immune-seq, with the latter targeted approach providing more in depth clonality signatures. References comparison results show the importance of continued community effort to develop more representative and accurate immunorepertoire germ line references for clonotype annotation in diverse populations. Integrating both RNA sequencing and immune repertoire sequencing approaches allows accurate phenotype and clonotype determination for immune landscape in various tissues.

#7046 Proteogenomic and immunologic profiles of head and neck cancer patients of African ancestry.

F. Yang, F. Chen, C. Shay, N. F. Saba, **Y. Teng**:
Emory University, Atlanta, GA

Blacks/African Americans (BAAs) with head and neck squamous cell carcinoma (HNSCC) have worse survival than Whites. However, the complex molecular biomarkers and signatures of HNSCC among BAAs and molecular distinction associated with HNSCC disparities are largely unknown. Here we show the results of a multi-omics analysis of 500 patients (48 BAAs and 452 Whites). Comparative analyses between the racial groups were performed at the level of genomics, pathways, molecular subtype, tumor immune infiltration, protein alterations and prognosis. We found that overall survival in BAAs with HPV-unrelated HNSCC is significantly shorter than in White patients. Ancestry-related differential mutation spectrum, DNA methylation, gene and protein expression pattern and immune infiltration landscape were identified. Particularly, FAT1 mutation is significantly associated with its gene expression in BAA HNSCC and poor overall survival in this group. In BAA HNSCC, SALL3 gene expression is positively associated with its gene CNVs, while RTP4 gene expression is inversely correlated with its methylation. High EGFR_pY1068 and RAD50 levels correlate with poor prognosis in BAAs with HNSCC. The immune infiltration enrichment scores of Th17 cells, activated dendritic cells, monocytes and neutrophils in BAA HNSCC were significantly lower than those in White HNSCC. By combining multi-omics analysis and data validation using in-house-made tumor tissue arrays, this study comprehensively elucidates the genetic landscape, immune response, and tumor biology in BAA and White HNSCC patients, providing a molecular basis for future research in identifying appropriate screening modalities and therapeutic interventions leading to improved outcomes in BAAs with HNSCC.

#7047 Comparative analysis of transcriptomic and immunological profiles in treatment-naïve black and non-Hispanic White women with high-grade serous ovarian cancer.

H. Huang[1], R. Keathley[1], U. Kim[1], H. Cardenas[1], P. Xie[1], J. Wei[1], G. Zhao[1], E. L. Barber[1], E. Lengyel[2], K. P. Nephew[3], V. Bae-Jump[4], B. Zhang[1], D. Matei[1]; [1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL, [2]University of Chicago, Chicago, IL, [3]Indiana University, 5School of Medicine,, Bloomington, IN, [4]University of North Carolina, Chapel Hill, NC

Background: Ovarian cancer is a highly lethal gynecological malignancy and high-grade serous histology (HGSOC) accounts for the majority of cases. Platinum-based chemotherapy is the primary treatment. Notably, Black women face the highest mortality-to-incidence ratio across all ethnic groups. This study investigated transcriptomic and immunological differences in tumors from Black compared to NHW women that might explain the poor clinical outcomes observed within this patient cohort. Methods: We collected primary tumor specimens from 36 Black and 31 treatment-naïve NHW patients. After RNA isolation, RNA sequencing (RNA-seq) identified differentially expressed transcripts and Enrichr performed pathway enrichment studies. To confirm the observed gene expression differences, we employed quantitative reverse transcription PCR (qRT-PCR), western blotting, and multiplex immunohistochemistry (mIHC). Additionally, we conducted cell proliferation, colony formation, and cell viability assays to functionally validate potential target genes of interest. Results: Our findings revealed 277 genes with significant differential expression between Black and NHW patients (FDR-adjusted p-value < 0.05). Among these, 103 coding genes were up-regulated, while 81 coding genes were down-regulated in tumors from Black compared to NHW patients. Gene Ontology analyses of these significantly differentially expressed genes highlighted enriched pathways related to DNA damage response, including the insulin receptor (INSR) gene, p53/apoptosis signaling components such as Forkhead box proteins A1 (FOXA1) and FOXB1, as well as genes involved in the cholesterol/lipid modulation pathway, including Low-density lipoprotein (LDL) receptor and Stearoyl-CoA Desaturase (SCD). Notably, silencing INSR and FOXA1 enhanced sensitivity to platinum-based drugs and inhibited cell growth and colony formation. Furthermore, we identified differences in the proportions of key immune cell types between the two patient groups, with tumors from Black patients exhibiting a significantly lower proportion of CD4+ Naïve T-cells and CD4+ regulatory T-cells (Tregs). Conclusions: Overall, our study reveals significant differential gene expression patterns between HGSOC tumors from Black and NHW patients, as well as differences in the proportions of immune cell types. These discoveries provide valuable insights into the biological mechanisms underlying the disparities in outcomes observed between black and NHW patients afflicted with HGSOC. It is critical to further investigate how these biological differences affect clinical outcomes and treatment response in Black women.

#7048 Multiomics characterization of breast angiosarcoma from an Asian cohort reveals enrichment for angiogenesis signaling pathway and tumor-infiltrating macrophages.

T. Ko, Z. Guo, B. Kannan, B. Lim, J. Lee, A. Lim, Z. Li, E. Lee, C.-Y. Ng, B. Teh, J. Chan;
National Cancer Centre Singapore, Singapore, Singapore

Recent epidemiological data suggests a rising incidence of breast angiosarcoma (AS-B) in the Western population, with over two-thirds related to irradiation or chronic lymphedema. However, unlike head and neck angiosarcoma (AS-HN), AS-B disease characteristics in Asia remains unclear. We examined clinical patterns of angiosarcoma patients (n = 176) seen in an Asian tertiary cancer centre from 1999 to 2021, and specifically investigated the molecular and immune features of AS-B in comparison to AS-HN. Data from whole genome sequencing (WGS) (AS-HN, n = 44; breast, n = 7), NanoString PanCancer IO360 gene expression profiling (AS-HN, n = 42; breast, n = 7) and 10X Visium spatial transcriptomics (AS-HN, n = 4; breast, n = 2) were analyzed. Majority of cases were AS-HN (n = 104; 59.1%), while AS-B (n = 16, all females) accounted for 9.1% of the cases. The median age at diagnosis was 43 years (range, 26 to 74). Four cases (25%) were related to prior irradiation, while 6 out of 8 cases evaluated were positive for human herpesvirus-7 on immunohistochemistry. Although all cases were non-metastatic at diagnosis and were treated with curative-intent surgery, 6 patients (37.5%) experienced rapid relapse within a median of 7.8 months. Based on WGS, 4 of the 7 AS-B had non-synonymous somatic variants in 48 genes (range, 2 to 28 per case). Among the notable variants found were in kinases (KDR, JAK2, FLT4, ATR, EPHB1 and PRKACA). Other variants were found in cancer-related genes (e.g. ATRX, FOXO1, SMAD3, PTCH1, NOTCH4, HIF1A and SETD1A). These genes were functionally annotated by performing over representation analysis (www.webgestalt.org) on publicly available databases (e.g. Gene Ontology and KEGG). They were enriched in cancer-related pathways such as regulation of cell differentiation, VEGFR and receptor tyrosine kinase signaling pathways. By NanoString profiling, compared to AS-HN, AS-B was enriched for angiogenesis, notch signaling and metastasis-associated matrix remodeling pathways. Conversely, AS-B was depleted of lymphoid compartment, immune cell adhesion and migration expression signatures. Based on the gene expression signatures, AS-B was enriched for macrophages, CD8+ T cells and was depleted for T-reg cells. Furthermore, spatial transcriptomics showed that compared to AS-HN, tumor-infiltrating leukocytes (TILs) in AS-B were enriched for macrophage and T-cells but were depleted for B-cells and NK cells. The location of TILs could provide information on the feasibility of immunotherapy in angiosarcoma. In conclusion, we observed a convergence of both mutational and expression signatures on angiogenesis signaling pathways in our AS-B cases. The spatial transciptomic data revealed that AS-B was enriched for tumor-infiltrating macrophages and T-cells which might have implications on the role of immunotherapy.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Mitochondrial Function 1
Poster Session

#7052 p53 underpins a dependence on oxidative phosphorylation in glycolysis-competent colorectal cancer.

X. Zhao[1], M. Han[2], Q. Yan[2], Y. Yue[2], K. Ye[2], Y. Zhang[1], L. Teng[2], L. Xu[1], X. Shi[2], T. La[1], Y. Feng[1], R. Xu[1], V. K. Narayana[3], D. P. De Souza[3], T. Liu[4], M. Baker[1], R. F. Thorne[2], X. Zhang[1], S. Chen[2], L. Jin[1];

The use of mitochondrial inhibitors to target oxidative phosphorylation (OXPHOS) in cancer treatment presents a challenge due to dose-limiting toxicities. Moreover, while glycolysis-deficient cancers are vulnerable to OXPHOS inhibition in preclinical models, the full extent of phenotypical and mechanistic consequences of inhibiting OXPHOS in cancers capable of glycolysis is not yet well understood. Our results presented here offer promising insights into potential therapeutic gains from combining p53 restoration strategies with OXPHOS inhibitors, even when applied to glycolysis-competent CRC cells. Treatment with mitochondrial complex I inhibitors did not cause energy stress in CRC cells capable of glycolysis. It does, however, induce DNA replication stress, apparent through an observed cell cycle arrest at the S phase, enrichment of the G2/M DNA-damage checkpoint regulation pathway, and replication fork slowdown. Intriguingly, CRC cells harboring wildtype p53 exhibited more severe replication stress than those carrying mutant p53. Furthermore, siRNA knockdown of p53 attenuates replication stress and reduces cell cycle arrest, underlining the important role of p53 in CRC cell responses to OXPHOS inhibition. Our targeted metabolomics analysis reveals that OXPHOS inhibition results in reductions in the purine nucleotides, adenine monophosphate (AMP) and guanine monophosphate (GMP), as well as the pyrimidine nucleotide, uridine monophosphate (UMP), in CRC cells, regardless of their p53 mutational status. By supplementing cell culture mediums with the purine nucleobases adenine and guanine, and the pyrimidine nucleoside uridine, we observed a partial reversal of the replication fork slowdown and reductions in cell viability. This suggests nucleotide deficiencies are involved in the induction of DNA replication stress caused by OXPHOS inhibition. The nucleotide deficiencies were associated with a decrease in the nucleobase precursor aspartate. By adding aspartate at a supraphysiological concentration, to overcome the low expression of the excitatory amino acid transporter 1 required for cellular import of aspartate, we were able to restore the levels of nucleotides. Collectively, our findings suggest broader potential cancer treatment paradigms via OXPHOS targeting, extending beyond glycolysis-deficient cancers. Our data uncovers that CRC cells, which commonly exhibit the glycolytic phenotype, are susceptible to OXPHOS inhibition, with those carrying wildtype p53 showing heightened sensitivity. Therefore, p53 status could serve as a biomarker for predicting CRC responses to OXPHOS inhibitors. Moreover, our findings suggest that combined strategies of restoring p53 function, using small molecules such as APR-246, might enable reduced dosage of OXPHOS inhibitors in CRC treatment, thereby mitigating their dose-limiting toxicities.

#7053 Serine phosphorylation marks proteins for degradation by the mitochondrial matrix protease, ClpXP.

Y. Feng[1], M. M. Goncalves[2], Y. Jitkova[1], A. Keszei[1], C. Sarathy[1], V. Trudel[3], J. St-Germain[1], M. Tcheng[1], Y. Yan[1], R. Hurren[1], M. Schultz[1], B. Raught[1], A. Yudin[3], M. Mazhab-Jafari[1], S. Vahidi[2], A. D. Schimmer[1];

[1]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [2]University of Guelph, Toronto, ON, Canada, [3]University of Toronto, Toronto, ON, Canada

ClpXP is a conserved protein degradation system. In human mitochondria, ClpXP degrades damaged respiratory chain proteins and is vital for the survival of acute myeloid leukemia (AML) cells. This system consists of the barrel-like protease ClpP, capped by regulatory particles (RP) ClpX. In bacteria, ClpXP targets substrates with a co-translationally added SsrA sequence. However, in humans, the SsrA tag is absent, and the degradation markers for ClpXP remain unidentified. Notably, bacterial ClpXP homologues degrade substrates with phosphorylated arginine (pArg). We hypothesized that phosphorylated amino acids also mark substrates for ClpXP degradation in human mitochondria.

We showed that ClpXP preferentially degraded phosphorylated α-casein substrate over dephosphorylated α-casein. In contrast, ClpP activated by ONC201, without ClpX, degraded phosphorylated and dephosphorylated α-casein with equal efficiency. Next, we screened a panel of phosphorylated amino acids and peptides for their ability to inhibit ClpXP-mediated degradation of α-casein. Phosphorylated serine (pSer) amino acids and peptides inhibited ClpXP protease activity, while phosphorylated tyrosine (pTyr) or pArg did not. Likewise, Ser and free phosphate did not inhibit ClpXP protease activity. Thermal shift assays showed that pSer amino acids and peptides bind to ClpX, not ClpP. Hydrogen/deuterium exchange mass spectrometry revealed that the addition of Ala-pSer-Ala (ApSA) peptide, but not ASA peptide induced conformational changes in the negatively-charged N terminus of ClpX, thus revealing a putative binding site for ApSA.

Earlier, we established that ClpP interacts with the respiratory chain complex II subunit SDHA. Knocking down of ClpP in AML cells affected the respiratory chain and increased reactive oxygen species. Therefore, we tested how ClpXP knockdown impacts levels of phospho-serine SDHA (pSer-SDHA) in intact cells. Using shRNA, we knocked down ClpP and ClpX individually in OCI-AML2 cells. After target knockdown, we pulled down pSer proteins and probed for SDHA. Knockdown of both ClpP and ClpX increased the abundance of pSer-SDHA compared to control. We subsequently added recombinant ClpXP protein to total mitochondrial lysates and the pSer immunoprecipitated fraction from OCI-AML2 cells. This led to decreased levels of pSer-SDHA but did not alter levels of total SDHA, consistent with its preference for pSer-marked substrates suggesting that ClpXP degrades pSer-SDHA. Further analysis showed elevated pSer-SDHA levels only in the insoluble mitochondrial protein fraction after ClpX knockdown, suggesting these might be damaged proteins.

In conclusion, our findings demonstrate that serine phosphorylation promotes the degradation of damaged mitochondrial proteins by ClpXP protease.

#7054 *L1-ATP8B1* exacerbates high-level reduction-oxidation homeostasis to promote carcinogenesis via affecting PHB1 sumoylation in LUSC.

Rui Zhang[1], Xiao Zhang[1], Zeguo Sun[2], Pengpeng Liu[1], Guidong Chen[1], Weijia Zhang[2], Jinpu Yu[1]

[1]Tianjin Medical University Cancer Institute & Hospital, Tianjin, China,[2]Icahn School of Medicine at Mount Sinai, Tianjin, China

Long Interspersed Nuclear Element-1 (LINE-1, L1) plays important roles in carcinogenesis. However, the function of LINE-1 in lung squamous cell carcinoma (LUSC) remains unclear. Here we found that *L1-ATP8B1* was overexpressed in LUSC patients with short survival and associated with mitochondrial dysfunction in both the TCGA dataset and the TJMUCH cohort. Overexpression of *L1-ATP8B1* promoted cell proliferation and invasion *in vitro* and facilitated LUSC xenograft growth *in vivo*. *L1-ATP8B1* affected mitochondrial complex enzyme I activity via affecting cardiolipin-dependent PHB1 sumoylation and promoting PHB1 ubiquitination, inducing high-level cellular reduction-oxidation (redox) homeostasis. Synergetic therapy with an L1 inhibitor and an antioxidant dramatically interfered with redox homeostasis and restored mitochondrial function, abolishing *L1-ATP8B1*-induced growth and metastasis of LUSC xenografts *in vivo*. In conclusion, we for the first time demonstrated that metabolic disorder plays a vital role in L1-related carcinogenesis and identified *L1-ATP8B1* as a promising prognostic biomarker and therapeutic target for LUSC.

#7055 Elucidation of the interplay between phospholipid byosynthesis and oxidative stress in the pathogenesis of renal cell carcinoma.

R. Kato[1], D. Ikarashi[1], S. Maekawa[1], M. Kanehira[1], R. Takata[1], Y. Matsushita[2], T. Yoshimaru[2], T. Fukawa[2], T. Katagiri[2], W. Obrara[1];
[1]Iwate Medical Univ., Shiwa, Japan, [2]Tokushima Univ., Tokushima, Japan

Introduction: Renal cell carcinoma (RCC) is a primary malignant kidney tumor. We reported on the critical role of Protein of Relevant Evolutionary and Lymphoid Interest Domain 2 (PRELID2) in cell proliferation, emphasizing its regulatory function on mitochondrial ROS and maintenance of mitochondrial spare respiratory capacity. Recent studies have begun to clarify the molecular mechanism of phospholipid biosynthesis by PRELID1 and PRELID3 under oxidative stress conditions. Inspired by this evidence, we analyzed the relationship between PRELID2 and phospholipid biosynthesis, aiming to elucidate the molecular mechanism of PRELID2 related to the control of mitochondrial ROS.
Methods: To analyze the dynamics of phospholipids and related mitochondrial molecules induced by oxidative stress, we examined the expression of YME1L and its substrates (OPA1, PRELID1) using Western blotting, which has been shown to be related to the turnover of other PRELI family proteins. Lipidomic analysis was performed using LC-MS on samples from HEK293 cells with stable expression of PRELID2 and control cells, as well as renal carcinoma cell lines with suppressed PRELID2 expression using siRNA and control cells. Additionally, we analyzed the expression of mitochondrial respiratory chain complexes Cytochrome C and COX4 and their relationship with PRELID2 expression via Western blotting.
Results: Oxidative stress led to a noticeable decline in YME1L expression, which was correlated with decreased OPA1 and PRELID1 levels in control cells. Conversely, PRELID2-overexpressing cells retained stable expression of OPA1 and PRELID1. Furthermore, these cells exhibited a significant reduction in phosphatidyl glycerol (PG) levels. Suppressing PRELID2 expression in 786-O cells using siRNA resulted in significantly higher PG levels. When analyzing the molecules of the mitochondrial respiratory chain during oxidative stress induction, we observed that although oxidative stress induced a decline in cytochrome C expression in control cells, it remained consistent in PRELID2-expressing cells. However, PRELID2 expression did not affect COX4 levels.
Conclusions: Our findings underscore the pivotal role of PRELIDs in maintaining mitochondrial homeostasis, proving instrumental in the oxidative stress-driven progression of renal cancer.

#7056 The role of aggressive prostate cancer risk gene *ANO7* in prostate metabolism.

C. Lof, N. Sultana, N. Goel, G. Wahlstrom, J. Schleutker;
University of Turku, Turku, Finland

Prostate cancer (PCa), the most common male cancer worldwide, causes about 10% of cancer related deaths in Europe. It has a wide spectrum of clinical behavior that ranges from decades of indolence to rapid metastatic progression and lethality. However, the molecular mechanisms involved in aggressive PCa progression are still poorly understood. In PCa the expression of anoctamin 7 (ANO7) has been shown to diminish as the cancer progresses. We have previously linked single-nucleotide polymorphisms in the *ANO7* gene to the risk of aggressive prostate cancer and shown that in homozygous carriers of rs77559646, the variant leads to a total loss of ANO7 protein. ANO7 is a prostate-specific gene and is highly expressed in the luminal cells of the human prostate. ANO7 belongs to a family of calcium-activated chloride channels and select members of the anoctamin family have phospholipid scramblase activity. To uncover the cellular functions of ANO7 has proven challenging because ANO7 is not expressed in commercially available cell lines. To study the cellular functions of ANO7, we have generated stable prostate cell lines overexpressing ANO7 using lentiviral transduction. To gain information into what pathways ANO7 is affecting, we performed RNA-sequencing and gene set enrichment analysis. Interestingly, we found enrichment and downregulation of mitochondrial genes participating in oxidative phosphorylation in ANO7 cells. We assessed the mitochondrial function by measuring the oxidative phosphorylation capability of the cells and showed that the basal and maximal respiratory capacity of ANO7 overexpressing cells is indeed reduced. We also analyzed which of the three major mitochondrial fuels (glucose, glutamine and fatty acids) are not used as efficiently for oxidative phosphorylation in ANO7 overexpressing cells. The result proves that ANO7 cells are not utilizing glucose as effectively as control cells. Furthermore, the glycolysis stress assay showed that glycolytic capacity is increased in ANO7 overexpressing cells. In addition, a targeted metabolite screening revealed that aspartate is decreased in ANO7 cells, which again points towards perturbed mitochondrial function as aspartate is produced from a tricarboxylic acid cycle intermediate. By inhibiting the uptake of extracellular aspartate, we measured slower proliferation of ANO7 expressing cells, while inhibiting aspartate had no effect on control cells. Interestingly, preliminary results also suggest ANO7's involvement in regulation of phospholipid acyl chain length and saturation, offering insights into altered signaling observed in ANO7 cells. Taken together, this study shows for the first time that ANO7 rewires prostate mitochondrial functions and thus cellular metabolism, which could explain why it is beneficial for cancer cells to lose ANO7 expression.

#7057 Validation of OXPHOS gene amplification as a driver of treatment resistance in non-small cell lung cancer.

M. Benej, K. Benejova, R. Hoyd, C. Wheeler, D. Spakowicz, N. C. Denko;
The Ohio State University Wexner Medical Ctr., Columbus, OH

Lung cancer is the leading cause of cancer deaths in the U.S. and worldwide. Up to 90% of all lung cancers are non-small cell lung cancer (NSCLC). NSCLC is a complex and highly aggressive disease typical for poor prognosis and high rates of treatment resistance. Clinical management of NSCLC varies according to the stage. High-dose stereotactic body radiation therapy (SBRT) is the standard of care for localized non-resectable NSCLC. However, tumor hypoxia is a significant barrier to effective radiation therapy. In the last decade, first line NSCLC treatment has been substantially reinforced with the introduction of immunotherapy targeting immune checkpoints such as programmed cell death 1 (PD-1), yet long-term disease control occurs in less than 25% of NSCLC patients. Therefore, understanding the mechanisms of treatment resistance is essential to address the dire need of introducing novel synergistic therapies to enhance anti-cancer treatment response in refractory NSCLC tumors. The basis of tumor hypoxia has traditionally been attributed to the oxygen supply deficit as malformed tumor vasculature fails to meet the high demand of the rapidly proliferating tumor mass. However, our preliminary analysis of NSCLC patient datasets in the Cancer Genome Atlas (TCGA) PanCancer dataset revealed a significant correlation between high-level expression of nuclear genes encoding mitochondrial subunits essential for oxidative phosphorylation (OXPHOS), and high-level expression of hypoxia-regulated genes (Buffa hypoxia score). Furthermore, we have observed a direct correlation between copy number amplification (CNA) of several OXPHOS genes and hypoxia levels in patient samples. Because mitochondrial function consumes up to 90% of available cellular oxygen, its activity may be indirectly regulating oxygen availability in the tumor microenvironment by rapidly consuming oxygen upon its delivery to the tumor. Moreover, we have identified that almost 40% of NSCLC patients harbor CNA of these essential OXPHOS genes. To provide mechanistic insight into these clinical observations, we have generated mouse syngeneic NSCLC cell lines with modified mRNA expression levels of OXPHOS genes (representing deletion, diploid and amplified number of copies) identified in our screen and observed a direct effect on the rates of mitochondrial oxygen consumption in these cells. Our study investigates the previously unknown role of OXPHOS gene copy number in driving mitochondrial oxygen demand and thus contributing to tumor hypoxia and treatment resistance in NSCLC.

#7058 NSD2 overexpression drives multiple myeloma dependence on adenylate kinase 2 by diverting one-carbon metabolism to the epigenome.

A. Sobh[1], E. Encinas[1], A. Patel[1], G. Surapaneni[1], C. Kaestner[1], J. Poullard[1], M. Clerio[1], K. Vasan[2], T. Freeman[3], D. Lv[4], D. Dupere-Richer[1], A. Riva[1], B. Barwick[3], D. Zhou[4], L. Boise[3], C. Mitsiades[5], B. Kim[3], R. Bennett[1], N. Chandel[2], J. Licht[1];

[1]University of Florida, Gainesville, FL, [2]Northwestern University, Chicago, IL, [3]Emory University, Atlanta, GA, [4]UT Health Science Center, San Antonio, TX, [5]Dana-Farber Cancer Institute, Boston, MA

Chromosomal translocation (4;14), an adverse prognostic factor in multiple myeloma (MM), drives overexpression of the oncogenic histone methyltransferase NSD2. Genome-wide CRISPR screens in isogenic MM cells with high and low NSD2 expression identified adenylate kinase 2 (AK2), an enzyme critical for transport of ATP from the mitochondria, as an NSD2-driven vulnerability. AK2 suppression in t(4;14) MM cells decreased NADP(H) critical for conversion of ribonucleotides to deoxyribonucleosides by the enzyme ribonucleotide reductase (RNR). Consequently, metabolomic studies revealed depletion of deoxynucleotide triphosphates (dNTPs) in AK2-deficient t(4;14) MM cells, which resulted in replication stress, DNA damage and apoptosis. Exogenous supplementation with deoxynucleosides rescued AK2 depleted MM cells confirming the role of AK2 in dNTP homeostasis. In addition, NSD2 overexpression drives a large genome-wide increase in chromatin methylation, which depletes the methyl donor S-adenosylmethionine (SAM). Accordingly, we found that high NSD2 expression in MM cells disrupts creatine biosynthesis, a process dependent on SAM. The creatine/phosphocreatine system represents an alternative means of transporting high energy phosphate from the mitochondria. Hence, creatine supplementation restored NADP(H) levels and rescued AK2-deficient t(4;14) MM cells indicating that the hypersensitivity of these cells to AK2 depletion is driven by creatine deficiency due to NSD2 overexpression. Furthermore, AK2 inhibition impaired ATP-dependent protein folding increasing sensitivity of t(4;14) MM cells to proteasome inhibition. These findings delineate a novel mechanism in which aberrant transfer of carbon to the epigenome creates a metabolic vulnerability, with direct therapeutic implications for t(4;14) MM.

#7059 Remodeling of anaplastic thyroid cancer metabolic signature by natural alkaloid berberine.

T. Jarboe, N. R. DeSouza, K. Kopec, J. Geliebter, X.-M. Li, R. K. Tiwari;
New York Medical College, Valhalla, NY

Anaplastic thyroid cancer (ATC) is a rare, fatal cancer with a five-year survival of 4%. Universally diagnosed at stage IV, ATC is characterized by its lack of differentiation and metabolic dysregulation. Refractory to all established therapies, we propose natural alkaloid berberine (BBR) as a therapeutic with multitarget efficacy to alter mitochondrial metabolism and reprogram ATC's aggressive phenotype. Assays used monocyte cell line U937, ATC cell lines T238 and SW1736, and immortalized normal thyroid cell line Nthy-ori-3-1. All assays used 100μM concentration of BBR or DMSO vehicle control for 24 hours for a tumoricidal effect. Validation of in vitro findings via RNA-Seq was conducted by Genewiz from Azenta and Qiagen's Ingenuity Pathway Analysis was used for in silico modeling. Mitochondria were isolated via differential centrifugation. Modeling the ATC tumor microenvironment, U937 cells were activated and polarized into a proinflammatory macrophage phenotype. BBR treatment at the activation/polarization stages, 33 soluble inflammatory mediators were downregulated in the conditioned media compared to controls. In targeting the aggressiveness of anaplastic thyroid disease, BBR slowed proliferation by 80% selectively in ATC cells from 48 to 72 hours, while sparing normal cells. BBR reduced migratory capacity by 30% in ATC cells after 24, 48, and 72 hours and reduced migration and invasion by 30%. These observations were substantiated by Western blot analysis - BBR selectively decreased phosphorylation of MEK, ERK, and ribosomal protein S6, crucial downstream regulators of the pro-proliferative and pro-survival pathways in ATC cells. Further, BBR specifically modulated cancer-associated metabolism as observed through an increase in AMPKα phosphorylation, a major rate-limiting protein in cancer-induced dysregulation with an anti-tumor effect. Validation of in vitro findings via RNA-Seq revealed more than 400 significantly differentially expressed genes involved in mitochondrial metabolism, glycometabolism, sirtuin signaling, apoptosis, and proliferation. Following a comprehensive analysis, we identified significant downregulation of 25 of 37 total mitochondrially encoded genes (MTs) and 13 of 13 mitochondrially encoded protein-coding genes comprising the oxidative phosphorylation complexes illuminating a clear link between BBR treatment and altered mitochondrial metabolism in ATC. Additionally, protein expression of significantly downregulated mitochondrial genes identified via RNA Seq was validated via Western blot demonstrating decreased mitochondrially-encoded protein expression related to oxidative phosphorylation. This work reveals a novel role for BBR as an inhibitor of mitochondrial metabolism that can be used to reprogram the aggressive nature of ATC and open the door for promising combination therapy in the treatment of ATC.

#7060 Mitochondrial metabolism and racial disparity of bladder cancer.

K. Kami Reddy[1], J. Park[1], R. J. Bollag[2], M. K. Terris[2], S. P. Lerner[1], M. Siddiqui[3], Y. Lotan[4], J. Gao[5], B. A. Kaipparettu[1], N. Putluri[1];
[1]Baylor College of Medicine, Houston, TX, [2]Augusta University, Augusta, GA, [3]Univeristy of Maryland school of medicine, Baltimore, MD, [4]UT southwestern Medical Center, Dallas, TX, [5]The University of Texas MD Anderson Cancer Center, Houston, TX

Bladder cancer mortality is significantly higher in African American patients compared to their European American counterparts. This inferior survival of African American cancer patients is driven at least in part by distinctive intrinsic tumor biology, more specifically altered metabolic activity. However, underlying molecular mechanism for the African American bladder cancer mortality are largely unexplored. Our pioneering metabolomic findings demonstrate alterations in metabolic pathways between African American and European American bladder cancer, specifically those involved in driving energy metabolism. Along these line, we observed increased electron transport chain activity and ATP production in African American bladder cancer could be a result of distinctive rewiring of energy metabolism compared to their European American counterparts. We further performed gene set enrichment analysis by mapping metabolites to genes and observed that oxidative phosphorylation pathway was uniquely enriched in African American tumors compared to European American tumors. In addition, from in vitro assays, mitochondrial complex protein and activity were altered in African American bladder cancer. To determine the role of glutamine mediated increased electron transport chain activity and ATP production in African American bladder cancer, we evaluated the metabolic flux using 13C labeled tracers in both African American and European American bladder cancer cell lines. Metabolic flux analysis revealed that African American cell lines are more glutamine dependent and that producing increased tricarboxylic acid intermediates. Overall, our data indicate that elevated mitochondrial metabolism and oxidative phosphorylation driven by enhanced glutaminolysis may facilitate African American bladder cancer progression. These findings provide the rationale to use mitochondrial-specific inhibitors to target at least a subset of African American bladder cancer patients.

#7061 Targeting metabolic vulnerabilities in ARID1A/B dual-deficient dedifferentiated endometrial carcinoma.

Rebecca Ho[1], Eunice Li[2], Chae Young Shin[2], Shary Chen[2], David Huntsman[1], Yemin Wang[1]

[1]Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada, [2]Molecular Oncology, British Columbia Cancer Research Institute, Vancouver, BC, Canada

Background: Dedifferentiated endometrial carcinoma (DDEC) is an aggressive endometrial carcinoma defined histologically by undifferentiated carcinoma juxtaposed against stage 1 or 2 endometrial adenocarcinoma. DDEC responds poorly to conventional platinum/taxane-based chemotherapy, particularly in the case of extrauterine spread. This highlights a need to develop novel therapies for individuals with DDEC. Genetically, a third of DDEC cases have co-inactivating mutations of *ARID1A* and *ARID1B*. These genes encode core subunits of the sucrose/switch non-fermentable (SWI/SNF) complex that regulate transcription. Furthermore, dual loss of ARID1A/B is believed to play a role in driving DDEC tumor development. We hypothesize that ARID1A/B dual-deficiency in DDEC generates unique genetic deficiencies that allow for the development of novel therapies for this cancer. We approached this hypothesis by first conducting a preliminary analysis of the Cancer Dependency Map (DepMap), which has identified vulnerabilities in mitochondrial functioning in ARID1A/B dual-deficient DDECs. As such, we aimed to understand the role of mitochondrial oxidative phosphorylation (OXPHOS) and redox homeostasis in ARID1A/B dual-deficient DDEC to create new treatment options.
Methods: A panel of ARID1A/B dual-deficient and proficient endometrial cancer cell lines were treated with OXPHOS inhibitor IACS-010759 and reactive oxidative species (ROS)-inducing agent elesclomol to identify shifts in drug response between the two groups. To account for genomic differences between the cell lines, we also treated an ARID1B knock-out isogeneic cell line with the drugs. Additionally, changes in metabolism in the endometrial cancer cell lines were measured using Seahorse metabolic flux assays to determine if ARID1A/B dual-deficient cell lines have an increased dependency on OXPHOS for cell growth.
Results: While the Seahorse assays revealed no significant difference in OXPHOS and glycolysis activities between the two groups, drug sensitivity assays demonstrated that ARID1A/B dual-deficient cancers are more sensitive to OXPHOS inhibition and increased ROS production than the proficient cell lines. Depletion of ARID1B in an ARID1A deficient cell line sensitizes the cells to both drugs. Furthermore, IACS-010759 significantly suppressed the growth of ARID1A/B-deficient DDEC xenograft tumor growth.
Conclusion: ARID1A/B-dual deficient cancer cells rely on mitochondria function for survival. The underlying mechanisms are currently under investigation.

#7062 CIP2A enhances mitochondrial respiratory electron transport chain complexes and induces lung cancer *in vivo*.

F.-Y. Yang, D. Wang, L.-J. liang, G.-Z. Wang, G.-B. Zhou;
Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Identification of oncogenes that can induce cancer *in vivo* is critical to elucidation of tumorigenesis and development of targeted therapies. Here, we reported for the first time that forced ectopic expression of CIP2A, the cancerous inhibitor of protein phosphatase 2A (PP2A), in lung tissues induced lung adenocarcinoma in mice. CIP2A upregulated the transcription and translation of mitochondrial DNA (mtDNA), and increases the enzymatic activity of mitochondrial electron transport chain (ETC) complex IV and V, thus enhancing the function of mitochondria and promoting the level of oxidative phosphorylation in tumors. CIP2A inhibited the binding of PP2A-B56α to FOXO3a, leading to the enhancement of the phosphorylation level of FOXO3a. The phosphorylated FOXO3a then translocated into the mitochondrion, and acted as a transcription factor to regulate CIP2A-mediated metabolic reprogramming in cancer cells. We found that oxidative phosphorylation inhibitors effectively inhibited CIP2A-induced cell proliferation. In non-small cell lung cancer, CIP2A level in tumor tissues was positively associated with the level of mtDNA. Our results indicated that CIP2A is able to induce lung adenocarcinoma in mice and has a critical role in mitochondrial oxidative phosphorylation, and represents a promising therapeutic target for non-small cell lung cancer.

#7063 Monitoring metabolic plasticity in the tumor microenvironment *in vivo* by mitophagy generated extracellular vesicles.

P. V. GADE, M. Howard, A. Rojas, L. Hasanzadah, L. Liotta, F. Kashanchi;
George Mason University, Manassas, VA

Tumor metabolic reprogramming is a hallmark of cancer progression, survival, and therapeutic resistance. A targetable class of cancer metabolic adaptation exploits mitophagy known to be linked to the cancer phenotype. Mitophagy selectively eliminates dysfunctional mitochondria by targeting them, via autophagosome shuttling, to the lysosome for degradation. Cancer cell mitophagy is triggered by elevated oxidative stress and mitochondrial DNA damage caused by hypoxia, radiotherapy, and immunotherapy. A high mitophagy demand can overwhelm the lysosome capacity resulting in the accumulation of damaged mitochondria and can suppress biogenesis of healthy mitochondria. We hypothesize that the newly discovered secretory mitophagy mechanism exports damaged mitochondrial fission-released segments to reduce the overload pressure on the lysosomal system, and thereby sustains cancer cell survival in the face of therapeutic mitochondrial stress. We have discovered a form of secretory mitophagy occurring *in vivo* in a growing solid tumor. Our molecular analysis of the full repertoire of extracellular vesicles, EVs, shed into the resident tumor interstitial fluid, IF, *in vivo* yielded a rich set of information about the functional state of mitochondria within the tumor cells, and the host cells. A set of proteins required for sequential steps of fission-induced mitophagy preferentially populated the CD81 positive IF EVs, including PINK1, DRP1 and FIS1. The export of cellular mitochondria proteins to CD81 positive EVs was confirmed by density gradient isolation from the bulk EV isolate followed by anti-CD81 immunoprecipitation, Mito Tracker export into CD81 positive EVs, ultrastructural characterization and Exoview analyzer. Further, we stimulated mitochondrial oxidative stress and blocked the fusion of the mitophagosome with the lysosome, which markedly stimulated the export of the secretory mitophagy unit. The outcome is new understanding of the importance of secretory mitophagy that can constitute a therapeutic target, and a new clinically relevant means of monitoring the in vivo state of mitophagic flux within the tumor microenvironment by means of mitophagy derived EVs.

#7064 BRCA 1/2 haploinsufficiency-associated metabolic dysfunction in benign fallopian tube epithelia.

J. Ravix, I. Paudel, G. Pulivendala, R. Sowamber, E. Smith, M. Schlumbrecht, D. Lombard, S. George;
University of Miami Miller School of Medicine, Miami, FL

In 3-17% of women with BRCA1/2 mutations who undergo risk-reducing surgery, pre-neoplastic and neoplastic lesions are found in their fallopian tubes that display differential loss of heterozygosity of BRCA1/2. Precisely how mutations in BRCA1/2 predispose women to develop high grade serous ovarian carcinoma (HGSC) is not completely understood. Although linked to various processes localized in the nucleus, BRCA1/2 may also have essential roles in the cytoplasm, specifically in the regulation of key processes associated with mitochondrial homeostasis and metabolism. Understanding how haploinsufficiency of BRCA1/2 contributes to the potential neoplastic transformation of fallopian tube epithelial cells should reveal new insights into BRCA1/2 function, and ultimately provide novel opportunities for preventative interventions in individuals with this mutation and new treatment opportunities for HGSC associated with BRCA1/2 heterozygosity. We have identified distinct metabolic and mitochondrial deficits in BRCA2 mutation carriers compared to BRCA1 carriers and non-carriers. Fallopian tube epithelial cell lines derived from BRCA2 mutation carriers showed increased levels of mitochondrial respiration and activity followed by BRCA1 mutation carriers and non-carriers. Western blot analysis of mitochondrial proteins regulating glycolysis and oxidative phosphorylation showed differential expression based on mutation status. Transmission electron microscopy of BRCA2 mutation carriers showed increased disrupted mitochondrial networks when compared to wild type, suggesting that mutation status may contribute to increased mitochondrial fission. These observations reveal an entirely new aspect of BRCA1 and BRCA2 biology and further studies will disaggregate the effects of BRCA1 and BRCA2 on mitochondrial function, versus DNA damage repair. Ultimately, this work will provide new insight into the adaptive changes within FT cells which promote neoplastic transformation and inform how high-grade serous carcinoma (HGSC) cells distinctively respond to microenvironmental stimuli.

#7065 AMBRA1 coordinates mitochondrial function to regulate cancer stemness and tumorigenesis in hepatocellular carcinoma.

Yan Liu[1], Yunong Xie[1], Yimiao He[1], Stephanie Ma[2], **Man Tong**[1]

[1]School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, China,[2]School of Biomedical Sciences, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China

Hepatocellular carcinoma (HCC) is a prevalent and aggressive cancer, with emerging evidence highlighting the role of cancer stem cells (CSCs) in its progression. AMBRA1 has been implicated to exert both tumor-promoting and tumor-suppressive roles through regulating cell cycle and mitophagy in various solid tumors. However, the functional roles of AMBRA1 in modulating cancer stemness and tumorigenesis in HCC remain elusive. Initial analysis of The Cancer Genome Atlas data revealed a significant inverse correlation between AMBRA1 expression and stemness indices (TSS) in HCC patients, with low AMBRA1 levels associated with an upregulated oxidative phosphorylation (OXPHOS) gene signature. To elucidate the functional consequences of AMBRA1 modulation in liver tumor development and stemness maintenance, we exploited both hydrodynamic mouse models and human HCC cell lines. Our findings indicate that hepatic AMBRA1 deletion enhances cancer stemness and tumorigenesis both in vivo and in vitro. Moreover, HCC cells with reduced AMBRA1 expression demonstrated heightened mitochondrial activity, characterized by increased oxygen consumption, respiration, mitochondrial membrane potential, and intracellular ATP levels. Apart from OXPHOS, we also observed a concomitant up-regulation and enrichment of MYC targets in TSS-high and AMBRA1-low HCC patients, pointing towards a deregulated c-MYC signaling to promote cancer stemness under AMBRA1 regulation in HCC. Collectively, our results demonstrate that AMBRA1 loss enhances mitochondrial function to support hepatic tumorigenesis in HCC.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Modifications and Signaling to Cancer Drivers
Poster Session

#7069 NEK2 is frequently upregulated in esophageal adenocarcinoma associating with poor prognosis.
L. Chen, H. Lu, F. Ballout, T. Hu, Z. Chen, **D. Peng**;
University of Miami, Miami, FL

Esophageal adenocarcinoma (EAC) has become a significant clinical challenge due to rapid increase in the incidence during the past four decades in the USA and Western countries. However, the prognosis of EAC patients is still poor with 5-year overall survival rate about 20%. There is an urgent need to identify novel therapeutic targets associated with EAC biology. NEK2 is the first identified human NEK (Never in mitosis A (NIMA) related kinase) gene among the 11 serine/threonine kinases family. Aberrant NEK2 expression is reported in a variety of human cancers and plays important roles in tumorigenesis, progression, and drug-resistance. However, the expression of the NEK2 in EAC and its precancerous condition (Barrett's esophagus, BE) has not been investigated. Using bioinformatic approaches, we first analyzed the TCGA and 9 GEO databases (a total of 10 databases in which eight contain EAC and 6 contain BE) and found that NEK2 was significantly upregulated in EAC as compared to normal esophagus in 7 of the 8 databases. Meanwhile, genomic alterations of NEK2 are only found in 1.2% of EAC. We validated the overexpression of NEK2 using qRT-PCR, western blotting, immunohistochemistry in EAC cell lines and in primary EAC tissues. Functionally, we demonstrated that overexpression of NEK2 in EAC cells promoted tumor cell growth. Targeting NEK2 in EAC cells significantly inhibited EAC tumor growth. Our data suggests that frequent overexpression of NEK2 plays an important role in EAC.

#7070 MEK-ERK signaling maintains epidermal proliferation through H2A.Z deposition.

S. Droll, B. Zhang, C. Xue, M. Levine, X. Bao;
Northwestern University - Evanston, Evanston, IL

Recent studies have connected dysregulation of H2A.Z deposition to glioblastoma as well as lung, pancreatic, and metastatic breast cancers. The H2AZ1 and H2AZ2 isoforms, collectively known as H2A.Z, are histone variants that regulate gene expression, stem cell identity, and differentiation during development and in homeostatic tissue. Most tumors originate from epithelial tissues. We utilize skin epidermis, an accessible model of epithelial tissue, to understand the regulatory mechanisms controlling proliferation and differentiation. Primary human epidermal keratinocytes retain their abilities to proliferate, differentiate, and stratify in vitro. First, we observed that progenitor keratinocytes express high levels of H2A.Z mRNA and protein, and that H2A.Z levels significantly and progressively decrease during four days of calcium-induced differentiation. Using ChIP-sequencing, we find a significant, genome-wide decrease in H2A.Z chromatin occupancy in differentiated keratinocytes. Therefore, we hypothesized that H2A.Z is critical for progenitor function. Knock down of either H2AZ1 or H2AZ2 significantly impaired keratinocyte proliferation in holoclone assays. Furthermore, H2AZ1 or H2AZ2 knockdown inhibited epidermal stratification in organotypic culture. Canonically, two chromatin remodeling complexes, SRCAP and EP400, deposit H2A.Z into nucleosomes. While both SRCAP and EP400 knockdown diminish keratinocyte proliferation, only SRCAP knockdown decreases H2A.Z deposition in epidermal keratinocytes. Finally, we find that MEK and ERK signaling is required to sustain expression of SRCAP, H2AZ1, and H2AZ2. MEK or ERK inhibition is sufficient to significantly decrease H2A.Z occupancy genome-wide in progenitor keratinocytes.

#7071 Pharmacological targeting of SUMOylation leads to cBAF complex stabilization and disruption of the synovial sarcoma signature.

K. V. Floros[1], J. Li[2], J. L. Roberts[1], R. Kurupi[3], C. K. Fairchild[1], B. Hu[1], Y. Xing[1], K. M. Dalton[1], S. A. Boikos[4], A. M. Stamatouli[5], M. G. Dozmorov[5], J. E. Koblinski[1], K. B. Jones[2], S. K. Radhakrishnan[1], A. C. Faber[1];

[1]Massey Comprehensive Cancer Ctr., Richmond, VA, [2]Huntsman Cancer Institute, Salt Lake City, UT, [3]Washington University School of Medicine, Saint Louis, MO, [4]Georgetown Lombardi Comprehensive Cancer Center, Washington, DC, DC, [5]Virginia Commonwealth University, Richmond, VA

Synovial Sarcoma (SS) is driven by the SS18-SSX translocation event and occurs often in people under 30. In general, SS is refractory to chemotherapy and other therapeutic approaches. SS18-SSX does not directly bind to DNA but instead alters BAF complexes away from a wild-type SS18-containing cBAF complex towards a SS18-SSX- containing ncBAF complex to drive a SS-specific transcription program. Small molecule targeted therapies are expanding beyond the kinome, providing additional tools to treat cancers that are not yet amenable to targeted therapies. Here we demonstrate that SS18-SSX activates the SUMOylation program and SS are sensitive to the small molecule SAE1/2 inhibitor, subasumstat (TAK-981). Mechanistically, we demonstrate TAK-981 de-SUMOylates the cBAF/PBAF complex member, SMARCE1, leading to stabilization and restoration of cBAF complexes. This phenotypic shift leads to a DNA damage and cell death response, resulting in tumor inhibition across mouse models of SS. As such, TAK-981 combined with standard-of-care chemotherapy enhances SOC-induced DNA damage, leading to tumor regressions. Targeting the SUMOylation pathway in SS restores cBAF complexes, positioning it as a clinical candidate to treat this refractory cancer.

#7072 MYC acetylated lysine residues drive oncogenic cell transformation and regulate select genetic programs for cell adhesion-independent growth and survival.

J. J. Pino[1], M. Hurd[1], Y. Zhao[1], K. Jang[1], M. Allevato[1], M. Vorontchikhina[1], W. Ichikawa[1], R. Gates[1], E. Villalpando[1], M. Hamilton[1], F. Failo[1], S. Pan[1], Y. Qi[2], Y.-w. Hung[2], T. Girke[1], D. Ann[2], V. Seewaldt[2], E. Martinez[1];

[1]University of California, Riverside, Riverside, CA, [2]City of Hope, Duarte, CA

The MYC oncogenic transcription factor is acetylated by the p300 and GCN5 histone acetyltransferases. The significance of MYC acetylation and functions of specific acetylated lysine (K) residues have remained unclear. Here, we show that the major p300-acetylated K148(149) and K157(158) sites in human (or mouse) MYC and the main GCN5-acetylated K323 residue are reversibly acetylated in various malignant and non-malignant cells. Oncogenic overexpression of MYC enhances its acetylation and alters regulation of site-specific acetylation by proteasome and deacetylase inhibitors. Acetylation of MYC at different K residues differentially affects its stability in a cell type- dependent manner. Lysine-to-arginine substitutions indicate that although none of the acetylated K (AcK) residues is required for MYC stimulation of adherent cell proliferation, individual AcK sites have gene-specific functions controlling select MYC-regulated processes in cell adhesion, contact inhibition, apoptosis, and/or metabolism, and are required for the malignant cell transformation activity of MYC. Each AcK site is required for anchorage-independent growth of MYC-overexpressing cells *in vitro*, and both the AcK148(149) and AcK157(158) residues are also important for the tumorigenic activity of MYC-transformed cells in vivo. These AcK residues may also preferentially activate transcription via facilitating MYC binding to several cancer-associated target gene promoters and via enhancing RNAP II recruitment. With the knowledge that MYC lysine residues can be acetylated by HATs GCN5 and P300, some HATs and HAT associated cofactors (i.e. YEATS2 and PIN1) are important for MYC recruitment to DNA binding. By identifying MYC acetylation-dependent coregulators and their oncogenic function, we proposed to understand whether and how MYC acetylation residues cooperate with its cofactors and influence malignant transformation in breast cancer cells.Overall, this study will uncover the functions and mechanisms of MYC acetylation in regulation of malignant transformation and the impact on breast cancer initiation and progression. By analyzing deregulated target genes and MYC-relevant coactivators, the MYC AcK site-specific signaling pathways identified may offer new avenues for selective therapeutic targeting of MYC oncogenic activities.

#7073 Integrating fragment-based crystallographic screening with dTAG-PROTAC degradation and genetic rescue to explore the function of eIF4E.

P. A. Clarke[1], S. Y. Sharp[1], M. Martella[1], C. I. Milton[1], C. East[2], M. Vinkovic[2], N. Wallis[2], G. Ward[2], C. Richardson[2], A. Woodhead[2];
[1]The Institute of Cancer Research, London, United Kingdom, [2]Astex Pharmaceuticals, Cambridge, United Kingdom

The translation initiation factor eIF4E is a rate-limiting factor for protein synthesis that binds the mRNA m7G-cap to initiate the recruitment and binding of eIF4F components such as eIF4G. Targeting eIF4E has long been considered a promising anticancer strategy but it has remained undruggable using conventional screening approaches. Fragment-based crystallographic screening is a powerful technique for probing the surface of proteins to identify potentially druggable binding sites. Here, we describe fragment-based screening using a combination of Xray crystallography and NMR to identify low affinity fragment hits binding to the mRNA cap-binding site or at an additional site of unknown functional relevance (site 2). Subsequent rounds of iterative structure-based design yielded a lead molecule, with 100nM binding potency for site 2, that could disrupt the eIF4E:eIF4G interaction and inhibit cap-dependent translation in cell lysates. To explore the functional relevance of site 2 we established a cell model expressing an eIF4E-FKBP12F36V fusion protein that was sensitive to degradation following treatment with the heterobifunctional dTAGV-1 molecule. Degradation of eIF4E resulted in inhibition of cell growth and reduced expression of MCL1 protein, that were rescued by re-expression of a non-degradable wild-type eIF4E. A mutation reported to block canonical eIF4G binding (W73F) disrupted binding to eIF4G but to our surprise retained the ability to rescue the eIF4E degradation phenotype. Mutation of site 2 (L85R and L134R) also disrupted the eIF4E:eIF4G interaction. The L85R mutant remained able to partially rescue the cellular responses, in contrast to the L134R mutant that could not rescue eIF4E loss. The W73F/L85R double mutant resulted in a combinatorial loss of eIF4E function. Despite disrupting eIF4E function in lysates, there was a significant drop-off of compound activity in cells. However, treatment of the W73F mutant with compound recapitulated the combination of the W73F canonical eIF4G binding mutation with the L85R site 2 mutation. This approach demonstrates the power of coupling fragment screening with target-degradation and genetic rescue approaches to find and explore novel functional pockets. Our data suggest it may be necessary to disrupt the extended protein-protein interaction made by both the canonical and non-canonical regions of eIF4E to drive a strong functional effect in cells. However, the discovery of a lead compound, the associated structural understanding, and the knowledge that one site 2 mutation inactivates eIF4E provides hope that a significantly more potent small molecule inhibitor or degrader could drive a more profound cellular effect which may lead to improved cellular activity and a deeper understanding of eIF4E biology.

#7074 Perturbed RNA N6-methyladenosine methylome in SETD2 mutant clear cell renal carcinoma.

S. Shaikh, R. Wagner, R. Hlady, K. D. Robertson;
Mayo Clinic College of Medicine and Science, Rochester, MN

Clear cell renal carcinoma (ccRCC), which arises from the epithelial cells of the proximal tubule represents 70% of all renal cell carcinoma. Mutations that drive ccRCC in conjunction with near ubiquitous and early VHL loss include, PBRM1 (33 - 45%), BAP1 (15%) and SETD2 (13%). Loss of SETD2 leads to diminished occupancy of H3K36me3 in active gene bodies, which is progressively deregulated in primary RCC and metastasis, linking loss of H3K36me to tumor progression and metastasis. N6-Methyladenosine (m6A) is an important post-transcriptional regulator of RNA transcript stability and half-life. Preliminary findings have shown H3K36me3 (deposited by SETD2), targeting the core m6A methyltransferase machinery (METTL3, METTL14 and WTAP) to the mRNA by virtue of its interaction to METTL14 subunit. The goal of this study is to investigate if H3K36me3 depletion as observed in SETD2 mutant ccRCC, leads to a deregulated m6A methylome. We further investigate how deregulated methylome in key pathways leads to cancer initiation and progression in ccRCC. To accomplish our goals, we generated isogenic ccRCC cell lines with H3K36me3 depletion by knocking out SETD2. RNA-immunoprecipitation and sequencing for m6A (MeRIP) showed global deregulation of m6A methylome in SETD2KO isogenic ccRCC cell lines. We also show a number of pro-tumorigenic genes and pathways including cell invasion, inflammation and stemness being differentially methylated and expressed in SETD2KO ccRCC cell lines. Furthermore, we show SETD2KO cells being more sensitive to METTL3 inhibition suggesting the relevance of m6A hypermethylated transcripts in promoting pro-tumorigenic and growth promoting processes in SETD2KO ccRCC cell lines.

#7075 Global epitranscriptomic and transcriptomic footprint revealed upregulation of methylated single minded 2-small variant (meSIM2-SV) in colorectal cancer (CRC) by NTMT1(METTL11A) via m6A-YTHDF1-dependent manner..

S. K. Rai[1], T. Gong[1], Z. Gao[1], Y. Qin[1], M. Huo[1], K. Nakastu[1], H. Yang[1], Y. Fu[1], L. Wu[1], M. Jijiwa[1], M. Nasu[1], S. Chen[1], G. Huang[2], P. Fei[1], Y. Deng[1];
[1]John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI, [2]Shanghai University of Medicine and Health Sciences, Shanghai, China

Establishing global footprint of altered m6A mRNA is a unique method to identify the new prognostics biomarkers. Altered N6-methyladenosine(m6A) RNA methylation regulates cancer progression with uncharacterized mechanism. Here, we present novel link between m6A modification on 5'-UTR SIM2-SV contribution in colorectal cancer progression. MeRIP and RNA-seq data from 68 fresh frozen CRC samples revealed 13,843 altered m6A methylated peaks and found highest in chromosomes 1, 2, and 3. Analysis uncovered 119 overlapping genes and clusters into 32 up-regulated genes with 56 up-hyper peaks, 8 up-regulated genes with 9 up-hypo peaks, 12 down-regulated genes with 14 down-hyper peaks, and 28 down-regulated genes with 40 down-hypo peaks. A significant increase in the SIM2 m6A and RNA level led us to perform correlation analysis between the SIM2SV and m6A RNA regulators. SIM2SV was significantly correlated with YTHDF1 m6A-readers and m6A-NTMT1 writer, suggesting important roles of SIM2SV in CRC oncogenicity. m6A-sequencing identified m6A enrichment in 5'-UTR of SIM2SV gene which further verified. siNTMT1 and siYTHDF1 manipulation in HCT116 and RKO cell lines verified a decrease in SIM2SV gene/protein expression, and m6A level. Knockdown effects also showed decrease in cell proliferation, clonogenicity and induced cell cycle arrest in the G2/M phase for NTMT1 and YTHDF1 versus SIM2 Knockdown showed cell cycle arrest in S/G2 phase. Our investigation revealed the role of new writer NTMT1 for methylated SIM2SV gene expression in colorectal cancer proliferation via m6A-YTHDF1(as “decoder”) dependent manner. Further investigation on m6A modification specifically on SIM2 mRNA revealed the essential roles of its writer NTMT1 and its reader YTHDF1 in CRC development, evidently supporting the importance of the unique landscape of m6A epigenetic modification in colorectal neoplasm, which not only advance our understanding of CRC pathobiology but also provides a new set of molecular targets for building up effective tools to fight CRC.

#7077 The oncogenic transcription factor ERG has distinct roles and signaling in different prostate cancer cell types.

Saranya Rajendran, **Peter C. Hollenhorst**

Indiana University School of Medicine, Bloomington, IN

ERG is the most common oncogene in prostate cancer, as it is aberrantly expressed in about 50% of cases due to the TMPRSS2/ERG gene rearrangement. ERG is not normally expressed in the adult prostate. The normal function of ERG is confined to hematopoietic stem cells and blood vessels. Aberrant expression of ERG in prostate epithelial cells is oncogenic when combined with mutations that activate the PI3K/AKT signaling pathway. The RAS/MAPK pathway can also regulate ERG function through direct phosphorylation of ERG by ERK. The function of these regulatory events and how they can be exploited to develop therapy for ERG-positive prostate cancer remains unclear. Here we find that ERG expression in prostate epithelial cells with low PI3K/AKT pathway activity drives epithelial to mesenchymal transition and stemness properties. This function requires ERG phosphorylation via a positive feedback loop with the TLR4 signaling pathway, and can be repressed by a TLR4 inhibitor. However, activation of the PI3K/AKT pathway rearranges the ERG cistrome and alters ERG function, where ERG now promotes luminal epithelial differentiation. In the presence of activated AKT, new ERG targets include genes involved in vascular development and ERG phosphorylation is regulated through a positive feedback loop with the VEGF signaling pathway. Despite these differences in cellular differentiation, we find that ERG can promote stemness and tumorigenesis in both AKT-high and AKT-low cellular backgrounds. ERG functions in prostate epithelial cells appear to mirror ERG functions in hematopoietic stem cells and blood vessels. These findings suggest strategies of combinatorial inhibition of ERG function through signaling pathway inhibition.

#7078 Targeting eIF6 to modulate ribosomal subunit association dynamics in cancers.

K. M. Harish, P. Roshan, A. Biswas, S. Anagnos, R. Luebbers, S. Origanti;
Saint Louis University, St. Louis, MO

Deregulation of ribosomal subunit levels and accessibility are hallmarks of cancer. Eukaryotic translation initiation factor 6 (eIF6) is a key regulator of ribosomal subunit association that is over expressed in many cancers including lung, colon, ovarian and breast cancers, and deregulation of eIF6 is correlated with a poor cancer prognosis. Association of eIF6 with 60S is critical for 60S assembly. However, eIF6 must be released from 60S prior to translation to permit inter subunit interactions between 60S and 40S and to facilitate the formation of translationally proficient 80S monosome. Release of eIF6 is deregulated in the ribosomopathy- Shwachman Diamond Syndrome that is predisposed to leukemias. Also, loss of eIF6 markedly delays tumorigenesis without affecting normal growth, which presents eIF6 as a viable therapeutic target. A potential therapeutic strategy is to target the eIF6 and 60S ribosomal interaction interface. Through biophysical analyses we had identified residues that are critical for the interaction between eIF6 and 60S ribosomal subunit. We show that targeting these key residues in the eIF6-60S interaction interface markedly delays colonic cancer growth and inhibits protein synthesis. Furthermore, we show that the levels of other eIFs and the release factors: SBDS, and EFL1-GTPase are unaltered in the mutant cells suggesting that the translational inhibition is primarily attributed to the deregulation of eIF6. Interestingly, targeting eIF6 leads to an upregulation of p53 independent of the DNA damage response, suggesting that ribosomal stress contributes to the stabilization of p53. Previously, it was shown that translation of Cdc42 was upregulated by eIF6 to promote invasiveness. However, Cdc42 levels were unaltered in the mutant cells. Future studies will determine the mRNA substrates that are translationally deregulated in the mutants. We will also determine the effect of disrupting eIF6 function in inhibiting tumor growth and progression *in vivo*.

Category: MCB, Subcategory: MCB07-Gene regulation sub classification: Translational Control

#7079 The Wnt/β-catenin signaling pathway regulates cellular metabolism through the suppression of HAL and ARG1 in liver cancer cells.

S. Nakagawa[1], K. Yamaguchi[1], K. Takane[1], S. Tabata[2], T. Ikenoue[1], Y. Furukawa[1];

[1]University of Tokyo, Tokyo, Japan, [2]National Cancer Center, Yamagata, Japan

Aberrant activation of the Wnt/β-catenin signaling pathway plays a crucial role in a wide range of human tumors including colorectal and liver cancer. The activated signaling causes nuclear accumulation of β-catenin, which leads to the elevated expression of target genes of TCF/LEF (T-cell factor/lymphoid enhancer factor) transcription factors through their interaction with nuclear β-catenin. Recent studies have identified a lot of genes induced by this pathway such as *MYC*, *CCND1*, *AXIN2*, and *LGR5*, and clarified their roles in tumorigenesis. However, the roles of the genes down-regulated by the pathway remain to be elucidated. Our previous study revealed that the histidine ammonia-lyase gene (*HAL*) encoding an enzyme involved in the catabolism of histidine was down-regulated by the signaling pathway in liver cancer. In addition, we identified a region that is involved in the Wnt-dependent regulation of *HAL*. To clarify the regulatory mechanism of *HAL* by the pathway, we searched for transcription factors that are associated with the regulatory region, and identified CEBPA and FOXA1, two liver-enriched transcription factors. It is of note that the expression of these factors was reduced by the TCF/β-catenin complex. Further investigation identified arginase 1 (*ARG1*) encoding an enzyme that catalyzes the hydrolysis of arginine as another target gene of CEBPA and FOXA1. Consistent with these data, inhibition of the Wnt signaling increased the expression of ARG1 as well as HAL in liver cancer cells. Furthermore, the up-regulation of HAL and ARG1 by the inhibition of this pathway decreased intracellular concentrations of histidine and arginine, suggesting that the Wnt signaling plays an important role in cellular metabolism through the regulation of the two transcription factors. These findings shed light on the role of the Wnt/β-catenin signaling pathway in the metabolism of amino acids in liver cancer cells.

#7080 Regulation of caveolin-1 by RAS/RAF oncogenic signaling in cancer cells.

V. Castro Aceituno, T. Cui, H. Feng, L. Yang, S. Nair, T. M. Williams;
City of Hope National Medical Center, Duarte, CA

Background and Purpose: Caveolin-1 (Cav-1), a scaffolding protein implicated in cellular signaling and membrane dynamics, undergoes intricate regulation at multiple levels. Recent evidence has suggested a potential association between oncogenic mutations and alterations in Cav-1 expression. Our study aimed to comprehensively explore how RAS/RAF mutations influence Cav-1 expression in cancer cells, as well as the underlying molecular mechanisms, using tetracycline (tet)-inducible cell lines and cancer cell lines harboring endogenous BRAF or KRAS mutations.

Experimental Design: We assessed the regulation of Cav-1 expression using tet-inducible cell lines with $BRAF^{V600E}$, $KRAS^{G12D}$, or $KRAS^{G12C}$ mutations. We measured the half-life of Cav-1 at protein levels by using cycloheximide. We monitored Cav-1 localization and degradation dynamics by SNAP-based pulse-chase assay. Additionally, we performed protein and gene expression analyses by immunoblotting and qRT-PCR, luciferase reporter assay, and immunofluorescence to dissect the impact of BRAF and KRAS mutations on Cav-1 regulation at various stages of its life cycle.

Results: We found a significant downregulation of Cav-1 at both mRNA and protein levels upon induction of BRAF or KRAS mutations. The use of $KRAS^{G12C}$, $BRAF^{V600E}$, ERK, and/or MEK inhibitors in tet-inducible cell lines rescued the effects observed upon induction. The rescue effects have also been observed in H23, MiaPaCa-2 and 8505-C cancer cell lines bearing either BRAF or KRAS mutations. Notably, $BRAF^{V600E}$ exhibited a more pronounced reduction in Cav-1 expression than other mutations. We observed shortened half-life of Cav-1 at protein levels after induction of RAS/RAF mutations by using cycloheximide, and SNAP-based pulse-chase. These mutations accelerated lysosomal-mediated degradation of Cav-1 as determined by immunoblotting and immunofluorescence, which was reversed by lysosomal inhibitors.

Conclusions: Our study establishes a novel regulatory paradigm wherein RAS/RAF mutations exert a multi-faceted influence on Cav-1 dynamics in cancer cells. The transcriptional and translational downregulation, coupled with accelerated lysosomal degradation, collectively contributes to the decreased half-life of Cav-1 following the induction of BRAF or KRAS mutations. These findings provide insights into the intricate molecular mechanisms underpinning the dysregulation of Cav-1 in the context of RAS/RAF mutations, offering potential avenues for therapeutic interventions.

#7081 Comprehensive investigation of NAT10's catalytic and non-catalytic functions in cancer cell proliferation.

S. P. Raikundalia, **M. Dalhat**, E. A. Patrasso, A. Suh, D. Arango;
Northwestern University - Chicago, Chicago, IL

N-acetyltransferase 10 (NAT10) is emerging as an oncoprotein in multiple cancers including acute myeloid leukemia and liver cancer. In addition, my preliminary studies show that NAT10 is a stress response that promotes the resilience of cancer cells to anti-tumor drugs. However, the underlying mechanisms by which NAT10 promotes cancer growth and drug resistance are unknown. NAT10 is an RNA acetyltransferase, where it acetylates cytidines in rRNA, tRNA, mRNA, and lncRNAs. Our previous work demonstrated that NAT10 promotes translation efficiency and mRNA stability through the acetylation of cytidines in mRNA. However, NAT10 is a multifunctional protein. Besides acetylating RNA, NAT10 also acetylates proteins at lysine residues, has RNA helicase activity, and can serve as a scaffold in ribonucleoprotein complexes. Based on this complexity, it is imperative to elucidate whether NAT10 exerts its oncogenic activity via RNA acetylation, protein acetylation, disruption of RNA structures, or non-catalytic functions. Strikingly, our preliminary results indicate that the acetyltransferase function of NAT10 is dispensable for cell proliferation. To evaluate NAT10's oncogenic activity unbiasedly, we are now performing a deep mutagenesis scanning (DMS) assay. For this purpose, we generated a library of mutants in hundreds of NAT10 residues. This library was transduced in multiple cell lines from acute myeloid leukemia and liver cancer carrying a PROTAC system, which allow us to deplete NAT10 in a rapid and controlled manner while expressing ectopically thousands of NAT10 mutants. In this conference, I will talk about, my results, how DMS is a powerful tool to delineate the molecular functions of candidate oncoproteins, and the implications of our results for the potential drugging of NAT10 in cancer.

Keywords: Cell proliferation, NAT10, RNA modifications, Deep mutagenesis scanning.

#7082 Epidemiology meets epitranscriptomics: Exploring the cancer-related role of a novel *TERT*-antisense transcript and its regulation by RNA methylation.

B. W. Papenberg[1], O. Florez-Vargas[1], M. Ho[1], K. Forsythe[1], C. Zhang[1], C.-H. Lee[1], S. Mbulaiteye[1], P. J. Batista[2], L. Prokunina-Olsson[1];
[1]National Cancer Institute, Rockville, MD, [2]National Cancer Institute, Bethesda, MD

Human telomerase reverse transcriptase (TERT) maintains telomeres at chromosome ends and its dysregulation is implicated in various human health conditions. Multiple GWAS signals are detected within the *TERT* genomic region at chr 5p15.33. As a potential proxy for these signals, we investigated a highly polymorphic variable number tandem repeat (VNTR)2-1 within intron 2 of *TERT*, with 57-143 copies of a 42 bp repeat unit per allele. By functional annotation of VNTR2-1, we predicted that it generates an intronic transcript antisense to *TERT* with a variable-size open reading frame (ORF) of 2502-5211 bp (834-2038 aa). Specific to the *TERT*-antisense transcript, we predicted N6-methyladenosine (m6A) consensus motifs within each 42 bp unit of VNTR2-1, with longer VNTR2-1 regions carrying more m6A motifs. In a stranded RNA-seq dataset of African pediatric Burkitt lymphoma (BL) tumors, which have high *TERT* expression, we detected the VNTR2-1-containing *TERT*-antisense transcript in a subset of tumors (n=35/113, 30.9%), confirming the expression of this novel transcript. VNTR2-1 expression was also experimentally validated by 5'-RACE/Nanopore-seq in Raji (BL cell line) and UMUC3 (bladder cancer cell line). Additionally, the VNTR2-1 transcript was visualized in UMUC3 cells using RNA-FISH.

The consensus 42 bp VNTR2-1 repeat sequence and its m6A-deficient variants were cloned into a m6A-deficient dual-luciferase reporter vector (m-psiCHECK-2) and expressed in UMUC3 cells, showing an m6A-motif dose-dependent response driving luciferase protein expression. Transient treatment with STM2457, an inhibitor of the m6A writer METTL3, reduced the expression of the luciferase reporter, confirming that m6A motifs within VNTR2-1 are methylated by METTL3. Additionally, Long-term cigarette smoke condensate (CSC) treatment of UMUC3 reduced luciferase expression, suggesting alterations of VNTR2-1 m6A due to smoke exposure.

We explored potential peptides produced from VNTR2-1 transcript by analysis of public mass spectrometry datasets using PepQuery and identified several unique VNTR2-1 peptide fragments in human tumors. Next, we cloned a synthetic FLAG-tagged gene containing three VNTR2-1 consensus repeats with native Kozak sequence and translation start/stop codons. Western blotting confirmed the translation of the VNTR2-1 peptide that was ablated by start codon mutation, suggesting that the native Kozak sequence is sufficient for VNTR2-1 translation. These results support VNTR2-1 as a peptide-producing transcript.

In conclusion, we identified a novel intronic transcript produced by VNTR2-1 antisense to *TERT*. This m6A-regulated transcript could function through several mechanisms, such as a lncRNA or translated peptide, potentially regulating *TERT* expression and telomerase function in health and disease conditions, including cancer.

#7088 MALDI-IHC high-plex protein biomarker imaging for fast, non-iterative identification of lung carcinoma subtypes.

Catherine A. Kita[1], Kristina Schwamborn[2], Gargey Yagnik[1], Kenneth J. Rothschild[1], Mark J. Lim[1]

[1]AmberGen Inc, Billerica, MA,[2]Technische Universitat Munchen, Munchen, Germany

Lung cancer is the second most common cancer worldwide, with over 2.2 million new cases in 2020 and is the leading cause of cancer-related deaths worldwide. Most lung cancer (80-85%) is non-small cell (NSCLC), comprising mostly adenocarcinoma and squamous cell carcinoma, while roughly 10-15% of lung cancer is small cell lung cancer (SCLC), also termed neuroendocrine lung cancer. Subtype identification is critical for determining treatment, and with limited samples, it is critical to get the most data possible from each tissue section. NSCLC subtypes can be treated with chemotherapy or targeted drugs, whereas SCLC tends to respond best to a combination of chemotherapy and radiation. While there have been many improvements in the detection and treatment of lung carcinoma, the immuno-histochemical (IHC) confirmation of subtype remains a prolonged and often iterative process. To overcome this limitation, we have developed a new IHC approach which uses antibodies labeled with novel photocleavable mass-tags combined with matrix assisted laser desorption ionization (MALDI) mass spectrometry imaging. The approach, termed MALDI-IHC, provides fast (1 hr/cm^2 imaging time) and highly multiplexed IHC (100+-plex) without the need for iterative cycling procedures. Here, we present a 20+-plex panel for the determination of subtype in lung cancer. An antibody panel comprised of established clinical biomarkers was developed to differentiate between the lung carcinoma subtypes and provide potentially prognostic information. This included markers for adenocarcinoma (TTF-1, Napsin A), squamous cell carcinoma (p40, CK5), and small cell lung cancer (CD56, Chromogranin A and Synaptophysin), as well as general carcinoma markers for t cells, b cells, macrophages, and fibroblasts These markers were first validated individually by immunofluorescence and then compared to MALDI-IHC on annotated tissues. Here we present an overview of the antibody validation for the 20+-plex lung carcinoma panel. Biomarker presence and peak signal intensity for the various subtypes was then determined using pathologist classified tissues for normal lung, adenocarcinoma, squamous cell carcinoma and small cell lung cancer. We report application of the MALDI-IHC approach to the simultaneous determination of lung carcinoma subtypes on a 99-core human lung tissue microarray (TMA) comprised of normal, normal adjacent, cancer adjacent, and cancerous tissues. Moreover, because MALDI-IHC is a non-destructive process, it can be followed by conventional H&E staining on the same tissue section for accurate co-registration of traditional pathology annotations with the highly multiplexed MALDI-IHC results. In the future, even larger, 100+-plex antibody panels can be used for precision medicine on a wide range of cancers, in order to determine the molecular subtypes and guide treatment paths.

#7089 Proteomic evaluation of combination data in acute myeloid leukemia to inform mechanism of action and new targets.

L. Chan[1], Z. Ozen[1], A. Iannetta[1], E. Miele[1], F. Kar[1], A. Jarnuczak[1], G. Nelson[1], A. Markovets[1], J. Roderick-Richardson[1], J. Urosevic[2], L. Drew[1], J. Mettetal[1]; [1]Astrazeneca, Waltham, MA, [2]Astrazeneca, Cambridge, United Kingdom

Background: Acute myeloid leukemia (AML) is a prevalent adult leukemia. In the US, around 20,380 individuals were diagnosed with AML in 2023. Despite standard therapies, relapse and resistance persist. Cyclin-dependent kinase 9 (CDK9) has been recognized an actionable therapeutic target in AML. The potent inhibitor, AZD4573, induces durable apoptosis and suppresses tumor growth. Our study reveals that combining AZD4573 with standard-of-care (SoC) treatments deepens cell death responses in multiple AML cell models. We also used proteomics tools to understand the mechanisms underlying the vulnerability and resistance in SoC and CDK9 combinations.

Methods: In the drug combination study, three SoC agents (cytarabine, decitabine, and venetoclax) were evaluated in combination using a 6x6 dose-response matrix in four AML cell models (MOLM13, MOLM16, MV411, and OCI-AML2). The HSA synergy score and Emax drug activity were used to assess the benefits of the drug combinations. In the proteomics evaluation study, MOLM13 cells treated for 7 days under different conditions - (1) vehicle control; (2) cytarabine alone; (3) decitabine alone; (4) venetoclax alone; (5) AZD4573 alone; (6) AZD4573+cytarabine; (7) AZD4573+decitabine; (8) AZD4573+venetoclax - were collected for proteomics analysis using LC-MS/MS. Differential expression and missing pattern analyses were used to identify dysregulated proteins. Functional enrichment analysis was employed to identify dysregulated biological processes and pathways in response to different treatments.

Results: Our drug combination screens demonstrated the efficacy of AZD4573 in combination with cytarabine, decitabine, and venetoclax in 3 of 4 AML cell models. In our proteomic analysis, we took two approaches. First, we compared the proteomes of AML cells treated with SoC agents, identifying shared downregulated pathways such as serine biosynthesis, notably pointing to the rate-limiting enzyme PHGDH as a potential therapeutic target in AML. Cytarabine and decitabine induced an inflammatory response, while venetoclax increased the expression of cell division regulators like Aurora kinase B (AURKB). Interestingly, targeting AURKB with AZD2811 has been shown to overcome venetoclax resistance in AML. Second, we compared proteome changes induced by various AZD4573 combinations. We identified IRF2BP2 as a shared vulnerable protein across the three AZD4573 combinations. POUF2F2 expression was significantly induced by cytarabine but suppressed when combined with AZD4573. Given that POUF2F2 activates the PDK1-Akt pathway, our findings suggest that AZD4573-induced POUF2F2 downregulation suppresses the PDK1-AKT pathway, inhibiting tumor progression.

Conclusions: Our proteomics analysis identifies vulnerable and resistant pathways and proteins, shedding light on the mechanism of action and revealing potential new targets for AML.

#7090 A scaled proteomic discovery study for prostate cancer diagnostic signatures using Proteograph workflow with trapped ion mobility mass spectrometry.

Mark Flory[1], Matthew Chang[1], Jessie May Cartier[1], Jane Lange[1], Travis Moore[1], James McGann[1], Ryan Kopp[2], Michael Liss[3], Robin Leach[4], Brenna Albracht[4], James Dai[5], Michael Krawitzky[6], Eltaher Elgierari[7], Jessica Chu[7], Paul Pease[7], Max Mahoney[7], Shadi Ferdosi[7], Ryan Benz[7], Khatereh Motamedchaboki[7], Asim Siddiqui[7], Mahdi Zamanighomi[7], Amir Alavi[7], Harendra Guturu[7], Daniel Hornburg[7], Serafim Batzoglou[7]

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]Urology, School of Medicine, Oregon Health & Science University, Portland, OR,[3]Urology, University of Texas Health San Antonio, San Antonio, TX,[4]Cell Systems and Anatomy, University of Texas Health San Antonio, San Antonio, TX,[5]Biostatistics, Fred Hutchinson Cancer Research Center, Seattle, WA,[6]Bruker Daltonics, Billerica, MA,[7]Seer, Inc., Redwood City, CA

Background and Aims: The low cancer specificity of serum Prostate-Specific Antigen (PSA), the principal biomarker for prostate cancer detection, leads to a high frequency of unwarranted prostate biopsies. To alleviate this deficit, we executed a proteomic discovery study seeking PSA reflex signatures using the Proteograph™ Product Suite, a multi-nanoparticle-based deep plasma/serum proteomics workflow (Seer, Inc.), with timsTOF Pro mass spectrometry (Bruker) to interrogate over 900 serum specimens from patients that underwent prostate biopsy due to elevated PSA and/or abnormal digital rectal exam.
Methods: Our study followed rigorous design principles including uniform collection, randomization and blinding of specimens, all of which were processed with the Proteograph Product Suite. Liquid chromatography-mass spectrometry (LC-MS) analyses leveraged the Bruker timsTOF Pro MS platform utilizing 30-minute reversed-phase chromatography and a label-free dia-PASEF (data independent acquisition - parallel accumulation serial fragmentation) data acquisition method. Peptides deriving from a chosen subset of specimens designed to maximize peptide diversity were pooled, fractionated and analyzed using DDA (data-dependent acquisition)-PASEF to build a spectral reference library.
Results: The DIA-NN algorithm was employed through the cloud-based Proteograph Analysis Suite (PAS) to search LC-MS data. Leveraging our study-specific spectral library proteomic depth achieved was approximately 3600 protein groups identified (median) per patient serum specimen and more than 4400 in at least 25% of samples across the study. Customized machine learning workflows and the SeerML pipeline were used to identify and assess diagnostic power of new proteomic signatures.
Conclusions: Our data demonstrate the remarkable proteomic depth achievable in a scaled patient serum specimen discovery study using a combination of Proteograph and timsTOF platforms. This significant effort revealed serum proteomic signatures with increased diagnostic performance over that provided by PSA blood measurement and traditional patient-associated metadata alone, providing a foundation for future clinical tests aimed to reduce the current high frequency of unnecessary prostate biopsy.

#7091 Significance of the tryptophan catabolism pathway in triple-negative breast cancer shows potential targets in certain subsets relating to the serine pathway.

J. Jeon, A. Achreja, M. Slayton, O. Animasahun, M. Nenwani, M. Paserba, Z. Farah, S. D. Merajver, D. Nagrath;
University of Michigan, Ann Arbor, MI

Background: Breast cancer (BC) is the most prevalent form of cancer worldwide, encompassing 12.5% of all forms of cancers with the fifth highest mortality rate. Triple negative cancers (TNBC), which account for 15~20% of BCs, are one of the most aggressive and heterogeneous forms of BCs, characterized by the loss of ER, PR, and low HER2 expression. This heterogeneity and plasticity are partly due to the adaptable nature of their metabolism, a dynamic phenotype which is commonly observed in many aggressive forms of cancer. One of the key metabolic pathways that can confer this aggressive proliferative characteristic is the tryptophan catabolism pathway. Tryptophan is an essential amino acid required for the proper function of all mammalian cells, with IDO1 being a key enzyme that converts tryptophan to kynurenine, marking the start of the catabolism pathway. IDO1 expression is observed to be elevated in various types of cancer including BCs and has been associated with immune suppression/evasion via resource competition and tumor progression by supplying resources required for proliferation. Despite this, tryptophan catabolism is one of the lesser studied and understood pathways in cancer metabolism, especially in the context of TNBCs.

Methods: Previous analysis had shown the tryptophan catabolism pathway is downregulated in certain subsets of TNBCs. To understand the effective function of the pathway with regards to proliferation, we targeted the upper-most step of the catabolism pathway by inhibiting IDO1 with epacadostat and indoximod in different types of TNBC cell-lines and observed for changes in their growth rates via proliferation assays. We also performed parallel stable-isotope tracer-based flux analysis with [U-13C11]-Tryptophan and [U-13C3]-Serine with mass spectrometry to characterize flux changes with the goal of discovering potentially lethal metabolic pathways.

Results: We observed higher proliferative sensitivity to IDO1 inhibition in TNBC cell-lines with a genetic dysfunction in the *de novo* serine synthesis pathway. To understand these differences at the metabolic level, we quantified the differential contributions of tryptophan and serine to nucleotide and NAD^+ synthesis and the TCA cycle with the parallel tracer experiments. Comparison of the lines with dysfunctional *de novo* serine synthesis to those with normal or amplified flux towards the pathway showed a higher interdependence with the kynurenine pathway in the dysfunctional group. These results indicate a differential potential for targeting the kynurenine pathway in relation with the serine synthesis pathway.

Conclusion: Targeting the IDO1 enzyme in the kynurenine pathway shows significant correlations between the *de novo* serine pathway and the tryptophan catabolism pathway in TNBCs that may lead to metabolic targets conferring potential therapeutic benefits.

#7092 Cancer biomarker discovery with scalable biofluid proteomics.

Danielle B. Gutierrez, Jessica L. Moore, Jaison Arivalagan, Tiffany Louie, Leslie Wilkinson, Ray Clemens

Proteome Center, Discovery Life Sciences, Huntsville, AL

Biofluid proteomics opens opportunities for the discovery of early detection, diagnostic, and prognostic cancer biomarkers through non-invasive or minimally invasive screening. Plasma and serum are accessible sample types, however, the high dynamic range of proteins creates analytical challenges for the sensitive detection of potential biomarkers. In this work, we compare two proteomic approaches for large-scale cancer biomarker discovery: the Olink Proximity Extension Assay and the Seer Proteograph Product Suite. Olink Explore 3072 is an immunoassay that gains specificity by using dual antibody recognition to measure approx. 3,000 proteins in each sample. Antibody pairs are tagged with oligonucleotides, which hybridize and are amplified before measurement by next generation sequencing. Seer Proteograph is an enrichment strategy that uses a proprietary mix of functionalized magnetic nanoparticles with affinity for certain amino acids and functional groups in native state proteins. The resulting peptides are measured using untargeted mass spectrometry to identify proteins at the peptide level, paving the way for the identification of proteoforms and peptide variants. Aliquots of human plasma from 78 samples representing a range of cancer indications were obtained through the Discovery Life Sciences biobank and used for analysis by both the Olink and Proteograph workflows. Olink analysis achieved Pearson correlation scores of greater than or equal to 0.8 when correlating each of seven process controls to each other for all approx. 3000 proteins. On average, greater than or equal to 75% of the proteins were detected across all panels in all sample groups except for Normal and Benign groups (64% and 74% respectively). After stringent FDR filtering to ensure only high-quality data was analyzed, the Seer Proteograph workflow quantified 4,323 proteins across all 78 samples. Pearson correlation scores of greater than or equal to 0.96 were achieved when comparing digestion controls, process controls, and sample cleanup controls. Both platforms achieved detection of proteins across the dynamic range of plasma, including low abundance proteins. The Olink Explore 3072 and Seer Proteograph platforms were found to be complementary, with approx. 15% overlap in measured proteins. Cancer biomarker discovery at the proteomic level is bolstered by recent advances in analytical capabilities, as revealed by the Olink Explore and Seer Proteograph platforms. Importantly, complementary implementation of these two workflows will enable comprehensive biomarker analysis.

#7093 Prediction of overall survival in stage II and III colon cancer through machine learning of rapidly-acquired proteomics.

K. Xu[1], X. Yin[2], T. Guo[3], S. Zheng[1], Y. Shao[1];

[1]The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]The Affiliated Hospital of Qingdao University, Qingdao, China, [3]Westlake University, Hangzhou, China

The use of adjuvant therapy in stage II-III colon cancer (CC) has been controversial for decades. No markers or models now is satisfactory enough to be adopted widely by the medical community. Here, we analyzed the proteomics of paraffin-embedded tissue (FFPE) biopsy samples from 230 CC patients (stages II-III) with up to 10 years of survival by using pressure cycling technology (PCT) and data-independent acquisition (DIA) mass spectrometry. Using machine learning, we established a novel and practical protein-based clinical classification system for CC prognosis which was further verified in an independent validation cohort. Using the nine protein-based clinical model, we improved the area under the curve (AUC) value to 0.926 in the training cohort and 0.872 in the validation cohort. Our promising model will be a potential approach to prognostication to aid in rational follow-up schedule-making and risk-adaptive individualized therapies.

#7094 Clinical metabolomics reveals baseline biomarkers of hepatic dysfunction correlating with irregular drug-induced ALT and bilirubin elevations.

J. K. Meissen[1], K. Contrepois[1], S. Regan[2], J. Tan[2], A. J. Foster[2], J. Yuan[1], S. Sharma[1], D. Williams[2], A. I. Rosenbaum[1];
[1]AstraZeneca US, South San Francisco, CA, [2]AstraZeneca US, Cambridge, United Kingdom

AZD4573 is a highly potent and selective Cyclin-Dependent Kinase 9 inhibitor. The AZD4573 First-in-Human (FIH) study revealed variable alanine transaminase (ALT) and/or bilirubin elevation and a clear correlation to dose or PK exposure could not be defined. While concurrent ALT elevation ≥3x upper limit of normal (ULN) and bilirubin elevation ≥2x ULN (potential Hy's law) is a biochemical finding indicating potential drug-induced liver injury, quantitative modeling disconnected ALT and bilirubin elevation demonstrating that the observations were not Hy's Law cases. Furthermore, we implemented a targeted metabolomics workflow to investigate the ALT and bilirubin elevation mechanism and identify predictive biomarkers to better understand and/or predict any hepatic stress liabilities associated with AZD4573 clinical development. We implemented an established metabolomics methodology to 359 samples from 15 patients yielding 47,000 total data points. Data was separated into 98 different dosing intervals from the 15 patients to identify the ALT and bilirubin-associated metabolic changes conserved across all patients while incorporating metabolic differences in individual patents with ALT and bilirubin elevation in only a fraction of multiple doses. Orthogonal Partial Least Squares modeling identified several metabolites and pathways altered as a function of maximum ALT or bilirubin levels. Post-dose conjugated bile acids were elevated when ALT and bilirubin were elevated. Pre-dose creatine levels were decreased when ALT and bilirubin elevation occurred, and pre-dose glutamate levels were elevated when ALT elevation occurred. Pre-dose decreased total carnitines and kynurenine pathway activation were observed when ALT and bilirubin elevation occurred, but the effect did not reach statistical significance. Elevated bile acids are an established characteristic of cholestasis and suggest cholestasis as a probable mechanism for AZD4573-induced reversible liver stress. Interestingly, decreased creatine, glutamate elevation, decreased total carnitine, and kynurenine pathway activation are all associated with some form of liver stress or disfunction which may explain the irregular ALT and bilirubin elevations observed in patients receiving AZD4573; while ALT itself is a biomarker of liver damage, these pre-dose biochemical changes may illuminate potential preceding liver stress. Dosing patients already experiencing higher liver stress levels may be more susceptible to drug-induced ALT and bilirubin elevation, and patients with increasing in-study liver stress may only present at later doses. This work demonstrates metabolomics utility to elucidate possible mechanisms of liver toxicity as well as to identify potential predictive biomarkers for further investigation to explore individual patient risk in clinical studies.

#7097 Integrated proteomics and metabolomics reveals new insight into the synergistic interaction of valproic acid plus simvastatin in prostate cancer xenograft model associated with down-modulation of YAP and TAZ signaling.

F. Iannelli, R. Lombardi, S. Costantini, M. Roca, L. Addi, F. Bruzzese, E. Di Gennaro, **A. Budillon**, B. Pucci;
Istituto Nazionale Tumori di Napoli - IRCCS - Fondazione G. Pascale, Napoli, Italy

Background: Despite advancements in therapeutic approaches, including taxane-based chemotherapy and androgen receptor targeting agents, metastatic castration-resistant prostate cancer (mCRPC) remains an incurable disease, underlying the need of novel strategies that can target the complexities of this disease and bypass the development of drug-resistance mechanisms. We previously demonstrated the synergistic antitumor interaction of the antiepileptic with histone deacetylase inhibitory activity valproic acid (VPA), and the lipid-lowering drug simvastatin (SIM). This combination sensitizes mCRPC cells to docetaxel treatment and revert docetaxel-resistance, both in vitro and in vivo models, by targeting cancer stem cells compartment via mevalonate pathway/YAP axis modulation.
Methods: Proteomic and metabolomic/lipidomic analysis on tumor samples were performed by LC-MS/MS-based shotgun proteomics and by 1H-NMR approach, respectively. Progenesis QI for proteomics v. 4.2 was used as label-free quantification platform. Functional annotation analysis were performed by using the DAVID v6.8 (Database for Annotation, Visualization and Integrated Discovery); g:Profiler WikiPathways databases; Reactome version 66; Ingenuity Pathway Analysis software. Partial least squares-discriminant analysis (PLS-DA) and Loading plot were performed by Metabo Analyst v5.0 tool.
Results: Tumor samples derived from 22Rv1 mCRPC cells xenografted mice, treated or not with VPA/SIM combination were characterized by a combined proteomic and metabolomic/lipidomic approach. In deep bioinformatics analysis confirmed a specific impact of VPA/SIM on Hippo pathway, with a clear down regulation of YAP and its targets (CTGF, CycD1 ANKH1) in treated *vs* untreated tumors, functionally related with modulation of cancer-related extracellular matrix remodelling and metabolic reprogramming. Treatment also downregulated TEAD transcription factor mediating YAP-induced expression, along with the upregulation of 14-3-3, responsible for YAP cytoplasmic retention and degradation, paralleled by the up-regulation of YAP up-stream negative regulators such as LATS1 and AMPK. VPA/SIM also modulated intermediates of TCA, urea cycles and glycolysis and decreased cholesterol and fatty acids.
Conclusion: In summary, this study provides further insights into the molecular mechanism of the VPA/SIM antitumor effect suggesting the potential of repurposing these two generic and safe drugs in combination with standard antitumor therapies also in other tumors besides mCRCP.

#7098 Identifying of potential therapeutic targets of Taiwanese breast cancer by functional proteomics.

Chi-Cheng Huang[1], Wei-Chi Ku[2], Chi-Jung Huang[3], Ling-Ming Tseng[1]

[1]Taipei Veterans General Hospital, Taipei, Taiwan,[2]Fu-Jen Catholic University, New Taipei, Taiwan,[3]Cathay General Hospital, Taipei, Taiwan

The aim of the study is to conduct translational research of crucial breast cancer prognostic genes with functional proteomics. We have collected 61 breast cancer core biopsy samples, which were used for targeted sequencing for genetic variant analysis, mass-spectrometry analysis for protein expression and stain with H&E for whole slide image with Aperio Scanncer.

After analysis of variant (ANOVA) of LC-MS/MS data, we found 17 proteins with highly differential expression between these 5 molecular subtypes from 61 patients. We then search for the protein-protein interaction (PPI) network from STRING database and found the strong network including 6 proteins namely Collagen Type II Alpha 1 Chain (*COL2A1*), Collagen alpha-1(XI) chain (*COL11A1*), Collagen alpha-1(VI) chain (*COL6A1*), Collagen alpha-2(VI) chain (*COL6A2*), Thrombospondin 1 (*THBS1*) and Lumican (*LUM*).

To further investigate on the expression of these 6 target proteins in literature, we used Oncomine for data mining to query their mRNA expression profiles. Intriguingly, we discovered the mRNA expression of these targets are intensively distributed in many cancer types. This finding suggested the high potency of *COL2A1, COL11A1, COL6A1, COL6A2, THBS1* and *LUM* as potential targets in breast cancer treatment. Our study has the potential contributing to the knowledge of breast cancer susceptibility, early detection, surveillance, and potential actionable targets, developing optimized screening programs and treatment protocols for distinct molecular subtypes.

#7099 Prognostic value of serum proteomic signature in NSCLC patients on immune checkpoint inhibitors: Impact of treatment regimen and PD-L1 levels.

L. Kim[1], T. Um[2], Y. Chae[2], A. Cho[1];

[1]Ascension, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL

Background:The VeriStrat test, a blood-based proteomic test utilizing MALDI-ToF mass spectrometry, employs machine learning for prognostic assessment in non-small-cell lung cancer (NSCLC) across various stages, histologies, and treatments. Recently, its prognostic utility has extended to patients undergoing immune checkpoint inhibitor (ICI) treatment. Yet, the influence of treatment regimen and PD-L1 levels on its prognostic power remains less explored.
Methods: In this retrospective study, 174 NSCLC patients receiving ICI monotherapy (ICI mono) or combination with chemotherapy (combination) underwent VeriStrat testing from 2016 to 2023. Blood sample spectra categorized patients into VeriStrat 'Good' (VS-G) or VeriStrat 'Poor' (VS-P) groups. Overall survival (OS) and progression-free survival (PFS) were calculated using the log-rank test for the first ICI-containing regimen post-serum sample draw.
Results: Among 174 patients, 97 received combination therapy, and 77 received ICI alone. Within the 99 patients with PD-L1 levels <50%, 38 patients received IO monotherapy (23 pts for standard of care, 5 pts for poor candidacy for chemotherapy, 5 pts for clinical trial, 3 pts for patient refusal, and 2 pts for physician discretion). Survival analysis results are presented in Table 1.
1

survival analysis by treatment regimen and PD-L1 level

		Hazard Ratio VS-G/VS-P	95% CI	p-value			
ipilimumab+nivolumab	PFS	0.57	0.04-7.89	0.52	Total n=22	VS-G n=19	VS-P n=3
	OS	0.33	0.03-3.47	0.11			
pembrolizumab	PFS	0.90	0.19-4.31	0.88	Total n=25	VS-G n=20	VS-P n=5
	OS	0.33	0.08-1.43	0.01*			
carboplatin+pemetrexed+pembrolizumab	PFS	0.45	0.17-1.19	0.02*	Total n=41	VS-G n=30	VS-P n=11
	OS	0.61	0.22-1.68	0.27			
PD-L1>=50	PFS	0.93	0.34-2.54	0.89	Total n=39	VS-G n=29	VS-P n=10
	OS	0.45	0.17-1.20	0.18			
PD-L1<50	PFS	0.60	0.22-1.11	0.09	Total n= 99	VS-G n=79	VS-P n=20
	OS	0.47	0.21-1.04	0.01*			
PD-L1>=50 + ICI mono	PFS	0.55	0.12-2.65	0.69	Total n=23	VS-G n=18	VS-P n=5
	OS	1.25	0.32-4.96	0.75			
PD-L1<50 + ICI mono	PFS	0.77	1.15-3,91	0.70	Total n=37	VS-G n=30	VS-P n=7
	OS	0.24	0.51-1.10	0.0004*			
		Hazard Ratio combination/ICI mono	95% CI	p-value			
PD-L1<50 +VS-G	OS	0.70	0.36-1.33	0.24	Total n=76	ICI mono n=30	Combination n=46
PD-L1<50 +VS-P	OS	0.45	0.14-1.44	0.006*	Total n=20	ICI mono n=7	Combination n=13
		Hazard Ratio ICI mono/combination	95% CI	p-value			
PD-L1>=50 +VS-G	OS	2.18	0.69-6.90	0.27	Total n=29	ICI mono n=22	Combination n=7
PD-L1>=50 +VS-P	OS	NA	NA	0.21	Total n=10	ICI mono n=3	Combination n=7

Conclusions: Our findings suggest that the prognostic value of the VeriStrat test may vary based on the treatment regimen. In clinical scenarios utilizing ICI monotherapy for patients with PD-L1 levels <50%, the role of VeriStrat seems more significant. A prospective study with a larger sample size for validation is warranted.

#7100 Quantitative proteomics reveal the mechanism of TTFields therapy for glioblastoma.

Q. Mei[1], Y. Gao[2], R. Li[3], C. Wang[2], G. Hu[1], H. Huang[2];

[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, [2]State Key Laboratory of Chemical Biology, Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, Shanghai, China, [3]Cancer Center, Shanxi Bethune Hospital, Shanxi Academy of Medical Sciences, Tongji Shanxi Hospital, Third Hospital of Shanxi Medical University, Taiyuan, Shanxi, People's Republic of China, Taiyuan, China

Glioblastoma (GBM) is a highly malignant brain tumor, and conventional treatments such as surgical resection and chemotherapy have limited effectiveness, with a high rate of recurrence and poor prognosis for patients. In 2011, the FDA approved a novel therapy for recurrent GBM known as Tumor Treating Fields (TTFields). TTFields use alternating intermediate-frequency (200 kHz) and low-intensity (1-3 V/cm) electric fields to interfere with tumor cells, inducing apoptosis and inhibiting tumor growth. This study aimed to explore the molecular mechanisms of TTFields therapy at the systems biology level using quantitative proteomics technology. We analyzed U87 cells before and after TTFields treatment using quantitative proteomics and identified a total of 7679 proteins. Among them, 804 proteins were significantly upregulated after TTFields treatment, and 1141 proteins were significantly downregulated. Pathway enrichment analysis of differentially expressed proteins showed that upregulated proteins were mainly associated with cell proliferation, cell cycle, and transcription, possibly representing compensatory responses to the TTFields treatment. Further analysis revealed a significant upregulation of the tumor proliferation key protein PARP1, which was validated by protein immunoblotting experiments. Based on this analysis, we hypothesized that combining TTFields with Olaparib (a PARP1 inhibitor) might enhance the sensitivity of TTFields. Subsequently, we performed cell proliferation experiments to evaluate the concomitant application strategy, and the results demonstrated that Olaparib in combination with TTFields treatment significantly reduced the survival rate of U87 cells compared to single-drug treatment. In conclusion, using quantitative proteomics, this study revealed the biological processes underlying the inhibitory effects of TTFields on GBM proliferation. Under TTFields intervention, the expression of PARP1 was upregulated, and the use of a PARP1 inhibitor in combination significantly increased the sensitivity of TTFields. Therefore, this study not only elucidated the molecular mechanisms of TTFields therapy for GBM treatment at the systems biology level, but also provided support for further enhancing the efficacy of TTFields.

#7101 Remodeling of cancer cells by chemotherapy.

G. Qian[1], L. Schaffer[1], K.-M. Moon[2], L. Foster[2], T. Ideker[1], M. Hu[1], S. Alkhairy[1], E. Lundberg[3];
[1]University of California San Diego - UCSD, La Jolla, CA, [2]University of British Columbia, Vancouver, BC, Canada, [3]Stanford University, Stanford, CA

Cisplatin is a commonly administrated chemotherapy drug for cancer treatment. Although the direct mechanism of cisplatin is largely well-defined, it is challenging to comprehensively assess its systemic effects. Cellular responses to perturbations are intricate processes involving modifications to protein complexes across diverse cellular compartments. Therefore, substantial research endeavors have been directed towards unraveling protein organization in cells. We recently built a multiscale integrated cell map, MuSIC, that combines fluorescence-stained images and interactions derived from affinity purification mass spectrometry to allow comprehensive characterization of cellular structure and functional networks of 5,254 proteins of the human bone osteosarcoma epithelial line (U2-OS). To exploit the biology of U2OS, we integrated dynamics into this map to determine the proteome reorganization upon cisplatin exposure. Thus, we developed a data-driven approach integrating high throughput size exclusion chromatography mass spectrometry (SEC-MS) data with large-scale cell maps built from static-state information to systematically map at all scales the remodeling of cell architecture in drug-treated cells. Here, we acquired drug-perturbed protein-protein interactions (PPIs) from the SEC-MS data by treating U2-OS with cisplatin. Integrating the differential interactions identified from SEC-MS PPIs with the scaffold large-scale hierarchy (MuSIC) allows retention of the upper cellular organization to systematically map drug impact on protein complexes in the cell. This pipeline serves as an explorative method to identify the drug-responsive organelles, alterations of hierarchical structures, and translocation of proteins. Apart from the well known alterations of DNA damage repair complexes, we also recapitulate remodeling in metabolism pathways, splicing, cAMP-dependent kinase activity, and histone modification. We identify 26 novel protein assemblies containing members that are previously associated with cisplatin biology. This pipeline exploits the potential of a well-established network by integrating the high throughput data modality, allowing for the screening of a range of chemical agents and stimuli to generate differential networks.

#7102 The central dogma of hepatocellular carcinoma: Genomic, transcriptomic, and proteomic changes.

H. MA, C. YU, L. NG;
The University of Hong Kong, Hong Kong, Hong Kong

Cancer is a disease condition characterized by remarkable heterogeneity, wherein numerous molecular features display considerable disparities even with the same patient cohorts, leading to varied treatment outcomes. The primary factor contributing to the substantial differences observed across cancers stems from unique combinations of genetic mutations. Epigenetic alterations further contribute to differential gene expression and splicing, thereby enhancing transcriptomic diversity. The protein products originating from the cancer transcriptome constitute the specific intracellular and extracellular environment, consequently exerting supplementary effects on epigenetic, transcriptomic, and proteomic changes. The complex interplay and mutual influence between genetic aberrations, transcriptomes, and proteomes significantly contribute to shaping the extensive spectrum of molecular characteristics observed in cancer. With label-free mass spectrometry, RNA-sequencing, and low-pass whole genome sequencing, the quantification of the proteome, transcriptome, and genetic abbreviation of the cancer can be evaluated. With the mouse hydrodynamic tail vein injection (HDVI) models of hepatocellular carcinoma (HCC), different subtypes of HCC derived from different genetic abbreviations can be generated. With the proteome, transcriptome, and genetic abbreviation data of the better-defined HCC from HDVI models and HCC patients, the patient-derived HCC can be classified according to the origin of the genetic abbreviation used in the generation of the HDVI-derived HCC. Furthermore, the proteome of patient-derived plasma will be analyzed, and the signature change unique to HCC classified by different origins of genetic abbreviation will provide an abstract of the proteome, transcriptome, and genetic abbreviation of the HCC tissue. The transcriptomics and proteomics data of HDVI mice produced from five distinct sets of genetic abbreviations have been measured. The proteome and transcriptome of tissue, as well as the proteome of plasma, from a small cohort of HCC patients were studied and classified using this resource to illuminate the fundamental landscape of HCC. The final results will be presented and discussed at the meeting.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: DNA Damage and Repair
Poster Session

#7106 Distinct functions of EHMT1 and EHMT2 in cancer chemotherapy and immunotherapy.

Z. Kang[1], P. Fu[1], H. Ma[1], T. Li[1], K. Lu[1], J. Liu[1], V. Ginjala[1], P. Romanienko[1], Z. Feng[1], M. Guan[2], S. Ganesan[1], B. Xia[1];
[1]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, [2]Huashan Hospital Fudan University, Shanghai, China

EHTM1 (GLP) and EHMT2 (G9a) are closely related protein lysine methyltransferases often thought to function together as a heterodimer to methylate histone H3 and non-histone substrates in diverse cellular processes including transcriptional regulation, genome methylation, and DNA repair. Here we show that EHMT1/2 inhibitors cause DNA replication stress, accumulation of single-stranded replication gaps, increased expression of STING, emergence of cytosolic DNA, and activation of the cGAS-STING pathway. Remarkably, EHMT1/2 inhibition strongly potentiates the efficacy of alkylating chemotherapy and anti-PD-1 immunotherapy in mouse models of tripe negative breast cancer. Mechanistically, the effects of EHMT inhibition on DNA replication and alkylating agent sensitivity are largely caused by the loss of EHMT1-mediated methylation of DNA ligase I (LIG1), whereas the elevated STING expression is, at least part, caused by its promoter demethylation. Moreover, depletion of EHMT2, and not EHMT1, leads to STING induction, which is correlated with more complete demethylation of the STING1 promoter. On the other hand, depletion of EHMT1, and not EHMT2, results in cytosolic DNA accumulation, which presumably activates the cGAS-STING pathway. These results reveal distinct functions of the two EHMT paralogs and provide enlightening paradigms and corresponding molecular basis for combination therapies involving alkylating agents and immune checkpoint inhibitors.

#7107 Clustered DNA double strand breaks for cancer treatment via multi-gRNA CRISPR system.

G. Badakul, N. Sharma, J. A. Nickoloff;
Colorado State University, Fort Collins, CO

Radiation therapy is one of the most common cancer treatments. Ionizing radiation generates DNA double-strand breaks (DSBs), which are the most lethal type of DNA damage. The dominant pathway for repairing DSBs is non-homologous end joining (NHEJ), but homologous recombination (HR) is also important. NHEJ is dominant pathway in all cell cycle phases while HR is largely restricted to S and G2 phases. Unrepaired or misrepaired DSBs can lead to cell death. KU70/80 and DNA-PKcs are essential for NHEJ. KU70/80 binds to broken ends, and DNA-PKcs binds to DNA-bound KU70/80, which activates DNA-PKs kinase allowing NHEJ to proceed. Clustered DSBs (two or more DSBs separated by <200 bp) generate small DNA fragments that are efficiently bound by KU70/80 and DNA-PKcs, but fail to activate DNA-PKcs kinase, inhibiting NHEJ and shifting repair toward HR. Thus, clustered DSBs are poorly repaired and more cytotoxic than dispersed DSBs. There are two types of ionization radiation: high LET and low LET. High LET radiation has a higher ionization density and therefore induces more clustered DSBs than low LET, which explains why high LET radiation is more cytotoxic at a given dose. A major limitation of radiotherapy is normal tissue damage. We hypothesize that mimicking high-LET-induced clustered DSBs using CRISPR/Cas9 targeted to cancer-specific DNA sequences (e.g., indel mutations) will effectively kill cancer cells but spare normal cells. In this approach, DSBs are not targeted to specific genes, nor is CRISPR/Cas9 used for gene editing. Instead, cancer cell killing is achieved by inducing poorly repaired DSBs anywhere in cancer cell DNA. Thus, this therapeutic approach is distinct from conventional targeted therapies that are oncogenic pathway-dependent, and this eliminates oncogenic pathway-dependent resistance mechanisms. However, types of resistance are possible, such as upregulated DSB repair. Our data indicate that the cytotoxicity of clustered DSBs depends on the number of small DNA fragments induced, thus we observe similar cytotoxicity with a localized, 4-DSB cluster and with three non-localized 2-DSB clusters, as each generates 3 small fragments per target chromosome. This finding significantly increases available targets as 2-DSB clusters can be induced at indels and flanking (wild-type) sites, generating clustered DSBs in cancer cells but efficiently repaired dispersed DSBs in normal cells lacking the cancer indel. Data also indicates that a single DSB targeted to each amplicon of highly amplified regions is also cytotoxic, and we are exploring the effectiveness of combination clustered DSBs targeted to amplified regions. We are also exploring how DSB repair inhibitors (like ATMi, DNA-PKcsi or RAD51i) can augment cytotoxic DSB effects, potentially mitigating that resistance pathway. These proof-of-principal studies represent the first approach to targeted cancer therapy that is oncogenic pathway-independent.

#7109 Fasn inhibition enhances the efficacy of chemotherapy by inhibiting DNA damage response in colorectal cancer.

M. Banerjee, Y. Zaytseva, S. Hasani, P. Ryachahou, T. Izumi, B. Evers, T. Gao;
University of Kentucky, Lexington, KY

Altered lipid metabolism plays a significant role in progression of colorectal cancer, however, its role in chemotherapy resistance remains poorly understood. We previously identified FASN, the rate limiting enzyme in de novo lipogenesis, as an important regulator of colorectal cancer progression. However, TVB-3664, a potent and specific small molecule inhibitor of FASN, showed limited effect in reducing tumor burden in pre-clinical studies as a stand-alone therapy. Therefore, the goal of this study is to evaluate the combinatorial efficacy of TVB-3664 in improving the therapeutic indices of standard chemotherapy in colorectal cancer. Using a combination of colon cancer cell lines and patient derived organoids we showed that TVB-3664 potentiates chemotherapy drug-induced double-strand DNA breaks (DSBs) and apoptotic cell death by altering histone acetylation levels. In addition, TVB-3664 treatment blocked DNA damage response (DDR) by decreasing ATM expression and Chk1/2 phosphorylation. Mechanistically, inhibition of FASN prevents the activation of both DSB repair pathways, namely homologous recombination (HR) and classical non-homologous end joining (NHEJ), by blocking BRCA1 and 53BP1 recruitment to γH2AX foci, respectively. Moreover, we found that the inhibitory effect of TVB-3664 on DNA repair requires ACLY-dependent acetylation as genetic or pharmacological inhibition of ACLY attenuates TVB-3664-inducded DNA damage. Functionally, combining TVB-3664 with irinotecan synergistically decreased xenograft tumor growth and significantly delayed tumor relapse after withdrawal of therapy. Taken together, we identified a novel mechanism by which FASN inhibitors improve the efficacy of conventional chemotherapy by blocking DNA damage response to delay tumor recurrence and overcome a major challenge in treating colorectal cancer patients.

#7110 Characterizing pY240-PTEN:Ki-67 interactions and development of a PPI disrupting peptide.

B. Jones, S. Patel, F. Furnari;
University of California San Diego - UCSD, San Diego, CA

Glioblastoma (GBM) is the most aggressive and common malignant primary brain tumor. Standard of care for GBM patients involves chemotherapy and ionizing radiation which induce DNA damage to kill tumor cells; however resistance to these treatment modalities commonly develop through various mechanisms. One novel mechanism of radioresistance is through enhanced homologous recombination (HR) DNA damage response (DDR) mediated by nuclear-localized tyrosine-phosphorylated PTEN (pY240-PTEN) recruited to chromatin through interaction with the PP1 Binding Domain (PP1BD) of Ki-67. PTEN is known to play an important tumor-suppressive role and is found to be mutated in approximately 40% of GBMs. A Y240F-PTEN knock-in mouse model has shown that loss of Y240 phosphorylation results in IR sensitivity. Ki-67 dependent, pY240-PTEN facilitated DDR may be regulated by currently uncharacterized interactions within the Ki-67 PP1BD and determination of these interactions may enable development of complex-disrupting peptides capable of radiosensitizing glioma cells. To this end, I have identified residues in the Ki-67 PP1BD that are essential for pY240-PTEN interaction via streptavidin pulldown of N-terminal biotinylated peptides synthesized with alanine mutations at all residues spanning the Ki-67 PP1BD. Orthogonally, glioma cell lines have been engineered that stably express Ki-67 minigene constructs harboring mutation of the identified PP1BD residues. The effects of these mutations on PTEN:Ki-67 interaction, as well as DDR, HR, chromatin accessibility, and colony formation efficiency are currently being interrogated. Competitor peptides have been designed based on candidate Ki-67 residues and evaluated for their ability to bind PTEN. Further optimization of these peptides has led to candidates that are being assessed for stability and potential to radiosensitize glioma cells. In addition, regulation of pY240-PTEN:Ki-67 interaction by posttranslational modification of the Ki-67 PP1BD by aurora B kinase and cyclin dependent kinase 1 has been investigated through pulldown of biotinylated peptides harboring phosphorylated candidate residues. Lastly, Ki-67 has been knocked out in U87 glioma cells, as well as TS528 glioma stem like cells, and the resulting effect on IR sensitivity and DDR is being investigated in the absence, or presence of PTEN. Overall, this project has begun to characterize the regulation and critical molecular interactions between pY240-PTEN and Ki-67, elucidating potential strategies that could disrupt these interactions to enhance the efficacy of radiotherapy.

#7111 Homoharringtonine is effective in treating acute lymphoblastic leukaemia via WEE1 downregulation and inducing DNA damage.

Chun-fung Sin, Kei-ching Yuen, Anan Jiao, Bai-lin Li, Hau-wai Yu

Pathology, The University of Hong Kong, Hong Kong, Hong Kong

Acute lymphoblastic leukaemia (ALL) is an aggressive haematolymphoid malignancy that originated from clonal mutations in lymphoid precursors. The prognosis is poor in adult patients and relapse/refractory disease is not uncommon which carries dismal prognosis. There is an urgent need to develop novel therapeutics. Homoharringtonine (HHT) is a plant alkaloid which can bind to ribosomal A-site and thus inhibit protein synthesis. It was used to treat acute myeloid leukaemia in China during 1980s. Herein, we conducted a study to explore the therapeutic efficacy and mechanism of action in ALL. T-ALL (DND-41, PEER) and B-ALL (PALL-2, SUP-B15) cell lines were treated with HHT for 24 and 72 hours. Cell viability was reduced at a time and dose-dependent manner in all cell lines we tested, with increased in percentage of apoptosis. Western blot showed upregulation of p53, with PARP and caspase 3 cleavages upon treating with HHT for 24 hours. Moreover, we observed WEE1 downregulation which allowed cell cycle progression through G2/M with damaged DNA. Comet assay showed evidence of DNA damage. Proteomics study by label-free protein quantitation showed downregulation of proteins involving in homologous recombination-mediated DNA repairing machinery, including BRCA1 and RAD51. The findings not only showed therapeutic efficacy of HHT in ALL, but also demonstrated the first evidence of DNA damage induced by HHT which might account for its therapeutic effects. Further studies will be conducted for delineating the mechanisms of DNA damage and its relationship with therapeutic efficacy.

#7112 Preclinical profile of novel and potent small molecule inhibitors of PARG.

Sukanya Patra, Manoj Pothuganti, Githavani Kummari, Venu Sankeshi, Jyothipriya Kapaka, Navnath Karche, Anirban Kayet, Ramamohan Mekala, Srikant Viswanadha

Satyarx Pharma Innovations Private Limited, Hyderabad, India

Poly(ADP-ribose) glycohydrolase (PARG) is primary enzyme involved in the dePARylation process of DNA repair, specifically in the single strand break repair (SSBRs). PARG is a macrodomain protein with exo- and endo-glycohydrolase activity that liberates free ADP-ribose and PAR chains, respectively. It interacts with various Poly(ADP-ribose) polymerase (PARP) proteins to facilitate appropriate and timely DNA repair. The balance between PARP and PARG activity is essential for efficient DDR. Inhibition of PARG lead to altered DNA repair in cancer cells. We have identified highly potent PARG inhibitors with picomolar IC_{50} in . PARG is the primary enzyme for dePARylation and accounts for 90% of dePARylation activity. Treatment of HCC-1806 cells with PARG inhibitors showed dose dependent increase of PARylation signature, with sub micromolar IC_{50}. Compounds also demonstrate significant functional, anti-proliferative activity in ovarian and breast cancer cell lines besides a favourable ADME profile. Further pharmacokinetic and pharmacodynamic characterization of the identified hits is currently in progress.

#7113 Targeting the repair of DNA-protein crosslinks induced by bifunctional alkylating agents.

C. Turner, H. Cerrato, V. Melehov, C. Healy, K. P. Rice;
Colby College, Waterville, ME

Bifunctional alkylating agents, such as nitrosoureas, platinum-based therapeutics, and chloroethylhydrazines, have demonstrated clinical successes against cancer by inducing cytotoxic interstrand or intrastrand DNA crosslinks. However, the less well-characterized capacity of these agents to couple DNA to chromosomally-associated proteins may also contribute to these compounds' observed cytotoxicities. Bulky DNA-protein crosslinks (DPCs) could obstruct the DNA metabolism critical to cancer proliferation, thus contribute to genomic instability and cell death. To endogenously repair DPCs, human cells often utilize a DPC-specific proteolytic mechanism dependent on the metalloprotease SPRTN. Complementary approaches for quantifying DPCs, generated ex vivo, to assess the capacity of several bifunctional alkylating agents to induce these lesions in cultured human leukemia cells are presented here. In the first approach, proteins were isolated from lysates of drug-treated cells and protein-bound DNA was quantified as a ratio to the total DNA present in the lysates. In the complementary approach, DNA was extracted from lysates of drug-treated cells using a modified 'STAR' assay in which genomic DNA is isolated and the DNA-bound proteins were quantified by fluorescein isothiocyanate labeling. Micromolar concentrations of the nitrogen mustard mechlorethamine and nitrosourea lomustine induced significant DPC formation while more modest DPC formation was observed using similar concentrations of the chloroethylating agents carmustine and laromustine, as well as cisplatin. Bifunctional alkylating agents dependent on epoxide functionality, including dianhydrogalacticol and diepoxybutane, required drug concentrations of at least one order of magnitude larger to produce similar DPC yields measurable by these techniques. A strategy to interfere with the DPC repair pathway via SPRTN knockdown and assess increased sensitivity of cancer cells to bifunctional alkylating agents is also presented. Chemotherapeutic sensitization by targeting SPRTN could suggest a therapeutic strategy to improve effectiveness of several DNA-targeted anticancer agents, especially if extended to other therapeutics that trap DPCs such as inhibitors of topoisomerase and poly(ADP-ribose) polymerase. Further, identifying structure-function relationships with respect to bifunctional alkylating agents and DPC formation could inform the future development and clinical utilization of these chemotherapies.

#7114 Exploring the landscape of PARP and PARG inhibitor selectivity in live cells using NanoBRET™ target engagement assays.

A. Michaud[1], K. Teske[1], J. Wilkinson[1], C. Zimprich[1], J. Vasta[1], **C. Corona**[2], M. Zhou[2], E. Dominguez[1], K. Dunn-Hoffman[1], M. Robers[1];
[1]Promega Corporation, Madison, WI, [2]Promega Corporation, San Luis Obispo, CA

The 17-member poly(ADP-ribose) polymerase (PARP) family of proteins mediate a number of cellular processes including gene transcription, cell-division and DNA-repair. PARPs catalyze the addition of poly- or mono- ADP-ribose chains on target proteins, modifying their function and/or recruitment in various pathways. Poly(ADP-ribose) Glycohydrolase (PARG) catabolizes PAR units and facilitates the recycling of PARP and other modified effector proteins. A number of PARPS are implicated in human disease, and PARP inhibitors (PARPi's) have seen major clinical success, however, many PARPs (especially mono PARPs) are understudied and chemical tools for understanding cellular PARPi selectivity and potency across the entire family are lacking. Similarly, several PARG inhibitors have been developed to date, but tools for directly assessing target engagement in a cellular context are sorely needed. Here we describe the development and application of target engagement assays for characterizing PARP and PARG inhibitor selectivity and affinity in live cells. This method is based on the NanoBRET™ assay platform, which is a proximity-based probe displacement assay that operates in live cells. Using NanoBRET™ technology, we have developed a single probe that covers 12 out of 17 PARP family members. We explored the family-wide selectivity of a diverse panel of clinical and preclinical PARP inhibitors in live cells, representing the first family-wide, cell-based method for profiling PARP selectivity. We also describe the development of a second probe that reports on PARG target engagement. Target engagement of PARG was observed for three out of five tested inhibitors, suggesting a potential indirect mode of action for certain inhibitors on PARG glycohydrolase activity. These assays offer a complementary approach for studying target engagement within the PARylation cycle.

#7115 Mutational signatures in PDXs for improved understanding of drug response and companion biomarkers identification.

H. Khoury, **S. Cairo**, M. Gilardi, M. Ritchie, G. Silberberg;
Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

Genomic DNA editing is a continuous process that occurs during the entire cell life span. The type and frequency of these modifications can be related to the physiological or pathological activity of intrinsic mechanisms such as DNA surveillance and repair or to extrinsic events that may induce an alteration of DNA sequence by exposure to agents that directly or indirectly induce accumulations of DNA alterations. In the past few years, large-scale analyses have revealed mutational signatures across human cancer types. These signatures can be used as markers of defective internal processes, such as DNA repair deficiency, or external exposures, such as carcinogens, like tobacco, or genotoxic therapies such as radiation and chemotherapy. Our TumorGraft platform, a collection of 1500 patient-derived xenograft generated from more than 50 different types of cancer, is one of the most comprehensive preclinical oncology platforms worldwide, and aims to recapitulate the variety of the patient population and tumor biology complexity. This platform is currently used to evaluate the efficacy of new drugs, and all our models are very well characterized at the molecular level, including whole transcriptome, proteomics and phospho-proteomics, quantification, and genomic variation calls. This allows accurate selection of models with the molecular characteristics of the target patient population, as well as to identify biomarkers predictive of treatment efficacy. This could eventually lead to the development of companion biomarkers in the clinical setting to improve the identification of patients that will benefit from the treatment and those that should be spared. To maximize the chances of identifying relevant molecular traits associated with tumor response, we have been utilizing the Pharmaco-Pheno-Multiomic (PPMO) integration workflow, a machine learning approach which combines phenotypic and therapeutic response profiles with multiple omics datatypes to generate complex biomarker profiles. To provide additional insights on the molecular characteristics of our tumors, we decided to perform the mutational signatures profiling of our models by using whole exome sequencing data. The results obtained were crossed with patient's clinical history and showed good correlation between the mutational signatures identified and the treatments received by the patient, in particular for exposure to platinum salts. The addition of PDXs mutational signatures strongly improves our knowledge on these models and confers an important parameter for model selection. Moreover, the integration of mutational signature profiles in the PPMO workflow would make a significant contribution for companion biomarkers identification.

#7116 Targeting the CBP/p300 axis in lethal prostate cancer impacts DNA repair.

S. Sardar[1], L. Ravindranath[1], C. McNair[2], S. N. Chand[3], W. Yuan[4], D. Bogdan[4], J. Welti[4], A. Sharp[4], M. Schiewer[5], L. Butler[6], J. de Bono[4], K. Frese[7], N. Brooks[7], N. Pegg[7], K. Knudsen[8], A. A. Shafi[1];

[1]Center for Prostate Disease Research (CDPR), Bethesda, MD, [2]Jefferson Health Thomas Jefferson University, Philadelphia, PA, [3]Incyte, Philadelphia, PA, [4]The Institute of Cancer Research, London, United Kingdom, [5]Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA, [6]The University of Adelaide, Adelaide, Australia, [7]Cell Centric Ltd, Cambridge, United Kingdom, [8]The American Cancer Society, Philadelphia, PA

Prostate cancer (PCa) is the 2nd leading cause of cancer related deaths in US men. PCa is an androgen dependent disease driven by the androgen receptor (AR). Currently, androgen-deprivation therapy (ADT) is the standard of care first-line therapy for metastatic PCa. Resistance to ADT uniformly leads to lethal disease, termed castration-resistant prostate cancer (CRPC). Thus, there is an unmet clinical need to identify and develop novel strategies to treat CRPC. CBP/p300 are potent co-activators for AR. High expression of CBP/p300 is associated with locally advanced disease and castration resistant function of AR, resulting in poor patient outcomes and further highlighting the need to discern the role of CBP/p300 to potentially develop therapeutic targets for precision medicine. Previous studies have relied on non-specific compounds and genetic silencing to target CBP/p300. In this study, CBP/p300 mediated bromodomain activity is targeted by CCS1477 (inobrodib), a first-in-class bromodomain inhibitor developed by Cell Centric. CCS1477 treatment demonstrated effective inhibition in growth and clonogenicity assays. Inhibition of the CBP/p300 bromodomain with CCS1477 resulted in significant downregulation of AR-FL, AR-V7, and its targets' mRNA expression in addition to inhibition of associated factors such as c-MYC and its downstream targets in PCa cell lines as well as patient derived xenograft (PDX) models. This study shows that CBP and p300 are highly expressed and correlate closely with AR gene expression and AR activity score in primary PCa and CRPC patient samples. The clinical significance of CBP/p300 expression in PCa has been investigated via elucidation of CBP/p300 transcriptional reprogramming and its role in DNA damage response (DDR) pathways. Specifically, findings revealed that CBP/p300 bromodomain suppression sensitizes to AR-dependent DNA-repair. Transcriptional mapping identified CBP/p300 as regulators of cell proliferation and DNA repair processes, which were functionally confirmed across several PCa model systems. To assess relevance, exogenous challenge with radiation revealed that CBP/p300 are required for AR-mediated DNA repair, and CBP/p300 expression is linked to DNA repair capacity in the clinical setting. Molecular analyses revealed that CBP/p300 facilitate double-strand break (DSB) repair efficiency via homologous recombination (HR) mediated DDR. Congruently, CBP/p300 strongly correlated with HR gene expression in PCa patient tissue. These collective findings reveal that CBP/p300 govern repair of DNA DSBs by regulating HR, thus modulating genome integrity and promoting CRPC growth. These studies identify CBP/p300 as a driver of PCa tumorigenesis through coordinated control of critical transcriptional events and lay the groundwork to optimize therapeutic strategies for advanced PCa via CBP/p300 inhibition, potentially in combination with AR-directed therapies.

#7117 Convection enhanced delivery of a novel ATR inhibitor synergizes with systemic lomustine for improved treatment of glioblastoma.

A. Josowitz[1], **T. Lee**[1], R. K. Sundaram[1], J. Pothupitiya[1], E. J. Brown[2], A. Sule[1], J. Beckta[1], Y. Wang[1], J. Vacca[3], O. Gilad[3], R. S. Bindra[1], W. M. Saltzman[1]; [1]Yale University, New Haven, CT, [2]University of Pennsylvania, Philadelphia, PA, [3]Aprea Therapeutics, Doylestown, PA

Developing effective strategies for treating glioblastoma (GBM), the most common and aggressive form of brain cancer, has been a long-standing challenge. Despite rigorous treatment regimens including surgical resection with concomitant radiotherapy and chemotherapy, the prognosis for this disease remains poor, largely due to tumor recurrence, resistance to conventional therapeutics, pharmacokinetic and brain delivery challenges, and dose-limiting toxicities of existing therapies. The DNA damage response and DNA repair mechanisms such as the ataxia telangiectasia and Rad3-related (ATR) pathway are key mediators of therapeutic responses, and recent studies have shown that targeting DNA repair proteins alongside standard-of-care options is a promising anti-tumor strategy. Here, we employ a combination approach using a next-generation macrocyclic ATR inhibitor, ATRN-333, to sensitize GBM tumors to alkylators. We establish the potency of ATRN-333 and report a robust synergistic interaction between it and the alkylator lomustine in GBM cell-based assays and in a murine flank tumor model. This combinatorial treatment was then applied to a mouse intracranial tumor model, where we utilized a convection enhanced delivery (CED) system combined with nanoparticle technology for direct intracranial administration of ATRN-333. ATRN-333 was successfully encapsulated into a novel polymeric nanoparticle formulation using poly(ethylene glycol)-co-poly(ethylene brassylate-co-dioxanone) (PEG-EB-co-DO). CED of both free and encapsulated ATRN-333 potently sensitized intracranial GBM tumors to low-dose (5 mg/kg) systemically-delivered lomustine, reducing tumor size and conferring a substantial survival benefit compared to cohorts treated with lomustine or the ATR inhibitor alone. The combination approach was well tolerated by the mice, with no hematological toxicity observed as assessed by bone marrow analysis and blood cell counts. Our results demonstrate that ATR inhibitor/lomustine combination therapy, used in conjunction with a CED platform, is a powerful avenue for GBM treatment and a viable option for potential clinical implementation. Note: AJ and TL contributed equally to this work.

#7118 Fanconi Anemia complementation group A is significantly involved in regulating R-loops and facilitating homology-directed repair of DNA double-strand breaks.

F. Li, Haibo Yang, Boya Gao, Liang Luo, Alyan Zafar, Fenghua Yuan, Li Lan and Yanbin Zhang, L. Luo, A. Zafar, F. Yuan, Y. Zhang;
University of Miami Miller School of Medicine, Miami, FL

Homologous recombination (HR), a fundamental DNA double-strand break (DSB) repair pathway, is a universal mechanism employed by cells to accurately mend breaks in both strands of the DNA helix, ensuring genomic stability. Displacement loops, commonly referred to as D-loops, play a crucial role as intermediate structures in HR. Furthermore, recent studies indicate that the unique DNA: RNA three-stranded structure, known as R-loops, may serve as a starting point for homologous pairing and contribute significantly to enhancing HR efficiency by promoting D-loop formation. Besides, the formation of R-loops might assist in recruiting DNA repair proteins, especially those related to HR, thereby accelerating the repair of damaged sites. In this study, we find that highly purified human Fanconi Anemia complementation group A (FANCA) protein effectively induces the formation of R-loops and binds R-loop substrates with high affinity, preferring guanine-rich sequences in vitro. In comparison, FANCA exhibits both a weaker capacity to form D-loops and a lower affinity for binding to D-loops in vitro. Additionally, we have also observed that the interaction between FANCA and RNA facilitates the generation of D-loops in vitro. We then use the DART (damage at RNA transcription site) system to reveal the colocalization of FANCA with R-loops in a highly transcribed genomic locus upon DNA damage in cells. Next, we further demonstrate FANCA's participation in forming R-loops in the initial DSB repair stage and assisting in removing R-loops later. Additionally, we uncover FANCA's ability to aid in the generation of R-loops at specific DNA DSB sites within transcriptionally active regions in both Tet-DR-GFP U2OS cells and DIvA (DSB inducible via AsiSI) cells. Importantly, the R-loop formation ability of FANCA is independent of the Fanconi Anemia (FA) pathway. In conclusion, our findings indicate that FANCA, independent of the FA pathway, can enhance HR in non-transcriptionally active DNA DSB sites through D-loop formation. Furthermore, FANCA significantly elevates transcription-Coupled Homologous Recombination (TC-HR) efficiency by catalyzing the formation of DNA: RNA hybrids, generating temporary R-loops at DNA damage sites and thereby contributing to genomic stability maintenance.

#7120 Investigating PARP1 selective inhibitor DSB1559 efficacy in BRCA1-associated triple negative breast cancer.

A. Nelson[1], K. F. Zheng[1], C. Wanderley[1], D. E. Michaud[1], P. M. Cowley[2], G. M. Campbell[2], B. E. McGuinness[2], A. Wise[2], J. Guerriero[1];
[1]Brigham and Women's Hospital, Boston, MA, [2]Duke Street Bio Ltd., London, United Kingdom

Background: Poly (ADP-ribose) polymerase inhibitors (PARPi) have improved outcomes of BRCA-associated breast cancer. However, toxicity can limit patient response as well as the ability to be combined with other therapeutics. Current PARPi broadly inhibit members of the PARP protein family, however only inhibition of PARP1 is needed for PARPi-mediated cell death. As inhibition of PARP2 is associated with hematological toxicity seen in PARPi patients, selectively inhibiting PARP1 may reduce PARPi toxicity and lead to better outcomes for patients. Here we characterize and test the efficacy of the PARP1 selective inhibitor (PARP1i) DSB1559 compared to Olaparib in BRCA1-associated triple negative breast cancer (TNBC).

Methods: NanoBRET, PARylation, and pharmacokinetic/pharmacodynamic assays were performed to examine DSB1559 potency, PARP family selectivity, and *in vivo* behavior. Immunocompetent FVB/n mice bearing BRCA1-deficient TNBC (*CMV-Cre;Brca1*$^{f/f}$*;Trp53*$^{f/f}$) tumors were treated daily with PARPi (Olaparib) or PARP1i (DSB1559) for 60 days and followed for survival. CellTiter-Glo and qPCR assays were used to examine DSB1559 effect on cell viability and STING activation, respectively.

Results: DSB1559 is a novel and potent PARP1 inhibitor which has superior selectivity for PARP1 compared to Olaparib and PARP1i AZD5305. DSB1559 has highly desirable physico-chemical and in vitro ADME properties, which translate to high oral bioavailability and moderate clearance in rodent PK studies. Additionally, DSB1559 demonstrated superior tumor residence time and tumor/plasma ratio compared to AZD5305. Compared to Olaparib, DSB1559 significantly increased STING activation and reduced cell viability in BRCA1-associated murine TNBC cells. BRCA1-associated TNBC-bearing immune-competent mice treated with DSB1559 had significantly reduced tumor growth and increased overall survival (median survival 74 days) compared to Olaparib (median survival 18 days). Analysis of changes in the tumor microenvironment are ongoing.

Conclusions: Taken together, DSB1559 is a highly selective PARP1 inhibitor that demonstrates superior efficacy compared to Olaparib in a BRCA1-associated immune-competent TNBC model.

#7121 The novel WEE1i, APR-1051, is a potentially well tolerated and effective treatment for cyclin E-overexpressing cancers.

M. M. Hansbarger[1], S. J. Rocca[1], S. Ritzmann[1], J. Vacca[1], B. Tokiwa[1], J. Weinstein[1], H. Zabierek[1], J. Frye[1], M. Carleton[1], E. J. Brown[2], O. Gilad[1];
[1]Aprea Therapeutics, Inc., Doylestown, PA, [2]University of Pennsylvania, Philadelphia, PA

Previous studies have demonstrated that WEE1 inhibitors (WEE1i) are a promising cancer therapeutic through synthetic lethality with Cyclin E overexpression. One challenge for two of the leading WEE1i, AZD1775 and ZN-c3, has been the observed off-targeting of PLK family members, namely, PLK1, PLK2 and PLK3. In addition, the therapeutic application of these inhibitors in clinical trials has been limited by adverse hematological effects, including anemia. Herein, we describe the testing of a novel WEE1i (APR-1051) that, based on preclinical studies: 1) demonstrates reduced off-targeting of PLK1, PLK2 and PLK3, and 2) has the ability to suppress the growth of CCNE1-overexpressing xenografted tumors while causing little impact on red blood cell and reticulocyte levels. APR-1051 has an IC50 of 2.2 nM for WEE1 in vitro and has shown the ability to limit the proliferation of various cancer cell lines in culture. Interestingly, the genotoxicity of APR-1051 is suppressed by increasing concentrations of PLK1 inhibitors, suggesting that off-targeting of PLK1 by other WEE1i may compromise efficacy of this targeted cancer treatment in addition to the risk of producing PLK1i-associated adverse effects. APR-1051 demonstrated effectiveness in suppressing the growth of Cyclin E-overexpressing breast and ovarian cancer cells lines, thus pinpointing Cyclin E as a potential biomarker for APR-1051 treatment. Importantly, dose and scheduling of APR-1051 that causes significant suppression of CCNE1-amplified high-grade serious ovarian cancer tumors in mice is well tolerated, with red blood cell and platelet counts remaining within non-pathogenic ranges after a 28-day treatment period. In addition, inhibition WEE1 by APR-1051 occurs at an IC50 that is 200-fold lower on average than the IC50 of hERG potassium channel inhibition, implying that APR-1051 will potentially exhibit low cardiotoxicity. APR-1051 is now progressing through IND-enabling studies. Together, these findings underscore the potential of APR-1051 as a novel WEE1i for the treatment of Cyclin E-overexpressing cancers.

#7122 A novel USP1 inhibitor coupled with a novel proteomic response biomarker for precision oncology therapy.

I. Alchanati[1], A. Morley[2], A. Hay-Koren[1], F. Fierro[1], G. Otonin[1], S. Herman[1], A. Shtrikman[1], Y. Katzenelenbogen[1], G. Arad[1], B. Tivon[1], K. Pevzner[1], **E. Seger**[1]; [1]Protai, Tel Aviv, Israel, [2]O2H Discovery, Cambridge, United Kingdom

Ubiquitin-specific protease 1 (USP1) is a well-characterized deubiquitinating enzyme (DUB) that plays a critical role in DNA damage repair (DDR). It was shown to regulate various key repair processes, most notably proliferating cell nuclear antigen (PCNA) in the Translesion Repair (TLS) pathway and FANCD2/FANCI in the Fanconi Anemia (FA) repair pathway. Research indicates that USP1 deficiency leads to a decrease in cell survival and disruption of genomic stability, suggesting that USP1 inhibitors (USP1i) may hold promise in treating DDR deficient tumors. Through the integration of computational and medicinal chemistry approaches, we discovered a novel, potent inhibitor of USP1, showing anti-USP1 activity in both cell-free enzymatic assay and in measurement of PCNA-ubiquitination change upon USP1 inhibition in cells. We demonstrate anti tumor activity in DDR-related and other indications. By utilizing our platform to analyze the basal proteomics of resistant and sensitive cell lines treated with USP1i, we revealed a distinctive proteomic biomarker signature for USP1i response. This data demonstrates the potential of our novel USP1 inhibitor to serve as a potent therapeutic agent for DDR-deficient and other biomarker-positive cancer patients.

#7123 Biomarker-targeted alkylator and DNA damage repair inhibitor combination for refractory and relapsed acute myeloid leukemia (AML).

P. Bhardwaj, R. Sundaram, A. Baassiri, M. Matthews, J. VanOudenhove, S. Gueble, S. Halene, R. Bindra;
Yale University, New Haven, CT

Isocitrate dehydrogenase 1 and 2 (IDH1/2) convert isocitrate to α-ketoglutarate in the tricarboxylic acid (TCA) cycle. A missense mutation in IDH1/2 leads to accelerated conversion of α-ketoglutarate into 2-hydroxyglutarate (2-HG), an oncometabolite that competitively inhibits α-ketoglutarate-dependent dioxygenases including Ten-Eleven Translocation (TET) enzymes. TET enzymes are DNA demethylases that convert 5-methylcytosine to 5-carboxycytosine and regulate CpG island promoter methylation signatures. In IDH1/2 mutant glioma, inhibition of TET2 enzyme by 2-HG can lead to promoter hypermethylation of O^6-methylguanine methyltransferase (MGMT) and reduce its expression. Approximately 10-15% of de novo or treatment-related AML harbor mutually exclusive mutations in IDH1/2 or TET2, and emerging resistance towards clinical IDH1/2 inhibitors, therefore warrants novel therapeutic options. We performed a pan-cancer TCGA analysis and observed MGMT promoter hypermethylation and reduced expression in IDH1/2 AML. Our independent study on 10 AML patients (5 IDH1/2 and 5 TET2 mutant) corroborated the TCGA data and showed a significantly reduced expression of MGMT in comparison to 7 wild-type AML samples. As MGMT resolves O^6-alkylguanine lesions during DNA damage, we performed an exhaustive alkylator screen, where temozolomide (TMZ) and our novel compound KL-50 emerged as the top hits that imparted a maximum therapeutic index in multiple MGMT (MGMT+/–) isogenic AML cell line models. Both TMZ and KL-50 induced MGMT-dependent DNA strand breaks and replication stress and activated ATM and ATR DNA damage response pathways in a time-dependent manner. Inhibition of ATR activation with Ceralasertib, an ATR inhibitor (ATRi) currently in clinical trials for chronic myelomonocytic leukemia and myelodysplastic syndromes, imparted a profound MGMT-dependent synergy with TMZ and KL-50. Researchers have established in glioma that mismatch repair (MMR) loss confers resistance to TMZ, and reported studies also show evidence of MMR loss in refractory or relapsed AML patients. Thus, we developed numerous MMR-deficient isogenic AML cell lines in an MGMT+/– background and observed MMR loss-mediated resistance to TMZ and abrogation of its synergy with ATRi. Unlike TMZ, KL-50 retained a profound synergy with ATRi in an MGMT-dependent manner irrespective of MMR status. We are currently investigating our novel KL-50 and ATRi combination in MGMT/MMR isogenic cell line-based *in vivo* AML models and in AML patient-derived xenografts to establish it as a promising novel biomarker-targeted therapy for AML patients.

#7125 Inhibition of IDH1 impairs homologous recombination and induces sensitivity to PARP inhibitor in pancreatic cancer.

M. Zarei[1], O. Hajihassani[1], H. J. Graor[1], A. W. Loftus[2], S. Tahhan[1], F. Nakazzi[1], P. Naji[2], L. D. Rothermel[2], J. R. Brody[3], J. M. Winter[2];
[1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]University Hospitals Cleveland Medical Center, Cleveland, OH, [3]Oregon Health & Science University, Portland, OR

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a major cause of cancer-related deaths in the United States. While Poly (ADP-ribose) polymerase (PARP) inhibitors hold promise in treating PDAC with Homologous Recombination Deficiency (HRD). However, HRD occurs in only 10% of cases, leaving 90% with intact Homologous Recombination Proficiency (HRP). Our research highlights the key role of wild-type isocitrate dehydrogenase 1 (IDH1) in maintaining cellular function. We found that inhibiting IDH1 increases DNA damage, suppressing the DNA repair pathway crucial for genomic integrity. This makes cancer cells susceptible to PARP inhibitors, offering a new PDAC treatment approach.
Methods: The effect of IDH1 inhibition (Ivosidenib) combined with PARP inhibition (Olaparib) on in vitro growth inhibition were assessed through Trypan blue and PicoGreen in drug combination assays. Additionally, we investigated the molecular mechanism underlying the synergistic effects of drug combination. To further evaluate the therapeutic potential of IDH1 inhibition in combination with PARP inhibitors, we examined tumor growth in xenograft models of PDAC in athymic nude mice.
Results: Our data report that, mechanistically, IDH1 inhibition decreased expression of HR DNA repair pathway molecules, such as BRCA1 and BRCA2, and leading to decreased HR repair efficiency in pancreatic cancer cells. Short-term cell viability data demonstrated that targeting IDH1 with ivosidenib when combined with DNA-damaging agent (Olaparib) had a synergistic effect in HRP cell lines (MiaPaCa-2 and Panc-1) with a positive synergy score and Bliss score greater than 1. Additionally, we assessed long-term cell survival using colony formation assays, which yielded a dramatic reduction in cell survival for both Panc1 and MiaPaCa-2 cells when olaparib was combined with ivosidenib, as compared to single-agent controls. Consequently, this reduction increased the levels of apoptosis induced by olaparib. Furthermore, we discovered that these two compounds complemented each other in DNA damage response, leading to an increase in the DNA damage biomarker γ-H2AX. In vivo studies using xenograft models demonstrated that the combination of ivosidenib and olaparib synergistically enhanced anti-tumor activity as compared to either single-agent used alone.
Conclusion: Our data provides insights into the mechanisms underlying the susceptibility of PDAC tumor growth to a dual treatment approach involving an IDH1 inhibitor and a PARP inhibitor, particularly in the context of HRP cancer. This highlights the promise of precision medicine for pancreatic cancer treatment, though further pre-clinical studies are needed for validation and refinement.

#7126 Synergistic combinations and tissue type-specificity of compounds targeting components of the DNA damage response pathway in 2D culture and 3D spheroid cell viability assays.

J. J. T. Melis, D. J. F. Kluitmans, J. J. Kooijman, J. Dylus, S. Wetemans, S. Geerdink-Datema, J. A. D. de Roos, Y. Grobben, G. J. R. Zaman; Oncolines B.V., Oss, Netherlands

Poly (ADP-ribose) polymerase (PARP) inhibitors have changed the landscape of treatment for homologous recombination (HR)-deficient cancers. PARP inhibitors are synthetically lethal with deficiencies in genes involved in the HR pathway, such as *BRCA2*, but resistance against PARP inhibitors is a major problem in the clinic. The use of new synergistic drug combinations targeting different components of the DNA damage response (DDR) pathway may overcome PARP inhibitor resistance. Sixteen small molecule inhibitors acting on different targets in the DDR pathway (including PARP, Polθ and ATR) were profiled in 2D culture and 3D spheroid cell viability assays. Intracellular ATP content was used as an indirect readout of cell number. Compound synergies were determined by profiling combinations of compounds in a 6-by-6 matrix, and quantifying synergistic effects using the Excess over Bliss score [1]. A pair of isogenic *BRCA2*-deficient and -proficient DLD-1 colon adenocarcinoma cell lines was used as a model of *BRCA2*-deficient tumors. In 2D cell viability assays, PARP inhibitors and the Polθ inhibitor ART558 were more active in *BRCA2*-deficient compared to *BRCA2*-proficient DLD-1 cells, whereas an ATR inhibitor (ceralasertib) was equally potent in both cell lines. Combining olaparib with ART558 in 2D culture and 3D spheroid studies showed synergistic effects in *BRCA2*-deficient DLD-1 cells. Moreover, olaparib synergized with ceralasertib in both *BRCA2*-deficient and -proficient DLD-1 cells. Different DDR-targeting inhibitors were profiled in over a hundred cancer cell lines from diverse tumor tissue origin in 2D assays. This showed a relatively high potency for PARP inhibitors in ovarian cancer cell lines compared to cell lines derived from other tissue types, which is consistent with the clinical application of PARP inhibitors for treatment of ovarian cancers. For ATR inhibitors and ART558, kidney and myeloid cancer cell lines were found to be most sensitive, respectively, suggesting potential therapeutic utility of ATR and Polθ inhibitors for treatment of these cancer types. The genomic determinants of the different sensitivities were investigated by comparing compound potencies in the cell viability assays with the mutation status of more than 500 genes involved in cancer or the DDR pathway in the cell lines. Additionally, cancer cell line sensitivity was correlated with the expression levels of more than 19,000 genes in these cell lines to identify novel RNA signatures capable of predicting response to DDR-targeting inhibitors. This study uncovers new synergistic drug combinations that increase the efficiency of PARP inhibitors, and provides new insights into the determinants of cancer cell line sensitivity to compounds targeting different components of the DDR pathway. [1] Liu *et al.* Stat. Biopharm. Res. 10, 112-22; 2018

#7127 An ATM inhibitor: ZN-B-2262 in combination with radiation /ADCs containing topoisomerase inhibitors for the treatment of solid tumors.

D. Zhou, Z. Wang, Y. Liu, T. Fu, Z. Cheng;
Zion Pharma Limited, Shanghai, China

Background: ZN-B-2262 is a best-in-class, IND-approved, small molecule serine/threonine kinase receptor inhibitor targeting Ataxia Telangiectasia Mutated (ATM), which plays a key role in DNA damage response (DDR) associated with double-strand breaks (DSB). Radiotherapy (RT) and topoisomerase inhibition can directly cause DSB. ZN-B-2262 is expected to enhance the therapeutic effect of RT, or antibody drug conjugates (ADCs) containing topoisomerase inhibitors by suppressing DSB DNA repair and blocking checkpoint controls.

Methods: The inhibition of isolated recombinant ATM, ATR, mTOR, DNA-PK, PI3Kα, PI3Kβ, PI3Kδ and PI3Kγ enzymes was evaluated using In-Cell-Western assay to determine the effect of ZN-B-2262 on ATM enzyme activity by detecting phosp-KAP1 (Ser824) expression. The inhibition of phospho-ATM (Ser1981) was evaluated by ATM assay on HT29 cells using a High-Content Imaging System (HCS). Therapeutic efficacy, as measured by tumor growth inhibition (TGI), was evaluated using ZN-B-2262 in combination with DS-1062 (Trop2 ADC), irinotecan or RT in MDA-MB-468 triple negative breast cancer (TNBC), SW620 colorectal cancer, and Fadu head and neck squamous cell carcinoma (HNSCC) subcutaneous xenograft murine models, respectively. In addition, ZN-B-2262 was tested for Human Aldehyde Oxidase (AO) activity. Safety margins were determined based on the ratio of unbound AUC obtained from 28-day GLP animal toxicology studies and predicted human PK at efficacious dose.

Results: ZN-B-2262 exhibited strong inhibition against ATM with the IC_{50} at 4.4 nM. No inhibition effect was observed on other IKK family enzymes with IC_{50} value >10 uM. ZN-B-2262 showed high inhibition activity on phosp-KAP1 with IC_{50} of 13.25 nM and on phospho-ATM with IC_{50} of 21.5 nM. In the MDA-MB-468 xenograft efficacy study, ZN-B-2262 combined with a clinically relevant dose of DS-1062 showed significantly superior tumor inhibition effects compared to DS-1062 alone. In the SW620 xenograft efficacy study, in combination with irinotecan, ZN-B-2262 showed synergistic tumor inhibition effects. In the Fadu xenograft efficacy study, ZN-B-2262 demonstrated synergistic anti-tumor activity when combined with RT. Sustained and enhanced anti-tumor efficacy was observed post withdrawal of ZN-B-2262 combined with RT, which was not observed after stopping treatment of RT alone. Based on 28-day GLP tox in rat and dog, the predicted human safety margin is 25- to 50-fold.

Conclusion: ZN-B-2262, in combination with ADCs containing topoisomerase inhibitors, (e.g., Dato-Dxd), or RT, is expected to be a best-in-class (possibly first-in-class) compound, for the treatment of solid tumors. In particular, ZN-B-2262 should demonstrate improved PK and minimal inter-patient PK variability compared to current ATM clinical candidates since ZN-B-2262 is not an AO substrate.

#7128 Novel Ku-DNA binding inhibitors impact on the cellular and *in vivo* DNA damage response to radio- and radiomimetic-therapy.

P. L. Mendoza-Munoz[1], D. Chauhan[2], N. S. Gavande[2], J. R. Dynlacht[1], J. E. Garrett[1], **J. J. Turchi**[1];
[1]Indiana University School of Medicine, Indianapolis, IN, [2]Wayne State University, Detroit, MI

DNA-PK, the DNA-dependent protein kinase, is a validated target for cancer therapeutics that plays a central role in the non-homologous end joining (NHEJ) DNA repair pathway and the DNA damage response (DDR). NHEJ is a key mechanism of DNA double-strand breaks (DSB) repair, especially those induced by ionizing radiation (IR). Ku 70/80 heterodimer is required as initiator in this process, acting as an essential DNA-binding component of DNA-PK that senses DNA damage. Blocking the DNA-PK kinase activity in combination with DSB inducing agents has been widely used as a therapeutic strategy to drive clinical efficacy of radiation therapy for cancer treatment.

We have reported a unique approach of DNA-PK inhibition by developing Ku-DNA binding inhibitors (Ku-DBi's), small molecule inhibitors that target the interaction between Ku70/80 and DNA. Ku-DBi's demonstrated a direct interaction with Ku70/80, a potent inhibition of Ku-DNA binding and DNA-PK catalytic activity, and *in vitro* and cellular NHEJ inhibitory activity. This results in the potentiation of non-small cell lung cancer (NSCLC) cellular sensitivity to DSB generating therapies, as a function of inhibiting DNA-PKcs autophosphorylation and dysregulation of signaling to the DDR. In this study, we have expanded our structure activity relationship analyses to focus on optimizing selectivity, cellular uptake and Ku inhibitory activity. The new series of Ku-DBi's include oxindole derivatives of the X80 core structure that achieve these goals. These novel compounds display increased cellular uptake while retaining potent Ku inhibitory activity and enhanced cellular inhibition on DNA-DSB repair. Ku-DBi's optimization has enabled in vivo analyses of Ku-DBi - ionizing radiation combination therapy in human xenograft models of non-small cell lung cancer. The impact of Ku-DBi treatment on therapeutic efficacy, toxicity, Ku/DNA-PK inhibition, and DDR signaling will be presented. These data represent a significant advance in the development of Ku-DNA binding inhibitors and their therapeutic intervention for cancer treatment.

#7129 DNA polymerase beta expression in head & neck cancer modulates the poly-ADP-ribose-mediated replication checkpoint.

M. Khan[1], A. Angajala[2], D. Gibbs[3], J. Liu[3], C. Ragin[3], R. Sobol[1];
[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]University of South Alabama, Mobile, AL, [3]Fox Chase Cancer Center, Temple Health, Philadelphia, PA

Head and Neck Squamous Cell Carcinoma (HNSCC) impose a significant health burden, necessitating innovative therapeutic strategies to enhance treatment efficacy. Current standard treatments, including surgery, radiation therapy, and chemotherapy, often exhibit limited effectiveness and cause substantial side effects. This underscores the critical need for novel therapies that selectively target cancer cells, sparing normal tissue. Survival from HNSCC is poor, and importantly, a racial disparity between African Americans (AfAm) and European Americans (EuAm) has been known for some time. Ancestry Informative Markers (AIMs) are associated with altered mRNA expression of Polβ where higher expression of Polβ was observed among AfAm patients in comparison to EuAm patients. Our research focuses on DNA polymerase beta (Polβ) and its role in replication stress and response to chemotherapy and DNA damage response modifiers. Elevated expression of Polβ is linked to increased DNA damage and genomic instability, contributing to treatment resistance. In this regard, our investigations reveal a regulatory role for base excision repair (BER) proteins, including Polβ, in the cellular response to inhibitors of poly(ADP-ribose) glycohydrolase (PARG), an enzyme involved in poly(ADP-ribose) (PAR) degradation. Inhibition of PARG triggers a robust intra-S phase response, activating ATR and CHK1 signaling. Exploiting the synthetic lethality between PARG inhibition and ATR/CHK1 inhibition, we have demonstrated the ability to overcome Polβ overexpression mediated treatment resistance in HNSCC cells. Specifically, our in vitro studies demonstrate that the response to a combination of an ATR inhibitor and PARG inhibitor is impacted by Polβ expression in HNSCC cells, with synergistic effects surpassing the efficacy of the individual inhibitors. Similarly, the combination of a CHK1 inhibitor and PARG inhibitor proves effective in cells with elevated Polβ expression, offering a potential dual therapeutic strategy. These combinations exhibit promising potential for HNSCC treatment when Polβ expression is elevated. In conclusion, our findings propose a novel therapeutic paradigm for HNSCC, employing combination therapy with ATR or CHK1 inhibitors and PARG inhibitors. This approach offers a targeted strategy, presenting a promising avenue for the development of more effective and less toxic treatment modalities in the management of HNSCC and may help overcome resistance from elevated expression of Polβ.

#7130 Dysregulated DNA repaired elicited by type 1 PRMT inhibitor in clear cell renal cell carcinoma enables development of novel combination therapies.

K. Arevalo[1], J. Walton[2], J. Meens[2], A. Ng[1], L. Ailles[2];

[1]University of Toronto, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada

Clear cell renal cell carcinoma (ccRCC) is the most prevalent form of kidney cancer, notorious for its resistance to treatment and dismal prognosis. Advanced or metastatic cases on average display an 8% 5-year survival rate. Given the considerable number of diagnoses in advanced stages, it is evident that we require innovative therapeutic approaches. Our lab has developed a methodology to establish cell lines from tumors and adjacent normal tissues sourced from patients. Consequently, we've amassed a collection of cell lines, including those from patient-derived ccRCC and normal kidney cells. Using these ccRCC models, we demonstrated that the type I protein arginine methyltransferase inhibitor, MS023, elicits a dysregulated DNA repair phenotype. RNA-Seq analysis of ccRCC cells treated with MS023 unveiled a marked downregulation of genes associated with the homologous recombination (HR) pathway for double-strand break repair and the Fanconi Anemia (FA) pathway for interstrand crosslink (ICL) repair. In a follow-up investigation using paired normal and cancerous cell lines from the same patient, we identified resistance to MS023 in normal kidney cells that is not mirrored in the corresponding ccRCC cell line. This hints at a potential therapeutic window and provides a strong rationale for clinical pursuit. Poly-ADP ribose polymerase (PARP) inhibitors are known to yield a synergistic effect when employed in HR-deficient diseases, such as BRCA-deficient breast cancers. Since MS023 induces an HR-deficient phenotype, we hypothesize that combining it with Talazoparib, a PARP inhibitor, will produce a similar synergistic effect. Additionally, mitomycin C (MMC) is a clinically approved compound that induces ICLs. As MS023 impedes ICL repair by downregulating crucial ICL-repairing genes, combining these two drugs should likewise generate a synergistic effect. Through a drug screen across two of our ccRCC cell lines, we discovered that the cells exhibit sensitivity to various PARP inhibitors. Employing synergy checkerboard assays and the highest single-agent model of synergy, we have found that the combination of MS023 and Talazoparib, as well as the combination of MS023 and MMC, demonstrate synergy, significantly reducing cellular viability at lower doses of the combination treatments compared to mono-treatment conditions at their respective doses. Preliminary *in vivo* studies using patient-derived xenograft models have revealed that both MS023 and Talazoparib are well-tolerated in mice, both when administered individually and in combination. Our current knowledge base indicates that MS023 holds promise for clinical investigation, both as a standalone treatment and in combination with Talazoparib or MMC. These results present an exciting opportunity to shed new light on the challenging therapeutic landscape faced by ccRCC patients today.

#7131 Base excision repair regulation of replication stress induced poly(ADP-ribose) checkpoints.

M. Ibrahim[1], M. Khan[2], R. Q. Al-Rahaleh[2], J. Clark[1], F. Hayat[1], Q. Fang[1], C. A. Koczor[1], M. E. Migaud[1], **R. W. Sobol**[2];
[1]University of South Alabama, Mobile, AL, [2]Brown University, Providence, RI

PARP-inhibitors (PARPi) have been developed to treat homology-directed repair deficient cancers such as BRCA1/2-defective breast and ovarian tumors. However, acquired resistance to PARPi is now common, suggesting the need to identify new protein targets. To that end, a missed opportunity is found in the PARP1/PARP2 activation mechanism in response to DNA damage and replication stress and the resulting protein complexes and enzymes that depend on and coordinate PARP-mediated DNA repair processes. We have found that PARP1/PARP2 activation, whether from acute DNA damage, from replication stress or both triggers a temporal and coordinated interplay of base excision repair and single-strand break repair (BER/SSBR) proteins and enzymes. In turn, the recruitment of these BER and SSBR proteins suppresses PARP1/PARP2 activation, thereby functioning as a network of PARP1/PARP2 regulators, modulating the PARP-mediated response to replication stress. To that end, we find that loss of expression of these key BER/SSBR proteins releases a break on replication-stress induced PARP1/PARP2 activation, triggering un-restrained PARP1/PARP2 activation and elevated levels of replication-dependent poly(ADP-ribose) (PAR). We next confirmed that the loss of these downstream BER enzymes render cancer cells responsive to PARPi's when the BRCA1/2 pathways are restored. Further, we show that BER expression regulates the cellular response to inhibitors of the PAR degrading enzyme PARG, suggesting that XRCC1-dependent BER proteins regulate replication-stress dependent PAR accumulation. The increase in PAR due to PARG inhibition, that is further regulated by BER, drives a strong intra-S phase response, indicated by activation of ATR and CHK1 signaling. As the checkpoint governed by ATR and CHK1 functions as a protective mechanism, we show that PARG inhibition is synthetically lethal with ATR and CHK1 inhibition and this may be explained by our demonstration of PARGi-mediated trapping of essential BER proteins at the site of damage and PAR accumulation. Together, these studies reveal a significant role for BER/SSBR proteins in regulating replication stress induced PARylation and the resulting intra-S phase checkpoint.

#7132 Preclinical characterization of LAE119, a novel PARP1 selective inhibitor and trapper.

M. Li, Y. Chen, J. Chen, L. Jiang, X. Lin, J. Gu;
Laekna Therapeutics Shanghai Co., Ltd., Shanghai, China

Current PARP inhibitors primarily target PARP1/2 and demonstrate high efficacy against tumors with deficiencies in homologous recombination repair, such as those with BRCA mutations. However, these inhibitors are also associated with significant hematological toxicities. Studies have indicated that the synthetic lethality observed with BRCA mutations is mainly driven by PARP1, while PARP2 is not essential in this context. PARP2 has been shown to be crucial for the survival of hematopoietic stem/progenitor cells in animal models. Therefore, selective inhibition of PARP1 could potentially reduce toxicity and improve therapeutic outcomes. Here we introduce LAE119, a potent and selective PARP1 inhibitor and PARP1-DNA trapper. It demonstrates more than a 1000-fold selectivity for PARP1 DNA trapping compared to PARP2. In comparison to most PARP inhibitors including AZD5305, LAE119 exhibits extremely long residence time on PARP1 in both biochemical and cellular assays. It demonstrates robust anti-proliferation activity against BRCA2$^{-/-}$ DLD-1 cells and MDA-MB-436 cells, with IC_{50} value of 0.6 nM in both cell lines. In CAL51 cells, which has a BRCA2 mutation but with low PARP1 expression level and are much less sensitive to AZD5305, LAE119 demonstrates much better activity than AZD5305, particularly when PARP1 level is increased with transgene expression. LAE119 demonstrated substantial tumor inhibition in MDA-MB-436 and Capan-1 xenograft models. LAE119 also displays favorable ADME properties and PK profiles. It has high tumor/plasma ratio which is beneficial for sustainable anti-tumor effect and reduction of off-target effects. In rat hematologic toxicity study, LAE119 at 10 mpk QD dose was well tolerated and had minimal effects on hematologic parameters. Both in vitro and in vivo data strongly support the further clinical investigation of LAE119.

#7133 Phenomics-enabled discovery and optimization of small-molecule RBM39 degraders as an alternative to CDK12 targeting in high-grade serous ovarian cancer (HGSOC).

C. Neumann, H. Shankaran, K. Nadella, K. Biette, S. Rowley, E. Gardner, S. Swaidani, V. Manda, L. Chen, D. Beshnova, A. Saeed, C. Bailey, J. Paulsen, P. Rearden, C. Brooks, A. Bhandari, C. Gibson, L. Schaevitz, I. Haque, H. Donnella, M. Cuccarese, M. Evangelista;
Recursion Pharmaceuticals, Salt Lake City, UT

Phenomics-enabled drug discovery is a powerful approach to identify novel targets and relationships previously unappreciated in biology. We built a phenomics platform leveraging high content microscopy and generated unique phenoprints for >7,000 genes using CRISPR/Cas9 technology and a diverse chemical library of >1 million compounds. This phenomics dataset contains an unprecedented quantity of gene-gene, gene-compound, and compound-compound relationships. We applied our phenomics platform and an inference based target-agnostic drug discovery approach to discover novel genes and small molecules that mimic CDK12 inhibition, an important transcriptional regulator of DNA damage response, while avoiding inhibition of the paralog CDK13. We discovered a novel and unappreciated association between CDK12 and RBM39 as well as small molecule degraders of RBM39. We established structure activity relationships (SAR) solely leveraging our phenomics platform, to generate REC-1170204, an RBM39 degrader. Unlike inhibitors of CDK12, we show that REC-1170204 does not directly inhibit CDK12, CDK13 or other kinases. However, REC-1170204 demonstrates candidate quality properties with improved potency, selectivity, and drug-like characteristics. Finally we show that REC-1170204 shows efficacy in High Grade Serous Ovarian cancer (HGSOC) pre-clinical models and synergizes with PARP inhibition in a PARP-resistant patient-derived xenograft (PDX) model. Together, our data suggests that targeting RBM39 may provide an attractive and safer approach to targeting CDK12 in the clinic.

#7134 Treatment of pancreatic cancer cells with tumor treating fields (TTFields) and PARP inhibitors.

H. Ene, K. Ben Meir, A. Martinez-Conde, R. Frechtel-Gerzi, H. Gabay, D. Gerasimova, R. Engelman, **E. Dor-On**, A. Haber, M. Giladi, Y. Palti;
Novocure Ltd, Haifa, Israel

Background: Therapeutic options for advanced stage pancreatic cancer are limited. Patients harboring germline BRCA mutations benefit from PARP inhibitors (PARPi); unfortunately, such mutations are rare in pancreatic cancer. Tumor Treating Fields (TTFields), electric fields that disrupt cellular processes crucial for cancer cell viability, have shown effectiveness against pancreatic cancer cells, and are currently under clinical investigation for the treatment of patients with pancreatic cancer. The mechanism of action of TTFields in various cancer types has suggested involvement of BRCA downregulation. The current study examined the potential sensitization of BRCA wild-type pancreatic cancer cell lines to PARPi with TTFields application.
Methods: BxPC3 and AsPC1 human pancreatic BRCA wild-type cancer cells were treated for 72 h with TTFields (frequency of 150 kHz; intensity of 1 and 0.5 V/cm RMS, respectively), using the inovitro device. The PARPi niraparib and olaparib were each administered to the cells at various concentrations, with or without co-application of TTFields. At treatment cessation, cell count, colony formation, and apoptosis were measured.
Results: Applying PARPi to pancreatic cell lines yielded a dose-dependent cytotoxic and anti-clonogenic effects, and induced apoptosis. TTFields application also induced such effects when applied alone, while delivery of TTFields together with PARPi amplified the effects demonstrated by PARPi alone.
Conclusions: Concomitant application of TTFields and PARPi in BRCA wild type pancreatic cancer cells exhibits a potential improvement relative to the mono-therapies. This could be rationalized based on the previously demonstrated ability of TTFields to induce a state of BRCAness in cancer cells, and suggests benefit for TTFields and PARPi co-treatment in the absence of background BRCA mutations.

#7135 Preclinical effects of Tumor Treating Fields (TTFields) with PARP inhibitors in ovarian cancer.

Y. Berckmans[1], H. Ene[2], K. Ben-Meir[2], A. Martinez-Conde[2], R. Monin[2], B. Van den Ende[1], S. Van Mechelen[1], R. Frechtel-Gerzi[2], H. Gabay[2], R. Engelman[2], **E. Dor-On**[2], A. Haber[2], M. Giladi[2], U. Weinberg[2], Y. Palti[2], I. Vergote[1], A. Coosemans[1];

[1]Leuven Cancer Institute, KU Leuven, Leuven, Belgium, [2]Novocure Ltd, Haifa, Israel

Purpose: Among gynecological malignancies, ovarian cancer is the leading cause of mortality. Poly (ADP-ribose) polymerase inhibitors (PARPi) represent standard-of-care treatment for selected cases of advanced epithelial ovarian cancer. PARPi exhibit sensitivity in homologues recombination deficient (HRD) tumors, in which there are mutations in the Fanconi Anemia (FA)-BRCA pathway, while about 75% of ovarian cancer patients are homologues recombination proficient (HRP). TTFields are non-invasive electric fields that disrupt cellular processes critical for cancer cell viability and tumor progression. Recent research showed that TTFields induce an HRD-like state (also known as BRCAness state) in various cancer types. The current study aims to investigate the impact of TTFields applied together with PARPi in ovarian cancer preclinical models.

Methods: *In vitro,* A2780 (HRP), OVCAR3 (HRD), and A2780cis (platinum-resistant) ovarian cancer cells were treated with TTFields (1 V/cm RMS, 200 kHz, 72 h), alone or with addition of PARPi (olaparib or niraparib, at various concentrations). Efficacy was measured by analyzing cell count, colony formation, and apoptosis induction. The overall effect was calculated by multiplying cell count with colony formation. TTFields-treated cells were evaluated for the expression of FA-BRCA pathway proteins and for formation of γH2AX, a DNA damage marker, using Western blot and fluorescent microscopy, respectively. *In vivo*, ID8-fLuc (HRP) cells were inoculated intraperitoneally to 6-8-week-old C57BL/6 mice. Seven days post inoculation, mice were treated with sham-vehicle, TTFields, olaparib (50 mg/kg), or both over a period of four weeks. Tumor growth was analyzed using bioluminescent imaging at treatment cessation, and survival analysis was performed.

Results: TTFields application resulted in reduced cell count, increased overall effect, and increased apoptosis *in vitro*. When TTFields were applied together with PARPi, a high and moderate synergistic interaction was shown respectively the BRCA wild-type A2780 cells and the platinum-resistant A2780cis cells. However, in the BRCA mutant OVCAR-3 cells the effect was additive. A downregulation of FA-BRCA protein expression was confirmed after TTFields treatment of the ovarian cells, with consequent DNA damage. In the tumor-bearing mice, TTFields and olaparib co-treatment resulted in reduced tumor volume and a survival benefit relative to the monotherapies and to control-treated mice.

Conclusions: The data suggest potential advantages for TTFields concomitant with PARPi in ovarian cancer, even without underlying BRCA mutations - consistent with the BRCAness state induced by TTFields - and also suggests benefits in platinum-resistant ovarian cancer.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 6
Poster Session

#7139 Anti-cancer effects of benzimidazole derivative BNZ-111 on paclitaxel-resistant ovarian cancer.

J.-W. Lee[1], K. Lee[2], B. Koh[2], Y.-Y. Lee[1], D.-S. Bae[1];
[1]Samsung Medical Center, Seoul, Korea, Republic of, [2]Korea Research Institute of Chemical Technology, Daejeon, Korea, Republic of

Ovarian cancer, a leading cause of cancer-related deaths in women, remains a formidable challenge, especially in the context of platinum-resistant disease. This study investigated the potential of the benzimidazole derivative BNZ-111 as a novel treatment strategy for platinum-resistant ovarian cancer. With improved pharmacokinetic parameters, BNZ-111 effectively disrupts tubulin polymerization through hydrogen bonds and hydrophobic interactions. It demonstrated strong cytotoxicity in both chemo-sensitive and chemo-resistant epithelial ovarian cancer cell lines, inducing apoptosis and G2/M cell cycle arrest. In vivo experiments using orthotopic and patient-derived xenograft models showed significant tumor growth inhibition without apparent toxicity to vital organs. Unlike paclitaxel, BNZ-111 proved effective in paclitaxel-resistant cells, potentially by bypassing interaction with MDR1 and modulating β-3 tubulin expression to suppress microtubule dynamics. This study suggests that BNZ-111, with favorable drug-like properties, holds promise as a therapeutic option for platinum-resistant ovarian cancer, addressing a critical clinical need in gynecologic oncology

#7140 A new series of flavonoid derivatives with anti-cancer activity includes SDN207, SND210, SND524, and SND562 as potent microtubule-targeting agents.

A. J. Arribas[1], E. Cannas[1], E. Gaudio[2], P. Biniecka[2], D. Stoicescu[2], F. Bertoni[1];

[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland, [2]Floratek Pharma, Aubonne, Switzerland

Background: Plant-derived compounds, including flavonoids, can be potent anti-cancer agents, but low bioavailability, lack of specificity, and complexity in their synthesis can hamper their clinical development. Here, we present seven novel flavonoid derivatives, and test them for their anti-tumor activity in various models derived from hematological cancers and solid tumors.

Methods: MTT assessed anti-proliferative activity after 72h of exposure to increasing concentrations of drugs. Tubulin Polymerization Assay was performed with 3-fold dilutions (15-0.02 µM), compared to paclitaxel (1-3 µM) or vinblastine (3 µM) as references. The OncolinesProfiler analysis was used to compare IC50 fingerprints determined on the Oncolines cell line panel to the IC50 fingerprints of 213 pre-profiled reference drugs.

Results: SDN207, SND210, SND216, SND462, SND504, SND524, and SND562 were designed and synthesized using a flavonoid polyphenol scaffold selectively modified to markedly increase cytotoxicity towards cancer cells. All seven compounds showed dose-dependent anti-proliferative activity across 15 lymphoma cell lines derived from germinal center B-cell-like (GCB) diffuse large B cell lymphoma (DLBCL) (n=6), activated B cell-like (ABC) DLBCL (n=2), mantle cell lymphoma (n=4), and marginal zone lymphoma (MZL) (n=3). Activity in the nM range was seen with five compounds: SDN207 (median IC50 1.6 nM; 95%CI, 1.3-3.2), SND210 (1.4 nM; 95%CI, 0.9-3.3), SND216 (19.5 nM; 95%CI, 10-38 nM), SND562 (28.9 nM; 95%CI, 15.4-57.7), and SND524 (46.7 nM; 95%CI, 32-133.3). Both other compounds had a median IC50 of 2 µM (SND462, 95%CI, 1.1-4.5 µM; SND504, 95%CI, 0.5-3.9 µM). There were no differences based on lymphoma histology. The anti-tumor activity was maintained in MZL cell lines with acquired resistance to BTK and PI3K inhibitors (n=3). Six compounds were also assessed for their anti-tumor activity in models other than lymphomas (SDN207, n=31; SND210, n=20; SND462, n=4; SND504, n=4; SND524, n=9; SND562, n=35), confirming the higher activity for SDN207, SND210, SND562, and SND524. Regarding the mechanism of action, up to now, a tubulin polymerization assay was performed for three compounds. Microtubule depolymerization (SND207), and microtubule polymerization (SND524, SND562) were observed at concentrations as low as 20 nM. The OncolinesProfiler identified the tubulin-targeting agents vinblastine, vincristine, paclitaxel, and docetaxel among the top reference compounds most correlated with SND207 and SND210 (*i.e.*, Pearson correlation > 0.5).

Conclusions: Novel compounds developed using plant-derived skeletons have shown in vitro anti-tumor activity in lymphomas, leukemias, and solid tumors, including models of resistance to targeted agents. Microtubule targeting appeared as a possible mechanism of action for at least four of them.

#7141 The novel microtubule-destabilizing compound AUS_001 maintains unique binding to the colchicine site of tubulin and elicits reversible cellular effects relative to other anti-tubulin agents.

H. Lelie[1], Y.-C. Chou[2], A. J. King[2], Z. Boiarska[3], A. E. Prota[4], M. O. Steinmetz[4], **M. Koutsioumpa**[1];

[1]Australis Pharmaceuticals, Inc., Simi Valley, CA, [2]Eurofins Discovery, St. Charles, MO, [3]Universita degli Studi di Milano, Milano, Italy, [4]Paul Scherrer Institut, Villigen PSI, Switzerland

Our previous work showed that the prenylated hydroxy-stilbene AUS_001 exerts a strong safety profile and potent anti-proliferative responses, as assessed in 30 types of cancer cell lines, stemming from its microtubule destabilization activity. The aim of the current study was to delineate the molecular mechanism of microtubule destabilization by AUS_001 and to provide insight into its high potency and low toxicity. Surface plasmon resonance (SPR) experiments revealed the direct interaction of AUS_001 with tubulin with an apparent equilibrium dissociation constant, Kd, of 2.13×10^{-5}M. Size exclusion competition assays and an X-ray crystal structure of the tubulin-AUS_001 complex at 2.1 Å resolution establish ligand binding within the colchicine site on tubulin. Since colchicine-site ligands are well known to inhibit the curved-to-straight conformational transition of tubulin, which is an essential process for microtubule formation, these results readily explain the microtubule-destabilizing activity of the compound. Notably, while both combretastatin A4 (CA-4) and AUS_001 are both colchicine-site stilbene ligands, CA-4 binds in the *cis* configuration, while AUS_001 maintains a *trans* configuration leading to a substantially different pocket engagement. Comparison of the tubulin-AUS_001 complex structure with the ones of tubulin-colchicine and tubulin-plinabulin revealed that AUS_001 elicits different rearrangements in the T7 loop of β-tubulin versus colchicine and occupies a different zone of the pocket relative to plinabulin, further elaborating its unique binding properties. Interestingly, AUS_001 exhibits a higher relative affinity than colchicine itself, as assessed by i) an ultrafiltration-based tubulin-ligand release assay and ii) a radioligand colchicine competition assay. However, fitting steady state SPR data for AUS_001 binding to tubulin revealed fast association and dissociation rates and was indicative of reversible binding. The latter finding is corroborated by AUS_001-triggered reverse biological effects including morphological alterations, cell cycle G2/M arrest, and by a decrease of cell viability upon discontinuation of the drug treatment in glioma and pancreatic cancer cells. Conversely, colchicine, CA-4 or paclitaxel administered at the same doses as those applied for AUS_001 failed to reverse the drug-induced phenotypes upon removal resulting in sustained cytotoxicity. In conclusion, we fully characterized the unique binding mode of AUS_001 to the colchicine site of tubulin and elucidated the reversible nature of the target engagement. AUS_001 features a distinctive and reversible molecular interaction with tubulin which provides a plausible explanation for its favorable safety profile compared to other microtubule targeting agents.

#7142 Optimizing estradiol dimers through linker design: Enhancing anticancer efficacy by targeting microtubule dynamics.

P. Dzubak[1], M. Jurasek[2], J. Řehulka[1], S. Gurska[1], P. Polishchuk[1], P. Draber[3], L. Huml[2], P. B. Drasar[2], A. Ivanova[1], O. Mokshyna[1], L. Hruba[1], M. Hajduch[1]; [1]Palacky University in Olomouc, Olomouc, Czech Republic, [2]University of Chemistry and Technology Prague, Prague, Czech Republic, [3]Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic

We investigated the development and anticancer efficacy of novel estradiol dimers (ED), targeting the dynamics of microtubules—an essential factor in effective cancer therapy. Employing copper-catalyzed azide-alkyne cycloaddition (CuAAC), two distinct series of ED variants were synthesized. The initial series included thirteen dimers, derived from 17α-ethinyl estradiol, incorporating varied five-atom linkers with central carbon, nitrogen, or oxygen atoms, and, in some instances, modified with benzyl groups containing hydroxy or methoxy substituents. These dimers were evaluated for their cytotoxic properties and impact on the cell cycle, revealing certain structures with substantial efficacy, compared with the original ED. The subsequent series, encompassing twelve variants, concentrated on structural alterations within the aromatic bridges linking the estradiol units. In this series, linkers of simpler composition and fewer substituents demonstrated increased selectivity and potency against cancer cell lines, particularly ED3 and ED5, which exhibited cytotoxicity levels comparable to established tubulin inhibitors. Both dimers series showed the ability to disrupt microtubule assembly and mitotic processes, confirmed through cell-based evaluations and in vitro tubulin assembly assays. Complementing these results, in silico modelling and binding free energy calculations exhibited a strong correlation with the demonstrated biological activities, especially in terms of binding affinity to the colchicine site. Collectively, these findings highlight the promise of estradiol dimers as potential anticancer agents and emphasize the critical role of linker structures in enhancing their biological effectiveness. Work was supported by the Ministry of Education, Youth and Sports of the Czech Republic through infrastructural projects (CZ-OPENSCREEN - LM2018130; EATRIS-CZ - LM2018133) and National Institute for Cancer Research (Programme EXCELES, ID Project No. LX22NPO5102) - Funded by the European Union - Next Generation EU.

#7144 BR0L075 (SCB01A), a microtubule inhibitor targeting the colchicine binding site, induces immunogenic cell death.

A. Bano, X. Liu;
University of Houston, Houston, TX

BPR0L075 (also known as SCB01A in phase II clinical trial) is a novel anti-microtubule drug with potent anti-tumor and anti-angiogenic activity in vitro and in vivo. BPR0L075 inhibits tubulin polymerization (microtubule de-stabilizer) by binding to the colchicine-binding site of tubulin. We previously reported that BPR0L075 overcomes paclitaxel (microtubule stabilizer) resistance and induces vascular-disruption in vitro and in vivo. We observed that breast and ovarian cancer cells treated with BPR0L075 in vitro induced key hallmarks of immunogenic cell death (ICD). In both human and murine, ovarian (OVCAR3, ID8) and breast cancer (MDA-MB-231, 4T1) cell lines, treatment with low nanomolar concentration of BPR0L075 significantly decreased the viability of cells evidenced by SRB assay. Using a known ICD inducer mitoxantrone as a positive control, both flow cytometric analysis and immunofluorescence staining assays demonstrated that BPR0L075 treatment led to a time- and dose-dependent translocation of calreticulin, an endoplasmic reticulum chaperone protein, on the plasma membrane of dying cells which sends an “eat me” signal. The BPR0L75 treatment also led to secretion of High Mobility Group Box 1 (HMGB1), a non-histone chromatin-binding nuclear protein, as well as adenosine triphosphate (ATP) from the cell into the extracellular space using ELISA assay. These damage-associated molecular patterns (DAMPs) are known to lead to antigen-presenting cell recruitment, phagocytosis, maturation of dendritic cells, and chemotaxis. The appearance of the ICD biomarkers (calreticulin exposure, HMGB1 and ATP release) supports BPR0L075 as an ICD-inducing antimitotic agent. Further in vivo studies are warranted to delineate the effect of BPR0L075 on immune activation and recruitment of immune cells to the tumor microenvironment.

#7145 Identification of Debio 0432 as a potent and selective USP1 inhibitor for cancer therapy.

N. Luong[1], A. Kunze[1], N. Quesnot[1], E. R. Aho[2], L. Berry[2], S. Boiko[2], A. J. Buckmelter[2], S. Lofek[3], S. Vigano[3], V. Gerusz[4], C. Chardonnens[3];
[1]Debiopharm International S.A., Lausanne, Switzerland, [2]Forma Therapeutics, Watertown, MA, [3]Debiopharm Research and Manufacturing SA, Martigny, Switzerland, [4]Debiopharm Research and Manufacturing SA., Martigny, Switzerland

Introduction: Debio 0432 is a Ubiquitin Specific Protease 1 (USP1) inhibitor at preclinical stage. This study presents the first data on this small molecule and its activity as an anti-cancer therapy in multiple preclinical models. USP1 is a deubiquitinase, member of the deubiquitinating enzyme (DUB) family that plays an important role at the replication fork during DNA replication. Its prominent role in DNA repair, targeting Proliferating Cell Nuclear Antigen (PCNA) that regulates polymerase recruitment in the translesion synthesis (TLS), makes it an emergent target in the DNA damage repair (DDR) field.
Methods: In silico docking has been used to identify a likely binding site of Debio 0432. Biochemical and cellular assays have been performed to show its activity on the target and in cell lines of different cancer types. In vivo models in cell line derived xenograft (CDX) and patient derived xenograft (PDX) were then used to confirm the activity of the compound and to study PK/PD relationship.
Results: Debio 0432 likely binds USP1 in an allosteric pocket and is very selective across the 58 members of the USP family. Furthermore, it does not affect any kinase. Its biochemical activity on USP1 is in the low nanomolar range and cellular activity ranges between from single digit nM to above 1uM. In vivo, Debio 0432 shows antitumor activity in the BRCA mutant breast cancer model MDA-MB-436. The downstream target Ub-PCNA, selected as pharmacodynamic marker, is modulated in a dose and plasma exposure-dependent manner. Further in vivo experiments in PDX models showed dose-dependent activity in different cancer types, in both BRCA wild type and mutant models. Treatments in all in vivo studies were well tolerated.
Conclusion: Overall, we show that Debio 0432 is a selective and potent small molecule targeting USP1, an emerging target in the DDR field. It shows good activity in different preclinical models and is well tolerated at active doses. Debio 0432 is currently undergoing IND-enabling studies and in preparation for entry into clinical development.

#7146 HSK39775: A USP1 inhibitor for the treatment of cancers with homologous recombination deficiencies.

J. Xu[1], Y. Li[1], **J. Wang**[1], P. Tang[2], J. Wang[2], C. Zhang[2], P. Yan[2];
[1]Haisco Pharmaceutical Group Co., Ltd., Shanghai, China, [2]Haisco Pharmaceutical Group Co., Ltd., Chengdu, China

Tumors with BRCA1/2 mutations or homologous repair deficiency (HRD) are vulnerable to agents that target DNA repair pathways, including platinum-containing chemotherapeutics and poly (ADP-ribose) polymerase-1 (PARP1) inhibitors. Despite the significant therapeutic benefits in patients with BRCAm or HRD, innate and acquired resistance to PARPi is still a challenge in the clinic. To address this clinical challenge, we developed HSK39775, a potent, highly selective inhibitor of ubiquitin carboxyl-terminal hydrolase 1 (USP1), which acts as an oncogenic and PARP inhibitor resistance driver involved in DNA damage repair pathway through the deubiquitylation of proteins in Translesion Synthesis pathway and Fanconi Anemia pathway, paired with BRCA as a synthetic lethality target. HSK39775 was active in enzymatic level to inhibit USP1/UAF1 complex. Enzymatic panel screening containing 50 deubiquitinase demonstrated high selectivity of HSK39775. Ubiquitinated PCNA was accumulated treated by HSK39775, indicating target engagement. HSK39775 also demonstrated potent anti-proliferation activity against cancer cell lines with BRCA mutation and excellent selectivity between BRCA WT vs. BRCAm. Combining HSK39775 with PARP inhibitors indicated synergy in cell lines with partial or insensitivity to each agent alone. Triple-negative BRCA mutant breast cancer xenograft model demonstrated strong dose-dependent tumor growth inhibition of HSK39775 as a single agent with Tumor Growth Inhibition (TGI) of 63.2% at 30 mg/kg QD, and ubiquitinated PCNA was also accumulated in HSK39775 treated tumor tissue. Meanwhile, combination with PARP inhibitors significantly enhanced the therapeutic efficacy of HSK39775 in xenograft model and led to tumor regressions and durable tumor control even at low dose (TGI:89% (HSK39775, 5 mg/kg + Olaparib, 50 mg/kg)). Interestingly, HSK39775 inhibited the tumor growth of a HRP and BRCA wild-type lung cancer xenograft as a single agent with TGI of 94% at 30 mg/kg QD, suggesting the therapeutic effect of USP1 inhibitors beyond canonical BRCA mutant or HRD tumors. In summary, these results indicate HSK39775 as a potent and selective USP1 inhibitor and support further development.

#7147 ASN-3186 is a potent and selective inhibitor of USP1 for the treatment of BRCA1/2 mut and HRD+ cancers.

Qiaoling Sun[1], Yunfei Chen[1], Maojiang Wu[1], Jing Lv[1], Hongyue Jin[1], Peng Zeng[1], Xia Song[1], Wenfeng Hou[1], Qi Huang[1], Wei Niu[1], Mengyao Zhang[1], Tie-Lin Wang[1], Alice Chen[2]

[1]Asieris Pharmaceuticals, Shanghai, China,[2]Asieris Pharmaceuticals, Palo Alto, CA

Ubiquitin-specific protease 1 (USP1), a well-characterized member of the deubiquitinating enzyme family, selectively cleaves ubiquitin from various target proteins, including DNA repair protein PCNA. USP1 contributes to oncogenesis by playing critical roles in DNA damage repair processes including translesion synthesis and the Fanconi anemia pathway. Despite the clinical benefit achieved with PARP inhibitors (PARPi) in BRCA-mutated (BRCAm) or homologous recombination deficient (HRD+) populations, some patients either do not respond to therapy or develop resistance. USP1 inhibitors may have the potential to address this unmet clinical need as USP1 functions in distinct DNA damage repair pathway as compared to PARP. ASN-3186 is a novel, potent, and selective USP1 inhibitor with enzyme IC50 value of single digit nanomolar and selectivity >1000-fold against other family members. ASN-3186 demonstrated potent anti-proliferative activity in the BRCA1m triple negative breast cancer (TNBC) cell line, MDA-MB-436 (IC50 <30 nM). MDA-MB-436 CDX mouse model confirmed dose-dependent, single-agent inhibitory activity of ASN-3186 in vivo with higher potency than KSQ4279, possibly due to ASN-3186's higher oral bioavailability. Efficacy is consistent with increase of pharmacodynamic biomarker ub-PCNA. The combination of ASN-3186 and PARPi Olaparib yielded a more robust and durable anti-tumor response, with near-complete tumor regression demonstrated at higher combination dose. Moreover, addition of ASN-3186 significantly sensitized Olaparib's minimal anti-tumor activity in CAOV3 (ovarian, HRD high) and MX-1 (TNBC, BCRA1/2 mut) models, which are resistant to PAPRi, indicating that it has the potential to overcome PARPi resistance. Synthetic lethal activity was also observed when ASN-3186 was combined with DNA damage drug Gemcitabine. Furthermore, ASN-3186 displayed desirable ADME and PK profiles with high oral bioavailabilities (>75%) across species. These data support further clinical development of ASN-3186 as a potential best-in-class USP1 inhibitor, both as a single agent as well as in combination with PARPi, for treatment of BRCA1/2 mut and HRD+ cancers.

#7148 Small molecule inhibitor of FEN1 nuclease utilizing a novel metal-binding pharmacophore synergizes with inhibitors of USP1, PARP, PARG and ATR.

Jason Munguia, Sanjay Agarwalla, Elaine Guo, Dave Martin, Junhua Fan, Dave Lonergan, David Puerta, Zachary Zimmerman, **Konstantin Taganov**

Blacksmith Medicines, San Diego, CA

Flap endonuclease 1 (FEN1) is a structure-specific metallonuclease that cleaves 5' DNA flaps during replication and repair. FEN1 is an attractive target for development of anticancer therapeutics because it is overexpressed in many tumor types and has a large number of synthetic lethality partners including genes in Homologous Recombination (HR) pathway (Mengwasser et al., 2019; Guo et al., 2020).

Utilizing fragment-based drug discovery approach we identified a novel metal-binding pharmacophore that binds to the two magnesium ions in the FEN1 active site. Further elaboration using fragment growth strategies resulted in highly potent and selective inhibitors. The current lead (BSM-1516) is ~65-fold more potent against FEN1 than its related enzyme Exonuclease 1 (Exo1) in biochemical assays (IC_{50} of 7 nM and 460 nM, respectively), an improvement of more than an order of magnitude in selectivity compared to earlier efforts. FEN1 target engagement in live cells was validated by cellular thermal shift assay (CETSA EC_{50} of 24 nM). Inhibition of FEN1 led to its increased association with chromatin in S-phase cells and recruitment of PARP1 enzyme.

In clonogenic assay, BRCA2-deficient DLD1 cells were ~15-fold more sensitive to FEN1 inhibition than their isogenic BRCA2-wild-type counterparts (EC_{50} of 350 nM and 5 µM, respectively), confirming the increased susceptibility of HR deficient cancer cells to FEN1 inhibition. Treatment of BRCA2-deficient but not wild-type DLD1 cells with BSM-1516 resulted in cell cycle arrest and dose-dependent decrease of S-phase BrdU incorporation into DNA. Cell cycle arrest of BRCA2-deficient DLD1 cells was accompanied by DNA damage signaling and by accumulation of chromatin-bound RPA32, a marker of ssDNA.

To explore synthetic lethal interactions of FEN1 with other DNA repair genes we performed FEN1-inhibitor-anchored CRISPR screen. This analysis revealed that in addition to HR pathway inactivation, genomic perturbations in EXO1, USP1 and PARP1 genes sensitized cells to FEN1 inhibition. Synergistic relationships of BSM-1516 and its combination potential were further explored in viability studies with a panel of DDR inhibitors (n=25) in BRCA2-proficient and deficient cell lines. Strong synergy was identified with multiple drug classes that included inhibitors of USP1 (KSQ-4279), PARP (Olaparib, Niraparib, Talazoparib, AZD5305), PARG (PDD 00017273) and ATR (AZD6738, VE-822, Elimusertib).

In vitro ADME assays and in vivo PK studies showed that BSM-1516 has properties suitable for in vivo testing, either as a single agent or in combination with synergistic DDR inhibitors, an investigation that is currently underway.

#7149 Discovery of a novel USP1 inhibitor: Targeted therapy for BRCA-mutated and PARPi-resistant cancers.

J. Kim, S. Kim, S. Park, S. Lee, K. Yoo, H.-J. Lee, J. Kang, K.-O. Lee;
AIGEN Sciences, Seoul, Korea, Republic of

Harnessing synthetic lethality offers an innovative approach to targeted cancer treatment. USP1, a specific deubiquitinating enzyme, has gained attention as a potential synthetic lethality target for BRCA-mutated cancers. At AIGEN Sciences, Inc., we've integrated the advanced capabilities of our human-in-the-loop (HITL) AI drug discovery platform, AIGEN ChemTailor. This cutting-edge platform thrives on continuous learning enhanced by expert feedback, refining our approach to drug discovery. Using AIGEN ChemTailor, we synthesized a specific USP1 inhibitor. Its inhibitory capabilities were validated through the Ubiquitin-rhodamine 110 assay. Notably, our inhibitor presented remarkable anti-proliferative effects on BRCA1 mutant cells (MDA-MB-436) while showing no activity against BRCA wild-type cells (HCC1954), highlighting its specificity. The efficacy of our inhibitor was enhanced when combined with PARP inhibitors, such as olaparib or AZD5305, especially in UWB1.289 cells. Impressively, the USP1 inhibitor also effectively targeted PARPi-resistant cell lines, including A2780-ola, UWB1.289-nir, HCC38-ola, MDA-MB-468-ola, U251MG-ola, and OVCAR8-ola. Clonogenic assays with MDA-MB-436 and MCF-10A emphasized our inhibitor's selectivity towards BRCA mutant phenotypes. Subsequent studies demonstrated the compound's mechanism: inducing replication stress by impairing of DNA synthesis and activating DNA damage pathways via ATR signaling. Preclinical mouse studies highlighted favorable pharmacokinetics and involved the assessment of anti-tumor effects in animal models. In summation, our USP1 inhibitor, developed using AIGEN ChemTailor and advanced molecular modeling techniques, stands out as a potent therapeutic against BRCA-mutated cancers and PARP inhibitor-resistant strains.

#7150 Molecular insights into the oncogenic influence between mutant HER3, mutant KRAS, and their synergistic interplay in colorectal cancer pathogenesis.

M. K. Kilroy, B. Park, R. Mishra, W. Feroz, C. Wischmeier, J. T. Garrett;
University of Cincinnati, Cincinnati, OH

Colorectal cancer (CRC) is a disease of the colon and rectum that will claim about 52,550 American lives in 2023. In recent years, more attention has been paid to HER2 and HER3's roles in colorectal cancers, as they may cause resistance to targeted therapies. We are investigating the role of naturally co-occurring HER3 and KRAS mutations in colorectal cancer, as about 6% of all colorectal cancers contain a HER3 mutation and 41% contain a KRAS mutation. We have observed that there is a statistically significant co-occurrence of HER3 and KRAS mutations in CRCs while there is mutual exclusivity with mutations in EGFR or HER4 and mutant KRAS in CRC examining 6791 samples from 17 studies. There is a tendency for co-occurrence with HER2 and KRAS mutations that is not statistically significant in these CRC tumor samples. We have found that genetic knockdown of both KRAS and HER3 with siRNA targeting KRAS and HER3 in the CRC cell line SNU-407 ($HER3^{V104M}$, $KRAS^{G12D}$) results in a statistical reduction in cell proliferation in comparison to genetic knockdown with only KRAS or HER3. Using the SW620 CRC cell line ($HER3^{WT}$, $KRAS^{G12V}$) as a comparison, we have observed that knocking down HER3 using siRNA had no effect on cell proliferation whereas KRAS knockdown reduced proliferation and the combination showed no statistical difference compared to knocking down only KRAS. Additionally, we have found that there is a striking increase in total HER3 levels in SNU-407 cells when treated with the $KRAS^{G12D}$ inhibitor MRTX1133. This feedback loop could limit the efficacy of the KRAS inhibitor. We wished to delineate mutant HER3's binding partner(s) as HER3 is kinase impaired. Strikingly, we have found that EGFR immunoprecipitates with HER3 in SNU-407 cells. We are expanding our studies to CRC patient derived xenografts (PDXs) with co-occurring HER3 and KRAS mutations and have generated patient derived organoids from these PDXs. Ongoing studies are determining if there is a synergistic relationship with KRAS inhibitors and HER family inhibitors including a HER3 antibody-drug conjugate. Our findings may present a new paradigm for targeted combination therapies in colorectal cancer with the eventual goal of increased overall patient survival.

#7151 Targeting metabolic pathway in triple negative breast cancer with a small molecule inhibitor.

A. Dheeraj[1], F. J. G. Marques[2], D. Tailor[1], A. Bermudez[2], B. Grau[1], S. Pitteri[2], S. V. Malhotra[1];
[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]Stanford University, Palo Alto, CA

Background: Triple Negative Breast Cancer (TNBC) is the most aggressive type of breast cancer, making up 15-20% of diagnosed cases, and has high rates of metastasis and recurrence. Most women with this disease experience a recurrence after curative-intent therapy for early breast cancer, while a smaller proportions are diagnosed with distant metastases initially. Cancer cells are characterized by their reprogramming of glucose metabolism. Cancer cells show increased proliferation along with higher energy and substrate demands. Through our efforts to find effective therapies for TNBC, we have identified CET019, a new small molecule that effectively suppresses the growth of breast cancer cells.
Methods: Cell viability and clonogenic assays were performed on a range of TNBC cells, including MDA-MB-231, MDA-MB-468, SUM159, HCC1395, HCC1806, EMT6, and 4T1. Cell cycle distribution was assessed through flow cytometry. LC-MS/MS analysis was performed on TMT-labeled samples for global proteome profiling. The efficacy of CET019 (30 mg/kg) was tested using tumor and patient derived xenograft studies.
Results: Our studies show that CET019 suppresses the clonogenic potential and growth of various triple-negative breast cancer cells. The CET019 treatment causes cell cycle arrest in TNBC cells at the G2/M phase. Proteomics analysis suggests that CET019 specifically affects metabolic and proteosomal pathways. In vivo studies with CET019 found an inhibition of tumor growth kinetics in the mouse xenograft study with different TNBC models, as compared to the control group. We also observed that CET019 inhibited metastatic lung nodules. The results were further substantiated in three Patient Derived Xenograft (PDX) models.
Conclusion: In summary, our study has identified a novel small molecule candidate CET019 as a promising lead candidate for TNBC treatment, paving the way for further development.“The complete chemical structures of the compounds used will be disclosed at the time of presentation at the meeting.”

#7153 PHI-101 synergizes with chemotherapy and venetoclax in preclinical models of acute myeloid leukemia.

Hee-sun Hwang[1], Gi-Jun Sung[1], Kyung-Ah Kim[1], Ky-Youb Nam[1], Kyu-Tae Kim[1], June H. Han[1], Jeong-Hyeok Yoon[1], Bao Nguyen[2], Li Li[2], Tessa Seale[2], Donald Small[2]

[1]Pharos iBio Co., Ltd, Anyang, Korea, Republic of,[2]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD

FLT3 mutations are one of the most frequent genetic alterations in AML, resulting in poor prognosis. Although the development of FLT3 tyrosine kinase inhibitors (TKIs) provided new treatment options, patients with FLT3-mutant AML still suffer from high relapse rates when treated with FLT3 TKI alone. Accumulating evidence supports a combination treatment strategy to lower the recurrence rate. We have previously shown that PHI-101 demonstrated potent activity in various FLT3 mutant AML cell lines when used alone. Here we explore the use of PHI-101 in combination with other therapeutics in preclinical models of AML. We investigated the preclinical efficacy of the combination of PHI-101 with FDA-approved AML therapeutic agents in FLT3 mutant (MV4-11, Molm13, Molm14) and wild-type (THP-1) AML cell lines. Cell growth inhibition was assessed by CCK-8 and/or CellTiter-Glo assays. The Chou-Talalay method was used to calculate the combination index (CI) to test for synergy. Western blotting analysis was performed to explore the potential mechanisms underlying the combination effects. AML xenograft mouse models were used to assess the in vivo efficacy of PHI-101 combination therapy. Statistical comparisons included unpaired t-tests or one-way ANOVA. Combination treatment of PHI-101 with venetoclax or azacytidine showed strong synergistic effects on growth inhibition against both FLT3-ITD mutant (CI<0.3) and wild-type AML cells (CI <0.6). It is noteworthy that the FLT3-ITD homozygous cell line (MV4-11) showed especially strong synergism (CI <0.1). In the xenograft mouse model experiments, 14-day treatment with either PHI-101 alone or in combination with venetoclax or azacytidine showed significant suppression of tumor growth compared to venetoclax or azacytidine alone (in average tumor growth inhibition (TGI) 88.3% vs 8.6%)($p<0.05$). In particular, PHI-101 3 mg/kg/day (mpk) with venetoclax 80mpk resulted in a stronger anti-tumor effect (TGI 94.2%) compared to PHI-101 (TGI 87.4%) or venetoclax alone (-9.6% of TGI) ($p<0.05$) even 21 days after stopping the treatment. In addition, PHI-101 treatment showed a survival advantage in AML animal models, and the combination with venetoclax led to significantly longer survival compared to the control groups. Our preclinical data showed that the combination of PHI-101 with venetoclax or azacytidine resulted in a highly effective anti-leukemic response against AML cells by inducing DNA damage, BCL-2 inhibition, and MCL-1 degradation. Additionally, treatment of mice with low-dose PHI-101 inhibited tumor regrowth and further potentiated venetoclax or azacytidine response in vivo. Our results suggest that the combination of PHI-101 and venetoclax or azacitidine may have the advantage of improving clinical responses in FLT3-ITD AML patients and offers a potential therapeutic option to treat patients with newly diagnosed or relapsed/refractory FLT3-mutant AML.

#7154 Ivospemin/doxorubicin combination modulates polyamine metabolism to improve survival in murine ovarian cancer models.

Cassandra E. Holbert[1], Jackson R. Foley[1], Ashley C. Nwafor[1], Ting-Ann Liu[1], Elizabeth Bruckheimer[2], Jennifer K. Simpson[2], Tracy Murray Stewart[1], Robert A. Casero[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Panbela Therapeutics, Waconia, MN

Polyamines are small polycationic alkylamines that are absolutely required for the continual growth and proliferation of cancer cells. As cancer cells maintain elevated polyamine pools through dysregulated polyamine metabolism, its pharmacological modulation is a promising avenue in cancer therapeutics. The polyamine analogue ivospemin has shown efficacy in slowing pancreatic and ovarian tumor progression in vitro and in vivo and has demonstrated encouraging results in pancreatic cancer clinical trials. Considering nearly 75% of late-stage ovarian cancer patients develop resistant to platinum-based chemotherapies, limiting treatment options, the aim of our study is to determine the potential efficacy of ivospemin in combination with doxorubicin, a common chemotherapeutic used in platinum-resistant ovarian tumors. We have previously shown that ivospemin exposure decreases polyamine content in a variety of cancer cell lines through downregulation of the polyamine biosynthetic enzyme ornithine decarboxylase (ODC) and induction of the polyamine catabolic enzyme spermidine/spermine-N1-acetyltransferase (SSAT). Here we examine the potential of combining ivospemin with doxorubicin. Ivospemin treatment reduces cell viability in ovarian adenocarcinoma cell lines and increases the toxicity of doxorubicin regardless of cisplatin sensitivity. Cells treated with the combination exhibit a greater decrease in polyamine levels than cells treated with either single agent. This increased polyamine depletion and decreased survival is accomplished through modulation of polyamine metabolism, predominately through an additive induction of SSAT activity. Using the syngeneic VDID8+ ovarian murine model, we further evaluated the ability of ivospemin to improve response to doxorubicin at clinical and sub-clinical dosing. Ascites fluid was used as a marker for tumor burden and evaluated for polyamine content. We found that the combination treatment increases median survival, delays tumor onset, and decreases overall tumor burden compared to either clinical or subclinical doxorubicin dosing schemes. Combination treatment also decreases overall polyamine content in the ascites by 75%. N1-acetylated spermidine is enriched in ascites from combination-treated mice, consistent with an upregulation of SSAT in response to treatment. Recognizing the non-representative mutational status of the VDID8+ model as a limitation, we are currently evaluating the combination of ivospemin and doxorubicin in genetically defined murine models that better recapitulate human high-grade serous ovarian carcinomas. Ongoing studies will determine influences on the tumor microenvironment and will mechanistically evaluate the cooperativity of ivospemin and doxorubicin on pathways outside of polyamine metabolism.

#7155 Dichloroacetate reverses cisplatin resistance in ovarian cancer through promoting ROS production.

Y. Do, **S. Lee**, C. Shin, H. Chung, J. Kim, E. Ha, S. Shin, J. Seo;
Keimyung University School of Medicine, Daegu, Korea, Republic of

Chemotherapy resistance and the high rate of ovarian cancer relapse pose major challenges in the treatment of ovarian cancer. The development of chemoresistance contributes to poor overall prognosis associated with ovarian cancer and high cancer-related mortality in women worldwide. Herein, we found that Dichloroacetate (DCA), a pan-pyruvate dehydrogenase kinase (PDK) inhibitor, is a potent agent to overcome Cisplatin (CP) resistance in ovarian cancer treatment. Firstly, we elucidated that phosphorylation of pyruvate dehydrogenase (pPDH) was elevated in CP-resistant ovarian cancer cells. Then, blockage of pPDH by DCA treatment significantly inhibited cell migratory and invasive capacity in CP-resistant ovarian cancer cells through the transition of motile mesenchymal phenotypes into epithelial characteristics. DCA markedly decreased the number of sphere formations and attenuated the stem cell-like properties in CP-resistant ovarian cancer cells. In combination with CP treatment, DCA effectively inhibited cell proliferation in chemoresistant ovarian cancer cells by triggering apoptosis. Collectively, we suggested that DCA is a promising drug to reverse CP resistance for ovarian cancer treatment. We further tested the underlying mechanisms of DCA to restore CP sensitivity in ovarian cancer. We found that CP treatment promoted reactive oxygen species (ROS) production to induce cell death in CP-sensitive ovarian cancer. However, CP-resistant ovarian cancer cells exhibited higher basal levels of ROS compared with sensitive cancer cells, and CP treatment failed to generate ROS production. That means ovarian cancer cells steadily adapted to elevated ROS levels, then becoming ROS-adapted ovarian cancer cells to survive. Interestingly, DCA treatment results in the buildup of ROS production, causing cell death in CP-resistant ovarian cancer. Therefore, our study suggests that ROS production can be an attractive target in DCA treatment to restore CP sensitivity in ovarian cancer.

#7156 Targeting the β-catenin signaling axis in osteosarcoma.

M. Curcic, S. Gaikwad, S. Srivastava;
Texas Tech University Health Sciences Center, Abilene, TX

Osteosarcoma, an aggressive bone malignancy predominantly affecting children, poses a formidable challenge for therapeutic interventions. Here we evaluated a recently approved FDA drug, PCT, for potential anti-cancer effect in osteosarcoma model. Initial assessments of cytotoxicity encompassing various human and murine osteosarcoma cell lines—OS-17, OS-25, U2OS, SAOS2, MG63, and K7M3—revealed an IC_{50} ranging 1-3 µM. Subsequent investigations demonstrated significant anti-clonogenic activity and G2M phase cell cycle arrest. Annexin-PI assay showed a notable apoptotic effect of PCT, shedding light on the mode of cell death. Given the pivotal role of β-catenin signaling in human osteosarcoma pathogenesis and metastasis, targeting β-catenin components holds promise for therapeutic intervention. *In silico* docking studies suggested that PCT may have similar anti-cancer effect compared to β-catenin inhibitors (e.g., MSAB, ICG001). Our western blot analyses in multiple osteosarcoma cell lines demonstrated that PCT inhibits β-catenin pathway. Fluorescence microscopy and PCR analyses substantiated PCT's ability to hinder the nuclear translocation of β-catenin, providing mechanistic insights into its anti-tumor properties. Our preliminary data also suggests that AXL, an upstream regulator of β-catenin pathway, was modulated by PCT. In summary, our findings indicate that PCT exhibits therapeutic potential against osteosarcoma by targeting the β-catenin pathway. Further mechanistic studies are currently underway in our lab.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Pharmacology and Pharmacogenetics
Poster Session

#7160 Germline predictors for bevacizumab induced hypertensive crisis in ECOG-ACRIN 5103 and BEATRICE.

F. Shen[1], G. Jiang[1], S. Philips[1], E. Cantor[1], L. Gardner[1], G. Xue[1], G. Cunningham[1], N. Kassem[1], A. Oneil[2], D. Cameron[3], T. Suter[4], K. Miller[1], G. Sledge[5], B. Schneider[1];

[1]Indiana Univeristy, Indianapolis, IN, [2]Dana Darber Cancer Institute, Boston, MA, [3]Edinburgh Cancer Research Centre, Edinburgh, United Kingdom, [4]Swiss Cardiovascular Center, Bern, Switzerland, [5]Caris Life Sciences, Dallas, TX

Introduction: Bevacizumab is a beneficial therapy in several advanced cancer types. Predictive biomarkers to better understand which patients are destined to benefit or experience toxicity are needed. Associations between bevacizumab induced hypertension and survival have been reported but with conflicting conclusions.

Methods: We performed post-hoc analyses to evaluate the association in 3,124 patients from two phase III adjuvant breast cancer trials, E5103 and BEATRICE. Differences in invasive disease-free survival (IDFS) and overall survival (OS) between patients with hypertension and those without were compared. Hypertension was defined as systolic blood pressure (SBP) ≥ 160 mmHg (n=346) and SBP ≥ 180 mmHg (hypertensive crisis) (n=69). Genomic analyses were performed to evaluate germline genetic predictors for the hypertensive crisis.

Results: Hypertensive crisis was significantly associated with superior IDFS ($p = 0.015$) and OS ($p = 0.042$), but only IDFS ($p = 0.029$; HR = 0.28) remained significant after correction for prognostic factors. SBP ≥ 160 mmHg was not associated with either IDFS or OS. A common single-nucleotide polymorphism, *rs6486785,* was significantly associated with hypertensive crisis ($p = 8.4 \times 10^{-9}$; OR = 5.2).

Conclusion: Bevacizumab-induced hypertensive crisis is associated with superior outcomes and *rs6486785* predicted an increased risk of this key toxicity.

#7161 Preclinical pharmacology modeling (pharmacokinetics/efficacy) of narazaciclib (HX301 or ON123300) to predict its clinical effective dose.

T. Yang[1], H. Ke[1], J. Liu[2], K. Gong[2], **H. Q. Li**[1];
[1]Hanx Bio, Hangzhou, China, [2]Crown Bioscience, Beijing, China

Background: Acute myeloid leukemia (AML) is an aggressive leukemia of myeloid lineage. CSF1R (colony-stimulating factor 1 receptor) regulates the proliferation, differentiation and polarization of cells of myeloid lineages, e.g. monocytes/macrophages. CSF1R expression is aberrantly upregulated in many AML, leading to a hypothesis that CSF1R is a putative leukemogenic driver in a subset of AML and thus could be a potential target for treating AML. Previous studies demonstrated that Narazaciclib (HX301 or ON123300), an investigational kinase inhibitor (TKi), exhibited high potency activity against CSF1R (IC_{50} 0.285 nM) and inhibition of macrophage proliferation and AML tumor growth both *in vitro/in vivo*, implicating its potential use as an AML therapeutic[1] (An et al., 2023 AACR Annual Meeting). In addition, narazaciclib has recently completed the dose escalation phase 1 study in advanced solid tumors. However, the therapeutic window of narazaciclib as a CSF1Ri for treating AML remains to be determined. The present study attempted to utilize both preclinical PK and *in vivo* efficacy models to predict the effective clinical dose of narazaciclib for guiding the future AML clinical trials.
Methods: A single dose of narazaciclib at various of dose levels was orally administrated in NOD/Scid mice, and plasma samples were collected at designated timepoints. The concentrations of narazaciclib in plasma were analyzed by LC-MS. In a Ba/F3-ETV6-CSF1R *in vivo* xenograft tumor model in Nod/Scid mice, narazaciclib at various dose levels was orally administrated daily. Tumor volumes were measured twice weekly.
Results: The mouse PK study showed that narazaciclib displayed overall similar absorption pattern as seen in unpublished human clinical data. Narazaciclib was absorbed rapidly after oral dosing with a mean T_{max} ranging from 1 to 2 hours in mouse. However, narazaciclib was cleared faster in mouse, with a mean $T_{1/2}$ ranging from 1.9 to 2.8 hours, than in human. In addition, the exposures of narazaciclib, as measured by C_{max} and AUC in plasma, increased in a relatively dose-proportional manner, as seen in human patients. In the Ba/F3-ETV6-CSF1R xenograft model where the tumor cell growth is solely dependent on the CSF1R kinase activity, narazaciclib at 10 mg/kg did not induce any anti-tumor effects with a TGI of -14.61%. In contrast, narazaciclib at 50 mg/kg and 100 mg/kg exerted significant anti-tumor effects with a TGI of 85.49% and 94.55%, respectively. Based on the mouse PK results, narazaciclib at 50 mg/kg in mouse is estimated to have an AUC of approximate 2000 h*ng/mL, which is equivalent to the dose of 160 - 200 mg/d in human patients. Therefore, 160 mg dose level is predicted to be an effective dose for narazaciclib in AML patients.
Conclusions: Narazaciclib at 160 mg/d is predicted to be an effective dose in AML patients.

#7162 Killing a fly with a sledgehammer: standard flat-dosing administration of Atezolizumab leads to marked overexposure in real-world lung cancer patients.

S. Marolleau[1], A. Mogenet[2], M. Hamimed[1], C. Boeri[1], L. Greillier[2], **J. Ciccolini**[1];
[1]Aix-Marseille University, Marseille, France, [2]Assistance Publique Hopitaux de Marseille, Marseille, France

Atezolizumab is an anti-PDL1 approved for treating small cell lung cancer and non-small cell lung cancers. A threshold of 6 µg/ml in plasma has been associated with target engagement with Atezolizumab. The extent to which patients could be overexposed with the standard 1200 mg Q3W flat-dosing remains unknown, but several *in silico* studies have suggested that flat-dosing with immune checkpoint inhibitors could lead to plasma concentrations far above the necessary levels to be efficacious. Here, we monitored Atezolizumab peak and trough levels in 27 real-world patients with lung cancer as part of routine therapeutic drug monitoring. Individual pharmacokinetic parameters were calculated using a population approach and optimal dosing-intervals were simulated with respect to the target trough levels of Atezolizumab. No patient displayed plasma levels below 6 µg/ml. The results showed that the mean trough level after the first course was 78.3 ± 17 µg/ml, i.e., 13 times above the target concentration associated with target engagement. The overall response rate was 55.5%. Low-grade IRAEs was observed in 37% of patients. No severe immune-related toxicities was observed. On univariate analysis, no relationship was found between exposure metrics of Atezolizumab (i.e., Cmin, Cmax, AUC at the first cycle or during the forthcoming courses) and pharmacodynamic endpoints (i.e., efficacy, toxicity). First-line Atezolizumab treatment and treatment for NSCLC were both significantly associated with efficacy on univariate analysis (p=0.0067 and p=0.0497, respectively), but further multivariate analysis did not confirm this relationship (p=0.2465 and p=0.9981). Smoking status was moderately associated with toxicities on univariate analysis (p=0.03), but this effect was not confirmed on further multivariate analysis (p=0.99). None of the other covariates (i.e., age, sex, NLR, number of metastatic sites, associated chemotherapy) were associated with efficacy or toxicity. Further simulations suggested that the dosing interval could be extended from the standard 21 days (i.e., Q3W) to 49 up to 136 days (mean: 85.7 days, i.e., Q12W dosing), while ensuring plasma levels always above the 6 µg/ml target threshold. This observational, real-world study confirms for the first time in real-world patients that the standard 1200 mg Q3W fixed-dose regimen of Atezolizumab results in significant overexposure in plasma. Of note, this overexposure was not associated with increased side-effects. As plasma levels always exceed pharmacologically active concentrations, the inter-individual variability we observed in PK parameters did not impact efficacy and could not explain differences in response. Our data suggest that dosing intervals could be markedly extended with respect to the target threshold associated with efficacy, thus lowering drug-cost in the future.

#7163 Pharmacokinetics assessment of intranasal NEO100 treatment on blood-brain barrier disruption and brain penetration of drugs in rodent brain.

A. Thaghalli Shivanna[1], T. Margaryan[1], M. Stavnichuk[1], W. Knight[1], S. Patel[1], E. Cabrales[1], A.-C. Tien[1], T. Chen[2], N. Sanai[1], A. Tovmasyan[1], S. Mehta[1];
[1]Barrow Neurological Institute, Phoenix, AZ, [2]University of South California, Los Angeles, CA

Background: Insufficient drug concentrations reaching the brain-localized tumor tissue remains one of the major challenges in the treatment of glioblastoma (GBM). An intranasal (IN) formulation of NEO100 (NeOnc Technologies, Inc., Los Angeles), a highly purified version of perillyl alcohol, has been recently reported to enhance drug concentrations in the brain upon IN co-delivery. Here, we report detailed pharmacokinetics (PK) and tissue analysis to quantitatively examine the extent of increase in drug concentrations in the brain after IN NEO100 administration. Furthermore, we also confirmed that IN NEO100 increases brain drug concentration by circumventing the blood brain barrier.
Method: For PK analysis, either IN or oral formulation of a three-drug cocktail (ZEI, consisting of ZN-c3, everolimus, and infigratinib) was used to evaluate the impact of 3% IN NEO100 on the brain penetration profile of the three individual drugs. Athymic mice were grouped into four cohorts to receive 1) oral ZEI; 2) IN ZEI; 3) oral ZEI with IN NEO100; and 4) IN ZEI with IN NEO100. At 2, 4 and 6 hours post ZEI dosing, drug levels in plasma and brain tissue were measured by liquid chromatography tandem mass spectrometry (LC-MS/MS). For BBB disruption study, athymic mice were treated with IN delivery of saline (negative control) or 3% NEO100 one hour post intravenous Evans blue (2%) administration. Tumor bearing mice with disrupted BBB served as positive control. Two hours post Evans blue administration, animals were perfused, and brains were collected and sectioned for confocal microscopy to image Evan's blue autofluorescence.
Results: PK analysis revealed that brain-to-plasma ratios (K_p) for ZN-c3, everolimus, and infigratinib remained nearly equal, independent of the route of administration, *i.e.* 0.11, 0.03, and 0.82 vs 0.09, 0.03, and 0.87, for IN vs oral routes, respectively. Administration of the ZEI together with IN NEO100, either through oral or IN routes, resulted in higher drug concentrations, both in the plasma and in the brain. However, while overall drug exposure was increased, K_p values of the drugs were not changed. Confocal imaging of brains from mice treated with 3% IN NEO100 did not show presence of Evans blue autofluorescence while positive control mice with disrupted BBB within the tumor core displayed high Evans blue fluorescence.
Conclusions: Co-administration of IN NEO100 with ZN-c3, everolimus, and infigratinib increases their brain and plasma exposure. As a result, no significant increase in brain-to-plasma partition was registered for any of the three drugs tested in this study. IN NEO100-mediated increase in brain drug concentration was independent of BBB disruption

#7164 Exposure-efficacy and exposure-safety relationships of tarlatamab to inform dose selection and benefit-risk assessment in patients with advanced small cell lung cancer (SCLC).

P.-W. Chen, M. Minocha, S. M. Kong, E. S. Anderson, A. Parkes, P. Martinez, B. E. Houk, C.-W. Lin;
Amgen R&D, Thousand Oaks, CA

Introduction: Tarlatamab is a first in class, half-life extended bispecific T-cell engager (BiTE) immunotherapy targeting delta-like ligand 3 (DLL3) that has shown promising anti-tumor activity and survival outcomes with manageable safety profile in clinical studies of patients with previously treated SCLC (NCT03319940, NCT05060016) (Ahn et al, 2023; Paz-Ares et al, 2023). Here we characterized the exposure-efficacy and exposure-safety profiles associated with tarlatamab treatment in SCLC, including the effects of patient-specific covariates (brain or liver metastasis, smoking status, number of prior lines of therapy, prior PD-1/PD-L1 inhibitor therapy, sum of target lesion diameters, and presence of anti-drug antibody).

Methods: The analysis dataset consisted of 412 subjects with SCLC from ongoing Phase 1 DeLLphi-300 study (dose range 0.003 mg to 100 mg Q2W and 200 mg Q3W) and Phase 2 DeLLphi-301 study (10 mg and 100 mg Q2W). Serum tarlatamab exposure averaged over the first cycle (28 days) was utilized as the predictor of response in the regression analysis. Efficacy endpoints included objective response rate, disease control rate, best tumor size response, progression-free survival and overall survival (OS). Safety endpoints included overall treatment related adverse event (TRAE), overall treatment emergent adverse event (TEAE), and TEAEs of cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS) and associated neurologic events, and neutropenia. Only the grade ≥ 3 adverse events (AEs) were evaluated.

Results: Significant exposure-response relationships were established for all key efficacy measures across the dose range investigated. Plateau in the exposure-efficacy relationship (maximal efficacy) was observed at the recommended dose of 10 mg Q2W. Exposures associated with lower doses were estimated to have lower efficacy. No clear trends for exposure-response relationships were identified for the evaluated AEs except for grade ≥ 3 neutropenia, where a shallow trend was observed for increased neutropenia rate with increasing tarlatamab exposures. Of all the evaluated covariate relationships, only higher baseline sum of target lesion diameters was statistically significantly correlated with worsening of OS.

Conclusions: Overall results in this SCLC population suggest tarlatamab exposures associated with the recommended dose of 10 mg Q2W exhibited near maximal efficacy and a favorable benefit-risk profile. None of the evaluated patient-specific covariates resulted in clinically meaningful changes in efficacy or safety, and therefore do not warrant a dose adjustment.

#7165 Clinical population pharmacokinetic (popPK) analysis of NBF-006, a novel siRNA inhibitor of glutathione-S-transferase P (GSTP) encapsulated in a lipid nano particle (LNP), for treatment of advanced non-small cell lung cancer (NSCLC).

M. P. Hall[1], Z. O'Brien[1], X. Chen[2], A. Hendrix[2], S. Brenes-Coto[2], S. Zabludoff[1];

[1]Nitto Biopharma, San Diego, CA, [2]Amador Bioscience, Pleasanton, CA

GSTP has an important role in detoxification and antioxidative damage response. Additionally, GSTP has a chaperone function that regulates multiple oncogenic pathways such as KRAS and JNK. Since alternative pathways could compensate for the inhibition of a single kinase, targeting multiple pathways could lead to more effective therapy.

NBF-006 is a drug product comprised of GSTP siRNA encapsulated within a novel LNP. It is designed to deliver siRNA to localized and metastatic lung tumors. Unlike other well-established drug modalities, there is a general need for increased understanding of the PK of RNA therapeutics. For NBF-006, we present popPK analysis of patients who have undergone treatment in a Phase I (a/b) clinical study. A primary goal of popPK modeling is to identify PK parameters and sources of variability in a population. Other goals include correlating drug exposures with administered doses through identification of predictive covariates in a target population and establishing whether fixed dosing as opposed to weight-based dosing can be utilized in future clinical studies. Ultimately this analysis will help to inform decision-making for dosing regimens in future clinical trial designs and to better predict PK variability across populations.

A total of 48 advanced NSCLC (N=38), pancreatic (N=5), or colorectal cancer (N=5) patients received 4 doses (QW) of NBF-006 by infusion at 0.15, 0.3, 0.6, 1.2 or 1.6 mg/kg followed by a 2-week rest period. In all studies, serial blood samples were collected at weeks 1 and 4. Plasma concentrations of siRNA were determined by hybridization ELISA. PopPK analysis was performed to characterize NBF-006 PK and to explore intrinsic and extrinsic covariate effects that could affect NBF-006 exposure.

The analysis included 695 quantifiable PK observations. A popPK model with two-compartment disposition and linear elimination adequately described the PK profile of NBF-006. Exploratory data analysis of dose-normalized PK profiles suggested that exposure increased proportionally with increasing dose from 0.15 to 1.6 mg/kg. Little to no apparent accumulation nor exposure reduction was observed between weeks 1 and 4. The impact of individual patient covariates, including body weight, baseline ALT, sex, KRAS mutation, cancer type and race, was assessed on PK parameters. None of the covariates evaluated had a significant effect on NBF-006 clearance or central distribution volume (Vc) in the model. Vc showed a slight positive trend with higher body weight, but was not statistically significant.

A popPK model was successfully developed for NBF-006. No covariates were identified that impact NBF-006 exposure. The lack of a relationship of exposure with body weight suggests the potential to use fixed dosing in future clinical studies.

#7166 Pharmacokinetic analysis of omomyc therapeutic protein in preclinical and human tumor tissue using targeted mass spectrometry.

M.-E. Beaulieu[1], S. Martinez-Martin[1], M. Mueller[2], Y. Feng[2], J. Vowinckel[2], **A. Lachaud**[2], L. Soucek[1];

[1]Peptomyc SL, Barcelona, Spain, [2]Biognosys AG, Schlieren, Switzerland

MYC is a pleiotropic transcription factor consisting in three paralogs which coordinate gene expression and regulates cell proliferation, cell differentiation, cell cycle, metabolism and apoptosis. The 3 paralogs (c-, N-, and L-MYC) have similar biological functions but show distinct tissular and timing expression patterns. To function, MYC must heterodimerize with its partner MAX and bind DNA via its basic, helix-loop-helix, leucine zipper domain (B-HLH-LZ). It has been estimated that MYC is aberrantly expressed in up to 70% of human cancers and hence MYC has been termed a “most wanted target for cancer treatment”. However, due to its nuclear localization, its intrinsic disorder and lack of an enzymatically active site, development of clinical grade potent & selective small molecules targeting MYC remains an obstacle. Omomyc is a 91-amino-acids-long polypeptide that derives from the B-HLH-LZ domain of human MYC, containing four amino acid substitutions. Omomyc is capable of forming homodimers and heterodimers with MYC and with MAX and such dimers blunt MYC activity by preventing its access to target DNA sequences (E-boxes) and replacing it by inactive complexes. Previous studies showed the cell-penetrating properties of recombinant Omomyc and its subsequent nuclear localization, where it displaces MYC from its genomic locations, causing a specific shutdown of MYC transcriptional signature and effectively stopping cell cycle progression. Further in vivo preclinical experiments showed that Omomyc blocks MYC-driven transcription and proliferation, induces apoptosis and recruitment of intratumoral immune infiltrates, overall significantly abrogating tumor progression and reducing tumor grading. A targeted LC-MS/MS assay for the absolute quantification of 4 Omomyc proteotypic peptides was developed to assess the structural integrity of Omomyc and quantify functional Omomyc in tumor tissue. LLOQ and linear range of the panel was determined by spiking in dilution series of recombinant Omomyc protein into preclinical tumor tissue lysates. Finally, in the context of Omomyc clinical trial (NCT04808362), we used the panel to for quantification of functional Omomyc in FFPE tumor biopsies from 18 patients who received i.v. injection of Omomyc therapeutic. Data show that 2 h after i.v. administration, higher concentrations of the drug are reached in the tumors compared with serum and persist there with at least one order of magnitude higher concentration than in serum 72 h after administration in preclinical models. Functional Omomyc protein could be quantified in all of the 18 clinical tumor biopsies from treated patients showing that characterized LC-MS/MS proteomic assay can be used in the normal routine of a clinical trial for accurate quantification of therapeutic miniproteins.

#7167 Impact of patient specific factors on exposures of tarlatamab, a half-life extended DLL3-directed bispecific T-cell engager in patients with advanced small cell lung cancer.

Stephanie M. Kong[1], Mukul Minocha[1], Po-Wei Chen[1], Pablo Martinez[2], Erik S. Anderson[2], Amanda Parkes[2], Brett E. Houk[1], Chih-Wei Lin[1]

[1]Clinical Pharmacology Modeling & Simulation, Amgen R&D, Thousand Oaks, CA,[2]Clinical Development Oncology, Amgen R&D, Thousand Oaks, CA

Background: Tarlatamab is a first in class, half-life extended delta-like ligand (DLL3) targeted bispecific T-cell engager (BiTE) immunotherapy that has shown antitumor activity with durable objective responses and promising survival outcomes in the ongoing studies in patients with previously treated small-cell lung cancer (NCT03319940, NCT05060016) (Ahn et al, 2023; Paz-Ares et al, 2023). Here we describe the effects of patient specific factors [age, sex, bodyweight, ethnicity, estimates of renal and hepatic function, prior lines of therapy, baseline disease status, emergence of anti-drug antibodies (ADA)] on tarlatamab exposures.

Methods: Tarlatamab serum concentrations were available from 420 subjects (8509 samples) pooled across the ongoing Phase 1 DeLLphi-300 study (dose range 0.003 mg to 100 mg Q2W and 200 mg Q3W) and Phase 2 DeLLphi-301 study (10 mg and 100 mg Q2W). The data were analyzed using a nonlinear-mixed effects modeling approach implemented in NONMEM (v7.5) software. Model selection and evaluation was guided by standard statistical and graphical approaches. Impact of key baseline demographic variables on tarlatamab clearance and volume of distribution were evaluated.

Results: Tarlatamab exposures increased in a dose-proportional manner and were not impacted by age, sex, ethnicity, estimates of renal and hepatic function, prior lines of therapy or baseline disease status. Asian race resulted in 14% higher peak serum concentrations relative to Caucasian subjects. Higher body weight (99 kg; 90th percentile) was associated with a 24% decrease in Day 28 pre-dose concentration (Ctrough) relative to median bodyweight (73 kg). Lower body weight (54 kg; 10th percentile) was associated with a 27% increase in Ctrough relative to median bodyweight. Positive ADA status resulted in a 24% decrease in Ctrough. However, at the recommended dose of 10 mg Q2W, neither body weight nor ADA status had a clinically relevant impact on tarlatamab efficacy or safety measures (Ahn et al, 2023).

Conclusion: Overall, based on these analyses, no dose adjustment for tarlatamab is required based on age, sex, bodyweight, ethnicity, estimates of renal and hepatic function, prior lines of therapy, baseline disease status or emergence of ADA.

#7168 PBI-410 (GQ1010), A novel Trop-2-targeted ADC demonstrates a favorable safety and toxicokinetic profile in multiple preclinical assessments.

Y. Sun[1], V. Reddy[2], P. Kulanthaivel[2], Y. Feng[1], J. Zhao[1], Z. Chi[1], J. Wang[1], L. Shi[1], G. Qin[1], P. H. Song[1];

[1]GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China, [2]Pyramid Biosciences, Inc., Boston, MA

Introduction: Trop-2-targeting ADCs (Trop-2 ADC) have demonstrated notable clinical efficacy; however, safety concerns necessitate frequent dose adjustments or discontinuations. PBI-410 (GQ1010) is a next-generation TROP-2 ADC developed using GeneQuantum's Ligase-Dependent Conjugation (iLDC) technology, that integrates a highly stable linker and a novel camptothecin analogue payload, TopoIx. This study included comprehensive preclinical evaluations that demonstrated a favorable safety and TK profile and potential for broader therapeutic margin versus other Trop-2 ADCs approved or in development.

Methods: TopoIx underwent extensive Good Laboratory Practice toxicity assessments in Sprague-Dawley (SD) rats (payload alone) and as part of the intact ADC in Non-Human Primates. Rats were administered repeated intravenous infusions of 0.5, 1.25, and 2.5 mg/kg of H0011 once a week over 5 doses. The potential toxicity profile of PBI-410 was evaluated in cynomolgus monkeys via repeated intravenous infusions of 10, 30, and 60 mg/kg doses every 3 weeks for 3 doses, followed by a six-week recovery phase.

Results: TopoIx administration in SD rats exhibited good tolerance, with slight reductions in body weight gain and food consumption. Microscopic tissue changes resolved post-drug withdrawal, except for persistent findings in the sciatic nerve. Repeated doses of PBI-410 in cynomolgus monkeys were well-tolerated, primarily manifesting as skin pigmentation and associated microscopic alterations in specific tissues, such as eyes, esophagus, thymus, and lymph nodes typical for topoisomerase inhibitors. Importantly, these changes were reversible upon drug cessation. The HNSTD/NOAEL for PBI-410 was determined to be 60 mg/kg. This corresponds to mean C_{max} of 1760 µg/mL and AUC_{inf} of 235000 µg*hr/mL for ADC and for TopoIx mean C_{max} of 16.4 ng/mL and AUC_{inf} of 2610 ng*hr/mL. The lower exposure of TopoIx suggests minimum payload shedding in the systemic circulation. Notably, PBI-410 demonstrated a significantly enhanced safety profile compared to other Topo1-based Trop-2 ADCs, including an absence of hematopoietic and intestinal toxicities, and no pulmonary toxicity or interstitial lung disease (ILD) observed.

Conclusion: PBI-410 demonstrated a favorable and differentiated nonclinical safety profile and favorable TK relative to those reported to date for other Trop-2 ADCs in development. This profile, in addition to the potent anti-tumor response and synergistic activity in combination with anti-PD1 reported previously, position PBI-410 as a best-in-class potential Trop-2 ADC and partner of choice for anti-PD1 combination therapy. Additionally, TopoIx has displayed excellent properties among the TOP1 inhibitors, making it suitable for a broader therapeutic application based on exceptional potency while maintaining a favorable safety profile.

#7169 A real-world toxicity-atlas shows that adverse events of combination-therapies commonly result in additive interactions.

A. Kucukosmanoglu, S. Scoarta, **B. Westerman**;
VU University Medical Center, Amsterdam, Netherlands

Purpose: Combination-therapies are a promising approach for improving cancer treatment, but it is challenging to predict their resulting adverse events in an real-world setting.
Experimental Design: We provide here a proof-of-concept study using 15 million patient records from the US Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS). Complex adverse-event frequencies of drugs or their combinations were visualized as heatmaps onto a 2D UMAP grid. Adverse event frequencies were shown as colors to assess the ratio between individual and combined drug effects. To capture these patterns, we trained a convolutional neural network (CNN) autoencoder using 7,300 single-drug heatmaps. Additionally, statistical synergy analyses were performed based on BLISS independence or Chi-square testing.
Results: The trained CNN model was able to decode patterns, showing that adverse events occur in global rather than isolated and unique patterns. Patterns were not likely to be attributed to disease symptoms given their relatively limited contribution to drug associated adverse events. Pattern recognition was validated using trial data from ClinicalTrials.gov and drug combination data. We examined the adverse-event interactions of 140 drug combinations known to be avoided in the clinic and found that near all of them showed additive rather than synergistic interactions, also when assessed statistically.
Conclusion: Our study provides a framework for analyzing adverse events and suggest that adverse drug interactions commonly result in additive effects with a high level of overlap of adverse event patterns. These real-world insights may advance the implementation of new combination therapies in clinical practice.

#7170 Pharmacokinetic profiling of Re-Phenformin *in vivo*: A novel approach in pancreatic cancer therapy.

A. Mohammad Gholizadeh[1], L. Dai[1], F. Dagher[1], C. Xiong[2], C. Li[2], D. S. Chow[1];
[1]University of Houston, Houston, TX, [2]University of Texas M.D Anderson Cancer Center, Houston, TX

Phenformin, a biguanide medication, has long been utilized in the treatment of diabetes. Recent research indicates that phenformin may also serve as an effective anticancer agent. This study introduces the synthesis and evaluation of Re tricarbonyl phenformin complex (Re-$(CO)_3$-Phenformin, Re-Phen), as a derivative of Phenformin and novel anticancer agent for pancreatic cancer treatment. Re-Phen was synthesized, purified, and characterized through preparative HPLC, NMR, mass spectrometry, and FT-IR. Subsequent *in vitro* studies, utilizing the MTS assay, assessed its cytotoxicity against pancreatic cancer cell lines, including Kras* murine PDAC and MiaPaca-2 human PDAC. Notably, Re-Phen exhibited significantly higher cytotoxic effects in MiaPaca-2 cells (IC50= 0.755 mM) and Kras* cells (IC50= 0.410 mM) compared to Phenformin treatment (IC50= 4.02 mM and 2.36 mM, respectively). These results highlight Re-Phen's enhanced anticancer activity, outperforming Phenformin in potency. Further investigation into the pharmacokinetics of Re-Phen involved an *in vivo* study with rats intravenously administered 2 mg/kg of Re-Phenformin. Blood samples were collected at intervals (10 min to 24 h post-dose) and were analyzed by validated LC-MS/MS. The pharmacokinetic profile of Re-Phen was best described by a 2-compartment model, using Phoenix® WinNonlin (version 8.0), with a particular focus on comparing the profiles of Phenformin and Re-Phen. The study revealed that Re-Phen has a significantly extended half-life compared to Phenformin (9.13 hr vs 2.11 hr), indicating prolonged systemic retention. Additionally, Re-Phen demonstrated an increased area under the curve (AUC), suggesting greater systemic exposure at equivalent dosing (90.55 hr*ng/ml vs 7.13 hr*ng/ml). This could imply enhanced bioavailability or altered metabolic clearance of Re-Phen compared to its parent compound. The two-Compartment of Re-Phe, provide a deeper understanding of its pharmacokinetic characteristics. In conclusion, Re-Phen not only demonstrates superior anticancer efficacy *in vitro* but also exhibits a more favorable pharmacokinetic profile *in vivo*. The extended half-life and increased AUC of Re-Phen suggest the potential of offering improved therapeutic efficacy in pancreatic cancer treatment. These promising findings warrant further investigation and could position Re-Phen as a promising therapeutic agent for the pharmacological management of pancreatic cancer.

#7171 Non-linear IV pharmacokinetics of the ATR inhibitor berzosertib (M6620) in mice.

Joshua J. Deppas[1], Brian F. Kiesel[1], Jianxia Guo[2], Robert A. Parise[2], Christopher J. Bakkenist[3], Jan H. Beumer[1]

[1]Pharmaceutical Sciences, University of Pittsburgh School of Pharmacy, Pittsburgh, PA,[2]Cancer Therapeutics Program, UPMC Hillman Cancer Center, Pittsburgh, PA,[3]Radiation Oncology, University of Pittsburgh School of Medicine, Pittsburgh, PA

Introduction: The ataxia-telangiectasia and Rad3-related (ATR) protein kinase is an attractive target for cancer therapies as it is an apical initiator of DNA damage response (DDR) pathways that facilitate cell cycle arrest and DNA repair, thus promoting survival of cancer cells. Several ATR inhibitors (ATRi) are in clinical development including berzosertib (M6620, VX-970), which is currently being evaluated in combination with cytotoxic chemotherapies and radiation. Although clinical studies have examined plasma pharmacokinetics (PK) in humans, little is known regarding dose/exposure relationships and tissue distribution which may influence berzosertib's therapeutic window. To understand these concepts, we extensively described the PK of berzosertib in mouse plasma and tissue.

Methods: Dose proportionality was assessed using single IV doses of berzosertib (2, 6, 20 and 60 mg/kg) administered to female BALB/c mice. Mice were euthanized from 5 min to 24 h post-dose. Using a highly sensitive LC-MS/MS method, berzosertib was quantitated in red blood cells, plasma, and tissues. Non-compartmental analysis (NCA) was performed using Phoenix WinNonlin to determine relevant PK parameters. Dose linearity was assessed by statistical comparison of dose-normalized plasma C_{max} and dose-normalized tissue AUC across the four dose levels. Statistical analyses were performed using ANOVA with Tukey's multiple comparisons test. Berzosertib plasma protein binding was assessed *in vitro* from 300 ng/mL to 100 µg/mL using rapid equilibrium dialysis. An extensive PK study was also conducted in tumor-bearing mice to assess distribution by quantitating drug in tissues.

Results: The dose proportionality study indicated that both plasma C_{max} and AUC increase with dose, and dose-normalized concentration vs time profiles suggested nonlinear increases in exposure based on different terminal slopes. At the two highest doses, dose-normalized AUC in each tissue were greater than the exposure generated at the two lowest doses. However, log transformations of $AUC_{0\text{-}360}$ plotted vs dose generated a slope of 0.886 (95% CI: 0.718 - 1.054), suggesting a linear relationship. The fraction of unbound berzosertib in mouse plasma increased at concentrations above 10 µg/mL, which is a concentration exceeded at the two highest doses and where nonlinearity in exposure is observed. Tissue analysis revealed the following tissues had a tissue/plasma coefficient >1: bone marrow, kidney, liver, spleen, lung, tumor, lymph nodes, thymus, and heart.

Conclusion: IV berzosertib displayed nonlinear PK in mice. Increased doses of berzosertib were associated with greater than proportional increases in plasma and tissue exposure most likely due to saturation of plasma protein binding. Our results will help to understand preclinical pharmacodynamic and toxicity data and subsequent PBPK modeling to inform optimal dosing and clinical deployment of berzosertib.

#7172 Pharmacokinetic/biomarker (PK/BMx) analysis of the toll-like receptor 7 and 8 (TLR7/8) agonist EIK1001 in phase 1 studies in participants (Pts) with solid tumors.

D. Rasco[1], M. Patel[2], M. Johnson[3], A. Tolcher[4], D. Sommerhalder[4], O. Hamid[5], A. Alistar[6], J. Kochan[7], E. Kurland[7], M. Wang[7], **C. Cho**[7], S. Rebello[7]; [1]South Texas Accelerated Research Therapeutics (START), San Antonio, TX, [2]Florida Cancer Specialists & Research Institute, Sarasota, FL, [3]Sarah Cannon Research Institute (SCRI), Nashville, TN, [4]NEXT Oncology, San Antonio, TX, [5]The Angeles Clinic & Research Institute, Los Angeles, CA, [6]Atlantic Health System, Morristown, NJ, [7]Eikon Therapeutics, Hayward, CA

Introduction: Immune checkpoint inhibitors (ICIs) relieve immunosuppression of tumor-reactive T cells and enhance antitumor immune response; however, not all patients benefit and some become refractory. EIK1001 is a TLR7/8 agonist that stimulates myeloid and plasmacytoid dendritic cells, activating immune and inflammatory responses. This dual activity provides another pathway, distinct from effects on checkpoint proteins, to enhance antitumor T-cell activity alone or in combination with ICIs.

Methods: Adults with advanced solid tumors received a range of doses of EIK1001 (QW IV) alone and in combination with pembrolizumab (200 mg Q3W; NCT03486301) or atezolizumab (1200 mg Q3W; NCT04196530) in Phase 1 studies (n=128). PK samples were collected on Cycle 1 Day 1 (C1D1) and C1D8 predose and at 0.5, 1, 2, 4, 6, 8, 12, and 24 hrs postdose, with sparse sampling thereafter. Matched cytokine BMx samples were collected.

The PK analysis population comprised pts with at least one measurable EIK1001 concentration (1563 observations from 94 pts). PK data were analyzed using non-linear mixed effects in Phoenix (v8.3). Covariate effects of the combination drugs were tested using a stepwise approach with a significance level of 0.05 for forward addition. All other covariates were evaluated using exploratory plots and formally tested using a full matrix approach. Empirical Bayes estimates were used to generate individual steady-state concentration-time profiles and calculate post-hoc PK parameters. Exploratory analyses of exposure-safety and exposure-efficacy were conducted.

Results: EIK1001 PK was linear and dose-proportional over the doses studied. Tmax ranged from 4-12 hrs with no accumulation. Pop-PK analysis indicated that body size influenced clearance, but intrinsic factors of age, gender, tumor type, ECOG status, or hepatic/renal impairment (mild/moderate) did not. Combination drugs did not influence clearance. These attributes support BSA-based dosing and inform inclusion/exclusion criteria for future studies.

On C1D1, time-dependent increases in IL-6, IL-8, IFNγ, and IP-10 returned to baseline within 24 hrs. An earlier IL-8 increase (Tmax 3-5 hr) is consistent with TLR8 activation on various cells including neutrophils, whereas the delayed increase of IFNγ/IP-10 (Tmax 5-8 hr) suggests a downstream effect. Dose-dependent increases in cytokines were observed, with median peak changes from baseline of 1.13- to 7.97-fold for IFNγ and 0.63- to 12.1-fold for IP-10. The 2 highest doses provided evidence of robust target engagement alone or in combination.

Conclusion: The linear, dose-proportional PK of EIK1001 is well described by the Pop-PK model. Increases in IFNγ and IP-10 were consistent with the anticipated mechanism of action, with doses representing target engagement identified. Further development of EIK1001 is underway.

#7173 Animal pharmacokinetics of an anti-Her2+ immunoliposome of docetaxel.

M. Dacos, E. Diroff, S. Giacometti, J. Ciccolini, **R. Fanciullino**;
Aix-Marseille University, Marseille, France

Despite the success of docetaxel in combination with trastuzumab in HER2+ breast cancer, docetaxel still has serious limitations, including poor water solubility and the canonical systemic toxicity of taxanes. These side effects of taxanes need to be overcome to improve patient management. In this context, we have developed a nanoparticle drug delivery system. We have developed an immunoliposome loaded with docetaxel and grafted with trastuzumab using a microfluidic method by mixing an aqueous phase (KH2PO4 buffer) and an organic phase composed of phosphatidylcholine, cholesterol and PEGmal in a molar ratio of 50:31:1, to which docetaxel is added at a rate of 1.8% of the total lipid. We perform a thiolation reaction to graft the trastuzumab onto the polyethylene glycol chain. Resulting immunoliposomes were characterized by a mean diameter of 140 nm, a docetaxel encapsulation rate of 73% and a trastuzumab uptake rate of 400 units of trastuzumab by nanoparticle. C57BL/6 mice were administered with docetaxel 1.9 mg/kg and trastuzumab 160 ng/kg or a mixture of free drugs or as liposomes at the same dose by intraperitoneal injection. Blood was collected 1h, 2h, 3h, 6h, 8h and 24h after injection and plasma was analyzed by HPLC-UV with Paclitaxel as internal standard. For each treatment group, pharmacokinetic parameters and exposure metrics were calculated using PKanalix®: half-life T1/2, elimination rate constant Kel and area under the curve AUC at the end points (AUCtlast) and infinity (AUCinfinity). Statistical tests were performed with Sigmastats®. The results showed a marked change in pharmacokinetics with increased plasma exposure with liposomal docetaxel. Preliminary results show a longer half-life for liposomal docetaxel (40.76 h VS. 4.33 h, i.e., a 9.4-fold increase). The concentration of docetaxel appeared to decrease more rapidly between T1h and T6h with free docetaxel (Kel 0.16h-1) than with liposomal docetaxel (Kel 0.017h-1). The concentration of docetaxel reached a plateau over time, up to 24 hours (52.72± 9.45 ng/ml) in mice treated with immunoliposomes whereas Docetaxel was undetectable at T24h when treated with free drugs. There was a statistical difference in PK at T6h between liposomal docetaxel and free docetaxel, 69.86 ± 15.25 ng/ml and 53.67 ± 4.92 ng/ml, respectively ($p < 0.001$, non-paired t-test). Liposomal docetaxel showed higher AUC0-t (x3.75) and AUC0-∞ values (x5.9) compared to non-liposomal docetaxel. In conclusion, these preliminary results suggest that we have developed a promising immunoliposome for the systemic delivery of docetaxel in HER2+ breast cancer with sustained exposure.

#7174 Pharmacokinetics and immunogenicity of anti-PD-1 antibody in humanized FcRn mouse models compared to immunocompetent mouse models.

X. Tu[1], X. Feng[1], W. Wang[1], X. Ding[1], D. Huang[1], L. Bourre[2], X. Chen[1];
[1]Crown Bioscience, Inc., Taicang, China, [2]Crown Bioscience, Inc., San Diego, CA

Introduction: The development and use of therapeutic antibodies in cancer therapy has increased significantly in recent years, led by the success of approved immune checkpoint blockade antibodies targeting PD-1 and PD-L1 axis. However, obtaining more clinically relevant pharmacokinetics (PK), safety and efficacy data for antibodies is still challenging in preclinical phase. Humanized FcRn (hFcRn) transgenic mouse model has a more faithful catabolism compared to WT mice, providing more accurate and predictable PK data of innovative antibody-based therapeutics at discovery stage[1]. In this study, we sought to investigate pharmacokinetics and immunogenicity characteristics of anti-PD-1 antibody in hFcRn transgenic mice and provide guidance for its differentiation of prediction value for drug PK and safety by comparing to WT mice.

Methods: Non-tumor bearing hFcRn mice and wild type C57BL/6 mice were divided into 2 groups, 5 mice were enrolled into each group. Mice were administered anti-PD-1(Nivolumab) at 10 mg/kg single dose after grouping by intravenous (IV) injection. Blood samples at 12 timepoints (15min, 6h, 1, 2, 4, 7, 10, 14, 21, 28, 35, 42 days) post-dosing were collected for PK and Anti-Drug Antibody (ADA) analysis by MSD and ELISA.

Results: Nivolumab clearance in hFcRn mice followed a typical linear profile with rapid distribution phase and slow elimination phase ($t_{1/2}$ = 350 to 400 h). While the PK profile in C57BL/6 mice displayed non-linear clearance and very short elimination phase ($t_{1/2}$ = 45 to 50 h). This data demonstrated that hFcRn mice have better correlated half-life with human (Nivolumab single dose by IV with 10mg/kg, $t_{1/2}$ = 595 h)[2].

ADA analysis revealed that it was produced starting from Day 10 in wild type C57BL/6 mice and the frequency of ADA induced by Nivolumab in wild type mice (2/5) was higher than hFcRn mice (0/5). The variation of Nivolumab level was correlated with ADA production in wild type mice. This suggested hFcRn shows lower immunogenicity than wild type mice for human IgG drug and can potentially improve negative effect of ADA interference on PK evaluation.

Conclusion: The result of this study demonstrated that the PK data in hFcRn mouse model was more predictive of human PK profile compared to wild type C57BL/6 mice. This advances innovation in antibody-based therapeutics and translational applications, with improved PK, safety and efficacy evaluation for preclinical human IgG drug development in cancer therapy.

#7175 Web-based cross-database exploration of molecular pharmacology data from cancer cell lines and patient genomics.

W. C. Reinhold[1], A. Luna[1], F. Elloumi[1], S. Varma[1], D. Taniyama[1], M. Mizunuma[1], J. del Rivero[1], A. Thomas[1], K. Reilly[1], K. Pacak[2], M. Aladjem[1], Y. Pommier[1]; [1]National Cancer Institute, Rockville, MD, [2]National Institute of Child Health and Human Development, Rockville, MD

CellMiner Cross-Database (CellMinerCDB, discover.nci.nih.gov/cellminercdb) allows integration and analysis of molecular and pharmacological data within and across cancer cell line datasets from the National Cancer Institute (NCI), Broad Institute, Sanger/MGH, MD Anderson Cancer Center (MDACC), and the National Center for Advancing Translational Sciences (NCATS, discover.nci.nih.gov/rsconnect/cellminercdb_ncats/). Altogether, our database spans over 1,700 distinct cell lines, over 1,000 clinically relevant drugs, ~25,000 experimental compounds, and molecular profiling data, such as gene/protein expression, molecular signatures including epithelial mesenchymal transition (EMT), replication stress (RepStress), neuroendocrine evaluation (NE), DNA copy, methylation, mutational status, and gene dependencies (Broad DepMap). This rich and growing set of cell lines and tested drugs allows for novel avenues for response determinant discovery and clinical translation that is facilitated by 1) common annotations (e.g., tissues of origin and matched drug names) across pharmacogenomic datasets and 2) various univariate and multivariate analyses tools. A major challenge to clinical translation occurs in relating pre-clinical models to patient samples. As part of this work, we show how the CellMinerCDB infrastructure additionally supports annotated patient multi-omics data to aid researchers to relate findings from cancer cell lines with patient data; we use data from small cell lung cancer (SCLC) and neuroendocrine tumors as illustrative examples. This work provides significant pharmacogenomic integration that allows exploration within a comprehensive dataset of cancer cell lines and to inter-relationships with patient-derived datasets; this is being developed to display and mine patient samples as part of the complementary web-based tool (PatientTumorMiner).

#7176 Optimization of T cell co-stimulatory agonists: A semi-mechanistic PKPD model integrating drug properties and tumor-immune interactions.

J. Gan, W. Hedrich, Y.-Y. Lu, W. Xu, R. H. I. Andtbacka, F. Adrian, L. Schweizer;
HiFiBiO Therapeutics, Cambridge, MA

Background: Despite the success of some immune checkpoint inhibitors in the treatment of cancer, T-cell co-stimulation has faced limited clinical success due to the intricacies around the optimal engagement of agonistic antibodies to co-stimulatory receptors, and the absence of biomarkers for patient selection. Understanding agonist-binding characteristics, pharmacokinetics, T cell subpopulation activation and differentiation kinetics, T cell life span in the tumor microenvironment, and the impact of T cell/tumor interactions on tumor growth kinetics is crucial for the positive clinical outcomes of T cell agonists. Currently there is not a suitable model to describe these complex interactions.

Methods: We investigated the pharmacokinetic (PK), pharmacodynamics (PD), and anti-tumor efficacy of an anti-TNFR2 agonist, HFB3-1, and an anti-OX40 agonist, HFB10-1, in syngeneic tumor models. Flow cytometry was employed to profile post-treatment tumor infiltrating lymphocytes (TILs) in dissociated tumor tissues. In vitro binding affinity was determined using Biolayer Interferometry. A semi-mechanistic model, integrating PK, tumor growth, and immune interaction networks (interactions among Teff, Treg, and tumor cells), was developed in Berkeley Madonna (version 10.5.1). This was subsequently adapted to a human tumor growth model with T cell interaction networks to assess the impact of doses and dosing regimens on tumor growth inhibition.

Results: A semi-mechanistic PKPD model was successfully developed incorporating drug properties including binding affinity, agonistic effect, ADCC activity, and pharmacokinetics, and tumor growth characteristics including tumor growth kinetics, TIL composition, interaction, proliferation, and turnover. This model was applied to investigate the effect of FcγR, dose, and dosing frequency on *in vivo* efficacy. Following incorporation of human PK and human tumor microenvironment properties into the model, tumor growth characteristics were simulated under varying human dosing regimens. Simulation results indicated that lower and less frequent doses optimize T cell co-stimulation for optimal anti-tumor activity.

Conclusion: Our semi-mechanistic PKPD model elucidates the intricate interactions between T cell co-stimulatory agonists and the tumor-immune cells in the tumor microenvironment. The model advocates for pulsatile agonism as the optimal anti-tumor activity for T cell co-stimulation agents. This model serves as a valuable tool for guiding dose and dose regimen optimization for T cell co-stimulatory agonists in clinical development.

#7177 Development and validation of clinical pharmacodynamic biomarkers to assess treatment response to HPK1 inhibition and guide dosing decisions.

L. Jia[1], Y. Marikar-Coplin[1], J. Chen[1], K. Xu[2], D. A. Mele[2], N. Luheshi[3], S. Iyer[2], A. I. Rosenbaum[1], S. Terrillon[1];
[1]AstraZeneca, South San Francisco, CA, [2]AstraZeneca, Waltham, MA, [3]AstraZeneca, Cambridge, United Kingdom

Checkpoint inhibitors represent promising cancer therapeutics as they have the potential to reignite T cell activity and reverse T cell exhaustion, which is a critical mechanism of immune evasion by tumors. Hematopoietic progenitor kinase 1 (HPK1) is a negative regulator of T-cell signaling that has recently emerged as a novel target for cancer immunotherapy. Inhibition of HPK1 can restore T cell function and anti-tumor immune responses, and several HPK1 inhibitors are currently under pre-clinical development, or clinical evaluation. Identifying clinically useful pharmacodynamic (PD) biomarkers in response to HPK1 inhibition is critical to characterize exposure-response relationship in early-phase trials and inform dose selection for later-phase studies. However, development and implementation of clinical PD assays are challenging because high sensitivity and specificity are required. Here, we developed a multi-biomarker strategy that combines a proximal biomarker (SLP-76 (Ser376) phosphorylation, a specific substrate of HPK1) and distal biomarkers (cytokine production) to evaluate target engagement (TE) and establish proof of mechanism (POM) of HPK1 inhibitors to determine their comprehensive PD profile. These PD biomarker assays were developed using peripheral blood as a surrogate tissue to assess HPK1 inhibition-induced pSLP-76 level decrease and cytokine levels increase, thus reflecting drug inhibitory effects and T-cell activity recovery. However, the lack of basal levels of these biomarkers presented a challenge for clinical workflow, as ex-vivo T-cell receptor stimulation of the clinical specimen is required after collection. Phosphoflow cytometry was prioritized over several technology platforms evaluated for quantifying blood pSLP-76 levels because of superior assay performance and signal stability under the developed clinical workflow. Blood cytokines upregulated upon HPK1 inhibition were first identified using targeted proteomics. IFNγ, IL2, TNFα, and IL17A were next confirmed and validated using quantitative immunoassays. Both pSLP-76 and whole blood cytokine workflows were thoroughly optimized for every step of sample handling from specimen processing at clinical sites to sample analysis at testing lab to ensure standardized, precise, and robust assay performance for clinical application. In addition, consistent HPK1 inhibition potency values were achieved using blood from cancer patients, demonstrating that the established PD biomarker assays apply to the clinical target population. In conclusion, robust peripheral TE and POM biomarkers were successfully developed to support future phase I/II studies with HPK1 inhibitors. These are expected to enable characterization of the exposure-response relationships and help define the therapeutic window and optimal dose.

#7178 Neuronal cells derived from iPSCs cell to evaluate neurotoxicity after 48 or 72 hours in high-through put screening format.

F. Sabatier[1], J. Chaigne[1], M. Martin[1], R. Barbeau[1], L. Houssin[1], S. Bonnin[1], A. King[2], **V. Jahnke**[1];
[1]Eurofins Cerep, Celle-Levescault, France, [2]Eurofins Panlabs, St-Charles, MO

Neurotoxicity is a major concern in central nervous system drug discovery and a frequent cause of attrition in clinical trials or approved drug withdrawal. Neuropathy is a side effect defined by the injury of peripheral nerves causing a loss of sensation/motion. Drug development pipelines typically involve testing in cell lines followed by animal investigations with translation to humans. The induced pluripotent stem cells (iPSCs) have widened new model systems to study adverse toxicities. With evolution in regulatory guidance the use of human- iPSC-derived tissue provides high-throughput access and a more relevant testing environment. Neuropathy is one of the most chemotherapy adverse effects. In this study we have screened 8 compounds. Bortezomib (proteasome inhibitor), gemcitabine (approved ovarian cancer treatment), ivermectin (parasitic diseases treatment), flavopiridol (approved CDKs inhibitors), SNS-032 (approved CDKs inhibitor), mefloquine (anti-malaria drug), digitonin (nonionic detergent) and tamoxifen (hormone receptor-positive breast cancer treatment). These molecule toxicities were tested on neuronal-derived iPSCs Dopaneurone, GABAneurone, Glutaneurone, Motorneurone, Microglya and Astrocytes in high throughput screening. For the project, cells were plated in 384 well/plates. DMSO tolerance was performed (up to 10%). Drugs were added, then, after 48h or 72h, total protease and protease activities were measured using CytoTox-Glo™. Compounds were tested at 7 concentrations (from 10^{-4} to 10^{-9}M).In this study we have validated cell culture and the assay conditions. The signal window range was good after 48h and 72h of treatment. No toxicity was found until 10% DMSO. A specific neurotoxicity signature was measurable for each drug tested. Digitonin, our positive control, induced toxicity in all IPSCs after 48h and 72h of incubation. On the contrary, Tamoxifen, our negative control, did not induce any neurotoxicity. The other molecules generated a signature of severe to mild neurotoxicity. These results are in agreement with their known adverse side-effects. In conclusion, this panel is a good tool to anticipate possible neurotoxicity within the 3Rs respect. It can be used in early drug de-risking or neuroprotection screening, with the aim of preventing/reducing/curing neuropathy in at-risk populations.

#7179 OBI-992, a novel TROP2 targeting antibody drug conjugate demonstrates superior in vivo PK/PD properties and a favorable safety profile.

C.-S. Shia, S.-N. Wen, R.-Y. Hsu, J.-S. Tu, H.-W. Chang, W.-F. Li, M.-T. Lai;
OBI Pharma, Inc., Taipei City, Taiwan

Background: TROP2 targeting antibody-drug conjugates (ADC) have demonstrated promising clinical responses for the treatment of various solid tumors. However, these ADCs still exhibit serious safety issues, such as hematologic toxicities and interstitial lung disease. OBI-992, a novel TROP2 targeting ADC, which is derived from the conjugation of an anti-TROP2 antibody with a topoisomerase I inhibitor, exatecan, via an enzyme-cleavable linker. OBI-992 is designed to have high serum stability and broad therapeutic index. Herein, we describe the results from preclinical studies of OBI-992, including in vitro and in vivo stability, pharmacokinetics/pharmacodynamics (PK/PD) profile, and safety evaluation.

Material and Methods: To characterize OBI-992, the linker stability was evaluated by ex vivo serum stability and rat PK studies. PK/PD properties, including systemic and tumor exposures as well as receptor occupancy, were evaluated in a human lung cancer xenograft model. In vitro toxicity testing, including ADC toxicity on differentiating neutrophils and FcγR mediated toxicity, was evaluated using human monocyte THP-1 cells. A 6-week repeat dose toxicity study in cynomolgus monkeys was conducted to evaluate the safety and toxicokinetics of OBI-992.

Results: Ex vivo serum stability demonstrated that OBI-992 exhibited better linker stability than the benchmark datopotamab deruxtecan (Dato-DXd). In vivo PK evaluation in rats showed that OBI-992 had lower C_{max} and AUC of free payload than Dato-DXd, indicating a better PK profile of OBI-992 in rats. A PK/PD study in tumor-bearing mice revealed that OBI-992 exhibited higher tumor exposure of free payload than Dato-DXd, resulting in a better antitumor efficacy. In addition, the antitumor effect positively correlated with percentage of receptor occupancy in a dose-dependent manner. In vitro cytotoxicity testing demonstrated that OBI-992 had lower toxicity in differentiating neutrophils and THP-1 cells compared to Dato-DXd, suggesting that OBI-992 may cause less off-target toxicity. Toxicokinetics of OBI-992 in cynomolgus monkeys revealed that the systemic exposure of ADC was similar to that of total antibody. Furthermore, the systemic exposure of ADC and total antibody were found to increase in a dose-proportional manner. Major toxicities in monkeys were target-related skin lesions. The highest non-severely toxic dose (HNSTD) was determined to be 60 mg/kg.

Conclusions: OBI-992 exhibits remarkable antitumor efficacy and a favorable safety profile, supporting further clinical development of OBI-992 in TROP2 positive cancers.

#7180 Tumor growth modeling to support dose justification of Dato-DXd in hormone receptor positive, HER2 negative breast cancer (HR+HER2-BC) subjects.

Z. Tang[1], Y. Jiang[1], H. Yang[1], D. Dai[1], C. Gong[2], L. Irons[2], Y. Pan[3], Y. Hong[3], S. Liang[3], S. Ren[1], A. Phipps[4], D. Zhou[2];
[1]Astrazenea, Gaithersburg, MD, [2]Astrazenea, Waltham, MA, [3]Daiichi Sankyo Inc, Basking Ridge, NJ, [4]Astrazenea, Cambridge, United Kingdom

BACKGROUND: Dato-DXd, a TROP2-directed antibody-drug conjugate, has demonstrated efficacy and a manageable safety profile in multiple tumor types. A dosing regimen of 6 mg/kg every three weeks (Q3W) has been proposed as the optimal schedule based on phase I data in patients with non-small cell lung cancer (NSCLC)[1]. Dato-DXd demonstrated statistically significant and clinically meaningful improvement in PFS compared with ICC in patients with HR+HER2-BC in TROPION-Breast01[2]. A tumor growth inhibition (TGI) model was developed to support dose justification at 6 mg/kg in HR+HER2-BC subjects.
METHODS: A tumor growth inhibition (TGI) model was developed based on tumor size data from HR+HER2-BC patients received 6 mg/kg Dato-DXd Q3W in a Phase I study (N = 39, Data cutoff July 2022). The TGI model described the tumor size as the result of an exponential tumor growth, a tumor shrinkage that was driven by Dato-DXd cycle-specific AUC, and a resistance term suggesting that the shrinkage effect by Dato-DXd decreases over time. Cycle-specific Dato-DXd AUC was derived based on the AUC and time at each cycle for each individual. Simulations were conducted using the TGI model to compare tumor size change from baseline at 4, 6, and 8 mg/kg in HR+HER2-BC patients, with consideration of dropouts.
RESULTS: The TGI model well-described tumor size data with reasonable parameter estimations. Simulated time-courses of tumor sizes at Dato-DXd 4, 6, and 8 mg/kg suggested that Dato-DXd at 6 mg/kg may lead to greater tumor shrinkage effect than that at 4 mg/kg in HR+/HER2-BC patients. At approximately 180 days post first treatment, tumor shrinkage at 6 mg/kg was almost 2-times greater than at 4 mg/kg (-51% vs. -25%, respectively).
CONCLUSION: Simulations based on the TGI model suggested greater tumor size reduction at Dato-DXd 6 mg/kg compared to 4 mg/kg in HR+HER2-BC patient population.

#7181 Low dose interleukin-6 (SON-080) for neuropathies: Toxicology and clinical plans.

S. Dexter[1], G. Hedou[2], R. T. Kenney[3], D. J. Rezac[4], P. Mohan[1];

[1]Sonnet BioTherapeutics, Princeton, NJ, [2]Sonnet BioTherapeutics, CH SA, Geneva, Switzerland, [3]Sonnet BioTherapeutics, Potomac, MD, [4]Latham Biopharm Group, Elkridge, MD

Neuropathies are conditions in which peripheral nerves degenerate, resulting in sensory and motor symptoms that can profoundly affect the patients' quality of life. Chemotherapy-induced peripheral neuropathy (CIPN) is induced by most antineoplastic agents, affecting cancer patients during or following completion of treatment. Neuropathy-specific pain medication is most often inefficient against pain, can cause major side effects that limit their use, do not address non-pain related symptoms, and do not stop CIPN progression. Most evidence suggests that physical exercise is the most efficient approach to reduce neuropathy symptoms and potentially, progression. Other publications have causally linked exercise, through the ability of contracting muscles to release low levels of interleukin-6 into the bloodstream thereby activating several metabolic and physiological pathways that help regenerate muscle and nerve tissue, affect glucose homeostasis, increase lipolysis, improve microvascular blood flow and reduce inflammation. Preclinical disease models of CIPN and diabetic peripheral neuropathy (DPN) have confirmed that IL-6 administered at low doses is capable of stimulating peripheral nerve growth, thereby ameliorating motor and sensory functions and normalizing the associated pain or sensation disturbance of neuropathy. The maximum tolerated (MTD) dose of recombinant human IL-6 (rhIL-6) has been established as a treatment for thrombocytopenia in hundreds of cancer patients using the drug product that was produced in the 1990's (Process A) dosed intravenously (IV) or subcutaneously (SC). We have developed a cGMP compliant version of rhIL-6 (SON-080) using a state-of-the-art process (Process B) that meets current regulatory guidelines for cell lines and processes. An analytical comparison of SON-080 with Process A rhIL-6 concluded that both drugs are highly comparable for at least 14 different key physicochemical characteristics. Therefore, we expect similar *in vivo* behavior with Process B material as compared with the Process A molecule. In order to support clinical plans for the safety and toxicity of rhIL-6, a dose range and schedule of administration that matches the current clinical protocol was performed in a cynomolgus monkey primate toxicology model. Under these conditions, SON-080 was found safe and well tolerated with a No Adverse Effect Levels (NOAEL) of 30µg/kg, the highest dose tested. On this basis, a fully controlled Phase 1b/2a clinical study, SB211, is ongoing to evaluate safety, tolerability, and efficacy of subcutaneous SON-080 dosage and administration schedule that targets an exposure mirroring the endogenous release levels elicited by moderate to heavy exercise. Confirmation of safety in the first portion of the trial will pave the way for efficacy evaluation with the objective to provide CIPN patients with a novel, safe, and effective treatment for painful neuropathies.

#7182 Blood brain barrier masks effects of dosing strategy.

M. Stoddard[1], A. Chen[2], **L. Yuan**[3], D. Van Egeren[4], A. Chakravarty[1];
[1]Fractal Therapeutics, Lexington, MA, [2]Columbia University, New York, NY, [3]Fractal Therapeutics, Inc., Lexington, MA, [4]Stanford University, Palo Alto, CA

The penetration of the blood brain barrier (BBB) presents a significant challenge in the design of drugs targeting brain tumors. The BBB desynchronizes drug concentrations between the body and brain, complicating the relationships between drug dose, effective concentration, and toxicity. In this work, we sought to understand the nature of these relationships in the context of dose schedule, in order to suggest minimally toxic and maximally effective strategies. We developed a two-compartment pharmacokinetic model to simulate the exchange of a drug between the body and the brain. Drug exchange was based on passive diffusion through the barrier and active transport into the brain as described by Michaelis-Menten kinetics. In the model, tumor cells exhibit binary resistance to the drug under a logistic growth model. The drug reduces the growth rate of the sensitive population while the resistant population suffers a small growth penalty because of the mutation conferring resistance. Strategy effectiveness was quantified in terms of survival time, the time until 95% of carrying capacity was reached, and toxicity was evaluated as the peak moving average over 18 days. Although the BBB complicates prediction of drug action, it simplifies drug impact by masking schedule effects. Our work suggests that drug concentrations in the brain increase with initial treatment until equilibrium between active transport, diffusion, and drug metabolism is reached. Fluctuations in drug concentration resulting from breaks between bolus dosing are greatly reduced in the brain relative to the body, and high frequency (daily) dosing results in a nearly constant equilibrium drug concentration. The rate at which equilibrium is reached and the drug concentration in the brain are unaffected by dosing period, as long as the average dose per day is constant. Our model suggests that the impact of dosing cycle length on survival time is negligible. Neutropenia is minimized by schedules with dosing cycle lengths that factor evenly into the 18-day neutrophil recovery period. These schedules have consistent toxicity throughout. Strategies with two, three, six, nine, and eighteen day cycles induce neutropenia least. As fluctuations in drug concentration are small at the equilibrium steady-state, effects of scheduling on drug interactions are predicted to be minimal. As drug concentration in the brain at equilibrium and latency to equilibrium are independent of dosing period, these parameters must be modulated through changes in the amount of drug dosed. The use of a loading dose may compensate for latency. Although this analysis is based on hypothetical drugs, it provides practical insights that are applicable across a wide range of systemically dosed small-molecule therapeutics. Further, the modeling framework derived here can be readily extended to guide the design of dosing schedules for real-world therapeutic interventions.

#7183 Liver toxicity of amanitin-based antibody drug conjugates (ATACs) is caused by unspecific uptake of the ATAC into liver cells.

C. Orlik, K. Decker, M. Vranic, M. Schmitt, A. Pahl, M. Kulke, T. Hechler;
Heidelberg Pharma Research GmbH, Ladenburg, Germany

Background: Antibody drug conjugates (ADCs) were developed to increase the therapeutic window (TW) of cytotoxins by combining their efficacy with the precision of antibodies (Ab). Nevertheless, adverse events, still limit the use of ADCs. The tox profile of an ADC is determined by its on- and off-target effects. On-target tox is caused by specific binding of the ADC to healthy target-positive cells; off-target tox is caused by target-independent binding of the ADC, e.g. via the Ab backbone or by payload release in circulation. In this study, we unravel the off-target tox mechanisms of ADCs that use amatoxins (RNA polymerase II inhibitor) as payload (ATACs) and use this knowledge to improve the TW of ATACs. Amatoxins are distinct from other ADC payloads as they are hydrophilic and thus require active transport to pass the cell membrane. The primary transporter of amatoxins in humans is the OATP1B3 transporter, which is exclusively expressed on hepatocytes. Thus, unspecific ATAC tox can be caused by free amatoxin, premature released in circulation and uptake by liver cells via OATP1B3, or by uptake of the ATAC via a yet unknown mechanism.

Material and Methods: ATACs are based on cysteine-reactive and site-specific amatoxin-linker constructs by HDP. *In vitro*: Binding of ATACs to FcγRI by BLI; Cytotoxicity of ATACs on HEKwt, HEK-OATP1B3 and THP1 cells. *In vivo*: Single i.v. dose of ATAC; Tolerability in mice; Efficacy in s.c. tumor models; Blood sampling for PK analysis; ADC/total Ab detection by ELISA; DAR-loss analysis and toxin measurement by (intact) LC-MS.

Results: Liver tox caused by premature release of amatoxin in circulation was investigated thoroughly *in vivo*. DAR-loss, survival analysis, ADC and Ab measurements, indicated that the release of amatoxin in circulation cannot be the root-cause for off-target ATAC toxicity. Further, it was ruled out that the ATAC is taken up by OATP1B3 *in vitro* and *in vivo*. Thus, uptake of the intact ATAC via yet unknown mechanisms is responsible for liver tox. As liver tox is also known for other ADCs, several uptake mechanisms are described, one of which being FcγR-mediated uptake. Indeed, ATACs bind to the FcγR and trigger target-independent cytotoxicity on $FcγR^{\pm}$ cells. Point mutations at L234 and L235 (LALA mutation), the amino acids in the Fc part of the Ab responsible for FcγR binding, were shown to reduce FcγR binding. The LALA mutation significantly increased the tolerability of ATACs in mice and monkeys, whereas the anti-tumor efficacy was not impaired, leading to an improved TW.

Conclusion: Our data show that liver toxicity of ATACs is caused by unspecific uptake of the ATAC into liver cells at least partially mediated by FcγR. This knowledge was used to optimize the Ab backbone to minimize unspecific uptake into liver cells. Insertion of a LALA mutation to avoid uptake via FcγR reduced off-target toxicity of ATACs leading to better tolerability and an increased TW.

#7184 Simulating extended dosing intervals for atezolizumab: A comparative analysis between NONMEM and Pumas.

F. Bateman[1], O. Arisa[1], N. Corvalan Cabanas[2], Y. Zeng[1], C. Peer[2], K. Schmidt[2], W. D. Figg, Sr.[2];
[1]NIH-CC, Bethesda, MD, [2]NIH-NCI, Bethesda, MD

The initially approved dosage regimens of 840 mg every 2 weeks, 1200 mg every 3 weeks, and 1680 mg every 4 weeks are considered excessive concerning the specified minimum effective concentration of 6 ug/mL and the significant exposure-response relationship with Adverse Events of Special Interest (AESI). Our previous research, demonstrated through simulation, indicated that an extended-interval dosing regimen (840 mg every 6 weeks) after two standard loading doses maintained efficacy with a nonsignificant exposure-response relationship with AESI.In alignment with the FDA's initiative "Project Optimus," which aims to optimize drug dosing for improved therapeutic outcomes, we explore alternative dosage regimens for atezolizumab. Through a comparison of the traditional 30-year-old industry standard NONMEM software and the recently developed PumasAI software, we simulate these regimens, utilizing our previously published article as a benchmark. Given the rapid evolution of artificial intelligence (AI) and machine learning, it is crucial for pharmacokinetic modeling to adapt and leverage these advancements. We anticipate that this paper will contribute to the integration of AI and machine learning software in pharmacokinetic analysis, aligning with the goals of "Project Optimus" to ensure that drug concentrations are optimized for efficacy and safety.

Table 1: Comparative Summary of Simulated Pharmacokinetic Parameters: Pumas vs. NONMEM

			Pumas			NONMEM		
Regimen	*Cycle*	*Week*	*Cmax (ug/mL)*	*Cmax (ug/mL)*	*Cmax (ug/mL)*	*Cmax (ug/mL)*	*Cmin (ug/mL)*	*Weekly AUC (ug*day/mL)*
1200 mg q3w	1st	3	384(278-533)	64.1(31.4-112)	919(640-1290)	394 (278-559)	75.6 (44.5-121)	1003 (755-1342)
	7th	21	541(371-795)	146(53.8-349)	1750(977-3210)	583 (414-847)	180 (75.9-396)	2014 (1169-3535)

#7185 Long acting injectable FHD-609 micro-suspension: A potent BRD9 degrader with comparable efficacy, reduced frequency of dosing in preclinical models.

Meiyun Lin, Ammar Adam, Abira Pyne Ramakrishnan, Hafiz Ahmad, Xiaohuan Wu, Brandon Antonakos, Chong-Hui Gu, Ashish Ramani, Victoria Amaral, Claudia Dominici, Qianhe Zhou, Mike Collins, Jessica Piel, Sal Topal, Brian Ethell, Kelly McKiernan, Scott Innis

Foghorn Therapeutics, Cambridge, MA

Bromodomain-containing protein 9 (BRD9) is a unique component of the non-canonical Brahma-associated factor (ncBAF) complex, essential for cancer cells relying on this complex for survival. This makes it an attractive target for cancer treatment. In synovial sarcoma (SS), SS18-SSX fusion protein drives disease progression and integrates into BAF complexes, promoting tumor growth. Targeting BRD9 degradation is a potential therapeutic approach for SS tumors, as it depletes the essential SS18-SSX fusion protein upon which cancer cells depend for survival within the BAF complex.
FHD-609, a potent heterobifunctional degrader of BRD9, has been administered intravenously (IV) in medical facilities twice weekly during clinical trials. In order to facilitate less frequent and more convenient patient-centric dosing, a long acting injectable formulation was developed that allows subcutaneous (SC) or intramuscular (IM) dosing every 4 weeks in preclinical studies. The formulation is an aqueous microsuspension containing the drug along with a polymer and surfactant which provides sustained release of FHD-609 upon injection. We compared the long acting injectable formulation dosed once every 4 weeks to the IV formulation dosed twice a week for the pharmacokinetic and pharmacodynamic properties, as well as the efficacy of the long in xenograft models of different sensitivities, including cell line-derived xenografts (CDX) and patient-derived xenografts (PDX). Our results showed that a single dose of the injectable suspension formulation was well-tolerated in mice and exhibited a significantly flatter PK profile than IV injection with a lower peak to trough ratio and detectable compound concentrations 4 weeks post dose. Moreover, it demonstrated comparable in vivo efficacy and BRD9 protein degradation to the standard intravenous (IV) administration. The long acting FHD-609 injectable formulation has the potential to offer better patient compliance and acceptance in clinical settings than IV dosing. The long acting injectable formulation provides a promising and effective drug delivery option for various protein degraders that are not orally bioavailable.

#7186 *In vitro* evaluation of myelosuppressive effects of ATRi tuvusertib and ATMi lartesertib (M4076), alone and in combination.

Jatinder Kaur Mukker[1], Rohan Kulkarni[1], Yongzhao Huang[2], Emer Clarke[2], Ioannis Gounaris[3], Anup Zutshi[1], Karthik Venkatakrishnan[1], **Anna Tafuri**[4]

[1]EMD Serono, Billerica, MA,[2]Discovery Life Sciences, Seattle, WA,[3]Merck Serono Ltd. (an affiliate of Merck KGaA, Darmstadt, Germany), Feltham, United Kingdom,[4]Merck KGaA, Darmstadt, Germany

Introduction: In cancer therapy, combinations of drugs interfering with different molecular pathways enhance efficacy and reduce resistance development, but may also increase the risk of toxicity. DNA damage repair inhibitors (DDRi) induce on- and off-target adverse events including hematological and gastro-intestinal toxicities[1], which impact the therapeutic window. We evaluated the hematopoietic effect of ATRi tuvusertib and ATMi lartesertib, alone and in combination, on erythroid, megakaryocytic and myeloid bone marrow cell lineages.

Methods: Mobilized peripheral blood CD34+ cells were plated in 96-well plates in specific media cultures allowing growth and differentiation of all three lineages. The cells were cultured for a total of 7 (neutrophils and platelets) to 10 (erythroids) days in the absence of drugs to generate maturing populations. Various concentrations of tuvusertib and lartesertib were incubated in cell media and assessed using LC/MS methods to ensure they remained chemically stable for the duration of the experiments. After *in vitro* differentiation, the lineages were cultured in the continuous presence of various concentrations of tuvusertib (0.003 to 3 µM) and/or lartesertib (0.01 to 10 µM) encompassing an unbound plasma concentration range evaluated in phase 1 studies of these agents and their combination. Cells were evaluated in triplicate by flow cytometry on day 3 and 7 of drug exposure for neutrophils (CD34, CD38, CD33, CD15), megakaryocytes and platelets (CD41, CD42b), and erythroid cells (CD71, CD235a). In another set of experiments, to simulate a "drug holiday", cells were exposed to tuvusertib, lartesertib and their combination for 24 h, washed out and further cultured as described above before evaluation.

Results: Tuvusertib and lartesertib were stable in the specific media cultures up to day 7 of drug exposure. Continuous treatment with tuvusertib as a single agent inhibited the hematopoietic cells of all lineages more profoundly than lartesertib as monotherapy. Effects were consistently more pronounced after 7 days than 3 days of drug exposure. Continuous treatment of a combination of tuvusertib and lartesertib inhibited hematopoietic cells of all lineages. Treatment for 24 h followed by wash-out demonstrated a lesser effect compared to continuous treatment.

Conclusion: The phenotypic and functional changes induced by tuvusertib and lartesertib on *in vitro* cultures of erythroid, myeloid, and megakaryocytic cells are consistent with clinical observations in monotherapy studies, suggesting these models may be used to better understand and predict the hematological effects of monotherapies and combinations in the clinic. *In vitro* washout experiments may help support the concept of intermittent clinical regimens and warrant further investigation.

#7187 Entresto protects against doxorubicin-induced cardiotoxicity in mice model of breast cancer.

A. Pandit, A. Costas, B. Sapkota, S. Thota, R. Begum, N. Chintalaramulu, H. W. Green III, J. Francis;
Louisiana State University, Baton Rouge, LA

Doxorubicin (Dox) is a potent chemotherapeutic agent with high efficacy; however, dose-dependent cardiotoxicity undermines its effectiveness in cancer therapies. Entresto, a combination of sacubitril and valsartan (Sac/Val), offers a multi-modal approach. It enhances the beneficial response of the neurohormonal system of the heart while curbing the detrimental effects of the renin-angiotensin-aldosterone system and mitigating further cardiac damage by decreasing sensitivity to natriuretic peptides. The objective of this study is to assess the potential cardioprotective effects of Entresto on doxorubicin-induced cardiotoxicity (DIC) in a mouse model of breast cancer. To achieve this, a syngeneic tumor model of breast cancer was employed. Twenty-five 10-week-old female Balb/c mice were randomly divided into 5 groups: control, Tumor, Tumor + entresto, Tumor + Dox, and Tumor + entresto + Dox. Tumor groups were injected with 4T1 wild-type cells into the mammary fat pad via intraperitoneal injection. Subsequently, after a week, Dox groups were treated with Dox at 8 mg/kg body weight/week for 3 weeks, while control and tumor + entresto received saline. Following Dox treatment, control, and tumor + Dox animals were gavaged daily with saline, while Entresto groups were gavaged with entresto (60 mg/kg) for 3 weeks. Echocardiography assessed cardiac function at baseline and 3 weeks post-DOX treatment. All mice were euthanized at 4 weeks. Our results demonstrated that entresto treatment significantly ameliorated Dox-induced decreases in ejection fraction and fractional shortening while maintaining improved cardiac functions. Entresto also reversed Dox-induced altered levels of cardiac biomarkers (ANP and BNP). Gene and protein expression analyses in heart tissues revealed that entresto modulated the levels of autophagy-related (Beclin-1 and p62), apoptosis-associated (caspase 3 and Bcl-2) and antioxidant-related (Nrf2 and Keap1): genes and proteins expression altered by Dox treatment. Additionally, Entresto attenuated histological evidence of cellular toxicity, apoptosis, and fibrosis in Dox-treated animals with breast cancer. These findings suggest that Entresto confers cardiac protection against DIC in a mouse model of breast cancer without interfering with the antineoplastic effects of Dox. It underscores the potential clinical relevance of Entresto to enhance the safety and efficacy of doxorubicin-based cancer therapies.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Reversal of Drug Resistance 2
Poster Session

#7191 Targeting IGF1R/INSR pathway with approved ALK inhibitors inhibits AKT signaling and overcomes proteasome inhibitor resistance in multiple myeloma.

A. Besse[1], T. Totu[2], M. Kraus[3], A. P. A. Janssen[4], J. Veprkova[1], M. Mendez Lopez[3], O. Slaby[1], M. Buljan[2], M. van der Stelt[4], C. Driessen[3], L. Besse[1];
[1]Masaryk University, Brno, Czech Republic, [2]Swiss Federal Laboratories for Materials Science and Technology, St. Gallen, Switzerland, [3]Cantonal Hospital St. Gallen, St. Gallen, Switzerland, [4]Leiden University & Oncode Institute, Leiden, Netherlands

Background: Resistance to proteasome inhibitors (PI) bortezomib (BTZ) and carfilzomib (CFZ) is a major obstacle to the successful treatment of multiple myeloma (MM); thus, identification of novel therapeutic options is an unmet medical need. ALK inhibitors have been shown to exhibit anti-MM activity in monotherapy or in combination with CFZ. Our data showed that MM cells were negative for ALK; thus, we aimed to identify the mechanism of action of the ALK inhibitor ceritinib in MM cells and the mechanism of synergy between ceritinib and CFZ.
Methods: A set of PI-naïve and PI-resistant MM cells was used in this study. Genome-wide CRISPR/Cas9-based screening using the Brunello library was performed in the AMO-1 cell line. Kinase inhibitor selectivity data were retrieved from ChEMBL, v30 database. RNA sequencing was used to determine expression changes after treatment, and RNA-seq data from patients included in the CoMMpass study were analyzed. Western blotting was performed to assess the levels of total and phosphorylated protein. Unbiased LC-MS/MS was performed to determine the effects of ceritinib and CFZ on the intracellular metabolites. An *in vivo* mouse model based on the orthotopic injection of AMO-BTZ cells into the femur of NSG mice was used to determine the effect of the drug combination *in vivo*.
Results: Among approved ALK inhibitors, ceritinib has been identified as the most synergistic cytotoxic combination with CFZ in PI-naïve and PI-resistant MM cells. An in silico search of the ChEMBL database identified InsR and IGF1R as receptor tyrosine kinase that are inhibited by ceritinib. PI-naïve, PI-resistant cell lines, as well as MM patients were negative for ALK, but positive for InsR and IGF1R expression. CRISPR/Cas9-screening identified genes involved in the negative regulation of mTORC signaling (DDIT4, NPRL2/3, TSC1/2) and the transcription factor FOXO1 as the major resistance candidates to ceritinib. Subsequently, FOXO1 inhibition using a selective chemical inhibitor protected the cells from ceritinib-induced cytotoxicity. Next, ceritinib inhibited mTORC signaling and induced the expression of genes related to cell cycle arrest, which are downstream of FOXO1. Likewise, ceritinib, by targeting the InsR/IGF1R, impaired purine-pyrimidine and amino acid homeostasis, suggesting metabolic and proliferation shut-down and amino acid starvation due to downstream mTORC and Akt inhibition and FOXO1 induction. The combination of ceritinib and CFZ was superior to CFZ in PI-resistant MM in vivo and showed strong synergistic cytotoxicity in primary cells from MM patients progressing under or after PI-containing therapy.
Conclusion: Ceritinib, an FDA-approved drug, overcomes PI resistance in MM by inhibiting InsR/IGF1R and downstream Akt signaling. Therefore, ceritinib is a promising treatment option for PI-resistant MM.

#7192 Teriflunomide overcomes gemcitabine resistance by inhibiting the GSK3β/mTOR pathway in pancreatic cancer.

C. Xu[1], Y. Li[1], S. Sui[1], M. Chen[1], L. Melstorm[2], H. Han[3], S. Rosen[4], A. Goel[1];

[1]Beckman Research Institute of The City of Hope, Monrovia, CA, [2]City of Hope National Medical Center, Duart, CA, [3]The Translational Genomics Research Institute, Phoenix, AZ, [4]City of Hope National Medical Center, Duarte, CA

Background: Pancreatic cancer (PC) is a lethal malignancy that is partly attributable to the acquisition of chemoresistance to conventional chemotherapies. Hence, developing strategies to overcome such chemoresistance is essential. Teriflunomide, an active metabolite of leflunomide, has been widely utilized in managing autoimmune disorders, and emerging evidence suggests that it can augment the efficacy of chemotherapy in cancer. We investigated the therapeutic effect of teriflunomide in overcoming resistance to Gemcitabine-based therapy in PC.

Methods: We performed docking and genomewide transcriptomic profiling analyses to identify therapeutic targets of Teriflunomide associated with Gemcitabine resistance (Gem-R) in PC. Subsequently, we analyzed the TCGA dataset to determine the prognostic significance of candidate genes in PC patients. A series of experiments were performed in PC cells, and the key findings were validated in patient-derived 3D organoids and a Gem-R Mia-PaCa2 xenograft model.

Results: Docking and transcriptomic profiling studies identified GSK3β, MAPK8, and MAPK9 as potential targets of Teriflunomide, which were significantly upregulated in Gem-R cell lines ($P < 0.05$). GSK3β was independently associated with poor overall and disease-free survival in PC patients. Combined Teriflunomide and Gemcitabine treatment exhibited superior synergistic anti-tumor potential, as evidenced by reducing PC cell proliferation, clonogenicity, invasion, and migration. The combined treatment with Teriflunomide and Gemcitabine primarily inhibited GSK3β phosphorylation, resulting in the silencing of the downstream AKT/mTOR pathway. Lentiviral-based silencing of GSK3β inhibited the AKT/mTOR pathway and reduced the IC50s of Gemcitabine in PC cells. Furthermore, co-administrating both drugs to Gem-R Mia-PaCa-2 xenograft mice significantly reduced tumor growth rates and volumes. These findings were recapitulated in patient-derived 3D-organoids, where the combined treatment resulted in fewer and smaller organoids vs. each drug individually ($P < 0.05$).

Conclusions: We provide novel evidence that Teriflunomide helps overcome resistance to Gemcitabine by inhibiting the GSK3β/AKT/mTOR pathway, which could improve treatment outcomes in PC.

#7193 ABCB1-mediated chemotherapeutic drug resistance is reversed by a potent p53-MDM2 inhibitor NVP-HDM201.

H. Patel[1], C. Cai[1], Z. Wu[1], Q. Teng[1], H. Li[2], Z.-S. Chen[1];

[1]St. John's University, Jamaica, NY, [2]Shenzhen Hospital of Guangzhou University of Chinese Medicine, Shenzhen, China

The failure of chemotherapy in cancer persists as a result of overexpression of various ATP-binding cassette (ABC) transporters. ABCB1 is one such transporter that actively pumps out chemotherapeutic drugs and it is one of the reasons for multidrug resistance (MDR). In the last few years, activation of p53 has been targeted as a therapeutic strategy in the treatment of cancers. Siremadlin (NVP-HDM201) is a potent and selective inhibitor of p53-MDM2 interaction. The objective of this study was to explore the ability of HDM201 to reverse tumor MDR attributable to overexpression of ABC transporters. According to our findings, HDM201 significantly increased the sensitivity of ABCB1-overexpressing cells to ABCB1 substrates, such as colchicine and doxorubicin. We found that HDM201 reverses ABCB1-mediated MDR by interacting with ABCB1 and blocking its function without affecting the expression and cellular localization of ABCB1. Moreover, HDM201 promoted the accumulation of paclitaxel in cell lines that overexpress ABCB1. At both high and low doses, HDM201 increased the ATPase activity of ABCB1. The computational support for the cross-reactivity of this p53 inhibitor with human ABCB1 comes from docking simulation results that align with the binding conformation of HDM201 within the vast cavity of the transmembrane region of ABCB1. In conclusion, by blocking the transport function of ABCB1, HDM201 can reverse ABCB1-mediated MDR *in vitro*.

#7194 Targeting AXL and MCL-1 to eradicate lazertinib tolerance in EGFR-mutated NSCLC cells.

T. Yamada, Y. Matsui, K. Takayama;
Kyoto Prefectural University of Medicine, Kyoto, Japan

Lazertinib, a novel third-generation EGFR-tyrosine kinase inhibitor, has shown marked efficacy in patients with EGFR-mutant lung cancer. However, after various periods of therapeutic intervention, most patients eventually acquire resistance to lazertinib. A potential therapeutic approach to address this clinical issue is to overcome the initial drug resistance mechanism. To determine the underlying adaptive lazertinib resistance mechanisms, we evaluated signal transduction, cell apoptosis, and drug sensitivity in mutant EGFR-expressing non-small cell lung cancer (NSCLC) cells treated with lazertinib. The siRNA screening assay demonstrated that AXL knockdown significantly inhibited cell viability in the presence of lazertinib, indicating that AXL activation contributes to lazertinib resistance. However, long-term culture with a combination of lazertinib and AXL inhibitors eventually led to the proliferation of residual cells and increased MCL-1 expression, which was mediated by the nuclear translocation of the transcription factor YAP. Cell-based assays showed that triple therapy with an MCL-1 or YAP inhibitor, in combination with EGFR-TKI lazertinib, an AXL inhibitor, significantly reduced cell viability and increased apoptosis. These results demonstrate that AXL and YAP/MCL-1 signals contribute to the adaptive lazertinib resistance in EGFR-mutant NSCLC cells, suggesting that the initial dual inhibition of AXL and YAP/MCL-1 might be highly effective in eliminating lazertinib-resistant cells.

#7195 Repurposing non-oncology drugs with MET inhibitory effect to overcome osimertinib resistance in lung cancer.

K. K. To[1], K. Leung[1], W. C. Cho[2];

[1]Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong, [2]Queen Elizabeth Hospital, Hong Kong, Hong Kong

Background and Aim: Osimertinib is the only 3rd generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor approved for the 1st line therapy of advanced NSCLC patients with EGFR mutations. However, drug resistance is severely limiting its clinical efficacy. Aberrant MET activation is an important mechanism causing osimertinib resistance. There is no effective therapeutic option after osimertinib failure. This study investigated the repurposing of non-oncology MET inhibiting drug to overcome osimertinib resistance.

Method: A few clinically-approved drugs with putative MET inhibitory effects were identified by a computational drug repurposing tool called “DRAR-CPI” via analysis of the chemical-protein interactome of known MET inhibitors (crizotinib, cabozantinib, foretinib, and tivantinib). Fexofenadine (FEX), originally indicated for allergic rhinitis and chronic urticaria, was chosen for detailed investigation in osimertinib-resistant NSCLC cell lines that exhibit aberrant MET activation with/without other EGFR-dependent osimertinib resistance mechanisms. The selectivity of kinase inhibition by FEX was evaluated by a KINOME profiling assay against a panel of human protein kinases. Western blot analysis was conducted to examine the activation status of Met and EGFR downstream signaling. RNA sequencing was performed to identify differentially expressed genes (DEGs) triggered by the most promising repurposed drug, presumably contributing to osimertinib resistance circumvention. Sulforhodamine B assay was used to evaluate cell proliferation. The circumvention of osimertinib resistance by FEX was further verified in a patient-derived tumor xenograft (PDX) from an advanced-stage osimertinib-refractory NSCLC patient.

Result: FEX was found to inhibit recombinant MET kinase in cell-free assays in a dose- and time-dependent manner. It also inhibited MET phosphorylation and other downstream signaling molecules in osimertinib-resistant NSCLC cell lines harboring EGFR T790M+MET amplification or EGFR T790M loss+MET amplification. KINOME profiling revealed a similar kinase inhibition profile between FEX and cabozantinib using Spearman rank order correlation analysis. Among the tested osimertinib-resistant NSCLC cell lines, FEX showed the highest effectiveness in potentiating the anticancer effect of osimertinib in H820 cells (having MET amplification & EGFR T790M mutation). Transcriptome profiling analysis in H820 cells before and after FEX treatment revealed that the majority of DEGs were enriched in EMT-related biological processes and pathways. FEX was further shown to significantly potentiate the antitumor effect of osimertinib in a drug refractory PDX model, without inducing notable weight loss in the animals.

Conclusion: These findings advocate the clinical evaluation of repurposing FEX to overcome osimertinib resistance.

#7196 Evaluation of *nab*-sirolimus in combination with fulvestrant or PI3K pathway inhibitors to overcome resistance in breast cancer cell lines.

K. Myint[1], S. Wallace[1], **S. Hou**[2], M. Zalath[2], B. McMorran[2], A. Kwon[2], I. Vivanco[1];
[1]King's College London, London, United Kingdom, [2]Aadi Bioscience, Inc., Pacific Palisades, CA

Background: Endocrine therapy (ET) is the standard of care for hormone receptor positive (HR+) breast cancer (BC), but ET resistance develops in most patients (pts). One resistance mechanism involves cross talk between the PI3K-AKT-mTOR and estrogen receptor (ER) signaling pathways, resulting in increased ER signaling and tumor proliferation. This is mitigated by mTOR inhibition as demonstrated by improved outcomes with exemestane plus the mTOR inhibitor (mTORi) everolimus in pts with HR+ advanced BC. While PI3K inhibitors (PI3Ki [e.g. alpelisib]) are efficacious in pts with HR+, *PIK3CA*-mutated BC, resistance can occur due to acquired genomic alterations in the PI3K-AKT-mTOR pathway. Combination therapy that targets a critical downstream node, mTOR, could delay or overcome acquired resistance due to activation of upstream components of the PI3K-AKT-mTOR pathway. *nab*-Sirolimus is an intravenously administered, albumin-bound nanoparticle form of the mTORi sirolimus, with significantly greater tumor accumulation, mTOR target suppression, and improved antitumor effects than oral mTORis in nonclinical tumor models. We evaluated the antiproliferative and cytotoxic effects of *nab*-sirolimus in combination with ET or PI3Kis in BC cell lines.
Methods: HR+, *PI3K*-mutated BC cell lines (MCF7 or MDA-MB-361) were incubated for 5 days with increasing concentrations of *nab*-sirolimus and the selective ER degrader fulvestrant. MDA-MB-361 cells or HR-negative (HR−), *PI3K*-mutated BC cells, MDA-MD-453, were incubated for 5 days with increasing concentrations of *nab*-sirolimus and PI3K-AKT-mTOR pathway inhibitors gedatolisib or alpelisib. Antiproliferative/cytotoxic effects of single-agent and combination treatment were assessed via an automated trypan blue exclusion assay.
Results: Addition of 20 or 80 nM *nab*-sirolimus to fulvestrant (12.5-500 nM) markedly decreased cell viability and nearly doubled cell death in MCF7 and MDA-MB-361 cells. Antiproliferative effects of low-dose gedatolisib (2.5-10 nM) were enhanced by 61-71% when *nab*-sirolimus (20 or 80 nM) was added to MDA-MB-453 cells. While low doses (2.5, 5, and 10 nM) of gedatolisib alone led to limited cytotoxicity (4.2-9.6%), up to 48.9% of cell death occurred when 20 or 80 nM *nab*-sirolimus was added. Results were similar with alpelisib (1 uM) plus *nab*-sirolimus (20 or 80 nM). Western blot showed increased p4EBP1 in response to fulvestrant or PI3Ki treatment, which was reversed with the addition of *nab*-sirolimus.
Conclusions: *nab*-Sirolimus enhanced the cytotoxic effects of fulvestrant in HR+ BC cells and of PI3Kis in HR+ and HR− BC cells. Addition of *nab*-sirolimus to ET or other PI3K-AKT-mTOR pathway inhibitors may overcome mechanisms of resistance; further exploration is warranted to elucidate clinical relevance.

#7197 Elacridar sensitizes liver cancer to the PKC-inhibitor ICA-1S.

A. O. Olatunji, M. Marzan, M. Acevedo-Duncan;
University of South Florida, Tampa, FL

Liver cancer is a disease in which cancer cells form in the tissues of the liver. Globally, liver cancer is one of the most frequent fatal malignancies; in the United States, liver cancer is the sixth leading cause of cancer death. Generally, there is a poor prognosis for liver cancer. Chemotherapy and immunotherapy are the best available treatment options. This research aims to provide an alternative treatment option with drugs that specifically attack liver cancer cells. Protein Kinase C (PKCs) are signaling molecules that have been reported to be associated with multiple cellular processes and cancer. PKC activity reportedly is elevated in colorectal cancer cells and metastasizes to the liver. 5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide (ICA-1S) is a PKC-ι specific inhibitor we have previously shown to be effective against some cancer cell lines by decreasing cell growth and inducing apoptosis. In this study, we investigated the effectiveness of ICA-1S against liver cancer cell lines; HEPG2 and PLC5/PRF/5. An equal number of HEPG2 and PLC5/PRF/5 cell lines were seeded into 6 well plates, treated with different concentrations (0.1µM, 0.5µM, 1µM, 5µM, and 10µM) of ICA-1s every 24 hours for three days after which the media was discarded, and cells were counted. The percentage inhibition of ICA-1S on HEPG2 and PLC5/PRF/5 cell lines was calculated. To investigate the resistance inflection, the proliferation assay was also conducted with a combination of an efflux pump inhibitor, Elacridar(10µM), and different concentrations (0.1µM to 10µM) of ICA-1S. The expression of PKC-ι was investigated across all treatments. The dose-response result for treatment with ICA-1S for both HEPG2 and PLC5/PRF/5 cell lines showed a resistance inflection point at 0.5µM and 1µM, where the proliferation rate of the cells declined by 50% and 79% for HEPG2, and 41% and 54% for PLC5/PRF/5 respectively; beyond these points, the cell proliferation rate significantly rises. The results of dose-response for treatment with a combination of ICA-1S and Elacridar showed a continuous decline in cell proliferation rate up to 78% and 84% for HEPG2 and PLC5/PRF/5 respectively as the concentrations of ICA-1S increased from 0.1µM to 10µM. The PKC-ι level was downregulated in the combination treatment. We have shown in this study that liver cancer cells exhibit resistance to PKC inhibitor, ICA-1S, at high concentrations. This resistance inflection may be due to several factors including the activation of drug-efflux proteins. Thus, we proved that the introduction of an efflux pump inhibitor, Elacridar, sensitizes the liver cancer cells to ICA-1S, offsets the resistance of the liver cancer cells to ICA-1S at high concentrations, and enables ICA-1S to be effective in downregulating PKC-ι and decreasing cell growth of liver cancer cells.

#7198 A small molecule Notch1 inhibitor (ASR490) restores chemosensitivity in triple-negative breast cancer.

N. Tyagi[1], B. Chandrasekaran[1], A. Tyagi[1], B. Singh[1], M. Chandran[1], A. Singh[2], A. Sharma[2], C. Damodaran[1];
[1]Texas A&M University, College Station, TX, [2]Penn State Cancer Institute, University Park, PA

Metastatic triple-negative Breast cancer (mTNBC) is an aggressive and often a chemo resistant disease for which no effective druggable target has yet been identified. We and others reported that the aberrant expression of neurogenic locus Notch homolog protein 1 (Notch1) serves as a molecular signature for TNBC. Hence, we postulated that pharmacologically targeting Notch1 in conjunction with a standard chemotherapeutic agent (Doxorubicin: DXR) may completely eradicate TNBC growth and overcome systemic and debilitating toxicity. Hence, this study aims to elucidate the role of our recently discovered notch1 inhibitor ASR490 and its ability to chemosensitize TNBC without significant systemic toxicity.

In our results, pretreatment of $1/_{10}^{th}$ of the *inhibitory concentration of* ASR490 combined with $1/_{10}^{th}$ or $1/_{20th}$ of DXR significantly inhibited the growth of TNBC cells (MDA-MB-231 and BT549). Notably, DXR treatment induced Notch1 activation which led to chemoresistance in TNBC; however, co-treatment with the Notch1 inhibitor ASR490, led to the downregulation of Notch1 activation and eradication of the cell viability and clonogenicity of the TNBC cells. Further, molecular analysis suggested that pretreatment of 1/10th of ASR490 facilitates DXR-mediated sensitivity, by inhibiting the DNA repair pathway and upregulating (cleaved) caspase 3, (cleaved) caspase-9 and poly (ADP-Ribose) polymerase (PARP)-mediated apoptosis. Similarly, the combination effectively blocked the epithelial and mesenchymal transition (EMT) regulators and suppressed metastatic properties of MDA-MB231 and BT-549 cells. Moreover, combining ASR490($1/_{10}$th) and DXR ($1/_{20}$th) significantly eradicated xenotransplanted TNBC tumors compared to ASR490 or DXR alone. In addition to being effective at inhibiting tumor growth, the significantly lower dose requirements of DXR and ASR490 in combination makes it a highly safe therapeutic modality. These findings suggest that aberrant activation of Notch1 is responsible for TNBC chemoresistance and concomitantly inhibiting Notch1 activation is an effective therapeutic strategy to restore chemosensitivity in TNBC.

#7199 The retinoid X receptor (RXR) agonist IRX4204 potentiates the efficacy of trabectedin and pioglitazone in myxoid liposarcoma preclinical models.

M. Meroni[1], I. Craparotta[1], F. Mirimao[1], N. Panini[1], P. Ubezio[1], E. Bello[1], S. Renne[2], M. D'Incalci[3], R. Frapolli[1];
[1]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy, [2]Humanitas Research Hospital, Milan, Italy, [3]Humanitas University, Milan, Italy

Myxoid liposarcoma (MLS) is characterized by a chromosomal translocation that results in the formation of the FUS-DDTI3 fusion protein, which blocks the final step of adipocytic differentiation from adipoblasts to adipocytes. Trabectedin (ET) is a marine drug able to displace FUS-DDTI3 from the promoters of its target genes, restoring adipogenesis and leading to long-lasting clinical responses in MLS patients. However, after prolonged treatments with ET, resistance occurs, and no further therapies are available. Recent studies indicate that the PPARγ agonist pioglitazone (PIO) reactivates adipocytic differentiation in MLS preclinical models resistant to ET, restoring treatment efficacy. While the combination of ET and PIO is being studied clinically, our goal here is to further potentiate the stimulation of adipocytic differentiation to obtain even better tumor growth inhibition. Since the PPARγ and the RXR heterodimerize, and the heterodimer is permissive, we will exploit this property by combining PIO with the RXR agonist IRX4204. The DL221 human MLS cell line was treated with PIO or IRX4204. To assess adipocytic differentiation, cells were stained with LD540 and DAPI for fluorescence microscopy. FABP4 and ADIPOQ expression was measured using RT-PCR. Drug efficacy and tolerability were evaluated in MLS patient-derived xenografts ML017 (sensitive) and ML017/ET (trabectedin-resistant). Mice were randomized to receive PIO (150 mg/kg p.o. qdx28), ET (0.15 mg/kg i.v. q14dx2), IRX4204 (10 mg/kg i.p. qdx28), or their combinations. PIO and IRX4204 induced mature adipocyte-like morphological alterations and lipid droplet accumulation in the DL221 cell cytoplasm, and when PIO and IRX4204 were combined, these effects were more evident. In parallel, the expression of the adipocytic markers FABP4 and ADIPOQ increased. *In vivo*, the addition of IRX4204 to ET and PIO improved the efficacy of treatments in both the ML017 ($p<0.0001$) and the ML017/ET ($p<0.0001$) models, causing faster tumor responses and extending animal survival. Interestingly, even in the absence of ET, the combination of PIO and IRX4204 caused a significant inhibition of tumor growth compared to the single drugs in both the ML017 ($p<0.001$) and the ML017/ET ($p<0.0001$) models. IRX4204 in combination with ET and PIO was able to improve their antitumor activity, enhancing, at least *in vitro*, their differentiating capabilities and inducing faster inhibition of tumor growth. The combination of IRX4204 and PIO, even without ET, could be a clinically effective option, especially for patients not suitable to receive ET or as maintenance therapy. Further studies are ongoing to better define the mechanism of action of these combinations through *in vivo* histological and molecular analysis.

#7200 Non-cytotoxic inhibition of nuclear encoded mitochondrial protein MAGMAS resensitize treatment resistant prostate cancer cells to taxane therapy.

A. Duran[1], K. Whitley[1], K. Santiago[1], A. Mohammed[2], C. Casiano[1], B. Das[2], F. Almaguel[1];
[1]Loma Linda University, Loma Linda, CA, [2]Long Island University, Brookville, NY

Metastatic prostate cancer (PCa) is the leading cause of PCa-associated deaths and one of the leading causes of cancer mortality in men. Novel therapeutics, such as Prostate Specific Membrane Antigen (PSMA) ligand therapy, are emerging as effective treatment strategies for metastatic prostate cancer. However, most men succumb to Metastatic Castration Resistant Prostate Cancer (mCRPC) due to treatment resistance. MAGMAS, a 13.8 kDa mitochondrial protein, imports nuclear-encoded mitochondrial proteins into the mitochondrial matrix. MAGMAS is overexpressed in several aggressive tumors, such as breast cancer, glioblastoma, and prostate cancer. When overexpressed, MAGMAS plays a role as a cytoprotective protein by acting as a reactive oxygen species (ROS) scavenger that maintains sufficient ROS levels to promote cell proliferation but below the threshold levels that could lead to apoptosis. This study was designed to investigate the pro-survival and therapy-resistance functions of MAGMAS in treatment-resistant PCa cells. Predictively, we observed that the docetaxel (DTX)-resistant PC3-DR and DU145-DR PCa cell lines expressed significantly higher levels of MAGMAS compared to their drug-sensitive parental cell lines. We hypothesized that inhibiting Magmas reduces the aggressive properties of highly proliferative DTX-resistant metastatic PCa cell lines and re-sensitizes them to DTX. MAGMAS knockdown in DTX-resistant PC3 and DU145 cells in the presence of increasing DTX treatments enhanced sensitivity to DTX. Consistent with these results, pharmacological inhibition of MAGMAS with the novel BT#9 inhibitor in combination with increasing DTX concentrations also enhanced sensitivity to DTX in these cell lines. Additional studies using cell migration/invasion assays and tumor-sphere formation assays are underway to further establish MAGMAS as a potential therapeutic target to attenuate the aggressive properties of chemo-resistant PCa cells. Lastly, we will investigate the diagnostic potential of MAGMAS as a biomarker for advanced PCa and BT#9 as an imaging/therapeutic-specific agent for treatment-resistant tumors.

#7201 Targeting TAZ-TEAD in minimal residual disease enhances the duration of targeted therapy in melanoma models.

C. A. Ott[1], T. Purwin[1], M. Tiago[1], K. Lou[1], P.-Y. Chen[2], S. Chowdhury[2], G. Mersky[1], N. Hacohen[3], J. Lamar[4], C. Capparelli[1], G. Bollag[2], A. Aplin[1]; [1]Thomas Jefferson University, Philadelphia, PA, [2]Opna Bio, San Francisco, CA, [3]Broad Institute of MIT and Harvard, Cambridge, MA, [4]Albany Medical College, Albany, NY

Targeted therapies in cancer are limited by drug tolerance. In melanoma, tolerance to MAPK pathway inhibitors is associated with loss of SOX10 and enhanced YAP1/TAZ-TEAD activity. We show that loss of SOX10 is sufficient to up-regulate a TEAD transcriptional program with a strong dependence on TAZ. We developed a unique gene signature based on the transcriptomic changes following TAZ or YAP1 depletion. Expression of active TAZ was sufficient to mediate tolerance to BRAF inhibitors and MEK inhibitors. In WM983B cells, depletion of TAZ significantly reduced cell growth, whereas YAP1 knockdown resulted in little to no effect. These studies demonstrate that TAZ-TEAD activity plays an important role in melanoma drug tolerance and the development of acquired resistance.

#7202 Strategy of targeting PKCβI protein to overcoming the acquired gemcitabine resistant pancreatic cancer cells.

E. Bae, Y. Lim, J. Hong, W. Byun, S. Chun, S. Hong, S. Lee;
Seoul National University College of Pharmacy, Seoul, Korea, Republic of

Pancreatic cancer (PC) is one of the most malignant cancers with limitation of treatment options such as resection surgery, radiation therapy and gemcitabine-based chemotherapy. To treating PC patients, gemcitabine-based chemotherapy is common and effective for PC, acquired gemcitabine resistance is one of the major reasons for treatment failure. Therefore, there is a need to suggest effective strategies and novel therapeutic approach for gemcitabine-resistant PC. Protein Kinase C β1 (PKC β1) is known as involved in multiple signal transduction related to oncogenic functions in cancer. We suggested that PKC β as one of the novel biomarker of drug resistance and further investigated the molecular mechanism. Among the natural products as small molecule inhibitor, we found that evodiamine has potent antitumor activity and various biological activities. Based on various biological activities of evodiamine, the scaffold was synthesized and investigated for antiproliferative and antitumor activities against gemcitabine resistant PANC-1 (PANC-GR) cells. Also, target validation experiment was employed to elucidate the molecular mechanism and verifying the target to overcoming gemcitabine resistance. Mechanistically, evodiamine derivatives have shown that inhibition of PKC β1 can modulate the proliferation of PANC-GR cells and exhibited tumor growth inhibitory activity in xenograft mouse model.

Keywords: Pancreatic cancer cell, Gemcitabine resistance, Protein Kinase C β1 (PKC β1), Molecular mechanism

#7203 Anti-HDGF antibody attenuates the rise of resistance to EGFR tyrosine kinase inhibitor in NSCLC patient-derived xenograft tumors.

C. Q. Zhou, **A. Li**, K. Ri, A. Sultan, H. Ren;
University of Maryland School of Dentistry, Baltimore, MD

Mutant epidermal growth factor receptor (EGFR), a major oncogenic driver in non-small cell lung cancer (NSCLC), is found in the tumors of 15% (western countries) to 50% (Asian countries) of patients. EGFR-targeted therapy using tyrosine kinase inhibitors (TKIs) is a standard of care for those patients who developed metastatic or recurrent diseases. However, despite having an 80% initial response rate, most patients had partial tumor regression and their disease would progress when acquired resistance emerges. Thus, developing more effective treatment is an unmet need. The clinical response of these patients can be recapitulated in mouse models of patient-derived xenograft (PDX) tumor bearing sensitizing EGFR mutations. In this study, treating established PDX tumors with osimertinib, a third generation EGFR TKI, induced partial tumor regression (50% to 70% size reduction from baseline) followed by progression with a median progression-free survival (PFS) of 26 to 28 days. Interestingly, co-administering an antibody against hepatoma-derived growth factor (HDGF) with osimertinib resulted in enhanced tumor regression (98% to 100% size reduction from baseline) which translated into significantly extended animal survival with a median PFS of 103 or 135 days. Immunohistochemical and western blot examination of tumors collected at different treatment timepoints indicated that AKT/mTOR and MAPK pathways were reactivated after initial suppression in TKI monotherapy arm despite persistent EGFR inhibition. Since AKT/mTOR and MAPK pathways are key survival and proliferative signaling pathways, their reactivation can promote TKI tolerance of tumor cells and the emergence of TKI resistance. However, blocking HDGF attenuated the reactivation of these pathways which could partially explain the enhanced efficacy of osimertinib plus anti-HDGF antibody combination treatment seen in this study. Our results suggest tumor-derived HDGF could play a crucial role in the rise of acquired resistance to osimertinib. Identifying the exact cells and molecular pathways utilized by HDGF to promote tumor cell tolerance to TKI will help us understand how TKI sensitive tumor cells survive EGFR blockade and emerge as resistant cells.

#7204 Therapeutic potential of targeting autophagy to overcome chemoresistance in glioblastoma.

K. Kiang, G. Leung;
The University of Hong Kong, Hong Kong, Hong Kong

Glioblastoma (GBM) is the most malignant subtype of brain tumor in adults, characterized by relentless recurrence and an overall survival of approximately 18 months. Temozolomide (TMZ) has been the basis for current standard of care and represents the control-arm in GBM trials. Despite the use of TMZ having shown promising results in improving patient survival, drug resistance and tumor relapse is almost inevitable. Current literature has provided strong evidence on autophagy modulation as an adjuvant therapy to cytotoxic treatments. By using in vitro and in vivo GBM models, combination regimen with TMZ and an autophagy activator significantly enhanced the cytotoxic effect in tumors that were resistant to chemotherapy. Combined treatment readily induced a mortal autophagy flux in chemo-resistant GBM cells resulted from its high intrinsic autophagy. Our findings suggest that treatment resistant tumors are more sensitive to autophagy activation when compared to treatment-naive tumors. As they often exhibit higher basal level of autophagy after long-term chemotherapy, a mortal autophagy flux can be readily achieved. In conclusion, combination therapy of a cytotoxic drug with autophagy modulator is emerging as a novel therapeutic strategy in the adjuvant setting for cancer patients.

#7205 PLK1 inhibition overcomes PARP inhibitor resistance in triple-negative breast cancer.

A. K. Siraj, P. Poyil, D. Padmaja, S. K. Parvathareddy, K. Alobaisi, R. Begum, O. Almalik, F. Al-Dayel, K. S. Al-Kuraya;
King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

Patients with aggressive breast cancer (BC) subtypes usually do not have favorable prognosis despite improvements in treatment modalities. These cancers remain a major cause of morbidity and mortality in women globally. This has fostered a major effort to discover actionable molecular targets to treat these patients. Polo-like Kinase (PLK1) is one of these molecular targets that are under comprehensive investigation for the treatment of such tumors. However, its role in the pathogenesis of BC from Middle Eastern ethnicity has not been explored. Therefore, we examined the expression of PLK1 protein in a large cohort of more than 1500 Middle Eastern ethnicity BC by immunohistochemistry. Correlation with clinico-pathological parameters and the prognosis was performed. PLK1 overexpression was observed in 27.4% of all BC and was significantly associated with aggressive clinico-pathological markers. The antitumor effect of PLK1 and PARP inhibitors either alone or in combination was tested in two BRCA mutated, and one BRCA proficient TNBC cell lines. We showed that combined inhibition significantly reduced cell survival and induced apoptosis in TNBC cell lines. Furthermore, our data suggest that PLK1 inhibition overcomes PARP inhibitor resistance in TNBC cell lines. These findings would pave the way to explore the future use of PLK1 inhibitors in the clinical setting of PARPi-resistant patients.

#7206 Inhibition of CAD, an enzyme of de novo pyrimidine synthesis, to overcome EGFR-TKI resistance in NSCLC.

L. Saeednejad Zanjani, L. Zhao, S. Wang, M. Federoff, X. Sun, J. He;
Thomas Jefferson University, Philadelphia, PA

Given the fast-growing cancer cells, there is an increased demand for large amounts of energy and nucleotides for DNA and RNA synthesis. Thus, targeting nucleotide metabolism, specifically de novo nucleotide biosynthesis, is a promising strategy for cancer treatment. Hyperactivation of Carbamoyl-phosphate synthetase, aspartate transcarbamylase (CAD), a key enzyme catalyzing the first three steps of de novo pyrimidine synthesis, is a common event in tumors and has been associated with chemoresistance in tumors. Our analysis, using TCGA data, revealed that increased expression of CAD is associated with poor prognosis in non-small cell lung cancer (NSCLC). Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) have demonstrated significant benefits to patients with NSCLC harboring EGFR-activating mutations; however, acquired resistance limits their long-term efficacy. Therefore, it remains urgent to discover the underlying mechanisms for discovering novel therapeutic strategies for overcoming TKI resistance. Our previous findings demonstrated that blockade of S6K1 overcomes acquired resistance to EGFR-TKIs in NSCLC. It was reported that S6K1 is involved in de novo pyrimidine biosynthesis. In this study, we aimed to investigate whether CAD mediates S6K1-induced EGFR-TKI resistance in NSCLC. Immunohistochemistry analysis on a tissue microarray of lung adenocarcinoma tissues indicated that increased co-expression of p-CAD and S6K1 proteins is associated with clinicopathological parameters and poor survival outcomes. Our in vitro results showed an increased expression level of CAD and p-CAD proteins in TKI-resistant cells compared with parental cells upon TKI treatment. Knockdown of CAD by siRNA led to sensitizing TKI-resistant cells to osimertinib, as indicated by BrdU cell proliferation assay. Inhibition of S6K1 by a siRNA or specific inhibitors PF-470867 and LY2584702 effectively reduced the phosphorylation levels of CAD protein in TKI-resistant cells, suggesting that S6K1 may serve as an upstream regulator of CAD for TKI resistance. The String database predicted a protein-protein interaction between S6K1 and CAD. Indeed, our co-immunoprecipitation (co-IP) results revealed a direct association between S6K1 and CAD proteins. Importantly, TKI treatment enhanced the binding between S6K1 and CAD. Taken together, these findings provide evidence that CAD may mediate S6K1-mediated EGFR-TKI resistance in NSCLC. Our ongoing and future work will assess whether inhibition of CAD sensitizes resistant cells to TKI *in vivo* and elucidate the associated mechanism.

#7207 Targeting hippo signaling pathway to overcome chemoresistance in glioblastoma.

C. Wong, M. Kiang, K. Leung;
The University of Hong Kong, Hong Kong, China

The study aims to investigate whether the Hippo signaling pathway contributes to temozolomide chemoresistance in glioblastoma, and to validate whether the combinational treatment of temozolomide and YAP inhibitor is effective against glioblastoma. Temozolomide-sensitive and temozolomide-resistant U87 and U251 GBM human cell lines were previously established. Temozolomide-resistant cells were maintained in low-dose temozolomide. Here, we investigate whether Hippo signaling contributes to temozolomide chemoresistance. By modulating the Hippo signaling pathway through YAP gene knockdown, the outcome on cell proliferation was studied by cell viability assay (in vitro) and mouse orthotopic xenograft (in vivo). Finally, the therapeutic effect of YAP inhibitor is studied in vitro and in vivo respectively. Our data showed that YAP is overexpressed in temozolomide-resistant glioblastoma cells. Nuclear translocation of YAP (which becomes its active state) is increased in temozolomide-resistant cells. In fact, YAP inhibition show decreased cell viability and higher susceptibility to temozolomide. In addition, mice with tumor injection of the YAP knockdown cells reduced tumor size with temozolomide treatment. Similarly, YAP inhibitor resensitizes temozolomide-resistant cells to temozolomide. Combinational treatment of YAP inhibitor and temozolomide is effective in shrinking tumor size in mouse xenograft models. In conclusion, our data suggest dysregulated Hippo signaling pathway contributes to temozolomide chemoresistance, thus targeting the Hippo signaling pathway resensitizes GBM cells to temozolomide. This research provides pre-clinical evidence on using YAP inhibitor for combinational therapy with temozolomide for the treatment of glioblastoma.

#7208 Targeting histone demethylase KDM6B to overcome cisplatin resistance in testicular germ cell tumors.

R. Singh, D. Shokry, R. I. Boyd, B. C. Rennels, C. Powell, M. Kahn, S. J. Freemantle, M. J. Spinella;
University of Illinois at Urbana-Champaign, Champaign, IL

Testicular germ cell tumors (TGCTs) represent the most common carcinoma of young men and are believed to arise from the transformation of primordial germ cells (PGCs). TGCTs are highly curable with platinum-based chemotherapeutics. However, resistance to cisplatin does occur, leading to therapeutic failure with very limited further therapy options. Previously we demonstrated polycomb and histone H3K27me3 methylation is repressed in cisplatin resistance TGCT cells. In TGCT patients the expression of H3K27 histone methylase EZH2 and H3K27 histone demethylase KDM6B is significantly associated with recurrence free survival. Induction of H3K27 methylation using demethylase inhibitor JSK-J4 or knockdown of KDM6B resulted in restored cisplatin sensitivity in cisplatin resistant TGCT cells. Furthermore, Inhibition of H3K27 demethylase by GSK-J4 or genetic knockdown of KDM6B sensitized TGCTs to cisplatin *in vivo* suggesting potential clinical utility of targeting H3K27me3 in refractory TGCTs. To explore underlying mechanisms H3K27me3 ChIP-seq was performed that demonstrated genome-wide loss of H3K27me3 in cisplatin resistant cells. Integrative analysis of H3K27me3 ChIP-Seq and transcriptomics is ongoing. Together findings suggests that repression of H3K27 methylation may be a viable approach to overcome treatment failure in cisplatin resistant TGCTs.

#7209 Overcoming platinum resistance of high-grade serous ovarian cancer targeting the activated JAK/STAT pathways via extracellular vesicles.

K. Suzuki[1], A. Yokoi[1], K. Yoshida[1], Y. Yamamoto[2], H. Kajiyama[1];

[1]Nagoya Univ. Graduate School of Medicine, Nagoya, Japan, [2]National Cancer Center Research Institute, Tokyo, Japan

High-grade serous ovarian cancer (HGSOC) is the most common subtype of ovarian cancer. While HGSOC usually responds to initial treatment, most cases eventually relapse and develop platinum-resistant ovarian cancer (PROC). The molecular definition of PROC is still unclear, and overcoming PROC has been the biggest challenges. Extracellular vesicles (EVs) have an essential role in cell-to-cell communication within both the primary and distant microenvironments. In this study, we aimed to identify molecular mechanisms of PROC via EVs to suggest novel therapeutic strategies. Platinum responses were categorized by primary treatment-free interval of platinum less than 6 months as PROC, and more than 36 months as platinum good response. Ascites and tumor tissues have been collected prior to initial chemotherapy in patients with HGSOC for analysis according to platinum response. mRNA sequencing in tumor tissues identified significantly upregulated JAK/STAT pathways in PROC. The JAK/STAT family was highly expressed in PROC than the good response group, and also increased than adjusted normal ovaries and fallopian tubes. In addition, PROC cell lines and PROC patient-derived xenograft model tumor tissues showed high JAK expression. Small RNA sequencing for HGSOC tissues and ascites-EVs revealed that miR-135a-5p and miR-221-5p were highly expressed in both PROC tissues and ascites, and the expression of the two miRNAs had a positive correlation between tissues and ascites. Overexpression of the two miRNAs in HGSOC cell lines resulted in higher JAK family expression and resistance to cisplatin. JAK inhibitors (JAKi) had equivalent efficacy for platinum-sensitive/resistant HGSOC cell lines and JAKi highly suppress tumor growth in the PROC mouse model. In addition, suppression of JAK family expression in PROC cell lines significantly increased sensitivity to cisplatin. JAKi also had a synergistic effect with cisplatin for PROC cell lines. IPA analyses in mRNA sequencing in tumor tissues, TGF-β was highly expressed in upstream regulators in PROC, and TGF-β stimulation resulted in the upregulation of the two miRNAs in mesothelial cells, but not in HGSOC cell lines and fibroblasts. In summary, we here demonstrate novel molecular mechanisms of PROC via EVs and provided the rationale for JAK-targeted therapy for PROC. EV-miRNAs can regulate the PROC activated JAK/STAT pathway and can be diagnostic and therapeutic biomarkers for PROC definition or JAKi indications, suggesting that patient stratification in precision medicine for initial treatment of HGSOC.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeted, Combination, and Differentiation Therapies
Poster Session

#7213 Tumor targeted activation of an attenuated exatecan protodrug through Click Chemistry demonstrates efficacy in murine tumor studies.
S. Srinivasan, S. Wagner, G. Coricor, T.-H. Nguyen, J. M. McFarland, J. M. Mejia Oneto;
Shasqi, Inc., San Francisco, CA

Shasqi is advancing the Click Activated Protodrugs Against Cancer (CAPAC®) platform based on click chemistry, a Nobel Prize winning technology. The platform is modular and comprises 1) an activator that target specific antigens, and 2) inert cancer drugs, protodrugs, which are selectively activated at tumors via click chemistry. The CAPAC technology separates the tumor targeting function from the payload and re-unites them at the tumor creating the flexibility to optimize activity while limiting toxicity during preclinical and clinical development. The modularity of the platform enables the rapid development of new therapies as well as unlocking unique treatment benefits such as tunable combinations and payload cycling. We envision that CAPAC will expand the scope of potential targets, widen the therapeutic window, and enhance the safety of locally activated cancer therapeutics. Here, we demonstrate the efficacy and safety of our exatecan protodrug (SQP07) used with intratumorally injected activators.
The activators, tetrazine-modified sodium hyaluronate biopolymer(s), are injected at the tumor site and followed by a systemic dose of SQP07, a trans-cyclooctene (TCO)-modified protodrug of exatecan (Exa). An efficient covalent reaction between tetrazine and TCO moieties releases active Exa at the tumor. In vitro cytotoxicity studies showed that SQP07 activated with tetrazine was effective against mouse and human tumor cell lines (MC38, CT26, EMT6 and NCI-N87); SQP07 without activator had potency attenuated by 60-133 fold.
In vivo tumor distribution and activity of SQP07 with the intratumoral biopolymer activators was evaluated in an NCI-N87 gastric cancer xenograft model. Female C.B-17 SCID mice received a single intravenous dose of vehicle (10% HPCD), Exa (50 mg/kg) or biopolymer (40 or 100 µL intratumorally) followed by SQP07 or SQP07 alone (50 mg/kg Exa mol equivalent). 1 hour after biopolymer + SQP07 treatment, activated Exa was highly concentrated in the tumor and stroma. This led to tumor regression in animals up to 40 days, performing significantly better than the free drug cytotoxic, Exa alone. Similarly, median survival with biopolymer + SQP07 was higher (>81 days) compared to Exa (68.5 days). Toxicity, measured as body weight loss, was comparable (~5%) and transient between Exa and biopolymer + SQP07. SQP07 alone treatment without the biopolymer was not differentiated from the vehicle control.
These data show that the CAPAC platform, which separates the targeting agent from the payload, is an effective way to administer cytotoxic therapies systemically. Additional work with other tumor models, different biopolymers and the SQP07 protodrug is ongoing.

#7214 A click chemistry-based HER2 targeting agent activates a decoupled MMAE payload making it highly differentiated in efficacy and safety than ADCs.

S. Srinivasan, S. Wagner, G. Coricor, J. M. McFarland, T.-H. Nguyen, J. M. Mejia Oneto;
Shasqi, Inc., San Francisco, CA

Shasqi is advancing the Click Activated Protodrugs Against Cancer (CAPAC®) platform based on click chemistry, a Nobel Prize winning technology. The platform is modular and comprises of 1) an activator that targets specific antigens, and 2) inert cancer drugs, protodrugs, which are selectively activated at tumors via click chemistry. The CAPAC technology separates the tumor targeting function from the payload and reunites them at the tumor creating the flexibility to optimize activity while limiting toxicity during preclinical and clinical development. The modularity of the platform enables the rapid development of new therapies as well as unlocking unique treatment benefits such as tunable combinations and payload cycling. We envision that CAPAC will expand the scope of potential targets, widen the activity window of antibody drug conjugates (ADCs). Here we compare a HER2-targeting activator + a monomethyl auristatin E (MMAE) payload with an ADC that binds the same target and carries the same payload, as well as other targeting formats.

The activator SQT01 is composed of a HER2-binding Fab conjugated with tetrazines (Tz). The protodrug SQP22 is formed by coupling trans-cyclooctene (TCO, with a releasable linker) to MMAE, a cytotoxic spindle poison. An efficient covalent reaction between tetrazine and TCO moieties releases active MMAE at the tumor.

Mice bearing human NCI-N87 HER2+ tumor were treated with 1) SQT01, 2) a non-binding isotype Fab-Tz, or 3) saline. After 18 h, all mice received either vehicle (10% HPCD), SQP22 protodrug, a non-releasable MMAE TCO-protodrug analog of SQP22, or a di-peptide-containing TCO-protodrug analog. We also tested CAPAC's approach with SQT06 (a full-length IgG trastuzumab-Tz conjugate) that was followed by an SQP22 dose after 4 days. The dosing of SQP22 with the Fab-Tz and IgG-Tz is timed to allow for systemic clearance of the targeting activator. Fabs have a shorter half-life than IgG, so we dosed SQP22 at 18 h after SQT01 instead of the 4-day timepoint with SQT06. To allow comparisons with ADCs, additional groups received a single dose of commercially available disitamab vedotin (DV) or a HER2-Fab-vedotin.

SQT01+SQP22 induced a strong tumor growth inhibition comparable to SQT06+SQP22, but significantly better than DV, and SQT01+non-releasable protodrug analog. Dosing with SQT01 with a protease cleavable dipeptide-TCO protodrug analog or a molar equivalent dose of HER2-Fab-vedotin were highly toxic and intolerable. Based on preclinical observations, SQT01+SQP22 was safe and tolerated, and there was no observed body weight loss.

These data demonstrate that the CAPAC platform, which separates the targeting agent from the payload, provides a clear benefit in terms of safety and efficacy compared with small or large format proteins with the classic fixed construct of ADCs (e.g. a fixed drug to antibody ratio).

#7215 Nectin-4 targeted therapy with MMAE protodrug results in anti-tumor efficacy mediated by click chemistry.

G. Coricor, J. M. McFarland, S. Srinivasan, S. Wagner, N. Yee, T.-H. Nguyen, J. M. Mejia Oneto;
Shasqi Inc., San Francisco, CA

Shasqi is advancing the Click Activated Protodrugs Against Cancer (CAPAC®) platform based on click chemistry, a Nobel Prize winning technology. The platform is modular and comprises 1) an activator that target specific antigens, and 2) inert cancer drugs, protodrugs, which are selectively activated at tumors via click chemistry. The CAPAC technology separates the tumor targeting function from the payload and reunite them at the tumor creating the flexibility to optimize activity while limiting toxicity during preclinical and clinical development. The modularity of the platform enables the rapid development of new therapies as well as unlocking unique treatment benefits such as tunable combinations and payload cycling. We envision that CAPAC will expand the scope of potential targets, widen the therapeutic index of antibody drug conjugates (ADCs). Here we present a Nectin-4-targeting activator with a monomethyl auristatin E (MMAE) payload.

Nectin-4 is a clinically validated tumor target expressed in a wide range of solid tumors, making Nectin-4 an attractive target for developing new therapeutic approaches for cancer patients. Substantial numbers of Nectin-4 targeting drugs are being developed but exhibit high rates of drug toxicities and highlight the need for alternative approaches that are efficacious and safe. We have developed a Nectin-4 Fab binder conjugated with tetrazine (~2.3 tetrazines per protein), SQT03, and tested it in combination with SQP22, an attenuated protodrug of MMAE conjugated to *trans*-cyclooctene (TCO). The reaction between tetrazine and TCO moieties releases MMAE at the tumor site. We have previously demonstrated that SQP22 is highly attenuated *in vivo* at doses that are > 20x the toxic dose of free MMAE, and in combination with a HER2 targeting activator, led to significant tumor growth inhibition in NCI-N87 gastric cancer xenograft model. The separation of an antigen-targeting activator from the payload by CAPAC technology allowed the rapid development and subsequent testing of SQT03 in combination with SQP22 *in vitro* and *in vivo*. SQT03 displayed <10nM binding affinity to Nectin-4 positive cells by flow cytometry analysis. *In vivo*, dosing of SQT03 occurs 8-24hrs prior to SQP22 to reduce systemic activation and to enable specific release of the active cytotoxic payload at the tumor site. In the T47D breast cancer xenograft model, a single dose of SQP22 at 8-24hrs after SQT03 led to tumor regression without body weight loss, in contrast to the 5% of body weight loss presented by two doses of Enfortumab-vedotin required to lead to similar activity.

The presented data illustrates how the CAPAC platform can be used to test various therapeutic combinations, accelerating development, and reducing the time it takes to bring treatments to the clinic. The results support further development and testing of MMAE protodrug with Nectin-4 targeting agent in clinical settings.

#7216 Improving anti-tumor efficacy by modulating a separate HER2 activator and an MMAE payload and reuniting both through click chemistry.

S. Wagner, M. Aleckovic, G. Coricor, S. Srinivasan, J. McFarland, T.-H. Nguyen, J. M. Mejia Oneto;
Shasqi, San Francisco, CA

Shasqi is advancing the Click Activated Protodrugs Against Cancer (CAPAC®) platform based on click chemistry, a Nobel Prize winning technology. The platform is modular and comprises 1) an activator that target specific antigens, and 2) inert cancer drugs, protodrugs, which are selectively activated at tumors via click chemistry. The CAPAC technology separates the tumor targeting function from the payload and reunites them at the tumor, creating the flexibility to optimize activity while limiting toxicity during preclinical and clinical development. The modularity of the platform enables the rapid development of new therapies as well as unlocking unique treatment benefits such as tunable combinations and payload cycling. We envision that CAPAC will expand the scope of potential targets and widen the therapeutic index of antibody drug conjugates (ADCs). Here we present proof of concept for a HER2-targeting activator with a monomethyl auristatin E (MMAE) payload. The activator SQT01 is composed of a HER2-binding Fab conjugated with tetrazines (Tz), a click chemistry component. The protodrug SQP22 is formed by coupling *trans*-cyclooctene (TCO), another click chemistry component, to MMAE, a cytotoxic spindle poison. SQT01 binding was confirmed via flow cytometry, while SQP22 was evaluated for stability and activation via the reaction of Tz and TCO moieties activating MMAE at the tumor site. *In vivo* activity was evaluated in a HER2+ gastric cancer (NCI-N87) xenograft model. SQP22 was stable in plasma and had minimal *in vivo* anti-tumor activity without the activator. When combined with SQT01 in tumor-bearing mice, SQP22 was rapidly activated and led to active MMAE at the tumor site within 15 minutes. In efficacy studies, this activation resulted in significant tumor growth inhibition compared to an isotype control or disitamab vedotin, an ADC that targets HER2 and carries an MMAE payload. Treatment with SQT01 and 3 daily doses of SQP22 resulted in 4/6 complete responses with no body weight loss. This response can be differentiated from the activity of the isotype control by modulating the dose levels of SQT01 or SQP22 and the time interval between the two. In a dose escalation study, increasing dose level combinations were evaluated. In another efficacy study the optimal timing between the administration of SQT01 and SQP22 was investigated. It was found that anti-tumor efficacy is maintained over a 4 to 24 hours dose gap, but non-specific activity is decreased by dosing SQP22 8 - 24 hours after SQT01, corresponding to increased safety. Additional toxicology studies are ongoing. This data indicates that the CAPAC platform, which separates the targeting agent from the payload, can be optimized for antigen specific efficacy and safety by modulating dose amounts and time intervals between both components.

#7217 Orthogonal targeting of NAD metabolism and ErbB2/ErbB3 signaling in pancreatic adenocarcinoma.

K. Chougoni, N. Kim, M. M. Dcona, D. T. Dcona, G. K. Malhotra, S. R. Grossman;
USC - University of Southern California, Los Angeles, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) is now the third leading cause for cancer related deaths in the US with a five-year survival of ~10% that has improved little over the past 20 years. Thus, there is a critical need to fully understand mechanisms of PDAC tumorigenesis in order to develop novel and effective therapies. Nicotinamide Adenine Dinucleotide (NAD), a critical co-factor and energy source required for cellular processes such as DNA repair and epigenetic regulation is frequently upregulated in PDAC. We recently reported a novel oncogenic axis connecting the NAD-dependent epigenetic regulator and oncogene C-terminal Binding Protein (CtBP) with the EGFR family growth factor receptors ErbB2/ErbB3 (ErbB2/3) in PDAC cells and tumors. Indeed, previous reports have shown ~30% of human PDAC tumors overexpress ErbB3, and our work has shown that PDAC tumor cell growth relies on maintenance of ErbB3 expression. Moreover, we show that the majority of PDAC cells with high levels of ErbB3 expression are uniquely sensitive to the ErbB2-targeted tyrosine kinase inhibitor lapatinib. In addition, we have recently shown that co-targeting NAD and CtBP with small molecule inhibitors is an effective and synergistic therapeutic strategy in PDAC model systems.

Methods and Results: In the current study, we demonstrate NAD-dependent regulation of ErbB2/3 signaling in PDAC cells *in vitro*. Upon depletion of NAD using the NAD salvage pathway inhibitor GMX1778 in human PDAC cells, we observed a striking coordinate decrease in the levels of both ErbB2 and ErbB3. Furthermore, stable knockdown of the limiting enzyme of the complementing Preiss-Handler NAD synthetic pathway, Nicotinamide Adenine Phosphoribosyl Transferase, also resulted in robust downregulation of ErbB2/3 protein levels, suggesting a direct linkage in PDAC cells between the status of NAD metabolism and synthesis and activity of the key growth factor receptors ErbB2/3.

Conclusions: Our findings highlight the novel connection between NAD and ErbB2/3 in PDAC. Furthermore, our data suggests combining chemical or biologic inhibitors of ErbB2/3 with an inhibitor of NAD synthesis may result in highly synergistic cytotoxic effects in PDAC cells and PDAC preclinical models. Such data could support the future development of a human PDAC clinical trial repurposing agents targeting NAD synthesis and ErbB2/3 that are already FDA-approved or currently in clinical testing.

#7218 Venetoclax triggers apoptosis and augments the effectiveness of doxorubicin against acute myeloid leukemia cells.

O. Aloudat[1], O. Al Odat[2], T. Budak-Alpdogan[3], S. Jonnalagadda[2], Y. Chen[4], M. Pandey[1];

[1]Cooper Medical School of Rowan University, Camden, NJ, [2]Rowan University, Glassboro, NJ, [3]Cooper University Hospital, Camden, NJ, [4]College of Science and Mathematics, Rowan University, Glassboro, NJ

Acute myeloid leukemia (AML) is a hematologic malignancy characterized by the clonal proliferation of immature blast cells in the peripheral blood and bone marrow. AML is the second most common type of childhood leukemia, and 50% to 60% of relapses occur within the first year of diagnosis. Chemotherapy side effects and resistance are becoming major clinical issues. Although anthracyclines are one of the most commonly used induction regimens for children with AML in the United States, clinicians avoid them due to adverse effects and clinical resistance issues. To address this clinical issue, we are looking for a novel AML approach to boost the usage of anthracyclines. Since Bcl-2 protein overexpression in AML is related to uncontrolled growth, poor prognosis, and chemoresistance. Multiple clinical trials have suggested combining venetoclax (a selective Bcl-2 inhibitor) with well-established medicines to boost efficacy and overcome resistance. We suggest that inhibiting Bcl-2 is a feasible strategy for increasing the use of anthracycline medicines. We proposed combining doxorubicin and venetoclax as an alternative approach for AML patients. In a panel of three AML cell lines, Kusami-1, U937, and THP-1, our western blot revealed that Kusami-1 had the highest expression of Bcl-2 proteins. Surprisingly, venetoclax causes Kusami-1 cell death and increases the efficacy of doxorubicin in a dose-dependent manner, suggesting that utilizing a lower clinical standard dose may avoid major adverse effects such as cardiotoxicity. Furthermore, the Annexin V Apoptosis Detection Kit indicated that venetoclax coupled with doxorubicin synergistically promoted total apoptosis in Kusami-1 cells. The combination medication shown promising and synergistic in vitro anti-leukemic action against AML cell lines and represents a potentially viable treatment option for AML patients. Future research will use the combination approach in AML cell lines, as well as in patient samples and *in vivo* experiments.

#7219 Preclinical investigations of concomitant tumor treating fields (TTFields) with cisplatin for treatment of cervical cancer.

R. Frechtel-Gerzi[1], D. Gerasimova[1], E. Zeevi[1], R. Monin[1], H. Fishman[1], I. Schlachet-Drukerman[1], H. Mumblat[1], A. Martinez-Conde[1], R. Engelman[1], E. Dor-On[1], **I. Tzchori**[1], A. Haber[1], M. Giladi[1], U. Weinberg[1], Y. Palti[1], G. M. Palmer[2], A. Alvarez Secord[3];

[1]Novocure Ltd, Haifa, Israel, [2]Duke Cancer Institute, Duke University Medical Center, Durham, NC, [3]Duke Cancer Institute, Duke University Medical Center, Haifa, Israel

Introduction: Cervical cancer, although largely preventable, continues to be a significant health concern. Early-stage treatment is commonly surgery; while advanced, recurrent, or metastatic disease often requires systemic therapy. Chemotherapy, mainly cisplatin is the backbone of first-line therapy. TTFields are electric fields that disrupt cellular processes critical for cancer cell viability and tumor progression. In other tumor types, TTFields applied with cisplatin has exhibited benefit. This *in vitro* study assessed the preclinical efficacy of TTFields for cervical cancer and explored efficacy for concurrent use with cisplatin.
Methods: Effects on cell count in cervical cancer cell lines exposed to TTFields (0.5 V/cm for Ca Ski cells, 1 V/cm RMS for HeLa and SiHa cells; 72 h) across a range of frequencies (100-400 kHz) were evaluated. TTFields (200 kHz) were then applied with varying cisplatin doses followed by cell count, colony formation, and apoptosis assays. Overall effect was calculated as the product of percent reductions in cell count and colony formation. TTFields-treated cells were evaluated for formation of the DNA damage marker γH2AX using fluorescent microscopy; and for the expression of Fanconi Anemia (FA)-BRCA pathway proteins through Western blotting.
Results: TTFields treatment reduced cell count in all cervical cancer cell lines tested. Cisplatin exhibited dose-response effects, which were enhanced when TTFields were co-applied. TTFields led to downregulated expression of FA-BRCA pathway proteins, which are involved in repairing cisplatin-induced DNA damage, resulting in increased DNA damage.
Conclusions: These preclinical results suggest that TTFields should be further explored as a potential treatment for cervical cancer. TTFields-induced downregulation of the FA-BRCA pathway possibly explains the enhanced efficacy when TTFields are applied together with cisplatin, providing mechanistic insight.

#7220 Emerging combination strategy: FANCI suppression induces PARP1 redistribution to enhance efficacy of PARP inhibitors in breast cancer.

Y.-z. Huang[1], M.-Y. Sang[1], P.-W. Xi[1], R.-X. Xu[1], M.-Y. Cai[1], Z.-W. Wang[1], J.-Y. Zhao[1], Y.-H. Li[1], J.-F. Wei[2], Q. Ding[1];

[1]Jiangsu Province Hospital (The First Affiliated Hospital With Nanjing Medical University), Nanjing, China, [2]Jiangsu Cancer Hospital, Nanjing, China

While polyADP-ribose polymerase (PARP) inhibitors have made advancements in the treatment of breast cancer, challenges such as chemotherapy resistance and limited application persist. Fanconi AnemiaComplementation Group I (FANCI), a DNA repair protein associated with breast cancer development, represents a potential target for novel combination therapeutic strategies. However, the role of FANCI in breast cancer and its impact on the efficacy of PARP inhibitors require further investigation.

In our study, we analyzed FANCI expression in breast cancer tissues and cell lines, and its correlation with clinical parameters and patient prognosis. Lentiviral vectors were utilized and functional assays were performed to evaluate the effects of FANCI modulation on breast cancer cell growth and migration. Co-immunoprecipitation assays and protein interaction analysis were conducted to identify the interaction between FANCI and PARP1 and determine the specific binding region. The functionality and nuclear distribution of PARP1 were assessed upon FANCI modulation. Finally, the sensitivity of breast cancer cells to the PARP inhibitor talazoparib upon FANCI knockdown was evaluated *in vitro* and *in vivo*.

Our findings demonstrated that FANCI was overexpressed in breast cancer and associated with poor prognosis. FANCI significantly promoted breast cancer cell proliferation both *in vitro* and *in vivo*. We identified the interaction between FANCI and PARP1, specifically at the FANCI helical domain 2 binding site. FANCI knockdown led to reduced nuclear localization of PARP1 and decreased PARP1 activity. Importantly, combination treatment with FANCI knockdown and talazoparib significantly inhibited cancer growth *in vitro* and *in vivo*. Additionally, we found that the cyclin-dependent kinase (CDK) 4/6 inhibitor palbociclib, which effectively suppresses FANCI protein expression, exhibited a robust synergistic effect with talazoparib both *in vitro* and *in vivo*.

In conclusion, FANCI is a novel therapeutic target for breast cancer. Suppression of FANCI regulates PARP1 redistribution and activity, making breast cancer cells more responsive to PARP inhibitors. This combination therapeutic strategy shows potential in enhancing the effectiveness of PARP inhibitors for breast cancer treatment, regardless of BRCA mutations.

#7221 A compound targeting the circadian clock protein CRY2 enhances therapeutic efficacy of bevacizumab in a colorectal cancer (CRC) xenograft model.

J. Lo[1], S. Soni[1], G. Smbatyan[1], L. Torres-Gonzalez[1], P. Mittal[1], Y. Yang[2], F. Battaglin[1], P. Chan[2], Y. Pan[2], S. Algaze[1], P. Jayachandran[1], K. Ashouri[1], A. Wong[1], W. Zhang[1], J. Millstein[2], I. K. Singh[3], E. T. Roussos Torres[1], S. M. Mumenthaler[2], S. A. Kay[2], H.-J. Lenz[1];
[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, [3]University of Delhi, Delhi, India

Anti VEGF A antibody Bevacizumab combined with standard chemotherapy has improved outcomes for CRC patients. However, a subset of CRC patients acquires resistance to anti-VEGF treatment and underlying mechanism is poorly understood. Our recent study reported that circadian clock transcription factor BMAL1 drives transcription of VEGFA conferring resistance to bevacizumab treatment. Our rational is to stabilize negative regulator of circadian clock CRY protein to inhibit BMAL1 activity in a negative feedback loop. In this study, we evaluated whether CRY stabilizers SHP656 and SHP1705 in combination with bevacizumab can synergistically enhance anti-tumor effect in CRC mouse models.

Methods: *In vitro* tube formation assay was performed with HUVECs cells to investigate the effect of CRY stabilizer on tube formation. For *in vivo* experiments, 10^6 HCT116 human CRC cells were injected subcutaneously into the right flank of 8-week-old nude mice. Mice (5mice/group) were randomized into: A. vehicle (2% carboxymethylcellulose PO 5 days/week; control IgG IP, 2 days/week); B. bevacizumab (5mg/kg IP, twice/week); C. 10mg/kg SHP656; D. 30mg/kg SHP656; E. 30mg/kg SHP1705; F. 10mg/kg SHP656 + bevacizumab; G. 30mg/kg SHP656 + bevacizumab; G. 30mg/kg SHP1705 + bevacizumab. SHP 656 & 1705 was given PO; 5days/week. Tumor volume was measured three times a week. The survival curve was plotted using Kaplan and Meier method and assessed for statistical significance with log-rank test.

Results: The *in vitro* tube formation assay showed significant inhibition of tube formation in HUVEC cells treated with SHP1705 plus bevacizumab compared to treated with bevacizumab alone. In *in vivo* study, the tumors treated with 30mg/kg SHP1705 + bevacizumab significantly suppressed tumor growth compared to bevacizumab monotherapy (one way-ANOVA, $P < 0.05$). 30mg/kg SHP1705 + bevacizumab significantly improved survival of the mice (Log-rank test, $P < 0.05$). No significant survival benefit was observed with bevacizumab alone. 3/5 mice treated with SHP1705 + bevacizumab showed decreased tumor volume and achieved complete regression for more than 4 months without additional treatment. In combination with bevacizumab, higher dose of SHP656 (30mg/kg) delayed tumor growth and extended survival compared with bevacizumab monotherapy (though did not reach statistical significance) whereas the lower dose of 10mg/kg did not show anti-tumor effect, demonstrating a dose dependent response.

Conclusion: Our study shows that CRY stabilizers in combination with bevacizumab significantly enhances anti-tumor efficacy in CRC mouse models. Although mechanism of action of SHP compounds on angiogenesis pathway still needs further investigation, these findings may support development of novel treatment strategies modulating circadian clock to overcome bevacizumab resistance in CRC patients.

#7222 Antiandrogen equipped with HDAC inhibitors activates autophagy-mediated growth inhibition in castrate-resistant prostate cancer.

B. Chandrasekaran[1], K. Yalla[2], A. Tyagi[1], V. Shukla[1], N. Tyagi[1], B. Tyagi[1], M. Vashishta[1], A. Oyelere[2], C. Damodaran[1];
[1]Texas A&M University, College Station, TX, [2]Georgia Institute of Technology, Atlanta, GA

Targeting androgen receptor (AR) by pharmacologic intervention is one of the practical approaches for the treatment of castration-resistant prostate cancer (CRPC). Hence, this study aimed to develop novel molecules that employ multiple mechanisms to inhibit AR expression and curtail the growth of CRPC. The target antiandrogen-equipped histone deacetylase inhibitors were synthesized, adapting the convergent chemistry we used to synthesize the first-generation compounds. The final compounds were characterized using 1H-NMR, 13C-NMR, and high-resolution mass spectrometry. We synthesized and analyzed several compounds, in which KK62 emerged as the lead compound. KK62 significantly inhibits a panel of CRPC cell lines in nanomolar concentrations without causing toxicity to healthy prostate epithelial cells. The molecular analysis suggested that inhibition of AR and AR-splice variants was evident, followed by downregulation of PSA expression in AR-positive CRPC cell lines. Further analysis confirmed that KK62 overcomes dihydrotestosterone (DHT) induced AR signaling and enzalutamide-resistant CRPC cells by downregulating AR and AR-splice variants in CRPC cells. Subsequent analysis confirmed that KK62 induces autophagy signaling by upregulating autophagosome (LC3B) and lysosome (LAMP1) markers expression and facilitating the autophagosome and lysosome fusion, which resulted in the induction of apoptosis in all AR-positive CRPC cell lines. The pro-apoptotic markers, such as BAX and cleaved caspase, were upregulated, whereas the downregulation of pro-survival markers was evident in KK62-treated CRPC cells. Our ongoing castrated and non-castrated xenotransplanted CRPC tumors and Patient-derived xenograft in vivo studies would validate our in vitro findings and confirm that KK62 is a potent compound that may improve therapeutic advances in treating CRPC.

#7223 A triplet therapeutic strategy targeting MEK, BCL-XL, and EGFR, for KRAS-mutant pancreatic ductal adenocarcinoma.

G. W. Tushoski-Aleman, A. J. Crespin, C. J. Oguejiofor, J. A. McKean, K. M. Herremans, T. J. George, C. J. Allegra, S. J. Hughes, S. Han; University of Florida, Gainesville, FL

KRAS mutations drive over 90% of pancreatic cancers, but KRAS has been proven difficult to target. Downstream of KRAS, MEK inhibition in combination with BCL-XL inhibition is synthetically lethal and an effective treatment for gynecologic, but not colorectal malignancies. Like colorectal cancer, pancreatic cancer often exhibits aberrant HER/EGFR activity. We hypothesized that a triplicate regimen targeting MEK, BCL-XL, and EGFR/HER would be effective for pancreatic cancer. Trametinib (MEK inhibitor), Afatinib (pan-EGFR/HER inhibitor), and Navitoclax (BCL-XL inhibitor); or DT2216 (a BCL-XL/BCL-1 proteolysis targeting chimera, PROTAC) were explored using various combinatorial strategies. These drug combinations were tested using four primary human pancreatic cancer cell lines using live cell imaging (Incucyte) and an in vivo murine model. Group comparisons were analyzed using one-way ANOVAs, and adjusted p-values <0.05 were considered significant. We observed that no single-agent treatments were effective. MEK inhibition plus anti-BCL-XL (Trametinib + Navitoclax or Trametinib + DT2216) demonstrated efficacy in one of the four cell lines. We noted synergistic effects on reduced cell growth and increased cell death when EGFR/HER inhibition was included by the administration of Afatinib. The triplet combination resulted in synergistic effects in three of four cell lines with Navitoclax and four of four cell lines with DT2216 ($q<0.05$). This effect was confirmed with DT2216 inhibition of BCL-XL in an in-vivo murine model. In conclusion, our study shows that a combinatory strategy targeting MEK, BCL-XL, and pan-EGFR/HER receptor kinase shows significant synergistic effects in pancreatic cancer. Clinical trials that assess the efficacy and safety of this strategy for patients with KRAS-mutant pancreatic cancer are warranted. Our data also suggests that novel KRAS inhibitors as monotherapy are likely to fail.

#7224 Investigation of the efficacy of duocarmycin SA in combination with FDA approved drugs in acute myeloid leukemia cells *in vitro*.

W. A. Chen[1], D. Aguilar[1], L. So[1], Y. Jawhar[1], N. Nguyen[1], N. Drew[1], T. G. Williams[1], C. A. Casiano[1], S. Dovat[2], K. Boyle[1], O. L. Francis-Boyle[1];
[1]Loma Linda University, Loma Linda, CA, [2]Pennsylvania State University, State College, PA

Acute myeloid leukemia (AML) is a hematological malignancy that is characterized by the arrest of hematopoietic stem cell differentiation, clonal expansion of myeloid hematopoietic precursors and poor patient survival outcomes. Despite therapeutic advancements, the prognosis of AML patients remains poor and improving patient survival outcomes continues to be a challenge. Therefore, the objective of this study was to investigate the efficacy of Duocarmycin SA (DSA- an antitumor antibiotic that induces DNA alkylation) in combination with FDA approved drugs currently used in the treatment of AML. In this study, DSA was evaluated in combination with doxorubicin (an anthracycline that disrupts topoisomerase II mediated DNA repair) or etoposide (a topoisomerase II inhibitor used to treat relapsed/refractory AML) in human AML cells *in vitro*. We hypothesized that DSA in combination with doxorubicin or etoposide would exhibit synergistic effects by improving the efficacy of both doxorubicin and etoposide in AML cells. The human AML cell lines (Molm-14 and HL60) were used for all studies. The phenotype of the cells was confirmed by flow cytometry and the IC_{50} of the drugs were determined using the MTT assay. Our results showed that the AML cells were $CD45^{\pm}$, $CD33^{\pm}$, $CD13^{\pm}$ and $CD4^{\pm}$. The IC_{50} of DSA alone for Molm-14 cells and HL60 cells were 11.12 pM and 114.8 pM, respectively. DSA alone induced DNA double-stranded breaks, significantly decreased the production of colonies and significantly increased apoptosis in AML cells in a dose-dependent manner. The IC_{50} of doxorubicin alone and etoposide alone was 68.6 nM and 129.7 nM, respectively. DSA in combination with the FDA approved AML drugs showed increased cytotoxic efficacy by observable decreases in AML cell viability. In summary, 1) picomolar concentrations of DSA alone was sufficient to significantly reduce AML cell viability; 2) DSA in combination with doxorubicin or etoposide significantly reduced AML cell viability and reduced the IC_{50} concentration of doxorubicin and etoposide. Thus, highlighting the therapeutic potential of using DSA in combination with doxorubicin or etoposide as a drug combination strategy to improve AML patient survival outcomes by decreasing the concentration of drugs necessary to treat patients and reducing off-target toxicity.

#7225 Combination JAK1/2 and CDK8/19 inhibition demonstrates enhanced efficacy in myeloproliferative neoplasms.

Z. Zaroogian[1], E. Adamczyk[2], A. Moszyńska[2], M. Obacz[2], U. Pakulska[2], B. Durham[1], M. Mazan[2], S. Mowla[1], K. Wnęk[2], A. Hanasoge Somasundara[1], B. Barczuk[2], A. Gołas[2], R. Levine[1], T. Rzymski[2], R. Rampal[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Ryvu Therapeutics, Krakow, Poland

Myeloproliferative neoplasms (MPNs) are characterized by aberrant activation of the JAK-STAT pathway. Ruxolitinib (RUX) is a JAK1/2 inhibitor used to treat myelofibrosis (MF) and hydroxyurea-resistant/intolerant polycythemia vera. While RUX has demonstrated important clinical benefits, a large proportion of patients have persistent disease manifestations despite therapy. CDK8 regulates phosphorylation of STAT proteins in a RUX-independent manner; thus, CDK8 inhibition may alter downstream STAT target gene expression. RVU120 is a highly selective and potent CDK8/19 inhibitor that inhibits STAT1/5 phosphorylation. We hypothesized that the combination of RUX and RVU120 would act in a cooperative manner to attenuate JAK-STAT signaling and reduce MPN phenotypes *in vivo*.

Using *JAK2*^{V617F} mutant leukemic cell lines, we identified dose-responsive changes in viability with RUX and RVU120 in all cell lines. Pharmacodynamic analysis validated that STAT5 protein phosphorylation was decreased by RUX/RVU120, although at different phosphorylation sites by RUX (pTYR694) and RVU120 (pSER726/731); exposure to RUX+RVU120 inhibited phosphorylation at both sites. Notably, analysis of combinatorial effects of RUX+RVU120 on viability demonstrated drug synergies (combinatorial index <1) in RUX-naïve and resistant SET-2 cells. Nascent RNA expression data exploring JAK-STAT and mediator-related pathways of pathogenesis will be presented at the meeting.

For *in vivo* studies, we used two previously-described murine models of MF and PV. Briefly, retrovirally-transfected (*MSCV-MPL*^{W515L}*-IRES-GFP*) or *Jak2*^{V617F}-conditional knock-in bone marrow (BM) was intravenously injected into lethally-irradiated congenic recipients. Mice were randomized and treated for several weeks with vehicle (VEH), single-agent RUX/RVU120, or RUX+RVU120 arms. Spleen weights between VEH and RUX/RVU120 treated mice at time of terminal sacrifice were significantly reduced across both models ($p<=0.009$). In *MPL*^{W515L} mice, WBCs and PB GFP% were significantly reduced ($p<0.002$) and histopathology demonstrated near-elimination of BM reticulin fibrosis and improved trilineage hematopoiesis between RUX+RVU120 and RUX arms. Data on overall survival, cytokine profiles, and the impact of RVU120 on dynamic gene expression will be presented at the meeting.

The combination of RVU120 and RUX demonstrated biochemical synergy and differential inhibition of STAT5 phosphorylation *in vitro*. Further, *in vivo* treatment with RVU120/RUX+RVU120 resulted in significant reductions of disease manifestation (splenomegaly, WBC, fibrosis scoring, hematopoiesis) when compared to VEH/RUX. These data nominate JAK1/2 and CDK8/19 inhibition as a potential novel therapeutic strategy in MPNs; further work on nascent RNA expression and cytokine profiles will potentially elucidate additional mechanisms of action.

#7226 Synergy between ONC201 and temozolomide on ATF4 integrated stress response in glioblastoma.

J. Chen[1], T. J. Roady[2], L. Zhou[2], W. S. El-Deiry[2];

[1]Brown University, Providence, RI, [2]Legorreta Cancer Center at Brown University, Providence, RI

Glioblastoma multiforme (GBM) is the most common primary brain tumor in adults, with a median survival of 15 months. The standard of care involves surgical resection followed by chemoradiotherapy. Even with the full course of treatment, GBM is uncurable, and patients eventually relapse. Although temozolomide (TMZ) is the first-choice chemotherapeutic for GBM, tumor drug resistance limits the effects of the treatment. There is a growing need for new therapies with enhanced efficacy on GBM tumors. Dordaviprone (ONC201) is a TNF-related apoptosis inducing ligand (TRAIL)-inducing compound that is increasingly being studied for GBM treatment. This imipridone small molecule induces apoptosis by activating the integrated stress response, which involves transcription factors ATF4 and CHOP. Subsequently, these transcription factors upregulate proapoptotic protein TRAIL and its receptor, Death Receptor 5 (DR5).

This study aims to investigate the combinatory effects of chemotherapeutics TMZ and ONC201 on GBM. Preliminary studies examined the cell viability of GBM cell line U251MG after dual treatment of 0 to 10uM of ONC201 and 0 to 200uM of TMZ using the CellTiter-Glo assay. Synergy was observed between the two drugs at higher concentrations of TMZ. This synergistic interaction was further characterized using western blots. When 0, 2, and 4uM of ONC201 were administered alone or in combination with 0, 60, and 120uM of TMZ, greater ATF4 expression was observed with the dual treatments than with the monotherapies. Subsequent western blots were conducted using three GBM cell lines (U251MG, T98G, and SNB19-GFP) at three time points (8, 24, and 48 hours). All cell lines were treated with 0 and 5uM of ONC201 alone or in combination with 0 and 200uM of TMZ. For all three cell lines, ATF4 expression increased in the combined presence of TMZ and ONC201. However, the effects of TMZ on ONC201-induced ATF4 expression were most pronounced in U251MG and least conclusive in T98G. Additionally, the time points in which this increase in ATF4 expression occurred varied among cell lines. CHOP expression was also probed and was seen to increase with the combination treatment in U251MG. These observations suggest a potential synergistic relationship between chemotherapeutics ONC201 and TMZ in the ATF4 integrated stress response pathway in GBM. By exploring the effects of this dual treatment on upstream and downstream factors in the pathway, we can identify, characterize, and potentially target the root cause of this synergy.

#7227 Isatin analogs potentiate the cytotoxicity of venetoclax in acute myeloid leukemia cells.

U. Golla[1], S. Patel[1], J. Hengst[1], C. Annageldiyev[2], J. Schramm[2], S. Amin[1], D. Desai[1], D. Claxton[2], S. Dovat[2], A. Sharma[1];
[1]Penn State College of Medicine, Hershey, PA, [2]Milton S. Hershey Medical Center, Hershey, PA

Acute Myeloid Leukemia (AML) is a rare but common hematological malignancy in children and adults. AML is a highly heterogeneous disease caused by the acquisition of several mutations affecting multiple cellular processes, thus requiring concomitant targeting of key survival nodes to treat effectively. As current first-line therapies for AML suffer with poor outcomes, drug resistance, and high relapse rates, there is an immediate need for new combinatorial therapies that are both safe and effective. Venetoclax (VEN), a selective inhibitor of antiapoptotic protein B-cell lymphoma-2 (BCL2), has been FDA-approved for treating adult AML and displayed potential in pediatric leukemia treatment. However, the activation of an antiapoptotic BCL2 family member, Myeloid Cell Leukemia 1 (MCL1), is often a primary mechanism of resistance to VEN therapy. Our group has developed Isatin analogs (ISA) that exhibited diverse biological activities, including anti-cancer activities alone or in combination with standard agents. ISA demonstrated anti-leukemic activity by targeting leukemic stem cells (LSCs) with high aldehyde dehydrogenase (ALDH) activity. In this study, we demonstrate ISA induces apoptosis by downregulating antiapoptotic MCL1 levels in pediatric and adult AML cell lines. Based on the inhibitory effects of Isatin analogs on key signaling pathways (PI3K/AKT, STAT3) and MCL1, we combined ISA with a BCL2 inhibitor, VEN, for effective AML treatment. The combination of ISA with VEN exhibited synergetic cytotoxicity in naïve (MOLM-13, MV4-11) and VEN-resistant (HL-60, OCI-AML3, U937, and KG-1) human AML cell lines by bliss analysis. ISA also showed significant synergetic cytotoxicity in combination with ABT-737, a BH3 mimetic inhibitor of Bcl-xL, Bcl-2, and Bcl-w. Combinatorial treatment of AML cell lines with sub-lethal doses of ISA and VEN showed a significant increase in cellular apoptosis as indicated by the levels of annexin V measured by flow cytometry. Immunoblotting analysis after co-treatment with ISA and VEN showed downregulation of MCL1 levels along with alteration of other key apoptosis regulators in both VEN-sensitive (MV4-11) and inherently VEN-resistant (U937) AML cell lines. Current and future studies will primarily focus on further exploiting the molecular mechanism of action for the combinatorial approach. Furthermore, our aim will be to demonstrate activity in primary patient cells along with preclinical efficacy in AML animal models. To summarize, in vitro findings showed synergetic cooperation between ISA and VEN in combination for effective induction of apoptosis and anti-leukemic activity in AML cells that are sensitive and resistant to VEN.

#7228 In-vitro efficacy of Dordaviprone/GSK126 combination therapy on castration resistant and neuroendocrine prostate cancer.

Connor Purcell, Praveen Srinivasan, Maximilian Pinho-Schwermann, William MacDonald, Elizabeth C. Ding, Vida Tajiknia, Wafik El-Deiry

Legorreta Cancer Center at Brown University, Providence, RI

Neuroendocrine prostate cancer (NEPC) is an aggressive histologic subtype associated with poor prognosis that commonly arises in later stages as a mechanism of treatment resistance. Activation of oncogenic drivers, in combination with epigenetic changes (such as EZH2 overexpression and DNA methylation) further promotes tumor proliferation and expression of downstream neuroendocrine lineage pathways (in part controlled by transcription factors, including SOX2, ASCL1, and BRN2). Importantly, EZH2 inhibitors (EZH2i) can restore AR expression in CRPC (Ku et al., 2017). Imipridones, including Dordaviprone (ONC201), show promise in treating neuroendocrine tumors by interacting with DRD2 and CLpP (Anderson et al., 2022). These results warrant investigation into the potential for synergism in imipridone/EZH2i combination therapies.

In the PCa cell lines LNCap, PC3, 22Rv1, and DU145 the combination of ONC201 and EZH2i GSK126 was assessed. Cell viability data after treatment with ONC201 and GSK126 reveals several dose ranges with potential synergistic activity after 72h. Preliminary western blots after 72 hours of GSK126 treatment indicate modulation of proteins relevant to the mechanism of action of imipridones, specifically DR5 and CLpP, in LNCap, PC3, and 22Rv1. Notably, the decrease in DR5 expression warrants investigation into the effects of EZH2i on TRAIL sensitivity and whether imipridones may rescue DR5 expression to maintain TRAIL sensitivity.

Subsequent experiments will investigate dosing and time point-based effects on viability and protein expression, in addition to assessing the synergy of other imipridones and EZH2i's. Further, while the cell lines PC3, 22Rv1, and DU145 are castration-resistant, the neuroendocrine prostate cell line NCI-H660 will be used as a positive control as it expresses higher neuroendocrine features, including DRD2. Additionally, the modulation in DR5 expression warrants inquiry into the effects of combination therapy on tumor-immune cell interactions. Further, we will manipulate the expression of neuroendocrine transcription factors to assess changes in therapy sensitivity.

#7229 In situ trans-differentiation therapy effectively terminates the growth and recurrence of glioblastoma.

H. Zhao[1], Z. Li[1], X. Zhang[2], C. Zhao[3], Z. Zhu[1], **Y. Liu**[1];

[1]Neuregen Therapeutics, Shanghai, China, [2]State Key Laboratory of Cognitive Neuroscience & Learning and McGovern Institute for Brain Research, Beijing Normal University, Beijing, China, [3]Shool of Biomedical Engineering and informatics, University of Posts and Telecommunications, Chongqing, China

Background: Glioblastoma (GBM) is the most common and malignant brain tumor in adults, and remains almost invariably lethal due to its aggressive and invasive nature. The standard first-line treatment for GBM is surgical resection, postoperative radiotherapy and chemotherapy with temozolomide (TMZ), but it exhibits short-term effects due to a high recurrence rate of GBM is its (up to almost one hundred percent). This long-existing clinical challenge has demanded development of novel and effective therapeutic strategies. *In situ* cell trans-differentiation therapy which direct reprograms tumor cells into terminally differentiated benign cells represents a novel therapeutic strategy for tumors. We further explored the application of in situ trans-differentiation therapy for glioblastoma.

Results: In the present study, we have conducted a large-scale screen for transcription factors which can reprogram glioblastoma cells into terminally differentiated postmitotic cells. Over-expression of a combo of selected trans-differentiation factors that possess the highest trans-differentiation rate effectively reprogramed human glioma cells into neuronal-like cells with characteristic neuronal morphology and expression of neuronal genes in culture, as a result substantially reducing glioblastoma cell proliferation and tumor development after orthotopic transplantation. With replicable recombinant oncolytic virus vectors, product candidate can specifically replicate in glioma cells, therefore transcription factors can be specifically delivered to all tumor cells rather than normal cells. In either cell line-derived or patient-derived tumor tissue xenograft models, intra-tumoral injection product candidate inhibited glioblastoma cells growth at an exceptionally high efficiency. Remarkably product candidate combination with TMZ resulted in a complete regression of tumor and no recurrence was observed in animal model cases.

Conclusion: In summary, our findings have established a novel therapeutic approach for treating glioblastoma by terminating sustained proliferation of glioma cells via transcription factors-induced *in situ* cell trans-differentiation and supported further clinic investigations in patients.

#7230 A novel platform for identifying therapeutic index in pancreatic cancer.

V. Pantazopoulou, D. Engle;
Salk Institute for Biological Studies, La Jolla, CA

Pancreatic ductal adenocarcinoma (PDA) remains highly aggressive with a mere 12% 5-year survival rate, which underscores the urgent need for improved therapeutic approaches. The current standard of care primarily includes surgery and chemotherapy. However, existing therapies often result in severe side effects and offer limited success. The limitations are not only due to the development of treatment resistance but also due to the killing of normal cells, and as such a low therapeutic index. Targeted therapies aimed at the primary drivers of PDA, such as the $KRAS^{G12D}$ mutation or the activated ErbB pathway, have shown promise in providing novel treatment options. We have previously demonstrated that combining targeted therapies, specifically $KRAS^{G12D}$ and EGFR inhibitors, results in reduced tumor growth in both human and murine PDA organoid models *in vitro*. However, less is known about how these targeted therapies affect normal cells. Here, we are using co-cultures of normal pancreas and PDA organoids to create a platform that allows us to identify combinations of targeted therapies that can achieve a higher therapeutic index. Our goal is to identify treatment combinations that allow for the use of lower individual drug dose, while exhibiting enhanced anti-tumor efficacy and minimizing toxicities to normal organoids. This approach holds significant promise for improving patient outcomes and addressing the challenges associated with current PDA treatments.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Vector Systems, Oncolytic Virotherapy, and Gene Therapy
Poster Session

#7234 The second-generation high-fidelity base editor AccuBaseTM (ceBE) can proficiently modify multiple genes within a human primary T cell while minimizing Off-target effects.

H. Ying[1], G. Li[1], L. Wang[1], C. Lu[1], Q. Lai[1], C. Yao[1], F. Lv[1], S. Zhu[2], T. Xu[1];
[1]Base Therapeutics (Shanghai) Co., Ltd., Shanghai, China, [2]Shanghai University of Traditional Chinese Medicine, Shanghai, China

Off target mutations, chromosomal rearrangements and Indels are the biggest limitation to the use of gene editing tools today. Base editing system provides an efficient method to modify the genome without double strand breaks (DSB). The biggest problem for base editing is the sgRNA-independent off-target. We utilize synthetic biology strategies to create a novel base editor AccuBase™ (ceBE) that has the highest editing efficiency in the industry, with zero off target events. This was achieved by strategically inserting deaminases into Cas9 at specific, tolerance-verified sites, a process guided by an extensive transposon-based genetic screening, protein engineering, and direct evolution approach. AccuBase™ protein forms a complex with the sgRNA, but it has not yet engaged with the target DNA and is not in contact with any non-targeting dsDNA. This mechanism avoids guide RNA independent indiscriminate off-target mutations that was a common problem of the first generation base editing tool. Upon guided by sgRNA, the AccuBase™ protein associates with the target double-stranded DNA, triggering structural alterations within the AccuBase™ protein. This results in the outward exposure of the deaminase domain, facilitating the editing of the target base. AccuBase™ (ceBE) substantially reduces off-target effects while maintaining on-target editing when compared to BE4max. This improvement has been confirmed in multiple human cell lines, mouse cell lines, human primary T and NK cells, human embryonic stem cells, and in animal embryos. In this study, we apply AccuBase™ to achieve multiplex gene modifications in primary human T cells, demonstrating its capacity for highly efficient multiplex gene disruption without inducing off-target effects. Importantly, the multiplex base-edited T cells exhibit enhanced *ex-vivo* cell expansion and do not exhibit the double-strand break-induced translocations observed in T cells edited with Cas9 nuclease.

#7235 Exosome-mediated delivery of siRNA against NRF2 for treatment of lung cancer.

R. Kandimalla[1], M. Wallen[2], J. Jeyabalan[2], D. N. Moholkar[3], W. Spencer[2], R. C. Gupta[4], F. Aqil[1];

[1]Brown Cancer Center, University of Louisville, Louisville, KY, [2]3P Biotechnologies, Louisville, KY, [3]University of Louisville, Louisville, KY, [4]Brown Cancer Center, University of Louisville and 3P Biotechnologies, Louisville, KY

Nuclear factor erythroid 2-related factor 2 (NRF2) activation is the third most common genetic event in lung adenocarcinomas (25%), primarily induced by loss of function mutations in its master regulator, KEAP1. NRF2 is a key modulator of tumor growth and metabolic reprogramming, resulting in resistance to traditional chemotherapeutics. Due to its role in modulating oxidative stress, sustained NRF2 overexpression promotes disease progression, particularly in lung cancer. This study demonstrates the effective knockdown of NRF2 expression by small interfering RNA (siRNA) delivered via a nanoplatform based on bovine colostrum exosomes to lung cancer cells, both *in vitro* and *in vivo*, resulting in inhibition of proliferation and disease progression. Bovine colostrum is an abundant source of exosomes. Here we present a novel exosome-polyethyleneimine matrix (EPM) to deliver therapeutic siRNA targeting NRF2 expression (si*NRF2*). Specific delivery of the EPM to tumors was further enhanced via folic acid (FA) functionalization, targeting folate receptors highly expressed on lung tumor cells. Exosomes were isolated from standardized colostrum powder through rehydration and differential centrifugation, and characterized by size, polydispersity index (pdi) and surface charge by Zetasizer, and the presence of surface protein markers by Western blot. si*NRF2* was loaded onto the EPM, and the resultant EPM-*siNRF2* complex was harvested by PEG precipitation. Entrapment efficiency was determined using 5'-^{32}P-labeled siRNA as a tracer. The gene knockdown efficiency of EPM-*siNRF2* was assessed in lung cancer (A549) cells by Western blot and the therapeutic effect of target knockdown *in vitro* was confirmed by analyzing the corresponding modulation in downstream targets of NRF2. The anti-tumor effect was then evaluated using both subcutaneous and orthotropic lung tumor models in immunocompromised mice. The EPM exhibited high entrapment efficiency (>90%) of si*NRF2* (up to 20 µg) and protected entrapped siRNA from enzymatic degradation upon exposure to RNases. EPM-si*NRF2* dose dependently decreased NRF2 expression in A549 lung cancer cells. When formulated with FA-functionalized exosomes, EPM-si*NRF2* inhibited subcutaneous and orthotropic lung tumors in mice by over 57% ($p<0.01$) and 84% ($p<0.001$), respectively. Mice treated with FA-EPM-si*NRF2* showed decreased levels of NRF2 in tumor tissue, but not in the adjacent lung, indicating FA-mediated targeted delivery.

This bovine colostrum exosome based EPM technology showcases high efficiency in gene knockdown and lung tumor inhibition, providing a promising nanoplatform for delivering nucleic acid therapeutics to the tumor site.

Funding: Supported from the NIH grant R44 CA-221487, 3P Biotechnology Contract and, in part, Agnes Brown Duggan Endowment.

Keywords: Bovine colostrum, Exosomes, NRF2, siRNA, Lung cancer.

#7236 Selective deletion of the KRAS mutant gene with ADGN-123 and ADGN-121 peptide-RNA nanoparticles: A new strategy to overcome acquired resistance to KRAS^{G12C} and KRAS^{G12D} small molecule inhibitors.

G. Divita[1], A. Grunenberger[2], V. Guzman-gonzalez[2], E. Czuba[2], k. Boularache[2], M. Guidetti[3], V. Josserand[3], N. Desai[1];
[1]AADIGEN, Pacific Palisades, CA, [2]DIVINCELL, Nimes, France, [3]IAB, Grenoble, France

KRAS codon12 mutations are among the most commonly observed mutations in cancers. Recently, KRAS^{G12C} inhibitors (sotorasib and adagrasib) have been approved and KRAS^{G12D} inhibitor MTRX-1133 has shown preclinical efficacy in *KRAS^{G12D}* mutated cancers. However, these inhibitors are limited by adaptive resistance, mainly associated with the emergence of secondary KRAS mutations, activation of feedback pathway and amplification of KRAS^{G12C} allele. We have developed a new potent strategy combining gene editing with tumor selective peptide nanoparticles, to overcome acquired resistance to KRAS^{G12C} and KRAS^{G12D} inhibitors.

ADGN-123 and ADGN-121 are gene-editing complexes containing proprietary sgRNA targeting KRAS^{G12C} and KRAS^{G12D} respectively, complexed with proprietary peptides. ADGN-123 and ADGN-121 were evaluated on pancreas, colorectal, and lung cancer cells harboring KRAS$^{G12C\ or\ G12D}$ mutations. ADGN-123 was evaluated on NCI-H358 and Mia-PACA generated clones resistant to sotorasib/adagrasib and harboring KRAS^{G12C,R68M} and KRAS^{G12C,Y96D} secondary mutations. ADGN-121 was evaluated on ASPC-1 and PANC-1 generated clones resistance to MRTX-1133 . *In-vivo* efficacy of IV-administered ADGN-121 (0.25-1.0 mg/kg, day 1 and 7) was evaluated in PANC-1 (KRAS^{G12D}) mouse xenografts.

ADGN-123 and ADGN-121 selectively silenced KRAS^{G12C} and KRAS^{G12D}, respectively, in cancer cells resulting in inhibition of cell proliferation (IC_{50}: 10-30 nM) and of the phosphorylation of ERK and AKT. we showed that ADGN-123 containing gRNA^{G12C}/$mRNA_{Cas9}$ blocks the proliferation (IC_{50} : 10-20 nM) of cells with secondary KRAS$^{G12C/R68M}$ and KRAS$^{G12C/Y96D}$ mutations or with KRAS in a permanent active state and effectively inhibits ERK phosphorylation. We showed that ADGN-121 containing gRNA^{G12D}/$mRNA_{Cas9}$ can effectively inhibit the proliferation (IC_{50} : 10-15 nM) of ASPC-1 MRTX-1133R and PANC-1 MRTX-1133R cells with high level of KRAS^{G12D}-GTP active state. No resistance was detected after ADGN-123 or ADGN-121 treatments. We demonstrated that only two IV-administrations of ADGN-121 containing gRNA^{G12D}/$mRNA_{Cas9}$ abolished PANC-1 tumor growth in a dose dependent manner, resulting in significant tumor regression at 1.0 mg/kg. In contrast, no effect on tumor growth was observed with nonspecific gRNA. ADGN treatments were well tolerated, with no signs of clinical toxicity detected after single or repeat administration.

Our study provides a proof-of-concept that ADGN complexes can be applied to target driver mutations of cancers *in vivo* and permanently disrupt the oncogenic alleles, leading to major tumor regression. ADGN-123 and ADGN-121 constitute a potent alternative strategy to overcome resistance associated to small molecule inhibitors of KRAS^{G12C} and KRAS^{G12D}

#7237 Peptide-mRNA complex mediated restoration of BRCA-1 tumor suppressor function in BRCA-1 mutated cancers as a new therapeutic strategy.

G. Divita[1], A. Grunenberger[2], L. Cabrera[2], N. Durany[1], N. Desai[1];
[1]AADIGEN, Pacific Palisades, CA, [2]DIVINCELL, Nimes, France

BRCA1 and BRCA-2 proteins are involved in the repair of DNA damage such as double-strand breaks during S and G2 phases, by intervening in homologous recombination (HR) steps. Breast cancers arising from BRCA-1 mutation carriers (10% of BC) and from epigenetically silenced BRCA-1 (30% of sporadic BC) are associated with a lack of expression and/or function of BRCA-1, which induces genomic instability. Herein, we describe a new potent strategy combining mRNAs with a tumor selective peptide nanocarrier, to selectively rescue BRCA-1 function as potential therapeutic approach in cancers.
Proprietary BRCA-1 derived mRNA were complexed with proprietary short amphipathic peptides and the resulting nanoparticles were evaluated on several breast cancer cells, harboring different BRCA-1 alterations.. Sensitivity to Veliparib (PARPi) following the nanoparticle treatments were evaluated on PARPI resistant and PARPi sensitive cells. The recruitment of RAD51 to sites of double stranded DNA break was quantified by immunofluorescence. *In-vivo* efficacy of varying sequences of BRCA-1 mRNA-peptide nanoparticles (2.0 mg/kg, weekly, IV; ADGN-901, -902, -903) and veliparib (50mg/kg, daily, oral) were evaluated on breast cancer (HCC1937-BRCA-1 deficient, PARPi resistant) mouse xenografts.
We showed that ADGN-901 inhibits the proliferation of BRCA-1 deficient cell lines from 20 to 60% depending on the type of BRCA-1 alterations. ADGN-902, specifically reduces the proliferation of cells expressing N-terminal truncated BRCA-1, by 50 to 60% and ADGN-903 inhibits proliferation >60% of all cells harboring defects in BRCA-1. Interestingly, ADGN-901 and ADGN-903 were able to resensitize the PARPi resistant cells to veliparib inhibition. We demonstrated that ADGN-903 restores BRCA-1 function in homologous recombination. ADGN-903 prevents RAD51 recruitment to the damage site by reducing RAD51 protein level as well as formation of RAD51 foci following irradiation. IV administration of ADGN-901 and ADGN-903 (2.0 mg/kg) had a strong inhibitory effect on HCC-1937 tumor growth while ADGN-902 and veliparib were inactive. ADGN-901 reduced tumor growth by 95% and ADGN-903 abolished tumor growth with strong tumor regressions. ADGN-901 and ADGN-903, were also evaluated on large tumors of about 500-600 mm^3 and were highly effective in preventing further progression and achieving shrinkage of large tumors. ADGN-901 and ADGN-903 treatments are well tolerated, without inducing clinical toxicity. BRCA-1 mRNA-peptide nanoparticles are effective in rescuing BRCA-1 function and inducing tumor regressions in BRCA-1 altered breast cancer cells and tumors. Our study provides a proof-of-concept that restoration of wild type BRCA-1 expression could be a potent therapeutic strategy for BRCA-1 altered tumors whether or not they are PARPi resistant.

#7238 Exploring the potential of targeted DNA Nanobot delivery systems for gene delivery.

M. Shahhoessini[1], J. R. Spitzner[1], C. R. Lucas[1], C. E. Castro[2], **P. D. Halley**[1];
[1]DNA Nanobots, LLC, Columbus, OH, [2]The Ohio State University, Columbus, OH

Gene therapy is a cornerstone of modern medicine's quest for precision treatment to cure human disease including cancer. The current approach to gene delivery technology employs viral vector delivery systems. While effective, these vectors present significant challenges including immunogenicity, safety concerns due to off-target non-tissue specific delivery, payload limitations, and significant cost ultimately diluting their therapeutic potential. Thus, novel approaches to gene delivery are necessary. One such approach to address these critical limitations involves DNA Nanobots, a DNA-based nanotechnology that allows for a tissue-/target-cell specific gene delivery system. Utilizing DNA origami molecular assembly techniques, our DNA Nanobots offer a customizable and highly precise delivery platform, free from viral vector constraints. This innovative approach has the potential to transform the landscape of gene therapy by providing a safer, more efficient, and targeted alternative. Key technical advancements with our DNA Nanobots Gene Delivery Platform include: •CRISPR Cas-9 Integration: By incorporating CRISPR Cas-9 functional proteins, our nanobots were shown to enhance gene editing precision in primary human T cells, broadening therapeutic applications across various genetic conditions. •Targeted mRNA Delivery: Our nanobots revealed promising results in the targeted delivery of mRNA, vital for vaccine development and personalized treatments. •Efficient antisense/siRNA Delivery: Prior studies have overcome traditional challenges including endosomal escape and cytoplasmic entry, demonstrating effective siRNA delivery critical for gene silencing therapeutic development. In summary, DNA Nanobots mark a paradigm shift in gene therapy. Their ability to deliver various nucleic acids with high specificity and efficiency addresses many of the current methodological limitations especially off-target safety concerns and high cost. This advancement not only enhances the therapeutic index of existing treatments but also opens avenues for novel therapeutic strategies, potentially reshaping the future of molecular medicine and gene therapy.

#7239 Eradication of B cell lymphoma in a mouse model through *in vivo* transduction of T cells with an aCD19-CAR utilizing a CD3-targeted lentiviral vector.

K. Krotova[1], G. Nenavath[1], N. Packiriswamy[1], R. Vandergaast[1], Y. McDaniel[1], M. Moy[1], Z. Larson[1], L. Schnebeck[1], C.-H. Chin[1], K. Gromer[1], K.-W. Peng[2], S. J. Russell[2];

[1]Imanis Life Sciences, LLC, Rochester, MN, [2]Vyriad, Rochester, MN

One of the challenges in CAR-T cell therapies is the need for ex vivo processing of autologous T cells. The generation of CAR-T cells directly within the patient has therefore become an attractive alternative. Here, we pseudotyped lentiviral vectors with a VSV-G protein engineered to de-target the LDL receptor and to bind to CD3 via a displayed CD3-specific single-chain antibody (G-CD3), allowing for targeted recognition of T cells. In ex vivo experiments, we demonstrated that engineered G-CD3-LV specifically recognizes and transduces T cells in PBMC and whole blood without apparent off-target transduction of other cells. Furthermore, unlike G-WT-LV, which necessitates T cell activation for transduction, G-CD3-LV does not require pre-activation or the presence of cytokines for successful T cell transduction. The presence of CD3 antibodies on the surface of G-CD3-LV alone was sufficient to activate T cells, as evidenced by CD25 expression and the induction of T cell proliferation. For in vivo evaluation of retargeted LV efficiency NSG mice implanted with NALM6 B-lymphoma were treated with G-CD3 LV encoding αCD19-CAR/GFP (G-CD3/LV-CAR). The tumor was established by tail vein injection of NALM6/F-Luc cells, and 3 or 10 days later animals were humanized via intraperitoneal (IP) injection of human PBMC. Four hours after PBMC transfer, G-CD3/LV-CAR was delivered by IP route. Blood was drawn every week to monitor the generation of CAR-T cells, cytokine levels, and vector copy numbers. Tumor burden was monitored by bioluminescence imaging. Treatment with G-CD3/LV-CAR at both time points resulted in complete tumor eradication. Subsequently, significant levels of CAR-T cells were observed in the blood through Flow analysis, peaking at two weeks after LV injection. Importantly, mice treated on day 10 after tumor establishment reached higher levels of CAR-T cells compared to those treated on day 3 (CAR-T levels were 38±6.5% vs. 10±2.38% of hCD45+ cells, respectively). These results suggest that CAR-T cells proliferated proportionally in response to the level of tumor antigen. With the eradication of the tumor, CAR-T levels in the blood diminished. We also demonstrated that the levels of CAR-T cells correlated well with vector copy numbers. Throughout the treatment, mice did not exhibit any signs of toxicity or body weight loss. Additionally, by measuring cytokines in the blood produced by human cells, we found only a moderate increase in hIFNγ (0.852±0.681 ng/ml) at the peak of CAR-T cell levels in the blood, while the levels of hIL-2 and hTNFα were below the detection limit. In summary, these data highlight the efficiency and potential applicability of fully retargeted, serum stable LV vectors for in vivo CAR-T generation, offering promising prospects to optimize CAR-T cells therapy applications.

#7240 Intratumor delivery of plasmid DNA encoding immune stimulating agents induces both local and systemic responses.

R. Heller[1], L. C. Heller[1], G. Shi[1], J. Synowiec[1], J. Singh[1], A. Otten[2], M. J. Jaroszeski[2];
[1]USF Health Morsani College of Medicine, Tampa, FL, [2]University of South FLorida, College of Engineering, Tampa, FL

Immune checkpoint inhibitors (ICIs) have significant clinical benefits, but are limited by both primary and acquired resistance. The absence of T cells within the tumor microenvironment (TME) is a significant hurdle, reducing the efficacy of ICIs against solid tumors. Multiple studies have been initiated to modify the TME to enhance the effectiveness of ICIs. We previously demonstrated that the intratumor delivery of a plasmid encoding interleukin-12 (pIL-12) using gene electrotransfer (GET) resulted in a significant increase in T effector cells and a reduction in T regulatory cells and myeloid derived suppressor cells within the TME, inducing a robust immune response. Combining pIL-12 GET with ICIs resulted in local and systemic responses in both preclinical and clinical studies. While encouraging results were obtained, improvements were possible. For example, the established GET technology requires high applied voltage for plasmid delivery. In addition, satisfactory delivery cannot be immediately detected. Our current research has focused on developing the next generation GET technology to overcome these issues. This new system includes a pulse generator, a heat source and a tissue impedance measuring device. An array that incorporates independently addressable electrodes was also developed. A moderate elevation of the tissue temperature coupled with the electrode array enabled a 75% reduction in the applied voltage. We tested the approach in the B16.F10 mouse melanoma model. Delivery of pIL-12 with the new system resulted in 100% long-term complete regression and 100% protection from challenge. In addition, monitoring impedance within each independent section of the electrode array revealed different pulse numbers were needed to achieve delivery in each section. We next evaluated a combination therapy, pIL-12 plasmid combined with a plasmid encoding a PD1 peptide, delivered with the next-gen device. In a multi-tumor model, the plasmids were delivered to the subcutaneous tumor; tumors generated with an intraperitoneal injection were untreated. This new therapy induced complete regression of the subcutaneous tumor and blockage of peritoneal tumor growth as assessed via in vivo imaging. Peritoneal tumor growth was not affected by single plasmid delivery or when both plasmids were delivered with the established GET technology. Work is ongoing to translate this approach to clinical evaluation.

#7241 Combination of CDK4/6 inhibitor promotes the antitumor effect of oncolytic adenovirus against canine breast cancer cells.

N. Hashimoto[1], H. Tazawa[1], S. Kikuchi[1], S. Kuroda[1], Y. Urata[2], S. Kagawa[1], T. Fujiwara[1];

[1]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, [2]Oncolys BioPharma, Inc., Tokyo, Japan

Background: Oncolytic virotherapy has emerged as a novel antitumor platform to induce tumor-specific cytopathic effect against human cancer cells. However, whether oncolytic virotherapy is effective to canine cancer cells remains unclear. We developed telomerase-specific oncolytic adenoviruses OBP-301 and a p53-armed OBP-702 based on human adenovirus serotype 5. OBP-301 and OBP-702 have therapeutic potential against various types of human cancer cells. As recent report has suggested that human adenovirus serotype 5 induces cytopathic effect against canine cancer cells, OBP-301 and OBP-702 are expected to have therapeutic effects against canine cancer cells. Furthermore, it has been reported that CDK4/6 inhibitors clinically used for human breast cancers promote the replication of oncolytic adenoviruses, suggesting that combination of CDK4/6 inhibitors promote the therapeutic potential of oncolytic adenoviruses. In this study, we investigated the therapeutic potential of OBP-301 and OBP-702 against canine breast cancer cells in monotherapy and combination therapy with CDK4/6 inhibitor.

Methods: Two canine breast cancer cell lines (CMT-U27, AZA-CB) were used in this study. The antitumor effect of OBP-301 and OBP-702 against canine breast cancer cells was analyzed using the XTT assay. The therapeutic potential of combination therapy with CDK4/6 inhibitor (palibociclib) was further analyzed. Virus-mediated induction of adenovirus E1A and p53 expression was analyzed by Western blotting. The in vivo antitumor effects of OBP-301 and OBP-702 were assessed using CMT-U27 subcutaneous tumor model.

Results: OBP-301 and OBP-702 had cytopathic effect against CMT-U27 and AZA-CB cells. The antitumor activity of OBP-702 was superior to that of OBP-301. The combination of palbociclib and OBP-301 showed a more profound antitumor effect compared with monotherapy against CMT-U27 and AZA-CB cells. The expression of E1A and p53 was increased in virus-treated CMT-U27 and AZA-CB cells in a dose-dependent manner. Intratumoral administration of OBP-301 and OBP-702 significantly suppressed the growth of subcutaneous CMT-U27 tumors compared with mock treatment.

Conclusion: Our results suggest that telomerase-specific oncolytic adenoviruses have cytopathic effect against canine breast cancer cells via virus infection and replication. Furthermore, combination of CDK4/6 inhibitor may be a promising strategy for promoting the antitumor effect of oncolytic adenovirus against canine breast cancers.

#7242 Immunostimulatory gene therapy co-expressing immune activators TMZ-CD40L and 4-1BBL with a PD-L1-targeting Affibody molecule to reactivate T cell immunity.

L. A. White[1], I. Vaask[1], J. Hardin[1], E. Eriksson[1], A. Sandegren[2], F. Y. Frejd[2], T. Lovgren[1], A. Loskog[1];
[1]Uppsala University, Uppsala, Sweden, [2]Affibody AB, Solna, Sweden

Immunotherapy has been used to make great strides in helping cancer patients, and new approaches to reactivate patient immunity are constantly being developed. We are developing immunostimulatory gene therapy using adenoviruses as gene vehicles to inflame the tumor microenvironment and drive anti-tumor immunity. One consequence of immune activation is PD-L1 upregulation, so to optimize our treatment, we are using a novel gene therapy vehicle expressing both immune activators and a PD-L1-blocking Affibody molecule. Affibody molecules are tri-helical proteins engineered to bind specific target molecules with high affinity. These molecules have successfully been used to image cancer cells in the body and can block target proteins. Affibody molecules are advantageous over other affinity molecules due to their small size, averaging about 6 kDa, and their high stability. The small size makes an Affibody molecule an ideal candidate for use in viral vectors, where genetic space is limited. In the present study, we tested the biological activity of a PD-L1 targeted Affibody molecule expressed from a viral vehicle compared to the synthetic protein, using a Bio-IC *in vitro* luciferase assay. Further, the capacity of the PD-L1-binding Affibody molecule to prevent inhibitory signaling was evaluated in an ovarian cancer/immune cell co-culture assay.
Our results demonstrate that cell lines infected with viral gene vehicles successfully express and release the Affibody molecule as demonstrated with PCR and ELISA. Furthermore, the supernatants containing the Affibody molecule and synthetic Affibody molecule inhibited the activity of PD-L1 in the BioIC assay. Next, an adenovirus vector containing trimerized-CD40L and 4-1BBL (LOAd703), known to upregulate PD-L1 in stimulated dendritic cells, was modified to co-express the anti-PD-L1 Affibody molecule (LOAd724). Gene expression was confirmed using PCR, flow cytometry (CD40L, 4-1BBL) and ELISA (anti-PD-L1 Affibody molecule). The tumor/immune cell co-culture is underway. In summary, Affibody molecules can be expressed from adenoviral gene vehicles alone or in combination with immunostimulatory genes. Further studies are warranted to understand the role of local PD-L1 blockade in the tumor microenvironment following LOAd724 therapy.

#7243 CRISPR-cas9 genetic targeting of metastatic pancreatic cancer.

K. Bowland[1], J. Lai[1], S. K. Teh[1], A. Bennett[1], A. Skaist[1], Y. Zhang[1], E. Thompson[1], R. H. Hruban[1], N. J. Roberts[1], R. Karchin[1], C. A. Iacobuzio-Donahue[2], J. R. Eshleman[1];

[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Metastatic cancer affects millions of people worldwide annually and is the leading cause of cancer-related deaths. Most patients with metastatic disease are not eligible for surgical resection, and current therapeutic regimens have varying success rates, some with 5-year survival rates below 5%. Here we test the hypothesis that metastatic cancer can be genetically targeted by exploiting somatic single base substitution mutations that occur as part of normal aging prior to transformation. These passenger mutations are targetable because ~10% of them form novel tumor-specific “NGG” protospacer adjacent motif (PAM) sites targetable by CRISPR-Cas9. We studied five patients with pancreatic cancer (pc) who underwent a rapid autopsy to determine areas of evolutionary conservation that were maintained throughout all metastases in each patient’s cancer. Using whole genome sequencing validated by high-depth capture sequencing, we found that 90% of somatic PAM targets were maintained between primary carcinomas and metastases. We identified regions of loss of heterozygosity (LOH) surrounding tumor suppressor genes and oncogenes in the primary tumor where PAMs were 100% conserved in metastases. These regions of truncal LOH represent genetic vulnerabilities in these carcinomas and a CRISPR-based gene therapy approach targeting PAMs in these regions may be a novel way to genetically target metastatic cancer. Using multitarget sgRNA which cut at a known number of sites in the human genome, we determined a relationship between the number of CRISPR-Cas9 cuts and growth inhibition in PC cells. We found that 8-10 target sites in non-coding regions were sufficient to induce >95% cancer cell death. Furthermore, only 2-3 targets were required to achieve a comparable level of cell death in the presence of a DNA double strand break inhibitor. Finally, using cocultures of PC cells transduced with sgRNA targeting multiple tumor specific PAMs, we demonstrate selective cell killing of three different PC cell lines. Importantly, deep sequencing of patient-matched normal lymphocytes lacking the tumor-specific PAMs treated with the same sgRNA array exhibited no editing at the targeted loci. This work establishes a bioinformatic platform for the discovery of tumor-specific CRISPR targets in the context of metastatic disease and demonstrates selective killing of cancer cells while sparing the patient’s normal cells. These data establish the proof of principle for a gene therapy approach targeting metastatic disease.

#7246 Enhancing PDAC therapy through *in vivo* correction of *KRAS*^{G12D} using enIscB-directed base editor combined with ICB.

C. Yang, Q. Fang, T. Zhou, Y. Xie, J. Yu, J. Hao;
Pancreas Center, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer; Tianjin Key Laboratory of Digestive Cancer; Tianjin's Clinical Research Center for Cancer, Tianjin, China

In this study, we aim to investigate the therapeutic potential of *in vivo* genetic therapy using AAV-mediated adenine base editor (ABE) delivery for pancreatic ductal adenocarcinoma (PDAC) carrying the *KRAS*^{G12D} mutation (PDAC^{G12D}), and further explore its potential when combined with immune checkpoint blockade (ICB). The *KRAS*^{G12D} mutation is a dominant genetic alteration representing a highly sought-after and effective therapeutic target in PDAC. However, the *in vivo* genetic therapy for *KRAS*^{G12D} in PDAC has been rarely explored. Programmable base editors have been shown to install genetic mutations precisely and have significant therapeutic value, providing a promising strategy for genetic therapy of PDAC^{G12D}. Here, we engineered ABEs derived from various programmable nucleases, considering the protospacer adjacent motif (PAM) or target adjacent motif (TAM) sequence. The hypercompact A8e-enIscB demonstrated the highest editing efficiency in HEK293T^{G12D} and PANC-1 cell lines. Subsequently, A8e-enIscB was packaged into a single-AAV system and delivered to humanized mice subcutaneously transplanted with patient-derived organoid^{G12D} (PDO^{G12D}). We found the delayed tumor progression with BE-based genetic therapy. Additionally, a substantial editing efficiency in tumor tissues and lower off-target editing in normal tissues was observed. By comparing single-cell transcriptome sequencing data between BE-treated and non-treated samples, we observed a reprogrammed immune microenvironment characterized by elevated infiltration of cytotoxic CD8^{+} T cells and NK cells, as well as decreased recruitment of suppressive PMN-MDSCs, Tregs and TAMs upon correction of *KRAS*^{G12D}. Furthermore, AAV-directed ABE genetic therapy could significantly sensitize PDAC to ICB therapy (anti-PD-1, anti-CTLA4) in humanized PDAC PDO/PDX mouse models. Accordingly, an ongoing work in which the genetic therapy combined with ICB phase IA investigator-initialized trial will be designed to evaluate the safety of this regimen. In summary, our study demonstrates the efficiency and safety of innovative genetic therapy for correcting the *KRAS*^{G12D} mutation in PDAC. Furthermore, we demonstrated the therapeutic potential of combining this genetic therapy with ICB.

#7247 Exosome-mediated delivery of RNA and DNA: Enhanced efficiency with polycationic PEI-PEG.

Disha Nagesh Moholkar[1], Raghuram Kandimalla[2], Margaret Wallen[3], Jeyaprakash Jeyabalan[4], Wendy Spencer[3], Farrukh Aqil[5], Ramesh C. Gupta[6]

[1]Department of Pharmacology and Toxicology, University of Louisville, Louisville, KY,[2]Brown Cancer Center, University of Louisville, Louisville, KY,[3]3P Biotechnologies, Inc., Louisville, Louisville, KY,[4]Department of Pharmacology and Toxicology, 3P Biotechnologies, Inc., Louisville, Louisville, KY,[5]Department of Pharmacology and Toxicology and Brown Cancer Center, University of Louisville, Louisville, KY,[6]Department of Pharmacology and Toxicology, University of Louisville and 3P Biotechnologies, Inc., Louisville, Louisville, KY

Emerging advances in gene therapy over the past few decades have revolutionized biomedical research. Our lab has pioneered bovine milk and colostrum-derived exosomes (Exo) and devised a nanoplatform for nucleic acid delivery achieving targetability with folic acid (FA) functionalization. We showed that bovine colostrum exosomes complexed with high MW polyethyleneimine (PEI-60K) can efficiently delivery siRNA and plasmid DNA (pDNA) in vitro and in vivo. We hypothesize that lower MW PEI may improve transfection efficiency and enhance oral uptake of EPM-siRNA, in addition to presumably higher degradability in a cellular system. We now report that exosomes and PEI of lower MW (25K)-PEG copolymer is as effective or more effective for delivery of siRNA and pDNA than PEI-60K. Incubation of exosomes, PEI-25K and siRNA in the presence of 5'-^{32}P-labeled siRNA as a tracer showed high siRNA entrapment (>90%) based on the distribution of the radioactivity in EPM-siRNA precipitate compared with the supernatant. The efficacy of the EPM matrix is gene specific. As treatment of A549 lung cancer cells with EPM-(PEI-60K)-si*KRAS* showed 60% knockdown of target KRAS gene, which was enhanced to 70% by EPM-(PEI-25K)-si*KRAS*. Moreover, p53-pDNA delivered by EPM-25K resulted in nearly 2-fold higher expression of p53 in p53-null H1299 lung cancer cells compared with EPM-60K. However, still lower MW PEI (PEI-15K) diminished the transfection efficiency (36% KRAS knockdown). EPM formulated with PEI-60K and 25K had similar effect on cell viability of HEK293 cells. Upon *in vivo* testing, EPM-25K loaded with si*KRAS* and functionalized with folic acid (FA) showed time-dependent growth inhibition of A549-innoculated orthotopic lung tumors in NOD Scid mice eliciting 76% ($p<0.01$) tumor growth inhibition. The tumor inhibition was accompanied with 50% ($p<0.05$) knockdown of the target gene in the tumor tissue, while the adjacent lung tissue showed no modulation. The anti-tumor efficacy of si*KRAS* delivered by FA-functionalized EPM-25K is the same or somewhat higher than the efficacy reported previously with FA-functionalized EPM-60K.In conclusion, based on our *in vitro* and *in vivo* results, lower MW PEI (PEI-25K) is a suitable alternative for PEI-60K with boosted efficacy in terms of knockdown of KRAS. Our proposed technology offers a platform to advance and overcome the obstacles in the clinical translation of gene therapy.

Funding: Work supported from funds provided by 3P Biotechnologies and in part Agnes Brown Duggan Funds. Disha Nagesh Moholkar is supported by IPIBS Fellowship, University of Louisville.

#7248 Simultaneous isolation and parallel analysis of genomic DNA and RNA for gene therapy.

H. Wei;
Beckman Coulter, Inc., Indianapolis, IN

Introduction Viral vectors, such as adeno-associated vector (AAV), play a crucial role in delivering transgenes for gene therapy research. The success of vector transduction is vital for efficacy, which is measured through vector copy number (VCN) and transgene expression. In preclinical studies, both VCN and transgene expression are commonly tested from the same sample to ensure accuracy. We have reported a method for simultaneous high-quality genomic DNA and RNA extraction without splitting the sample, utilizing SPRI bead-based technology that has consistent performance across diverse tissue types and brain regions.

Methods AAV was administered to mouse and non-human primate (NHP) models. At the conclusion of each experiment, tissue samples from the adrenal gland, brain, gonads, heart, kidney, liver, lung, skeletal muscle, spinal cord, and spleen were harvested. All tissue samples that demonstrated around 15 mm^3 were snap-frozen in liquid nitrogen before nucleic acid extraction. The extraction process was carried out manually or on an automated liquid handler. The quality and quantity of DNA and RNA were then assessed from all tested tissues before downstream assay.

Results Our study found that all mouse tissue types (n=72/tissue type) and NHP (n=11/tissue type) had an average gDNA and RNA yield that exceeded the minimum yield cutoff of 25 ng/µL for DNA and 6.25 ng/µL for RNA. We also analyzed DNA from tissues treated with two different AAV serotype-treated tissues in the mouse model, which showed that transduction across all the tissues was highly efficient for both AAV serotypes. Furthermore, we observed variations in transgene expression levels (copies/1 µg RNA) among different tissue types. Similar patterns of VCN and transgene expression were also observed in NHP models.

Conclusions Efficient gene therapy depends on a safe and effective viral vector. The simultaneous extraction of gDNA and RNA simplifies the process, saves time, ensures quality, and facilitates integration into existing lab automation. This leads to consistent and error-resistant performance in analyzing vector copy and transgene levels.

#7250 Serial assessment of GEN2, a retroviral vector for gene transfer of an optimized thymidine kinase and GM-CSF, for genomic integration into peripheral blood mononuclear cells (PBMCs) in a Phase 1 clinical trial in adult patients with solid tumors.

A. L. Hannah[1], N. Kasahara[2], L. Liu[1], A. Wang[1], J. McNulty[1], R. G. Johnson, Jr.[1];
[1]GenVivo, San Marino, CA, [2]University of California San Francisco, San Francisco, CA

GEN2 is a non-replicating retroviral gene transfer vector encoding a sequence-optimized herpes simplex thymidine kinase (HSV-TK), which activates the antiherpetic pro-drug ganciclovir (GCV), resulting in chain termination during DNA replication, triggering cancer cell apoptosis and release of neoantigens (NA). GEN2 also encodes hGM-CSF, which may augment antitumor immunity by enhancing NA presentation to immune effector cells. GEN2 in combination with valganciclovir (an oral formulation of GCV) was evaluated in a dose-escalating Phase 1 clinical trial in 61 adult patients (pts) with an advanced solid tumor (NCT04313868), with serial assessment of PBMCs to detect any GEN2 integration and replication competent retrovirus (RCR). Methods: PBMCs were obtained in Cycle 1 (following 1st /3rd dose), prior to and 2 hours after Cycle 2, and thereafter at 6-month intervals for 15 years, or until death or withdrawal of consent. Digital droplet PCR (ddPCR) for psi and envelope gene sequences in extracted genomic DNA from PBMCs was used to detect vector genome integration and replication competent retrovirus (RCR), respectively. Results: All 82 samples obtained from the intravenous cohorts 1-12 were below LOD (Limit of Detection) for RCR. All results for integration were BLOQ (Below Limit of Quantitation), whereas 4 samples collected at two hours following the end of infusion were above LOD, likely resulting from non-integrated cDNA. GEN2 continues to be studied in clinical trials in adult patients with solid tumors. Per the 2020 FDA Guidance for Industry (Long Term Follow-Up After Administration of Human Gene Therapy Products), serial assessment of vector integration is mandated throughout a pt's participation in a gene therapy clinical trial and for 15 years following the last dose. These guidance documents were originally conceived when gene therapy was developed for treatment of rare hereditary diseases in pediatric pts; however, adult pts enrolled in early-stage clinical trials for cancer typically do not have a prolonged life expectancy (BMC Cancer 2011 11:426). In the context of proper and warranted usage of pts' blood for testing, attention should be drawn to the limited expectation for a 2nd malignancy within the lifespan of this pt population, and the absence of detectable RCR in cancer patients receiving retroviral vectors over decades. A recent review noted no evidence of RCR in 1,595 post-treatment PBMCs obtained from 60 clinical trials (Mol Ther 2023 31(3):801). Our results confirm that GEN2 also shows negligible genotoxic risk for gene therapy of cancer at doses tested to date.

#7251 Surface-engineered extracellular vesicles to modulate antigen-specific T cell expansion for cancer immunotherapy.

X. Lyu, T. Yamano, S. Imai, T. V. Le, R. Hanayama;
Kanazawa University, Kanazawa, Japan

Tumor immunotherapy, including immune checkpoint therapy, CAR T cell therapy, and TCR-T cell therapy, has made significant progress in the treatment of cancer. Recently, newly developed nanomaterials have also been applied to anti-tumor immunotherapy. Among them, extracellular vesicles (EVs) have been well-engineered in recent years due to their low immunogenicity, high stability, and wide distribution in biological fluids. Despite the recent development of several EVs-based cancer immunotherapies, their clinical efficacy remains limited. In this study, we have developed engineered EVs designed to mimic the function of antigen-presenting cells, which can co-deliver multiple immune-activation signals to tumor-associated T cells. We named these vesicles Antigen-presenting Extracellular Vesicles (AP-EVs). AP-EVs express a high level of MHC I-peptide complexes, costimulatory molecules, and surface-bound cytokines, allowing for the simultaneous presentation of multiple immune modulators to antigen-specific CD8+ T cells. AP-EVs promote the clonal expansion and differentiation of antigen-specific cytotoxic T lymphocytes, resulting in potent anticancer immune responses. Notably, our findings indicate that combination therapy involving AP-EVs and anti-PD-1 yields superior anticancer immunity against established tumors compared to anti-PD-1 monotherapy. This synergistic effect underscores the potential of our engineered EVs as a novel and highly effective strategy for cancer immunotherapy.

#7252 Characterization of targeting peptide sequences for peptide-mediated delivery of siRNA in HER2+ breast cancer.

A. Miserendino, S. Tekle, J. Kalogeros, A. Alexander-Bryant;
Clemson University, Clemson, SC

Introduction: This work presents the characterization of two novel HER2 targeting peptides to measure which has the most compatible properties to be used as a siRNA carrier to knock down the CD44 gene in HER2+ breast cancer.

Procedures: Targeting peptides were electrostatically complexed with non-targeting siRNAs at different N:P ratios to determine the minimum binding ratios needed to form nanoparticles. Different ratios of peptide-siRNA complexes were tested to determine the minimum molar ratio at which the peptides would protect siRNA from degradation. Cytotoxicity assays were performed to determine cytotoxicity levels at different peptide concentrations. Dynamic light scattering assay was performed to determine peptide-siRNA nanoparticle size and zeta potential. Immunofluorescent microscopy was used to determine the targeting of the peptide to HER2+ cells compared to cells not expressing HER2.

Summary of Results: Peptide-siRNA complexes for the P51 and P25 peptides formed at a minimum 20:1 N:P ratio. P25 and P51 peptides both successfully protects the siRNA at N:P ratios from 20:1 to 60:1 for both degradation agents. Cytotoxicity assays show that in the SKBR3 cell line, the P25 and P51 peptides both showed above 80% viability until the 70:1 ratio; however, in the BT474 cell line, the P25 showed above 80% viability to the 50:1 ratio, but the P51 was only viable in the 20:1 ratio. The results of these studies illustrate how both peptides protect siRNA but that the P51 peptide is toxic to some HER2+ breast cancer cell lines.

Conclusions: Results show that both peptides target HER2+ breast cancer and are compatible carriers of siRNA, protecting the siRNA well within a cell-like environment. However, from MTS studies, P25 appears less cytotoxic to the cell lines than P51, which shows higher cytotoxicity at high molar ratios. We observed that the P25 protects siRNA from degradation, is cytocompatibility, and promotes efficient internalization into HER2+ cell lines. Future work will include the development of a tandem peptide, including a targeting peptide fused with a fusogenic peptide to increase cancer targeting and efficacy of this targeted treatment.

Acknowledgments: This research was supported in part by the Dabo Swinney All-In Foundation as well as Materials Assembly and Design Excellence in South Carolina (MADE in SC) under the National Science Foundation EPSCoR Program under NSF Award #OIA-1655740. Data presented in this material was partially collected using SC BioCRAFT facilities supported by the National Institute of General Medical Sciences (NIGMS) of the National Institutes of Health under award number P30 GM131959.

#7253 Oncolytic virus therapy with two-factor authentication shows robust safety and efficacy in liver cancer.

C. M. Moles[1], P. Weijmarshausen[1], R. Basu[1], B. Ho[1], M. Farhat[1], T. Flaat[1], B. F. Smith[2], M. Whitt[3], S. E. Woodfield[4], S. A. Vasudevan[4];
[1]Humane Genomics, New York, NY, [2]Auburn University College of Veterinary Medicine, Auburn, AL, [3]University of Tennessee Health Science Center, Memphis, TN, [4]Baylor College of Medicine, Houston, TX

Background: Humane Genomics is pioneering multi-factored authenticated oncolytic virotherapy (OVT) using glycoprotein receptor matching and aptazyme technology to positively control replication in cytoplasm. Using VSV as a platform the OVTs show excellent safety and remain highly lytic. Sindbis virus glycoprotein was mutated to eliminate natural infectivity and retargeted to GPC3 with a codon optimized nanobody. An aptazyme was used to regulate viral replication. As far as we are aware, this was the first report of a functional ON switch using a cancer biomarker.
Methods: 293T cells were used for virus rescue and titration by TCID50. Identity was confirmed by Nanopore sequencing. We evaluated safety on off-target SK-Hep-1 and NCI-H28 cell lines, and efficacy on target HepG2 and patient derived HB17 cells. Cell health and GFP was measured at multiple timepoints up to 72 hours.
Results: Safety testing of HGI498 on SK-Hep-1 (GPC3 negative) and NCI-H28 (GPC3 negative, biomarker negative) showed no virus induced cell cytopathic effects in a range of $0.01 \leq MOI \leq 1$. HGI498's efficacy testing on HepG2 and HB17 showed tumor cytotoxicity at MOI 0.01 ($p<0.001$). Endpoint dilution assay showed a 159-fold and 316-fold difference between off-target NCI-H28 and on-target HepG2 and HB17, respectively. We incorporated an optimized aptazyme with the GPC3 targeted glycoprotein (HGI572), which was similarly rescued, titered, and evaluated for selectivity. HGI572 demonstrated approximately 1000-fold higher titer on target HepG2 and HB17 cells than off-target cells. Initial *in vivo* MTD study shows that both HGI498 and HGI572 are well tolerated, and are currently being investigated *in vivo* for efficacy on Hep3B in NSG mice. HGI498 has shown no seroprevalence (*in vitro*) and is stable at cryostorage for a minimum of 11 months.
Conclusion: We have successfully engineered a two-factor authentication enabled OVT to address an unmet need for a therapy for liver cancer. As far as we are aware, this is the first report of an ON switch using a cancer protein to control viral replication, and the ON/OFF control is the highest to date.

#7254 Evaluation of scFv and diabody pseudotyped Sindbis engineered retrovectors for targeted cancer therapy.

M. Sato[1], A. Cunha[1], S. Collins[2], N. Kasahara[2], C. Roh[1], R. G. Johnson, Jr.[1];
[1]GenVivo Inc, San Marino, CA, [2]UCSF, San Francisco, CA

Engineering viral vectors to target specific cells and organs after intravenous delivery remains a challenge. Transcriptional targeting with cell-specific promoters is a commonly used approach but does not change vector biodistribution. We have developed a novel gene delivery system targeted to tumor cells by pseudotyping the vector with Sindbis Virus (SB) envelope bearing an antigen-binding domain. Prototype vectors were generated by inserting a universal IgG binding domain from Protein A into the SB envelope (SB-ZZ). Antibodies (Abs) against various cell-surface targets (HLA, HER2, CD47, EGFR, Nectin-4), were conjugated to SB-ZZ vectors delivering a luciferase (Luc) reporter gene. Targeted transduction was confirmed on cells expressing the corresponding antigens by significantly higher Luc activity compared to SB-ZZ vectors without Abs. SB envelopes were further engineered by adding or removing furin cleavage sites and linkers, transduction-enhancing point mutations, and direct incorporation of single-chain variable fragment (scFv) in different VH and VL orientations, or diabody (DB) sequences, against the same targets. The specificity of optimized HER2-targeting vectors delivering the Luc reporter was evaluated in SKBR3 (HER2 over-expressing) and MDA-MB-468 (HER2-null) cells. Robust Luc activity was observed in SKBR3 cells, but only negligible activity in MDA-MB-468 cells. In MDA-MB-468 cells overexpressing HER2, significantly higher transduction was observed compared to the wild-type cells. When comparing HER2-targeting vectors with scFv vs. DB sequences based on the same antibody, transduction capability was higher with the DB motif in HER2-positive cell lines. Targeting vectors delivering HSV-eTK were also constructed, and ganciclovir (GCV)-mediated cell killing was evaluated *in vitro*. SKBR3 cells transduced with HER2-targeting vectors showed significantly more cell killing after GCV treatment than after transduction with an amphotropic reference vector. Our results indicate a method for directing gene therapy vectors to specific populations of tumor cells, and provide a framework for highly modular targeted gene therapy and immunotherapeutics. Experiments are underway to examine *in vivo* delivery of targeted vs amphotropic vectors.

#7255 Peptide-based siRNA delivery for tumor-specific targeting of lactate dehydrogenase C.

A. Naik[1], H. Qasem[2], J. Decock[3];

[1]Carnegie Mellon University Qatar, Ar-Rayyan, Qatar, [2]College of Health and Life Sciences, Ar-Rayyan, Qatar, [3]Qatar Biomedical Research Institute, Doha, Qatar

Background: Breast cancer is the most common cancer worldwide and the leading cause of female cancer-related deaths, highlighting the pressing need for novel therapeutic interventions. Treatment of triple negative breast cancer in particular remains a challenge due to disease aggressiveness and the lack of durable treatment options. We speculate that targeting of Lactate Dehydrogenase C (LDHC) could be a novel approach given its highly tumor specific expression and immunogenic properties. We recently demonstrated that LDHC acts as a key regulator of the DNA damage response and tumor mitotic fidelity. Moreover, silencing of LDHC significantly improved treatment response to DNA damage response related anti-cancer drugs, highlighting its therapeutic potential for cancer precision medicine.
Methods: We characterized and evaluated several cell penetrating peptide-siRNA complexes for efficient silencing of LDHC in tumor cells using a 10R polyarginine peptide or bifunctional 10R-RGD, cRGD-10R or iRGD-10R peptides with tumor homing and penetrating abilities.
Results: Peptide-siRNA complex formation and tumor cellular uptake was confirmed using gel retardation assays and fluorescent confocal imaging. Biophysiochemical characterization and transmission electron microscopy revealed the complexes to be uniform in size with a low polydispersity index and positive zeta potentials. LDHC silencing in breast cancer cells using the peptide complexes demonstrated a 30-53% reduction in LDHC expression, with the 10R-siRNA and cRGD-10R-siRNA complexes showing the highest silencing efficiency. In 3D breast cancer spheroids, transfection with the 10R-siRNA complex resulted in a 20% downregulation of LDHC expression. Further analysis of the bifunctional-siRNA complexes in 3D cultures is ongoing as well as cytotoxicity analyses on non-cancerous cell lines.
Conclusions: Our findings demonstrate that peptide-mediated delivery of LDHC siRNA can reduce LDHC expression in 2D and 3D breast cancer cultures, suggesting that they could be used as a valuable approach for therapeutic intervention.

#7257 Examining the promise of precision medicine in immuno-oncology: Vectors for targeted therapeutic delivery.

C. Richardson, P. Rao, C. Koole, M. J. Karney, S. Kumar;
Azenta Life Sciences, Burlington, MA

At the forefront of therapeutic delivery is an array of vectors and targeting methods that hold immense promise for precision medicine. Vehicles such as viral vectors (AAV and lentivirus), lipid nanoparticles (LNPs) or liposomes, and peptide micelles each possess distinct and inherent properties, empowering researchers with tools to navigate the intricate challenges of specificity and efficiency in drug transport. Herein, we discuss and demonstrate design principles underpinning these vectors, elucidating their unique mechanisms for targeted delivery including:- A high-throughput viral packaging process to enable rapid downstream CRISPR or shRNA screening- Proprietary AAV plasmid synthesis and preparation techniques to maintain ITR integrity and improve gene delivery- Rapid synthesis, in vitro transcription, and novel sequencing of mRNA constructs for complete characterization of critical components such as the polyA tailBy synthesizing advancements in vector technologies, this poster serves as a roadmap for researchers and practitioners navigating the evolving landscape of targeted drug delivery in immuno-oncology.

#7258 Combinatorial effects of viral oncolysis and miRNA modulation as a novel therapeutic of pancreatic ductal adenocarcinoma.

M. Kanitz Ruschel, I. Davis, H. Mills, K. Gourishetti, D. Bhere;
University of South Carolina School of Medicine, Columbia, SC

Pancreatic cancer is a devastating illness that affects numerous individuals each year. Unfortunately, pancreatic ductal adenocarcinoma (PDAC) is an aggressive form of this disease that accounts for a disproportionate number of cancer-related deaths. Despite representing only 3.3% of all cancer cases in the United States, pancreatic cancer is responsible for a staggering 8.3% of cancer-related fatalities. In 2023, 64,050 patients were diagnosed with PDAC alone. Current treatment options, which are limited to surgery, radiation, and chemotherapy, have failed to improve clinical outcomes. Recent research has revealed miRNA (miR) as a contributor to the suppression and progression of various cancers, including PDAC. Specifically, dysregulation of miR-7 has been associated with PDAC. Downregulation of miR-7 is linked to more aggressive cases of the disease. Another potential therapeutic approach to treating cancer is the use of oncolytic viruses (OV). These viruses can replicate in cancerous cells while leaving healthy cells unharmed, making them an attractive treatment option. In this study, we utilized exosomes isolated from human Umbilical Cord stem cells (hUCs) enriched with miR-7 and combined with OHSV to examine their effect on established PDAC cell lines. We utilized cell viability assays, microscopy, and western blot analysis to evaluate the impact of the combinatorial approach on the underlying molecular mechanisms. Our findings suggest that the successful transfer of miR cargo and treatment with oHSV into the target PDAC cells arrested cell proliferation by targeting apoptotic pathways.

#7259 Effectiveness and comparison of CAR-T cell therapies for synovial sarcoma; HER2-targeted CAR-T and NKG2D-based CAR-T.

T. Miyazaki[1], C. Imai[2], N. Oike[1], Y. Murayama[1], T. Ariizumi[1], M. Baba[1], Y. Kasahara[3], H. Kawashima[1];
[1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [2]Toyama University Graduate School of Medicine, Toyama, Japan, [3]Niigata Cancer Center Hospital, Niigata, Japan

Introduction: In Japan since 2019, CAR-T cell therapy has been used to treat patients with relapsed or refractory B-cell acute lymphoblastic leukemia and diffuse large B-cell lymphoma and has shown excellent clinical results. Clinical studies of CAR-T cell therapies targeting various antigens, such as HER2, have been conducted, but the therapeutic outcome in sarcoma is still limited. We have previously reported that HER2-targeted CAR-T cells show antitumor effects for synovial sarcoma in vitro. The purpose of this study is to compare HER2-targeted CAR-T cells and NKG2D-based CAR-T cells in antitumor effect and specific responses for synovial sarcoma in vitro.
Materials and Methods: Surface expressions of HER2 and NKG2D ligands on three synovial sarcoma cell lines were detected by using recombinant human HER2 Fc chimeric protein and that of NKG2D, followed by staining with PE-conjugated anti-human IgG secondary antibody. We generated 4-1BB-type second generation CAR-T cells targeting NKG2D ligands and examined their antitumor effects and specific responses against synovial sarcoma cells. In addition, we compared the differences between HER2-targeted CAR-T cells and NKG2D-based CAR-T cells by co-culturing with synovial sarcoma cells using short-term assay (WST-8 assay), long-term assay (Real-time Cell Analysis) and CD107a assay.
Results: HER2 and NKG2D ligands were found to be expressed by flow cytometry in three synovial sarcoma cell lines. In vitro, NKG2D-based CAR-T cells showed antitumor effects against synovial sarcoma cells, including degranulation and cytokine production. Furthermore, NKG2D-based CAR-T cells showed stronger antitumor effects than HER2-targeted CAR-T cells in both short- and long-term assays and expressed higher levels of CD107a.
Conclusions: In this study, NKG2D-based CAR-T cells showed more antitumor effects than HER2-targeted CAR-T cells in vitro. Although the reason for this is not clear, we hypothesize that NKG2D ligands may be induced in synovial sarcoma cells by co-culture with CAR-T cells because HER2 is a cancer-specific antigen, whereas NKG2D ligands are ligands for activating receptors of natural killer cells. Further studies, including in vivo studies, will be conducted to verify the difference in anti-tumor effects between these CAR-T cells.

#7260 An HSV-1-based vector for local delivery of IL-12 and IL-2 reshapes the immune landscape leading to tumor clearance and systemic immune surveillance.

D. M. Previte, T. J. Parry, S. M. Krishnan;
Krystal Biotech, LLC, Pittsburgh, PA

Clinical use of recombinant interleukin (IL)-12 and -2 therapy has been hindered due to unfavorable kinetics and toxicity associated with systemic exposure. Durable targeted delivery to the tumor microenvironment (TME) is a promising therapeutic strategy to overcome these clinical limitations, prompting the development of KB707, a replication-defective herpes simplex virus type 1 (HSV-1)-based vector encoding human IL-12 and -2, for the treatment of solid tumors. Prior studies in mice demonstrated that local vector-encoded cytokine administration enhanced murine IL-12/IL-2 expression while limiting systemic exposure compared to conventional protein therapy. In a syngeneic, B16-F10 melanoma mouse model, intratumoral murine KB707-equivalent treatment led to improved survival in a unilateral tumor model and an abscopal effect in a bilateral tumor model. Additionally, the majority of previously treated animals survived rechallenge with B16-F10 in the absence of further therapy, indicative of systemic anti-tumor immune memory. Together, these results suggested that vector-mediated delivery of IL-12 and -2 could elicit both local and systemic anti-tumor immune responses. To elucidate the underlying changes to the immune landscape, B16-F10 tumor-bearing animals were treated intratumorally with vector or vehicle control on day 0 and were sacrificed on day 7; a second cohort of tumor-bearing animals received two vector doses (days 0 and 7) and were sacrificed on days 8, 10, 12, or 14. Immune cell profiling of samples taken from the tumor, tumor draining lymph node (dLN), spleen, and whole blood were analyzed by flow cytometry, and serum cytokine analysis was conducted by multiplex ELISA. Flow cytometric analysis of tumors revealed that vector treatment resulted in increased frequencies of proliferating and activated effector $CD8^+$ and $CD4^+$ T cells, peaking 24 hours post-second dose. These results correlated with high levels of the proinflammatory cytokines IFNγ and TNFα in the serum of vector recipient animals. The blood, spleens, and dLNs also showed increased frequencies of activated effector $CD8^+$ and $CD4^+$ T cells, peaking 24-72 hours post-second dose. Interestingly, although IL-2 alone has been shown to promote immune suppression and tumor outgrowth by mediating regulatory T cell (Treg) expansion and infiltration in certain contexts, the frequency of Tregs in treated vs. control tumors was substantially reduced after first and repeat dosing. Together, these results support a mechanism by which vector-driven local expression of IL-12 and IL-2 can expand and activate effector T cells both in the TME and systemically while simultaneously repressing Tregs, consistent with the previously described inhibition of primary tumor outgrowth, abscopal effects on secondary tumors, and prevention of recurrence observed with this therapeutic approach.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: YAP/TAZ/TEAD Modulators
Poster Session

#7264 OPN-9840, a non-covalent potent pan-TEAD inhibitor, exhibits single agent efficacy in preclinical malignant mesothelioma models.

P.-Y. Chen[1], B. Matusow[1], J. Tsai[2], P. Li[2], H. Nguyen[1], G. Habets[1], G. Bollag[1], S. Chowdhury[1];
[1]Opna Bio LLC, South San Francisco, CA, [2]Plexxikon Inc., South San Francisco, CA

The Hippo pathway regulates critical cellular processes during development. In ~10% of human cancers, Hippo pathway dysregulation results in YAP/TAZ overactivation and increased TEAD-dependent transcription that promotes tumor growth and therapy resistance - often by supporting drug-tolerant persister survival. In 40% of malignant mesotheliomas (MM), neurofibromatosis 2 (*NF2*) gene mutations inactivate the Merlin protein, an upstream negative regulator of TEAD. Preclinical studies indicate high TEAD dependency in *NF2*-mutant MM. We have discovered an array of potent covalent and non-covalent small molecule inhibitors that occupy the palmitate-binding pocket of TEAD proteins, with varying paralog selectivity profiles. OPN-9840 is an oral non-covalent pan-TEAD inhibitor displaying dose-dependent and on-target *in vitro* and *in vivo* efficacy for NCI-H226, an *NF2*-mutant MM cell line. OPN-9840 showed equivalent binding in thermal shift assays (10^{o}C delta Tm) for depalmitoylated TEAD1-4 proteins, and blocked TEAD reporter activity (IC_{50} 100nM) and NCI-H226 cell growth (IC_{50} 400nM). In an NCI-H226 xenograft model, OPN-9840 dosed orally for 14 days exhibited dose-dependent tumor growth inhibition (TGI) from 5 to 50 mg/kg PO (88 to >100% TGI) with tumor regression in the 15 (2/8 mice) and 50 mg/kg (4/8 mice) dose groups. qPCR of OPN-9840-treated tumors confirmed 50-70% downregulation of canonical TEAD targets, *CTGF* and *CYR61*. OPN-9840 shows a favorable safety profile, including a lack of cytotoxicity (IC_{50}>50µM) in HEK293T and HepG2 cells. Additionally, OPN-9840 caused no body weight loss in the NCI-H226 xenograft model following 14 days of dosing. *In vitro* evaluation of OPN-9840 in the blood-brain barrier (BBB) specific parallel artificial membrane permeability assay exhibited high BBB penetration potential (-Log P_e = 4.7). High oral exposure was achieved at all dose levels ($AUC_{0\text{-}24}$ > 100,000 h•ng/mL) after 14 days in the NCI-H226 study. We next investigated synergy between TEAD inhibition and targeted therapy in MM. Combined treatment of one of our pan-TEAD covalent compounds, OPN-9652 (from a separate chemical series to OPN-9840), at 50 mg/kg with 1 mg/kg trametinib resulted in NCI-H226 xenograft tumor regression (130% TGI) whereas trametinib alone only led to decreased tumor growth (74% TGI). RNA-Seq of treated tumors revealed that OPN-9652 and trametinib synergistically inhibited TEAD downstream target genes, including *ANKRD1* and *CTGF*. OPN-9652 as a single agent caused significant downregulation of E2F targets, such as *MYC* and *TP53*, suggesting decreased proliferation. In summary, OPN-9840 is a potent pan-TEAD inhibitor that shows monotherapy efficacy in MM. As we observed synergy between another pan-TEAD inhibitor, OPN-9652, with trametinib, we are exploring synergy of OPN-9840 with additional targeted therapies in tumor types beyond MM.

#7265 ETS-005, a highly selective TEAD4 palmitoylation inhibitor with potent anti-tumor activity and brain penetrating capability.

J. Lu, W. Du, M. Gao, X. Fan, J. Li, L. Feng, M. Wang, Y. Li, X. Zhong, W. Cui, Q. Zheng, **J. Zhu**;
ETERN Therapeutics Co., Ltd., WuXi, China

The Hippo pathway is a highly conserved network that regulates cell proliferation, tissue regeneration, and organ size by orchestrating YAP/TAZ-TEADs, the core effectors of signaling. Aberrant activation of YAP/TAZ has been implicated in tumorigenesis, tumor progression, metastasis and the resistance to targeted therapeutics, including MAPK and RTK inhibitors. Among the four TEAD paralogs, TEAD4 is found widely overexpressed in various solid tumors and potentially less associated with YAP/TEAD-related renal toxicity. Here we reported the identification of ETS-005, a highly selective TEAD4 small molecule inhibitor that shows preference for binding to the palmitoylation pocket of TEAD4 than other TEAD paralogs over 15 folds. ETS-005 displayed low nanomolar inhibition of cell proliferation in NF2 or LATS1/2 mutant mesothelioma in vitro, and robust anti-tumor efficacy in vivo. ETS-005 showed favorable oral availability, high brain penetration capability and broad safety window. Moreover, ETS-005 had relative long projected $T_{1/2}$ in human, supporting a more convenient clinical QD dosing schedule. Our study demonstrated that selective TEAD4 palmitoylation inhibitor ETS-005 exhibited potent anti-tumor activity as much as pan-TEAD palmitoylation inhibitors while may gain broader therapeutic index. Additionally, ETS-005 also exhibited profound synergistic effects in drug combination studies, offering broad opportunities combined with MAPK and RTK therapies. ETS-005 is currently in IND-enabling study and expected to enter Phase 1 in 2024.

#7266 *VGLL4* is the target of the 3p25 homozygous deletion and presents a novel therapeutic vulnerability for TEAD1/4 but not TEAD1 inhibitors.

F. Muller, S. Kunnimalaiyaan, P. Mangrolia, J. Olson;
Sporos Bioventures, LLC, Houston, TX

The Hippo pathway, a critical cell proliferation regulator, remains an underexplored oncogenic pathway in precision oncology. It is executed through YAP1/TAZ co-activators and the TEAD transcription factor family (TEAD1-4), driving expression of tumor-promoting genes. Palmitic acid site TEAD inhibitors have shown strong pre-clinical and clinical activity, but identification of genetic markers of vulnerability and patient selection remain an urgent and open question. Sporos undertook a broad bioinformatic analysis of Hippo pathway components and regulatory genes to identify genetic alterations that drive TEAD activity and potentially act as targetable vulnerabilities. Here, we present a key finding from this investigation. The 3p25 locus undergoes frequent homozygous deletion in solid tumors especially lung squamous cell carcinoma. While *VHL* was long assumed to be the target tumor suppressor gene of this deletion - we show that *VGLL4* is in the only gene in the peak of GISTIC statistically significance in lung squamous cell carcinoma and *VGLL4* and *ATG7* are both in the peak in Renal Clear Cell Carcinoma (RCC). These data unambiguously establish that *VGLL4* deletion is a major oncogenic driver in lung squamous cell carcinoma (SCC) and a contributor in RCC. Because VGLL4 is the major negative relator of the YAP/TEAD transcriptional complex and directly competes with YAP for TEAD binding - we hypothesize that Lung SCC with *VGLL4*-homozygous deletion would be uniquely dependent on YAP/TEAD activity and show selective sensitivity to TEAD inhibitors. While we were unable to locate a Lung SCC *VGLL4*-deleted PDX, we identified a *VGLL4*/*ATG7* homozygous deleted RCC PDX, KI2552, in the CrownBio collection. We show that treatment with SPR1, Sporos's novel TEAD1/4 inhibitor, decreases tumor growth and dramatically extends survival of mice bearing *VGLL4*/*ATG7*-deleted KI2552 RCC PDX. On the other hand, VT103, a strong TEAD1 inhibitor which shows comparable pre-clinical activity to SPR1 in the NCI-H226 mesothelioma CDX - did not show any activity in KI2552 PDX. These data emphasize the importance of targeting paralogs besides TEAD1 to broaden anti-neoplastic activity beyond mesothelioma and suggest that *VGLL4*-homozygous deletion confers TEAD inhibitor sensitivity even in carcinomas where it isn't the principal driver and portent exceptionally anti-neoplastic activity in neoplasms where it is. Given the wide distribution of the 3p25 homozygous deletion - our findings open a large new potential responder population to TEAD inhibitors and warrant inclusion of *VGLL4* in NSG diagnostic sequencing panels.

#7268 The SOS1 inhibitor MRTX0902 demonstrates activity across cancer models with mutations in proximal components of the RAS-MAPK pathway.

N. Sudhakar[1], L. Yan[1], F. Qiryaqos[1], J. Laguer[1], D. Briere[1], A. Hebbert[1], A. Calinisan[1], S. Coma[2], J. Pachter[2], J. G. Christensen[1], P. Olson[1], S. Khare[1]; [1]Mirati Therapeutics, San Diego, CA, [2]Verastem Oncology, Needham, MA

Genetic alterations in the RAS-MAPK pathway are one of the most frequent causes of human cancers. While targeted therapies are approved for patients harboring mutations in *KRAS* G12C in advanced or metastatic non-small cell lung cancer, there remains a need for an effective therapy for cancers characterized by additional RAS-MAPK pathway mutations across cancer types. Previous studies have shown that genetic or pharmacological inhibition of Son of Sevenless homolog 1 (SOS1) demonstrates antiproliferative activity in cancer cells addicted to KRAS signaling, including cell lines with oncogenic mutations in *KRAS, SOS1, PTPN11,* or *EGFR* or a loss-of-function mutation in *NF1*. These genetic alterations each function to increase SOS1-mediated GTP-loading of KRAS and increase signaling flux through the MAPK pathway. Inhibition of SOS1 by MRTX0902 is anticipated to shift the tumor cell equilibrium of KRAS towards the inactive GDP-bound KRAS, leading to MAPK pathway inhibition. MRTX0902 is a selective inhibitor of SOS1 under evaluation in clinical trials for the treatment of advanced, unresectable, or metastatic cancers with mutations in the KRAS-MAPK pathway. In the present studies, we have shown that MRTX0902 demonstrates single-agent anti-proliferative activity and modulates ERK1/2 phosphorylation (pERK) across a panel of human tumor cell lines harboring oncogenic mutations in *SOS1*, *PTPN11*, *BRAF* (class III) and *NF1*. Furthermore, oral administration of MRTX0902 as a monotherapy in preclinical human tumor cell-derived xenograft models harboring these oncogenic mutations results in significant tumor growth inhibition. Additionally, combination with the RAF/MEK clamp avutometinib demonstrated greater antitumor activity versus either monotherapy treatment. These data support the clinical utility of MRTX0902 as a single agent or combination partner of avutometinib for the treatment of human cancers harboring oncogenic mutations implicated in dysregulation of RAS-dependent signaling including *SOS1*, *PTPN11*, *NF1*, and *BRAF* (class III).

#7269 Karyopherin α-2, a nuclear export protein, promotes cancer progression in lung adenocarcinoma.

I. Cheon[1], **S. Kim**[2], S. Cho[1], H. Lee[3], J.-S. Yoon[4], J. Lee[3], S. Chun[5], H. Won[4], S. Hong[6], Y. Ko[3], Y.-H. Ahn[1];

[1]Department of Molecular Medicine and Inflammation-Cancer Microenvironment Research Center, College of Medicine, Ewha Womans University, Seoul, Korea, Republic of, [2]Seoul St. Mary's Hospital, Seoul, Korea, Republic of, [3]Eunpyeong St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of, [4]Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of, [5]Bucheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of, [6]Department of Pathology, College of Medicine, Chung-Ang University, Seoul, Korea, Republic of

Introduction: Karyopherin α-2 (KPNA2), a nucleocytoplasmic transport protein, regulates the nuclear import of macromolecules and contributes to carcinogenesis. Actually, KPNA2 is upregulated in various types of cancer tissues and serum from cancer patients. In particular, it is associated with cancer invasiveness and poor prognosis in patient. Here, we tried to present the molecular mechanism and clinical significance of KPNA2 in lung cancer progression and metastasis.

Method: First, we retrospectively analyzed the data extracted from EMR for patients with non-small cell lung cancer receiving curative surgical resection in Uijeongbu and Bucheon St. Mary's Hospitals (n=165). Immunohistochemistry staining was performed on the tumor microarray samples using antibodies against KPNA2. The functional assay and gene silencing was conducted.

Result: The clinical and pathological information of the experimental group is as follows. Based on the TMA staining, mean KPNA2 score was 36.5 [0-240] and median value was 10. Based on the TMA staining, patients with high KPNA2 expression were related to lymphatic invasion ($p = 0.00782$), advanced stage ($p = 0.0202$), and current smoker ($p = 0.0074$). KPNA2 expression was higher in squamous cell carcinoma than in adenocarcinoma histotype. Patients with high KPNA2 expression showed shorter survival than those with low KPNA2 (median OS (months), 72.8 vs 42.2, $P < 0.0001$; median RFS (months), 72.8 vs 32.1, $P < 0.0011$) and relevant to high recurrence (recurrence rate (%), 24.7 vs 44.7, $p = 0.007$). Further, high KPNA2 expression was associated with poor survival outcomes. Knockdown of KPNA2 in lung cancer cells suppressed the invasion and migration of lung cancer cells and inhibited metastasis in a mouse model of lung cancer. Inversely, KPNA2 overexpression promoted cancer cell growth, invasion, and migration. Moreover, ectopic expression of KPNA2 made lung cancer cells less sensitive to
anticancer drugs, Talazoparib and Olaparib, indicating that KPNA2 enhances drug resistance in lung cancer cells.

Conclusion: Collectively, this study suggest that KPNA2 promotes invasiveness and metastasis and is associated with poor patient outcomes; therefore, KPNA2 will be a good therapeutic target or a biomarker in lung adenocarcinoma.

#7270 Combination targeting of SKP2 and KDM5B induces senescence in castration-resistant prostate cancer cells via AKT signaling.

L. K. Brown, T. Kanagasabai, G. Li, S. I. Celada, Z. Chen;
Meharry Medical College, Nashville, TN

Prostate cancer (PCa) is the second-leading cause of cancer mortalities and morbidities in the United States and is the most commonly diagnosed malignancy in men. Despite the fact that androgen deprivation therapy is the first-line option to initial responses, most PCa patients invariably develop castration-resistant prostate cancer (CRPC). CRPC is a lethal type of malignancy, therefore, novel and effective treatment strategies are needed. The goal of this study was to evaluate the combination treatment of small molecule inhibitors, SZL-P1-41, a SKP2 target and PBIT, a KDM5B target on PCa growth and progression; as well as to delineate the underlying mechanisms of suppressing CRPC. Literature reports that S-Phase Kinase Associated Protein 2 (SKP2) is upregulated in PCa and Lysine-specific demethylase 5B (KDM5B) serves as a histone demethylase with a crucial role in cancers. Studies showed that KDM5B is increased in human PCa and KDM5B knockout decreases carcinogenic properties of PCa cells. We previously reported that SKP2 loss partially decreases the growth of prostate tumors and that KDM5B levels are reversely regulated by SKP2 in PCa cells. However, the mechanisms of KDM5B and SKP2 interplay on PCa malignancy is unknown. We hypothesize that combination of PBIT and SZL-P1-41 treatment will enhance anti-cancer effects on PCa progression by inducing cellular senescence. Here, we showed that inhibition of KDM5B and SKP2 decreased the proliferation of PCa cells, and KDM5B KO cells were more vulnerable to SKP2 inhibition. More importantly, a combined inhibition of KDM5B and SKP2 significantly blocked malignant progression and migration of PCa cells. Mechanistically, combined inhibition of KDM5B and SKP2 in PCa cells abrogated AKT activation, resulting in an induction of cellular senescence, which was measured via Western blot analysis and senescence-associated β-galactosidase (SA-β-Gal) staining. Taken together, our results show that combined inhibition of KDM5B and SKP2 is more efficacious in inhibiting proliferation and migration in CRPC cells, and this regimen would be an ideal therapeutic approach for treating CRPC.

#7271 Proteasome inhibitor FHND6091: A potent therapeutic candidate for*PTEN*-deficient cholangiocarcinoma.

Y. Zhu[1], J. Shi[2], C. Li[2];

[1]Jiangsu Chia Tai Fenghai Pharmaceutical Co.Ltd/ Nanjing Chuangte Pharmaceutical Technology Co., Ltd., Nanjing, China, [2]Nanjing Chuangte Pharmaceutical Technology Co., Ltd., Nanjing, China

Background: Cholangiocarcinoma (CCA), characterized by high genetic heterogeneity, poses a significant challenge due to limited therapeutic options. Notably, the tumor suppressor gene PTEN is frequently altered in more than 50% of CCA clinical specimens. PTEN deficiency enhances proteasome subunit expression and proteasome proteolytic activity, and facilitates the potential therapeutic efficacy of proteasome inhibitors in CCA. The proteasome inhibitor FHND6091, a novel drug developed by Jiangsu Chia Tai Fenghai Pharmaceutical Co., Ltd., has obtained IND approval from NMPA and is currently undergoing a first-in-human phase 1 trial for multiple myeloma (MM) and mantle cell lymphoma (MCL).

Method: This study employed a comprehensive approach, encompassing both in vitro and in vivo pharmacology studies. The investigation involved purified human proteasome activity assays, cell viability assays, and in vivo anti-tumor activity studies utilizing a cholangiocarcinoma patient-derived xenograft (CCA PDX) model with PTEN deficiency.

Results: FHND6091 exhibited potent inhibitory effects on the β5 subunit of the 20S proteasome, with IC50 value of 2.22 nM. In cell viability assessments, FHND6091 demonstrated selective efficacy in PTEN-deficient CCA cell lines, with IC50 value of 5.87 nM in HCCC-9810 (*PTEN* deletion, homozygous loss of exon 6 to 9) and 10.08 nM in RBE (*PTEN* intact expression). In a PDX xenograft model with PTEN deficiency, gavage administration of FHND6091 BIW at 1.0 mg/kg (first week) / 1.5 mg/kg (subsequent two weeks) exhibited advanced anti-tumor activity (TGI = 52.32%) compared to intraperitoneal administration of Bortezomib at 0.5 mg/kg BIW (TGI = 31.88%). Tissue distribution studies in rats revealed the preference of FHND6091 for liver accumulation, with an exposure (AUC0-t) approximately 44 times that of plasma after a single dose. These data corroborated that FHND6091 could achieve a specific level of exposure in the target organ liver.

Conclusion: FHND6091, characterized by its irreversibility, high potency and oral bioavailability, emerges as a promising proteasome inhibitor for the treatment of both hematologic and solid tumors. These findings strongly support FHND6091 as a potential candidate for the treatment of CCA in clinical settings. Furthermore, the regulating of sensitivity to proteasome inhibitors by the PTEN status extends beyond cholangiocarcinoma to encompass various human cancers, such as ovarian, prostate, and digestive system malignancies. This broader implication establishes a theoretical foundation supporting the potential efficacy of FHND6091 as a therapeutic agent for solid tumors.

#7273 Small molecule activation of PP2A in the treatment of melanoma.

H. Johnson[1], A. Singh[1], A. Raza[1], S. Narayan[2], A. K. Sharma[1];
[1]Penn State College of Medicine, Hershey, PA, [2]University of Florida, Gainesville, FL

Protein phosphatase 2A (PP2A) is a heterotrimeric holoenzyme functioning as a serine/threonine phosphatase, where it accounts for about 50-70% of all serine/threonine phosphorylation in the cell. Yet, PP2A is commonly inactivated in cancer, likely due to its role as a tumor suppressor. Due to the important role PP2A plays in many cellular processes, including those involved with tumor progression, there is a current need for novel therapeutics capable of targeting PP2A in cancer. Currently, none of the current PP2A modulators have made it into approved clinical use. As such, we have recently synthesized the PP2A activators, PPA24 and PPA27, using molecular docking and fragment-based drug design based on the structures of recently reported PP2A activators, iHAP1 and NSC49L. We were previously able to establish PPA24 as the lead compound in treating colorectal cancer (CRC) *in vitro*, compared to PPA27 and the parent compounds. Nevertheless, a single dose NCI-60 screen of both PPA24 and PPA27 indicated the cell selectivity present in both compounds and revealed the potential effect these compounds could have in other cancers. Further evaluation with an extended NCI-60 5-dose screen of PPA24 and PPA27 demonstrated a strong potential for both compounds in treating melanoma. Overall, the NCI-60 screen displayed PPA27 as most effective in melanoma across all cell lines screened, while PPA24 was found to be effective in both CRC and melanoma cell lines, agreeing with our previous findings. A cell viability screening of PPA24 and PPA27 in our laboratory across 5 melanoma cell lines (SK-MEL-2, SK-MEL-28, A375, Mel1241, and 451Lu) identified IC_{50} values in the range of 3.45-8.94 μM for PPA27 and 5.99-14.45 μM for PPA24. The parent compounds, iHAP1 and NSC49L, were also evaluated and NSC49L was found to be less effective in melanoma than previously found in CRC cells. Both PPA24 and PPA27 were found to be effective in cell lines with and without BRAFV600E mutation, though it appears the metastatic cell line, 451Lu, required an increased concentration for all compounds as compared to the IC_{50} values found in the other melanoma cell lines. Further evaluation revealed PPA24 and PPA27 as dose-dependently inducing apoptosis in cells with BRAFV600E (A375) and BRAF WT (SK-MEL-2). Together, these findings show the potential of PPA24 and PPA27 as therapeutic treatments for melanoma with or without BRAF mutations and are currently being further evaluated in several in vitro and in vivo melanoma models in our laboratory.

#7274 Optimization of intermittent dosing strategies of KRAS G12C inhibitors in preclinical lung cancer model.

Valeria Estrada Navarro, Vincent Panneton, Lauren Dong, Hyejin Choi, Divya Venkatesh, Rachana Maniyar, Isabell Schulze, Jedd D. Wolchok, Taha Merghoub

Sandra and Edward Meyer Cancer Center, Weill Cornell Medicine, New York, NY

Cysteine-binding targeted drugs AMG-510 and MRTX-849 provide a new therapeutic approach for advanced KRASG12C mutant cancers. However, clinical response has been limited. Responders eventually develop adaptive resistance by gaining additional MAPK pathway mutations, resulting in limited therapeutic benefit. High-dose pulsatile treatment with MAPK pathway inhibitors has been proposed as an alternative strategy to alleviate adaptive resistance while maintaining tumor control. The sensitivity of tumor cells to pan-inhibitors of the MAPK pathway, crucial for proliferation, creates a therapeutic opportunity window for immune cells to restore their function during an intermittent regimen. Congruently, we have previously shown that intermittent pan-MAPK pathway inhibitor treatment delays drug resistance, supports T cell activation, and enhances tumor delay when combined with immunotherapy. In this study, we investigated the effects of continuous and pulsatile KRASG12C inhibition on tumor and immune cells in order to design combinatorial strategies with immune-modulating agents that overcome drug resistance. Our data suggest that a weekly single high-dose regimen of AMG-510 is less effective at achieving tumor control in preclinical mouse models of KRAS mutant lung cancer compared to daily treatments. However, supplementing this pulsatile regimen with lower maintenance doses markedly slows the growth of LLC KRASG12C lung cancer. Flow cytometry analysis revealed that high-dose pulse regimen enhances T cell activation, evidenced by increased expression of TCF-1, Ki67, PD-1, and GITR, along with lower expression of co-inhibitory molecules Lag-3 and Tim-3, 3 days after treatment. In vitro, AMG-510 also improves the antigen presentation of OVA-expressing LLC-KML lung cancer cells via MHC class I and, to a lesser extent, MHC class II. Furthermore, we found that while combinatorial therapy with PD-1 blockade alone does not significantly impact tumor control, the combination with CTLA-4 blockade shows efficacy across pulsatile and continuous AMG-510 dosing cohorts. Overall, our findings suggest that the utilization of intermittent dosing regimens for selective KRASG12C inhibitors is a promising approach for improving clinical responses in lung cancers with KRAS mutations. Future experiments will aim to delineate MAPK pathway behavior in vivo and in vitro under pulsatile and continuous treatment, assess immunogenicity, and further characterize immune changes in the different treatment regimens, with the goal of designing more efficient cancer therapies utilizing selective KRAS inhibitors.

#7275 GS-P-328, a brain-penetrant small molecule p53 Y220C reactivator for tumors harboring p53 Y220C mutation.

M. Liu, K. Geng, B. Lu, **Y. Xia**, F. Yang;
Changchun GeneScience Pharmaceutical Co., Ltd., Changchun, China

As a tumor suppressor, p53 can prevent tumor development through multiple pathways. However, mutation of TP53 and the resultant inactivation of p53 allow evasion of tumor cell death and rapid tumor progression. The oncogenic Y220C mutation is the ninth most frequent p53 missense mutation in cancer. Y220C mutation creates a narrow, hydrophobic pocket on the surface of the p53 DBD that reduces its thermal stability. As a result, the Y220C mutation causes a rapidly unfold of the p53 protein under physiological conditions, abrogates p53 signaling and drives tumorigenesis. There are approximately 100,000 new Y220C mutation cancer cases per year worldwide with limited treatment choices. The initial clinical evaluation of PC14586 that can restore missense-mutant p53 protein has seen efficacy in patients harboring p53 Y220C mutation even though there is still room for improvement. Here we report a brain-penetrable, highly potent p53 Y220C reactivator which has great *in vitro* activity as well as induce tumor shrinkage in multiple tumor models at a much lower systematic exposure comparing to PC14586. *In vitro*, GS-P-328 could bind to p53 Y220C protein with a single nM potency and potently induce cell death in a wide range of p53 Y220C tumor cells while have no anti-proliferative effects with p53 WT cells. GS-P-328 is also active in patient-derived cell (PDC) models in various tumor background including SCLC, gastric, ovarian and colon. *In vivo*, GS-P-328, at approximately 1/3 of systematic exposure comparing to a leading clinical reactivator, causes tumor shrinkage in multiple CDX models. GS-P-328 could induce MDM2/p21 upregulation in cell systems. *In vivo*, GS-P-328 could induce 2 fold and more increase in MDM2/p21 protein levels in tumor tissues at approximately 1/3 of plasma concentrations comparing to PC14586. More importantly, in a NUGC3-luc intracranial model, GS-P-328 could strongly inhibit growth of cancer cells in the mouse brain. GS-P-328 has a favorable ADME profile in rodents, dogs and NHPs, as well as a much better safety profile. GS-P-328 is now under IND-enabling study and P1 study is planned in early 2025.

#7276 Potent anti-proliferative activity of brincidofovir in Diffuse Large B-cell Lymphoma with overexpression of transcriptional repressor TLE1.

J. Lee[1], T. Ko[2], E. Lee[2], B. Kannan[2], B. Lim[2], Z. Li[2], Z. Guo[2], J. Loh[1], C.-Y. Ng[2], K. Chai[2], N. Binte Muhammad Taib[2], K. Lim[2], D. Huang[2], J. Lim[2], M. Hazama[3], K. Fukushima[3], B. Teh[2], S. Lim[2], C. Ong[2], J. Chan[2];

[1]Duke-NUS Medical School, Singapore, Singapore, [2]National Cancer Centre Singapore, Singapore, Singapore, [3]SymBio Pharmaceuticals Ltd, Tokyo, Japan

Introduction: Brincidofovir (BCV) is a biologically-active acyclic nucleoside phosphonate and clinically-approved anti-viral agent. Recently, BCV has been demonstrated to display potent anti-proliferative and immunogenic properties in NK/T cell lymphoma (NKTCL). However, its effect on other lymphoma types remain unclear.

Methods: We investigated BCV in an expanded cohort of B-cell lymphoma cell-lines (diffuse large B-cell lymphoma [DLBCL], n = 16; Burkitt lymphoma, n = 2; Hodgkin lymphoma, n = 1), in comparison with NKTCL cell lines (n = 11). Mouse xenograft models were deployed to assess *in vivo* effects. Whole transcriptomic sequencing (RNAseq) was performed to examine Epstein-Barr virus (EBV) status and explore potential mechanisms of action.

Results: BCV inhibited viability in all B-cell lymphoma cell-lines in a dose-dependent manner (IC50 0.0798 to 8.414 µg/ml). Marked sensitivity (IC50 < 1 µg/ml) was demonstrated in nine cell-lines, including the *MYC*/*BCL2*-rearranged double-hit DLBCL cell-line OCI-LY18 (IC50 0.5 µg/ml). Intraperitoneal BCV (40 mg/kg, 2X per week) inhibited tumor growth in NOD/SCID mice OCI-LY18 xenografts, compared with vehicle alone ($p < 0.001$, two-tailed t-test). RNAseq showed that most cell-lines (n = 16) were EBV negative. Interestingly, the transcriptional repressor *TLE1* was amongst the top upregulated genes in the BCV-sensitive cell-lines (log2foldchange = 8.12, adjusted $p = 0.0004$). DLBCL patient samples from two independent datasets showed that *TLE1*-high tumors conferred worse overall survival (GSE11318, n = 200: HR 2.77, 95%CI 1.78 to 4.30, $p < 0.0001$; GSE10846, n = 414: HR 1.94, 95%CI 1.35 to 2.80, $p = 0.0004$). Gene set enrichment analysis showed that pathways involved in oxidative phosphorylation and oncogenic signaling were significantly upregulated in the BCV-resistant cell-lines compared to the rest. Notably, these findings are in stark contrast to NKTCL, in which TLE1 loss instead confers BCV sensitivity *in vitro* and is associated with poor survival outcomes in patients (n = 36; HR 3.44, 95% CI 1.23-10.49, $p = 0.0301$).

Conclusions: Taken together, these results suggest that BCV may be a potential novel therapeutic agent for the treatment of B-cell lymphomas. Further work will be required to investigate the role of TLE1 and other molecular features as potential predictive biomarkers.

#7278 Discovery of a novel WRN inhibitor, ZM-3329 that efficiently inhibits MSI-H tumor growth.

F. Zhou[1], G. Yang[1], Y. Liu[2], L. Xue[1], Y. Guo[2], Z. Li[1], W. Wang[2], J. Li[2], R. Tang[1];

[1]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China, [2]Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Microsatellite instability-high status (MSI-H) is typically associated with endometrial and gastrointestinal cancers. These tumors harbor large numbers of frameshift and single-nucleotide variants and are characterized by a high tumor mutational burden (TMB). The clinical benefits of immune checkpoint inhibitor (ICI) therapy on MSI-H cancers were well-demonstrated, however, 50% of these cancers are intrinsically resistant to PD-1 therapies and resistance inevitably develops with prolonged treatment. Thus, a novel efficient therapeutic strategy for MSI-H cancer is still needed. Werner syndrome ATP-dependent helicase (WRN) is a member of the RecQ helicases family and has recently emerged as a promising synthetic-lethal target in the treatment of MSI-H tumors. In MSI-H tumors, microsatellite sequences consisting of repeated nucleotides are unstable, and replication slippage causes a unique secondary structure that hinders the progression of replication forks. With its helicase activity, WRN unwinds this secondary structure to restart DNA synthesis and sustain MSI-H tumor cell growth. WRN knockdown or helicase enzyme-dead effectively inhibits cell proliferation and tumor growth in multiple preclinical MSI-H models. Here we identified ZM-3329, a novel and highly potent WRN inhibitor. Helicase activities were efficiently inhibited by ZM-3329 with IC_{50} less than 30 nM, and equal potency was identified on HCT-116 cell proliferation inhibition. In a panel of 124 tumor cell lines, ZM-3329 only specifically inhibited the growth of MSI-H but had no significant effects on the MSS (Microsatellite stable) tumor cell lines, indicating high selectivity against MSS. Additionally, ZM-3329 strongly inhibited the growth of MSI-H patient-derived organoids. The intracellular mechanism of action study revealed that inhibition of WRN by ZM-3329 in MSI-H cells led to the accumulative DNA damage signatures which was demonstrated by the increase of γH2AX and P21 expression, and arrested cell cycle to G2/M. ZM-3329 demonstrated favorable pharmacokinetic profiles in pre-clinical species, supporting oral administration in humans. ZM-3329 showed robust anti-tumor activities in multiple MSI-H xenograft models with significant tumor regression observed. Meanwhile, mice were tolerant well in all tested doses, and no abnormality was observed. In conclusion, a novel WRN inhibitor was developed, and robust antitumor activities were demonstrated in xenograft tumors and PDOs with different tissue types. In terms of synthetic lethality between MSI-H and WRN as well as broad anti-tumor activities across different tumor types, ZM-3329 would be developed as a tissue-agnostic therapy for MSI-H patients.

#7279 Discovery of SHR1127, an orally bioavailable, highly potent and selective KRAS G12D inhibitor.

X. Li, F. Shen, L. Zhang, W. Wang, L. Kong, Y. Bao, Y. Mao, Z. Wang, S. Lin, Z. Zhang, J. Feng, M. Hu, F. He;
Shanghai Hengrui Pharmaceutical Co., Ltd., Shanghai, China

Mutant KRAS is the most frequent oncogenic driver in nearly 23% of human cancers. As the most common KRAS alteration, KRAS G12D mutation occurs in approximately 35%, 13%, and 4% of pancreatic, colorectal, and non-small cell lung cancers, respectively. It was worth noting that the clinical PoC of KRAS G12D inhibitor has been preliminarily validated by intravenous administration of HRS-4642 weekly. However, there still represents an extraordinary unmet clinical need requiring an oral KRAS G12D inhibitor featuring higher potency and favorable pharmacokinetic profiles. We disclose herein the development of an orally bioavailable, highly potent and selective KRAS G12D inhibitor, SHR1127.SHR1127 demonstrated picomolar binding affinity, with a K_D value of 0.06 nM in a SPR binding assay with GDP-loaded KRAS G12D protein. SHR1127 significantly inhibited ERK phosphorylation with IC_{50}s of 0.05 nM and 0.19 nM in GP2d and AGS cell lines, respectively. More importantly, 3D viability assay showed that SHR1127 displayed extremely high anti-proliferative activity against GP2d, AGS and AsPC-1 cell lines with the IC_{50}s of 0.05, 0.83 and 0.92 nM, respectively. The selectivity over KRAS WT PC9 cells, KRAS G12C and G12V mutant cell lines was more than 500-fold. Additionally, SHR1127 displayed excellent human hepatocyte stability ($T_{1/2}$ > 1000 min) and desirable physicochemical properties. Moreover, SHR1127 exhibited favorable pharmacokinetic profiles with dose-dependent exposure and acceptable oral bioavailability. In the GP2d xenograft model, SHR1127 showed a robust anti-tumor activity in a dose-dependent manner, leading to tumor regression (TGI = 125%) as low as 5 mg/kg (p.o. dosage, bid), without body-weight loss during 21 days of treatment. Furthermore, SHR1127 demonstrated no off-target activities at 1000 nM in 97 kinase panel and 78 safety panel screening. SHR1127 showed good safety window in the 14-day toxicology study in rat and dog.

In summary, SHR1127 has been successfully developed as an orally bioavailable KRAS G12D inhibitor, exhibiting excellent cellular activities with good selectivity over KRAS WT. More importantly, SHR1127 showed favorable pharmacokinetic profiles across species, and robust tumor regression in a GP2d xenograft model at the dose of 5 mg/kg. In addition, SHR1127 demonstrated no off-target toxicity and good safety window. An IND submission for SHR1127 is planned in the first half of 2024.

#7280 Potential activity of TEAD inhibitor in Hippo-altered cancer including NF2 mutant solid cancer and TAZ-CAMTA1 fusion-driven epithelioid hemangioendothelioma (EHE).

J. Byun, S. Jung, H. Moon, S. Lim, S. Park, S. Baek, Y.-Y. Kim, J. Park, J. Kim, S. Lee, Y. Ahn;
Hanmi Pharmaceutical Co., Ltd., Seoul, Korea, Republic of

The Hippo pathway, a conserved signaling, modulates diverse processes including cell proliferation, survival, differentiation, organ size, and tissue homeostasis. The core kinases, MST1/2 and LATS1/2 phosphorylate downstream effectors, YAP/TAZ, and sequestrate them in cytoplasm[1)]. The upstream regulator, NF2 activates these kinases and its loss-of-function mutation leads to YAP nuclear translocation, which in turn promotes tumorigenesis[2)]. Dysregulation of Hippo pathway triggers constitutive YAP/TAZ accumulation and binding to TEAD family that upregulate prosurvival target genes such as CTGF and CYR61[1)], which are deeply associated with drug resistance and tumor microenvironment[3)].

TEADs, a transcription activation complex with primary key partners of YAP/TAZ, function in response to the Hippo altered-pathway[4)]. Although a number of reports in the area of small molecules targeting YAP/TAZ-TEAD complex is exponentially increased, there is a lack of understanding regarding how TEAD subtypes may contribute to cancer progression. Moreover, TAZ-CAMTA1 gene fusion is a driver oncogene expressed in more than 90% of epithelioid hemangioendothelioma (EHE), a vascular sarcoma[5)]. Here, we explore the potential of anti-cancer efficacy on our established TAZ-CAMTA1 fusion-driven EHE model. Our TEAD inhibitor effectively suppressed TEAD reporter activity in MCF7-TEAD-luc cells and induced 10~100 nM range of growth inhibition in NF2 or LATS mutant mesothelioma by disrupting YAP-TEAD1/3 protein-protein interactions (PPI). We found that knockdown TEAD1 as well as TEAD3 downregulate growth ability of NF2 altered solid cancer cells such as LOU-NH-91 and YD8.

Our TEAD inhibitor, showing TEAD1/3 isoform specificity, exhibited a superior anti-proliferative effect in broader range of Hippo-altered solid cancer cells than of selective TEAD1 inhibitor. This highlights the importance of targeting TEAD1 and suggest that TEAD3 inhibition can enhance anticancer effects.

We established the TAZ-CAMTA1 fusion-expressing cells, demonstrating its oncogenic function through increased anchorage-independent growth and upregulation of TEAD target genes, CTGF and CYR61, compared to parental NIH3T3. Our TEAD inhibitor suppressed TAZ-CAMTA1 fusion-TEAD1 PPI in NanoBRET system. It also inhibited TAZ-CAMTA1 driven colony formation. Our inhibitor more greatly prevented the growth of TAZ-CAMTA1 expressing NIH3T3 cells than parental cells and exhibited mRNA expression inhibition of CTGF and CYR61 on qRT-PCR, showing superior effects compared to the selective TEAD1 inhibitor.

In conclusion, we emphasize the importance of TEAD inhibition for the treatment of Hippo-altered cancers including NF2 mutant solid cancer and TAZ-CAMTA1 fusion-driven EHE, highlighting the advantages of our TEAD1/3 inhibitor over the selective TEAD1 inhibitor.

#7282 Comparing TEAD palmitoylation inhibitors with differential TEAD selectivity in combination efficacy with targeted therapies and in renal safety.

T. T. Tang, L. Post;
Vivace Therapeutics, San Mateo, CA

Genetic alterations of the Hippo signaling pathway components resulting in YAP/TAZ activation have been reported in a variety of human malignancies. YAP/TAZ activation and functional requirement have also been linked to resistance to targeted therapies by providing the essential survival signal in drug-tolerant persister/dormant cells. As the main drivers for YAP/TAZ recruitment to chromatin, TEAD transcription factors are the major effectors of the Hippo-YAP/TAZ pathway involved in the regulation of cell proliferation, survival, and cell migration. There are four members in the TEAD family: TEAD1, TEAD2, TEAD3, and TEAD4. All four members have a conserved cysteine residue that gets auto-palmitoylated and a highly conserved central pocket in which the palmitate is buried. TEAD auto-palmitoylation is required for TEAD interaction with coactivator YAP/TAZ and transcriptional activity. We have discovered and developed highly potent and selective TEAD auto-palmitoylation inhibitors that interact directly with TEAD by occupying the central palmitate pocket, disrupt YAP/TAZ-TEAD protein interaction, suppress TEAD transcriptional activity, and selectively block *NF2*-deficient mesothelioma proliferation *in vitro* and inhibit *NF2* mutant tumor growth *in vivo*. One of these compounds, VT3989, is being evaluated in an ongoing phase 1 clinical trial, where partial responses in mesothelioma patients have been demonstrated, showing for the first time that the Hippo pathway is druggable and that the Hippo pathway is now a validated target for cancer therapy. It remained a question, however, which TEAD members are more important and whether it would be safer and as efficacious to inhibit one TEAD member than multiple TEAD members. Thus, we utilized our TEAD inhibitors with differential TEAD selectivity to determine the importance of TEAD1 selectivity in anti-tumor efficacy and in renal safety. We evaluated the anti-tumor efficacy of several potent TEAD1-selective and pan-TEAD inhibitors in *in vivo* combination studies using EGFR mutant / KRAS mutant xenograft models. We found that TEAD1-selective TEAD palmitoylation inhibitors are less efficacious than pan-TEAD/multiple-TEAD inhibitors in combination studies with targeted therapies (as such EGFRi and KRASi). In 14-day/28-day rat studies, TEAD1-selective TEAD inhibitors also exhibited proteinuric nephropathy similar to that observed with pan-/multiple-TEAD inhibitors. Therefore, based on our findings, we can conclude that TEAD1-selective TEAD palmitoylation inhibitors can have similar on-target effect on kidneys as TEAD inhibitors with broader TEAD selectivity while having reduced anti-tumor efficacy and durability of response in combination with targeted therapies.

PREVENTION / EARLY DETECTION / INTERCEPTION: Secondary and Tertiary Cancer Prevention Studies and Patient Communication Decision Making

#7286 Optimizing prediction of metastatic castration-resistant prostate cancer: Multimodal fusion of clinicopathological and genomic features with machine learning.

Mohammad K. Alexanderani, Francesca Khani, Matthew Greenblatt, Brian Robinson, Massimo Loda, Luigi Marchionni

Weill Cornell Medicine, New York, NY

Background: Transitioning from metastatic castration-sensitive prostate cancer (mCSPC) to its resistant variant poses risks of intensified medication, toxic side effects, and financial burdens for men undergoing treatment. Our study proposes a multimodal approach that integrates clinical, pathological, and genomic features to optimize prediction of metastatic castration-resistant prostate cancer (mCRPC) events. By applying machine learning (MML) techniques to multimodal data, we aim to stratify these patients based on the risk of developing mCRPC, contributing to the development of safer and personalized treatment strategies.
Methods: We analyzed a large cohort of patients with mCSPC (n=399) with a minimum of 36 month follow-up, annotated with clinical, pathological, and genomic features, encompassing relevant variables such as disease volume, PSA, metastases timing, variant classification, Grade Group, fraction of genome altered, MSI score, mutation counts, karyotypes, tumor mutational burden, and purity. Using a multimodal machine learning framework, we extracted informative features and employed eight distinct machine learning algorithms: K-Nearest Neighbor, Support Vector Machine, Decision Tree, and Logistic Regression, Support Vector Machine with RBF Kernel, Random Forest, and Gradient Boosting, in addition to a Deep Neural Networks architecture for building predictive models in supervised binary classification experiments. The models' performance was evaluated on separate training (80%) and testing sets (20%), and standard evaluation metrics, such as the area under the receiver operating characteristic curve (AUROC), and accuracy, were computed. Correlations were utilized to explore the relationships between features, and permutation analysis was employed to determine the importance of predictors. All raw data included in the analysis are available on *cBioPortal* database. The study is supported by the NIH-NCI-T32 for Next Generation Pathologists Program at our institution.
Results: Of the 399 mCSPC patients, 56% developed castration resistance, 50% had Grade Group 5 disease, and 69% exhibited missense mutations. In a series of 8 experiments, the Support Vector Machine with RBF Kernel ensemble model and SVC exhibited the highest performance with an AUROC score of 0.77, while the remaining models tested in the study demonstrated AUROC scores ranging from 0.62 to 0.75. Notably, the fraction of altered genome emerged as the top-ranked predictor, displaying the highest importance score.
Conclusions: Our study demonstrates the strong predictive performance of MML models in accurately identifying mCRPC events by leveraging routine clinical, pathological, and genomic data, offering valuable guidance for optimizing patient stratification and tailoring personalized therapeutic interventions.

#7287 High-grade serous ovarian carcinoma detected with *TP53* mutation panel and SiMSen-Seq.

A. Olsson Widjaja[1], P. Micallef[2], B. Ulfenborg[3], M. Lycke[1], U. Gyllensten[4], T. Carlsson[2], T. Osterlund[5], A. Stahlberg[5], A. Linder[1], K. Sundfeldt[1];
[1]Institute of Clinical Sciences, Gothenburg, Sweden, [2]Institute of Biomedicine, Gothenburg, Sweden, [3]School of Bioscience, Skovde, Sweden, [4]SciLifeLab Uppsala, Uppsala, Sweden, [5]Wallenberg Centre for Molecular and Translational Medicine, Gothenburg, Sweden

Background: Ovarian carcinoma (OC) has the highest mortality among gynecologic malignancies due to absent or unspecific symptoms. The high-grade serous ovarian carcinoma (HGSC) accounts for over 60% of the OC associated deaths. The most frequent genetic aberrations in HGSC are mutations in the *TP53* gene, detected in approximately 96% of the tumors. Previous studies have proposed potential diagnostic utility of detecting mutations in circulating tumor DNA (ctDNA) from OC patients. However, the need for diagnostic methods capable of detecting asymptomatic HGSC is unmet.
Objectives: The primary aims of this study were to design a screening tool for identification of HGSC and to evaluate the suitability of various clinical specimen types for diagnostic applications.
Methods: In this study, we designed a highly sensitive and robust screening tool using the simple, multiplexed, PCR-based barcoding of DNA for sensitive mutation detection using sequencing (SiMSen-Seq) technique for identification of HGSC (n=11) by *TP53* mutation profile in various clinical specimen for diagnostic applications. Specimens sampled included primary tumors, ascites, plasma, vaginal samples, and both liquid and solid samples from cyst-, endocervical-, and endometrial origin (n=94).
Results: The in-house designed panel amplified 17 regions, encompassing 619 nucleotide positions within the *TP53* gene. Pathogenic variants were identified in 10/11 of the primary tumors, with a VAF ≥ 9% (range: 9-91). Preliminary data indicated that all (100%) paired samples obtained corresponding somatic mutations between two or more of the different compartments from the same patient.
In total 10/10 ascites-, 16/16 cyst-, 8/8 plasma-, 5/8 vaginal-, 17/22 endocervical-, and 14/19 endometrial samples showed somatic variants at a consensus read depth of 3 and a minimum VAF ≥ 0.1%.
Conclusion: The present study suggests that the *TP53* mutation panel can identify somatic variants in a variety of non-invasive liquid biopsies. Additionally, the assessment of the *TP53* mutation panel exhibits potential for forthcoming clinical utilization as a diagnostic tool.

#7288 Evaluation of silica spin-column and bead formats for rapid promoter DNA methylation analysis by qMSP in clinical and point-of-care settings.

F. Zamuner[1], A. Ramos-Lopez[2], A. Garcia-Negron[2], A. Purcell-Wiltz[3], A. Cortes-Ortiz[3], A. Roman[2], K. Gosala[1], E. Winkler[1], D. Sidransky[1], M. Brait[1], R. E. Guerrero-Preston[2];

[1]Johns Hopkins School of Medicine, Baltimore, MD, [2]LifeGene BioMarks, Toa Baja, PR, [3]San Juan Bautista School of Medicine, Caguas, PR

Late-stage cancers often lack effective management and treatment options, emphasizing the importance of early diagnosis for better prognosis and lower mortality rates. Molecular markers, such as DNA methylation tests, have shown promise in predicting and detecting cancer at its earliest stages. The COVID-19 post-pandemic scenario is providing a one in one-hundred-year opportunity of utilizing the excess installed PCR capacity world-wide to develop novel Quantitative Methylation Specific PCR (qMSP) screening strategies for cervical cancer screening in low-resource settings. This study aimed to compare the use of commercial bisulfite conversion kits in cervical epithelium liquid cytology samples (liquid cytology) from cancer screening clinics in the United States. Commercially available rapid bisulfite conversion protocols using silica spin column and magnetic beads were compared with conventional DNA extraction followed by bisulfite conversion protocols to profile DNA methylation by qMSP in a panel of methylated genes we previously developed to distinguish normal and cervical cancer patient samples. The results revealed that small sample volumes are suitable for methylation studies. Comparisons among four spin-column kits showed no significant differences in *β-actin* Cycle Threshold (Cts) values between Abcam, Epigentek, QIAGEN and Zymo D5021 kits. Zymo The best performing spin-column kit was compared with manual and automated versions of magnetic bead kits using a 96-well plate format for higher throughput. Methylation profiling of three genes (*β-actin ZNF516,* and *FKBP6*) with manual and automated magnetic bead kits revealed that automation increases throughput without a reduction in amplification efficiency in open PCR systems. Cost analysis showed that the direct kits 96-well plate format were more affordable compared to the Gold Standard manual protocol that uses spin-columns. An optimized version of Zymo D5046 magnetic bead kit provides the fastest turnaround time with similar amplification efficiency, when compared to spin-column or other magnetic bead kits. The test cost per sample is $5.41 dollars to process 83 samples in a 96 well-plate format in less than 2 hours. Another significant finding was showing the feasibility of using as low as 12µL of liquid cytology samples for DNA methylation testing, proving that bodily fluids are a liquid biopsy alternative to plasma. Overall, this comprehensive comparison is useful in determining optimal options for efficient and cost-effective cancer DNA methylation diagnostic tests, particularly in low-resource settings.

#7289 PancreaAlert: Intelligent nanoengineered biosensor for pancreatic cancer.

Meenal Karunanidhi[1], Hemalatha Kanniyappan[1], Edith Zhan[2], Ruth Mathew[3], Yani Sun[3], Junyi Wu[4], Yan Yan[4], Gnanasekar Munirathinam[1], Mathew T. Mathew[1]

[1]University of Illinois College of Medicine (Rockford), Rockford, IL,[2]Hononegah High School, Rockton, IL,[3]University of Illinois Chicago, Chicago, IL,[4]IIT, Chicago, IL

Introduction: Pancreatic cancer accounts for 3% of cancer cases and 7% of cancer deaths in the United States. It is currently in the third position with respect to cancer-related deaths, and it is expected to move to second place as of 2040. This is mainly due to its diagnosis in the later stage. If detected in the first or second stage surgery can be performed thus increasing the patient's survival rate. The current methods of diagnosis cannot do early stage or asymptomatic detection. So, detecting cancer-specific biomarkers can aid in the prognosis. Serum protein-based biomarkers carbohydrate antigen CA242, CA19-9, and carcinoembryonic antigen CEA are specific to pancreatic cancer. Thus, in this preliminary study, we aim to develop a nanoengineered electrochemical biosensor combined with machine learning to detect pancreatic cancer-specific biomarkers CA242, CA19-9, and CEA.
Methodology: Nanoengineering the biosensor: The gold working electrode of the gold- biosensor (DRP-250AT) was coated with graphene oxide nano colloidal solution and kept in UV overnight for the graphene oxide nanosheet to crosslink with the working electrode. Detection of biomarkers using an electrochemical biosensor: First, a Crosslinker (DSP) was added to ethanol cleaned biosensor to bind the analytes. Following that antibody specific to each biomarker were added to the biosensors. The addition of TBS superblock prevented non-specific binding. Then different concentrations of biomarkers were added, and the corresponding sensor was subjected to various electrochemical analyses such as electrochemical impedance spectroscopy and voltammetry. SEM-EDAX analysis: The antigen-antibody binding on the biosensor's surface was confirmed. Automation and machine learning: Python code was developed to automate the analysis process and machine learning models (support vector machine and neural network) were used to classify the concentrations into various risk levels. The sensitivity of the developed tool was high when compared with conventional methods like ELISA and confocal microscopy.
Results: From the electrochemical studies we found that with increasing concentration of biomarkers, there was a trend in output parameters: capacitance, resistance, impedance and area under the curve. By analyzing this trend, the concentrations of biomarkers can be detected. Using this data as input the machine learning model (accuracy greater than 80%) classified the concentrations into risk levels (normal, low risk, and high risk).
Significance: Nanoengineering with graphene oxide nanosheets enhances the sensitivity of electrochemical biosensors. Automation and machine learning models help in the analysis of large datasets produced by this sensor. Overall, this device aids in the prognosis of pancreatic cancer. Our preliminary results are encouraging but more thorough research is required to make this diagnostic tool a working application.

#7290 Novel plasmid-based screening method for cervical cancer.

A. Eli, Y. Hartman, B. B. Kasten, R. Arend, J. Warram;
University of Alabama at Birmingham, Birmingham, AL

Introduction: Alabama (AL) is tied for third-highest incidence rate and has second-highest death rate of cervical cancer as of 2020. Globally, cervical cancer has the fourth-highest incidence among cancers in women; 90% of deaths from cervical cancer in 2020 occurred in low- and middle-income (LMIC) countries. Inhibitor of differentiation/DNA binding 1 (Id1) expression correlates with tumorigenesis, clinical grade/stage, and aggressiveness of cervical cancer. Thus, Id1 expression could be exploited in novel screening approaches that aim to improve survival rates of cervical cancer in LMIC and clinically underserved settings. As a first step in developing an Id1-based screening approach, these preclinical studies utilized a plasmid that induces expression of a secreted reporter enzyme (secreted embryonic alkaline phosphatase, SEAP), controlled by the Id1 promoter sequence (pId1-SEAP). These studies examined relationships between Id1 expression and kinetics of reporter expression following plasmid transfection to detect human cervical cancer cells.
Methods and Results: To confirm the relevance of Id1 as a target in cervical cancer, immunohistochemical staining for Id1 was performed on a human cervical cancer tissue microarray. Western blotting was performed to determine Id1 expression in human cervical cancer cell lines (HeLa, SiHa, CaSki). Optimal transfection conditions with pId1-SEAP were determined experimentally for each line, and then media was sampled through a 48-hour period post-transfection to quantify reporter SEAP expression. Immunohistochemical stain for Id1 showed that early stage and late stage human cervical cancer tissues expressed significantly ($p < 0.05$) higher levels of Id1 compared to normal tissues, with stain optical density values being 3e5±1e5 for early and late stage compared to 3e4±3e4 for normal tissues (early stage p=0.0001, late stage p=0.0002). Western blot for Id1 in HeLa, SiHa, and CaSki lines showed that all three positively expressed Id1, with Beta-actin-normalized expression values of 0.78±0.12, 1.12±0.05, and 0.76±0.08, respectively. The cell lines transfected with pId1-SEAP expressed SEAP at rates significantly higher than control cells, with the highest rates of production seen during the 36-48-hour post-transfection period. Rates of SEAP production (counts/hour) during this time period were 1e4±3e3 (p=0.0278), 8e2±1e2 (p=0.0834), and 3e2±5e1 (p=0.0683) for transfected HeLa, SiHa, and CaSki cells, respectively.
Conclusions: The pId1-SEAP system enabled sensitive detection of cervical cancer cells. These preliminary data support future studies evaluating the *in vivo* performance of the system in preclinical models of early stage cervical cancer. Further development of this approach could enable sensitive and reliable detection of cervical cancer during early stages when treatment is most effective.

#7291 Detection of a truncated form of multidrug resistance protein 1 (MRP1) in plasma sEVs derived from cancer patients.

K. Bhandari, J. Kong, C. Xu, A. Jain, W.-Q. Ding;
University of Oklahoma Health Sciences Center, Oklahoma City, OK

Multidrug resistance protein 1 (MRP1/ABCC1) is an ATP dependent transmembrane efflux pump that confers to drug resistance. Overexpression of MRP1 has been observed in both pancreatic ductal adenocarcinoma (PDAC) and breast cancer tissues. Numerous proteomics studies have revealed the presence of MRP1 in small extracellular vesicles (sEVs) released from cancer cells. Cancer-derived sEVs are known to be released into the circulation, thus becoming attractive candidates for non-invasive biomarker development. However, whether the MRP1 level in plasma sEVs is indicative of human cancer has not been evaluated. This study examined the MRP1 expression in plasma sEVs derived from patients with PDAC, breast and colon cancer, and age- and gender-matched healthy subjects. The patient plasma samples were obtained primarily from the NCI-sponsored Cooperative Human Tissue Network and Stephenson Cancer Center. Healthy plasma samples were provided by the Oklahoma Blood institute. Human pancreatic cancer cell lines PANC-1, MIA PaCa-2 and BxPC-3, and the pancreatic ductal cell line hTERT-HPNE were tested for MRP1 expression prior to examination of plasma samples. Cellular and plasma sEVs were isolated using the double filtration followed by polymer precipitation method. Western blot was performed to assess the expression level of MRP1 and proteomics was applied to confirm the detection of a truncated form of MRP1 in plasma sEVs. MRP1 expression was detected in the sEVs derived from all three pancreatic cancer cell lines but absent in the sEVs from the HPNE line. Overexpression of a truncated MRP1 protein was detected in plasma sEVs derived from patients with early stage (stage I-IIA) and late stage (III-IV) PDAC, compared with that from matched healthy subjects (n=17 for each group). Similar findings were evident in plasma sEVs from patients with breast cancer (n=7), while the results remained inconclusive in plasma sEVs from patients with colon cancer (n=7). Protein structure analysis indicated that the truncated form of MRP1 likely consists of the regions between the QCRL-1 motif and the C-terminus of the protein. Proteomic analysis detected the peptides derived from the C-terminus region, consistent with the structural analysis. Furthermore, the truncated form of MRP1 can only be detected using antibodies against the epitopes in the C-terminus and QCRL-1 region of MRP1 protein. In summary, we have detected a truncated form of MRP1 protein in plasma sEVs derived from cancer patients, and the level of its expression is significantly elevated in patients with PDAC and breast cancer.

#7292 Surveying the landscape of somatic variation in healthy breast tissue for cancer risk prediction.

M. J. Przybilla[1], A. R. J. Lawson[1], P. Nicola[1], B. T. Pentecost[2], I. Martincorena[1], K. F. Arcaro[2], P. J. Campbell[1];
[1]Wellcome Sanger Institute, Cambridge, United Kingdom, [2]Wellcome Sanger University of Massachusetts, Boston, MA

Carcinogenesis centers on principles of somatic evolution, where a cell gradually accumulates mutations, eventually transforming into a tumor cell. Exploring somatic variation in the healthy population offers insights for predicting cancer risk and facilitating early detection. In breast cancer (BC), the emergence of the malignant clone occurs within a broader spectrum of abnormal cells, often referred to as the 'field effect.' BC development is intricately linked to hormonal regulation, with prior research indicating that the initial changes manifest during puberty and pregnancy. Although around 10% of diagnosed BCs affect young women (<45 years), with 35-55% of these cases arising within a decade after completed pregnancy (postpartum BC), effective screening tools are lacking. We propose a novel approach for the individualized quantification of somatic variation and the field effect using breast milk (BM) as a liquid biopsy. We conducted a retrospective analysis of 272 BM samples obtained from both the left and right breasts of 125 healthy donors, including 62 donors with elevated cancer risk due to a germline predisposition involving *BRCA*. Given the heterogeneous cellular composition of BM, encompassing epithelial cells and lymphocytes, we initially implemented a comprehensive analysis to reliably detect somatic mutations in whole BM, as well as in magnetically activated cell-sorted (MACS) epithelial-enriched (EE) and -depleted (ED) samples from a subset of donors. DNA extracted from all samples was used for NanoSeq, a single-molecule sequencing methodology, focusing on a targeted panel of 84 genes recognized as drivers in either BC or normal tissue. Our assessment of mutation burden estimates across all sample types revealed consistent results. Generally, cells accumulated somatic mutations linearly with age, but with a higher rate in individuals with a *BRCA2* cancer predisposition. We found several critical driver genes, including *PIK3CA*, *PIK3R1*, *TP53,* to be under significant positive selection using the ratio of non-synonymous to synonymous mutations. When we assessed the fraction of cells in each sample carrying mutations in these genes, we however detected a significantly higher fraction of mutated cells in individuals with germline predisposition - possibly representing a genetic manifestation of the epidemiologically higher risk of *BRCA* germline carriers.

As we expand our understanding of the interplay between the somatic mutation landscape and cancer risk, our efforts provide evidence for the utility of BM as an easily accessible, non-invasive sample. The proposed methodology, involving BM with precise genetic analysis through NanoSeq, presents a promising avenue for elucidating personalized somatic variation patterns. We anticipate that BM holds potential as a valuable tool for risk stratification, particularly for individuals under 45 and postpartum women.

#7293 Serum fusion gene transcripts to predict liver cancer.

J.-H. Luo, Y.-P. Yu, S. Liu, D. Geller;
University of Pittsburgh School of Medicine, Pittsburgh, PA

Hepatocellular carcinoma (HCC) is the most common type of liver cancers and one of the most lethal malignancies for human. Early diagnosis of HCC is crucial in reducing the mortality of the disease. In this report, we analyzed a panel of 9 fusion transcripts in the serum samples from 136 individuals (61 HCC patients and 75 individuals without HCC) using TaqMan qRT-PCR. Our results showed that 7 fusion genes were frequently detected in the serum samples of HCC patients, including MAN2A1-FER (100%), SLC45A2-AMACR (62.3%), ZMPSTE24-ZMYM4 (62.3%), Pten-NOLC1 (57.4%), CCNH-C5orf30 (55.7%), STAMBPL1-FAS (26.2%) and PCMTD1-SNTG1 (16.4%). We then divided the samples into training and testing cohorts based on the sample collection time: 82 individuals with samples collected before 2016 as the training cohort while 54 individuals with sample collected after 2015 as the testing cohort. Machine learning models was constructed based on the combination of different fusion genes with various cutoffs to predict the occurrence of HCC in the training cohort using leave-one-out-cross-validation approach. One of the machine learning models called 4-fusion genes logistic regression model (MAN2A1-FER<40, CCNH-C5orf30<38, SLC45A2-AMACR<41, Pten-NOLC1<40) produced a 91.5% accuracy, with a sensitivity of 87.1% and specificity of 94.1% in the training cohort. The same model generated an accuracy of 83.3%, with a sensitivity of 73.3% and specificity of 95.8% in testing cohort. When the training and testing cohorts were combined, the model produced an accuracy of 86%. When serum α-fetal protein (AFP) level was incorporated into the machine learning model, we found a 2-fusion gene+AFP logistic regression model (MAN2A1-FER<40, CCNH-C5orf30<38, AFP) generated an accuracy of 94.8% in the training cohort with a sensitivity of 93.5% and specificity of 96.3%. The same model generated 95% accuracy in both the testing cohort and the combined cohorts in the validation. Cancer treatment reduced most of the serum fusion transcript levels, reflecting the reduction of the tumor load. As a result, serum fusion gene machine learning models may serve as important tools in screening HCC and monitoring the impact of HCC treatment.

#7294 CREATE-2: Colorectal cancer & adenoma test evaluation of a multi-omic blood test.

James M. Cameron, Georgios Antoniou, Rose McHardy, David Palmer, Alexandra Sala, Matthew Baker

Dxcover Ltd., Glasgow, United Kingdom

Background: Colorectal cancer (CRC) is the third most common cancer worldwide, with almost 2 million new cases reported in 2020. CRC develops over time from a pre-cancerous stage (adenoma) - the 'adenoma-carcinoma sequence'. Pre-cancerous lesions, such as Higher Risk Adenomas (HRA), harbour an increased risk of developing into CRC and their features are defined according to size, number and histological features. Screening for signs of CRC is recommended for average-risk adults using faecal immunochemical testing (FIT) in the UK, to enable the removal of pre-cancerous lesions and treatment of early-stage cancers. However, the performance of FIT is limited. Approximately 10% of CRC diagnoses have a negative FIT result, and it currently has ~93% false positive rate. Moreover, the sensitivity for detecting AA is only 24%, highlighting the need for alternative strategies.
Methods: A promising strategy for earlier CRC detection is the clinical use of Fourier transform infrared (FTIR) spectroscopy. The Dxcover® Colorectal Cancer Liquid Biopsy is a rapid multi-omic test that interrogates a blood sample with infrared (IR) radiation and produces a distinctive signature that represents the whole biomolecular profile of the sample. Rather than focusing on individual biomarkers, the technique encompasses the full range of diagnostic information from both the tumor and the non-tumor response. In the initial CREATE (ColoREctal Cancer & Adenoma Test Evaluation) feasibility study, the potential of the technology was highlighted in a retrospective cohort of patients comprising 100 CRC, 92 adenoma samples and 104 colonoscopy screening controls diagnosed as non-cancer. At 90% specificity, the test reported 80% CRC sensitivity and 59% HRA sensitivity. CREATE-2 is a prospective, observational, multicenter study, currently recruiting patients across the United States. The primary objective of the study is to determine the diagnostic accuracy of the blood-based Dxcover Colorectal Cancer Liquid Biopsy for CRC and HRA, and collectively as advanced colorectal neoplasia. Primary outcomes are sensitivity, specificity, negative predictive value, and positive predictive value of the test as compared to the standard of care screening modality. The study population is comprised of patients aged 45-84 considered 'average-risk' for CRC, undergoing routine CRC screening as standard of care. Patients are treatment naïve for CRC/HRA and must be willing to consent to blood draw pre-bowel preparation, and follow-up for 24 months. A rapid blood test that is sensitive to pre-cancerous lesions and early-stage CRC could substantially improve patient outcomes. Current screening programs have addressable shortcomings, and the emergence of new technologies is essential to support earlier CRC detection.

#7295 A novel XNA technology-based assay to detect JAK2 V617F mutation by real-time PCR.

S. Shen, R. Brown, D. Kim, L. Pastor, A. Y. Fu, P. Kaur, A. Babu, W. Liu, A. Zhang, **H. Tanaka**, M. Y. Sha;
DiaCarta, Pleasanton, CA

The Janus kinase 2 (JAK2) gene is located on chromosome 9p24.1 and encodes a non-receptor tyrosine kinase that plays a central role in cytokine and growth factor signaling. The JAK2 protein is especially important for controlling the production of blood cells from hematopoietic stem cells. In fact, the JAK2 mutation at amino acid 617 (Valine 617 to Phenylalanine, V617F) is the most frequently detected mutation in myeloproliferative neoplasms (MPN), including essential thrombocythemia (ET), polycythemia vera (PV), and primary myelofibrosis (PMF). This dominant gain-of-function V617F mutation results in constitutive tyrosine phosphorylation activity, leading to uncontrolled blood cell production, including increased numbers of erythrocytes, neutrophils, and platelets. To detect the JAK2 V617F mutation in DNA from patient blood samples, we developed a unique real-time PCR assay using our proprietary XNA technology that enables the assay to selectively amplify the mutant sequence by using a synthetic DNA analog XNA (Xenonucleic Acid). The JAK2 V617F mutation detection assay is designed to detect a valine-to-phenylalanine mutation at amino acid 617 (V617F). PCR primers, TaqMan probes, and XNA were designed for the JAK2 V617F mutation, along with primers and probes for an internal control gene in the duplex setting. The analytical performance of the assay was verified and validated using a variety of control samples. The results revealed that the XNA completely suppressed the amplification of wildtype sequence while only the V617F mutant sequence was amplified. The JAK2 V617F mutation detection assay is highly reproducible with intra- and inter-assay coefficients of variation of less than 10%. Results for the assay's analytical sensitivity indicated that V617F could be detected with about 0.25% mutant allele frequency in 10 ng DNA input. In addition, no significant cross-amplification between V617F and V617I was observed. Thus, the JAK2 V617F mutation detection assay is specific for the V617F mutation. The JAK2 V617F mutation detection assay, using XNA-based technology, provides high sensitivity and specificity to detect the JAK2 V617F mutation. Thus, this assay would be a useful tool for clinical decision-making in determining the presence of the JAK2 V617F mutation in DNA from patient blood samples.

#7297 Inhibition of lung tumorigenesis and potentiation of cancer preventive vaccines by a small molecule CA170 targeting the immune checkpoint protein VISTA.

Q. Zhang[1], J. Pan[1], D. Xiong[1], **Y. Wang**[1], M. S. Miller[2], M. You[1];
[1]Houston Methodist Research Institute, Houston, TX, [2]National Cancer Institute, Bethesda, MD

The V-domain Ig Suppressor of T cell Activation (VISTA) is expressed on cells of the myeloid and lymphoid lineages and is an emerging target for cancer immunotherapy. Blocking VISTA activates both innate and adaptive immunity to eradicate tumors in mice. Furthermore, a tripeptide small molecule antagonist of VISTA, CA170, exhibited potent anticancer efficacy on carcinogen-induced mouse lung tumorigenesis. We have previously demonstrated that KRAS or EGFR vaccines are effective in preventing lung tumorigenesis driven by either KRAS or EGFR in a pure prevention setting but are less effective in mice carrying existing lesions. Here, we determined if combining an MHC class II-restricted multi-antigen vaccine targeting KRAS or EGFR with CA170 will provide enhanced efficacy in preventing lung cancer progression. Using tetracycline-inducible KRAS and EGFR transgenic mice, we found that lung tumor development was significantly suppressed when CA170, delivered by aerosol inhalation to minimize systemic toxicity, was combined with either KRAS or EGFR MHCII-directed peptide vaccines using a post-initiation model. Flow cytometry and single-cell RNA sequencing (scRNA-seq) revealed that CA170 significantly increases tumor infiltrating CD8+ T cells and enhances effector-memory T cell frequencies and functions of both CD4+ and CD8+ T cells. These changes coincide with significant reductions in G-MDSCs (granulocytic myeloid-derived suppressor cells) and Foxp3+ Treg populations within lung tumors from mice treated with CA170. We found that the KRAS and EGFR preventive vaccines primarily induced the expansion of $CD4^{\pm}$ effector T cells. VISTA antagonism by CA170 revealed strong efficacy against lung tumorigenesis with broad immunoregulatory functions that influence effector, memory, and regulatory T cells, and drive an adaptive T cell tumor-specific immune response that enhances the efficacy of the KRAS and EGFR preventive vaccines in transgenic mouse models of lung cancer.

#7298 A nutraceutical supplement derived from olive oil byproducts exhibits potential cancer preventive properties in preclinical studies and increases vitamin D levels.

A. Albini[1], L. Calabrone[2], F. Albini[3], P. Corradino[1], S. Cristoni[2], D. M. Noonan[4];

[1]IEO - European Institute of Oncology, Milano, Italy, [2]I.S.B.-Ion Source & Biotechnologies, Bresso (MI), Italy, [3]Royal Society for the Encouragement of Arts, Manufactures and Commerce, London, United Kingdom, [4]IRCCS MultiMedica, Milano, Italy

Introduction: Extra virgin olive oil is a basic component of the Mediterranean diet; it contains several molecules with antioxidant, anti-inflammatory, anti-angiogenic and pro-apoptotic properties against a variety of cancers and influencing cellular metabolism too. Olive mill waste water (OMWW), a liquid residue produced in vast amounts during olive oil extraction, represents an environmental issue but on the other side it is a rich source of phytochemicals with potential health benefits. Particularly, OMWWs are rich in different phenolic compounds, that show promise in preventing the development of several disease disorders, including cancer. We have assessed the anti-angiogenic and anti-tumor properties exerted by a nutraceutical from purified OMWW extract, in *in vitro* and *in vivo* models, and evaluated its effect in a human pilot study upon informed consent.

Experimental procedures: OMWWs ability to affect cell proliferation and survival on different cancer cell lines was assessed by MTT. OMWWs interference with human umbilical endothelial vein cells (HUVECs) tube formation, migration and invasive capacities was studied by endothelial cell morphogenesis and migration assays. The inhibition of angiogenesis and tumor cell growth was investigated by the matrigel assay and tumour xenograft. To evaluate contribution of potential metabolomic biomarkers, SANIST (surface-activated chemical ionization-electrospray-NIST technology) mass spectrometric data-based platform has been employed on sera from a pilot study (Aiello et al, in preparation).

Results: OMWW extract shown a potent inhibitory effect inhibiting cells proliferation of both cancer cell lines and HUVECs.OMWW inhibited several molecular targets expression, including IL8, Angiogenin, mTOR, VEGF, CXCR4, CXCL12 and CXCL8, in tumor cells and in TNF-α-stimulated HUVEC. We nalyzed sera from volunteers, after nutraceutical intervention with Oliphenoliaand we assessed several biological parameters. Endogenous vitamin D was significantly increased, as well as albumin, direct bilirubin, and calcium. We also observed glycemia and potassium decrease after Oliphenolia assumption. A previously unknow form of Vitamin D was also detected by mass spectrometry.

Conclusions: OMWW extract has shown a stronger anti-angiogenic and anti-tumor properties, with potential chemo-preventive potentials. Results of human pilot study shows Oliphenolia as a promising and interesting natural dietary supplement, rich in polyphenol compounds, that can exert anti-inflammatory and antioxidant activities.

#7299 Preventing CRC progression in FAP rat model using a combinational targeting of TRAIL signaling and inflammation.

V. Madka[1], G. Pathuri[1], K. Venkatachalam[1], S. P. Singh[1], A. Singh[1], N. Stratton[1], S. Lightfoot[1], S. Sei[2], M. S. Miller[2], **C. V. Rao**[1];
[1]OU Health Stephenson Cancer Center, Oklahoma City, OK, [2]National Cancer Institute, Rockville, MD

Colorectal Cancer (CRC) is among the leading causes of mortality globally, with high incidence rates in developed countries including the US. While FAP patients are prone to develop CRC in their lifetime, recent rising trends among young adults is also a major concern. Hence, preventing CRC would aid in reducing cancer mortality, especially in high-risk FAP patients for which there are no FDA approved preventive agents. Here, we evaluated TRAIL-inducing, orally active small molecule ONC201, alone and in combination with the NSAID naproxen (NAP) for CRC prevention in the PIRC rat model representing FAP cohort. Male PIRC rats were bred inhouse and randomized by age into placebo and intervention groups (N=15). Starting at 6 weeks of age, experimental groups were administered either ONC201 alone by gavage [25mg/kg; 2X/week or 50mg/kg; 1X/week]; NAP in AIN-76A diet [200 ppm; continuously or 1 week ON/OFF]; or a combination of both agents, while placebo group received vehicle only. After 26 weeks of treatment, rats were euthanized and intestines were evaluated for tumor incidence and multiplicity. H&E stained colonic tumor sections were histologically classified as hyperplastic polyps, adenomas (AD), and adenocarcinomas (ADCA). Gross tumor data indicated significant reduction in colonic polyps in both the NAP alone and NAP+ONC201 groups without any overt-toxicites. Histological analyses also demonstrated strong suppression of AD progression to ADCA as well as a significant decrease in the number of ADs and ADCAs ($p<0.05$) in the treatment groups compared to the placebo. ONC201 regimens modestly reduced AD (19%-27% less, $p<0.05$) but showed strong inhibition of ADCA (45%-59% less, $p\leq0.0001$). A significant reduction of AD and ADCA was seen in NAP continuous (54% & 87% less respectively; $p<0.0001$) and intermittent (34% & 68% less respectively; $p<0.0001$) dosing regimens. As anticipated, the NAP continuous treatment had better efficacy than the intermittent dosing regimen. Notably, the combination treatment showed >90% ($p<0.0001$) inhibition of ADCA and 40%-57% ($p<0.0001$) inhibition of ADs. Importantly, ONC201+ NAP treatment also resulted in an additional 45% - 70% reduction of ADCA ($p<0.0001$) when compared to the NAP alone treatment. Thus, our data showed that the combination groups with NAP intermittent dosing demonstrated ~90% inhibition of ADCA, suggesting the synergistic effect of the two agents in preventing CRC progression. Molecular analysis of the rat tumors and additional analyses in in-vitro tumoroid models suggested induction of TRAIL (TRAIL, DR5, FADD), increased apoptosis (Caspases), and a decrease in proliferation markers (PCNA, Cyclin D1) and pro-inflammatory cytokines (IL1b, IL13 etc.). Our data suggests NAP/ONC201 combo has no toxicities, warranting further investigation of CRC interception in high-risk FAP patients (Funding by NCI-PREVENT 75N91019D00020-75N91020F00004).

#7300 Synergistic inhibition of prostate cancer growth by the combination of xanthohumol and ursolic acid.

R. Clark, A. Saha, C. A. Friedman, R. Gorgoglione, S. Tiziani, J. DiGiovanni;
The University of Texas At Austin, Austin, TX

Within the United States, prostate cancer (PCa) is the most commonly diagnosed non-cutaneous cancer, and approximately 1 in 8 men will receive a diagnosis in their lifetime. As the second leading cause of cancer deaths in American men, about 1 in 41 will die because of prostate cancer. The World Health Organization has suggested that approximately one-third of all cancer deaths are preventable, and one of the suggested means of prevention is through the increased consumption of fruits and vegetables. Fruits and vegetables contain natural compounds known as phytochemicals which possess biological activity including some anti-cancer effects. By adapting the ATP-bioluminescence assay for cell viability, our laboratory screened a natural compound library to find combinations of these compounds that may synergistically inhibit PCa cell viability. One of the combinations to emerge from this screening process was xanthohumol (XAN) and ursolic acid (UA). We examined the ability of the combination to inhibit tumor growth in a mouse HMVP2 PCa allograft tumor model. Mice were fed diets supplemented with either XAN (0.2%) or UA (0.2%) alone or the combination. Mice on the combination diet showed a significant inhibition of HMVP2 PCa tumor growth compared to mice on the single-agent diets. In addition, *in vitro* studies were performed to support the allograft tumor study and to further examine the mechanism of action of the combination. A cell survival assay utilizing six different PCa cell lines indicated that the combination of XAN and UA synergistically inhibited the survival of all cell lines as calculated by the Bliss index. Mechanistic studies performed in PCa cells indicate that the combination of XAN and UA inhibits oncogenic signaling better than either agent alone. Additionally, unbiased metabolomics revealed that the tumors from mice fed the combination diet had significantly less S-adenosyl-L-methionine compared to all other groups. Overall, 13 metabolic pathways were significantly different in the tumors from mice fed the combination diet compared to all other groups. The current data suggest that using a combination of XAN and UA may be a valuable chemopreventive strategy for PCa in humans. Funding: This work was supported by NIH Grant CA228404.

#7302 Effect of estrogen receptor modulator bazedoxifene on progression of carcinogen induced bladder cancer in female F344 rats.

V. Madka[1], G. Pathuri[1], S. P. Singh[1], S. Chiliveru[1], A. Singh[1], A. Bao[1], N. Stratton[1], C. J. Grubbs[2], S. Sei[3], J. Clifford[3], B. Cholewa[3], C. V. Rao[1];
[1]OU Health Stephenson Cancer Center, Oklahoma City, OK, [2]University of Alabama at Birmingham, Birmingham, AL, [3]National Cancer Institute, Rockville, MD

Bladder Cancer (BC) is the second most common genitourinary cancer with high recurrence and mortality rate due to metastatic muscle invasive BC (MIBC). An estimated 82,290 adults in the United States will be diagnosed with BC and one-fifth of the patients will die with this cancer in 2023. Sex disparity of BC is well known with 4 times higher risk in men, but women are more likely to die from it than men. Studies suggest that estrogen receptor (ER)-α and ER-β are over expressed in 18% and 63% of bladder tumors and associated with highly proliferative tumors and reduced overall survival. Hence, ER signaling is considered an important target for intercepting BC. Since the majority of BCs are non-invasive at diagnosis, developing agents that block BC progression may be beneficial for clinical translation. Bazedoxifene (BAZ), a clinically approved second generation SERM, is a co-repressor for both the ER-α and ER-β receptors, and it is a competitive inhibitor of 17-β-estradiol. In this study, BAZ was tested for toxicity and efficacy in an N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN)-induced BC rat model. Female F344 rats are administered carcinogen BBN (150mg x twice a week) for 8 weeks to induce BC. For toxicity evaluation, 5 doses of BAZ were fed (2.5 ppm to 12.5 ppm in diet) to BBN treated rats (n=6) for 10 weeks. After termination, serum, various organs, and bladder tissues were evaluated for toxicity biomarkers and histopathology. For efficacy study, Female F344 rats (8 weeks of age) were (n=24) administered BBN as stated above. A week later, rats received either control or BAZ (5 ppm and 10 ppm) containing diets for 33 weeks and terminated. Bladders and other major organs were analyzed grossly for size, weight, and visible abnormalities including tumors. Formalin fixed tumor sections were stained and histopathologically graded. Results showed that BBN-exposed rat bladders were significantly larger and heavier due to tumors (0.77±0.10g, Mean±SEM; $p<0.0001$) as compared to vehicle treated rats' normal bladders (0.09±0.02g). Bladder tumor histopathology showed transitional cell carcinoma (TCC) and squamous cell carcinomas (SCC) with non-MIBC (NMIBC) and MIBC tumor grades in the vehicle control group. There was no significant difference in bladder weights between the 5 ppm and 10 ppm BAZ-treated vs. control group ($p>0.05$). However, histopathological evaluation showed ~20% ($p>0.05$) reduction in papilloma and NMIBC in the treated rats. Importantly, BAZ 5 ppm and 10 ppm treated rats had significantly less MIBC in a dose dependent manner (50%-70% less respectively; $p<0.001$) compared to control rats. In summary, our study demonstrates chemopreventive efficacy of bazedoxifene in interception of in BBN-induced rat bladder MIBC and warrants further investigation alone and in combination with complementary pathway targeting agents (Supported by NCI-PREVENT program 75N91019D00020-75N91020F00005).

#7303 The algal carotenoid diatoxanthin shows anti-cancer and cardio-protective properties: RNA seq analysis of potential targets.

D. M. Noonan[1], L. Calabrone[2], L. Pistelli[3], C. Brunet[3], C. Sansone[3], D. Morelli[1], G. Chiorino[4], F. Guana[4], A. Albini[5];

[1]IRCCS MultiMedica, Milano, Italy, [2]I.S.B.- Ion Source & Biotechnologies, Bresso (MI), Italy, [3]Stazione Zoologica Anton Dohrn, Napoli, Italy, [4]Fondazione Edo ed Elvo Tempia, Milano, Italy, [5]IRCCS European Institute of Oncology (IEO), Milano, Italy

Introduction: Natural bioactive pigments are of great interest for human health. Marine organisms are underexplored as source of useful metabolites. Diatoms produce diatoxantin (diatox), a xanthophyll with several properties (chemo-preventive, anti-inflammatory, antioxidant, photoprotective, immunomodulatory), that may have beneficial effects. Doxorubicin (doxo) is still one of the most effective chemotherapeutic drugs used in breast cancer (BC) treatment, but has side effects, particularly cardiotoxicity, mainly due to oxidative stress and cardiomyocyte damage. We have assessed the anti-cancer effects of diato, also verifying the absence of cardiotoxicity.

Experimental procedures: Diatox was administered to MDA-MB-231 triple negative BC (TNBC) *in vitro*, in combination with doxo by MTT and by 3D-spheroid assays. The modulation of diatox on the secretome of both TNBC cells and Human Umbilical-Vein Endothelial cell line (HUVEc) was assessed *in vitro* by angiogenesis arrays. Gene expression analysis was evaluated by measuring different inflammation and angiogenesis gene expression in cells treated with diato, by qPCR; while transcriptomic analysis was performed by RNA-Seq to verify diato effects on pathways involved in TNBC progression and in HUVEc inflammation.

Results: Diatox showed an inhibitory effect on the proliferation of MDA-MB-231 cells and, in combination with doxo, was able to inhibit TNBC spheroid growth, reducing their 3D-integrity and decreasing their viability. Diatoxx was able to down-regulate genes involved in inflammatory and angiogenic processes in HUVEc stimulated by TNFα (angiostatin, IL2, IL4 and PECAM-1 in antibody array and TGFβ1, TGFβ2, TIMP1 and TIMP2 gene in qPCR analysis). Moreover, diatox reduced several biological processes involved in inflammation and tumour development and metastasis, as demonstrated by RNA-Seq data. In TNBC cells diatox down-regulated ANGPT1, GPR37, ANG, QRICH2, MUC1 genes involved in angiogenesis processes, while EPHA7 was up-regulated. In TNFα-stimulated HUVEc, diatox down-regulated angiogenin, a powerful inducer of angiogenesis, and HSPA12A and EDNRB, which are involved in the regulation of macrophage cytokine production.

Conclusions: Diatox shows to be a promising chemo-preventive and angiopreventive natural compound in cancer prevention and therapy. Microalgae derived drugs can represent a potential and relevant source of novel nutraceutical and preventive substances, which can be considered as supplements in therapeutic strategies for cancer prevention. Acknowledgements: The studies were supported by Stazione Zoologica Anton Dohrn, by "Antitumor Drugs and Vaccines from the Sea "ADViSE" project (PG/2018/0494374).

#7304 Modulation of cytokine and chemokine profiles in pancreatic tumors and plasma *via* stage-specific intervention with *Momordica Charantia* juice in the LSL-KrasG12D/+, p48Cre/+ mouse model.

L. Bugata[1], R. Kumar[1], M. Kabir[1], R. Kant[2], C. Agarwal[2], R. Agarwal[2], K. Raina[1];

[1]South Dakota State University, Brookings, SD, [2]University of Colorado Denver-Anschutz Medical Campus, Aurora, CO

According to the American Cancer Society ≈64,050 people will be newly diagnosed with pancreatic cancer in the United States, while ≈55, 550 (men and women numbers combined) will die of this malignancy in 2023 alone. Epidemiological studies have indicated that a diet rich in natural agents might reduce pancreatic ductal adenocarcinoma (PDAC) risk, prompting investigations into a natural agent with health benefits in pancreatic diseases [such as the fruits of *Momordica Charantia* (Bitter Melon)] as a potential natural and non-toxic anti-cancer approach against PDAC. Previously we have reported the protective effects of oral Bitter Melon Juice (BMJ-standardized-lyophilized powder) against growth and progression of PDAC in preclinical animal models (xenograft and patient-derived tumor models). In a recent study we reported the efficacy of BMJ against pancreatic cancer in the LSL-KrasG12D/+, p48Cre/+ transgenic mouse model [this model mimics the stage-specific progression of intraepithelial neoplasms to PDAC as it occurs in humans]. Both male and female LSL-KrasG12D/+, p48Cre/+ transgenic mice were subjected to BMJ intervention (daily oral gavage, dose: 200mg/kg body wt.) during different stages in disease progression. Intervention was started at 4 or 15 weeks of mice age and continued till study end (10 and 30 weeks of mice age respectively). Additionally, in one group of mice, intervention was initiated at 6 weeks of mice age and continued till 41 weeks of mice age (study end). Outcomes were compared with wild-type and disease-positive untreated control groups. Pancreatic tissue/tumors were harvested at study end and blood plasma was also collected. In the present study, we performed a stage specific evaluation of tissue and plasma cytokine/chemokine profiling after BMJ intervention to gain detailed mechanistic insights into the potential of BMJ to mediate it is anti-pancreatic cancer effect *via* modulation of inflammatory pathways associated with PDAC growth and progression. BMJ (15 weeks of treatment) demonstrated a significant response in modulating cytokine/chemokine profiles in LSL KrasG12D/+, p48Cre/+ mice pancreatic cancerous tissues (30 weeks old mice). BMJ intervention specifically downregulated the levels of monocyte chemoattractant protein (MCP-1), macrophage inflammatory protein-1 (MIP-1-gamma), tumor necrosis factor (TNF) receptor (TNFR1), Vascular cell adhesion molecule 1 (VCAM-1/ CD106) and L-selectin (CD62L). Furthermore, Ingenuity Pathway Analysis indicated significant inhibitory predictions on TNF-α, NF-κB and MCP-1 (CCL-2) associated inflammatory pathways. Overall, these outcomes signify that the anti- cancer effects of BMJ in *KRAS* harboring PDAC tumors is associated with down-regulation of inflammatory pathways associated with growth and progression of pancreatic cancer.

#7305 Chemoprevention of colorectal cancer: Role of trace minerals in conjunction with calcium.

I. Harber, S. McClintock, J. Varani, **M. N. Aslam**;
University of Michigan Medical School, Ann Arbor, MI

Background: Colorectal cancer (CRC) is a leading cause of cancer-related deaths worldwide. CRC usually develops from adenomas (CRC precursors) after a long latency period. Prevention is crucial in reducing CRC incidence and progression to cancer. Among several prevention options, calcium has been a widely considered chemo-preventative agent.

Aims: Calcium plays a vital role in the regulation of epithelial cell differentiation, which is essential for epithelial growth control. Epidemiological studies have demonstrated that adequate calcium intake is crucial for protection against colonic polyp formation and colorectal cancer. However, recent interventional trials with calcium have had only modest and mixed results, and the question is how to improve efficacy. One potential strategy is to use calcium in combination with additional minerals and trace elements.

Results: Our preclinical studies employing monolayer cultures with CRC cell lines and colon organoids cultures from colon polyps have shown that a calcium-rich mineral combination derived from fossilized red algae (Aquamin) is more effective than calcium alone in inducing differentiation, suppressing growth and upregulation of calcium-sensing receptor. When colonic adenomas in culture were subjected to differential proteomic analysis, Aquamin upregulated several proteins involved in proliferation suppression, DNA mismatch repair and inducing differentiation, and apoptosis. Two long-term mouse studies have demonstrated that Aquamin is more effective in suppressing polyp & CRC incidence compared to calcium alone. Based on these findings, we conducted a 90-day FDA-approved trial (a pilot study with ten subjects per arm) comparing the two interventions in human subjects at risk for CRC. Results showed that Aquamin treatment reduced proliferation and increased cell differentiation observed by immunohistochemistry. Proteomic analysis also revealed that the minerals upregulated several proteins related to growth suppression, inducing differentiation and those contributing to cell-cell and cell-matrix adhesion functions and downregulated proteins involved in proliferation and nucleic acid metabolism.

Conclusion: These results provide convincing evidence that a multi-mineral combination derived from red algae can provide benefits in preventing CRC that are not seen with calcium alone. Further studies, such as a polyp-prevention trial in human subjects, are warranted to advance these CRC prevention efforts.

#7306 Licochalcone A is an excellent candidate for preventing luminal and non-luminal breast cancers.

Atieh Hajirahimkhan[1], Elizabeth T. Bartom[1], Sriram Chandrasekaran[2], Ruohui Chen[1], Jeremy J. Johnson[3], Susan E. Clare[1], Seema A. Khan[1]

[1]Northwestern University - Chicago, Chicago, IL, [2]University of Michigan, Ann Arbor, MI, [3]University of Illinois Chicago, Chicago, IL

Breast cancer (BC) risk reducing drugs have minimal impact due to their adverse effects and low acceptance by risk-eligible women. Further, they are ineffective against hormone receptor negative (HR-) BC. Novel agents with reduced toxicity and sufficient efficacy that extends beyond HR+ BC are needed. We showed previously that licochalcone A (LicA) from licorice has antioxidant/anti-inflammatory effects, inhibits aromatase, and blocks estrogen genotoxic metabolism. We hypothesize that LicA prevents HR+ and HR- BC through reprogramming metabolism and antioxidant pathways. We prepared microstructures from the fresh tissue of contralateral unaffected breast of 6 postmenopausal women with unilateral BC. After exposing them to DMSO (control) or LicA (5 µM), we performed total RNA sequencing followed by differential gene expression, pathway identification, and metabolism flux analyses. The NanoString metabolism panel was employed in 6 additional subjects. We performed live cell imaging to monitor proliferation of HR- and HR+ pre-malignant and malignant, as well as BRCA mutated cells. Xenograft models of HR+ and HR- tumors were established in female nude mice followed by 28-day treatment with vehicle or LicA (80 mg/kg.day, s.c.) and monitoring the tumor growth. Using LC-MS/MS we measured LicA in the blood and various tissues of intact BALB/c female mice receiving oral LicA (100 mg/kg) and assessed PK using Phoenix Platform. We observed significant (combined enrichment scores > 4 and FDR < 0.05) upregulation of antioxidant genes (up to 8-fold), consistent with upregulation of *NRF2* and the thioredoxin system. This was accompanied by significant downregulation of *RELA*- and *NF-kB1*-dependent inflammatory pathways. In addition, we observed decreased expression of *PI3K-AKT* genes and the pro-adipogenic transcription factors *SREBF1* and *SREBF2*, which may explain the downregulation (4 to 32-fold) of cholesterol biosynthesis, transport, and lipid metabolism genes. Metabolism studies confirmed these data and demonstrated a robust increase in the pentose phosphate shunt and NAD(P)H generation without enhancing ribose 5 phosphate formation, suggesting an antioxidant and antiproliferative environment. LicA also suppressed proliferation of pre-malignant and malignant cells, with sustained effects on aggressive cell lines at doses <10 µM. It reduced tumor growth in luminal (P = 0.008) and triple negative (P = 0.001) xenograft models. Oral bioavailability in serum and breast was in the low micromolar range and was sufficient to show efficacy.Our data suggest that LicA is an excellent candidate for both HR+ and HR- BC prevention by reprogramming metabolism and antioxidant pathways leading to decreased proliferation. Our next study will test an optimized oral formulation of LicA in intraductal models of HR+ and HR- precancer lesions in immunocompetent mice to further establish its preventive efficacy.

#7307 Silibinin regulates glucocorticoid signaling via mast cells: Potential treatment of androgen-resistant prostate cancer.

N. Mishra[1], S. Paudel[1], K. Raina[2], P. Maroni[1], C. Agarwal[1], R. Agarwal[1];

[1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]South Dakota State University, Brookings, SD

Prostate cancer (PCa) is the second most common cancer in American men. The American Cancer Society estimates that in 2023 there have been ~288,300 new cases of PCa and ~34,700 deaths from PCa in the United States. We previously showed that silibinin (SB; a natural flavonolignan from milk thistle seeds) is an effective therapeutic against PCa that inhibits cell growth and mitogenic cell survival via EGFR, IGFR-1, and NFκB signaling. However, the effect of SB on the tumor immunological microenvironment has not been elucidated. Mast cells (MCs) are archetypal solider of the immune system. The dynamics of PCa and MCs are complex, where they may contribute to tumor transformation/progression/regression; furthermore, their role in PCa is poorly understood. To address this gap and understand the role of SB in MC regulation, MCs were derived from the bone marrow (BMMCs) of C57BL/6 mice. BMMCs were generated in the presence of IL-3 and SCF, and were confirmed to be BMMCs using flow cytometry (dual staining: cKit/Fc€RI). Thereafter, the BMMCs were exposed to different doses of SB (25-100 µM) and two concentrations (25 µM; SB 25 and 100 µM; SB 100) were selected for further experiments. BMMCs treated with SB 25, SB 100, and untreated (control) were subjected to proteomic analysis using LCMS on Fusion Lumos mass spectrometer. A total of 3575 proteins were identified using the annotated mouse proteome. Statistical analysis was performed using ANOVA followed by Fisher's posthoc analysis ($p<0.05$, FDR<0.01) and 166 proteins were found to be have statistically significant differential expression amongst the three groups (n=4/group). These 166 proteins were selected for further pathway analysis using Ingenuity Pathway Analysis (IPA; Qiagen). Only pathways specifically demonstrated experimentally in prostatic tissues/cells were selected for further analysis. Important nodes found for SB regulation of MCs in PCa were androgen receptor (AR), transmembrane serine protease (TMPRSS), and NK3 Homeobox 1 (NKX3-1). AR, TMPRSS, and NkX3-1 are well established in PCA. Most important pathway found was glucocorticoid receptor (GR) signaling; nuclear receptor subfamily 3 group C member 1 (NR3C1) and HS90 were the most important proteins identified in GR signaling. GR signaling may cause androgen deprivation therapy (ADT)-resistance by directly activating AR-target genes (including TMPRSS2) and/or activating an independent transcriptome. NR3C1 has been shown to share target specificity with AR and is highly upregulated in the resistant tumors. Thus, SB could play an important therapeutic role, specifically in ADT-resistant tumors via regulation of MCs. Further studies are warranted to delineate these mechanisms. Understanding these mechanistic could also potentially aid to decipher a general mechanism of resistance to antiandrogens and potential of SB in treating ADT-resistant tumors.

#7308 Induction of apoptosis via the regulation of pro-apoptotic and anti-apoptotic proteins in pancreatic adenocarcinoma BxPC-3 cells by Chinese medicinal herbs *Scutellaria barbata* and *Oldenlandia diffusa*.

C. Choi, S. Wolf, R. Isaac, E. Choi, A. Shim, A. Campana, P. T. Uppala, R. Hayes, **B. Y. Wong**;
Andrews University, Berrien Springs, MI

Apoptosis is a controlled program cell death process that the body uses to combat cancer development. Pancreatic cancer is a devastating disease with a poor prognosis. It is usually symptom-free during development and is advanced at diagnosis. BxPC-3 is a pancreatic adenocarcinoma cell derived from a 61-year-old female with adenocarcinoma. *Scutellaria barbata* (SB) and *Oldenlanda diffusa* (OD) have been used in traditional Chinese medicine for treating liver, lung, and rectal cancers. They are included in most herbal cancer treatment formulas in Taiwan hospitals. We previously demonstrated that aqueous extracts of SB and OD selectively induced apoptosis in colon HCT 116 cancer cells but not in colon CCD 841 CoN normal epithelial cells by modulating the pro-apoptotic and anti-apoptotic proteins. They also induced and regulated apoptosis in pancreatic ductal carcinoma PANC-1 Cells. This study used the green/red/blue fluorescent Apoptosis /Necrosis Detection Kit and the Human Apoptosis Antibody Array - Membrane [43 Targets] Test (Abcam). Our fluorescent apoptosis data showed that a 2-hour treatment with 1.5 mg/mL and 3.0 mg/mL aqueous extract of SB and OD induced a statistically significant percentage of apoptosis in BxPC-3 cells (SB: 42.5 ± 3.5%, 48.5 ± 0.5% > 14.0% ± 4.0%, $p < 0.05$; OD: 72.0 ± 2.0%, 37.5 ± 1.5%> 14.0% ± 4.0%, $p < 0.05$) as compared to the negative control respectively. Similar results were obtained with the 4-hour incubation period (SB: 46.0 ± 8.0%, 54.5 ± 2.5% > 9.5% ± 2.5%, $p < 0.05$; OD: 49.0 ± 7.0%, 37.0 ± 0.0%> 9.5% ± 2.5%, $p < 0.05$). From the antibody array-membrane experiments, significant up-regulation of various pro-apoptotic proteins such as Bid, Bim, Bad, Bax, C3, C8, CD40, HTRA, IGFBP-4, IGFBP-4, p53, TNF-α, and TRAIL-2 as compared to the negative controls were observed; and regulation of anti-apoptotic proteins HSP27, IGF-II, and Survivin were also revealed. These results suggest that SB and OD contain phytochemicals that induce apoptosis in pancreatic adenocarcinoma BxPC-3 cells by regulating various apoptotic protein productions. Further study of their specific modulation effects of apoptosis is warranted to reveal their potential chemopreventive and therapeutic properties against pancreatic and other cancers.

#7309 Edible mushroom derived antioxidant, vialinin A, prevents melanoma growth and invasion.

A. Vo, A. Zafar;
Noorda College of Osteopathic Medicine, LLC, Provo, UT

Melanoma is the second leading invasive cancer with a greater capacity to invade and metastasize. Increased oxidative stress has been shown to be involved in melanoma growth and spread. Several antioxidants, vitamins, and other phytochemicals have been shown to prevent melanoma cancer growth. However, the chemopreventive efficacy of vialinin-A, an edible mushroom-derived p-terphenyl antioxidant, on cancer growth and invasion is unknown. We, therefore, hypothesized that with its potent anti-oxidative and anti-inflammatory actions, vialinin-A could prevent melanoma cell growth and invasion. B16-F10 melanoma cells were treated without or with various concentrations of vialinin-A. The cell viability was determined by MTT assay and apoptosis by annexin-V staining. Our results suggest that vialinin-A prevents melanoma cell growth in a dose-dependent manner. Vialinin-A also prevents the invasion and migration of melanoma cells. Further, vialinin-A prevents the generation of reactive oxygen species and promotes apoptosis of B16-F10 cells. In addition, vialinin-A increases the activation of caspase-3 and cleavage of PARP protein. Vialinin-A also regulated the expression of various anti-apoptotic, pro-apoptotic, and inflammatory markers in melanoma cells. In conclusion, our results suggest that vialinin-A, through regulating oxidative stress-modulated apoptotic pathways, could prevent melanoma cell growth and invasion and has potential chemopreventive properties.

#7310 Dietary feeding of silibinin effectively protects against UVB-induced basal cell carcinoma.

S. Paudel[1], N. Mishra[1], K. Raina[2], C. Agarwal[1], **R. Agarwal[1]**;

[1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]South Dakota State University, Brookings, SD

Exposure to UVB radiation causes various malignancies, including basal cell carcinoma (BCC) and squamous cell carcinoma (SCC). BCC is the most prevalent skin cancer type worldwide; ~3.6 million cases of BCC are diagnosed annually in the USA. Silibinin (SB) is a naturally occurring flavonolignan that is present in milk thistle seeds. It has been shown to effectively reduce BCC occurrence upon UVB radiation exposure, in both pre- and post-treatment studies, when applied topically. However, SB efficacy, when fed in diet, against UVB-induced BCC formation and growth has not been reported. We addressed this question employing Ptch+/- mice, where animals were divided into three groups. Group 1: control group, mice were fed adjusted vitamin diet (AIN-76A; TD94096) with no UVB exposure. Group 2: UVB group, mice were fed pellet control diet (semi-purified, modified AIN-76A) and exposed to UVB (240 mJ/cm^2) 3 times/week (Mon, Wed, Fri). Group 3: SB group, mice were fed 1% SB (w/w)-supplemented diet and exposed to UVB similar to that in Group 2. This protocol was followed for 26 weeks; thereafter, animals were sacrificed at 14 weeks and 26 weeks post-UVB initiation, and skin samples were harvested and analyzed for BCC formation. β-galactosidase staining showed the development of BCC lesions at 26 weeks in the UVB group; however, SB-fed group had both lesser number of BCC lesions and decreased area covered by BCCs as compared to the UVB group. Non-UVB exposed control group had no BCC lesions. To address if SB feeding starts exerting its efficacy earlier than 26 weeks, we selected the early efficacy timepoint for transcriptomics analysis to determine the mechanism of SB efficacy. Skin RNA samples from the 14-week time point (n=4/group; RIN≥7; DV200>85%) were subjected to library preparation (550 ng of total RNA; Zymo-Seq RiboFree Total RNA Library Kit), ribosomal RNA-depletion RNA sequencing (80 million paired-end reads/sample), and data processing. About 16,000 unique genes were identified, of which ~65% were protein-coding genes. The samples within each group were highly correlated (mean>0.99; Pearson's correlation). The UVB cluster was sequestered away from the other groups, indicating that the SB diet effectively mitigated the effects of UVB exposure, even at the transcriptome level. Additionally, gene ontology and pathway enrichment analysis (Ingenuity Pathway Analysis, Qiagen) of differentially expressed genes ($p<0.05$; fold change≤2) showed UVB-induced aberration and SB-associated enrichment in mitotic prometaphase, metaphase, and anaphase pathways, RHO GTPase signaling, and cell cycle regulation; the top functional network found to be dysregulated was lipid metabolism. Taken together, these results highlight the potential of dietary SB intake (apart from topical SB) to be an effective modality against UVB-induced BCC formation and growth and identify molecular targets that are plausibly involved in SB efficacy.

#7311 Lipid soluble vitamin B1 derivatives, benfotiamine and fursultiamine, prevent breast cancer cells growth.

C. C. O'Neill, **A. P. Langmead**, K. V. Ramana;
Noorda College of Osteopathic Medicine, LLC, Provo, UT

Breast cancer is the leading cause of cancer death in women in the US and the second leading cancer after skin cancer in women worldwide. According to the CDC, women from 45-84 years of age are most at risk, with approximately 30% of deaths in this group being from cancer. Increased free radical formation, and oxidative and inflammatory responses have been shown to be major contributing factors for the progression of breast cancer. Several antioxidants and vitamins have been tested for their efficacy in preventing breast cancer. However, the role of vitamin B1 derivatives in the prevention of breast cancer is not known. Therefore, we hypothesize that with potent anti-oxidative and anti-inflammatory actions, lipid-soluble derivatives of vitamin B1 (thiamine), such as benfotiamine and fursultiamine, could prevent breast cancer growth and spread. We have treated human breast cancer cells such as MCF-7 and T-4D1 and mouse breast cancer cells 4T1 with vitamin B1 derivatives and examined the cancer cells growth. Our results indicate that treatment of various breast cancer cells with benfotiamine and fursultiamine prevents the proliferation of cancer cells in a dose-dependent manner. Further, both benfotiamine and fursultiamine by regulating the activation of caspase-3 and cleavage of PARP protein could prevent breast cancer cells growth. Benfotiamine and fursultiamine also regulates generation of reactive oxygen species in breast cancer cells. Further, vitamin B1 derivatives regulate the expression of various anti-apoptotic, pro-apoptotic, survival and inflammatory factors in both human and mouse breast cancer cells. We next planned to examine the effect of vitamin B1 derivatives on breast cancer growth in vivo using athymic nude mouse models. In conclusion, our in vitro results suggest that vitamin B1 derivatives, benfotiamine and fursultiamine, by promoting the apoptotic pathways prevent breast cancer cells growth and could be further developed as chemopreventive drugs.

#7312 Construction of a gene panel for liquid biopsy-based diagnostics of gynecologic cancer.

S. Schumacher, T. Carlsson, J. Malchau Lauesgaard, A. Linder, A. Olsson Widjaja, K. Sundfeldt;
University of Gothenburg, Gothenburg, Sweden

Background: Ovarian carcinoma (OC) is the leading cause of death from gynecologic cancers mainly due to late detection, where most patients are diagnosed at advanced stages (51% in stage III; 29% in stage IV). Despite an overall more favorable prognosis, endometrial carcinoma (EC) is the most common gynecologic cancer, with an increasing incidence and where some subtypes are associated with a poor prognosis. Identification of DNA mutations from precancerous lesions or early-stage OC and EC would allow for early intervention. Liquid biopsies through routine sampling such as endocervical sampling, or blood collection for isolation and analysis of ctDNA have previously been assessed for their use in detection of OC and EC. These studies have provided evidence that tumor-derived mutations can be detected in endocervical samples, supporting endocervical liquid biopsies as a potential source of ctDNA. Herein, we aimed to construct a diagnostic gene panel corresponding to common mutation profiles of OC and EC to detect early-stage malignancy through a non-invasive approach.

Methods: Using the NGS-method, Simple multiplexed PCR-based barcoding of DNA for sensitive mutation detection using sequencing (SiMSen-Seq), a gene panel was constructed targeting hotspot mutations in known OC- and EC-associated genes. Hotspots were identified using the Catalogue of Somatic Mutations in Cancer (COSMIC) database or retrieved from the literature and assays were designed for amplification of short DNA fragments. Precise assay development was carried out including multiple steps of careful validation to ensure high specificity and efficient amplification. Individual assays were validated in multiple steps using qPCR and fragment analysis.

Results: The gene panel was designed as two non-overlapping subunits for comprehensive diagnosis of OC and EC. The two constructed multiplexes, together composed of 125 single assays target genomic regions in 34 EC and OC-associated genes e.g., *PTEN*, *TP53*, *PIK3CA* and *CTNNB1*. Included assays had a median amplicon size of 92 bp (range 57-111 bp). Both multiplexes displayed good performance with distinguishable libraries at low DNA input (10 ng). Validation of individual assays showed high specificity and efficient amplification where >80% of assays displayed a sequencing coverage >500 UMI counts at a consensus depth of 3. Patient coverage calculations of COSMIC data suggested comparable coverage as similar published approaches.

Conclusion: The results suggest that the constructed gene panel has great potential to detect mutations in liquid biopsies collected from the gynecologic tract, despite low tumor DNA levels. Validation of the two multiplexes by fragment analysis and sequencing showed high performance, hence, prospective for the approaching sequencing of liquid biopsies.

#7313 Risk assessment, early detection, and strategic prevention of naturally occurring cancers in companion dogs.

J. F. Modiano[1], A. J. Schulte[1], R. Dicovitsky[2], T. A. DePauw[1], A. Khammanivong[1], M. Lewellen[1], L. E. Burt[1], D. A. Vallera[1], G. R. Cutter[3], A. L. Winter[2], K. M. Stuebner[1], A. Chehadeh[2], S. Pracht[2], A. Borgatti[1], M. S. Henson[1], E. B. Dickerson[1], C. Ober[4], K. L. Anderson[2], E. Nell[5], A. L. Sarver[1];
[1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, St. Paul, MN, [3]University of Alabama, Birmingham (Emeritus), Birmingham, AL, [4]Darkside Veterinary Imaging, Woodbury, MN, [5]Acuity Veterinary Imaging, Menlo Park, CA

Our research is (focused) on delineating the relationship of aging and cancer with the goal to develop prevention and intervention therapies. Our success towards this end is based on the ability to employ companion dogs in clinical studies, particularly given the similarities of aging and cancer in dogs and people. Here, we report results of the development of both a companion diagnostic and a potential therapeutic intervention from the canine clinical Shine On study. The Shine On study included a training set of 97 dogs in four groups, consisting of (1) healthy 2-4 year-old dogs that were skeletally mature but had not reached the age boundary where cancer risk is apparent, and three groups where dogs had pathologically confirmed (2) hemangiosarcomas, (3) other malignant cancers, or (4) benign splenic masses. It also included a test set of 209 dogs over 6 years of age with no evidence of cancer or other chronic diseases. Using the Shine On Suspicion (SOS) test, dogs could be assigned to a low-risk category, where the probability of developing cancer over the next 400 days (approximately 1/10th of a modern domestic dog's lifespan) was less than 4%, or to a high-risk category, where the probability of developing cancer over the same time period was almost 25%, and it increased to more than 50% by 1,450 days. Not surprisingly, the relative risk of cancer in dogs that were originally assigned to the low-risk category increased in a fashion that was comparable to that seen in dogs assigned to the high-risk category within 400-600 days after testing. We have used the bispecific ligand targeted toxin, eBAT, as a strategic preventative in seven dogs to date. The drug is well tolerated and associated with favorable outcomes (extended lifespan with no cancer deaths). Ongoing experiments seek to define the identity and functional properties of putative-niche forming cells and mechanisms through which we can modify the permissive environment to delay or prevent cancer in dogs - and eventually in humans.

#7314 Technological and economic values of an AI-based pre-screening multi-cancer early detection (MCED) liquid-biopsy test as a companion system for a cancer screening solution.

B. G. Kermani;
Crystal Genetics, Inc., Los Altos, CA

Multi-cancer early detection (MCED) liquid biopsy screening tests provide great promise for both first-time cancer detection, and recurrence monitoring applications. The prominent feature of asymptomatic cancer screening solutions is their demand for ultra-high specificity (e.g., circa 99.99%), while maintaining a reasonable sensitivity. However, the challenges of screening are not limited to these technical specifications. Among other challenges, psychological and economical barriers-to-entry can be mentioned. In this work, we discuss the value of adding a high-sensitivity liquid-biopsy prescreening system to a screening solution. Such a tandem system can retain the high specificity offered by the screening solution, while relieving some of the economical concerns in cancer screening, by providing an opportunity to forgo screening in individuals with negative prescreening results. In order to serve in a general multi-cancer scheme, the prescreening solution must be MCED in nature. While our screening solution is primarily single-cell genomics/proteomics-based, we adopted a predominantly proteomics-based solution for prescreening. A proteomics solution has the potential to be notably more economical due to its simplicity/maturity. This is in contrast to the relatively high cost of the 'omics-based screening methods. Nevertheless, proteomics-based solutions, historically, have suffered from limited sensitivity and low specificity. In order to attain a high sensitivity while maintaining a workable specificity, we have used a complex Artificial Intelligence (AI) based system, comprising machine learning (ML) and Expert Systems (ES). Our MCED blood-based prescreening solution has been successfully tested on a series of cancers, including (among others) the cancers of breast, lung, prostate, ovary, uterus, and cervix, with cancer signal detection sensitivity of ≈92% for early stages (Stage I or II). While a tandem prescreening-screening system is designed primarily for testing asymptomatic individuals for early detection of cancer, a prescreening method has other potential uses. For instance, it can be used for: 1) minimal residual disease (MRD) detection after treatment; 2) recurrence monitoring after achieving remission. In particular, in cases where the original cancer is aggressive and has a high chance of recurrence, e.g., triple-negative breast cancer (TNBC), such a prescreening test can be repeated several times in the course of a year, providing the patient with measurements that are affordable and near real-time. In conclusion, the introduced proteomics/AI-based prescreening system could provide an economical, yet high-sensitivity solution for general adoption, acting primarily as a molecular risk assessment tool, to be performed prior to using a high-specificity screening modality.

#7315 Collaboration between NIDCR and NCI promotes innovative research in head and neck cancers.

Z. Chen[1], W. Wang[2];

[1]National Institute of Dental and Craniofacial Research, NIH, Bethesda, MD, [2]National Cancer Institute, NIH, Rockville, MD

The Oral and Salivary Cancer Biology Program at National Institute of Dental and Craniofacial Research (NIDCR) supports research activities that improve early detection and treatment of cancers of the oral cavity, pharynx, and salivary glands. We promote basic science research on the regulatory pathways and transformation process of pre-cancerous lesions to primary and metastatic tumors, as well as translational science activities to develop novel technologies and therapeutics for the diagnosis, prognosis, and treatment of cancers. NIDCR and National Cancer Institute (NCI) have established long-term collaborations to promote and co-manage awards funded through The Immuno-Oncology Translational Network (IOTN) of the Cancer Moonshot program, Specialized Programs of Research Excellence (SPOREs), and Early Detection Research Network (EDRN) program. NIDCR and NCI have co-developed Notice of Special Interest (NOSI) and Request for Application (RFA) on Advancing Head and Neck Cancer Early Detection Research (AHEAD), which co-funded seven research projects to discover and develop molecular signatures of early detection and diagnosis of HPV positive and negative head and neck cancer (HNC). To further strengthen NIDCR and NCI collaboration, we jointly organized the symposium to promote HNC early detection and biomarker identification at the American Head and Neck Society (AHNS) 11th International Conference on Head and Neck Cancer in July 2023. In addition, NIDCR has organized a symposium to promote HNC research at the 2024 annual meeting of American Association for Dental, Oral, and Craniofacial Research (AADOCR) to celebrate the 75th anniversary of NIDCR. This AADOCR symposium will feature the collaboration between NIDCR with NCI in the Cancer Moonshot program focusing on immunoprevention and immunotherapy, HNC early detection and biomarker research in AHEAD and EDRN, and investigation of HPV positive and negative HNC and clinical translational research under SPORE. At this 2024 AACR annual meeting, NIDCR and NCI program directors will present the collaborations and funding opportunities between NIDCR and NCI, focusing on early cancer detections and biomarker discovery and validation. Collaboration between NIDCR with NCI provides a unique opportunity to promote basic, translational, and clinical research in advancing HNC early detection to benefit cancer patients.

#7319 Glycemic traits and colorectal cancer survival in a cohort of South Korean patients: A Mendelian randomization analysis.
S. Jun, S. Cho, M. Kim, J. Park, S. Jeong, A. Shin;
Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Clinical diabetic traits have been reported to be associated with increased colorectal cancer risk (CRC) in observational studies. Using the Mendelian randomization (MR) analysis method, we examined the causal association between glycemic traits, such as fasting glucose (FG), fasting insulin (FI), and glycosylated hemoglobin A1c (HbA1c), and survival in a cohort of CRC patients.
Methods: We conducted a two-sample MR analysis among a cohort of patients with locally advanced CRC at Seoul National University Hospital. Single-nucleotide polymorphisms robustly associated ($P<5\times10^{-8}$) with the three glycemic traits were obtained from the Meta-Analyses of Glucose and Insulin-related traits Consortium, Asian Genetic Epidemiology Network, and Korea Biobank Array. Three-year and five-year overall survival (OS) and progression-free survival (PFS) were used as outcomes. Survival analysis was conducted using subgroup analysis by cancer stage and subsite in a multivariate Cox proportional hazards model adjusted for age and sex to examine whether glycemic traits affected survival.
Results: A total of 509 patients were included in our final analysis. MR analysis showed that HbA1c levels were associated with poor three-year OS ($\beta=4.20$, $P=0.02$). Sensitivity analyses did not show evidence of any violations of the MR assumptions. In the cancer subgroup analysis of the Cox proportional hazards model, pooled hazard ratios for FG were significantly associated with poor three-year OS and PFS regardless of cancer stage. FI was not significantly associated with any three-year survival endpoints. Among stage III patients, three glycemic traits were significantly associated with both five-year OS and PFS. Location-specific subgroup analysis showed a significant association between three glycemic traits and five-year PFS in patients with left-sided colon cancer. FG was associated with poor three-year survival for colon cancer but not rectal cancer.
Conclusions: Our results suggest that FG and HbA1c could be used to predict prognosis in CRC patients. Lifestyle and/or pharmacological interventions targeting glycemic traits could help improve survival for CRC patients.

#7320 Expression of circadian rhythm genes and lethal prostate cancer.

J. B. Vaselkiv[1], S. C. Markt[2], H. E. Guard[1], A. Wang[1], K. L. Penney[3], K. H. Stopsack[4], L. A. Mucci[1];
[1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]Jazz Pharmaceuticals, Palo Alto, CA, [3]Brigham and Women's Hospital, Boston, MA, [4]Massachusetts General Hospital, Boston, MA

Background: The circadian rhythm regulates diverse physiological and oncologic processes. We have previously shown in epidemiology studies that disruption of the circadian rhythm may be associated with increased risk of aggressive prostate cancer, including germline polymorphisms in certain circadian rhythm genes. This study sought to investigate the relationship between tumor circadian rhythm gene expression and lethal prostate cancer.
Methods: We studied patients with primary prostate cancer in the Health Professionals Follow-up Study (HPFS) and Physicians' Health Study (PHS). We created a composite score of mRNA expression using principal components that incorporated 11 circadian rhythm genes: *AANAT, ARNTL, CLOCK, CRY1, CSNK1E, MTNR1A, MTNR1B, NPAS2, PER1, PER2, PER3*. An age-stratified analysis was performed, and the mean differences of the score both by Gleason score and compared to normal tissue were calculated. The relationship between the score in prostate tumor tissue and lethal prostate cancer (metastases/prostate cancer-specific death) vs. indolent disease (no metastases after >8 years of follow-up) was assessed using logistic regression. The contribution of each gene was evaluated by leave-one-out analysis, generating scores leaving out one gene and assessing the relationship between the modified score and lethal disease.
Results: Among 404 cancer patients in HPFS/ PHS, there were 119 lethal events over 30 years of follow-up (median: 17 years). The circadian rhythm gene score was lower in tumor tissue compared to tumor-adjacent, histologically normal tissue (mean difference in units of standard deviation [SD] of gene score: -0.31, 95% confidence interval [CI]: -0.48 to -0.15). In addition, the score was lower in Gleason 9-10 compared to Gleason 6 tumors (mean difference in SD units: -1.05, 95% CI: -1.55 to -0.54). The three *PER* genes were the most strongly correlated with each other and with the score (Spearman correlation coefficients from 0.52-0.88 for the score and 0.31-0.63 between *PER* genes). Higher circadian rhythm gene scores were inversely associated with lethal prostate cancer (odds ratio [OR] for highest vs. lowest quartile: 0.43, 95% CI: 0.20 to 0.90) in a dose-response fashion and after adjusting for clinical and pathologic factors. The association appeared to be stronger in patients aged ≥65 years (OR for highest vs. lowest quartile: 0.21, 95% CI: 0.08 to 0.47) compared to <65 years at diagnosis (OR: 0.78, 95% CI: 0.29, 2.17). Results were consistent in the leave-one-out analysis for all genes except *PER2* (OR for highest vs. lowest quartile: 1.00, 95% CI: 0.55 to 1.83) and *PER1* (OR: 0.55, 95% CI: 0.30 to 1).
Conclusion: This study examining intratumoral circadian rhythm gene expression contributes further evidence in support of the relationship between circadian rhythm disruption and aggressive prostate cancer. Tumor expression of *PER1* and *PER2* may be a predominant factor in the association.

#7321 Second primary cancer risks following breast cancer in *BRCA1/2* pathogenic variant carriers.

I. Allen[1], H. Hassan[1], Y. Walburga[1], C. Huntley[2], L. Loong[2], T. Rahman[3], B. Torr[2], A. Bacon[3], C. Knott[3], S. Jose[3], S. Vernon[3], M. Luchtenborg[4], J. Pethick[3], F. Santaniello[3], S. Goel[3], S. Allen[2], K. Lavelle[3], F. McRonald[3], D. M. Eccles[5], E. Morris[6], S. Hardy[3], C. Turnbull[2], M. Tischkowitz[1], P. Pharoah[1], A. C. Antoniou[1]; [1]University of Cambridge, Cambridge, United Kingdom, [2]Institute of Cancer Research, London, United Kingdom, [3]National Disease Registration Service, London, United Kingdom, [4]King's College London, London, United Kingdom, [5]University of Southampton, Southampton, United Kingdom, [6]University of Oxford, Oxford, United Kingdom

Background

Second primary cancer (SPC) risk estimates in breast cancer (BC) survivors carrying germline BRCA1/2 pathogenic variants (PVs) remain uncertain. We estimated relative and absolute SPC risks following BC in BRCA1/2 PV carriers using genetic testing laboratory data in England, linked for the first time to population-scale electronic health records data from the National Disease Registration Service and Hospital Episode Statistics.

Material and methods

The cohort contained 27,154 women diagnosed with primary BC and tested for germline BRCA1/2 PVs between 1995-2019. Follow-up began at the latest of the genetic test dates and one year following the BC diagnosis and continued until the first SPC diagnosis, death, migration, relevant surgery, and the end of 2020, whichever came first. We estimated overall and site-specific standardized incidence ratios (SIRs) by comparing observed and expected SPC counts, with expected counts calculated using incidences for the general English population accounting for calendar year, SPC site, age, and gender. We stratified the SIRs by age, estrogen-receptor status, and cancer site. We further assessed associations using Cox regression adjusted for age at BC diagnosis and estrogen-receptor status of the first BC, and estimated 10-year absolute SPC risks with Kaplan-Meier analysis.

Results

There were 1909 BRCA1 (138 with SPCs) and 1926 BRCA2 (101 with SPCs) PV carriers, with mean follow-up lengths of 4.2 and 4.4y and median follow-up lengths of 3.4 and 3.6y. In BRCA1 PV carriers, there were elevated contralateral BC (SIR:15.3, 95%CI:11.5-19.8), ovarian (SIR:43.3, 95%CI:30.9-58.9), non-breast and non-ovarian combined (SIR:2.23, 95%CI:1.63-2.98), colorectal (SIR:4.72, 95%CI:2.58-7.92) and uterine (SIR:3.42, 95%CI:1.25-7.44) SPC risks. In BRCA2 PV carriers, there were increased contralateral BC (SIR:7.53, 95%CI:5.33-10.3), ovarian (SIR:16.5, 95%CI:10.1-25.5), non-breast and non-ovarian (SIR:1.72, 95%CI:1.27-2.27) and pancreatic (SIR:6.57, 95%CI:2.63-13.5) SPC risks. Consistently, when we compared BC survivors carrying a BRCA1 PV to BC survivors without a PV in either gene, they were at elevated contralateral BC (HR:3.94, 95%CI:2.91-5.33), ovarian (HR:35.7, 95%CI:21.3-60.0), non-breast and non-ovarian (HR:1.53, 95%CI:1.11-2.12) and colorectal (HR:2.95, 95%CI:1.56-5.55) SPC risks, whereas BRCA2 PV carriers were at increased contralateral BC (HR:2.59, 95%CI:1.83-3.65), ovarian (HR:12.3, 95%CI:6.93-21.9) and pancreatic (HR:5.32, 95%CI:2.30-12.3) SPC risks. We estimated 10-year cumulative contralateral BC, ovarian, and non-breast and non-ovarian SPC risks of 15%, 6.3%, and 7.8% in BRCA1 PV carriers and 12%, 2.9%, and 6.2% in BRCA2 PV carriers.

Conclusions

Cancer risks were increased, at combined and specific sites, following BC in BRCA1/2 PV carriers. These findings could aid the clinical management of BC survivors carrying BRCA1/2 PVs.

#7322 Polygenic adaptation and co-regulatory dynamics in Chernobyl wolves: Unveiling immune and oncogenic stress interactions with implications for human cancer resilience.

C. Y. Yu[1], C. N. Love[2], M. Belete[1], H. Chandrupatla[1], L. K. Brady[1], S. Sridhar[1], S. C. Campbell-Staton[2];
[1]Genmab, Plainsboro, NJ, [2]Princeton University, Princeton, NJ

Wolves living in the Chernobyl Exclusion Zone (CEZ) for at least six generations have adapted to high radiation exposure and are a unique model for studying genetic selection under extreme conditions of oncogenic stress. The objective of this study was to build off previously described signatures of adaptation in CEZ wolves, identify networks of genes associated with immune adaptation in CEZ wolves, and determine prognostic significance of these genes in human cancer datasets to provide insight into immune adaptation and cancer immunity.

RNA from blood samples of wolves in CEZ, Belarus (BLR), and Yellowstone (YLS) were sequenced previously. Here we analyzed these data by mapping wolf transcripts to human orthologs. Radiation exposure (in CEZ and BLR) was quantified by intramuscular Cesium-137. Differential gene expression (DESeq2), network co-expression analysis (lmQCM), and gene set variation analysis (GSVA) assessed transcriptomic changes between populations. Germline single nucleotide polymorphism (SNP) for all three populations were inferred from RNA-seq data.

Genes differentially regulated between populations, including gene modules showing signatures of polygenic selection through increased rates of genetic divergence ($p < 0.05$) in CEZ wolf populations, were deemed as outlier genes. Those n=3,180 CEZ outlier genes were then investigated in human cancer data from The Cancer Genome Atlas (TCGA) to determine prognostic impact in 10 tumor types highly conserved between human and canines.

GSVA confirmed activation of neutrophil and macrophage signatures in CEZ wolves and suppression of several adaptive immune-related signatures ($p < 0.05$ vs BLR and YLS). A signature including immune checkpoint targets was also significantly differentially expressed in CEZ wolves. In TCGA, Cox PH analysis identified 23 genes over-expressed in CEZ wolves with significant positive prognostic impact in ≥ 2 human tumor types. PTPN6, previously identified to have positive prognostic value in bladder cancer[1], was also prognostic in three additional tumor types. In human bladder cancer, genes identified as differentially regulated in CEZ wolves were disproportionately associated with improved survival.

As predicted, gene signature variations in CEZ wolves reveal a distinct immune profile, likely shaped by prolonged radiation exposure. These findings, along with evidence of polygenic selection, suggest adaptation to multigenerational radiation exposure (an oncogenic stress). Notably, the enrichment of genes with positive prognosis in human cancer overexpressed in CEZ wolves present a valuable model to explore genetic underpinnings of cancer immunity and advance our understanding of cancer resilience in humans.

#7323 Tissue resident memory T cell abundances impact non-small-cell lung cancer immune microenvironment and patient prognosis.

Aidan Shen[1], Aliesha Garrett[1], Junhua Mai[2], Yangzhi Zhu[1], **Chongming Jiang**[1]

[1]Terasaki Institute for Biomedical Innovation, Los Angeles, CA,[2]Department of Nanomedicine, Houston Methodist Research Institute, Houston, TX

Tissue resident memory T cells (TRM) are a specialized subset of long-lived memory T cells that reside in peripheral tissues. However, whether TRM exerts any immunosurveillance role in the tumor immune microenvironment (TIME) and progression of non-small-cell lung cancer (NSCLC), which accounts for 85% of all lung cancers, remains unclear. Our comprehensive analysis of multiple independent single-cell and bulk RNA-seq datasets of patient NSCLC samples generated reliable, unique TRM signatures, through which we could infer the abundance of TRM in NSCLC. We discovered that TRM abundance is consistently positively correlated with CD4+ T helper 1 cells, M1 macrophages, and resting dendritic cells in TIME and significantly impacts the prognosis of NSCLC patients. In addition, TRM signatures are strongly associated with immune checkpoint genes and the prognosis of NSCLC patients, suggesting that TRM signatures are promising prognostic markers for immunotherapy in NSCLC. We then built a machine learning model to predict patient survival based on the TRM signatures and immune related genes. The accuracy of the model was validated by Kaplan-Meyer survival analysis, receiver operating characteristic curves, principal component analysis, and t-distributed random neighbor embedding. We developed a 4-gene risk score that effectively stratified patients into low-risk and high-risk categories. The patients with high-risk scores had significantly lower overall survival than patients with low-risk. The prognostic value of the risk score was independently validated by the Cancer Genome Atlas Program (TCGA) dataset and multiple independent NSCLC patient datasets. Notably, low-risk NSCLC patients with higher TRM infiltration exhibited enhanced T-cell activation, macrophage regulation, and other TIME immune responses related pathways, indicating a more active immune profile benefitting from immunotherapy. Altogether, this study provides valuable insights into the complex interactions between NSCLC TRM and TIME and their impact on patient prognosis, highlighting the importance of TRM in shaping the NSCLC microenvironment. The development of a simplified 4-gene risk score provides a practical prognostic marker for risk stratification.

#7324 Impact of BMI on immune pathways in preinvasive colorectal lesions.

L. R. Fanning[1], B. Hamidi[1], I. Korostenskij[1], S. Seal[1], T. L. Crawford[1], T. A. MacKenzie[2], E. L. Barry[3], J. E. Thaxton[4], M. J. Shrubsole[5], B. Vincent[6], J. A. Baron[6], A. V. Alekseyenko[1], K. Wallace[1];

[1]The Medical University of South Carolina (MUSC), Charleston, SC, [2]Dartmouth Geisel School of Medicine, Lebanon, NH, [3]Dartmouth Geisel School of Medicine, Hanover, NH, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]Vanderbilt Epidemiology Center, Vanderbilt University School of Medicine, Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN, [6]University of North Carolina School of Medicine, Chapel Hill, NC

Background: Obesity is a risk factor for colorectal neoplasia, possibly mediated by metabolic dysregulation or chronic inflammation. Circulating inflammatory cytokines have been associated with an increased risk of CRC, but no studies have examined the impact of BMI on immune gene expression in preinvasive lesions. Our analysis combines data from 3 retrospective epidemiologic studies among patients with colorectal adenomas or serrated polyps. Using a cross-sectional design, we investigate whether BMI categories (obese (OB), overweight (OW), normal (NL)) are associated with T-helper gene pathways.

Methods: For each patient, we include demographic, clinical, and specimen (archival FFPE for RNA isolation) data. Immune gene expression data was determined using the NanoString nCounter platform on a subset of cases (n=100) balanced by study site and lesion type from our cohort (n=630). Genes were normalized using a modified RUVseq methodology. We examined 4 pathways (Th1, Th2, Th17, Treg) defined by gene lists included in the NS immune v2. panel. Differences in pathway expression by BMI categories were analyzed using our distance-based methods (Wd* multivariate analysis of variance and TW2 pairwise method) adjusted for age & sex. Using linear regression analysis, we generated coefficients (p-values) for OW and OB vs NL for genes within each pathway.

Results: 86 samples passed QC. Th2 and Th1 pathways were significant for OW vs NL ($p<0.05$) whereas Th17 was marginally significant (<0.1). Several genes within the Th1, Th2, and Th17 pathways were enriched in OW vs. NL: e.g., *IL2* (coeff. 0.77 (p=0.008), *IL5* (coeff. 1.02, p=0.001), *IL17F* (coeff. 0.57, p=0.05), respectively. (Table)

Conclusion: Enrichment of genes specific to the Th pathways in OW persons suggest that metabolic immune modulation may be important in early colorectal carcinogenesis.

Differences in immune pathway and gene expression by BMI categories

The success of precision cancer prevention and treatment hinges on accurate discrimination between benign and pathogenic germline alleles in cancer susceptibility genes. Variants of uncertain clinical significance (VUS) present a challenge for cancer risk assessment and functional data will be essential to resolve many VUS. To address this, we developed a cloud-based environment to collate, curate, integrate and analyze all published functional data related to *BRCA1* and *BRCA2* missense VUS. Then, functional evidence criteria for pathogenicity were determined for each assay using the American College of Medical Genetics and Genomics/Association for Molecular Pathology (ACMG/AMP) classification guidelines and ClinGen criteria. Our approach involved retrieving published articles reporting one or more functional assays of *BRCA1/2* missense variants reporting variant impact on various biochemical and cell biological functions. Functional results were recorded using original authors' thresholds and categories, then converted to ordinal variables to harmonize: [0 = no functional impact], [1 = intermediate impact], and [2 = functional impact]. For *BRCA1*, we updated our previous published integration (Genet Med. 2021;23:306-315) with 14 additional publications, collating results from 53 instances of functional assays reporting functional data on 3,219 unique missense variants. For *BRCA2*, 28 publications were identified reporting data from 141 instances of functional assays on 4,759 unique missense variants. Utilizing a panel of 542 and 396 known pathogenic and benign reference variants for *BRCA1* and *BRCA2*, respectively, we determined the sensitivity, specificity, and ACMG/AMP odds of pathogenicity for each instance of the assay. The remaining variants were assigned a relevant functional assay code weight for each assay instance. Our study successfully derived ACMG/AMP evidence strength from functional data for 3,040 *BRCA1* (94% of 3,219) and 2,704 *BRCA2* (57% of 4,759) missense variants. This comprehensive work underscores the utility of functional data in informing classification of *BRCA1* and *BRCA2* missense VUS.

#7326 *TP53* p.Pro47Ser polymorphism in breast cancer susceptibility in Mali.

B. Diakite[1], Y. kassogue[1], M. Maiga[2], O. kassogue[1], K. Cisse[1], F. Diarra[1], C. B. Traore[1], B. Kamate[1], J. L. Holl[3], L. Hou[2];
[1]University of Sciences, Techniques And Technologies of Bamako, Bamako, Mali, [2]Northwestern University, Chicago, IL, [3]University of Chicago, Chicago, IL

Background: The aim of this study was to assess the potential association of p.Pro47Ser polymorphisms of TP53 with the risk of developing breast cancer in the Malian population.
Methods: We analyzed DNA samples from 72 breast cancer patients and 121 unrelated healthy, age-matched individuals to examine the presence of the polymorphisms. The genotyping of TP53 polymorphism was performed using PCR-RFLP and HRM (high-resolution melting) methods.
Results: The genotypic frequencies of PP, PS, and SS were found to be 63.9% PP, 30.6% PS, and 5.6% SS in breast cancer patients, compared to 70.2% PP, 22.3% PS, and 7.4% SS in the control group. The frequencies of P and S alleles of TP53 p.P47S polymorphism were 79.2% vs 81.4%, 20.8% vs 18.6%, and 5% vs 4.5% in patients and controls, respectively. In this study, no significant correlation was observed between TP53 p.Pro47Ser polymorphism and breast cancer in the Malian population (Pro/Ser vs Pro/Pro: OR = 1.55, 95% CI = 0.80-3.05, P = 0.19; Ser/Ser vs Pro/Pro: OR = 1.27, 95% CI = 0.34-4.74, P = 0.71; and Ser vs Pro allele: OR = 1.39, 95% CI = 0.80-2.32, P = 0.24).
Conclusion: Despite the absence of a genetic association between TP53 p.Pro47Ser and the risk of breast cancer in Malian patients, our findings suggest that individuals carrying at least one minor Ser allele are not protected against the disease.

#7327 Investigating the cell-type specific regulation of *IRF4* and its role in lung cancer via a lung cancer risk-associated pleiotropic variant.

A. Kane[1], J. Yin[1], E. Long[2], J. Feng[1], C. Grawe[3], H. Patel[1], J. Byun[4], C. Amos[4], K. Brown[1], J. Xia[5], M. Vermeulen[3], J. Choi[1];
[1]National Cancer Institute, National Institutes of Health, Rockville, MD, [2]Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [3]Faculty of Science, Radboud Institute for Molecular Life Sciences, Oncode Institute, Radboud University Nijmegen, Nijmegen, Netherlands, [4]Baylor College of Medicine, Houston, TX, [5]Creighton University, Omaha, NE

Although smoking is a main risk factor for lung cancer, genetic factors also contribute to the risk, as shown by over 50 genomic loci identified by genome-wide association studies (GWAS). A recent cross-ancestry lung cancer GWAS identified a common germline variant, rs12203592 (C/T), in chr6p25.3 as a new signal, and quantitative trait loci (eQTL) colocalization analysis using lung and blood tissues (GTEx v8) identified *IRF4* as a likely target of rs12203592. rs12203592 has previously been linked with diverse traits, including pigmentation phenotypes, smoking cessation, lymphoblastic leukemia, melanoma, and other skin cancers. rs12203592 also appears to have varied allelic effects in different cell types. Namely, the lung cancer risk-associated T allele is correlated with higher *IRF4* expression in lung tissue and blood cells (GTEx v8) but lower expression in primary melanocytes (n = 106; Zhang et al). Since previous studies established the melanocyte-specific allelic function of this SNP through lineage-specific transcription factors (TFs), we hypothesized that cell-type-specific TFs mediate the observed allelic effect in different tissue/cell types and further contribute to the unique role of IRF4 in lung tumorigenesis. To identify these potential cell-type-specific regulators, we performed mass spectrometry using the nuclear extracts from three cell lines representing lung, blood, and melanocyte lineage. The results nominated the NF-kB and ZEB protein families as the most prominent T-specific binders in the A549 lung cancer cell line, which was validated by electromobility shift assays. Consistent with these findings, tissue-based SNP-gene interaction analysis demonstrated that the mRNA levels of NF-kB and ZEB family members (4 of 7 genes) were correlated with *IRF4* expression with a significant interaction with rs12203592 in GTEx lung tissue ($P < 0.017$), where the correlation is mainly observed with the T allele. Notably, the SNP interaction was less pronounced in whole blood or melanocytes, and the correlation of these TFs and *IRF4* expression was mainly observed with the C allele in melanocytes. To begin to establish the roles of these TFs and IRF4 in lung tumorigenesis and given that *IRF4* was shown to promote endogenous DNA damage and proliferation of lung-lineage cell lines, we will investigate the roles of NF-kB and ZEB in *IRF4* regulation in these contexts using knockdown and overexpression of these TFs. To further investigate lung cancer-specific IRF4 function, we will identify potential targets of IRF4 among lung cancer-associated functional variants established through our previous studies. This data will help elucidate the context-specific roles of *IRF4* in lung cancer development and provide clues to gene regulation in a pleiotropic GWAS locus.

#7328 Relationship between PIN3 16bp duplication of TP53 and HPV in HIV women in Mali.

M. Maiga[1], B. Diakite[2], Y. Kassogue[2], B. Traore[2], O. Kassogue[2], B. Kamate[2], C. B. Traore[2], J. L. Holl[1], L. Hou[1];
[1]Northwestern University, Chicago, IL, [2]University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali

Background: TP53 polymorphisms can influence the immune response to HPV, affecting TP53's role in cell cycle regulation and apoptosis, crucial for controlling HPV infection and preventing cancer.
Objective: Explore the link between TP53 PIN3 16-bp duplication and HPV infection in HIV-positive Malian women.
Methods: This study explored the link between PIN3 16-bp duplication polymorphism of TP53 and HPV infection in 50 HIV-positive women in Mali. Data included surveys, self-sampled vaginal swabs, and blood collection. HPV typing used GeneXpert, and PIN3 genotyping utilized AS-PCR.
Results: Participants, primarily >30 years (92%), had a mean age of 43.30 ± 10.332 years. HPV prevalence was 36%, with P3 being the most common subtype (30.8%). PIN3 genotypic frequencies were A1A1 (50%), A1A2 (34%), and A2A2 (10%). History of sexually transmitted infections correlated with higher mutation rates (37.8% A1A2, 10.8% A2A2). A2A2 genotype prevalence was higher in HIV-positive women with specific HPV subtypes (P5, P4, HPV16, P3, P18/45). A1A2 genotype was observed in 60% of HPV subtype P3 cases and 20% of P4 and P18/45 cases.
Conclusion: These results suggest a link between TP53 gene polymorphisms and susceptibility to different HPV subtypes in HIV-positive women, warranting further research into their functional implications and impact on HPV-related diseases in this population.
Keywords: TP53 polymorphism, HPV, HIV, Malian population

#7329 Novel MAVE models for MLH1, MSH2, and PMS2 have high accuracy.

W. M. Korn, S. Padigepati, D. Stafford, F. Facio, B. Johnson, K. Nykamp, J. Reuter;
Invitae, San Francisco, CA

Lynch syndrome, the most common cause of hereditary colorectal cancer, is due to pathogenic germline variants in mismatch repair (MMR) genes. Variants of uncertain significance (VUS) in MMR genes hinder diagnoses and clinical management. Multiplex assays of variant effects (MAVEs) are high-throughput cellular assays designed to provide functional data on variant activity. Successful MAVE experiments accurately define the pathogenicity of single nucleotide variants and small insertions-deletions which can then be applied to clinical variant classification (VC). Here we report internally generated MAVE datasets for three MMR genes (MSH2, MLH1 and PMS2) and estimate their impact on patients.

Three separate pools of targeted variants were generated for three MMR genes. Pooled variants were introduced into cell populations such that each cell contained one variant copy of an MMR gene. Single-cell RNA expression profiles were generated for the cells which were then normalized and filtered. Supervised machine learning was used to find patterns in gene expression that were different between cells harboring established pathogenic (P) and benign (B) variants and to assess the accuracy of variant predictions. VC impact was estimated for all datasets by simulating VCs with the added MAVE evidence compared to the original VCs. Variants with an original VC that was different after MAVE evidence were counted as impacted.

Overall results are shown in Table 1, including the number of variants successfully targeted, the number of known P and B variants used for training and testing, the area under the receiver operating characteristic curve (AUROC), the distribution of calibrated predictions, and the estimated patient impact for each model. The MSH2, MLH1, and PMS2 MAVE models provide a high-quality source of functional evidence for VC with the potential to impact many patients in the future.

Table 1.

Gene	MSH2 model	MLH1 model	PMS2 model
Variants successfully targeted (n)	223	212	214
Known pathogenic (P) and benign (B) variants used to train the model	29 P 72 B	31 P 55 B	14 P 71 B
Known pathogenic (P) and benign (B) variants used to test the model	14 P 32 B	14 P 22 B	7 P 31 B

# of variants strongly predicted P (PPV ≥ 95%) or B (NPV≥ 95%)	44 P 177 B	52 P 160 B	26 P 183 B
# of variants with uncertain prediction (PPV < 80%, NPV < 80%)	2	0	5
Estimated # of impacted variants	4 LP>P 3 VUS>LP 26 VUS>LB 31 LB>B	0 LP>P 5 VUS>LP 17 VUS>LB 7 LB>B	4 LP>P 1 VUS>LP 17 VUS>LB 6 LB>B

#7330 Identifying proteomic risk factors for overall, aggressive and early onset prostate cancer using mendelian randomization and tumor spatial transcriptomics.

T. A. Desai[1], A. K. Hedman[2], M. Dimitriou[2], M. Koprulu[3], S. Figiel[4], W. Yin[4], M. Johansson[5], E. L. Watts[6], J. R. Atkins[1], A. V. Sokolov[7], H. B. Schioth[7], M. J. Gunter[8], K. K. Tsilidis[8], R. M. Martin[9], M. Pietzner[10], C. Langenberg[10], I. G. Mills[4], A. D. Lamb[4], A. Malarstig[2], T. J. Key[1], The PRACTICAL Consortium, R. C. Travis[1], K. Smith-Byrne[1];

[1]Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom, [2]Karolinska Institutet, Stockholm, Sweden, [3]University of Cambridge, Cambridge, United Kingdom, [4]University of Oxford, Oxford, United Kingdom, [5]International Agency for Research on Cancer, Lyon, France, [6]National Cancer Institute, Bethesda, MD, [7]Uppsala University, Uppsala, Sweden, [8]Imperial College London, London, United Kingdom, [9]University of Bristol, Bristol, United Kingdom, [10]Queen Marty University of London, London, United Kingdom

Background: Understanding the role of circulating proteins in prostate cancer risk can reveal key biological pathways and identify novel targets for cancer prevention.

Methods: We investigated the association of 2,002 genetically predicted circulating protein levels with risk of prostate cancer overall, and of aggressive and early onset disease, using *cis*-pQTL Mendelian randomization (MR) and colocalization. Findings for proteins with support from both MR, after correction for multiple-testing, and colocalization were replicated using two independent cancer GWAS, one of European and one of African ancestry. Proteins with evidence of prostate-specific tissue expression were additionally investigated using spatial transcriptomic data in prostate tumor tissue to assess their role in tumor aggressiveness. Finally, we mapped risk proteins to drug and ongoing clinical trials targets.

Results: We identified 20 proteins genetically linked to prostate cancer risk (14 for overall [8 specific], 7 for aggressive [3 specific], and 8 for early onset disease [2 specific]), of which a majority were novel and replicated. Among these were proteins associated with aggressive disease, such as PPA2 [Odds Ratio (OR) per 1 SD increment = 2.13, 95% CI: 1.54-2.93], PYY [OR = 1.87, 95% CI: 1.43-2.44] and PRSS3 [OR = 0.80, 95% CI: 0.73-0.89], and those associated with early onset disease, including EHPB1 [OR = 2.89, 95% CI: 1.99-4.21], POGLUT3 [OR = 0.76, 95% CI: 0.67-0.86] and TPM3 [OR = 0.47, 95% CI: 0.34-0.64]. We confirm an inverse association of MSMB with prostate cancer overall [OR = 0.81, 95% CI: 0.80-0.82], and also find an inverse association with both aggressive [OR = 0.84, 95% CI: 0.82-0.86] and early onset disease [OR = 0.71, 95% CI: 0.68-0.74]. Using spatial transcriptomics data, we identified MSMB as the genome-wide top-most predictive gene to distinguish benign regions from high grade cancer regions that had five-fold lower MSMB expression. Additionally, ten proteins that were associated with prostate cancer risk mapped to existing therapeutic interventions.

Conclusion: Our findings emphasize the importance of proteomics for improving our understanding of prostate cancer etiology and of opportunities for novel therapeutic interventions. Additionally, we demonstrate the added benefit of in-depth functional analyses to triangulate the role of risk proteins in the clinical aggressiveness of prostate tumors. Using these integrated methods, we identify a subset of risk proteins associated with aggressive and early onset disease as priorities for investigation for the future prevention and treatment of prostate cancer.

#7331 Establishing a single-cell eQTL dataset of lung tissues from Asian never-smokers to identify cell-type specific lung cancer susceptibility genes.

T. Luong[1], E. Long[2], J. Yin[1], B. Li[1], J. Shin[3], E. Sisay[1], A. Kane[1], A. Golden[1], Y. Chang[3], N. Banovich[4], N. Rothman[1], J. Byun[5], Q. Lan[1], C. Amos[5], J. Shi[1], J. Lee[3], E. Kim[3], J. Choi[1];

[1]National Cancer Institute, National Institutes of Health, Bethesda, MD, [2]Chinese Academy of Medical Sciences and Peking Union, Beijing, China, [3]Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]Translational Genomics Research Institute (TGen), Phoenix, AZ, [5]Baylor College of Medicine, Houston, TX

Lung cancer is one of the most prevalent and deadly forms of cancer worldwide. Whilst smoking is the main determinant, genetic factors also play a crucial role as genome-wide association studies (GWAS) have identified >50 loci associated with lung cancer risk. Yet, for most of these loci, it is still unknown how they contribute to lung cancer risk. Expression quantitative trait loci (eQTL) studies have been powerful in linking GWAS variants to potential target genes, providing genetic mechanisms underlying common diseases such as cancers. However, the current eQTL resources lack ancestral diversity and are primarily based on bulk tissues. Emerging single-cell eQTL (sc-eQTL) approaches can detect context-specific gene regulation but are mainly of blood samples or cultured cells and still representing European populations. This limits our abilities to test GWAS variants in cancer-relevant cell types as well as in diverse populations. To generate a resource to characterize lung cancer GWAS loci, we are building a lung sc-eQTL dataset of Asian population while addressing common challenges of tissue sc-eQTL. Namely, processing fresh tissue in a population scale is logistically challenging and costly, and epithelial cells (including cell types of lung cancer origin) are vulnerable to the dissociation and freezing/thawing process. To address these issues, we incorporated sample multiplexing and cell type balancing. We collected fresh tumor-distant normal lung tissues from 131 never-smoking Korean women and dissociated them before cryopreservation. We then performed single-cell RNA sequencing (scRNA-seq) using 10x Chromium Single Cell 3' v3.1 chemistry with multiplexing of ~6 samples/batch. To enrich for epithelial cells, we utilized flow cytometry with surface markers of four major lung cell types (epithelial: EpCAM+/CD45-, immune: EpCAM-/CD45+, endothelial and stromal: EpCAM-/CD45-) before 10X library preparation. Concurrently, we performed DNA genotyping and imputation using matched blood samples. Following scRNA-seq (~36,000 reads/cell) we performed a genotype-based sample demultiplexing using Demuxlet. By integrating Demuxlet and Scrublet, we identified ~89% of the detected cells as singlets. After applying QC to filter empty droplets and low-quality cells, we obtained 428,619 cells or 3,272 cells/patient. Cell annotation guided by Azimuth label transfer using the Human Lung Cell Atlas, identified 28 cell types including 7 of epithelial origins. We will further perform eQTL analyses for individual cell types using pseudo-bulk and LIMIX (linear mixed model) or SAIGE-qtl (poisson regression) methods followed by aggregation across the cell types. By incorporating lung cancer GWAS data, we will identify cell-type specific susceptibility genes. Our dataset will provide a unique resource for lung cancer research.

#7332 Healthcare professionals' perceptions and educational needs in genetic counseling for cancer risk management: An integrated mixed-methods systematic review.

S.-Y. Jung[1], S.-Y. Park[2], E.-G. Lee[1], H. Chae[1], M.-J. An[1], Y.-J. Kim[1], Y.-J. Choi[1], K. Ryu[1], S.-Y. Kong[1];
[1]National Cancer Center - Korea, Goyang-si, Korea, Republic of, [2]Daegu Catholic University, Daegu-si, Korea, Republic of

Background: The role of healthcare professionals (HCPs) is crucial in the genetic counseling process for managing hereditary cancer risks. However, HCPs face challenges due to a lack of specialized training and confidence, particularly in communicating genetic risks to patients. Hence, it becomes paramount to identify the essential skills and expertise required by HCPs for genetic counseling. Additionally, gaining insight into their perspectives regarding the content of genetic counseling that should be provided to patients is of utmost importance.
Methods: An integrated mixed-methods systematic review and content analysis were performed across five databases on 23 May 2023, employing predetermined search strategies. The quality of selected studies was assessed using the Mixed Method Appraisal Tool (MMAT), and data analysis was conducted using a deductive content analysis approach with MAXQDA 2020.
Results: The review encompassed 14 studies from seven countries, revealing moderate risk of bias. It was perceived by HCPs that hereditary cancer families require information in seven specific categories including, cancer risk-reducing strategies; personalized cancer risk; family implications of hereditary cancer; psychological issues; genetic testing; the role of pathogenic genes in hereditary cancers; and social issues related to genetic testing. The study also highlighted the educational needs of HCPs, pinpointing areas such as method for supporting decision-making; clinical management in hereditary cancer families; resources for supporting hereditary cancer families; guidance to support familial communication; genetic testing; the role of each profession; and methods for supporting psychological aspects.
Conclusion: The findings underscore the need for specialized training programs to equip HCPs with the necessary skills and knowledge for effective genetic counseling. Additionally, understanding HCPs' perspectives on the content of genetic counseling is vital for tailoring educational resources and enhancing the genetic counseling process in managing cancer risks.
Grants: This research was supported by a grant of the Korean Cancer Survivors Healthcare R&D Project through the National Cancer Center, funded by the Ministry of Health & Welfare, Republic of Korea (grant number: NCC 23F1940-1)

#7333 From provider discussion to test completion: Evaluating cancer genetic services in a diverse academic comprehensive cancer care population.

A. Naaseh[1], H. Rice[2], I. Temosihue[1], N. Zimmermann[1], E. Linnenbringer[1];

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]University of Michigan, Ann Arbor, MI

Objective: Genetic testing (GT) and counseling (GC) are important aspects of comprehensive cancer care, yet persistent equity challenges exist. We aim to characterize the evolving utilization of GT and GC services for potential hereditary breast, ovarian, pancreatic, and prostate cancers (HBOPP).
Methods: We performed a retrospective single-institution chart review of a balanced racial subset of HBOPP patients who met National Comprehensive Cancer Network (NCCN) criteria diagnosed from 2019-2013. Data were analyzed using chi-squared test and multivariable logistic regression.
Results: 503 HBOPP patients were studied. GT was discussed with 50.5% (n=254) of patients, 42.3% (n=213) completed GT, but only 8.7% had GC (n=44) (Table 1). Patients who were younger, had managed care, or had a family history of cancer were significantly more likely to have a GT discussion and complete GT (all p<0.01). Pancreatic cancer (RR 0.11; 95% CI 0.05-0.21) and prostate cancer patients (RR 0.05; 95% CI 0.02-0.10) were less likely to have a GT discussion with their provider than breast cancer patients. HBOPP patients had a lower likelihood of having a GT discussion with each additional year of age at diagnosis (RR 0.95; 95% CI 0.93-0.98). Among patients who had a GT discussion, prostate cancer patients (RR 0.14; 95% CI 0.04-0.47) and Black patients (RR 0.25; 95% CI 0.09-0.71) were less likely to complete GT. Ovarian cancer patients (RR 12.1; 95% CI 5.19-28.5) and patients with a family history of cancer (RR 2.26; 95% CI 1.05-4.86) were more likely to have GC.
Conclusions: Inequities persist in GT and GC. NCCN-eligible patients who were older or had prostate or pancreatic cancer were less likely to have GT discussion. We found that Black patients were less likely than White patients to complete GT. GC rates were low across all groups except patients with ovarian cancer. Multilevel and systemic interventions are needed to improve equity in cancer genetic services.

Access to, completion, and outcomes of genetic testing and counseling, by cancer type.

	Breast (n=212)	**Ovarian (n=48)**	**Pancreatic (n=105)**	**Prostate (n=138)**	**Total (n=503)**	**Test (p)**
Was there evidence a provider discussed and/or offered genetic testing?						
Yes	172 (81.1%)	36 (75.0%)	26 (24.8%)	20 (14.5%)	254 (50.5%)	<0.001
No	40 (18.9%)	12 (25.0%)	79 (75.2%)	118 (85.5%)	249 (49.5%)	
Is there any evidence that the patient received genetic testing?						
Yes	155 (90.1%)	32 (88.9%)	18 (69.2%)	8 (42.1%)	213 (84.2%)	<0.001
No	17 (9.9%)	4 (11.1%)	8 (30.8%)	11 (57.9%)	40 (15.8%)	
What were the patients results?						
Mutation positive	25 (16.3%)	5 (15.6%)	2 (11.1%)	0 (0.0%)	32 (15.2%)	0.095
Mutation negative	83 (54.2)	12 (37.5%)	13 (72.2%)	3 (37.5%)	111 (52.6%)

Was there evidence of any genetic counseling encounter?						
No	195 (92.4%)	27 (57.4%)	102 (97.1%)	133 (96.4%)	457 (91.2%)	<0.001
Yes	16 (7.6%)	20 (42.6%)	3 (2.9%)	5 (3.6%)	44 (8.8%)	

#7334 Germline mutations in cancer susceptibility genes in patients with mucosal melanoma.

A. Amouzegar, X. Wu, J. Long, S. Prabhakaran, L. Little, C. Gumbs, J. Malke, J. Simon, J. Zhang, J. Wargo, P. Scheet, J. W. Wong, P. Nagarajan, J. L. McQuade, A. Futreal;
UT MD Anderson Cancer Center, Houston, TX

Background: Mucosal melanoma (MM) is the rarest subtype of melanoma with markedly worse outcomes compared to cutaneous melanoma (CM). Unlike CM which is driven by somatic mutations due to UV exposure, risk factors for MM are less defined. While germline mutations in cancer susceptibility genes are well-studied in CM, they are less understood in MM. Herein, we aimed to identify the prevalence of germline mutations in cancer susceptibility genes in a large MM cohort.

Methods: A cohort of 247 MM patients (pts) from MD Anderson Cancer Center with available blood for germline sequencing was identified. Pt characteristics were reflective of U.S. MM population with median age of 63, 60% females and 84.6% white. Clinicodemographic features of pts including tumor site, key somatic mutations (BRAF, NRAS, KIT) and personal history of other malignancies were abstracted, and their frequencies were compared in pts with and w/o germline mutation. Frequency of *MITF* and *CHEK2* alleles were compared to expected population control rate based on TOPMED by Fisher's exact test.

Results: Among 247 pts, 10.9% had germline mutations, primarily in *MITF* (c.G952A:p.E318K) (2.4%) and *CHEK2* (c.1100delC:p.T367fs) (1.6%) at OR of 13.9 (95%CI 5.0, 30.9) and 16.4 (4.4, 42.9) compared to population control rate (Table 1). MM sites of origin were gastrointestinal (36%), genitourinary (34%) and head & neck (30%). In terms of somatic mutations, *KIT* (26%) was most common, followed by *NRAS* (15%), non-V600E BRAF (6.5%) and BRAF V600E (2.4%). These variables did not differ between those with and w/o germline mutation. Pts with germline mutation had a higher incidence of non-melanoma malignancies (48% vs 29%; p=0.044).

Conclusions: This study reports a high prevalence of germline cancer susceptibility mutations in the largest cohort of MM to date, including mutations which are actionable. There is overlap with known *MITF* risk alleles for CM. We are currently performing a GWAS to comprehensively understand the genetic architecture of risk in MM.

Table 1. Summary of identified germline mutations in the mucosal melanoma cohort.

Germline mutation	**Protein**

#7335 Characterizing germline variants in patients with small cell lung cancer.

S. Ul Haq[1], G. Downs[2], L. Zhan[3], D. Sacdalan[4], J. J. N. Li[5], V. Philip[3], R. H. Kim[4], G. Liu[5], S. V. Bratman[5], P. J. B. Sabatini[6], B. H. Lok[5];
[1]Schulich School of Medicine and Dentistry, Western University, London, ON, Canada, [2]Toronto General Hospital, Toronto, ON, Canada, [3]Princess Margaret Cancer Centre, Toronto, ON, Canada, [4]Institute of Medical Science, Temerty Faculty of Medicine, University of Toronto, Toronto, ON, Canada, [5]Department of Medical Biophysics, Temerty Faculty of Medicine, University of Toronto, Toronto, ON, Canada, [6]Department of Laboratory Medicine & Pathobiology, Temerty Faculty of Medicine, University of Toronto, Toronto, ON, Canada

Introduction: Small cell lung cancer (SCLC) has traditionally been considered to arise from environmental and lifestyle factors. Recent evidence has shown that germline mutations may also impact the development of SCLC, however, remains understudied. We sought to identify novel germline mutations in SCLC including unexplored copy-number variations (CNVs) in our cohort of patients.
Methods: We applied a custom hybrid-capture gene panel of 191 cancer predisposition and commonly mutated genes in SCLC to a pre-treatment cohort of 67 patients with SCLC. Variant calls were performed using VarScan2 (2.3.8), Pindel (0.2.5b8) and CNVs were assessed using DeCON 1.0.2. Calls were annotated using the American College of Medical Genetics (ACMG) criteria and classified using gnomeAD (release 2.11), ESP6500 (ESP6500SI-V2), 1000Genomes, ExAC (release 0.3), COSMIC (v70), dbSNP (build 147), and ClinVar (NCBI ClinVar 20190305). We annotated variants of uncertain significance (VUS) with several in
silico tools including MutationTaster, LRT, Polyphen2 HDIV, Polyphen2 HVAR, SIFT, PROVEAN, and Deepmind AlphaMissense. Kaplan-Meier survival analysis and log-rank tests were done to examine differences in overall survival (OS) and progression-free survival (PFS) from the date of diagnosis. Continuous variables were tested using Kruskal-Wallis H test and categorical variables using Fisher's exact test.
Results: The median age of our cohort was 68 years old, 64% (43/67) were male, 89% (60/67) were current/former smokers, and 58% (39/67) were Extensive-Stage. 64.6% (42/67) of patients self-reported a family history of cancer and 16% of the patients also self-reported personal history of cancer. In terms of self-reported ancestral background, 76% of were Caucasian, 1.5% were Middle-Eastern, 3% were Latin American, 14% were Asian, and 4.5% were Black. We identified pathogenic/likely pathogenic alterations in 7/67 patients. Five (71%) were novel alterations (*BCORL1, FANCC, ATR*, and *BBC3*) and a novel CNV (*SLFN11*) with the remaining two (29%) previously described mutations (*CHEK1* and *BRIP1*). We identified 191 VUS in 60/67 patients. 4.7-14.1% of VUS were in silico predicted to be pathogenic. Patients with the 7 pathogenic alterations had a numerically larger OS (HR = 0.50, 95%CI = 0.18-1.39, p = 0.18) and PFS (HR = 0.45, 95%CI = 0.16 - 1.24, p = 0.11) compared to the rest of the cohort. We identified 20 variants at low variant allele fractions (0.05 to 0.24), likely somatic mutations. Some genes identified are implicated with clonal hematopoiesis such as *GNAS, STAG, TET2*, and *MGA*.
Conclusion: In summary, we have identified several novel germline alterations (mutations and CNVs) in patients with SCLC. In addition, we utilized in silico prediction models to categorize potential high-risk VUS. Our findings suggest that beyond tobacco exposure germline alterations may also modulate development of tumorigenesis in SCLC patients.

#7336 Exploring the impact of cancer predisposition gene variants by functional analysis and whole genome sequencing analysis in hereditary cancer patients.

H. Kim[1], J. Park[2], G. Lee[1], J.-A. Hwang[1], J.-S. Ryu[1], Y.-R. Jung[1], S. Lee[1], K. Ryu[1], D. Lee[1], S.-Y. Jung[1], S.-Y. Park[1], W. Choi[1], S.-Y. Kong[1];
[1]National Cancer Center - Korea, Goyang-si, Korea, Republic of, [2]Hanyang University Guri Hospital, Hanyang University College of Medicine, Guri-si, Korea, Republic of

Background: Hereditary cancer confirmed by germline pathogenic variant has been increased with increasing next generation sequencing (NGS) panel tests in recent years. However, some cases who were suspected hereditary cancer represented having variant of uncertain significance (VUS) or no variants even though they had family members with many cancers. The aim of this study was to investigate variants function especially in splicing variants and to explore other candidate genes by whole genome sequencing (WGS) in suspected hereditary cancer patients.
Methods: Total of 44 patients who clinically suspected hereditary cancer without defined pathogenic variants after NGS panel test were enrolled. Among them 11 patients had intronic variants and their variant effects were predicted by SpliceAI, a deep learning-based tool. To define alternative splicing, total RNA was extracted from patients buffy coats and cDNA was synthesized using oligo dT. Then the cDNA was amplified by specific primers and performed sequencing. Also, WGS was performed in 15 patients then comprehensive analysis encompassing 392 unique genes was performed including 282 well-established hereditary cancer predisposition genes and 228 DNA repair-related genes. We confirmed the variant by various type of studies and predicted impact on protein by analysis.
Results: We analyzed intronic variants of 11 patients; ATM c.4611+3A>T(n=1). BRCA1 c.547+30A>G (n=2), BRCA1 c.5152+6T>C(n=1), MSH2 c.2635-7G>A(n=1), MUTYH c.934-2A>G(n=2), NF1 c.1527+4A>C(n=1), NF1 c.3871-14G>T(n=1), PALB2 c.3350+5G>A(n=1), and SMARCA4 c.3546+1G>A(n=1). Though two intronic variants (ATM c.4611+3A>T and SMARCA4:c.3546+1G>A) were observed a likelihood of aberrant splicing aggregate SpliceAI score more than 0.8, we observed three intronic variants induce alternative splicing (ATM c.4611+3A>T, NF1 c.1527+4A>C, and PALB2 c.3350+5G>A).In addition, WGS analysis demonstrated 6 out of 15 patients have germline variants in relevant genes. Four single nucleotide variants (SMARCAL1:c.1632delA, SETMAR:c.441dup, FAN1:c.590C>A, and PRF1:c.445G>A) were validated by sequencing and those were likely pathogenic variant (LPV) by ACMG/AMP criteria of ClinGen. Copy number variations were identified in 2 patients (PMS2 heterozygous deletion and RAD50 duplication) and structure variant of MSH2 was identified in one patient.
Conclusion: Our analysis showed in silico analysis results might be different from functional analysis and rare variants in cancer predisposition genes could be confirmed WGS. However, large number of patients study would be needed to confirm necessity of WGS for hereditary cancer. This work was supported by National Cancer Center, Korea (No_NCC-2110181).

#7338 Prevalence and risk factors of *PALB2* germline pathogenic variants.

M.-C. Kang, Y.-R. Jung, S. Lee, H.-S. Kang, S.-Y. Jung, M. Lim, K. Lee, E.-G. Lee, S.-Y. Kong;
National Cancer Center - Korea, Goyang-si, Korea, Republic of

Background: *PALB2*, located on chromosome 16, plays a vital role in DNA damage repair as a partner and localizer of BRCA2. *PALB2* germline pathogenic variant has been known to increase the risks of breast cancer, pancreatic cancer, and ovarian cancer. However, the prevalence of *PALB2* germline variants in Korean patients has not been thoroughly investigated. This study aimed to evaluate the prevalence of *PALB2* germline variants and the risk factors in Korean population. Methods: We analyzed the data of 3755 patients who performed hereditary cancer germline next generation sequencing (NGS) panels, including *PALB2*, at the National Cancer Center in Korea between 2008 and 2022. Genetic variants were classified using a five-tier system following the American College of Medical Genetics and Genomics guidelines as follows: pathogenic (PV), likely pathogenic (LPV), variants of uncertain significance (VUS), likely benign, and benign. We retrospectively reviewed 102 individuals who were confirmed to have the *PALB2* germline variant with PV, LPV and VUS. Also, we analyzed the clinical characteristics of patients with *PALB2* heterozygous PV or LPV.

Results: A total of 102 patients (2.7%, 102/3755) represented *PALB2* germline variants with 81 (79.4%) VUS, 14 (13.7%) LPV, and 7 (6.9%) PV. Detected twelve germline *PALB2* LPV or PV were as followings; c.3350+5G>A (n=6), c.454A>T (n=3), c.1048C>T (n=2), c.2016dup (n=2), c.1424C>G (n=1), c.1976_1977del (n=1), c.2095dup (n=1), c.2834+2T>C (n=1), c.2920_2921delAA (n=1), c.3317delT (n=1), c.902delA (n=1), and exon 11 deletion (n=1). 35 *PALB2* VUS were detected in 81 patients. Among 21 female patients with LPV or PV (median diagnosis age 50 years; 25-69), 18 carriers (85.7%) and 3 carriers (14.3%) were diagnosed with breast cancer and ovarian cancer, respectively. For 18 breast cancer patients, 3 patients had bilateral breast cancer and 3 patients had multi-organ cancers (ovary, thyroid, or colorectal and gastric cancer).Also, 15 carriers (71.4%) have first-degree relatives with breast, ovarian, pancreatic, lung, gastric, liver, thyroid, and colorectal cancer and 10 carriers (47.6%) have second-degree relatives with breast, pancreatic, lung, gastric, liver, prostate, lymphoma, laryngeal, and uterine cancer.

Conclusion: In our study, *PALB2* germline PV or LPV were detected at a low frequency of 0.56% in Korean cancer patients. Family history was an important risk factor for suspected germline pathogenic variants, and bilateral breast cancer was observed in 16.7% of breast cancer patients who harbored *PALB2* PV or LPV. This study was supported by grant from the National Cancer Center. (grant number HA23C0419; NCC- 23F1850; NCC-2110181).

#7339 Mayo Clinic breast cancer cohort: A valuable resource for breast cancer research.

N. L. Larson, J. Olson, K. Ruddy, F. Couch, D. Herman, F. Abraha;
Mayo Clinic, Rochester, MN

The Mayo Clinic Breast Disease Registry (MCBDR) was developed to serve as a cohort of newly diagnosed breast cancer patients to address questions of etiology, prognosis, and survivorship. Eligibility is limited to patients 18 years or older with a confirmed first stage 0-4 breast cancer diagnosis within the last year. Consent is completed via phone, patient portal, or in-person. Upon enrollment, a baseline questionnaire and blood collection are completed. Annual follow-up surveys that capture BC outcomes are sent to all living participants. The MCBDR cohort (N=9,215, enrolled between 2001 and 2023) is 99% female, with an average age at diagnosis of 58 years (SD=12.7). Currently, MCBDR has an average time since diagnosis of 9.8 years (SD=6.4). The participants are 94% white, and 55% live in Minnesota. At the time of baseline questionnaire completion, 77% were married, 84% had a bachelor's degree or higher, and 8% reported financial hardship. Further, 35% reported a history of smoking, 11% consumed more than two drinks per day, and 9% reported fair or poor social relationships.
Within MCBDR, 53% of the participants had stage 0 or 1 cancer at diagnosis, while 28% had stage 2, 9% stage 3, and 3% stage 4 BC. Tumors were triple negative in 9%, HER 2 positive in 9%, hormone receptor-positive and HER2 low or negative in 55%, and 27% had missing HER2 status. Pathological TNM staging was available on 98%, among which 33% were staged at T2 or higher and 27% were node-positive. Definitive BC surgery was completed at Mayo Clinic for 73%, with 35% undergoing mastectomies and 44% having lumpectomies. 74% were treated with radiation, 56% underwent chemotherapy, and 79% were treated with endocrine therapy.
Clinical genetic testing results have been nurse-abstracted for 94% of the cohort. Of those known to be tested, 521 (6%) had a pathogenic or likely pathogenic mutation identified in a BC causing gene. In addition, whole exome sequencing was completed on 71% of MCBDR participants in 2020, in which 167 previously unknown pathogenic or likely pathogenic mutations were identified.
After the initial diagnosis and active treatment phase, nurse abstraction identified 151 (2%) participants known to have been diagnosed with a contralateral BC diagnosis, and 4% known to have been diagnosed with a second primary other than breast. Recurrence in the same breast has been reported for 242 (3%), with 72% of those recurrences occurring within 5 years of initial diagnosis and another 19% occurring 5-10 years post diagnosis. Among the 1,262 (14%) who are deceased, 24% died from BC and 19% had distant metastases at diagnosis or a distant recurrence. Amongst all deceased, 6% died within 1 year of their diagnosis and 43% died within 5 years of diagnosis. For participants who died from BC, 10% died within 1 year of their diagnosis and 64% died within 5 years of diagnosis. MCBDR data has been used in numerous publications and is an essential resource for efficient observational research analyses.

#7340 Investigating the function and impact of UBASH3B in head and neck squamous cell carcinoma and its implications for racial health disparities.

M. Ndahayo, V. Mukhina, I. Gupta, D. A. Gaykalova;
University of Maryland, Baltimore, Baltimore, MD

Head and Neck Squamous Cell Carcinoma (HNSCC) is one of the top cancers with significant cancer health disparities among racial and ethnic groups. African Americans (AAs) with HNSCC demonstrate worse overall survival compared to European Americans (EAs). While the reasons behind this disparity are multifaceted, recent findings suggest that biological features in HNSCC may contribute to differences in disease progression. However, race-related biological factors in HNSCC have been relatively little explored. We have identified the gene UBASH3B, a protein tyrosine phosphatase that plays a role in the stabilization of the Epidermal Growth Factor Receptor (EGFR). High expression of UBASH3B in AAs is associated with significantly worse overall survival compared to high expression in EAs and low expression in AAs. This study seeks to examine the role of UBASH3B in HNSCC and determine its impact on tumorigenesis. We hypothesize that the upregulation of UBASH3B in AAs contributes to the survival disparity by promoting tumor progression through EGFR signaling. Preliminary data using The Cancer Genome Atlas (TCGA) shows overexpression of UBASH3B in tumor samples of both AAs and EAs HNSCC samples. Plus, the overexpression of UBASH3B is associated with perineural invasion. Additionally, among AA-HNSCC patients, advanced T-stage is associated with increased UBASH3B expression. Elucidating the role UBASH3B plays in tumorigenesis will give us a further understanding of HNSCC in African Americans and can serve as a potential therapeutic target for new treatment options, as well as the biomarkers for the detection of the high-risk group.

#7344 Role of ubiquitin receptor ADRM1 (Rpn13) in prostate cancer.

S. Chowdhury, H. Wang, C. Nayak, B. Karanam;
Tuskegee University, Tuskegee, AL

Adhesion-regulating molecule 1 (ADRM1) / Rpn13 is a component of the 19S regulatory subunit of the 26S proteasome [1]. ADRM1 plays a crucial role in the recognition of polyubiquitinated substrates of the proteasome and their subsequent deubiquitination and degradation [2]. ADRM1 transcript levels are commonly upregulated in diverse tumor types [3]. The androgen receptor (AR) plays a predominant role in prostate cancer (PCa) pathology. In this study, we investigated the expression of ADRM1/ Rpn13 in different stages of prostate cancer and its association with AR expression. TCGA data from UALCAN was used for understanding ADRM1 expression on different stages of diseases and single-cell RNA-sequencing data of prostate cancer cell line was obtained from Prostate Cancer Atlas. TCGA (cell, 2015) data set was used for investigating the correlation between ADRM1 and AR by using R programming. Our study from the TCGA dataset reveals that ADRM1 expression increased significantly with the aggressiveness of prostate cancer (increase consistently with the Gleason score) from the TCGA dataset. We analyzed ADRM1 and AR expression in different prostate cancer cell lines and obtained that ADRM1 expressed significantly higher in prostate cancer cell lines which had lower AR expression. TCGA (cell, 2015) dataset indicated a negative correlation between ADRM1 and AR expression in prostate cancer. Our preliminary analysis indicated that ADRM1 inhibitor might be a potential therapeutic option for AR-independent prostate cancer.

#7345 Double-strand break inference from mosaic chromosomal alterations.

A. Dutch, C. Bumgardner, Y. Jakubek;
University of Kentucky, Lexington, KY

Double-strand breaks (DSBs) can cause alterations and rearrangements in chromosomes leading to large structural mutations. There have been previous efforts to identify DSBs in tumors and utilize these as a measure of homologous repair deficiency and response to therapy. In contrast, DSBs have not been well characterized in non-tumor human tissues. To address this void, we explore the distribution of DSBs in hematopoietic stem cells (HSCs) through the analyses of mosaic chromosomal alteration (mCA) breakpoints. Specifically, this work explores the relationship between the likelihood of DSB occurrences and the chromosomes on which they occur. Using data from the UK Biobank, mCA breakpoints were labeled as either DSBs or nonDSBs by proximity to telomeres and centromeres. mCA calls from the UK Biobank were obtained from Loh et al 2020. The START_MB_RANGE and END_MB_RANGE fields were treated as two separate breakpoint events for each entry in the data. Each of these breakpoint ranges was checked to see if it was close to either of the telomeres or to the centromere. Those falling within one Mb were categorized as mCA breakpoints that were likely not a result of DSBs, but rather missegregation of chromosomes or chromosome arms. Ranges that met either of these conditions were labeled “nonDSB” while ranges that did not were labeled “DSB.” These labeled data were processed in R using the Hmisc package. The 1-alpha binomial probability was calculated for the total number of DSBs versus the total number of breakpoint events. The point estimate for each chromosome was plotted along with the upper and lower confidence intervals. This work investigates the properties of DSBs. It is important to note that the observed putative DSBs are not representative of the frequency of DSBs in HSCs, since the resulting mutations can have different impacts on cellular fitness. This point is highlighted by our finding of increased putative DSBs on chromosome 13, as copy number changes involving the 13q14 locus are well documented drivers of chronic lymphocytic leukemia. In this investigation we observe that the proportion of putative DSBs is not correlated with chromosome length ($p = 0.2$). This result is likely due to the differential fitness effect of mCAs. However, it may also reflect differences in the likelihood of DSBs across the genome. We are currently working on methods from Machine Learning to further understand if there are genetic features which can predict DSBs which give rise to mCAs in HSCs.

#7346 Optimizing pan-cancer driver pathway analysis from patient transcriptomics and phosphoproteomics.

E. Z. Deng, G. B. Marino, D. J. B. Clarke, W. Ma, P. Wang, A. Ma'ayan;
Icahn School of Medicine at Mount Sinai, New York, NY

Alterations in cell signaling pathways drive cancer progression. Such changes can be detected by transcriptomics and proteomics profiling of tumor samples. Although proteomics profiling captures these alterations more directly, RNA-seq transcriptomics remains the most widely available and cost-effective source of data for elucidating tumor-specific cell signaling mechanisms. The eXpression2Kinases (X2K) pipeline is a computational workflow that starts with differentially expressed mRNAs, the identified differentially expressed genes are then used as input for transcription factor enrichment analysis. Then, the top-ranked transcription factors are connected via additional protein-protein interactions from several databases. Finally, the top-ranked transcription factors and the proteins that directly interact and connect these factors are subjected to kinase enrichment analysis. Such analysis identifies protein kinases most likely responsible for the observed changes in gene expression. The X2K pipeline can be applied to analyze tumor-specific transcriptomics to infer upstream regulatory transcription factors, protein intermediates, and kinases that are likely the drivers of cancer progression. While the X2K pipeline infers regulatory pathways from transcriptomics alone, phosphoproteomics can be used to independently validate the inferred kinases, and to calibrate the parameters of the X2K pipeline. Furthermore, this multiomics approach predicts cell signaling pathways with multiple layers of evidence by linking changes observed in the phosphoproteome to changes observed in the transcriptome. Here, we used the transcriptomics and phosphoproteomics profiles from the Clinical Proteomic Tumor Analysis Consortium (CPTAC) pan-cancer dataset, including 1,020 samples across 10 different cancer types, to optimize the parameters of the X2K pipeline and predict pan-cancer as well as tumor-specific signaling pathways. While inferred pathways were distinct between different tumor types, we observed global enrichment of receptor tyrosine kinases and cell cycle kinases. These pathways were subsequently tested for association with patient survival to identify pathways that may be effective therapeutic targets, for example, PTK2 signaling was identified for many lung cancer tumors (LUAD and LSCC) as well as some breast, head & neck squamous. Altogether, the X2K pipeline presents a rational approach to better identify driver regulatory mechanisms from patient-specific profiling of tumors with both transcriptomics and phosphoproteomics.

#7347 A transcriptome correlation network analysis of the high grade serous ovarian tumor immune microenvironment.

Kaylin M. Carey[1], Eric B. Dammer[2], Corey Young[3], Rajesh Singh[1], Ti'ara Griffen[4], James W. Lillard[1]

[1]Morehouse School of Medicine, Atlanta, GA,[2]Goizueta Alzheimer's Disease Research Center, Department of Biochemistry, Emory University School of Medicine, Atlanta, GA,[3]Department of Health and Human Services, Division of Cancer Epidemiology, National Cancer Institute, National Institutes of Health, Bethesda, MD,[4]Translational Medicine Oncology, Genentech, South San Francisco, CA

High Grade Serous Ovarian Cancer (HGSOC) affects many women and is the most common and lethal histopathological type of ovarian cancer. The molecular subtypes delineated by TCGA--mesenchymal, proliferative, immunoreactive, and differentiated subtypes, offer a sophisticated and innovative framework for HGSOC classification. These subtypes not only provide a detailed molecular characterization but also contribute to understanding the HGSOC Tumor Immune Microenvironment (TIME), comprised of both immune and tumor cells. The interplay within the TIME significantly influences pro- or anti-tumor responses, creating an important link between molecular landscape and dynamic immune-tumor interactions. Currently, there is a lack of understanding for the key drivers of clinical outcomes, molecular phenotypes, and diagnostic biomarkers for HGSOC. Here, we answer the question, does immune cell type, and proportion, drive clinical and molecular subtyping of primary HGSOC? Primary ovarian tumor samples from The Cancer Genome Atlas, TCGA (n=358) samples were collected and RNA-sequenced. FPKM values were used to construct the Weighted Gene Correlation Network Analysis (WGCNA), Gene Ontology (GO) and Proportion Estimations of Immune and Cancer cells (EPIC). Enrichment of HGSOC network module overlaps using a Fischer Exact Test were used to identify novel components of HGSOC progression that were significantly associated with clusters of highly correlated gene expression profiles, HGSOC stage, grade, and molecular phenotypes. We show genes associated with T cell proliferation (CD84) and B cell regulation (CD37), epithelial to mesenchymal transition (DOCK2), adaptor proteins present in T cells and myeloid cells (LCP2), inflammatory and metabolic signaling modulators (AIF1,CD53, SASH3), immunosuppressors of T lymphocytes and dendritic cells (FGL2), cell proliferation (PI3K) and relevant tertiary lymphoid structure gene (TNFAIP8L2) significantly correlated with HGSOC progression in both estimated tumor and proportions of immune cells. Future studies aim to confirm phosphorylation cascades associated with the aggressive molecular phenotypes of HGSOC and immune cell pathobiology.

#7348 CytoCellDB: A gold standard database for classification and analysis of extrachromosomal DNA in cancer.

L. Brunk;
UNC Chapel Hill, Chapel Hill, NC

Extrachromosomal DNA (ecDNA), or double minute chromosomes, are established cytogenetic markers for malignancy and genome instability. More recently, the cancer community has gained a heightened awareness of the roles of ecDNA in cancer proliferation, drug resistance and epigenetic remodeling. A current hindrance to understanding the biological roles of ecDNA is the lack of available cell line model systems with experimental cytogenetic data that confirm ecDNA status. Although several recent landmark studies have identified numerous cell lines and tumor models with ecDNA, the current sample size limits our ability to detect ecDNA-driven molecular differences due to limitations in power. Increasing the number of model systems that are known to express ecDNA would provide new avenues for understanding the fundamental underpinnings of ecDNA biology and would unlock a wealth of potential targeting strategies for ecDNA-driven cancers. To bridge this gap, we created CytoCellDB, a resource that provides karyotype annotations, including ecDNA status, and leverages publicly available global cell line data from the Cancer Dependency Map (DepMap) and the Cancer Cell Line Encyclopedia (CCLE). We expanded the total number of cancer cell lines with ecDNA annotations to 632, or 34% of the cell lines in CCLE/ DepMap. Of these, 154 cell lines express ecDNA, which is a 240% increase from the current sample size. We demonstrate that a strength of our framework is the ability to interrogate ecDNA, and the compendium of other chromosomal aberrations, in the context of cancer-specific vulnerabilities, drug sensitivities, and other multi-omic features (genomics, transcriptomics, methylation, proteomics). We anticipate that this resource will lower the barrier to systematic, population-scale discoveries related to ecDNA and will provide insights into strategies and best practices for determining novel therapeutics that overcome ecDNA-mediated drug resistance.

#7349 Ligand-receptor signaling analysis and tumor-immune microenvironment deconvolution reveal differential adipose-tumor crosstalk in lean and obese colon cancer patients.

Obesity is a well-defined risk factor for colon cancer (CC). In the current study, we investigated the paracrine influences between tumors and adjacent adipose tissue to understand the interactions between adipose-tumor using transcriptomics data.

Stage I-III newly diagnosed CC patients (n = 130) as part of the ColoCare Study at the Huntsman Cancer Institute, University of Utah, and University of Heidelberg, Germany were included in the current study. Fresh-frozen colon tumor tissues and adjacent adipose tissues naïve to neoadjuvant treatment were collected during surgery. RNA sequencing was done using the NovaSeq X. Patients were classified as having a BMI <30 $kg \cdot m^{-2}$ (lean) or BMI ≥30 $kg \cdot m^{-2}$ (obese). Tumor-adipose signaling was investigated separately for lean versus obese patients. Differentially expressed genes (DEGs, FDRq<0.05 and |log2FC|>2) between paired tumor-adipose samples were identified through DESeq2, respectively for lean and obese participants. DEGs were filtered to obtain exclusively up-regulated genes for 1) tumor tissue in the obese 2) tumor tissue in the lean 3) adipose tissue in the obese 4) adipose tissue in the lean. Ligand-receptor pairs for adipose-adipose signaling (A-A), tumor-tumor signaling (T-T), adipose-tumor signaling (A-T), and tumor-adipose signaling (T-A) in tissues from lean versus obese patients were determined by mapping the exclusively up-regulated genes in the FANTOM 5 database. Single sample Gene Set Enrichment Analysis (ssGSEA) was performed to score each sample based on signatures of interest, i.e. TIMEx immune cell types. The associations of signatures between tumor-adipose were assessed by evaluating Spearman's correlation coefficients on the enrichment scores of each signature for paired tumor-adipose samples.

From RNA-seq, there were 430 protein-coding DEGs (144 up-regulated in the tumor, 286 up-regulated in the adipose) identified exclusively in the obese and; 704 protein-coding DEGs (421 up-regulated in the tumor, 283 up-regulated in the adipose) identified exclusively in the lean patients. In the obese, we observed ligand-receptor-mediated T-T signaling through *FGF5-FGFR3* and *PYY-NPY4R*; T-A signaling through *GCG-GCGR*; A-A signaling through *ICAM1-IL2RA*. In the lean, we found ligand-receptor-mediated T-T signaling through *ADAM2-ITGA6* and *LAMB3-ITGA6*; T-A signaling through *DLL3-NOTCH2*; A-A signaling through *DLK1-NOTCH2*. In addition, ssGSEA analysis showed different association patterns for the lean versus obese regarding the TIMEx immune cell types.

Our results suggest differential cross-talk between adipose and tumor tissue in lean vs. obese patients could influence the progression of CC. The next steps are to validate these interactions by using in vivo preclinical models to interrogate novel therapeutic targets for reducing the impact of obesity on CC.

#7351 Delineating the prostate cancer tumor microenvironment through scRNA-seq profiling at different timepoints.

I. Valencia, H. Pakula, M. Omar, M. Loda, L. Marchionni;
Weill Cornell Medicine, New York, NY

Distant metastasis remains the leading cause of death in patients with prostate cancer (PCa), however, the underlying mechanisms of this process remain unclear. Using samples from genetically-engineered mouse models (GEMMs) of PCa, we have identified eight different stromal cell states linked to epithelial mutations that may impact PCa progression to metastatic stages. To further investigate the unique intercellular interactions in the tumor microenvironment (TME) involved in mediating disease progression, we use single cell RNA sequencing (scRNA-seq) to profile primary PCa samples from different GEMMs including TRAMP, Hi-MYC, and FVBN, at different timepoints. Analysis of the scRNA-seq data revealed a significant enrichment of three clusters, designated as stromal c6 (s6), epithelial c7 (e7), and epithelial c10 (e10), exclusively in TRAMP, each expressing proliferative markers such as Mki67 and Top2a. To investigate the intercellular interactions among these clusters, we conducted ligand-receptor (LR) interaction analysis using CellChat. Notably, s6 is expressing the genes encoding ligands Bmp4, Fn1, and Igf1, which interact with the receptors Bmpr1b/Bmpr2, Itga3/Itgb1, and Igf1r, respectively expressed in e7. Subsequently, the transcriptomic profiles of these cells were used to build and validate a robust gene signature that can predict metastasis and survival in patients with PCa using a large cohort of 1239 samples, 930 of which were used for training while the remaining 309 samples were used for testing the model's performance. In conclusion, these results underscore the role of the TME mediating PCa progression and highlight the potential of leveraging the TME to extract predictive and prognostic features which can be later employed to build predictive and prognostic models for patients with PCa.

#7352 ScanCT: A tree-based machine learning model to detect single-cell genomic features associated with clinical outcomes.

Y. Zheng[1], L. Nguyen[1], P. Zhou[2], A. V. Hirayama[1];
[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]University of Wisconsin - Madison, Madison, WI

Single-cell technologies represent a revolutionary approach to resolving cell-type heterogeneity, identifying cells in specialized states, and detecting rare disease-associated cells. With the cost of single-cell technology decreasing substantially, its integration into clinical studies is gaining momentum. A new computational tool is needed to accommodate different single-cell genomics and clinical data formats while accounting for unwanted confounders.
The study aims to develop a tree-based machine learning model to leverage the unprecedented resolution of single-cell multi-omics data for delineating the genomic and phenotypic drivers behind diverse immunotherapy responses. The proposed model is called single-cell analysis of Clinical Tree (scanCT), inspired by the Generalized Unbiased Interaction Detection and Estimation method for unbiased gene and protein feature selection and easy interpretation.
The scanCT model learns from the data to select the genomic feature that best splits the cells from distinct clinical responses for each tree node. The confounding factors will be regressors in the nodes but not be used for branch splitting, while gene and protein features of interest will split the tree but not enter the regression model in each node. scanCT is built to be free from the biased selection towards variables of a larger number of categories or values. With tree-pruning and cross-validation, scanCT overcomes the over-fitting issue and enhances model generalization, especially for clinical studies with limited patients. Particularly, scanCT naturally fits the hierarchical cell type relationship and handles marker gene and protein interaction effects efficiently.
Our approach was tested on single-cell datasets from B-cell malignancy patients undergoing Chimeric Antigen Receptor (CAR)-T cell therapy. The results from the scanCT are highly interpretable. For instance, each branch is a gene-protein combination profile, and cells are naturally partitioned by clinical association. The linear regressions at each leaf node are the clinical predictions for cells following the splitting criteria. The regression intercept is an average estimation of toxicity (e.g., neurotoxicity) or efficacy after controlling for confounder (e.g., tumor burden). scanCT accommodates categorical or continuous clinical response and survival data and is robust to missing values, a frequent challenge in oncological studies.
scanCT represents a significant step forward in single-cell data analysis, which merges complex genotypic and phenotypic information with clinical outcomes. The efficacy and toxicity-associated genomic signatures will inform new manufacturing strategies to optimize CAR-T cell therapy products. The model and clinical association detections are expected to go beyond the B-cell malignancy field to benefit the broader cancer research community.

#7353 Exploring intrapatient heterogeneity in metastatic breast cancer: Insights into tumor evolution from a warm procurement trial.

I. Bishara[1], X. Liu[2], J. I. Griffiths[1], J. Liu[2], P. A. Cosgrove[1], J. R. McQuerry[3], F. Chi[1], P. Wallet[1], V. K. Grolmusz[1], B. Copeland[1], L. Pflieger[1], J. Chen[1], S. Majumdar[1], G. Ronquillo[1], T. Crowder[1], R. Emond[1], R. Factor[4], E. Barragan[1], D. Bowtell[5], A. Cohen[6], D. D. Schmolze[1], P. Lee[1], K. Ihle[1], L. Tumyan[1], A. Nath[1], J. Waisman[1], A. Bild[1], J. Chang[2];

[1]City of Hope National Medical Center, Duarte, CA, [2]University of Texas Health Science Center, Houston, TX, [3]Children's Mercy Kansas City, Kansas City, KS, [4]University of Utah, Salt Lake City, UT, [5]Peter MacCallum Cancer Centre, Melbourne, Australia, [6]Inova Schar Cancer Institute, Fairfax, VA

Metastatic breast cancers show variable clinical responses due to inherent heterogeneity, both within tumors and among patients. Studies mainly examine molecular diversity across different patients' tumors and genetic variance within a single tumor. Yet, the variability among multiple tumors or metastases in a single patient remains underexplored. Our study investigates this intrapatient heterogeneity, examining cell and tumor evolution from a single genetic source in metastatic breast cancer. In a warm procurement trial involving 6 patients with multi-site tumors, samples were collected for detailed molecular analysis. Whole exome sequencing (WES) and single-cell RNA sequencing (scRNA-seq) were used to analyze genetic similarities and disparities. WES data revealed mutational patterns and copy number alterations, showing homogeneity and heterogeneity in tumors within patients. Further, phylogenetic analysis with scRNA-seq variant calls paired with transcriptional phenotypes uncovered a MYC-enriched subclonal population in a metastatic site. Integrating WES and scRNA-seq data provided a clearer understanding of the genomic and phenotypic features in and between patients. Our WES study revealed significant interpatient variations in genetic drivers and CNA profiles. Among five patients, two showed APOBEC and HR mutations, linked to increased tumor mutations. Despite general genetic homogeneity, there were exceptions. Tumors in Patient 3's upper lymph nodes had distinct genetics compared to abdominal tumors. Unique genetic patterns were also noted in the pancreas and mesentery of Patients 3 and 7, respectively. Genetic findings were supported by transcriptional analysis, showing distinct expression patterns in specific sites. Phylogenetic analysis highlighted intratumor heterogeneity, as shown by variations in phylogenetic composition and gene expression across samples. Notably, in patients with the most samples (Patients 3 and 7), a conserved cell clade, evolved early and primarily located in a single site, displayed a high proliferation gene expression signature closely associated with Myc activity. This underscores the importance of early clonal expansions in tumor evolution and suggests potential therapeutic targets in these early, proliferative cells. Our study highlights the vital role of intrapatient heterogeneity in understanding cancer complexity and treatment resistance. By analyzing genetic and phenotypic variability in multi-site tumors within patients, and Myc's key role in tumor growth and evolution, our research offers new insights into tumor evolution. This underscores the need for personalized oncology treatments based on each patient's tumor genetics.

#7354 Proteogenomic and metabolomic characterization of acute myeloid leukemia.

A. Chu[1], **Y. Hsiao**[1], Y. Deng[1], C. Wang[2], J. Kyle[3], Y. Dou[2], J. C. Pino[3], C. Posso[3], L. Henry[1], L. Chen[4], G. Li[1], T.-S. Lih[4], Y. Geffen[5], F. Yu[1], L. Ding[6], G. Omenn[1], C. Kumar[1], S. M. Dhanasekaran[1], E. Traer[7], J. W. Tyner[7], H. Zhang[4], T. Liu[3], S. Gosline[3], B. Zhang[2], A. Chinnaiyan[1], A. I. Nesvizhskii[1], M. Cieslik[1], The CPTAC Consortium;

[1]University of Michigan Medical School, Ann Arbor, MI, [2]Baylor College of Medicine, Houston, TX, [3]Pacific Northwest National Laboratory, Richland, WA, [4]Johns Hopkins university, Baltimore, MD, [5]Broad Institute of Massachusetts Institute of Technology and Harvard, Cambridge, MA, [6]Washington University School of Medicine, St. Louis, MO, [7]Oregon Health & Science University, Portland, OR

Acute myeloid leukemia (AML) is a blood malignancy of poor prognosis with marked heterogeneity. To elucidate the underlying mechanisms that drive AML as part of the Clinical Proteomic Tumor Analysis Consortium (CPTAC) effort, we performed comprehensive genomics, transcriptomics, proteomics including multiple post-translational modifications (phosphorylation, acetylation, and glycosylation), metabolomics, and lipidomics characterization of 173 treatment-naïve AML patients. Applying the similarity network fusion method on both transcriptomics and proteomics data, we identified 8 proteogenomic clusters. These clusters recapitulate specific recurrent mutations and established clinical subtypes available within the cohort. We used single-cell RNAseq data as a reference to perform immune component analysis for collected bulk samples. The result reveals that our proteogenomic clustering also captures the variations of AML differentiation hierarchies including CD14+ monocyte-like and GMP-like AML. To assess the complex disease nature of AML, we performed functional analysis for each cluster to reveal interplay between multiple genomic aberrations such as NPM1, FLT3-ITD, DNMT3A mutations, complex chromosomal alterations, and the leukemia cell differentiation. Importantly, the multi-omics analysis performed not only connects previously identified molecular drivers and cell differentiation variations within AML, but also links them with observed cancer metabolomic reprogramming with their drug response implications. Moreover, our study also identified site-specific post-translational modifications previously not known in AML, highlighting the valuable insights and clinical relevance of these newly identified clusters.

#7355 Integration analysis of lncRNAs and R-loops in 3D genome organization and gene regulation in the cancer genome.

S. Wang, Z. Wang, Y.-H. Wang, H. Li, P. Stukenburg, C. Zang;
University of Virginia, Charlottesville, VA

Existing evidence shows that some long non-coding RNAs (lncRNAs) can recruit chromatin regulators and form R-loops to mediate CCTCC-binding factor (CTCF) binding at topologically associated domain (TAD) boundaries to activate transcription of target genes. However, it remains unclear to what extent such lncRNA-dependent chromatin organization events occur genome-wide in normal and cancer cells. By curated public data of lncRNA, CTCF, RAD21 profiles and integrative analysis of multi-omics data using innovative computational approaches, we investigated global associations of lncRNAs and R-loops with activities of transcription factors and chromatin regulators in gene expression regulations across multiple human cell types. We developed a comprehensive computational pipeline for cross-cell-type analysis of lncRNA and protein-coding gene expression profiles and transcription factor binding profiles. We identified a total of 542 candidate genomic regions where lncRNAs play a pivotal role in regulating target genes by facilitating CTCF/cohesin binding. R-loops are enriched at CTCF/cohesin binding sites, suggesting their potential contribution to CTCF binding. Additionally, our findings underscore the significant cell-type specificity of CTCF binding patterns across the genome. This work adds knowledge to cancer genome organization and gene regulation, and builds foundations for further functional and mechanistic studies of lncRNAs and R-loops in the human genome.

#7356 3 UTR variations in esophageal squamous cell carcinoma in African Americans.

C. Erkizan[1], R. Wadleigh[2];

[1]Washington-Liberty High School, Arlington, VA, [2]Institute for Clinical Research, Veterans Affairs Medical Center, Washington, DC

Esophageal squamous cell carcinoma (ESCC) predominantly affects African Americans (AA). Esophageal Cancer (EC) consists of two major histological subtypes: esophageal adenocarcinoma and squamous cell carcinoma. ESCC ranks among the most lethal cancers and is particularly aggressive among AA, comprising about 75% of total ESCC patients. The 5-year survival rate for localized EC in AA patients is 25%; in contrast, the survival rate for EC patients of Caucasian origin is 48%. However, for metastatic disease, the survival rate decreases dramatically to 5% regardless of race. To conduct an extensive mutation screening, we performed whole exome sequencing (WES) in 10 paired AA ESCC and control tissues. Mutations included nonsynonymous mutations in multiple genes and copy number variations. Here, we report on further analysis of the WES data to identify 3 UTR noncoding region alterations, comprising the highest proportion of noncoding variations. Whole exome sequencing was performed using Agilent SureSelect XT Human All Exon V6 + UTR kit on matched normal-tumor samples from 10 AA patients (nine males and one female) with advanced-stage ESCC. The ages of patients ranged from 53 to 80 years. All patients, except for one, reported tobacco use and alcohol consumption. Our analysis yielded 5378 variants in noncoding regions in our cohort. The most variations were found in the 3UTR location, with 46% of all noncoding variations. In our dataset, variations in the 3UTR region of 48 genes were predicted by CScape to assert an oncogenic effect. The highest ten oncogenic predictive scores are for *ETV1, FOXO3, MSI2, TCF7L2, KAT6A, FOXO1, IRF4, TRIM24, ELK4, and FGFR1* genes. Approximately 2500 genes having 3'UTR variations are over-presented in intracellular signaling and cell-cell communications, transcriptional regulation of pluripotent stem cells by OCT4, SOX2, NANOG, generic RNA polymerase II transcription, RHO GTPase cycle, and regulation of cytoskeletal remodeling. The combined effects of noncoding and coding region mutations may largely impact poor prognosis in AA with ESCC and yield targets for developing candidate therapeutics.

#7357 Comparative transcriptomic analysis reveals novel insights into targetable B-cell lymphoma mechanisms.

S. Kim, N. Rapier-Sharman, M. T. Told, K. L. O'Neill, B. E. Pickett;
Brigham Young University, Provo, UT

B-cell lymphoma is a severe type of lymphatic cancer that is often misdiagnosed in adolescents. While some cases of B-cell lymphoma respond well to chemo- and radiation therapy, there are severe side effects, and many cases are refractory and fail to achieve remission. On the other hand, though CD19 CAR T-cell therapy is highly effective at treating B-cell lymphoma, its association with long-term immunocompromisation justifies the exploration of alternative treatments. Comparing B-cell lymphomas to an autoimmune disease that affects the same tissue type may grant us additional insights into immuno-oncology related treatments for B-cell lymphoma. We have developed a novel tool to compare cancer and autoimmune disease by analyzing bulk RNA-sequencing (RNA-seq) data. This algorithmic approach uses the transcriptional profile to improve our understanding of B-cell specific mechanisms that can be targeted in B-cell lymphoma. Using this tool, we compared the transcriptional signatures of primary B-cell lymphomas with primary B-cells from patients with systemic lupus erythematosus, an autoimmune disease. We identified specific genes and enriched functions associated with B-cell lymphoma's immune signature. We expect that the results of our B-cell lymphoma analysis could be used to develop beneficial treatments alternative to current therapies, potentially mitigating side effects for B-cell lymphoma patients and increasing their quality of life.

#7358 Role of noncoding genome architecture in esophageal cancer.

H. V. Erkizan[1], R. Wadleigh[2];
[1]VA Medical Ctr. and Washington DC and George Washington University, Washington, DC, [2]VA Medical Ctr. and Washington DC, Washington, DC

Esophageal Cancer is a deadly disease with a tendency to be diagnosed at the later stages. Considered a rare disease, accounting for 1.1% of all cancers, EC comprises 2.6% of all cancer deaths. The survival rate for all stages is 21.7%. However, the survival rate decreases to 5.6 % for advanced-stage cancers. EC is more common in men and associated with older age and heavy alcohol and tobacco use. In the last 25 years, the death rate of EC has been decreasing slightly from 4.3 to 3.7. The death rates for lung, prostate, and colon cancers have decreased by half in the same time frame. Therefore, novel therapies and biomarkers are urgently needed to accelerate survival and reduce the death rates by at least half for patients with EC.We previously completed exome sequencing in a small sample size and observed that the mutations in the noncoding regions of the EC genome are highly affected. In this study, we perform exome sequencing in 110 paired esophageal tumors and normal tissues using an Agilent SSELXT HS Exon V8+UTR library enrichment kit. Twelve paired EC and normal tissues are sequenced using the PacBio Hifi system.In WES, we detected almost half of the noncoding region mutations in the 3UTR and 2kb downstream regions of the genome, significantly affecting 51 oncogenic or tumor suppressor genes. In addition, the involved genes are over-represented in critical signaling pathways and transcriptional regulation of pluripotent stem cells. The number of changes in the 5UTR and 2kb upstream are similar to the number of variations in the intronic regions. Apoptosis, stress response, and DNA double-strand break repair pathways are affected by 5UTR mutations. Mutations in the intronic regions frequently occurred in pro-tumorigenic immune regulation genes, such as IL-33 and IL-6, and oncogene-induced senescence.The combined effect of these genetic and coding region mutations on oncogenes, significant signaling pathways, cancer cell stemness, DNA damage repair pathways, and immune system regulation may significantly impact poor prognosis in EC patients. Further studies will verify the effectiveness of targeting these genes for developing candidate therapeutics.

#7359 Priority targets in pancreatic cancer.

Z. C. Nwosu, M. Pasca di Magliano, C. Lyssiotis;
University of Michigan, Ann Arbor, MI

Pancreatic ductal adenocarcinoma (PDAC) is a drug resistant and lethal cancer. To better understand this disease, we separately analyzed five published human PDAC microarrays, determined the differential genes in each dataset and defined a gene as ‘consistent’ if it is ‘upregulated’ or ‘downregulated’ in >4 datasets (adjusted *P*<0.05). We identified 2,010 consistently upregulated- and 1,928 downregulated genes, over 50% of which were previously uncharacterized in PDAC. These genes span multiple processes, including cell cycle, immunity, transporters, metabolism, signaling, transcription factors and epigenetics. - with cell cycle and glycolysis being the most altered. Many consistent genes correlated with tumor subtype, proliferation, metastasis, and ~41% predicted survival, notably, *OGN, PLOD2, DIAPH3, C2orf40*, *ADM*, *UPP1, ZNF189, DCBLD2*, *PLAG1,* and glycolysis genes*ALDOA, GAPDH, PKM* and *LDHA*. We identified 451 high priority targets, including 185 upregulated genes (notably in cell cycle and glycolysis) whose knockdown suppressed PDAC cell growth in prior RNAi screen studies. Our results represent an important milestone in the quest for mechanisms, drug targets and biomarkers and could enable the discovery of novel mechanisms and therapies in PDAC.

#7361 The prognostic value of TP53 and tumor suppressor gene mutations in temozolomide-treated IDH1 mutant low-grade glioma.

Y. E. Salem[1], B. O. Abu Alragheb[2];

[1]Al-Bashir Hospital, Amman, Jordan, [2]The University of Jordan, Amman, Jordan

Background: Temozolomide has been extensively utilized in the treatment of gliomas across various grades, offering significant therapeutic benefits. However, the impact of concurrent mutations in TP53 and other tumor suppressor genes (TSG) on treatment outcomes in patients with IDH1 mutant low-grade glioma (LGG) treated with temozolomide remains to be fully understood. This study aims to explore the influence of these genetic factors on the response to temozolomide therapy, focusing on identifying potential genetic markers that can predict therapeutic outcomes.

Methods: Our study exclusively analyzed The Cancer Genome Atlas (TCGA) LGG PanCancer dataset from cBioPortal, focusing on IDH1 mutant cases treated with temozolomide. Data analysis was carried out using Python 3.11. The cohort was categorized based on genetic alterations: TP53 mutation with additional TSGs (ATRX, CIC, FUBP1, NOTCH1) mutations (TP53mut/TSGmut), TP53 mutation without additional TSG mutations (TP53mut/TSGwt), and no TP53 mutations (TP53wt).

Results: In our study, 178 LGG samples with IDH-1 mutation treated with temozolomide were selected. Of these, 113 samples had a mutation in TP53, and 88 had an additional mutation in a TSG. For TP53mut/TSGmut compared to TP53wt, the analysis revealed significant differences in clinical outcomes (PFS: HR 1.95, CI: 1.17-3.26, p=0.011; OS: HR 1.6, CI: 1.13-2.26, p=0.008). When comparing TP53mut/TSGwt with TP53mut/TSGmut, the findings were (PFS: HR 1.36, CI: 0.63-2.92, p=0.432; OS: HR 0.93, CI: 0.31-2.79, p=0.896). Finally, the comparison between TP53wt and TP53mut/TSGwt showed (PFS: HR 1.45, CI: 0.62-3.39, p=0.397; OS: HR 2.31, CI: 0.64-8.3, p=0.200).

Conclusion: The presence of concurrent mutations in TP53 and other TSGs in IDH1 mutant LGG patients (TP53mut/TSGmut) is indicative of a more aggressive disease course and reduced response to temozolomide treatment, as evidenced by significantly worse clinical outcomes. In contrast, the TP53mut/TSGwt group did not exhibit significant differences in treatment outcomes. These findings underscore the importance of detailed genetic profiling in developing personalized treatment strategies for this patient population.

#7362 Integrated analysis of scRNAseq and spatial omics in brain metastatic lung cancer tumor tissue.

H. Hirose[1], T. Tsuji[2], Y. Kojima[3], A. Yoshizawa[4], Y. Arakawa[5], H. Ozasa[6], H. Wake[2], T. Shimamura[1];

[1]Tokyo Medical & Dental University, Tokyo, Japan, [2]Department of Anatomy and Molecular Cell Biology, Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]Laboratory of Computational Life Science, National Cancer Center Research Institute, Chuo-ku, Tokyo, Japan, [4] Department of Diagnostic Pathology, Graduate School of Medicine, Kyoto University, Kyoto, Japan, [5] Department of Neurosurgery, Graduate School of Medicine, Kyoto University, Kyoto, Japan, [6] Department of Respiratory Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Spatial omics technologies have made significant advances in recent years, improving our understanding of the spatial localization of cells and intercellular interactions. Intercellular interactions are essential for maintaining proper tissue function and homeostasis, and dysregulation of these interactions can contribute to various diseases, including cancer and autoimmune disorders. Ligand proteins, one of the signaling molecules responsible for cell-cell interactions, bind to cell surface receptors and trigger intracellular signaling pathways. The effective range of ligand signaling, i.e. the extent to which a cell spatially and directly transmits information via the ligand, has not been systematically studied, although it may determine the occurrence of cell-cell interactions. The authors have previously developed methodologies combining spatial transcriptomics and single-cell RNA sequencing to analyze intercellular interactions at the single-cell level in spatial dimensions. Additionally, we have devised a technique to model the spatial diffusion of ligands from spatial transcriptomics and estimate the spatial range of ligand action. In this study, we used these developed methods to elucidate events in the tumor microenvironment of brain metastatic lung cancer tissue. Specifically, an integrated analysis of metastatic brain tumor samples was performed using visium and single-cell data from the same patient. The results suggest the presence of a heterogeneous microglial subpopulation, including clusters enriched in cytokines and chemokines for angiogenesis and wound healing, clusters associated with immune tolerance via IL-10 signaling, clusters enriched in gene sets related to phagocytosis, antigen processing, and antigen presentation, and clusters related to clearance of pathogens and residues. The presence of homogeneous microglial subpopulations was suggested. Furthermore, these subpopulations exhibited different spatial distributions, suggesting that they interact with surrounding cancer cells through different mechanisms.

#7363 Clinical, genomic, transcriptomic and immunologic profile of BRAF mutant colorectal tumors.

E. Rousselle, S. Kazandjian, A. Rose;
McGill University, Montreal, QC, Canada

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related death worldwide. BRAF, a protein kinase of the Mitogen-Activated Protein Kinase (MAPK) pathway, is mutated in 12% of colorectal cancers and is a poor prognostic factor for patients. BRAF mutations at the V600 codon are most studied but non-V600 BRAF mutations also exist and behave differently. BRAF V600 CRC treated with BRAF+MEK inhibitors show 12% response rates while we observe 65% response rates in BRAF V600 Melanoma. Additionally, no approved targeted therapies exist for non-V600 BRAF mutant cancers and retrospective studies show poorer PFS with BRAF+MEK inhibitors vs BRAF V600 cancers. We interrogated publicly available data of BRAF mutant CRC to uncover differences in the tumor microenvironment and signalling pathways of BRAF V600 and non-V600 tumors in hopes of uncovering better treatments.
Methods: We analyzed the clinical and genomic profile of BRAF mutant CRC tumors from the GENIE v12 data. Gene Set Enrichment Analysis was performed on RNAseq from the TCGA data (discovery cohort) and the combined data from CPTAC and Sidra-LUMC data (validation cohort). We investigated the composition of tumor infiltrating immune cells using CIBERSORTx (deconvolution algorithm for bulk RNAseq).
Results: Non-V600 mutations (n=219/1061) were most represented in patients of Asian or Black race compared to White patients ($p<0.0001$) and importantly, were found in younger patients ($p<0.0001$). We identified n=67 and n=74 BRAF mutant RNAseq samples in the discovery and validation cohorts, respectively. In the discovery cohort: BRAF V600 CRC were enriched for Interferon Gamma Signaling, Complement pathway, and IL6 JAK STAT3 Signaling ($p<0.05$) while the non-V600 BRAF mutant CRC showed an enrichment for Wnt-beta Catenin, Notch, and Hedgehog Signaling pathways ($p\leq0.05$). In the validation cohorts these same pathways were enriched in V600 and non-V600 BRAF mutant tumors. Interestingly, enrichment of genes co-mutated (GENIE data) in non-V600 BRAF mutant CRC also revealed the Wnt pathway. Non-V600 CRC tumors have a higher proportion of M0 macrophages ($p=0.0035$) and CD4 memory resting T cells ($p<0.0001$) while patients with V600 CRC have higher proportions of CD8 T cells ($p=0.006$) and activated mast cells ($p=0.0341$).
Conclusion: No optimal therapeutic strategies have been defined for these potentially actionable non-V600 BRAF mutant CRCs. By exploring the multi-omic landscape of these tumors we have identified unique characteristics of non-V600 BRAF mutant CRC that could be therapeutically exploited.

#7364 Comprehensive multi-omics analysis for resectable hepatocellular carcinoma uncovers biomarkers to predict microvascular invasion.

I. Kang, W. Kwon, S. Lee;
Laboratory of Integrative Precision Oncology, Seongnam, Korea, Republic of

Introduction: Microvascular invasion (MVI) is a well-known prognostic factor in predicting cancer relapse after curative resection of resectable hepatocellular carcinoma (HCC).Therefore, there is a clear unmet need for a precision strategy based on cancer-specific multi-omics features to predict the MVI feature at the initial diagnosis of HCC.
Methods: Using gene expression profiling for resected human HCC (Discovery cohort, n=240), we identified the transcriptomic signature predicting the MVI feature. Comprehensive analyses were performed using the dataset from the cancer dependency map (DepMap) project, including cancer-specific molecular characterization with multi-omics data, and drug sensitivity with compound screening, and integrative *in-silico* prediction methods to uncover MVI. The transcriptomic signature predicting the MVI feature were validated in independent translational cohorts (TCGA-LIHC; n=373, KOREA; n=188, TOKYO; n=183, MODENA; n=78, ZHONGSHAN; n=159).
Results: The MVI signature with 1028 genes was identified from robust statistical testing from the discovery cohort, and robust validation for the prediction performance of the MVI signature showed significant accuracy in the validation cohort (AUC=0.865, $p<0.01$). Multi-omics analysis revealed aggressive tumor biology associated with the MVI signature and specified biomarkers.
Conclusions: Integrative multi-omics profiling for resectable HCC uncovers biomarkers to predict MVI. A novel combination of biomarkers performs in sorting out the tumor with aggressive tumor biology. A precision strategy to discover resectable tumors beneficial from surgical resection can be established from consecutive clinical trials based on this translational study.

#7365 Drug-centric prior improves drug response signature identification in partially overlapping, large-scale pharmacogenomic datasets.

D. Thirumalaisamy[1], S. K. Joshi[2], M. Gonen[3], O. Nikolova[1];

[1]Oregon Health & Science University, Portland, OR, [2]Stanford University, Stanford, CA, [3]Koc University, Istanbul, Turkey

Introduction: With the accumulation of large-scale pharmacogenomic data such as whole-genome RNA sequencing, copy number and mutation profiles for tens of thousands of samples, further screened with thousands of small molecules and other perturbagens, the question arises how to best leverage partially overlapping datasets generated at different facilities. Notably, Haibe-Kains et al. observed discordance in state-of-the-art pharmacogenomic repositories. As research groups across the world continue to generate drug screens of variable size and quality, the need for approaches that can learn from such partially overlapping experiments and improve the signal to noise ratio emerges with increasing importance.

Methods: A previously published Bayesian group factor analysis model was shown to outperform other approaches in predicting drug response and identifying gene signature from pharmacogenomic datasets particularly by leveraging shared information for a given gene across multiple omics assays. Here, we applied the same model in a similar fashion to now learn from shared observations for the same drug across multiple partially overlapping and noisy small molecule screens. We integrate gene expression, mutation and drug response data from the two largest pan-cancer repositories at the Broad and Sanger Institutes, respectively. We train joint models on partially overlapping data from both. We evaluate our performance in three ways: 1) we test if the joint model improves the prioritization of known consensus biomarkers for the drugs shared between the two cohorts; 2) we test if the joint model improves the recapitulation of shared drug mechanism of action as compared to the single dataset models; 3) we evaluate the joint models with respect to pathway enrichment as compared to the single dataset models.

Results: We evaluated the performance of our joint model for 5 drugs shared between the 2 resources: selumetinib, tanespimycin, nutlin 3A, mirdametinib and PLX4720. First, we show that training joint models on partially overlapping pharmacogenomic datasets can overall improve gene signature identification by improving the ranks of known consensus biomarkers. Second, we show that the joint model learns a latent representation of the drugs that better recapitulates the underlying known mechanisms of action for the three serine/threonine kinase inhibitors. Finally, we show that the joint model achieved improved pathway enrichment results for the targeted MAPK/ERK signaling pathway.

Conclusions: We present an application of a Bayesian group factor analysis model, where we employ a drug-centric prior to transfer information about drugs screened in multiple datasets. We show that joint models leveraging partially overlapping large-scale pharmacogenomic datasets from the Broad and Sanger institutes can overall improve drug signature identification.

#7366 Loss of STK11 suppresses lipid metabolism to attenuate KRAS-induced immunogenicity in patients with non-small cell lung cancer.

D. Principe[1], M. Pasquinelli[1], R. Nguyen[1], L. Feldman[1], A. Aissa[2], F. D. Weinberg[1];

[1]University of Illinois Chicago, Chicago, IL, [2]Federal University of Sao Paulo, Sao Paulo, Brazil

Background: Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related death in the United States. Though NSCLC is genetically heterogeneous, as many as 30% of NSCLC patients harbor gain-of-function mutations in the *KRAS* oncogene. Recent studies have demonstrated that *KRAS* mutations lead to extensive remodeling of the tumor immune microenvironment. However, though the effect of co-mutations in genes such as *TP53* and *STK11* are known to have prognostic relevance in *KRAS*-mutated patients, their mechanistic effect on tumor immunogenicity is largely unknown.

Methods: In the present single-center study, we enrolled a total of 189 NSCLC patients. Paraffin specimens from each underwent a standardized analysis including immunohistochemistry for PD-L1 expression, whole exome DNA sequencing, and whole transcriptome RNA sequencing.

Results: Patients with activating *KRAS* mutations demonstrated a significant increase in PD-L1 expression as well as in CD8+ T-cell infiltration, both of which were enhanced by co-occurring *TP53* mutation. Interestingly, in patients with loss-of-function *STK11* mutations, there was no association between *KRAS* mutation status and either PD-L1 expression or CD8+ T-cell infiltration. Subsequent genomic analysis demonstrated that *KRAS/TP53* co-mutated tumors had a significant decrease in the expression of glycolysis-associated genes, and increase in several genes involved in lipid metabolism, notably *Lipoprotein Lipase* (*LPL*), *Low Density Lipoprotein Receptor* (*LDLR*), and *LDLRAD4*. Conversely, in the immune-excluded *KRAS/STK11* co-mutated group, we observed diminished lipid metabolism and no change in anaerobic glycolysis. Interestingly, in patients with low expression of *LPL*, *LDLR*, or *LDLRAD4*, gain-of-function *KRAS* mutations had no effect on tumor immunogenicity. However, in patients with robust expression of these genes, *KRAS* mutations were strongly associated with increased immunogenicity and associated with improved overall survival.

Conclusions: These data suggest that gain-of-function *KRAS* mutations are associated with an increase in immunogenicity, though this appears to be dependent on a corresponding increase in lipid metabolism. Our data further suggest that the loss of *STK11* may function as a metabolic switch to suppress lipid metabolism in favor of glycolysis, thereby negating KRAS-induced immunogenicity. Hence, this concept warrants continued exploration, both as a predictive biomarker and potential target for therapy in patients receiving ICI-based immunotherapy.

#7368 Sentinel omics signatures: Comparative clinical and blood sample analysis from canine mammary tumor patients and their human guardian.

K. Son[1], A.-R. Nam[1], H.-M. Park[2], H. Kim[1], J.-W. Lee[1], J.-Y. Cho[1];

[1]Seoul National University, Seoul, Korea, Republic of, [2]Korea Research Institute of Standards and Science, Daejeon, Korea, Republic of

Breast cancer remains a leading cause of morbidity and mortality worldwide, necessitating innovative approaches for early detection and intervention. This study leverages the comparative biology paradigm, exploring the shared oncological pathways between humans and canines through a unique multi-omics approach. We have gathered a diverse cohort comprising healthy dogs, canine mammary tumor patients, and their respective human guardians, collecting comprehensive clinical data alongside blood samples. Employing RNA-seq, MBD-seq, and LCMS, we aim to construct a detailed transcriptomic, methylomic, and proteomic landscape to elucidate potential sentinel biomarkers indicative of an oncogenic environment shared between species. While results are forthcoming, the premise of our research rests on the hypothesis that environmental factors contributing to mammary cancer may manifest systemically, potentially affecting both canines and humans. By delineating these interspecies molecular signatures, we hope to advance the field of precision medicine, offering insights into early detection and the systemic nature of cancer pathobiology. This abstract presents the foundation and direction of our ongoing investigation, with a commitment to providing a comprehensive update, inclusive of significant findings, at the conference.

#7369 Passenger mutations link cellular origins and transcriptional identity in human lung adenocarcinoma.

S. Panja, P. Mantri, J. A. Martinez, **M. Imielinski**;
NYU Langone Health, New York City, NY

Lineage plasticity hinders identification of cellular origin of cancers, as malignant cells cease to resemble benign cells from which they presumably evolved. Lung adenocarcinoma (LUAD), the most common primary lung cancer in United States is thought to arise from alveolar type II (AT2) cells. However recent mouse models have shown that LUADs may also arise from other cell types such as basal and club. Although such mouse models are considered to be gold standard for identifying cell of origin for cancers, they are generally limited to a specific genetic context and lack all cell types that are present in human lung. Thus, to better understand the cellular origins of LUAD, we utilized a publicly available lung scRNA-seq atlas from Human Cell Atlas, spanning over 584,000 cells from 107 individuals to investigate cell type specific passenger mutational footprints of transcriptional coupled repair process (a sub-pathway of nucleotide excision repair that preferentially corrects mutations in highly expressed genes) across 295 lung cancer WGS profiles. As most mutations in self-renewing tissues are thought to occur prior to the onset of tumorigenesis, genes that are most highly transcribed in the cell of origin would have fewer somatic single nucleotide variants (SNV). To test this hypothesis, our study correlated somatic mutational density with gene expression profiles of cell types to identify Alveolar Type 0 (AT0, newly identified cell type) cells to be most strongly associated with LUAD mutation density, suggesting that the ancestor of LUAD cells in tumor spent most of their non-cancerous time in AT0 state. Interestingly studies have shown that following DNA damage in AT2 cells, transition to AT1 occurs to repair the damage. However, if the damage is detrimental, the transition of AT2 to AT1 is stalled and the cells remain in AT0 (i.e., a transitionary) state. We propose that such stalling for a long period of time can give rise to LUAD. Further our study identified a subset of LUAD patients with non-AT2 (i.e., proximal) origin. In particular, we observed significantly higher KRAS mutations in distal origin LUAD patients compared to those in proximal origin LUADs. Finally, a subset of LUAD patients with distal cell of origin adopted a more proximal transcriptional identity. Extending our analysis to lung squamous cell carcinoma (LUSC) patients, we observed basal resting cells to be the Cell of Origin (COO) for LUSC. Our study provides a novel approach for identifying cell of origin for cancers and points to a complex interplay between origin and identify in lung adenocarcinoma evolution.

#7373 Generative Bayesian networks for augmentation of molecular data from commercial genetics panels.
Dillon H. Tracy, Jeff Sherman, Maayan Baron

Zephyr AI, McLean, VA

Background: Computational models in medical research which use molecular features to predict patient sensitivities or outcomes are traditionally limited to producing a scalar output for a given disease phenotype, e.g. progression-free survival or drug response. Even for relatively intelligible models, it is generally difficult to place confidence limits on the prediction or develop an intuition for how a prediction varies with respect to “what-if” changes in those features or how sensitive a prediction is to changes in input variables. Moreover, while essential for understanding and modeling tumor behavior, molecular features from patient tumors in real-world settings are typically limited to profiles of hundreds of genes, while the biologically relevant inputs to the patient’s condition can be much larger.
Approach: To generate data required to enhance the interpretation of predictive models and extend the utility of real-world patient oncology datasets, a distribution of conditions consistent with the observed features and their incidence across cancer patient cohorts is required. We hypothesized we could synthesize patient samples drawn from the joint probability distribution of a broader universe of features when a subset of them is held fixed at the observed values. We model this joint distribution by learning a Bayesian network over a broad feature set for which some training data is available and generate feature profiles by applying Gibbs sampling to the learned network.
Results: We assessed the potential clinical utility of using these generated feature profiles in predicting drug response and enhancing biological interpretation of different model outputs. We found generative somatic mutations were useful for predicting cancer patient outcomes, including drug response predictions in breast cancer tumors from AACR Project GENIE. Synthesized patient feature profiles enhanced biological interpretability of nominal panel data (100-200 genes), providing a means to assign probabilities to outcomes and uncovering previously described mechanisms of drug response in real-world patient data.
Conclusion: We introduce an approach that leverages Bayesian networks to synthesize richly annotated patient feature profiles from limited molecular data routinely collected in real-world settings. This approach addresses challenges associated with limited molecular data, biological interpretability and evaluation of predictive models and enhances the utility of real-world datasets for cancer research.

#7374 Mathematical modeling of targeted radionuclide therapy and CAR-T cell immunotherapy for maximizing therapeutic efficacy in multiple myeloma.

V. Adhikarla[1], D. Awuah[1], E. Caserta[1], M. Minnix[1], M. Kuznetsov[1], A. Krishnan[2], J. Y. C. Wong[2], J. E. Shively[1], X. Wang[1], F. Pichiorri[1], R. C. Rockne[1]; [1]Beckman Research Institute - City of Hope, Duarte, CA, [2]City of Hope National Medical Center, Duarte, CA

Background: Resistance of cancer cells to monotherapies has led to the development of sequential or combination therapy regimens. However, dosing and scheduling of these therapies is challenging due to the numerous dosing and scheduling combinations that can be given. Mathematical models are thus critical tools for addressing this challenge as multiple therapy combinations can be tested *in silico* to finalize a patient-specific therapeutic regimen *in vivo*. Here we develop a mathematical framework for combining targeted radiation therapy (TRT) with Chimeric Antigen Receptor (CAR)-T cell immunotherapy and demonstrate the use of *in silico* techniques to schedule these therapies for maximizing survival.

Methods: In the mathematical framework tumor growth is assumed to be exponential and the effect of radiation on both tumor cells and CAR-T cells is modeled using the linear-quadratic model of cell survival to radiation. A predator-prey model is used to characterize the dynamics of tumor and CAR-T cells. Using a preclinical disseminated mouse model of multiple myeloma (MM1S), we evaluate tumor response to 200 nCi of ^{225}Ac-DOTA-Daratumumab (TRT) and 1 million cells of CS1 CAR-T cell therapy both as monotherapies as well as in combination. Tumor burden tracked using bioluminescence imaging from six groups of mice is used to calibrate model parameters: (a) No treatment. (b) Day 7 TRT. (c) Day 7 CAR-T cell therapy. (d) Day 7 TRT + Day 18 CAR-T cell therapy. (e) Day 7 TRT + Day 25 CAR-T cell therapy. (f) Day 7 TRT + Day 32 CAR-T cell therapy. Response to therapy is evaluated using progression-free survival (PFS), overall survival (OS) and time to minimum tumor burden (t_{min}), all of which are calculated using the predicted *in silico* tumor burden dynamics and the tumor burden at the start of first therapy. We evaluate these response metrics for various dosing and scheduling regimens.

Results: Therapy intervals that were too short or too long are shown to be detrimental for therapeutic efficacy. TRT too close to CAR-T cell therapy results in radiation related CAR-T cell killing, while the interval being too long results in tumor regrowth, negatively impacting tumor control and survival. If a single dose is split into multiple doses, the splitting is advantageous only if the first therapy delivered can produce a significant benefit as a monotherapy. Based on the model parameters we estimate the minimum required TRT activity and CAR-T cell dose to demonstrate an improvement in PFS.

Conclusions: The proposed model demonstrates the impact of different dosing and scheduling regimens of TRT and CAR-T therapy on survival metrics. It is a potent tool for translating preclinical results to the clinic and eventually tailor therapy regimens for patients.

#7376 Modeling the dynamics of lung cancer cells along the epithelial–mesenchymal spectrum in the stem and non-stem cell compartments.

Arianna Di Bernardo[1], Sarthak Sahoo[2], Melissa Balsamo[1], Elsa Quaranta[1], Mohit Kumar Jolly[2], Giulia Bertolini[1], Luca Roz[1]

[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [2]Indian Institute of Science, Bangalore, India

Epithelial-mesenchymal transition (EMT) is a crucial biological process during development which also appears to play a fundamental role in the dissemination of cancer cells. It is known that hybrid states (H), in which cells have mixed epithelial (E) and mesenchymal (M) properties, are particularly conductive to metastasis but the possibility of seeding secondary lesions is also closely linked to the intrinsic tumor initiation potential (stemness). An overall vision taking into account both the EMT spectrum and stemness properties could therefore be the key to fully understanding the metastatic process. In this study we aim to build a mathematical model capable of describing the transitions in the EMT spectrum distinguishing stem from non-stem cell subpopulations in lung cancer cells. Using E-cadherin and N-cadherin staining we evaluated experimentally by flow-cytometry the modulation of epithelial (E), hybrid (H) and mesenchymal (M) phenotypes in A549 lung cancer cells after the induction of EMT by TGFβ treatment and subsequent return to steady state after TGFβ withdrawal. Stem and non-stem populations were identified with the previously validated CD133 marker. To mathematically describe the cellular dynamics we used a system of differential equations assuming transitions E-H, E-M and H-M, for stem and non-stem compartments initially treated as decoupled. Parameters used in the equations were the three switching rates corresponding to the three transitions allowed. To test the robustness of the model we solved the equation multiple times (500) by first stochastically changing the initial conditions and then the initial parameters, obtaining the respective parameters optimized by minimizing the residual between experimental data and model. To decouple the parameters, equations were then solved stochastically 1000 times changing two of three initial parameters, obtaining the optimized third parameter and the respective minimal residual. Parameters fitting closely the experimental data during TGFβ-mediated EMT induction were obtained, indicating that the transition from H to M appears to be absent in the non-stem population but present in the stem population, while the transition from E to M is always present. We also observed that after TGFβ withdrawal the inclusion of an epigenetic decay factor is necessary to model the latency period before MET insurgence when EMT is previously induced in the system. We can conclude that during EMTinduction, the dynamics in the non-stem compartment can be described by a bifurcation model in which population E becomes either M or H and remains permanently in that state, stressing the stability of the H state and also that E cells might have a predisposition to transform into M or H. Furthermore, a portion of H stem cells is able transform into M during EMT and therefore appears more plastic which could underscore a greater metastatic potential.

#7377 Deep learning uncovers morphological patterns of YAP1/TEAD activity related to disease aggressiveness in cancer patients.

B. Schmauch[1], V. Cabeli[1], **O. Darwiche-Domingues**[1], J.-E. Le Douget[1], A. Hardy[1], R. Belbahri[1], C. Maussion[1], A. Romagnoni[1], M. Eckstein[2], F. Fuchs[2], A. Swalduz[3], S. [1]Owkin France, Paris, France, [2]University Hospital Erlangen, Erlangen, Germany, [3]Centre Leon Berard, Lyon, France, [4]Centre Georges-Francois Leclerc, Dijon, France, [5]New York University Langone Medical center, New York, NY, [6]Stanford university, Stanford, CA, [7]Institut Curie, Paris, France, [8]Sanofi, Paris, France

Hippo signaling emerged over the last decade as a major tumor-suppressing pathway. Its dysregulation is generally associated with abnormal expression levels of YAP1, WWTR1 (coding for the TAZ protein) and TEAD genes among others. This pathway has been shown to have a prognostic impact in several cancer types. In particular, the role of YAP1/TEAD activity across indications has been emphasized by several recent works, with potential implications on treatment options. Therefore, identifying patients with a deregulated pathway is key for a better clinical impact of the current potential therapies. Recent studies have been able to characterize RNA-seq based signatures of a deregulated Hippo pathway but a reproducible and cost-effective method to measure the activation of the pathway in clinical settings is needed. Here we first evaluate and confirm the robustness of a YAP1/TEAD activity signature recently published by Calvet et al. (RNA-based signature focused on TEAD downstream effectors), to predict the level of activity of this pathway across several cancer types available in TCGA. Our results confirmed that YAP1/TEAD activity is cancer type and subtype specific and that its high activity is correlated with poor prognosis in some of these cancers. We then trained deep learning models to predict YAP1/TEAD gene activation level, from H&E-stained histology slides in various cancer types from The Cancer Genome Atlas. We showed that histological markers associated with dysfunctional Hippo signaling are markers of disease aggressiveness and poor prognosis such as necrosis, poorly differentiated tumor, and inflammation. Altogether our results are opening the avenue of defining image-based biomarkers predictive of the YAP1/TEAD activity which could be used in clinical settings for better inclusion of subgroups of patients for targeted therapeutics against this hallmark of cancer development.

#7378 Using game theory to investigate the therapeutic potential of disrupting tumor-microenvironment interactions.

D. Van Egeren[1], A. Chen[2], M. Stoddard[3], **L. Yuan**[3], A. Chakravarty[3];
[1]Stanford University, Palo Alto, CA, [2]Columbia University, New York, NY, [3]Fractal Therapeutics, Inc., Lexington, MA

Cancer is a complex disease involving the interplay of several types of malignant and nonmalignant cells. The growth of tumors and surrounding stromal cells can be modeled as an ecosystem, where populations of cancerous and healthy cells interact and compete for resources. In this work, we have explored the application of game theoretic models of cancer to the design of novel anticancer therapies. Notably, a game theoretic-model of tumor-stromal interactions can capture the impact of interactions between cell types and can be used to investigate frequency-dependent parameters describing the impact of drug action during the initiation and growth of metastatic cancers. Previous studies using game theoretic models to describe cancer have focused on explaining progression patterns of specific tumors with known tumor-stromal interactions. This study takes a more general approach to cancer growth dynamics, modeling cancer as a simple game between healthy and cancer cells. This simplified model is used to make general predictions about cancer progression and the efficacy of treatment strategies. Our work suggests that disruption of beneficial interactions between healthy and cancer cells may be a viable treatment strategy for small tumors and preventing metastasis by ensuring that the healthy cell strategy is evolutionarily stable. The efficacy of treatment strategies that disrupt cancer cell cooperation or tumor-stromal dynamics changes as the cancer cell frequency changes. Our work suggests that drugs that target tumor-stromal cell interactions would need to be combined with other types of treatments to be effective against large tumors. Although based on a simplistic model of cancer initiation and progression, the framework derived here can be extended to the real-world design of experimental anticancer therapeutics, and fundamental analyses of this nature can be of practical utility in setting strategy for Target Product Profile design.

#7379 Deep learning based risk stratification of pre-operative CT scans is prognostic of overall survival in kidney cancers.

Brennan Flannery[1], Mohsen Hariri[1], **Thomas DeSilvio**[1], Amir Sadri[1], Jane Nguyen[2], Erick M. Remer[2], Smitha Krishnamurthi[2], Satish E. Viswanath[1]

[1]Biomedical Engineering, Case Western Reserve University, Cleveland, OH,[2]Cleveland Clinic, Cleveland, OH

Introduction: Preoperative risk stratification of kidney cancer patients is critical for treatment selection and improving mortality rates. Current clinical approaches such as cancer grading are limited by inter-reviewer variability, require invasive biopsy procedures, and might not capture the full extent of patient risk. We sought to evaluate a deep learning (DL) model to quantify patient risk and prognosticate overall survival in kidney cancer patients via CT scans.
Methods: This retrospective study used preoperative contrast CT scans from 4 public multi-institutional collections with date of death/censoring available. A deep learning (DL) network architecture was developed to analyze input CT scans via a convolutional feature extractor and a Cox proportional hazards-based cost function. The DL model assigned a risk score to each patient, with the median risk used as a cutoff for classifying patients as high-risk or low-risk. Model performance for prognosticating overall survival (OS) was evaluated separately in training, internal validation, and external validation cohorts via Kaplan-Meier analysis in terms of concordance index and hazard ratios, with risk groups compared via Wilcoxon log-rank tests ($\alpha = 0.05$).
Results: In the training/internal validation cohort (N=418, 8 institutions) and external validation cohort (N=102, 1 institution), the median age was 60 and 59 years, the male/female ratios were 62% / 38% and 75% / 25%, with a median follow up of 2.8 and 3.1 years, respectively. The DL model yielded a training c-index of 0.66 (95% CI: 0.63-0.68), internal validation c-index of 0.73 (95% CI: 0.70-0.76) and an external validation c-index of 0.67 (95% CI: 0.64-0.70). Kaplan-Meier analysis of associated survival curves based on DL-determined high- and low-risk patients demonstrated statistically significant separation in all cohorts: training ($p = 0.003$, HR = 8.63, 95% CI: 8.28-8.98), internal validation ($p = 0.027$, HR = 4.89, 95% CI: 4.52-5.26), and external validation ($p = 0.01$, HR = 6.54, 95% CI: 6.18-6.90). Baseline clinicopathological characteristics were not significantly different between DL high and low risk patients in external validation (chi-square testing; ISUP grade $p=0.375$, age $p=0.824$, race $p=0.567$, and sex $p=0.440$). ISUP grade was also not a significant predictor of OS in internal validation (HR=1.57, $p=0.211$, 95% CI: 1.28-1.85) or external validation ($p = 0.465$, HR=0.16, 95% CI: 0.33-0.74).
Conclusion: A deep learning model based on pre-operative CT scans was found to accurately prognosticate overall survival in kidney cancers in a multi-institutional setting, independent of clinicopathological factors. This model is being validated on larger cohorts, and in the context of targeted therapies.

#7380 Predicting immunotherapy outcomes from H&E images in lung cancer.

J. Loo[1], Y. Wang[1], P. Wong[1], E. Wulczyn[2], J. Lai[2], P. Cimermancic[1], D. F. Steiner[2], S. S. Weaver[1];
[1]Verily Life Sciences, South San Francisco, CA, [2]Google, Mountain View, CA

Checkpoint blockade immunotherapy is a cornerstone of lung cancer treatment, but there is a need to improve the identification of patients who will respond favorably. Here, we explored a deep learning approach to predict immunotherapy outcomes from hematoxylin and eosin (H&E) images in non-small cell lung cancer (NSCLC). We included 150 unique cases with metastatic NSCLC (113 adenocarcinoma, 29 squamous cell, 8 other) treated with anti-PD-1/PD-L1 immunotherapy (56 nivolumab, 49 atezolizumab, 44 pembrolizumab, 1 durvalumab) as mono or combination (14 with chemotherapy, 1 with ipilimumab) therapy in a single institution. Each case consisted of a representative H&E whole slide image (53 biopsies, 50 needle core biopsies, 47 resections) obtained prior to immunotherapy, and the outcome reported as the 1-year overall survival (OS). PD-L1 status (tumor proportion score ≥ 1%) was known for 70 cases. We preprocessed the H&E images using two deep learning models previously developed using The Cancer Genome Atlas dataset. First, we used a classification model to identify tumor regions and randomly sampled a fixed number of tumor patches for each case. Then, we used a self-supervised pathology foundation model to obtain a compressed visual representation of each patch, known as an embedding. Next, using our dataset, we trained a deep multiple instance learning (DeepMIL) model with a gated attention mechanism to predict the binary 1-year OS status (0=deceased, 1=alive) for each case. As a baseline, we also trained a linear-probe (logistic regression) model using the averaged embeddings. Given the small dataset size, 5-fold cross-validation was used to train and evaluate both the DeepMIL and linear-probe models, with cases randomly split across folds. For evaluation, we used survival analysis to compare the 0/1 case groups. Overall, across all 150 cases, univariable Cox regression showed that 1-year OS was more strongly associated with the DeepMIL status (46/104, HR=0.55, p=0.03) than the linear-probe status (55/95, HR=0.81, p=0.44). Results were consistent on the subset of 70 cases with known PD-L1 status, whereby OS was most strongly associated with the DeepMIL status (19/51, HR=0.40, p=0.04) compared to the linear-probe status (31/39, HR=0.46, p=0.09) and PD-L1 status (30/40, HR=0.65, p=0.32). In multivariable Cox regression adjusting for age group and smoking status, OS remained more strongly associated with the DeepMIL status (HR=0.45, p=0.08) than PD-L1 status (HR=0.72, p=0.47). In conclusion, the DeepMIL status predicted from H&E images showed a stronger association with outcomes compared to PD-L1 status, a standard biomarker for immunotherapy in NSCLC. These exploratory results demonstrate the potential of deep learning using pathology foundation models to improve immunotherapy outcomes prediction, even with small datasets. Such approaches may even enable the discovery of novel biomarkers from H&E images to advance precision medicine.

#7381 Mathematical modeling and validation of mechanistic target of rapamycin and N-myristoyltransferase signaling pathways in breast cancer.

Hormone receptor-positive (HR+) breast cancer (BC) makes up approximately 65% of all breast cancers diagnosed. The prognosis for early-stage disease is excellent with mainstay endocrine therapy (ET). Despite the effectiveness of standard ET, as many as 41% of HR+ early-stage BC diagnosed women will experience distant recurrence. The resistance to endocrine therapy and recurrence is partly attributed to the activation of the insulin pathway and the independence of HR+ BC cells on the ER pathway for their growth. Earlier, we demonstrated the crosstalk between insulin/mTOR and ER pathways. N-myristoyltransferase (NMT) exists in humans in two paralogues (NMT1 and NMT2) that catalyze myristoylation reaction. Recent studies from our laboratory demonstrated that NMTs are downstream targets of insulin and ER pathways. In this study, we have designed mathematical models using differential equations to study the activation of the insulin pathway and its effect on NMT. The mathematical modeling incorporated the partition of cellular organelles and the sequential flow of information with cascades of equations representing signaling reactions. The activated mathematical model was designed by activating the insulin receptor (IR) or insulin-like growth factor receptor (IGF1R) and compared with the control model. The mathematical models were validated by wet lab experiments. The HR+ BC cells (MCF7) were treated with insulin or IGF1 for short term and long term. The expression patterns of NMT1, NMT2, and mTOR were determined by cell fractionation and western blot analysis. The results revealed the correlation between the differential expression patterns of NMTs and the proliferation of MCF7 cells when the insulin pathway was activated by insulin or IGF. The mathematical modeling was validated by simulations and data fittings. The results demonstrated that differential equation-based mathematical modeling could predict the NMT-related oncogenic changes in HR+ BC cells.

#7382 Artificial intelligence derived features of collagen architecture identify high risk HPV associated oropharyngeal squamous cell carcinoma patients.

R. Nag[1], H. Li[2], G. Corredor[1], P. Fu[2], N. F. Saba[1], M. A. Bilen[1], T. Pathak[1], P. Toro[3], M. Mokhtari[2], K. Pandav[1], M. Gilkey[1], S. Koyfman[3], D. Chute[3], W. L. Thorstad[4], M. Mehrad[5], P. D. Castro[6], A. G. Sikora[7], R. D. Chernock[4], J. Luo[4], M. Frederick[6], V. Sandulache[6], D. J. Adelstein[3], J. Lewis Jr.[5], A. Madabhushi[1]; [1]Emory University, Atlanta, GA, [2]Case Western Reserve University, Cleveland, OH, [3]Cleveland Clinic, Cleveland, OH, [4]Washington University, St. Louis, MO, [5]Vanderbilt University Medical Center, Nashville, TN, [6]Baylor College of Medicine, Houston, TX, [7]The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Human papilloma virus (HPV) induced oropharyngeal squamous cell carcinoma (OPSCC) is a common subtype of head and neck carcinoma. Dysregulation of the extracellular matrix (ECM), an important part of the tumor microenvironment (TME), is shown in HPV related cancers. We studied collagen fibers (CF), the amplest component of the ECM, and evaluated whether their characteristics within the TME can offer a prognostic value in OPSCC.

Methods: Whole slide images (WSIs) of OPSCC patients were obtained from Washington University (WU, n=107), Houston Veterans Administration Hospital (HV, n=94), Cleveland Clinic (CC, n=336), John Hopkins University (JH, n=121) and Vanderbilt Medical Centre (VM, n=158). For the identified CF in tumor-stroma regions of WSIs, the extracted CF features included: CF fragmentation measure, CF bundling percentage, CF rigidity measure, CF anisotropy index, and CF density index. For survival analysis using overall survival (OS) and Disease-Free Survival (DFS) as endpoints, the median risk score in the training set (WU) was applied for risk stratification in the validation sets (HV, CC, JH, VM) by means of a Least Absolute Shrinkage and Selection Operator-Cox regression model. Multivariable Cox Proportional Hazards Regression was done for both OS and DFS.

Results: The patients defined as “high risk” had worse OS than those identified as “low risk” (HV(p=0.03), CC(p=0.03), JH(p=0.02), VM(p=0.04)). Multivariable analysis showed that CF features were prognostic independent of T/N stages, age, sex, and smoking status with HR=1.99 (95% CI=1.46-2.72, p=0.00001) for OS and HR=1.73 (95% CI=1.21-247, p=0.002) for DFS (Table 1).

Conclusion: Artificial intelligence derived features of CF architecture can help identify high vs low risk patients in HPV related OPSCC. These findings deserve further confirmation in larger prospectively collected OPSCC data sets and could impact future treatment paradigms.

Table 1: Multivariable Survival Analysis for OS and DFS, HR=Hazard Ratio, CI=Confidence Interval

Variable	**Overall Survival**		**Disease Free Survival**	
	HR (95% CI)	**P value**	**HR (95% CI)**	**P value**
Age (<65 years vs. >=65 years)	0.99 (0.93-1.06)	0.78444	0.96 (0.82-1.12)	0.62864
Sex (Female vs. Male)	0.56 (0.29-1.10)	0.09042	0.50 (0.22-1.13)	0.09385
Smoking status (Yes vs. No)	1.85 (1.31-2.62)	0.00051	1.03 (0.72-1.47)	0.86871
T-stage (T3/4 vs T1/2)	**1.86 (1.38-2.50)**	**0.00004**	**1.91 (1.36-2.69)**	**0.00018**
N-stage (N+ vs N0)	**1.76 (1.31-2.37)**	**0.00016**	**2.04 (1.46-2.86)**	**0.00003**
Collagen fiber features (High risk vs low risk)	**1.99 (1.46-2.72)**	**0.00001**	**1.73 (1.21-2.47)**	**0.00286**

#7383 G2PT: Mechanistic genotype-phenotype translation using hierarchical transformers.

I. Lee[1], S. Park[1], H. Nam[2], T. Ideker[1];

[1]University of California San Diego - UCSD, La Jolla, CA, [2]Gwangju Institute of Science and Technology, Gwangju, Korea, Republic of

Motivation: Many machine learning models have been proposed that use genotypes to predict various phenotypes. Recently, these models have focused not only on an accurate prediction but mechanistic interpretation, in that they attempt to describe the hierarchy of biological systems underlying the predicted phenotype. Such models still face major challenges, however, including how to robustly quantify the importance of systems mediating phenotypic outcomes and how to represent the bidirectional flow of information among genes, systems, phenotypes, and cell environment.

Results: To address these challenges we introduce G2PT, a general Genotype-to-Phenotype Transformer, which we apply here to the classic G2P problem of modeling tumor cell sensitivity to drugs. We show that the framework of hierarchical transformers can represent biological systems spanning a wide range of physical scales and provide a quantitative assessment of the interplay between biological components important for phenotype prediction. When used to analyze a high-throughput cell screen of 436 drugs exposed to 1,097 cell types, we show that the model achieves good performance in predicting cell sensitivity for 83% of drugs ($\rho > 0.5$ in cross-validation). G2PT provides a robust and interpretable model with potential application to many challenges in genotype-phenotype translation.

#7384 Regulation of phosphorylated VGLL1 by the positively charged binding pocket on the surface of TEAD4.

J. Choi[1], H. Le[2], Y. Park[2], Y. Yun[2], J. Kim[2], J. Wilianto[2], N. Shadiev[2], C. Sung[2], B. Ku[3], K.-Y. Chang[4], M. Won[5];
[1]Department of Bio AI Convergence, Chungnam National University, Daejeon, Korea, Republic of, [2]Calici Co., Ltd., Daejeon, Korea, Republic of, [3]Disease Target Structure Research Center, Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of, [4]OneCureGEN Co., Ltd., Daejeon, Korea, Republic of, [5]Personalized Genomic Research Center, Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of

Vestigial-like 1 (VGLL1) is a transcriptional co-activator that binds to TEA domain-containing transcription factors (TEADs), regulating hippo pathway. High expression of VGLL1 is associated with gastric cancer, breast cancer, and pancreatic cancers. VGLL1 is transcriptionally regulated by PI3K/β-catenin signaling and is phosphorylated by ribosomal S6 kinase 2 (RSK2) in the presence of TGF-β. It is clear that phosphorylation at S84 of the VGLL1 protein is critical for its interaction with TEAD4 to express their target genes involved in the proliferation and metastasis of cancer cells. In the isothermal titration calorimetry study, we observed S84-phosphorylated VGLL1 peptide bound to TEAD4. However, it is difficult to understand structure-based molecular mechanism of the phosphorylated VGLL1 at S84 due to lack of the detailed human VGLL1-TEAD4 complex structure for rational drug design. In this study, we modeled full-length human VGLL1-TEAD4 or YAP1-TEAD4 complexes and performed MMPBSA calculations or Kd/Ki predictions followed by MD simulations using Pharmaco-Net's CNN-based artificial intelligence model. Our study suggests that a positively charged binding pocket on the surface of TEAD4 can regulate interaction between Trp243 from YAP1 and phosphorylated-Ser84 from VGLL1. The newly identified binding pocket is composed of Lys297, Val414, and Tyr429, which can interact with phosphorylated Ser84 residue and maintain Omega loop-like structure shown in YAP1-TEAD4 complex. The computed binding energy for phosphorylated-VGLL1-TEAD was -134.80 +/- 8.20 Kcal/mol which was a similar binding energy to YAP1-TEAD4 complex. In addition, global peptide docking using S84-containing-VGLL1 peptide (SCVP) indicated that SCVP can bind to the same binding pocket with average 1.39 μM. This suggested that there could be a novel therapeutic approach targeting this interaction with SCVP, an agent that seems to mimic phosphor-VGLL1 interaction and thus demonstrates promise as a potential therapeutic intervention. Nevertheless, further experimental verification and clinical investigations are needed to validate these innovative findings.

#7385 Explainable AI model incorporating uncertainty estimation for enhanced MSI-H prediction and immunotherapy response in gastrointestinal cancer.

S. Park[1], M. Kim[1], J.-Y. Sung[2], J. Park[3], S. Lee[4], S. C. Wang[5], J. Cheong[6], T. Hwang[1];
[1]Mayo Clinic, Jacksonville, FL, [2]Kyung Hee University Hospital, Kyung Hee University College of Medicine, Seoul, Korea, Republic of, [3]Seoul National University Boramae Medical Center, Seoul, Korea, Republic of, [4]College of medicine, the Catholic university of Korea, Seoul, Korea, Republic of, [5]University of Texas Southwestern Medical Center, Dallas, TX, [6]Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Microsatellite instability-high (MSI-H) tumors respond well to immune checkpoint blockade and oftentimes not to chemotherapeutics. Despite value of determining MSI status to guide therapy, many patients' samples are not untested. Deep learning models may be able to predict MSI status by analyzing hematoxylin and eosin (H&E) stained whole-slide images (WSIs). Validation of this tool will provide another tool to increase MSI testing. However, to be deployed into clinical routine care, prediction models need be externally validated in large and diverse patient cohorts. In addition, these models should provide uncertainty of prediction to help clinicians make informed decisions.

Results: In this study, we introduce a novel Bayesian prediction model using whole-slide images (WSIs) and deep Gaussian processes (DGPs) in a weakly supervised learning context. Extensively tested on large datasets (n=3,146) from multiple centers, our model not only demonstrated superior performance but also showed that incorporating uncertainty into predictions significantly improves MSI prediction accuracy, achieving AUROC of >0.91 in colon cancer and >0.94 in gastric cancer. Additionally, an in-depth analysis within the gastric cancer cohort indicated a significant correlation between predicted MSI-H regions and immunotherapy response. Patients who responded to immune checkpoint inhibitors had a higher proportion of MSI-H regions (P-value < 0.05). This correlation was also observed in patients categorized as MSS but responsive to ICIs, highlighting the potential of our model to identify MSI-H patterns not detected through standard laboratory tests. This advancement could lead to more precise patient selection for ICI therapy, enhancing personalized treatment strategies in gastrointestinal cancer.

#7386 Multi-plane rectal tumor segmentation on pre-treatment MRI via human-in-the-loop deep learning.

Michael Kong[1], **Thomas DeSilvio**[1], Leo Bao[1], Brennan Flannery[1], Benjamin N. Parker[1], Stephen Tang[1], Gregory O'Connor[2], Amit Gupta[2], Emily Steinhagen[2], Andrei S. Purysko[3], Eric L. Marderstein[4], Aaron Carroll[5], Marka Crittenden[6], Michael Gough[5], Kristina Young[6], Satish E. Viswanath[1]

[1]Biomedical Engineering, Case Western Reserve University, Cleveland, OH,[2]University Hospitals Cleveland Medical Center, Cleveland, OH,[3]Cleveland Clinic Foundation, Cleveland, OH,[4]Northeast Ohio Veterans Affairs Medical Center, Cleveland, OH,[5]Providence Cancer Center, Portland, OR,[6]Earle A. Chiles Research Institute, Portland, OR

Introduction: Precise segmentation of rectal tumors on pre-treatment MRI is critical for in vivo clinical staging and treatment selection. While automated deep learning models can help alleviate laborious manual annotation, these require significant expertise and time commitment. Towards addressing these issues, we present initial results of an integrated human-in-the-loop refinement learning model for semi-automated segmentation of rectal tumors across multiple acquisition planes (axial, coronal) on pre-treatment MRI scans.

Methods: This retrospective study accrued baseline MRI scans from rectal cancer patients at four different institutions. A deep learning (DL) nnUNet tumor segmentation model was first trained on both axial plane and coronal plane T2w MRIs from two institutions, with segregated training and internal validation cohorts based on available radiologist annotations. The DL model outputs tumor delineations on both axial and coronal MRI scans in a separate human-in-the-loop (HITL) optimization cohort. Two rounds of HITL refinement learning were then conducted, where in each round model-generated segmentations were refined by two novice radiology readers. Refined annotations were then used to re-optimize the nnUnet model to yield final tumor segmentations. Model-generated segmentations were evaluated before HITL as well as after each round of HITL against “ground truth” radiologist annotations obtained for an external validation cohort, with performance quantified via dice similarity coefficient (DSC) as well as time taken for human annotation of MRIs. Statistical significance was determined via Wilcoxon rank-sum testing.

Results: A total of 381 MRI scans from 231 rectal cancer patients were considered. After one round of HITL refinement, DL-based segmentations yielded the best overall performance on the external validation cohort (N=20, two institutions) for both axial (DSC = 0.76) and coronal scans (DSC=0.75). A second round of HITL refinement did not yield significantly different model performance. By comparison, the pre-HITL DL segmentation model yielded significantly worse performance on both axial (DSC=0.60, p=0.0362) and coronal (DSC=0.62, p=0.0186) MRI scans. HITL refinement for rectal tumor annotation was also found to significantly improve reader efficiency by requiring only 18 minutes/scan compared to manual “ground truth” de novo annotations which took up to 38 minutes/scan (p<0.001).

Conclusion: Human-in-the-loop deep learning models can help generate accurate rectal tumor segmentations on pre-treatment MRI scans across both axial and coronal acquisition planes. Improvements to model generalizability, model efficacy, and reader efficiency suggest the potential for HITL-based semi-automated segmentation schemes for other medical imaging tasks.

#7387 Fully automated segmentation and volumetric measurement of intracranial meningioma using deep learning.

H. Kang[1], J. N. Witanto[2], K. Pratama[2], D. Lee[2], K. Choi[3], S. Choi[3], M.-S. Kim[3], J. Kim[3], Y. Kim[3], S. Park[2], C.-K. Park[3];

[1]Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of, [2]MEDICALIP Co. Ltd, Seoul, Korea, Republic of, [3]Seoul National University Hospital, Seoul, Korea, Republic of

Most intracranial meningiomas are small, asymptomatic, and incidentally found tumors. Since the growth of meningioma is the principal indication of treatment, accurate and rapid measurement of the volume of intracranial meningiomas is essential in clinical practice to determine the growth rate of the tumor. It could be useful for the management of meningiomas given their increasing incidence and the wait-and-see policy currently in use for asymptomatic meningiomas. The aim of this study was to develop and validate a computational model for fully automated meningioma segmentation and volume measurement on contrast-enhanced MR scans using deep learning.

The retrospectively collected axial contrast-enhanced T1-weighted section images from patients diagnosed with meningioma were manually segmented and used to construct automatic segmentation models with six U-Net- and nnU-Net-based architectures. The performance of each model was evaluated with the Sørensen-Dice similarity coefficient (DSC) with internal (IVS) and external validation sets (EVS), each consisting of 100 independent MRI examinations.

A total of 12,909 section images from 459 patients were applied for the training (median age 58 [52-66] [IQR]; 385 women [83.9%]). The median tumor volume of the training set was 2.36 cm^3. A 2D nnU-Net showed the highest median DSCs of 0.922 and 0.893 for the IVS and EVS, respectively. The nnU-Nets achieved superior performance in meningioma segmentation than the U-Nets. The DSCs of the 2D nnU-Net for small meningiomas less than 1 cm^3 were 0.769 and 0.780 with the IVS and EVS, respectively.

We successfully developed a fully automated and accurate volumetric measurement tool for meningioma using nnU-Net. The volumetry performance for small meningioma was significantly better than that achieved in previous studies. The results of this study are clinically applicable and are expected to be of great use in the management of monitored meningioma patients.

#7388 Deep learning-implemented molecular signature identification in vascular malignancies.

D. Lee, H. Heo, J. Kim, J. Kim;
University of Florida, Gainesville, FL

Angiosarcoma is a rare, aggressive sarcoma that forms malignant endothelium. Naturally occurring angiosarcoma in domestic dogs, also called hemangiosarcoma, is relatively common and offer a useful translational model for the rare human cancer. Distinct molecular subtypes of angiosarcoma have been identified; however, current methods are cost-prohibitive and time-consuming, posing challenges in the development of clinical applications. In this study, we hypothesize that artificial intelligence enables reliable image-based diagnostics and molecular characterization specific to angiosarcoma. The aims of our work are to develop a deep learning framework to provide diagnostic support for suspicious malignant cases, to detect morphological features associated with oncogenic mutations, and to identify immune phenotypes in this malignancy. For proof-of-concept and feasibility study, we first utilized convolutional neural network models to identify malignant features in angiosarcomas. We curated 4,079 images of hematoxylin and eosin (H&E) stained slides from seventy visceral angiosarcomas and 3,536 images of thirty splenic hematomas as benign controls obtained from client-owned dogs. ResNet-50 and AlexNet were trained on the images, and area under the receiver operating characteristic curve (AUC) was determined for disease classification. ResNet-50 and AlexNet yielded AUCs of 0.999 and 0.998, respectively. Next, we calculated the gradient of the model's prediction and applied it to the original image using Grad-CAM software. Grad-CAM results revealed that AlexNet highlighted histological regions representing malignant cellular components for decision-making, aligning with the pathological diagnostic context. In addition, we applied ResNet-50 to determine if the model could predict morphological features in angiosarcoma tissues representing the presence of *PIK3CA* mutation. We employed RNA-seq data to annotate *PIK3CA* mutation status on the matched histological images. Among 54 cases annotated with *PIK3CA* mutation status, 2,732 *PIK3CA* wild-type and 664 mutant tumor images were trained by ResNet-50. Our model demonstrated an AUC of 0.981 in the prediction of *PIK3CA* mutation. We further defined immunophenotypic groups using *xCell* algorithms on RNA-seq data, and immune scores were applied to histological images. ResNet-50 model resulted in an AUC of 0.953 to classify immune-high and immune-low angiosarcomas. RNA-seq datasets generated from 13 human angiosarcoma cases exist in our lab, along with the respective H&E slides. We also have immunohistochemical slides available for p53, phospho-p53 (Ser15 and Ser20), AKT, and phospho-AKT (Thr308) proteins conducted in both human and canine angiosarcoma tissues. Our ongoing work involves generating whole-slide images of H&E stains and immunostained slides to enhance the deep learning models for the molecular classification of angiosarcomas.

#7390 Learning Llama Agents for medical record analysis and standardization.

D. Hein[1], A. Christie[1], H. Zhong[2], E. Araj[1], J. Brugarolas[1], L. Cowell[1], P. Kapur[1], A. Jamieson[1];
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Lyda Hill Department of Bioinformatics, Dallas, TX

Introduction: The purpose of this study is to develop custom, open source, LLM enabled pipelines and agents for the extraction and standardization of data from free text medical records.

Procedures: This project aims to create a versatile tool for healthcare data analysis, with initial development utilizing our extensive collection (over 10,000 documents) of renal cell carcinoma pathology reports. These reports are an ideal starting point as they cover over 20 years of care and consist of a racially and ethnically diverse cohort with over a quarter of patients being from traditionally underrepresented backgrounds. The jargon-abundant and highly technical nature of kidney cancer pathology represents a major challenge. We will accomplish this objective using an approach that balances the harnessing advanced AI capabilities with ensuring practicality and efficiency in real-world applications. First, we will leverage the capabilities of GPT-3.5/4 to generate a comprehensive labeled dataset (referred to as pseudo labels - machine-applied labels that will be used for training a newmodel) tailored for pathology, radiology, and clinician reports of kidney cancer patients. Second, we will harness the pseudo labeled datasets to train a smaller, open-source, yet highly efficient model for our specific needs (termed model distillation). LLAMA 2, known for its high performance in diverse tasks, is our model of choice. Its open-source nature and relatively modest computational requirements make it ideal for deployment within medical institutions. The ability to run locally ensures the protection of patient health information and reduces reliance on costlier, proprietary models. The rationale is threefold: first, to benefit from the superior performance and reasoning capabilities of GPT models; second, to create a streamlined model that is resource-efficient and tailored to our specific requirements; third, to enable the final streamlined model to be freely available by utilizing open source LLMs (e.g., Llama 2). To assess the feasibility of our methodology, we evaluated the ability of GPT-3.5 to label our data with high accuracy.

Data Summary: Our pilot set of pathology reports consisted of 109 documents and 3 extraction fields: histology type, biopsy site, and biopsy procedure. Using GPT 3.5 we achieved an accuracy of over 95% in each extracted field type thereby demonstrating its ability to act as a proficient “teacher” model for our future open source “student” model.

Conclusions: Our preliminary results suggest that current state of the art LLMs are highly proficient in extracting and standardizing information from clinical reports. Building out a full, open source, LLM enabled pipeline will increase the accuracy, flexibility, and efficiency of medical data extraction across institutions and lead to quicker and more informed decision-making in patient care and research.

#7391 Beyond traditional staining: A virtual-IHC digital assay for HER2 score prediction from routine H&E images.

M. Naderi[1], N. Mitic[1], N. Spasic[1], D. Cikic[1], K. Ruf[1], N. Wagner[1], I. Mihajlovic[1], S. Todorovic[1], R. Jenoski[2], S. Mayer[2], M. Quick[2], C. Weston[1];
[1]Reveal Biosciences Inc., San Diego, CA, [2]Hologic Inc., Marlborough, MA

Background: In breast cancer diagnostics, the accurate assessment of HER2 status is essential for treatment stratification. Conventionally, HER2 immunohistochemistry (IHC) scoring necessitates specialized staining protocols, which are resource- and time-intensive. This study presents a virtual IHC (vIHC) digital assay to predict HER2 scores directly from hematoxylin and eosin (H&E) stained images, which are routinely acquired for all specimens. This methodology aims to accelerate standard practices by reducing the need for additional IHC staining, thereby decreasing laboratory workload, costs, and turnaround time. It also presents an opportunity to screen a wider array of samples promptly, potentially identifying candidates for HER2-targeted therapy that might otherwise be delayed or overlooked.

Methods: Serially sectioned breast core needle biopsy samples were stained with H&E and HER2-IHC following Leica-Bond staining protocols. Stained slides were imaged using the Hologic Genius™ Digital Diagnostics System with Research Use Only software for Whole Slide Imaging. From this initial image dataset, 240 regions of interest (ROIs) were manually selected in order to create a dataset that uniformly covers: (i) all HER2-IHC scores (0-3), (ii) a wide range of HER2 stain intensities, and (iii) expression patterns. The IHC scores were assigned to each selected ROI by a pathology expert, following the scoring recommendations of ASCO/CAP American Society of Clinical Oncology and College of American Pathologists, with the caveat that ductal carcinoma in situ was also given a score for the purpose of training the model. These ROIs were then extracted from the images of the serially sectioned H&E-stained slides using Reveal Bio's proprietary co-registration digital assay.

A predictive digital assay was developed at Reveal Biosciences to classify the 240 H&E-stained breast tissue ROIs into four HER2 IHC score categories: 0, 1, 2, and 3. For model evaluation, cross-validation was performed 10 times by randomly splitting the dataset of H&E ROIs into 80% for training MIL and 20% for testing the model, followed by averaging the performance metrics across the 10 dataset splits. The performance metrics included classification accuracy, precision, recall, and F1 scores for each HER2 score category.

Results: The vIHC digital assay for predicting the HER2 scores directly from H&E stained breast tissue images achieved the average classification accuracy of 93% across the four HER2 score categories on the test set of ROIs. This performance demonstrates that the model is capable of successfully distinguishing between the HER2 score categories directly from H&E images without the need for IHC staining. The results suggest that the vIHC digital assay could be a reliable and cost-effective tool for preliminary breast cancer screening, providing a valuable adjunct to traditional histopathological analysis.

#7392 Machine learning-based identification of H&E-derived morphologic features associated with CD8+ T cell immune exclusion.

Y. Wang[1], F. D. Gootkind[1], F. Peyraud[2], J.-P. Guegan[3], A. Italiano[2], G. T. Clifton[1], L. A. Dillon[1], X. Sher[1];
[1]Incendia Therapeutics, Boston, MA, [2]Institut Bergonie, Bordeaux, France, [3]Explicyte Immuno-Oncology, Bordeaux, France

Background: Immune exclusion is characterized by a predominance of CD8+ T cells in the stroma of the tumor microenvironment (TME) which are not in contact with tumor cells. Immune exclusion is a significant obstacle to effective cancer immunotherapy and reversing it has emerged as a new therapeutic opportunity. However, the objective assessment of immune exclusion remains a challenge due to the complexity of the TME and the need for immunostaining to quantify CD8+ cells in tumor and stroma. While artificial intelligence (AI) models applied to H&E images can quantify spatial tissue and cell features at scale, they are unable to identify the molecular subtypes of cells. Here we describe the development of a machine learning model that classifies tumors by their CD8-defined immune phenotypes using features extracted from H&E whole slide images alone.

Methods: AI-powered TME models (PathAI PathExplore™) were deployed on H&E images from 39 non-small lung cancer (NSCLC) and triple-negative breast cancer (TNBC) samples. CD8-based assessment of immune phenotypes was done using an adjacent section. 115 H&E-derived features from each of the 25 tumor samples (12 NSCLC, 13 TNBC) classified as immune excluded and 7 tumor samples (3 NSCLC, 4 TNBC) classified as immune infiltrated were used as input into a feature selection process to identify the subset of H&E features predictive of immune phenotype. The feature selection process was driven by an ensemble L1 norm support vector machine (Ens-L1-SVM) model containing 500 L1-SVM base models each trained by 80% of the data. The degree of immune exclusion was determined in the feature space by the distance to the separation hyperplane defined by the model. Out-of-bag error estimation was employed on the remaining 20% of data from each base model to assess model performance.

Results: The Ens-L1-SVM model identified 6 H&E features predictive of CD8-defined immune phenotypes, including the density ratio of lymphocytes to macrophages in the cancer epithelium, the density of fibroblasts, and the spatial distributions of cancer cells, macrophages, and lymphocytes. Immune phenotypes were classified by the Ens-L1-SVM model with an estimated accuracy of 97%. Additionally, all selected features and their direction of association aligned with prior knowledge of the mechanisms or manifestations of immune exclusion or infiltration in the TME.

Conclusion: This work illustrated that morphologic features derived from H&E images using AI-powered models can be effective predictors of CD8-defined immune exclusion, providing an option for patient stratification by immune phenotype using widely-available H&E images. While the Ens-L1-SVM model showed robust performance on a small number of samples and is expected to have good generalizability due to the linear nature of the model, additional validation across diverse datasets and various tumor indications is needed.

#7393 Tumor model to tumor treatment: Applying deep learning approaches to map multimodal data from cancer model systems to patients.

B. Karlberg[1], R. Kirchgaessner[1], J. R. Jacobson[2], K. Ellrott[1], S. J. Gosline[2];
[1]OHSU, Portland, OR, [2]Pacific Northwest National Laboratory, Seattle, WA

Despite large-scale efforts to measure the effect of drug screens in cancer cell lines, mapping the effects of drugs to patient samples has been a challenge. Biological differences between cell lines and patients, such as lack of immune system or microbiome, *in-vitro* survival adaptations, and biases in measurement technologies create differences across sample modalities that can confound analysis including prediction with machine learning. In this work, we propose a multiway batch correction strategy to enable algorithmic prediction of tumor drug response across model systems and patient data.Recent advances in batch correction algorithms have been motivated by the need to correct for batch effects in single-cell omics and include diverse approaches such as variational autoencoders (VAEs) and generative adversarial networks (GANs). Given the successes of these generative deep learning methods in single cell sequencing analysis, we worked to employ similar approaches to correct large omics measurements across various cancer datasets. Here, we describe mapping of datasets from diverse data sources and model systems to the same space, so that a predictive model of drug response built in a system such as cell lines can be used in biologically relevant models such as organoids, patient derived xenografts, and tumor data. Specifically, we introduce a modified loss function in a VAE using cosine similarity distance to minimize the effect of different cancer model systems in predicting cancer types. We evaluate the method on standard data types for drug response prediction - gene expression, copy number variation, and protein abundance. For this method, the cosine similarity is added as an additional term to the VAE reconstruction and Kullback-Leibler divergence loss terms. This injects a quantification of the dissimilarity between the tumor and tumor model distributions into the backpropagation and gradient descent for updating the model parameters resulting in an encoded representation of the data where the effect of data source has been attenuated while preserving the phenotypic signal. We evaluate our approach for biological signal preservation while reducing model system-specific noise with logistic regression and Euclidean distance. Our results show that the proposed VAE can effectively correct for platform effects and improve the accuracy of downstream integrative analyses. This study has the potential to improve the accuracy and translatability of proteogenomic drug response studies. The proposed modified VAE could be used to correct for platform effects in a variety of datasets, including those from different studies, different platforms, and different cancer types. This could lead to new insights into cancer biology, calibration of cancer patient digital twins, and the development of new diagnostic and therapeutic strategies.

#7394 Delineating spatial expression signatures of lung adenocarcinoma subtypes from spatial single-cell transcriptomics using graph neural networks.

A. Das[1], M. Hasib[1], Z. Liu[1], W. Meng[1], Y.-C. Chiu[1], G. Sica[2], S.-J. Gao[1];
[1]University of Pittsburgh Medical Center, Hillman Cancer Center, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Pittsburgh, PA

Lung Adenocarcinoma (LUAD) subtypes including complex acinar (CA), micropapillary, and solid regions are characterized by distinct morphological and biological features that bear significant implications for prognosis and treatment strategies. While histology-based subtype prediction has provided a structural understanding, it overlooks crucial biological insights related to molecular mechanisms and the influences of tumor microenvironments (TMEs). Recent advances in spatially resolved single-cell profiling enable precise measurements of gene expression at the cellular and sub-cellular levels within intact tissues. We hypothesize that spatial gene expression (SGE) patterns can effectively identify LUAD subtypes and characterize the influence of TMEs. Thus, to address the limitations of histology-based subtyping of LUAD, we developed an AI-driven approach that leverages SMI samples to predict LUAD subtypes and elucidate their underlying molecular landscape and associated TMEs.

For this study, we leverage the NanoString CosMx Spatial Molecular Imaging (SMI) NSCLC FFPE datasets comprising of 8 LUAD tissue samples, annotated by pathologists at UPMC for subtype identification. The dataset consists of approximately 98k cells per sample with 18 cell types and 960 genes per cell. We encoded the spatial organization of cells as a graph with nodes representing cells with expression features and edges based on k-nearest neighbors of 30 cells. We considered the prediction of micropapillary, CA, and solid for each tumor cell and developed a Graph Convolutional Network (GCN) with semi-supervised training to account for the unlabeled nodes. A subgraph splitting strategy with cross-validation was developed to train on localized spatial regions and ensure balanced label proportions in each subgraph. Our GCN achieved 92.63% test accuracy, surpassing non-spatial deep learning models (77.45%).

Notably, explanation analysis using the GNNExplainer algorithm of our trained model identified high-attribution cells in CA and solid TME, revealing unique differentially expressed genes (DEGs) - JUNB in CA, and VIM, GPX1, PSAP, IFI27 in solid tumors, compared to low-attribution cells within the same subtype. Further analysis revealed an enrichment of EMT and interferon alpha/gamma, suggesting a more inflamed phenotype than low-attribution cells. Differential expression analysis of high-attribution CA vs solid cells identified significant upregulation of NDRG1 in CA and COL1A1 in solid. Functional enrichment analysis of these DEGs revealed PI3k-Akt in CA and MAPK signaling pathway in solid, suggesting an aggressive solid TME and CA with high survival and metastasis. We further identified a distinct neutrophil-enriched TME associated with CA and revealed cell-cell communication through MIF interactions with the CD74/CXCR4 and CD44/CD74 axes.

#7395 Histology-based prognosis prediction using deep learning outperforms and is independent of the MGMT methylation status in patients with glioblastoma.

L. Fidon, C. Thiriez, A. Grimaldi, O. Darwiche Domingues, C. Maussion, **C. Hoffmann**;
Owkin, PARIS, France

Introduction: MGMT gene promoter methylation status is today the only biomarker of survival for GBM patients and predicts favorable response to temozolomide (TMZ). Here we propose a deep learning-based model using histology data (H&E slides) to predict the prognosis of patients with Glioblastoma (GBM) treated by standard of care (SOC).

Methods: We included TCGA GBM patients and selected only patients treated after 2005 (Stupp protocol start); compliant to WHO 2021 classification; treated by surgery and adjuvant therapy; with a follow-up superior to median overall survival (OS) (14.5 months). Short and long survivor labels were defined based on median OS cut-off. A deep learning pipeline was trained to predict these labels from the H&E slides (baseline surgery samples). First, the slides were automatically segmented into tissue and background, divided into a regular grid of tiles (112x112µm), and tiles were vectorized using a vision transformer-based feature extractor trained on H&E slides of 5,500 patients with 16 cancer subtypes (GBM excluded). In the second step, ABMIL deep learning model was trained to predict the survival category using the bag of tile features available from step 1 for each patient. The cohort was divided into five folds with even numbers of short and long survivors. For each fold, 50 ABMIL models were trained on the remaining folds and ensembled to predict the category of the patients in the fold. Training hyperparameters were tuned on a separated cohort excluding GBM patients.

Results: After filtering, we analyzed n = 192 TCGA GBM patients including 154 patients with a known MGMT promoter methylation status. Our histology-based model had an accuracy of 0.661 and a ROC AUC of 0.706. It stratified the population into short and long survivors with an Hazard Ratio (HR) of 0.48 (95% CI 0.34-0.69). Our model outperformed the MGMT methylation status that had an HR of 0.57 (95% CI 0.40-0.83). Moreover, our model was independent of MGMT methylation status and the combination of both was able to further improve prognosis prediction: we applied our model independently to the 91 patients with an unmethylated MGMT status (predicted: 43 low, 48 high) and to the 63 patients with a methylated MGMT status (predicted: 30 low, 33 high), and obtained HR of 0.42 (95% CI 0.27-0.67) and 0.49 (95% CI 0.28-0.86) respectively.

Conclusion: Having selected patients treated by the latest SOC and classified as GBM by the latest WHO criteria, we propose a model predicting survival based on histological specimens available in routine care, which outperformed the current unique biomarker MGMT methylation status. The combination of this status and our model improves prognosis predictions compared to each strategy alone.

#7396 Development of deep neural networks that guide more individualized radiotherapy to the lung.

M. Abazeed;
Northwestern University Feinberg School of Medicine, Chicago, IL

Introduction: Radiotherapy is dependent on an expert-based model that impedes implementation of many potentially useful applications that could aid decision makers. This model is a barrier to a learning healthcare system due to noise introduced by decision-maker variation. Surmounting this barrier will require compelling clinical outcome data and highly useful and accurate information systems. We sought to develop new augmented-intelligence capabilities to better predict both high-dose lung irradiation treatment efficacy (*i.e.*, local tumor control) and toxicity (*i.e.*, radiation-induced pneumonitis).
Methods: We curated one of the largest datasets of lung stereotactic body radiotherapy (SBRT) datasets globally (~1200 cases). We input pre-therapy lung computed tomography (CT) images using a bounding box approach that captures the gross tumor volume and adjacent normal lung into a multi-task deep neural network to generate an image fingerprint that predicts local failures after treatment. Separately, we input axial slices from CT scans of the lung into convolutional neural network (CNN) and trained using an outcome per slice method. We then aggregated intra-patient slices into a recurrent neural network (RNN) to estimate individual patient risk for pneumonitis. We validated our findings with the independent study cohort. Risk scores for local failure and pneumonitis were combined with clinical variables to assess the relative contribution of the deep learning-derived image risk scores.
Results: A total of 1045 patients met our eligibility criteria. Radiation treatments in patients with high local failure risk scores failed at a significantly higher rate than in patients with low scores; 3-year cumulative incidence of local failure in the internal study cohort was 20·3% (16·0-24·9) in patients with high scores and 5·7% (95% CI 3·5-8·8) in patients with low scores (hazard ratio [HR]=3·64 [95% CI 2·19-6·05], p<0·0001). Models that included the local failure risk score and clinical variables predicted treatment failures with a concordance index (C-index) of 0·72 (95% CI 0·67-0·77), a significant improvement compared with classical radiomics (p<0·0001) or clinical variables (p<0·0001) alone. Radiation pneumonitis risk scores were highly predictive of toxicity, with an accuracy and CI of 0.78 (95% CI 0.72-0.85). A model that includes dosimetry variates (V20), improved the CI to 0.85 (95% CI 0.80-0.90).
Conclusions: The image-based deep learning frameworks developed herein represent the first opportunity to use medical images to individualize radiotherapy dose and toxicity predictions. Our results signify a new roadmap for deep learning-guided predictions and treatment guidance in the image-replete and highly standardized discipline of radiation oncology. A phase 2 study assessing machine-derived dose predictions is currently enrolling patients.

#7397 Application of state transition theory for predicting responses of acute myeloid leukemia to chemotherapy.

L. Uechi, Y.-H. Fu, D. E. Frankhouser, L. Zhang, Y.-C. Chen, D. O'Meally, S. Branciamore, J. Irizarry, B. Zhang, G. Marcucci, Y.-H. Kuo, **R. C. Rockne**; Beckman Research Institute of The City of Hope, Duarte, CA

Acute Myeloid Leukemia (AML) is aggressive cancer that initiates in the bone marrow (BM) and circulates in the peripheral blood (PB). The AML initiation and progressions are complex disease evolution associated with gene mutations and chromosomal abnormalities that change expression profiles of downstream genes characterizing functional networks of leukemic cells. We previously reported the application of the state-transition theory to characterize AML disease progression by modeling transcriptome changes during AML progression as a dynamic system that undergoes state-transition in an AML state-space characterized by an AML potential. Here, we investigate the impact of treatment on transcriptome state-transition and examine the hypothesis that treatment dynamically alters the AML potential. We use the Cbfb-MYH11 (CM) knock-in AML mouse model and a ”5+3” chemotherapy regimen to model the impact of current standard of care for newly diagnosed AML. CM leukemic mice were treated with a combination of cytarabine (Ara-C; 50mg/kg/day; 5 days) and Daunorubicin (DNR; 1.5mg/kg/day; 3 days) after detection of overt leukemia, defined by > 20% leukemia blast (cKit+) detected by flow cytometry in the PB. Time-series samples of peripheral blood mononuclear cell (PBMC) (n=174) were collected weekly before, during, and following “5+3” chemotherapy and subjected to RNA sequencing. All samples were mapped to the AML state-space constructed based on time-sequential RNA-seq collected over the course of CM AML development. Based on the state-transition model, all 10 treated AML mice achieved partial response to chemotherapy with a mean time to relapse (return to leukemia state) of 5 weeks confirming the anti-leukemia effects of treatment by the blast percentages (ckit%) . We used the state-transition treatment model to study the dynamics of chemotherapy on the AML potential using state-space trajectories before, during, and after “5+3” chemotherapy. Dynamic changes of concentrations of Ara-C and DNR in the CM mouse model during ”5+3” chemotherapy were modeled by drug doses, half-life, and Heaviside step function. The drug effects were introduced to the AML potential as anti-leukemic treatment forces. Several treatment protocols were examined to find combinations of drug doses and timing that showed the longest survival rates. The model predicted that sequential doses reducing 50% of the original “5+3” chemotherapy dose would produce the longest survival rate. The model suggests that controlling the state-space trajectories in the healthy state with reduced doses will provide the most effective outcomes from “5+3” chemotherapy.

#7398 Unveiling the tumor microenvironment of hepatocellular carcinoma using AI trained by spatial transcriptomics: A preliminary study to predict response to immunotherapy.

Dongjoo Lee[1], Haenara Shin[1], Seungho Cook[1], Daeseung Lee[1], Hongyoon Choi[2], Won-Mook Choi[3], Changhoon Yoo[4], Kwon Joong Na[5]

[1]Portrai, Inc., Seoul, Korea, Republic of,[2]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Department of Gastroenterology, Liver Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[4]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[5]Department of Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul, Korea, Republic of

Background. Immune checkpoint inhibitors (ICIs), particularly targeting the PD-1 pathway, are promising in treating hepatocellular carcinoma (HCC). However, their variable effectiveness among individuals calls for a better understanding of the tumor microenvironment (TME) and reliable predictive biomarkers. Here, we employ spatial transcriptomics (ST) to develop a deep-learning model that aims to investigate the TME in HCC using Hematoxylin and eosin (H&E) staining images. Our focus is on identifying cell types within the TME that are linked to the response to ICI in a cohort of patients treated with nivolumab.
Methods. Our study leveraged 21 Visium ST datasets from HCC to develop a model aimed at inferring the cellular composition of TME from H&E images that matched with ST data. The comprehensive TME cell types enrichment score, encompassing Tumor Endothelial Cells (TECs), Tumor-Associated Macrophages (TAMs), B cells, T cells, and Cancer-Associated Fibroblasts (CAFs) in each spot, was calculated by the CellDART algorithm, a method that maps cell type by integrating with a reference scRNA-seq data. The model was trained in a patch-wise manner, utilizing a pre-trained ResNetRS50 as the backbone model. For the internal validation, Spearman correlation coefficients were evaluated for predicted cell types using H&E, and the trained model was correlated with cell type enrichment scores estimated by ST datasets of 4 samples independent of the training set. The model was applied to H&E images of 16 patients with HCC who underwent nivolumab treatment. The model predicted the 5 cell types enrichment score in the tumor and tumor-adjacent normal liver tissues.
Results. The internal validation set results demonstrate robust Spearman correlations between our model predictions and actual cellular compositions in the TME. Specifically, we observe strong correlations for T cells (rho = 0.66), TAMs (rho=0.46), CAFs (rho=0.32), B cells (rho=0.30), and TECs (rho=0.24). When we applied the model to the H&E images of the cohort of patients who underwent nivolumab, immunotherapy non-responders showed a significantly higher predicted enrichment score of CAFs in tumor-adjacent regions (Mann-Whitney test, $p<.01$). Upon stratifying patients based on stromal CAF prediction, those with low stromal CAF levels exhibited better overall survival (Log-rank test, $p<.05$).
Conclusions. We present a deep learning model to analyze TME in HCC solely on H&E images trained by ST data. Our findings showed a potential relationship between CAFs in tumor-adjacent regions and non-responders to nivolumab treatment in HCC. These insights underscore the potential to predict nivolumab treatment responders using H&E images combined with the deep learning model. This approach could provide a significant advancement in personalized treatment strategies for HCC patients.

#7399 Development of a reproducible AI-based spatial biomarker of the tumor immune infiltrate on H&E slides.

V. Di Proietto, **J. El-Khoury**, B. Adjadj, L. Gillet, U. Marteau, K. Schutte, K. Von Loga;
Owkin, Paris, France

Background: The immune infiltrate in the tumor microenvironment (TME) has been shown to be associated with prognosis in several studies. However, a comprehensive assessment of the TME composition is not performed in routine practice due to the lack of standardized methods and tools for quantification. The aim of our study is to develop a reproducible, artificial intelligence (AI)-based, spatial biomarker of the tumor related immune response to predict patients outcome on routine Hematoxylin & Eosin (H&E) slides. To the best of our knowledge, this is the first study that implements a robust H&E pipeline to assess, across multiple cohorts, the prognostic power and the added-value of a spatial marker in comparison to non-spatial measures such as the overall lymphocytes density on the slide.
Methods: We trained AI models on both publicly available (NuCLS and Lizard) and proprietary datasets to automatically detect cells and tissue types on H&E stained Whole Slide Images of cancers from different origins.
We used these models on TCGA COAD and TCGA BRCA and computed spatial measures related to the lymphocyte densities in the tumor core versus the invasive margin as well as the immune infiltration in the tumor stroma (in between tumor islets) versus in the tumor islets themselves.
Univariate and multivariate survival analysis is performed through repeated cross-validation. A log-rank test on the stratified groups is performed for each evaluated marker, using the median value as cutoff.
Preliminary results on TCGA-COAD and TCGA-BRCA show that spatial markers of the tumor-related immune response are individually associated with overall survival, reinforcing findings from prior studies emphasizing the importance of the spatial relationship between tumor and immune cells. Multivariate analysis with both linear and non-linear models is currently ongoing across selected cohorts.

#7400 AI-driven multimodal 3D tumor modeling with spatial molecular insights for predicting ICI response in gastric cancer.

Y. Choi[1], M. Kim[1], K. Redekop[2], I. Jang[1], J. R. Clemenceau[1], I. Barnfather[3], S. Nakkireddy[1], C. Hong[1], S. Park[1], J.-Y. Sung[4], J. Park[5], S. Kohei[6], A. Yu[6], S. Lee[7], S. Wang[8], J. Cheong[9], T. Hwang[1];

[1]Mayo Clinic,, Jacksonville, FL, [2]University of California,, Los Angeles, CA, [3]University of Manchester, Manchester, United Kingdom, [4]Kyung Hee University Hospital, Kyung Hee University College of Medicine, Seoul, Korea, Republic of, [5]Seoul National University Boramae Medical Center, Seoul, Korea, Republic of, [6]National Cancer Center Hospital East, Chiba, Japan, [7]College of medicine, the Catholic university of Korea, Seoul, Korea, Republic of, [8]UT Southwestern Medical Center, Jacksonville, TX, [9]Yonsei University College of Medicine, Seoul, Korea, Republic of

Traditional cancer research methodologies predominantly focus on 2D tumor modeling, including spatial profiling and AI-driven analysis at the 2D level. To advance beyond these limitations, we implemented Holotomography (HT), a 3D, label-free optical imaging method. This technique, leveraging refractive index contrasts, allows for enhanced visualization of tumor tissues, organoids, and cells in three dimensions. Using serial H&E sections and unstained slides, we created detailed 3D tumor models in gastric cancer, providing insights into tumor, immune, and stromal composition, as well as cell-cell interactions and extracellular matrix characteristics. AI algorithms further enhanced our 3D tumor modeling, offering novel perspectives on the initiation and progression of tumor, immune, and stromal components at the subcellular level. Analyzing gastric tumors treated with immune checkpoint inhibitors before, during, and after treatment revealed dynamic changes in spatial composition over time, offering unique insights into the evolution of the 3D tumor ecosystem. Additionally, by integrating spatial transcriptomic and in situ molecular imaging data, we developed a novel Multimodal 3D Tumor Model. This model not only uncovers subcellular-level molecular characteristics but also elucidates cellular interactions during treatment, suggesting potential biomarkers and therapeutic approaches. Lastly, by constructing 3D cellular interaction networks incorporating true 3D interactions, we provided an in-depth view of cellular communication within the tumor microenvironment. This pioneering approach, representing the first Multimodal 3D Tumor Model at the subcellular level, offers novel insights into gastric cancer's spatial evolution, potentially revolutionizing our understanding and treatment of gastric cancer.

#7401 High-level multiplexed virtual immunofluorescence staining using holotomography and deep learning.

J. Park[1], S.-J. Shin[2], G. Kim[1], K. Lee[2], J. Heo[3], Y. Park[1];

[1]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of, [2]Gangnam Severance Hospital, Seoul, Korea, Republic of, [3]Yonsei University College of Medicine, Seoul, Korea, Republic of

Multiplexed immunofluorescence (IF) staining plays a crucial role in cancer research, allowing simultaneous visualization of multiple biomarkers to elucidate complex cellular interactions within the tumor microenvironment. However, the conventional multiplexed IF approach has inherent limitations, characterized by labor-intensiveness and a constrained capacity for high-level multiplexing. These challenges hinder its scalability and comprehensive analysis of intricate molecular landscapes.To overcome the limitations of conventional multiplexed IF, we propose a novel approach that integrates holotomography (HT) and deep learning. HT is a label-free imaging technique that quantitatively measures the refractive index distribution of the specimen without any staining. To provide subcellular specificity to the label-free HT images, HT is integrated with virtual staining. Virtual staining is a deep learning-based framework that converts label-free images to the desired stained images, in this case, from HT images to multiplexed IF images. This synergistic combination of HT and deep learning may address the current limitations of multiplexed IF protocols.Our proposed methodology aims at high-level multiplexed virtual IF staining from label-free cancer tissue slides using HT and deep learning. This approach not only eliminates the need for chemical staining but also enhances the level of multiplexing through computational staining. Specifically, we acquire HT and fluorescence images of stained tissue slides for training. Utilizing this paired dataset, we then employ supervised learning to create a neural network that can map between label-free HT images and corresponding fluorescence images. Subsequently, the trained neural network is applied to label-free tissue slides, inferring fluorescence images without the need for chemical staining.We believe the proposed virtual staining framework will contribute to a more efficient and scalable paradigm for cancer research, facilitating a deeper understanding of tumor biology, and advancing the field of precision medicine.

#7402 Foundation AI models predict molecular measurements of tumor purity.

Y. Gerardin, D. Shenker, J. Hipp, N. Harguindeguy, D. Juyal, C. Shah, S. Javed, M. Thibault, M. Nercessian, D. Sanghavi, B. Trotter, **R. Leung**; PathAI, Inc., Boston, MA

Background: Molecular assays, such as comprehensive genomic profiling, play a critical role in characterizing patient disease and guiding treatment selection in oncology but require sufficient tumor nucleic acids in tissue samples for reliable results. Automated, accurate and reproducible quantification of tissue area and tumor nuclei from H&E slides to determine suitability for molecular testing could reduce the amount of time spent assessing tissue quality. To address this need, we developed pan-indication foundation AI models to quantify tissue and cell features within H&E whole-slide images (WSI) and compared tumor purity estimates to orthogonal molecular and manual methods.

Methods: Pan-indication artifact, tissue, and cell models were each trained using at least 2.8 million pathologist annotations across over 100,000 WSI from 14 stains, 25 organs, and 9 scanners and validated against pathologist ground-truth labels. This suite of foundation models was deployed on H&E WSIs of colon adenocarcinoma (COAD; N=442), melanoma (N=363), prostate cancer (PRAD; N=490), and non-small cell lung cancer (NSCLC; N=996) from TCGA[1]. Model outputs allowed for the segmentation of tumor regions and enumeration of cancer cells for the purpose of determining tumor purity scores, calculated as the fraction of cancer cells within tumor tissue on a WSI. For comparison, tumor purity values determined based on DNA copy number (ABSOLUTE), gene expression (ESTIMATE), DNA methylation (LUMP) and manual assessment[2] were obtained. Concordance between AI model scores and other tumor purity values was assessed using the intraclass correlation coefficient, ICC(2,1).

Results: AI model scores were correlated with orthogonal molecular measures of tumor purity in all four indications. AI model purity scores corresponded the most with ABSOLUTE (ICC range: 0.22-0.46), followed by LUMP (ICC range: 0.02-0.50) and ESTIMATE (ICC range: 0.03-0.34). Across indications, the highest agreement observed between AI model scores and molecular methods was in melanoma (ICC range: 0.34-0.50), while the lowest agreement was in PRAD (ICC range: 0.02-0.22). Compared against ABSOLUTE in NSCLC and PRAD, AI model scores showed the highest concordance, while the other two molecular methods and manual assessment all overestimated ABSOLUTE tumor purity.

Conclusions: Here, we describe a pan-indication AI-based approach for the quantification of tumor features in H&E-stained WSI. Foundation AI models successfully segment tumor tissue regions and enumerate cancer cells for determining tumor purity, and these predictions correlate with molecular metrics in four cancer indications. This work provides further evidence of how AI could improve the efficiency of molecular testing and enhance precision medicine approaches in oncology.

#7406 Visualization and analysis of cancer genomics data using UCSC Xena.
M. Goldman, B. Craft, J. Zhu, D. Haussler;
UC Santa Cruz Genomics Institute, Santa Cruz, CA

UCSC Xena (http://xena.ucsc.edu/) is a web-based visual integration and exploration tool for multi-omic data and associated clinical and phenotypic annotations. Researchers can easily view and explore public data, their own private data, or both using the Xena Browser. Private data are kept on the researcher's computer and are never uploaded to our public servers. We support Mac, Windows, and Linux.
Questions Xena can help you answer:* Is overexpression of this gene associated with lower/higher survival?* What genes are differentially expressed between these two groups of samples?* What is the relationship between mutation, copy number, expression, etc for this gene?
Xena showcases seminal cancer genomics datasets from TCGA, the Pan-Cancer Atlas, GDC, PCAWG, ICGC, and more; a total of more than 1500 datasets across 50 cancer types. We support virtually any type of functional genomics data: SNPs, INDELs, copy number variation, gene expression, ATAC-seq, DNA methylation, exon-, transcript-, miRNA-, lncRNA-expression and structural variants. We also support clinical data such as phenotype information, subtype classifications and biomarkers. All of our data is available for download via python or R APIs, or using our URL links.
Our signature Visual Spreadsheet view shows multiple data types side-by-side enabling discovery of correlations across and within genes and genomic regions. We also have dynamic Kaplan-Meier survival analysis, powerful filtering and subgrouping, differential gene expression analysis, GSEA, charts, statistical analyses, genomic signatures, and the ability to generate URLs to live views.
New features include:
* Genome-wide differential gene expression analysis
* GSEA analysis
* Select samples directly from the screen for filtering and creating subgroups
* Loading of Microsoft Excel files
Our beta prototype site for visualizing single-cell data delivers million-cell-scale multi-omics data for interactive visualization in a web browser. Contact us for access to our beta prototype site.
If you use us please cite our publication in Nature Biotechnology: https://www.nature.com/articles/s41587-020-0546-8

#7407 Melanoma clonal subline analysis reveals genetic factors driving intra-tumor heterogeneity.

A. Keskus[1], A. Goretsky[1], Y. Liu[1], X. Cui[1], T. Ahmad[1], E. Perez Guijarro[1], A. Bryant[1], E. Malloy[2], S. Malikic[1], G. Merlino[1], C.-P. Day[1], C. Sahinalp[1], M. Kolmogorov[1];

[1]NIH-NCI, Bethesda, MD, [2]University of Maryland, College Park, MD

Melanoma is the most invasive skin cancer caused by the malignant melanocytes. The use of immune checkpoint blockade (ICB) improved the survival rate in advanced melanoma. Yet, the response rate to ICB varies across patients due to the highly heterogeneous nature of melanoma. Recent studies reported genomic and epigenetic factors contributing to the therapeutic response. Identifying these factors involved in clonal evolution in melanoma is a key to better understanding the tumor progression and divergence in the therapy response.

To study melanoma heterogeneity, we generated twenty-four clonal sublines, each derived from a single cell isolated from a parental cell line derived from the M4 mouse melanoma model. DNA prepared from each subline and a spleen from a healthy mouse were subjected to long-read sequencing. Importantly, long-read sequencing allows direct detection of methylation states, small variants, and structural variants in the same run. The results thus provide excellent means to study genetic and epigenetic factors in clonal evolution. Each of these sublines was also implanted in distinct mice for survival and tumor growth analysis and further functional evaluation.

We developed Severus, a structural variation (SV) caller for long reads, which works with single (germline), paired (tumor-normal), and multiple samples (e.g., multi-site or time series). Severus takes advantage of improved phasing in long-read sequencing, attributes somatic variants to germline haplotype, and builds a haplotype-specific breakpoint graph that is used to cluster multi-break rearrangements and represent the derived chromosomal structure. We benchmarked Severus using multiplatform validated COLO829 truthset and CHM1/CHM13 haploid genomes, and Severus outperformed all other methods in terms of recall and precision.

The structural variation (SV) analysis using Severus with all the sublines showed enrichment of possibly clonal SVs in chr4, chr11, and mainly in chr13. Further investigation revealed SVs in chr13 were not distributed across the chromosome but clustered in certain regions. Analysis of somatic SNVs in chr13 corroborates the localized hypermutation profile, which indicates a possible kataegis. Interestingly, a loss of the chr13 copy affected by kataegis in one of the sublines coincides with a better survival rate, as compared to other sublines, in an allograft melanoma mouse model, which further supports the association between the kataegis and tumor progression. We also identified other clonal and subclonal events, including the homozygous deletion of Cdkn2a in most of the sublines, associated with their aggressiveness in vivo.

Our analysis allowed us to identify clonal and subclonal genetic and epigenetic factors involved in tumor progression and evolution in a melanoma model, which can potentially translate to human disease.

#7408 Robust profiling of cancer-related gene fusions: Analytical validation of PANCARNA for multiple cancer types.

H. Tang, H. Bao, R. Liu, S. Wu, S. Liu, X. Wu, Y. Shao;
Geneseeq Technology Inc., Toronto, ON, Canada

The impact of examining gene fusion presence in cancer patients is often overlooked, and as such, no well-established workflow currently exists for robust profiling of tumor samples in this area. We established a targeted RNA sequencing panel (PANCARNA) for investigating gene fusions across multiple cancer types and performed analytical validation to confirm performance. Furthermore, we report on the applicability of using targeted RNA sequencing for the purposes of gene expression profiling. This panel covers 117 genes associated with solid tumors. Thirty-nine FFPE samples with gene fusion status validated using an orthogonal method were used to evaluate analytical performance. Of the 39 standard samples, 33 samples were positive for gene translocation events and 6 were negative controls. Samples were collected from across 10 cancer types. To examine the robustness of the panel, 12 samples with known fusions were selected to undergo testing. Each sample was tested in triplicate across two experimental batches. Seraseq Fusion RNA Mix V4 (SeraCare, Cat. 0710-0497) standard samples were used to test the limit of detection for PANCARNA. Additionally, we explored a cohort of 22 samples with over expressed genes and 4 samples without overexpressed genes to test the expression profiling capabilities of PANCARNA and compared the results to immunohistochemistry stains. Of the 39 samples tested using the orthogonal method and targeted RNA-Seq, 38 were found to have concordant fusion calls in both methods (Positive percent agreement = 97.0%, 32/33; Negative percent agreement = 100%, 6/6; Overall percent agreement = 97.4%, 38/39). In reproducibility studies, the assay produced consistent intrarun and interrun results in all samples (Repeatability = 100%, 12/12; Reproducibility = 100%, 12/12). The limit of detection for multiple fusions of interest, such as *EML4-ALK, CD74-ROS1, TPM3-NTRK1*, and *SLC34A2-BRAF*, is found to be 0.5-1 copies per ng of RNA. *ETV6-NTRK1* can be reliably detected at 2-4 copies per ng of RNA. MET ex14 skipping events can also be detected in a few as 1-2 copies per ng of RNA. To validate the capability of PANCARNA to quantify gene expression, we tested 26 samples with known gene expression levels for three genes of interest (*ERBB2, EGFR, MET*). *ERBB2, EGFR* and *MET* amplification detection through PANCARNA was found to have a high concordance to IHC results (Sensitivity = 96.2%, 100%, 94.7%, respectively). In conclusion, PANCARNA demonstrated highly accurate and sensitive detection of clinically relevant gene fusions. This assay produces reliable results when detecting fusions and offers high concordance to results obtained through IHC/FISH, indicating that targeted RNA seq analysis can assist with profiling gene fusion events in a clinical setting.

#7409 SpatialCells: Automated profiling of tumor microenvironments with spatially resolved multiplexed single-cell data.

Guihong Wan[1], Zoltan Maliga[2], Boshen Yan[3], Tuulia Vallius[2], Yingxiao Shi[4], Sara Khattab[3], Crystal Chang[3], Ajit J. Nirmal[5], Kun-Hsing Yu[6], David Liu[4], Christine G. Lian[7], Mia S. DeSimone[7], Peter K. Sorger[2], Yevgeniy R. Semenov[3]

[1]Harvard Medical School/Massachusetts General Hospital, Boston, MA,[2]Laboratory of Systems Pharmacology, Program in Therapeutic Science, Harvard Medical School, Boston, MA,[3]Department of Dermatology, Harvard Medical School/Massachusetts General Hospital, Boston, MA,[4]Department of Medicine, Dana-Farber Cancer Institute, Boston, MA,[5]Department of Dermatology, Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[6]Department of Biomedical Informatics, Harvard Medical School, Boston, MA,[7]Department of Pathology, Harvard Medical School/Brigham and Women's Hospital, Boston, MA

Cancer is a complex cellular ecosystem where malignant cells coexist and interact with immune, stromal, and other cells within the tumor microenvironment. Recent technological advancements in spatially resolved multiplexed imaging at single-cell resolution have led to the generation of large-scale and high-dimensional datasets from biological specimens. This underscores the necessity for automated methodologies that can effectively characterize the molecular, cellular, and spatial properties of tumor microenvironments for various malignancies.

This study introduces SpatialCells, an open-source software package designed for region-based exploratory analysis and comprehensive characterization of tumor microenvironments using spatially resolved multiplexed single-cell data. We have provided detailed documents and tutorials at https://github.com/SemenovLab/SpatialCells.

SpatialCells is featured by its capability to computationally define regions of interest based on any group of cells and subsequently conduct region-based analyses. SpatialCells incorporates several modules to facilitate its functionality, such as the spatial module and the measurements module. Our workflow starts with developing the spatial module, including functions to establish regional boundaries and check the region in which a cell is located. In particular, SpatialCells supports macro-region and micro-region analyses. In the macro-region analysis, users can employ SpatialCells to divide the whole tissue into several subregions, such as tumor, tumor border, stroma border, and stroma. In the micro-region analysis, SpatialCells identifies small regions within an area, such as within the tumor area, enabling a finer-grained understanding of the cellular landscape. The measurements module contains functions to extract the properties of tumor cells, immune cells, and tumor-immune cell interactions, such as multivariate tumor proliferation index, immune infiltration score, and tumor-immune cell distances. These properties can be assessed for the whole tissue or local regions. Importantly, SpatialCells can efficiently process datasets containing millions of cells.

In summary, SpatialCells is a novel software solution for spatially analyzing the tumor microenvironment and automatically extracting quantitative features of cells using multiplexed imaging data in a streamlined fashion with the capacity to process samples containing millions of cells. Thus, SpatialCells facilitates subsequent association analyses and machine learning predictions at scale, making it an essential tool in advancing our understanding of tumor growth, invasion, and metastasis.

#7410 PyVIPER: A fast and scalable toolkit for the identification of dysregulated proteins in tumor-derived single-cell RNA-seq data.

L. Zanella[1], A. L. E. Wang[1], Z. J. Lin[1], L. J. Vlahos[1], M. Anglada Girotto[2], A. Zafar[1], A. Califano[1], A. Vasciaveo[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Centre for Genomic Regulation, Barcelona, Spain

Single-cell RNA sequencing (scRNA-seq) enabled the characterization of tumor microenvironment heterogeneity with unprecedented resolution. However, its low signal-to-noise ratio due to data sparsity hinders biomarkers quantitative measurements. To perform a more robust assessments of protein markers, we have previously introduced the use of the VIPER algorithm that estimates regulatory proteins activity using the expression of their downstream targets by leveraging lineage specific regulatory networks. We have shown that this approach compares favorably with both gene expression and protein abundance measurements to identify novel cell states corresponding to tumor subpopulations that are undetectable at the gene expression level, by inferring the mechanistic contribution of regulatory and signaling proteins to cellular phenotypes. VIPER-inferred cell states have been linked to critical functional roles, including immune-evasion and progression, disease heterogeneity and drug sensitivity in cancer. However, the ever-growing size of scRNA-seq datasets demands for scalable tools that simultaneously analyze tens or hundreds of thousands of cells in tumor contexts, such as tumor atlases and large clinical cohorts. We present PyVIPER, a fast, memory-efficient, and highly scalable Python framework that allows protein activity inference of large scRNA-seq datasets. PyVIPER is fully integrated with both AnnData and Scanpy frameworks for single-cell analysis and enables a seamless interface with cutting-edge machine learning libraries (e.g., sckit-learn and TensorFlow). PyVIPER provides multiple algorithms for enrichment analysis, novel modules for postprocessing and pathway analysis, and a set of procedures tailored for precision oncology studies in single cells, including OncoMatch, a validated platform to assess the fidelity of models (*in vitro* or animal) with human tumors for drug sensitivity elucidation. We benchmarked PyVIPER against several scRNA-seq cancer datasets obtaining runtimes reduction of several orders of magnitude (from hours to minutes) when compared to previous VIPER implementations. Taken together, PyVIPER scalability and its embedded toolkit for cancer data analysis address the need to efficiently extend protein activity analyses to large single-cell datasets, with the goal of providing cancer researchers with an effective platform to identify aberrant molecular mechanisms in cancer cells.

#7411 CAMStool: Cancer-associated somatic mutation selection tool for cancer risk prediction in whole-genome data.

J.-Y. Kim, S.-J. Park, S.-H. Park, S.-K. Kim;
Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of

Predicting cancer risk plays a useful role in presenting guidelines to prevent and manage cancers of individuals. Genomic variants have recently been widely used as a genetic factor, and the utilization of the genetic factor consisting of somatic mutations has shown remarkable predictive performance in many cancer prediction studies. Typically, the accuracy of such prediction studies is significantly affected by the composition of somatic mutations used as the genetic factor; however, in practice, choosing the optimal set of mutations with high prediction accuracy is a challenging task in cancer prediction research. From this perspective, we present a new analysis tool for selecting an optimal set of somatic mutations associated with cancers of interest, named CAMStool. The CAMStool is based on the statistical values, which are the effect size and its p-value of each somatic mutation for the cancers of interest. It heuristically searches for the only somatic mutations that directly increase the prediction accuracy of cancer, through statistical and machine-learning models. Then, our tool presents the finally selected somatic mutations as the final optimal mutation set, and additionally presents an optimal cancer risk prediction model through various machine/deep learning modeling using the optimal set as a genetic factor. For the evaluation, the CAMStool was applied to our real whole-genome dataset which are sequenced from normal-tumor tissues of 459 individuals with thyroid cancer. The CAMStool selected 36 and 55 optimal somatic mutations associated with the benign thyroid and non-invasive follicular thyroid cancer, and presented risk prediction models with sensitivity of 88.04% and 90.32%, respectively. Although the CAMStools has some limitations, it is expected to contribute to various cancer prediction studies that require selecting optimal mutation sets in the future. The CAMStools is written in R and will be released soon on our github (https://github.com/JaeYoonKim72).

#7412 METI: Deep profiling of tumor ecosystems by integrating cell morphology and spatial transcriptomics.

J. Jiang[1], Y. Liu[1], J. Qin[2], J. Wu[1], J. Chen[1], M. Pizzi[1], R. Segura[1], K. Yamashita[1], Z. Xu[2], G. Pei[1], K. Cho[1], Y. Chu[1], A. Sinjab[1], F. Peng[1], G. Han[1], R. Wang[1], X. Yan[1], E. Dai[1], M. Li[3], A. Futreal[1], A. Maitra[1], A. Lazar[1], X. Cheng[2], H. Kadara[1], J. Ajani[1], A. Jazaeri[1], J. Hu[4], L. Wang[1], J. Gao[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Institute of Basic Medicine and Cancer, Chinese Academy of Sciences, Hangzhou, China, [3]University of Pennsylvania, Philadelphia, PA, [4]Emory University, Atlanta, GA

The recent progression in spatial transcriptomics (ST) offers invaluable perspectives on the structure and dynamics of cells within the tumor microenvironment (TME). Though several analytical tools exist for tasks like spatial clustering and spatially variable gene identification, most of them are general methods lacking consideration of histological features in spatial data analysis. This oversight compromises their performance and interpretability when studying the TME. Here, we introduce a computational framework, the Morphology-Enhanced Spatial Transcriptome Analysis Integrator (METI). METI provides a comprehensive framework for spatially mapping both cancer cells and various TME cells, robust stratification of cell type and transcriptional states, and cell co-localization analysis. By integrating spatial transcriptomics with cell morphology and curated gene signatures, METI deepens our insight into the molecular landscape and cellular interactions within tissues, paving the way for intricate studies of the TME and its consequential impacts. The performance of METI has been assessed using ST data derived from a range of tumor tissues, encompassing gastric, lung, and bladder cancers, and premalignant tissues. Throughout these varied tissues and conditions, METI consistently exhibited robust performance.

#7413 Establishing a database for the discovery and validation of survival-associated genes in colon cancer.

B. Gyorffy;
Semmelweis University, Budapest, Hungary

Introduction: Unveiling the prognostic significance of genes as potential biomarkers in colon cancer (CRC) is crucial for the discovery of new therapeutic targets and the effective stratification of patients into clinically relevant groups. The primary objective of this study was to establish a transcriptomic cohort comprising clinical data from colon cancer specimens and to leverage this dataset to pinpoint genes with robust prognostic implications.
Methods: Our approach involved a comprehensive search of the Gene Expression Omnibus (GEO) to identify datasets containing both clinical information and raw gene expression measurements for individual colon cancer specimens. Subsequently, we curated and integrated these datasets into a unified database, and linked into our Kaplan-Meier plotter. This integration enabled the identification of genes whose expression changes were associated with altered survival outcomes. The identification of the most influential genes in relation to overall survival in stage 2 and stage 3/4 tumors was accomplished through both uni- and multivariate Cox regression analyses. To mitigate the impact of multiple hypothesis testing, a false discovery rate was computed for each marker.
Results: The database encompasses a total of 2,137 tumor samples derived from 17 distinct independent cohorts. Within this dataset, 1,343 samples are equipped with recorded relapse-free survival data, while 1,061 samples provide information on overall survival events along with the corresponding duration. In addition to survival-related metrics, the database encompasses a spectrum of supplementary clinical parameters such as gender, T (tumor size), N (lymph node involvement), M (metastasis), grade, stage, location, and microsatellite instability. The most significant genes associated with relapse-fee survival with FDR<1% in stage 2 CRC include CSF1R (HR=2.86), FLNA (HR=2.88), TPBG (HR=2.65), B2M (HR=2.62) and LOXL2 (HR=2.63). When ordered by the Cox regression p-value in stage 3 and 4 tumors, the five strongest genes were BHLHE40 (HR=2.6), COL4A2 (HR=2.02), TSC22D3 (HR=1.95), NPR3 (HR=1.91), and A2M (HR=1.86).
Conclusions: In this study, we successfully developed a robust integrated database dedicated to colon cancer. By leveraging this resource, we pinpointed the most impactful prognostic biomarkers and potential therapy targets specifically within stage 2 and stage 3/4 patients. Beyond its current applications, this database holds promise for future endeavors, serving as a valuable tool for identifying and prioritizing additional promising biomarkers and therapeutic targets in other sub-cohorts of colon cancer. The entire database can be utilized at www.kmplot.com.

#7414 Claire: a search engine leveraging deep databases for reliable detection of peptides, with a special focus on proteogenomic applications.

Miroslav Hruska, Petr Dzubak, Marian Hajduch

Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital in Olomouc, Olomouc, Czech Republic

As the field of cancer diagnostics and treatment evolves, the significance of peptides characterized by post-translational modifications and amino acid substitutions is becoming increasingly prominent. These molecular alterations frequently offer critical insights into tumor biology, aiding the development of targeted therapies and methods for personalized medicine. However, despite ongoing advances in shotgun proteomics, the field still faces multiple challenges for the reliable detection of rare peptide forms, for instance, amino acid substitutions when the corresponding DNA or RNA sequencing is unavailable. As a response to these challenges, our group has developed Claire—a probabilistic search engine employing large peptide databases for detection. These databases, often on the terabyte scale, further incorporate the estimates of peptides' prior probabilities to improve detection accuracy and utilize several optimizations to allow fast interpretation of tandem mass spectra. Claire outperformed state-of-the-art software, such as MSFragger and TagGraph when evaluated on the protein-level detection of single nucleotide variants in the public NCI60 proteome dataset. Further, Claire's analysis of a range of NCI60 datasets revealed high protein-level mutational burdens in genomically unstable cancer cell lines and detected mislabeling and contamination across several omics datasets. In a clinical domain, Claire discerned the hypermutation status of colorectal cancer patients' tumors, identifying candidates suitable for immunotherapy. Protein-level variation in peripheral blood mononuclear cells also recognized individuals, monozygotic twins aside, revealing the pseudonymous nature of germline proteome datasets, and raising the need for their protection. From a computational perspective, Claire can be run as a standalone software in the Linux operating system, or its capabilities accessed remotely using an interface on our cloud computing infrastructure. Claire has thus shown remarkable potential in enhancing peptide detection, offers substantial advancements for both clinical and research applications, and allows direct incorporation of its capabilities into various computational workflows.

#7415 Assigning mutational signatures to individual samples and individual somatic mutations with SigProfilerAssignment.

R. Vangara[1], M. Diaz-Gay[1], M. D. Barnes[1], X. Wang[1], S. Islam[1], I. Vermes[2], S. Duke[2], N. Narasimman[1], T. Yang[1], Z. Jiang[1], S. Moody[3], S. Senkin[4], P. Brennan[4], M. R. Stratton[3], L. B. Alexandrov[1];

[1]UC San Diego, San Diego, CA, [2]COSMIC, Wellcome Sanger Institute, Hinxton, United Kingdom, [3]Wellcome Sanger Institute, Hinxton, United Kingdom, [4]International Agency for Research on Cancer, Lyon, France

Analysis of mutational signatures is a powerful approach for understanding the mutagenic processes that have shaped the evolution of a cancer genome. To evaluate the mutational signatures operative in a cancer genome, one first needs to quantify their activities by estimating the number of mutations imprinted by each signature, a process known as *refitting* of mutational signatures. Although multiple tools for refitting known signatures were developed in the past decade, most provide support almost exclusively for single base substitution signatures and lack an online interface. Further, these tools have never been compared, and no existing tool supports probabilistically assigning signatures to a single somatic mutation. Here, we present SigProfilerAssignment, a desktop and online computational framework for assigning all types of mutational signatures to individual samples. SigProfilerAssignment is the first tool that allows both analysis of copy-number signatures and probabilistic assignment of signatures to individual somatic mutations. As its computational engine, the tool uses a custom implementation of the forward stagewise algorithm for sparse regression and nonnegative least squares for numerical optimization. The analysis of 2,700 synthetic cancer genomes with and without noise demonstrates that SigProfilerAssignment outperforms four commonly used approaches for assigning mutational signatures, with consistent top performance across cancer types and most signatures. SigProfilerAssignment stands out as the most precise and sensitive tool while maintaining high computational performance and bringing novel capabilities. SigProfilerAssignment is distributed as an open-source Python/R package available at https://github.com/AlexandrovLab/SigProfilerAssignment, with an online interface available as part of the COSMIC Mutational Signatures website at https://cancer.sanger.ac.uk/signatures/assignment/.

#7416 GeneSetR: A web server for gene set analysis based on genome-wide Perturb-Seq data.

O. F. Kuzu, F. Saatcioglu;
University of Oslo, Oslo, Norway

Identification of genotype-phenotype relationships is of utmost importance and a core effort in biology. Recent developments in efficient and precise gene targeting approaches coupled to omics methods have significantly improved deciphering of molecular interactions and relationships. However, many single gene perturbations can affect the expression of hundreds of other genes and analysis of the resulting omics-derived gene lists currently remains a significant challenge. Here we present Perturb-Seq based Gene Set Analyzer (GeneSetR), a user-friendly web-server that can analyze user-defined gene lists based on the data from a recently published genome-wide Perturb-Seq study, which targeted 9,866 genes with 11,258 sgRNAs in the K562 cell line. Through this tool, users can cluster gene lists following dimensionality reduction by various algorithms, undertake network analysis from RNA sequencing data, identify key nodes among the submitted genes, perform gene signature analyses, and generate heatmaps based on perturbation or gene expression data. GeneSetR enables researchers to readily identify gene clusters associated with specific phenotypes or biological processes, providing insights into the potential functional roles of these clusters and the role of single genes in them. With robust analysis capabilities, GeneSetR is a powerful resource to facilitate the exploration of genotype-phenotype relationships.

#7417 SpatialCS: A tool to effectively integrate histological annotations and spatial transcriptomics analysis.

Y. Chu[1], K. S. Cho[1], I. Khanduri[2], T. Zhou[1], J. Jiang[1], Y. Liu[1], X. Yan[1], G. Pei[1], Y. Dai[1], Y. Liu[1], R. Wang[1], A. Jadhav[1], S. Hernandez[1], H. Kadara[1], L. Solis Soto[1], S. Kopetz[1], D. M. Maru[1], L. Wang[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Spatial transcriptomics is revolutionizing our understanding of tumor ecosystems, providing insights into the spatial dimensions of cell locations, their organization, and interactions within tissues. A key challenge in this field is integrating histological annotations with spatial domains identified through unsupervised clustering methods like SpaGCN. This integration is crucial for accurate spatial domain identification and further analyses. However, clustering results often vary based on parameters such as resolution, leading to inconsistencies with histological annotations. This variation necessitates optimized parameter selection to achieve the best clustering outcomes.

We here introduce SpatialCS, a novel tool specifically designed to both visualize and quantify the alignment between histological annotations and the clustering results obtained from spatial transcriptomics data. SpatialCS employs a new index based on the asymmetric Wallace indices. This index penalizes spot pairs that are clustered together but do not share the same histology annotation type, with penalties scaled according to their transcriptional similarity. Additionally, we propose a purity index, derived by calculating the average transcriptional entropy of all clusters. This index serves as a measure of the homogeneity within each cluster. Furthermore, SpatialCS includes a unique visualization function. This function projects histological annotations onto the clustering results as outlines, making it easier to assess the consistency between histology annotations and clustering outcomes.

We have applied SpatialCS to Visium spatial transcriptomics data generated on four colorectal cancer liver metastases, each accompanied by comprehensive spot-level histological annotations in both tumor and normal compartments. The histologic annotations include but not limited to are tumor cells, tumor cell cluster subtypes, tumor stroma, tumor in the vessels, portal tract, individual bile ducts, portal vein and liver cell plates and non-neoplastic stroma. The application of SpatialCS has proven its effectiveness in identifying the most consistent clustering results, which were further confirmed by experienced pathologists. Notably, the output of SpatialCS offers helpful guidance for improving histological annotations. Together, SpatialCS not only provides a quantitative approach to evaluate the consistency between histological annotations and unsupervised clustering analysis but also showcases its potential to significantly enhance histological annotations.

#7418 LongFuse: Detecting gene fusion transcripts from high throughput long-read single cell RNA sequencing data.

C.-K. Shiau[1], Y. He[1], H.-Y. Lin[1], L. Lu[1], X.-D. Lu[2], J. Yu[2], R. Gao[1];

[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL, [2]Emory Univ. School of Medicine, Atlanta, GA

Gene fusion resulted from genomic translocation plays important oncogenic roles including but not limited to gene activation and changing protein coding sequences. Historically, fusion gene analysis has been limited to bulk levels resulting in mixed oncogene activation models. Single cell Nanopore RNA sequencing (scNanoRNAseq) has the unique strength in detecting full-length chimeric transcripts in thousands of single cells in parallel. However, robust computational tools for detecting fusion genes in single cells from scNanoRNAseq data are missing. Here, we developed LongFuse, a fast and accurate tool, to detect fusion genes and their splicing isoforms in single cells from scNanoRNAseq data. LongFuse implements an XOR logic gate algorithm to speed up fusion candidate searching and stringent criteria to eliminate false discoveries due to trans-splicing events and randomly ligated chimeras. We applied LongFUSE onto scNanoRNAseq data of both human prostate cancer cell line, VCaP, and tumor tissues with known *TMPRSS2-ERG* fusion. Our results showed that both cancer cell line and prostate tumors harbored a mixture of fusion positive and fusion negative tumor cells. Gene expression analysis revealed transcriptional differences between fusion positive and negative cells including genes involved in cancer cell proliferation and invasion programs such as *ELL2, ZBTB16, IGF1R, ANK3, MYPOP* and *PLPP1* genes. LongFUSE also calculates the splicing isoforms of fusion gene transcripts, allowing prediction of protein sequences of fusion gene transcripts. Taken together, our data demonstrated that LongFUSE is a robust computational tool for detecting gene fusions and their splicing isoforms at single cell level from scNanoRNAseq data.

#7419 Seq2Karyotype (S2K): A method for deconvoluting heterogeneity of copy number alterations using single-sample whole-genome sequencing data.

L. Pu[1], K. Szlachta[1], V. Valentine[1], X. Chen[1], J. Wang[1], D. Kennetz[2], D. Putnam[1], S. Natarajan[1], L. Dong[1], T. Look[3], M. Wlodarski[1], L. Wang[1], S. Burden[1], J. Easton[1], X. Chen[1], J. Zhang[1];

[1]St. Jude Children's Research Hospital, Memphis, TN, [2]Roche, Santa Clara, CA, [3]Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Broad copy number alterations (CNAs) at chromosomal band resolution have been used as cancer diagnostic and prognostic biomarkers for decades. These events have been characterized by cytogenetic imaging, an approach which is powerful for assessing heterogeneity but limited for locus fine mapping. While CNA detection by next-generation sequencing has become a standard analysis, existing methods rarely model CNA heterogeneity in bulk tumor samples and often require a paired normal sample for control. To overcome these limitations, we developed Seq2Karyotype (S2K, https://github.com/chenlab-sj/Seq2Karyotype), a new algorithm for in-silico karyotyping using single-sample whole-genome sequencing (WGS) data. S2K performs joint modeling of read-depth and allelic imbalance (AI) of high-quality heterozygous SNPs to identify reference diploid regions, followed by modeling and segmenting the deviation from the reference. Empirical coverage and AI of segmented regions are fitted to models of single and admixed CNAs to estimate clonality. The final karyotyping considers both the model fitness and minimization of evolution steps.To evaluate S2K's performance, we analyzed two cell lines commonly used for benchmark test: COLO829 (melanoma) and HCT1395 (breast cancer); both had single-cell (sc) WGS for validation. For COLO829, S2K replicated the four populations detected by scWGS but derived a different clonality estimate. The predominant clone, defined by loss of 1p, 10p, and chr18, was estimated to have 67% cellular fraction (CF) by bulk sample analysis of S2K in contrast to the 10% CF by scWGS analysis. In HCT1395, S2K identified three new CNAs present in >50% of the cells of the matching germline sample which were subsequently validated by FISH, karyotyping and SKY mapping.To demonstrate S2K's utility, we analyzed three diverse data sets: 17 neuroblastoma cell lines, 24 pediatric AML samples with karyotyping data, and two blood samples from children with myelodysplastic syndromes (MDS) known to harbor mosaic uniparental disomy (UPD). CNA-based intra-tumor heterogeneity was detected in 88% (15/17) of the neuroblastoma cell lines, comprised of 2-4 distinct populations with diverse ranges of CF (~10%-90%) and varying CNA patterns (e.g. admixture of tetraploid and diploid cells), which were validated by cytogenetics or scWGS. In the patient AML samples, S2K detected >95% of the previously reported cytogenetic events and 30% of additional copy-neutral loss-of-heterozygosity events. The mosaic UPD events in MDS patients were detected with projected clonality of 60% and 25%, respectively. These results not only demonstrate the accuracy of in-silico karyotyping performed by S2K but also reveal the dynamic intra-tumor heterogeneity in cancer cell lines, which may impact the design and interpretation of future experiments using these cell lines.

#7420 Optimizing proteomic data access and analysis in the cloud: Leveraging Terra's integration with the Proteomic Data Commons.

Emily LaPlante[1], Bingxing Huo[1], DR Mani[1], Ratna R. Thangudu[2]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]ICF, Rockville, MD

The Proteomic Data Commons (PDC) hosts cancer proteomics data with the goal of making this data available to the public to support development of cancer diagnostics, treatment, and progression tracking. As a part of the Cancer Research Data Commons (CRDC), the Terra platform provides a cloud workbench for the PDC data. FireCloud is a Broad Institute project funded by NCI to empower cancer researchers to access data, run analysis tools and collaborate securely in the cloud. It is powered by Terra, a secure, scalable cloud-native platform developed by the Broad Institute, Microsoft, and Verily, an Alphabet company. It provides batch workflow execution, interactive analysis including data visualization, and ~2,900 publicly available tools with the ability to import more tools from Dockstore.

The integration of PDC and Terra enables researchers to leverage the data navigation and file-level search capabilities on the PDC web browser (pdc.cancer.gov) and export selected data manifests to a Terra workspace. This integrated hand-off specifically allows metadata and cloud links to PDC data in Portable Format for Bioinformatics (PFB) to be transferred to Terra and used in analysis with cloud resources. A featured workspace for Terra-PDC integration includes tools for (i) downloading data files and relevant additional metadata; (ii) organizing the data and metadata for running the FragPipe workflow, a comprehensive collection of tools for reading and processing raw Mass Spec (MS) data; and (iii) implementing a pre-configured FragPipe workflow to process isobarically labeled MS data from Tandem Mass Tag (TMT) or Isobaric tags for relative and absolute quantitation (iTRAQ) experiments using information automatically imported from PDC via the PFB import. The pipelines can also be customized as needed to process any type of raw MS data the PDC supports. In addition, Terra connects to the NCI Genomic Data Commons (GDC) and hosts The Cancer Genome Atlas (TCGA) and Therapeutically Applicable Research to Generate Effective Treatments (TARGET) datasets allowing users to pull in other data types for co-analysis. As a whole, using the CRDC cloud resources, in conjunction with Terra, allows analysis of data on a massive scale, enabling multi-omic integration spanning the genomic and proteomic commons data, with easy sharing of data and tools.

#7422 Enabling biomarkers of chromosomal instability for tumor only targeted gene panel sequencing.

D. Gomez-Sanchez[1], J. Thompson[2], B. Hernando[2], D. Garcia-Lopez[3], H. de Galard[3], A. Roy[3], A. Cullen[3], L. Madrid[3], J. Teles[3], A. Piskorz[3], J. Yip[3], A. Cadiz[3], M. Escobar-Rey[2], R. Moreno-Vellisca[1], N. Carrizo[1], E. Alvarez[1], M. Quintela-Fandino[4], M. Barbacid[5], J. Ramos-Paradas[6], J. Coya[1], I. Ferrer[1], J. Zugazagoitia[7], L. Paz-Ares[7], G. Macintyre[8];

[1]12 de Octubre Hospital Research Institute & Spanish National Cancer Research Centre (CNIO), H12O-CNIO Lung Cancer Clinical Research Unit, Madrid, Spain, Madrid, Spain, [2]Spanish National Cancer Research Centre CNIO, Computational Oncology, Madrid, Spain, Madrid, Spain, [3]Tailor Bio, Cambridge, United Kingdom, [4]Breast Cancer Clinical Research Unit, Spanish National Cancer Research Centre (CNIO), Madrid Spain, Madrid, Spain, [5]Experimental Oncology Group, Molecular Oncology Program, Spanish National Cancer Center (CNIO), Madrid, Spain, Madrid, Spain, [6]Department of Pathology and Yale Cancer Center, Yale School of Medicine, New Haven, Connecticut, USA, Madrid, Spain, [7]12 de Octubre Hospital, Medical Oncology, Madrid, Spain, Madrid, Spain, [8]Spanish National Cancer Research Centre CNIO, Computational Oncology, Madrid, Spain, Cambridge, United Kingdom

Capture-based targeted sequencing is routinely used for small variant detection in cancer clinical care. Alongside targeted DNA, off-target DNA is also sequenced. These off-target reads are distributed across the genome, allowing for a whole genome copy number profile to be derived without the need for a SNP backbone. Here we present CopyRight, a method that generates robust genome-wide copy number profiles, which can be used for downstream chromosomal instability (CIN) quantification, overcoming various sources of technical noise with a novel approach that only requires a single tumor sample. We analyzed a variety of capture-based NGS protocols using our novel computational method, including the TruSight Oncology 500 (TSO500) panel, and compared them to the current gold standard for genome-wide copy number profiling from FFPE tissues: shallow whole genome sequencing (sWGS). Comparable results were obtained from targeted sequencing depending on sample purity, preservation method, and read depth. Additionally, benchmarks of CopyRight against other computational algorithms show an improvement in performance without the need for a matched normal tissue, the usual drawback for other methods in the cancer field.

CIN signatures are a new set of emerging biomarkers that reflect the diversity of defective pathways that have operated in a tumor, which require robust genome-wide copy number profiles. These CIN signatures can be used to predict response to cytotoxic agents and targeted therapies and could ultimately help guide therapy selection in patients. As most clinical sequencing workflows rely on targeted sequencing, CopyRight can be included in current clinical assays, enabling CIN biomarker quantification with no extra technical or experimental requirements.

#7423 BATCH-FLEX: Feature-level equalization of x-batch in heterogeneous cancer data.

Joshua Davis, Alyssa Obermayer, Thac Duong, Rebecca Hesterberg, Xuefeng Wang, Mingxiang Teng, G. Daniel Grass, Timothy Shaw

Moffitt Cancer Center, Tampa, FL

Purpose: Develop a shiny application to help integrate cancer datasets and guide researchers in selecting an appropriate method of correction for their technical artifacts.

Description: Integrative analysis of heterogeneous expression data remains challenging due to variations in platform, RNA quality, sample processing, and other unknown technical effects. As the field performs omics profiling of samples from cancer patients and murine models, there is the need for harmonizing, identifying, and correcting these technical effects to ensure robust analysis on the treatment and conditional effects of the underlying genetics or biological events. However, selecting and implementing different approaches for removing unwanted batch effects can be a time-consuming and tedious process, especially for more biologically focused investigators. In this project, we present Shiny BATCH-FLEX, a Shiny app to rapidly visualize batch correction by established batch correction methods such as ComBat, Mean Centering, ComBatSeq, and Limma RemoveBatchEffect. With BATCH-FLEX, users can visualize the contribution of variance of a factor before and after correction using principal component analysis, relative log expression plots, heatmaps, and explanatory variables. Users can also save all plots and matrices as a single ZIP file for further downstream analysis.

Results: As a proof of concept, we assessed BATCH-FLEX using simulated data generated from a linear model framework introduced by Gagnon-Bartsch and Speed, which assumes that gene expression measurements can be distilled to a combination of the biological signal, systemic nose, and random noise. BATCH-FLEX was able to successfully identify and remove the introduced effect using each of the batch correction methods listed above. Next, we evaluated BATCH-FLEX using a comprehensive collection of bladder cancer data consisting of microarray data from 13 studies spanning 1452 samples. Following the cleaning of study-dependent noise, BATCH-FLEX was successful in revealing the heterogeneity among bladder cancer based on known sample type annotations.

Conclusion: We have developed BATCH-FLEX, a tool for oncologic researchers to rapidly assess, select, and implement commonly used batch correction methods. This tool is available at https://github.com/shawlab-moffitt/BATCH-FLEX. Our integrative web portal of a Bladder Cancer Resource for Translational Science (BEACON) will also be shared at the meeting.

#7424 iStarTLS: Advanced detection and phenotyping of tertiary lymphoid structures.

K. Cho[1], J. Jiang[1], D. Zhang[2], Y. Liu[1], J. Chen[1], R. L. Segura[1], X. Yan[1], G. Pei[1], L. M. S. Soto[1], Y. Chu[1], A. F. Sinjab[1], C. Yee[1], S. Kopetz[1], A. Maitra[1], A. Futreal[1], A. Lazar[1], A. A. Jazaeri[1], H. Kadara[1], J. Gao[1], M. Li[2], L. Wang[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Pennsylvania, Philadelphia, PA

Tertiary lymphoid structures (TLSs) are clusters of immune cells formed in non-lymphoid tissues. They are often found at sites of chronic inflammation, notably within the invasive margins and the core of various solid tumors. TLSs are pivotal in mediating anti-tumor immunity. However, our understanding of TLSs in large/complex tissue contexts remains incomplete due to the lack of computational tools to effectively detect and phenotype TLSs. Recent advances in spatially resolved transcriptomics (SRT) present a broader spectrum of analytical possibilities for investigating the spatial phenotypic heterogeneity of TLSs and their interaction with stromal and cancer cells. Here, we present iStarTLS (Inferring Super-resolution Tissue ARchitecture for TLSs), a computational toolkit designed to process SRT data for TLS detection and phenotyping and showcase its performance on breast, bladder, and lung cancer samples. By effectively integrating spatial gene expression data with state-of-the-art machine learning techniques, we can substantially enhance our capabilities in TLS detection and comprehensive phenotyping. iStarTLS starts by enhancing the spatial resolution of spot-level gene expression data to near-single-cell resolution by leveraging high-resolution information provided by paired histology images. To detect TLSs and infer their cellular composition, we developed a TLS signature. Based on the high-resolution gene expression measurements and a curated reference panel of cell type-specific markers, we score cell type-specific gene signatures to obtain a cell type probability map across the whole tissue section. This map gives rise to a segmentation of key cell type components of TLSs, enabling the spatial mapping and colocalization of different cell types. Moreover, such an approach would allow us to infer the phenotypic states of cells within the TLSs, assess their cellular compositions, and discern their cellular organization in large, spatially heterogeneous tissues at a near-single-cell resolution. Notably, in conjunction with nuclei segmentation of high-resolution histology images, iStarTLS precisely maps high endothelial venules (HEVs), a key structure within TLSs often overlooked by previous studies. iStarTLS paves the way for uncovering novel mechanisms of immune-tumor interactions and designing personalized therapies targeting specific cellular components or states within TLSs.

#7425 UMI-nea: A fast and robust UMI analysis approach to accurately identify and quantify TCR repertoire from targeted RNA sequencing with wide range of input molecules.

J. Deng, J. Zhang, S. Tian, S. J. Rulli, H. Xu, J. DiCarlo, E. Lader;
QIAGEN Sciences Inc., Frederick, MD

The T-cell receptor (TCR) population in humans is comprised of highly diversified heterodimers, regulating the recognition of antigen-major histocompatibility complex. Tremendous TCR sequence diversity is produced by somatic recombination of several TCR gene loci each consisting of multiple gene segments. Next-generation sequencing has enabled comprehensive profiling of the TCR repertoire from different physiological and disease conditions ushering in much interest in using TCR-seq to assess T-cell diversity. However, during NGS library construction and sequencing, errors and enzymatic inefficiencies can compromise the accuracy of the final data, particularly around calling of the VD and VDJ recombined regions and subsequent clonotype assignment. To increase the accuracy of NGS sequencing, Unique Molecular Identifiers (UMIs), consisting of short random nucleotide bases, can be used to mark original molecules in NGS library allowing for error and bias corrections. There are two well studied technical limitations to apply UMIs: 1.) UMI sequences tend to collide when input molecule number is large 2.) UMI sequences are not insulated from PCR and sequencing errors. To address these limitations, many computational approaches had been published. Among them, very few can be used to solve UMI colliding errors and over-simplified error models were implemented for UMI sequencing error handling. Here we report a novel strategy and UMI structure which uses more complex UMIs that is longer and of different length. This results in minimizing UMI collision while maximizing sequencing quality. Our UMI analysis pipeline, “UMI-nea” is able to handle not only substitution errors but also indel errors and UMIs with different lengths. We developed a novel computational framework to parallelly process sequence comparisons to mitigate the elevated computational burden. To account for the varied dispersion of PCR efficiency for different molecules and error bearing UMIs from libraries with different input and with different sequencing depth, we also developed a statistical framework leveraging negative binomial model and single-cell knee plot to set a dynamic threshold for original molecule estimate. We verified UMI-nea with several simulated data and demonstrated that UMI-nea can achieve >99% completeness and homogeneity to recover the original molecule count with various error rates and UMI lengths, outperforming existing tools and methods in comparison. We applied UMI-nea to profile TCR for 8 PBMC samples sequenced on different Illumina platforms with different sequencing depths. We observed >85% reproducibility of clonotype calls on all samples. To test the sensitivity and specificity of UMI-nea, we sequenced pure cell line samples and cell line spike-in samples with different ratios and discovered very high recall and precision rates.

#7426 The GenePattern ecosystem for cancer bioinformatics.

M. M. Reich, T. Tabor, J. Liefeld, E. Huang, F. Kim, J. P. Mesirov;
UC San Diego, La Jolla, CA

As the availability of genomic data and analysis tools from large-scale cancer initiatives continues to increase, with single-cell studies adding new dimensions to the potential scientific insights, the need has become more urgent for a software environment that supports the rapid pace of cancer data science. The GenePattern ecosystem, first introduced in 2004 and updated continually to support the changing needs of cancer genomics research, supports the analytical, computational, and reproducibility needs of the world-wide cancer analysis community.The GenePattern server, available at www.genepattern.org, provides hundreds of analysis methods for scientists at all levels of computational sophistication, with the only requirement for use being a web browser. The GenePattern server offers bulk and single-cell RNA-seq, copy number variation, flow cytometry, network analysis, general machine learning, gene set enrichment analysis, proteomics, and many other modalities. Analysis steps can be linked together into pipelines that can then be edited, shared, and made public. All parameters of an analysis, including the code version, are recorded so that an analytical result can be reproduced at any point in the future.The GenePattern Notebook system, notebook.genepattern.org, is an integration of the Jupyter Notebook environment with the GenePattern server. It combines the research narrative capabilities of Jupyter with the non-programming approach and breadth of analyses available in GenePattern. Scientists using GenePattern Notebook can create documents that include richly-formatted text and multimedia, executable code, and GenePattern analyses. A single GenePattern notebook can therefore comprise a sophisticated analytical workflow that runs on multiple remote servers.We have recently expanded GenePattern Notebook into a new notebook environment, Genomics to Notebook, g2nb.org, which adds the ability to include analyses on any public Galaxy server as well as using the Integrative Genomics Viewer (IGV) and Cytoscape within notebooks. Each analysis or visualization appears a cell within a notebook, preserving the accessibility and ease of use of the notebook metaphor while retaining the essential aspects of each tool’s user interface. When run, the entire analysis appears to execute seamlessly within the notebook. The online workspace also includes a library of featured genomic analysis notebooks, including templates for common analysis tasks as well as cancer-specific research scenarios and compute-intensive methods. Scientists can easily copy these notebooks, use them as is, or adapt them for their research purposes.

#7427 Automated, real-time acquisition and quantification of peak, plateau-phase *in vivo* bioluminescent data.

A. Van Praagh, B. Nelson, P. Ballieu, M. Smith, M. Rule;
Spectral Instruments Imaging, LLC, Tucson, AZ

It is widely recognized that plateau-phase bioluminescent (BL) kinetic curve data should be used when reporting on BLI results from substrate-injection BLI model systems. The basis for this understanding is that plateau-phase BL data is uniquely suited in several ways: (i) it will optimize the detection of target, luciferase-expressing cells (especially when they are low in copy number or deep within the animal model), (ii) it will optimize BLI data reproducibility (with there being no change in signal values across the plateau phase), and (iii) it will also provide BLI data values that correlate consistently with the number of viable target cells in a given BLI model. Given this critical value of plateau-phase BL data, there is, nevertheless, a simple practical issue to be addressed: The overall manual process of generating BL kinetic curves, and then identifying and quantifying plateau-phase data is not insignificant—it takes time!In this poster, we review the performance of "*Kinetics*," a new feature in the Aura software platform from Spectral Instruments Imaging, LLC. *Kinetics* is designed to collect, present, and analyze BL kinetic curve data for up to 10 mice, in a completely automated and real-time fashion. Data outputs include a live graph that simultaneously presents individual mouse, whole body ROI (Total photon/sec) values *vs.* time post-luciferase injection, and analogous mean BL values per mouse group. Here in, we present an evaluation of the performance of *Kinetics* under various testing conditions. We initially evaluated *Kinetics'* ability to acquire, present and analyze the BL kinetic curves of 5 phantoms. The photon output rates of these phantoms (Total photons/sec) were programmed to mimic the rise, plateau, and fall sequence typically seen BLI studies. In an analogous fashion, we then tested *Kinetics'* ability to acquire, present, and analyze the BL kinetic curves of 5 to 10 live mice from several oncology models. Furthermore, we used *Kinetics* in oncology efficacy studies to monitor for expected changes in BL kinetic curve shapes (*i.e.,* for changes in the onset times and durations of the rise, plateau and fall phases in BL kinetic curves) between different treatment groups (*e.g.,* between positive controls groups and one or more treatment groups). In the same studies, we also used *Kinetics* to check for changes in BL kinetic curve shapes that might occur for a given treatment group across several time points, after pathogen challenge. Results from this set of experiments consistently and clearly illustrated the capability of *Kinetics* to acquire, present and analyze individual and mean BL kinetic curve data for up to 10 mice at a time, in an automated and real-time fashion. We believe that *Kinetics* from Spectral Instruments Imaging, LLC, has the potential to revolutionize the ease with which plateau-phase, BL kinetic curve data can be collected, presented, and used in a wide range of preclinical BLI studies.

#7428 S2Map: An online interactive analytical platform for quantitative signal measurement of cell Secretion Signal Map.

Z. Yue[1], L. Zhou[1], F. Huang[2], P. Chen[1];

[1]Auburn University, Auburn, AL, [2]University of Alabama at Birmingham, Birmingham, AL

Cell communication is predominantly governed by secreted proteins, whose diverse secretion patterns often signify underlying physiological irregularities. Unraveling the intricacies of these secreted signals at the single-cell level is crucial for a comprehensive understanding of regulatory mechanisms involving various molecular agents. To elucidate the array of cell secretion signals, encompassing both anisotropic and isotropic biomolecular cues from individual immune cells or disparate cell types, we introduce the Secretion Signal Map (S2Map). S2Map is an innovative online interactive analytical platform that incorporates qualitative metrics, the signal inequality index (SII) and the signal coverage index (SCI), which are exquisitely sensitive in facilitating the measurement of dissymmetry and diffusion of cumulative signals and signal dynamics in temporal analysis. S2Map's innovation lies in its depiction of signals through real-time secretion hotspots, and cumulative secretion contour lines, complemented by the visualization of potential cell secretion signal velocities via stream plots generated by regression models. We evaluated the SII and SCI performance in distinguishing the simulated signal diffusion model. Presently, S2Map hosts a repository of 12 datasets that map single-cell and two-cell secretion dynamics. These datasets serve as a resource to explore secretion signal types. We anticipate that S2Map will be a powerful approach to delve into the complexities of physiological systems, providing insights into the regulation of protein production, such as cytokines at the remarkable resolution of single cells. The S2Map server is publicly accessible via https://au-s2map.streamlit.app/.

#7429 A web-based application to co-register elemental imaging with histopathology to enhance the study of metal bioaccumulation within tumors.

Y. Lu[1], R. Steiner[2], S. Han[1], M. Chan[2], T. Punshon[2], B. Jackson[2], L. Vahdat[1], J. Marotti[1], J. Levy[3];
[1]Dartmouth Health, Lebanon, NH, [2]Dartmouth College, Hanover, NH, [3]Cedars Sinai Medical Center, Los Angeles, CA

Essential trace elements are crucial in various biological processes, including tumor growth, migration, and metastasis. For instance, copper ions are involved in mitochondrial metabolism, cell proliferation, tumor migration, metastasis and proangiongenic pathways. Localizing where metal ion homeostasis is disrupted is vital for understanding these processes beyond what bulk analysis can reveal. Elemental imaging offers high-resolution, quantifiable multi-elemental distribution maps, providing a more detailed analysis compared to traditional bulk measurements. However, aligning findings with tissue structures identified in histopathological data can be challenging. To address this, we developed a web-based application for the co-registration and analysis of Whole Slide Images (WSI) and elemental imaging data at the cellular level. The application integrates WSI with elemental maps generated by technologies such as ultrafast laser ablation and inductively coupled plasma time-of-flight mass spectrometry (LA-ICP-TOF-MS), as well as a range of other elemental imaging techniques. Hosted by the Biomedical National Elemental Imaging Resource, the current application allows for a streamlined data integration, co-registration, and analysis, including: 1) uploading WSI, elemental maps, and pathologist annotations, 2) automated preprocessing to identify tissue regions, 3) co-registration to merge WSI and elemental maps, 4) custom import, real-time overlay/editing of pathologist annotations transferred from WSI, 5) plotting, statistical tools and 6) data export. This application enables users to compare elemental abundance within/between tissue structures annotated on H&E or immunohistochemical slides. Derived data can pinpoint elements and mixtures whose abundance differs significantly across various pathological conditions. As an initial test, we applied the software on breast HER2/ER/PR tumors, varying in molecular subtype/histology. Preliminary results, using Bayesian lognormal regression models, adjusting for tumor subtypes, indicated a subtype-dependent variation in copper abundance. The relative difference in copper levels between tumor and stromal regions was notably less in HER2 tumors ($p=0.026$) compared to HR tumors ($p<0.0001$). Conversely, iron showed a consistently higher abundance in stromal areas across both subtypes ($p<0.0001$). Future enhancements include improved co-registration capabilities, hotspot analysis, machine learning, mixture effects, and cloud-based architecture. This method uniquely enables integration of elemental data with spatial transcriptomics, mapping gene transcripts on tissue slides. With current ST assays aligned with H&E slides, this tool facilitates co-registration, offering insights into biological pathways affected by metal homeostasis disruptions.

#7430 Development and demonstration of a user-friendly application to explore single-cell atlas for prostate cancer (PCa) and analyze newly generated single-cell and spatial PCa datasets.

S. Sharma, E. Shenderov;
Johns Hopkins University School of Medicine, Baltimore, MD

Background: Single-cell atlases provide a high-resolution and tissue-specific depiction of cellular state at the transcriptomic level. Newer technologies like spatial transcriptomics, MALDI, and long-read sequencing introduce orthogonal modalities to single-cell data, making the analyses of large atlases even more complex. RShiny package in R is used to develop user-friendly GUI applications that could enable users to use analysis tools in an interactive manner, thus minimizing the requirement of prior programming experience.

Methods: Publicly available scRNA-seq datasets were collected for a wide range of prostate-related pathologies. The datasets were evaluated for their quality based on cell count and availability of the appropriate markers in each compartment. Finally, 11 datasets out of 16 datasets were selected for building integrated datasets. These datasets were filtered for cell types with <10% mitochondrial RNA, and cells with <500 genes were removed from the datasets. The datasets were then clustered to evaluate the effects of cell cycle, dissociation-induced stress, and the presence of doublets. The quality-controlled datasets were batch-corrected using the Harmony package and the harmonized principal components were used in Seurat for clustering the integrated data. Tools used for the analysis of single-cell datasets, beginning from raw counts, have been developed in R with a focus on modularity. These tools are packaged into a simple and intuitive RShiny application which follows the workflow shown in Figure 1a.

Results: The atlas obtained include samples from healthy prostate, benign prostate hyperplasia, primary prostate tumor, ICC/IDC, castration-resistant prostate cancer (CRPC), and Neuroendocrine prostate cancer (NEPC). The dataset includes 72 patients and ~320k cells with a median number of ~1600 genes expressed. We were able to distinctly identify Luminal, Hillock, Club, Basal, Neuroendocrine, Endothelial, Fibroblast, Smooth Muscle, Myeloid, T, B, NK, Mast, and Plasma cells in the integrated along with some unknown cellular subtypes in the epithelial compartment. The integrated data was manually annotated using cell type-specific markers. The single-cell atlas obtained was weaved with the workflow tools into an RShiny app.

Conclusions: Besides being a useful reference for PCa, the atlas would find extensive use in understanding the transcriptomic landscape of PCa biology. The integrated dataset will also prove crucial in developing bulk RNA sequencing deconvolution and single-cell imputation algorithms. Finally, we aim to provide a user-friendly interface to the prostate cancer community for using the single-cell PCa atlas and analysis tools with minimal computational requirements.

#7431 IAMSAM: Image-based analysis of molecular signatures using the Segment-anything model - Integrative analysis tool for tumor microenvironment.

Dongjoo Lee[1], Jeongbin Park[1], Seungho Cook[1], Seongjin Yoo[1], Daeseung Lee[1], Hongyoon Choi[2]

[1]Portrai, Inc., Seoul, Korea, Republic of,[2]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, Korea, Republic of

Introduction. Spatial transcriptomics (ST) is a powerful approach for investigating gene expression patterns in tissues while preserving their spatial context. However, working with ST data presents challenges due to its complexity, high dimensionality, and the absence of user-friendly tools. IAMSAM (Image-based Analysis of Molecular signatures using the Segment-Anything Model) leverages the Segment-anything model (SAM), a cutting-edge deep learning model developed by Meta, which is specifically designed for image segmentation. We demonstrated IAMSAM's capabilities with publicly available ST datasets, showcasing its user-friendly interface, featuring its user-friendly interface for exploring pathophysiology and potential biomarkers.

Methods. IAMSAM is a web-based tool designed for analyzing ST data, utilizing the SAM for image segmentation. It offers two modes: everything-mode and prompt-mode. In everything-mode, the model automatically generates segmentation masks for the entire histologic image. In prompt-mode, users can draw rectangle boxes to provide input prompts for SAM. IAMSAM's downstream analysis includes the identification of DEGs, enrichment analysis, and cell type prediction of selected regions of interest. DEGs are represented in volcano plots and box plots, aiding in the identification of genes associated with image features of tumors such as cancer-enriched areas or stromal patterns. Enrichment analysis assesses gene sets for over-representation, providing insights into pathways and biological processes relevant to cancer. Cell type prediction utilizes the CellTypist API, offering valuable information about the cellular composition and heterogeneity within the tumor microenvironment.

Results. IAMSAM has been applied to publicly available ST datasets to demonstrate its effectiveness in cancer research. It accurately identified cancer markers in breast cancer samples and aligned with spot clustering results in various cancer samples, all of which have significant implications for understanding cancer biology. Prompt-mode effectively identified stromal regions in tumor sections, and with magnification, it uncovered microvessels in prostate cancer samples, providing valuable insights for cancer pathophysiology research. IAMSAM was also applied to fluorescence imaging, demonstrating its versatility and potential in various cancer-related studies.

Conclusions. IAMSAM is a valuable web-based tool for cancer research using spatial transcriptomics data particularly integratively analyzing tumor microenvironments with a user-friendly interface. IAMSAM opens up new avenues for spatial transcriptomics research in the context of cancer, making it a promising resource for cancer researchers.

#7432 Improving FAIRness of computational approaches for cancer: The computational resources for cancer research portal.

E. Stahlberg[1], L. Borkon[1], R. Frost[1], S. Jones[1], A. Khalsa[1], L. Lewis[1], E. Greenspan[2], S. Menon[1];

[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]Center for Biomedical Informatics and Information Technology, National Cancer Institute, Rockville, MD

The Computational Resources for Cancer Research website is a public portal supported by NCI that democratizes access to available computational resources for the cancer research community.

In supporting an emerging FAIR (Findable, Accessible, Interoperable, Reusable) data science ecosystem inclusive of software, models and data, the goals of the portal are to serve cancer data scientists by increasing understanding, access, and adoption of computational resources for cancer research, and to foster new collaborative research projects. Initially populated with resources developed in NCI supported collaborations with the US Department of Energy, the portal is serving as a unified reference and resource for computational resources developed broadly by the cancer community. These collaborative projects include CANDLE (the Cancer Distributed Learning Environment), IMPROVE (Innovative Methods and data for PRedictive Oncology model Validation and Evaluation), ADMIRRAL (AI Driven Multi-scale Investigation of Ras-Raf Activation Lifecycle), MOSSAIC (Model Outcomes using Surveillance Data and Scalable AI for Cancer) and ATOM (Accelerating Therapeutics for Opportunities in Medicine).

The resources include software, models, and datasets as well as descriptive use cases and references to tutorials associated with many of the described resources. The portal also integrates content from the Predictive Oncology Model and Data Clearinghouse (modac.cancer.gov) which can be accessed through REST APIs.

Ongoing development of the portal is driven by community insights and contributions including input from an interdisciplinary advisory committee, working groups, early users, and preliminary feedback received at AACR 2023. The portal will also support community contributions of computational resources. In addition, the portal highlights computational approaches in emerging and challenging areas, such as digital twins for cancer.

The portal will enable the cancer research community to learn about new computational research methods through use cases and educational material, access cancer related software, datasets, and AI models, engage with peers and cross-disciplinary researchers at different career levels through an interactive forum, explore emerging areas, such as computational imaging, community-based standards for data management, predictive radiation oncology, and digital twin technologies, learn about in industry and community events, conferences, and workshops, and create new collaborative research projects. The presentation will deliver insights into key resources offered through the Computational Resources for Cancer Research Portal, how the portal will help the cancer research community identify and adopt computational resources of interest, and how researchers can join and participate in this growing community.

#7433 CGC-hosted comprehensive pipeline for spatial transcriptomics analysis.

M. Rankovic[1], N. Vukojicic[1], N. Ilic Raicevic[1], V. Matovic[1], D. Sain[2], J. DiGiovanna[2], B. Davis-Dusenbery[2];
[1]Velsera, Belgrade, Serbia, [2]Velsera, Boston, MA

Spatial transcriptomics has been experiencing significant growth in the past years. Inspired by two widely adopted methodologies, particularly in situ hybridization and next-generation sequencing, with an emphasis on the single-cell RNA sequencing (scRNA-seq), this hybrid method facilitates whole transcriptome profiling while preserving spatial context at high resolutions, thus allowing the exploration of novel insights in cancer research. We introduce the highly configurable solution for sequencing-based technologies that allow comprehensive spatial analysis. The pipeline is available on NCI-funded Cancer Genomics Cloud (CGC) platform, powered by Seven Bridges. The CGC platform provides a collaborative cloud base computation infrastructure that collocates computation, over 1000 bioinformatics workflows, and 4+ PB data to researchers, making the analysis of the Cancer Research data Commons (CRDC) datasets accessible from any environment.

This pipeline is developed using reliable, widely adopted packages and can process datasets generated by several leading technologies. It comprises a set of common steps including quality control, data preprocessing, dimensionality reduction, cluster identification, detection of spatially variable features, and integration with scRNA-Seq reference. The pipeline is highly configurable, allowing for various settings to be modified and optimized for result refinement. Additionally, it allows the selection of only specific components of the pipeline to be executed. The key steps of the pipeline are visually represented, allowing researchers to get a detailed insight into results.

Here, we demonstrate a typical flow of spatial transcriptomics analysis on publicly available datasets using the developed pipeline. We illustrate the impact of pipeline settings on the analysis outcomes. Furthermore, we identify spatially variable genes whose expressions show a distinct localization within the tissue. Finally, we perform the data integration to predict the cell type composition within the determined spatial domains.

Spatial transcriptomics analysis is a powerful method that has highly improved critical aspects of cancer research, such as the characterization of tumor microenvironment, the discovery of novel biomarkers and the clarification of drug resistance mechanisms. The ongoing evolution of this method is expected to play vital role in our deep understanding of complex spatial relationships within tissues. This CGC-hosted workflow is developed to contribute to the promising advancements.

#7434 Deployment of a visualization tool directly linked to the CellEngine cytometry analysis software to accelerate analysis of complex cytometry data sets in the context of ongoing clinical trials.

D. Montamat-Sicotte, Z. Bjornson, D. Franckaert, N. Dupuis, E. Paramithiotis;
CellCarta, Montreal, QC, Canada

Introduction High-dimension cytometry panels have become a hallmark of clinical phase 1 and 2 trials. These panels can provide hundreds of readouts and need to be combined with subject metadata (e.g., health data, demographics, timepoint, and dose) to provide insights on the identification of biomarkers. Several bioinformatics tools are available to interpret these complex datasets; however, these usually require significant expertise in data manipulation, which sometimes forces the person doing the data interpretation to outsource the data visualization and statistical analysis to a bioinformatics team. As a consequence, the scientist can be one step-removed from the “raw” data, critically preventing the interpretation of biomarker effects in the context of the raw staining profiles and associated quality controls (e.g. in-run controls). Here, we show how a new tool integrated with the CellEngine cytometry analysis software can accelerate data interpretation without removing the scientist from the raw data.

Methods The visualization tool pulls live data from CellEngine, displaying both study- and cohort-level information in summary views as well as the sample-level staining profiles. As a live link, any changes made in CellEngine, such as ones to gating and compensation, or the addition of new samples during an ongoing study, are automatically reflected in the dashboard. This link also gives the ability to consult staining profiles and performance of controls directly within the tool without having to switch between applications. CellEngine is capable of analyzing 10,000s of samples at once, and thus can handle the largest of studies.

Results Here, we show how the visualization tool was used to accelerate the data interpretation of two different flow cytometry assays. In the first example, lymphodepletion and immune system reconstitution in patients undergoing CAR-T cell therapy was monitored using the tool. The live update of analysed data within the tool, coupled with the ability to verify the performance of the two controls ran with each sample, accelerated the data interpretation and improved the data quality. In the second example, we show how the software was used to follow cytokines responses across different timepoints in a vaccination program where samples were analysed using a polyfunctional intra-cellular cytokine staining panel. The tool greatly accelerated the interrogation of this complex data set and allowed the identification of trends within the different T cell responses.

Conclusion This new tool can help maximize the utility of high-dimensional cytometry in clinical trial analysis while allowing to keep the crucial link between graphical representation of large number of samples and the data associated with each individual flow cytometry staining profile.

#7435 PATTY: A bias estimation and correction model for bulk and single-cell CUT&Tag data.

S. S. Hu, Q. Chen, M. Grieco, C. Zang;
University of Virginia, Charlottesville, VA

The accurate detection of transcription factor (TF) binding sites and histone modifications (HM) on the genome-wide scale is essential for studying functional epigenetics and gene regulation. Cleavage Under Targets & Tagmentation (CUT&Tag) is a low-cost and easy-to-implement epigenomic profiling method that can be performed on a low number of cells and on the single-cell level. CUT&Tag experiments use the hyperactive transposase Tn5 for tagmentation. We find that Tn5 is subject to intrinsic sequence insertion bias (intrinsic bias). Additionally, the preference of Tn5 insertion toward accessible chromatin also affects the distribution of CUT&Tag reads (open chromatin bias). Both types of biases can significantly confound bulk and single-cell CUT&Tag data analysis, which requires careful assessment and new analytical methods. To address this challenge, we present PATTY (Propensity Analyzer for Tn5 Transposase Yielded bias), a computational method for systematic characterization and correction of biases in CUT&Tag data. We demonstrate that histone modification signals (H3K27me3 and H3K27ac) detected from CUT&Tag data after bias correction using PATTY are better associated with orthogonal biological features such as gene expression. PATTY-corrected single-cell CUT&Tag signals for histone modification can better cluster cells into their true cell types. This new computational method can improve both bulk and single-cell CUT&Tag data analysis.

CLINICAL RESEARCH: Biologic and Behavioral Effects of Cancer and Oncology Treatment
Poster Session

#7440 Symptom network analysis and unsupervised clustering of a cohort of oncology patients identifies drivers of symptom burden and patient subgroups with distinct symptom patterns.

B. H. Bergsneider[1], T. S. Armstrong[2], Y. P. Conley[3], B. Cooper[4], M. Hammer[5], J. D. Levine[4], S. Paul[4], C. Miaskowski[4], O. Celiku[2];
[1]Stanford University, Stanford, CA, [2]National Cancer Institute, National Institutes of Health, Bethesda, MD, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of California San Francisco, San Francisco, CA, [5]Dana Farber Cancer Institute, Boston, MA

Purpose: Inter-individual variability in oncology patients' symptom experiences poses significant challenges in prioritizing symptoms for targeted intervention(s). In this study, computational approaches were used to unbiasedly characterize the heterogeneity of the symptom experience of oncology patients to elucidate their symptom patterns and drivers of symptom burden.
Methods: Severity ratings for 32 symptoms on the Memorial Symptom Assessment Scale from 3088 oncology patients were analyzed. Gaussian Graphical Model symptom networks were constructed for the entire cohort and subgroups identified through unsupervised clustering of symptom co-severity patterns. Symptom network characteristics were analyzed and compared using permutation-based statistical tests. Demographic and clinical characteristic differences between subgroups were assessed using multinomial logistic regression.
Results: Network analysis of the entire cohort revealed three core symptom clusters: constitutional, gastrointestinal-epithelial, and psychological. Lack of energy was identified as central to the network, suggesting that it plays a crucial role in driving overall symptom burden and may be the most salient to target clinically. Unsupervised clustering of patients based on shared symptom co-severity patterns identified six patient subgroups with distinct symptom patterns and demographic and clinical characteristics. The first subgroup represented a baseline cohort of patients who are most affected by common constitutional symptoms of cancer care. The second subgroup represented patients with severe overall symptom burden. The third subgroup represented patients primarily experiencing neuropathy. The fourth subgroup represented patients with advanced disease and treatment-related symptoms but relatively high quality of life. The fifth subgroup represented younger patients with pronounced psychological disease burden. The sixth subgroup represented patients with minimal symptom burden. Age, treatment status, and Karnofsky Performance Score were the strongest determinants of subgroup membership, but their interplay (in one case even with ethnicity) reaffirms the complex multi-factorial nature of the symptom experience. For each subgroup, symptoms with the highest network centralities that should be prioritized for management were identified.
Conclusions: This study provides a translational research framework for clinicians to better understand and address the symptom care needs of oncology patients. The framework combines unbiased stratification of patients and in-depth modeling of symptom relationships to capture the heterogeneity in their experiences. When validated, the identified core symptoms and associated clinical determinants may inform precision-based symptom management.

#7441 Health-Related quality of life and DNA methylation-based aging biomarkers among survivors of childhood cancer: Results from the St. Jude Lifetime Cohort.

N.-M. Plonski[1], Y. Pan[1], C. Chen[1], Q. Dong[1], X. Zhang[1], N. Song[2], K. Shelton[1], J. Easton[1], H. Mulder[1], J. Zhang[1], G. Neale[1], E. Walker[1], H. Wang[3], R. Webster[4], T. Brinkman[4], K. R. Krull[4], G. T. Armstrong[4], K. K. Ness[4], M. M. Hudson[4], Q. Li[4], I.-C. Huang[4], Z. Wang[4],
[1]St. Jude Children's Research Hospital, Memphis, TN, [2]Chungbuk National Univeristy, Cheongju, Korea, Republic of, [3]Shanghai Jiao Tong University School of Medicine, Shanghai, China, [4]St Jude Children's Research Hospital, Memphis, TN

Background: Childhood cancer survivors often reported poorer health-related quality-of-life (HRQOL) compared to age/sex-matched controls, indicating toxic stress resulting from high burden of treatment-related late effects. This study aimed to investigate cross-sectional associations between poorer HRQOL and epigenetic age acceleration (EAA) using several epigenetic clocks as well as other DNA methylation (DNAm)-based aging biomarkers.
Methods: DNAm was generated using the Infinium EPIC BeadChip version 1 with blood-derived DNA (median [min-max] for age at blood draw = 34.5 [18.5-66.6] years) from 2,206 long-term survivors in the St. Jude Lifetime Cohort. DNAm-based aging biomarkers and epigenetic age using multiple clocks (e.g., GrimAge; DNAmB2M: beta-2-microglobulin; DNAmADM: adrenomedullin) were derived from the DNAm Age Calculator (https://dnamage.genetics.ucla.edu). HRQOL was measured using the Medical Outcomes Study 36-Item Short-Form Health Survey which assesses eight domains, and physical (PCS) and mental (MCS) component summaries. General linear models evaluated associations between HRQOL and epigenetic age acceleration (EAA, e.g., EAA_GrimAge) or other DNAm-based biomarkers (e.g., chronological age adjusted residuals of DNAmB2M, which was similar to the approach in which EAA was derived) after adjusting for age, sex and cancer treatment exposures.
Results: Worse physical and mental HRQOL was associated with greater EAA_GrimAge (PCS: β [95%CI]=-0.621 [-0.744, -0.499] years, $P=2.48\times10^{-21}$; MCS: -0.548 [-0.667, -0.430] years, $P=2.82\times10^{-18}$; and all eight individual HRQOL domains), followed by chronological age adjusted residuals of DNAmB2M (PCS: -0.101[-0.144, -0.058], $P=2.31\times10^{-5}$; MCS: (-0.053 [-0.094, -0.011], P=0.030; and seven HRQOL domains), and chronological age adjusted residuals of DNAmADM (PCS: -0.096 [-0.139, -0.053], $P=5.45\times10^{-5}$; and five HRQOL domains). EAA_Horvath (Horvath clock, the representative 1st generation epigenetic clock) was the least informative biomarker, which was not associated with any HRQOL domains.
Conclusions: Worse HRQOL in different domains was associated with EAA_GrimAge and chronological age adjusted residuals of DNAmB2M, although future longitudinal studies are needed to illuminate the cause and consequence relationship between HRQOL and aging biomarkers.

#7442 Exploring the role of chinese herbal medicine in adjunctive therapy for non-small cell lung cancer: A systematic review and meta-analysis.

L.-C. Wang[1], T.-L. Chen[2], L. Chen[3], M.-Y. Tsai[4];

[1]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung City, Taiwan, [2]National Chung-Hsing University, Taichung City, Taiwan, [3]Linkou Chang Gung Memorial Hospital, Taoyuan City, Taiwan, [4]Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung City, Taiwan

Non-small cell lung cancer (NSCLC) treatment traditionally relies on Platinum-based chemotherapy along with targeted therapy and immunotherapy. However, the emergence of drug resistance due to genetic factors and the progression of late-stage metastasis pose significant challenges. In Asian medical practices, the integration of Chinese herbal medicine (CHM) alongside conventional therapy has shown promise in improving treatment efficacy, ensuring safety, and mitigating adverse effects. This study aims to comprehensively summarize the prevalence and efficacy of CHM when combined with platinum-based chemotherapy in managing advanced NSCLC. Our analysis encompasses data from 14 randomized controlled trials involving 1451 patients, of which 739 received combined chemotherapy with CHMs while 712 received chemotherapy alone. Notably, the adjunctive use of traditional CHM demonstrated a marked increase in overall survival rates. Patients with NSCLC who received CHMs in combination with chemotherapy exhibited significantly higher Objective Response Rate (ORR) (RR = 1.37, 95% CI [1.20-1.58], p = .000) and Disease Control Rate (DCR) (RR = 1.13, 95% CI [1.07-1.21], p = .000) compared to those solely undergoing chemotherapy. The Karnofsky Performance Status (KPS) (SMD = 1.47, 95% CI [0.30-2.64], p = 0.014) also indicated substantial improvements in the quality of life assessment, involving a total of 277 cases. The systematic review identified 88 herbs and formulas, classified into two primary categories. The first category involves tonifying qi and nourishing yin, thereby enhancing the body's immune function and boost immune therapy, fortifying its ability to combat pathogens, and inhibiting cancer cell proliferation. Herbs such as *Rx.* Astragali (Huangqi), Rz. Atractylodis Macrocephalae (Baizhu), *Rx.* Glehniae (Shashen), and *Rx.* Ophiopogonis (Maidong) were among the most frequently prescribed CHMs. The second category consists of heat-clearing and toxin-removing medicines, effectively regulating the inflammatory response and infection around tumors while exhibiting potent anti-tumor activity, such as Herba Salviae Chinensis (ShiJianChuan) and Selaginella Doederleinii (ShiShangBai). The evidence derived from the meta-analysis strongly suggests that adjunctive CHM treatment can significantly enhance chemotherapy's effectiveness and improve tumor response. Subsequent research focusing on the development and application of CHM is warranted for the advancement of NSCLC treatment methodologies.

#7443 Investigating the impact of ferroptosis in a high-fat and high-oxidative stress hepatic steatosis environment .

C.-S. Chen, S.-C. Wang;
Kaohsiung Medical University, Kaohsiung, Taiwan

An iron-dependent mechanism of cell death, ferroptosis, occurs with intracellular iron accumulation and is associated with lipid peroxidation. Previous studies have shown that lipid peroxidation-induced ROS leads to DNA damage and promotes the progression of steatosis to advanced HCC. Therefore, we aim to study ferroptosis in a cell model with hepatocytes co-cultured with ACM (adipocyte culture medium) and low dose H_2O_2 for a high-fat/high ROS environment in vitro; an animal model with high-fat content and accompanying low dose carbon tetrachloride in vivo to observe the possibility of hepatocyte steatosis due to ferroptosis.

Animal model: Mice were fed a Western diet and provided with high fructose/glucose-containing sugar drinking water (WFSD) for 7 months while receiving a monthly extra-low dose of CCl_4.

Tissue staining: Liver sections were performed to observe histological abnormalities in each group.

Cell model: Pre-adipocytes, 3T3L1 were differentiated by adding IBMX, Dexamethasone, and Insulin (10 μg/ml). After differentiation, ACM was collected. The XTT assay was used to examine the relationship between cell death and ferroptosis by a ferroptosis inducer (Erastin) in high-fat and high-ROS environments.qPCR: To detect the expression of iron transport-related genes.Western Blot: To ascertain protein levels associated with ferroptosis.

Mitochondrial assay: Mitochondrial membrane potential (MMP), mitochondrial dynamics-related proteins, and fluorescence mitochondrial tracking and staining.

Ferritin, GPX4, IRP2, and ferroportin were upregulated when ACM co-culture with the hepatocytic AML12 cell line, and it also increased the sensitivity of ROS-related cell cytotoxicity, which was related to ferroptosis by the inducer, Erastin, in the high-fat/high-ROS cell environment. However, these results can be suppressed by UAMC3203, a ferroptosis inhibitor. As for the animal model with high-fat and carbon tetrachloride accompanied experiments, the mice had higher weight, Alanine Aminotransferase (ALT) levels, and developed tumors. Their liver sections showed lipid accumulation, histological fibrosis, and iron accumulation in both the WD and WD+CCl_4 groups, which corresponds to the IRP1 and IRP2 upregulated in both groups by qPCR result. Our research findings demonstrate that ferroptosis correlates with high-fat and high-ROS-induced hepatocellular damage. The related mitochondria dynamics changes in liver tissue and high-fat and/or high ROS provide evidence for ferroptosis-related hepatic steatosis.

We have established the effect of ferroptosis on hepatic steatosis in vivo and in vitro in nonalcoholic steatosis hepatitis (NASH). These results may enable the development of precise health prevention strategies by inhibiting ferroptosis to prevent the occurrence of liver diseases including hepatic steatosis and HCC.

#7444 Hepatotoxicity from L-asparaginase is associated with lipid changes in a mouse model.

V. Ruiz-Torres[1], J. J. Chia[1], M. Cohen[1], J. Tan[1], P. Bandaru[1], A. Brown[2], V. Huynh[3], E. Orgel[4], S. D. Mittelman[1];

[1]UCLA Mattel Childrens Hospital, Los Angeles, CA, [2]Baylor College of Medicine, Houston, TX, [3]Children's Hospital Orange County, Orange, CA, [4]Children's Hospital Los Angeles, Los Angeles, CA

L-asparaginase (Calaspargase-pegol, PEG) is currently an important component of acute lymphoblastic leukemia (ALL) treatment in children, adolescents, and young adults. Despite its high efficacy, toxicities including hepatotoxicity limit its use. Asparaginase-associated hepatotoxicity is often associated with obesity and fatty liver, highlighting lipid metabolism as a potential contributor to fatty liver. Therefore, we performed lipidomic analyses of plasma and liver from control and obese mice treated with one dose of PEG, to determine whether specific lipid moieties or classes may be associated with the hepatotoxicity produced by PEG. Control and obese 18-week-old male C57Bl6/J mice were treated with one dose of 3000 IU/kg PEG or vehicle (n = 6 per group). Hepatotoxicity was assessed one week later by liver histopathology and plasma alanine transaminase (ALT) and albumin levels. Liver and plasma lipidomic profiles were also analyzed by UHPLC-QTRAP-MS/MS. One week post Veh vs. PEG were compared using two-sided, unpaired t-tests. PEG increased liver steatosis scores in both control (Veh: 0.5±0.2, PEG: 3.7±0.3, $p<0.001$) and obese mice (Veh: 4.0±0.6, PEG: 6.7±0.2, $p<0.01$). While ALT levels did not show a clear pattern with PEG treatment, albumin level decreased in both control (Veh: 3.6±0.1, PEG: 2.7±0.2, $p<0.01$) and obese mice (Veh: 4.1±0.2, PEG: 2.8±0.1, $p<0.01$). Lipidomics analysis showed that plasma lipids generally decreased with PEG treatment in control (not shown) and more significantly in obese mice (Phosphatidylcholines [PC]: Veh 3000.0±381.1, PEG 507.2±71.5, $p<0.001$; Phosphatidylethanolamine [PE]: Veh 604.7±128.1, PEG 295.3±75.0, $p<0.001$; triglycerides [TG]: Veh 649.7±89.7, PEG 150.6±49.3, $p<0.001$). Similar patterns were observed in control (not shown) and obese livers for PC (Veh 11.1±0.8, PEG 5.7±0.8, $p<0.001$) and PE (Veh 6.7±0.8, PEG 3.5±0.5, $p<0.001$), whereas liver TG increased with treatment (Veh 220.1±113.5, PEG 586.6±113.4, $p<0.001$). Interestingly, there were strong negative correlations between steatosis score and liver PC ($r2=0.46$, $p<0.001$) and PE ($r2=0.62$, $p<0.001$). As low PC has been shown to induce fatty liver, this finding implies that PEG might induce steatosis via reduction in PC and its precursor, PE. Future work will investigate the mechanisms by which PEG reduces liver PE and PC levels, and whether this is causally related to steatosis and hepatotoxicity.

#7445 Association between C-reactive protein and cognitive impairment in IDH-mutant gliomas.

M. C. Kauss, M. L. Wright, D. Raval, E. Hsieh, K. Slattery, T. S. Armstrong, T. R. Mendoza, V. A. Guedes;
NIH-NCI, Bethesda, MD

Cognitive impairment is common in primary brain tumor (PBT) patients, as a result of the disease and secondary damage from directed and systemic therapy. Recently, the risk in patients with IDH-mutant gliomas and role of interconnectivity of the tumor with neurons and the tumor microenvironment has heightened interest in exploration of biomarkers of impairment to inform care. Here, we investigate Montreal Cognitive Assessment (MoCA) scores and peripheral blood levels of C-reactive protein (CRP) in a cross-sectional cohort of 47 adult IDH-mutant PBT patients enrolled in a natural history study (NHS, NCT02851706: PI T. Armstrong). MoCA raw scores (range 0-30) were dichotomized (≤ 25 = cognitive dysfunction). Baseline CRP was quantified in banked serum samples in duplicate using (V-Plex/Vascular Injury Panel-2, Meso Scale Discovery [MSD], Rockville, MD) in a QuickPlex SQ 120 instrument (MSD). Lab personnel were blinded to diagnosis and clinical status. To reduce skewness in CRP raw values, we used log transformation. Descriptive statistics, Pearson's correlation, and logistic regression were conducted using IBM SPSS and SAS Statistics software. The sample was predominately male (62%), white (70%), with high-grade gliomas (III/IV) (68%) and an average age at diagnosis of 36 years (SD: 9; median: 34; range: 20-53). The mean MoCA score was 25 (SD: 5; median: 26; range: 11-30). Dichotomizing MoCA scores showed that less than half (43%) of participants exhibited moderate-severe (≤ 25) cognitive impairment. MoCA binary group was negatively correlated with levels of CRP ($r=-0.42$, $p<.003$). The log mean concentration of CRP was higher in participants with cognitive impairment (7.99, SD=0.47 vs 7.57, SD=0.45, $p<.003$) than those without impairment. Finally, when controlling for age and sex, CRP remained predictive of cognitive impairment (OR 8.18, 95% CI 1.70,39.23). Higher levels of CRP were associated with lower MoCA scores in a cross-sectional sample of patients with IDH-mutant gliomas, suggesting an association between the severity of inflammation and cognitive impairment in IDH-mutant glioma patients. Further analysis in large, more diverse longitudinal cohorts will be needed to validate these findings in this population and compare to those with IDH-WT tumors and develop predictive models to inform biomarker development.

#7446 Transcriptomic and histological analysis of radiation-induced damage in the murine submandibular gland.

C. Paz, A. Glassey, **A. Frick**, L. Melzer, J. M. Robinson, R. M. Baus, R. J. Kimple;
Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI

Many head and neck cancer patients develop radiation-induced xerostomia (RIX). There are few clinical solutions for this condition and there is a critical need for novel therapeutics for this condition. To better understand the molecular alterations induced by radiation to the salivary glands, we used transcriptional profiling to assess acute and long-term alterations. Based on evidence that immunologic changes are induced by radiation, we used immune-depletion experiments to investigate the role of B-cells and macrophages in RIX. The submandibular gland (SMG) of male-C57/BL6-mice was irradiated (15Gy) mice were followed for 90 days. Saliva was collected throughout the time-course. SMGs were collected 3-, 7-, 60-, and 90-days following radiation. Tissues were analyzed by Nanostring Digital-Spatial-Profiling (DSP) utilizing the murine whole-transcriptome panel. Regions of interest corresponding to acini, ducts, and granular convoluted tubules (GCTs) were delineated and gene expression was assessed. Immunohistochemical staining was performed on SMG's for fibrosis (masons trichrome), α-amylase, F4/80, Lgr5, Sox2, and MIST1 to evaluate glandular structure, salivary proteins, immune-microenvironment and pro-acinar salivary-stem-cell presence. Specific immune populations were depleted using anti-CD20 and clodronate-liposome prior to radiation and salivary function and histology was assessed at 3-, 7-, and 60-days following radiation. Radiation resulted in a significant decrease in salivary production (p-value = 0.03) in immune competent models. Transcriptional pathway analysis identified early alterations in signal-transduction and innate immune-response. Late timepoints identified alterations in B-cell activity and Wnt signaling pathways. Histological evaluation of the tissues showed increased disorganization of the gland, with decreases in size and distribution of the acinar compartments (mean area stained: No RT=25.81% vs 90d RT=19.98%, p-value=0.005). Acutely, there was an increase in expression of MIST1 and macrophages (mean area stained: No RT=14.8% vs 7d RT=18.76%, p-value=0.0004) within the SMG that resolved by the 60- and 90-day time-points. Results of immune depletion studies will be presented.Results implicate alterations in macrophages and B-cells in radiation-induced damage. These data along with the data from our immune-depletion experiments will provide valuable mechanistic insight guiding modulation of cell-therapies for treatment of RIX which can be further tested in preclinical models.

#7447 Understanding survivorship: A national survey of post-treatment experiences in Black prostate cancer survivors.

Dottington Fullwood[1], Daniel Lee[1], Veronika Panagiotou[2], Samantha B. Siegel[3], Mariel Molina[4], Folakemi T. Odedina[1]

[1]Cancer Prevention, Survivorship, and Care Delivery, Mayo Clinic Comprehensive Cancer Center, Jacksonville, FL,[2]National Coalition for Cancer Survivorship, Silver Spring, MD,[3]The Permanente Medical Group, Davis, CA,[4]Edge Research, Arlington, VA

Prostate cancer, impacts over 3.1 million survivors, poses persistent challenges in post-treatment care, creating uncertainties regarding the best course of follow-up actions for leading productive lives. Unfortunately, these concerns, especially among ethnically diverse Black men, are frequently overlooked. The post-treatment journey for Black prostate cancer survivors is dependent on how they navigate survivorship to determine how it impacts their quality of life and emotional wellbeing. This study evaluated the post-treatment cancer experience and gauge satisfaction with care among a cohort of Black survivors (n = 45). Utilizing data from the 2023 National Coalition for Cancer Survivorship State of Survivorship Study (n = 1303), conducted between May 9th to June 6th, 2023, the research specifically targets self-identified Black males, constituting 10% of the study population and spanning an age range from 18 to 80 years. Results revealed that oncologists (44%) managed post-treatment care more than primary care physicians (30%). While conversation about follow-up care monitoring cancer tests regularly occurred (68%), while topics such as quality of life (27%), mental and emotional health (21%), and post-treatment survivorship care plans (9%) received minimal attention. Although most survivors felt generally informed about side effects (62% very informed), less than half felt their health care team was very helpful in dealing with them. Symptoms reported by survivors included feeling overly tired (47%), depression, anxiety, and mental health impacts (40%), and uncertainty about the cancer status (34%). Survivors engaging in diverse integrative treatments, including such practices as prayer and exercise, represented 29% and 28%, respectfully. Notably, 80% and 60% of individuals utilizing these modalities reported finding them effective during the post-treatment care phase. The journey from the point of prostate cancer diagnosis to post-treatment can impose a significant mental and physical toll on survivors. To address the emotional and psychological challenges associated with a diagnosis and post-treatment, survivors adopting integrative oncology modalities and exercise prescriptions to cope are crucial. These strategies may help survivors maintain a positive outlook and achieve optimal post-treatment health, with a focus on providing tailored resources that cater to the unique needs of Black survivors.

#7448 Serum IL-10 is associated with neurologic symptoms and interference in primary brain tumor patients.

K. A. Slattery, M. L. Wright, D. Raval, E. Hsieh, M. C. Kauss, T. S. Armstrong, T. R. Mendoza, V. A. Guedes;
NIH-NCI, Bethesda, MD

Background: Primary brain tumors (PBT) are associated with neurocognitive symptoms as a direct result of the tumor or its treatment. IDH-mutant gliomas are associated with longer survival, but with higher incidence of seizures and neurocognitive symptoms. Correlations between cytokines and neuroinflammation have been reported in other structural brain lesions but have not been evaluated in PBT. Here, we investigate elevated peripheral blood levels of proteins (cytokine levels) in a cross-sectional cohort (n=47) of adult, IDH-mutant PBT patients enrolled in a natural history study (NCT02851706, PI: T. Armstrong) versus healthy subjects (n=32) and the correlations between cytokine levels and patient-reported outcomes (PROs).

Methods: Patient-reported symptoms and activity-related interference were collected via the MD Anderson Symptom Inventory-Brain Tumor at study entry. Serum samples were stored at -80°C for batch processing and used for biomarker analysis. Ten cytokines (interleukin-1β [IL-1β], IL-2, IL-4, IL-6, IL-8, IL-10, IL-12p70, IL-13, interferon-γ [IFN-γ], and tumor necrosis factor-α [TNF-α]) were quantified in duplicate using an immunoassay (V-Plex/Proinflammatory, Meso Scale Discovery [MSD], Rockville, MD). Lab personnel were blinded to diagnosis and patient clinical status. Mean concentration (pg/mL) levels or 'present or not detectable' values were used. Descriptive statistics, Mann-Whitney tests, and Spearman correlations were conducted at $p < 0.05$.

Results: The patient sample was mostly male (62%), White (70%), employed (64%), had no prior recurrence (62%), high grade (3-4) tumors (70%), and an average age at diagnosis of 36 years (SD: 9; median: 34; range: 20-53). The healthy subject sample was mostly female (53%) and White (72%), with an average age of 46 years (SD: 19; median: 50; range: 19-78). Five cytokines (IFN-γ, IL-6, IL-8, IL-10, and TNF-α) were detectable in patients and healthy subjects with levels of IL-6, IL-10, and TNF-α higher in patients than healthy subjects. Serum levels of IL-10 (mean rank=50.7 vs 24.3, $p<0.001$) and TNF-α (mean rank=50.6 vs 24.2, $p<0.001$) were higher in PBT patients when compared to healthy subjects. Only IL-10, but not other cytokines, positively correlated with severity of patient-reported symptoms [pain (r=0.290, p=0.048), numbness/tingling (r=0.302, p=0.039)], and activity-related interference, including work (r=0.323, p=0.027), and walking (r=0.402, p=0.005).

Conclusions: Higher IL-10 levels and detection differences in other cytokines, may indicate a reduction in immune-mediating processes and heightening inflammation in patients. Future analysis will include replication of this work in a larger cohort across PBT types to evaluate risk, explore mechanisms, and associations with treatment types.

#7449 Incidence of secondary malignancies in early onset colorectal cancer (EOCRC) patients.

D. Vadehra, K. Attwood, A. George, S. Advani, S. Sonti, S. Mukherjee;
Roswell Park Comprehensive Cancer Center, Buffalo, NY

Introduction: The incidence of colorectal cancer in the younger population (20-49) continues to rise at a rapid pace. EOCRC patients are potentially at risk for developing additional secondary malignancies. There is a lack of reported data in the EOCRC space. In this analysis, we seek to examine the incidence, trends, and outcomes of secondary malignancies in EOCRC patients.

Methods: The surveillance, epidemiology, and end-result (SEER) database was utilized to assess and compare the incidence and factors associated with development of secondary malignancies among EOCRC patients. Patient characteristics were summarized by secondary cancer status and compared using the Pearson chi-square test. Further OS was assessed using Kaplan- -Meier methods and compared across groups using the log-rank test. Multivariable Logistic regression models using backward selection approach were used to evaluate the association between patient characteristics and risk of secondary cancers. All statistics were performed using SAS version 9.4 (SAS Institute Inc., Cary, NC).

Results: Of the 53,891 patients analyzed, 2578 (4.8%) patients with EOCRC developed a secondary malignancy in the SEER database from 2000-2019. The mean age for developing a secondary malignancy was 47.6 yo (median 48 yo; range 20-69). There was a higher likelihood of second cancers among men(56%), white patients (61.4%), those with stage II (25.5%). and III (32.8%) CRC. The patients who most commonly developed a secondary malignancy were in the age group 40-49(p <.001). Of the patients who developed a secondary malignancy, 1843 (71.5%) initially had a primary colon cancer compared to 920 (22.6%) having rectal cancer, with the remainder having a rectosigmoid cancer. Of the patients who developed secondary malignancies, a majority had received prior chemotherapy (58.5%), and a minority of patients received radiation therapy (20.6%) Patients who had a partner had a higher incidence of secondary malignancy (59.5%) and they were more likely to have resided in a metropolitan area compared to a nonmetropolitan area (86.6 versus 13.2% respectively). The most common sites of secondary malignancy were: an additional colorectal cancer (47.7%), followed by breast cancer (8.2%) urinary tract cancer (7.1%), thyroid cancer (7%) and prostate cancer (5%). Patients who developed a secondary cancer were found to have an improved disease specific survival (DSS) compared to those who did not develop a secondary malignancy (3 year mDSS 89% vs 74%; p <.001)The overall survival of patients who developed a secondary malignancy was worse than those who did not develop one (mOS 208 months vs 229 mos respectively) .

Conclusion: EOCRC patients are likely to develop secondary malignancies. Long-term screening should be recommended for these patients and integrated into their survivorship plans.

#7450 The impact of prior history of non-hematologic malignancies on time to first treatment and overall survival among individuals with CLL or MBL.

B. A. Vallejo, C. Allmer, K. G. Rabe, D. P. Robinson, Y. Wang, P. J. Hampel, E. D. Braggio, N. E. Kay, J. R. Cerhan, S. A. Parikh, S. L. Slager;
Mayo Clinic, Rochester, MN

Background: The impact of a prior history of non-hematologic malignancy (NHM) on clinical outcomes among individuals with newly diagnosed chronic lymphocytic leukemia (CLL) or monoclonal B-cell lymphocytosis (MBL), the precursor to CLL, is not well known.
Methods: In this prospective study, we identified individuals with CLL/MBL who were seen in the Division of Hematology at the Mayo Clinic, Rochester. Participants provided consent within nine months of diagnosis, had no prior history of hematological malignancy, and completed a self-reported risk-factor questionnaire, including a prior history of NHM. Time to first treatment (TTFT) was defined as the time between the date of diagnosis and the earliest date of the first CLL treatment, death, or the last known treatment-free follow-up date. Overall survival (OS) was defined as the time from diagnosis to death or the last follow-up. We used Cox regression to estimate hazard ratios (HR) and 95% confidence intervals (CI) for associations between a prior history of a NHM with OS and TTFT. We adjusted for sex and the CLL International Prognostic Index (CLL-IPI), a score comprised of five key CLL prognostic factors, including age and Rai stage.
Results: Among the 1,090 CLL/MBL individuals, 833 (76%) had CLL. The median age at diagnosis was 64 years (range 24-89), with 65% being men, and 230 (21%) reported a prior history of NHM. The most common tumor was non-melanoma skin cancer (NMSC, 8.9%, 96 individuals), followed by prostate, testicular, and penile tumors (7.3%, 51 individuals), and melanoma (1.9%, 20 individuals). CLL/MBL patients with a prior history of a NHM were more likely to be over 65 years old (29%) than under 65 years old (14%, $p < 0.0001$). After a median follow-up of 2.9 years (range 0-21), 470 CLL/MBL patients progressed, requiring CLL treatment. CLL/MBL individuals with a prior history of NHM had a longer TTFT compared to those without (HR=0.69; 95% CI: 0.53-0.90; p=0.006). Individuals with a prior history of NHM who had either intermediate or high-very high CLL-IPI score had significantly longer TTFT (HR= 0.55; 95% CI: 0.33-0.92; p=0.02, and HR=0.65; 95% CI: 0.43-0.97; p=0.03, respectively) compared to those without NHM. After a median follow-up of 8.6 years (range 0-21), 359 individuals died. CLL/MBL patients with a prior history of NHM also experienced reduced OS compared to those without (HR=1.46; 95% CI: 1.08-1.97, p=0.013), particularly among those with low (HR=1.70; 95% CI: 0.96-3.00, p=0.07) or intermediate-risk (HR=2.08; 95% CI: 1.24-3.51, p=0.006), according to CLL-IPI. After excluding NMSC, results remained constant.
Conclusions: At the time of diagnosis, one out of five CLL/MBL individuals had a prior history of a NHM. These individuals had a longer time to first CLL directed treatment and reduced OS, even after accounting for other important CLL prognostic factors, which deserves additional studies.

#7451 Translational models of ovarian cancer-associated cognitive impairment and chemotherapy-induced peripheral neuropathy.

N. Lomeli[1], D. Argueta[1], D. C. Pearre[2], J. Lepe[1], K. Gupta[1], D. A. Bota[1];
[1]UC Irvine, Irvine, CA, [2]Providence Specialty Medical Group, Burbank, CA

Cisplatin is widely used to treat ovarian malignancies, and over 70% of ovarian cancer patients report experiencing cancer-related cognitive impairment (CRCI) and chemotherapy-induced peripheral neuropathy (CIPN) during and after chemotherapy treatment. Most pre-clinical CRCI/CIPN studies have been conducted on non-tumor bearing rodents. We developed two novel clinically relevant models of CRCI/CIPN: (1) the ID8 syngeneic mouse model in B6(Cg)-Tyrc-2J/J female mice, and (2) the SKOV3.ip1 ovarian cancer xenograft model in female Cr:NIH-RNU rats. We examined cognitive function and serum cytokine levels with respect to cancer progression and/or in response to cisplatin. B6 female mice were injected with 10^7 ID8 cells or 0.9% saline, i.p. Mice received cisplatin (2.3 mg/kg/day, i.p.) or 0.9% saline (OvT+CIS, OvT+VEH, respectively) for 5d, followed by 5d of rest for two cycles. RNU rats were injected with 10^7 SKOV3.ip1 cells or 0.9% saline, i.p. Rats received cisplatin (5 mg/kg, i.p) or 0.9% saline (OvT+CIS, OvT+VEH, respectively) every other week for four cycles. OvT+CIS and OvT+VEH mice and rats showed impairments in novel object recognition (NOR), with discrimination ratios ≤0.5. Cisplatin transiently increased hyperalgesia in OvT+CIS mice, which persisted longitudinally in OvT+VEH mice. Serum cytokine levels were elevated in OvT+VEH mice (IL-2, IL-10, INFγ) and OvT+VEH rats (IL-4, IL-10) compared to OvT+CIS ($P<0.05$). Ovarian cancer may evoke progressive sensory and neurocognitive deficits and increase systemic pro-inflammatory cytokine levels in the absence of chemotherapy. Future studies will address hyperalgesia and cognitive differences between healthy control and ovarian cancer models +/- cisplatin, and biological mechanisms underlying CRCI and CIPN.

#7452 ApoE genotype influences susceptibility to doxorubicin-induced cognitive impairment in juvenile rats.

C. Patel, J. Willekens, F. Diglio, P. Cole;
Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Many pediatric cancer survivors experience chemotherapy-induced cognitive impairment (CICI), which negatively impacts the quality of life. Despite extensive research into the multifactorial causes of CICI, there are no FDA approved drugs available to prevent it and the interpatient variability in susceptibility to CICI is not well understood. Among pediatric cancer survivors, those with the E4 allele of Apolipoprotein E (ApoE) are more likely to exhibit cognitive dysfunction than those with the more prevalent ApoE3 allele, suggesting the ApoE4 allele increases susceptibility to CICI. To mimic a curative pediatric treatment regimen, in our experimental model, five-week-old rats homozygous for either human ApoE3 or ApoE4 allele were treated with doxorubicin (DOXO) (2mg/kg/week for 4 weeks) or saline. ApoE4 rats were more likely than ApoE3 rats to exhibit DOXO-induced impairments in visual memory. However, there was no difference between ApoE3 and ApoE4 rats in sensitivity to DOXO-induced spatial memory impairments. Contrast-enhanced magnetic resonance imaging (MRI) was done to evaluate the blood-brain barrier (BBB) integrity because of literature suggesting that the ApoE4 allele contributes to BBB weakness. However, no significant difference was observed in the BBB integrity between ApoE3 and ApoE4 rats. To delve deeper into the neuropathological basis of DOXO-induced cognitive impairment on the ApoE4 allele, ongoing experiments involve immunohistochemical analyses targeting neurogenic changes in neural stem cell proliferation (DCX), neuronal maturation (Syn and PSD95), as well as glial differentiation (Iba1 and GFAP) in brain regions including hippocampus (dentate gyrus) and cortex. Additionally, to determine the effect of DOXO treatment on ApoE4, we are investigating the role of mitogen-activated protein kinase (MAPK) signaling pathways within brain regions pertinent to memory and recognition. In summary, ApoE genotype contributes to differential susceptibility to CICI.

#7453 Psychometric analysis of Neuro-QoL Perceived Cognitive Function tool in primary brain tumor patients.

M. L. Johnson, E. Vera, K. Reinhart, H. Miller, A. Choi, T. Kunst, B. McIver, E. Grajkowska, M. L. Wright, T. S. Armstrong, T. Mendoza;
National Cancer Institute, Bethesda, MD

Cognitive dysfunction is commonly reported but variable in course and severity in the primary brain tumor (PBT) population. Brief, reliable, and sensitive measures of patient-reported outcomes (PRO) of cognitive symptoms on function are needed for clinical care and research. This study aims to assess the reliability and validity of the Neuro-QoL Perceived Cognitive Function tool (NQC) and explore associations with symptoms and objective testing of cognitive dysfunction in a cohort of PBT patients enrolled in a natural history study (NCT02851706: PI T. Armstrong). Patient sample characteristics and PROs, including NQC (<40 = moderate/severe (MS) dysfunction), a symptom burden measure (MD Anderson Symptom Inventory-Brain Tumor (MDASI-BT), scores ≥5 = MS) and the Montreal Cognitive Assessment ((MoCA), scores ≤ 25 indicating cognitive impairment (range: 0-30)) were collected. Descriptive statistics and a psychometric analysis consisting of bivariate correlations, Cronbach's alpha, and factor analyses using principal axis factoring with nonorthogonal rotation were performed. Cohen's kappa and correlation were used to assess agreement between objective and subjective measures of cognitive function. The cohort included 327 patients who completed the NQC at study entry [median age: 47 years (range: 18-85), primarily white (78%) males (55%) with high-grade tumors (73%), 65% with a Karnofsky Performance Status (KPS) ≥ 90 (good), and 29% reporting MS cognitive dysfunction]. Factor analysis of the NQC identified two underlying factor groupings: concentration/focus and executive function with Cronbach's alphas of 0.92 and 0.91 that are interpretable and provided adequate fit for the data. While the NQC was moderately correlated with several MDASI-BT symptom factors, it was highly associated with the cognitive factor (r = -.646). To assess agreement, a subset of patients also completed the MoCA (n=172). These were primarily male (58%), white (79%), had high-grade tumors (67%), and a good KPS score (67%). In this subset, 24% had MS cognitive dysfunction as measured by the NQC while 44% were cognitively impaired using the MoCA resulting in a kappa agreement of 0.07. The correlation between the MoCA score and NQC T-score was -0.292. Understanding the impact and prevalence of cognitive symptoms, objective cognitive testing, and perceived impact is essential for PBT patient care and identifying supportive care interventions. Select NQC psychometric properties demonstrate reliability and validity in this population, with strong agreement with self-report of cognitive symptoms but weaker correlation with objective testing, highlighting the variability in perceived impact. Future research in cognitive function will explore the use of objective testing and perceived impact, its predictors in select populations (i.e., IDH-mutant tumors), and examine its association with biomarkers.

CLINICAL RESEARCH: Cancer Immunity and Inflammation
Poster Session

#7458 Inhibition of brain cancer progression via resolution of inflammation.

J. Capuano[1], K. Vasquez[1], K. Quinlivan[1], R. Bayer[1], S. Virani[1], M. Gillespie[1], M. Kieran[2], C. Serhan[3], D. Bielenberg[4], D. Panigrahy[1];
[1]Beth Israel Deaconess Medical Center / Harvard Medical School, Boston, MA, [2]Dana-Farber Cancer Institute / Harvard Medical School, Boston, MA, [3]Brigham and Women's Hospital / Harvard Medical School, Boston, MA, [4]Boston Children's Hospital / Harvard Medical School, Boston, MA

While inflammation is a hallmark of cancer, the mechanisms that disrupt its resolution in cancer are not well understood. A paradigm shift is emerging in our understanding that the resolution of inflammation is an active process controlled by specialized pro-resolving mediators (SPMs), including protectins and resolvins, which are endogenous lipid autacoids present in multiple tissues including the brain and cerebrospinal fluid. SPMs counter-regulate pro-inflammatory cytokine production and stimulate phagocytosis of cellular debris (“pro-resolution”) without being immunosuppressive. We hypothesized treatment with pro-resolving agonists such as SPMs presents a novel debris-clearing and resolution-enhancing therapeutic approach to complement cytotoxic brain cancer therapies. Here, we demonstrate the failure of resolution of inflammation via dysregulated SPMs may be a critical risk factor for aggressive brain cancer growth. Moreover, chemotherapy and targeted therapy further disrupt inflammation resolution via a tumor cell death (“debris”)-induced cytokine storm by macrophages. The SPM receptors GPR37 (protectin D1), GPR18/DRV2 (resolvin (Rv) D2), GPR32 (RvD1), and ChemR23/ERV (RvE1) are expressed in tumor-infiltrating macrophages and endothelial cells in the brain tumor microenvironment. Plasma levels of SPMs were significantly reduced in the medulloblastoma-bearing mice, suggesting that brain cancer progression is associated with a failure of endogenous resolution of inflammation. To determine whether failed resolution in brain cancer can be rescued by lipid mediator agonists, we systemically administered SPMs to subcutaneous and orthotopic glioblastoma and medulloblastoma murine brain tumor models. Significantly, RvD1 and RvD2 each inhibited the growth of human glioblastoma tumors by 15-fold at nanogram concentrations without toxicity. Likewise, RvD2 inhibited the growth of human medulloblastoma tumors by 3-fold. Protectins, PDX and $PD1_{n-3}$, each inhibited growth of human medulloblastoma in mice by approximately 5-fold. Systemic administration of PDX or RvD2 prolonged survival of mice injected with orthotopic human D556 medulloblastoma and also glioblastoma models. Flow cytometry analysis of orthotopic glioblastoma tumors revealed increased immune infiltration into the brain tumor microenvironment in the PCTR1-treatment group when compared to the tumor-bearing non-treated group. At nanogram per day doses, protectins and resolvins suppressed orthotopic debris-stimulated brain tumor growth by activating macrophage and microglial phagocytosis of tumor cell debris and counter-regulating pro-inflammatory cytokines, including TNF-α, CCL2, CXCL1, and CCL4. Thus, stimulating the resolution of inflammation via the clearance of cellular debris with pro-resolving agonists represents a novel therapeutic approach to brain cancer, including glioblastoma and medulloblastoma.

#7459 iNOS inhibition through L-NMMA reveals immunostimulatory effects in obesity-associated triple-negative breast cancer (TNBC) tumors.

I. Uzair[1], K. Sun[2], S. Hynes[3], W. Qian[1], J. Zhou[1], K. Ortega Martinez[1], L. Guzman[1], P. Matre[1], J. Chang[1];

[1]Houston Methodist Research Institute, Houston, TX, [2]Houston Methodist Hospital, Houston, TX, [3]University of Galway, Galway, Ireland

Purpose of study: This study examines how obesity, an inflammatory condition, impacts treatment outcomes in triple-negative breast cancer (TNBC). Obesity fosters an unfavorable tumor microenvironment (TME) marked by immune suppression, metabolic shifts, and protumoral cytokine release. Elevated nitric oxide (NO) levels linked with obesity compromise vascular integrity, promoting breast cancer metastasis. This study examines whether combining standard chemotherapy (docetaxel) with NOS inhibition via L-NMMA could reshape the TME and bolster antitumor effects in TNBC within an obese mouse model.
Experimental Procedure: C57bl/6 mice, a TNBC syngeneic mouse model, were fed a high-fat diet (HFD) or normal diet (ND) for 10 weeks. Tumors were induced orthotopically via E0771 cell line injection into the mammary fat pad. Upon reaching 100 mm^3, mice were randomized into vehicle and L-NMMA treatment groups. Digital spatial transcriptomics using NanoString™ GeoMx and nCounter platforms were conducted on FFPE tumor tissue sections from ND, HFD, and HFD+LNMMA treated mice. A panel targeting 64 protein markers aided in immune cell phenotyping and TME assessment.
Results: HFD-induced tumors exhibited increased growth, elevated pro-inflammatory cytokine levels, and heightened iNOS expression. Unsupervised hierarchical clustering after nCounter analysis revealed a distinct protein expression signature in HFD tumors associated with T cell infiltration and exhaustion, as evidenced by the upregulation of CD3, CD4, PD-1/PD-L1, FOXP3, and CTLA 4. Markers for identifying immunosuppressed macrophages (F4/80 and CD163) were also elevated. Remarkably, LNMMA treatment on HFD tumors led to reduced tumor growth and lower expression levels of these markers, alongside a downregulation of survival/proliferation markers such as p53, Ki67, and key members of the Pi3k signaling pathway such as phospoAktSer473.
Conclusions: Our findings indicate a distinct immunomodulatory mechanism of iNOS inhibition in HFD tumors, which displayed expression profiles marked by heightened immunosuppressive markers when compared to ND tumors. LNMMA treatment reversed this phenotype, aligning the profile closer to ND tumors. These discoveries underscore the potential of inhibiting iNOS to reshape the immune tumor microenvironment (TME) and modulate pathways linked to cell proliferation and survival. This presents a promising avenue for enhancing the effectiveness of treatments for triple-negative breast cancer (TNBC).

#7460 Characterizing the role of PCBP1 in the activation of the cGAS-STING/type I Interferon axis to promote anti-tumor immunity.

C. Frereux, P. Chakraborty, A. C. Dalton, B. V. Howley, B. Granger, J. A. Q. Karam, S. G. Vaena, M. J. Romeo, P. H. Howe;
Medical University of South Carolina, Charleston, SC

The emergence of immunotherapies has encouraged the need to better understand the molecular mechanisms that modulate the tumor immune microenvironment to kill cancer cells as well as the strategies used by cancer cells to evade the immune system. In several cancer types, the Poly(rC) Binding Protein 1 (PCBP1) has shown to have tumor suppressive effects, however its function in regulating the tumor immune environment remains unclear. To investigate this in the context of breast cancer, we established a CRISPR-Cas9-medited knock-out of PCBP1 in a Py8119 murine breast cancer cell line. PCBP1$^{-/-}$ cells revealed a decrease in the activation of the cGAS-STING pathway and is associated with lower levels of type I interferons (IFNs) and Interferon Stimulated Genes' (ISGs) expression. The cGAS-STING pathway plays an important role in innate immunity as it fights pathogenic infections and tumorigenesis through the production of type I IFN and ISGs. It also promotes the priming and infiltration of T cells at the tumor site to fight cancer cells. Our results suggested that PCBP1 is acting on the activation of the cGAS-STING pathway and could further modulate the tumor immune microenvironment. We then confirmed our results *in vivo* by establishing a tumorigenic C57BL/6 PyMT transgenic mouse model with conditional knockout for PCBP1 in mammary cells. Our data demonstrate that PCBP1$^{-/-}$ PyMT mice have higher tumor burdens compared to PCBP1$^{+/+}$ PyMT mice and also show a decreased ISGs' signature by RNA-sequencing, qPCR and western blot, as previously observed *in vitro* in the Py8119 PCBP1$^{-/-}$ cell line. Additional single nuclei RNA-sequencing analyses confirmed that this downregulation of ISGs is observed in mammary cancer cells where PCBP1 is knocked-out. Strikingly, IHC and flow cytometry analyses of PCBP1$^{-/-}$ tumors isolated from these mice also revealed a decrease in CD8^{+} T-cells. Therefore, PCBP1 silencing may promote tumor growth by impairing the activation of the cGAS-STING/IFN-I/ISGs axis, which may contribute to the decrease in CD8^{+} T-cells' infiltration at the tumor site. Additionally, we are further investigating the molecular mechanisms mediated by PCBP1 that trigger this activation of the cGAS-STING pathway.

#7461 Obesity promotes breast cancer progression via complement 1q.

Tao Zhang, Shimeng Liu, Myles Brown

Dana-Farber Cancer Institute, Boston, MA

Obesity markedly impacts the onset and progression of various tumors. Yet, the mechanisms by which obesity-driven remodeling in macrophages modulates tumor progression are not yet fully elucidated. Using single-cell RNA sequencing and in vivo syngeneic murine models, we identified an enriched subset of macrophages expressing high levels of C1q complex genes in the adipose tissue of obese mice. Intriguingly, these C1q-positive macrophages are also prevalent within the tumor microenvironment. Our data suggest that obesity induces cell apoptosis in both adipocytes and tumor cells, and that macrophages engulf these apoptotic cells via a C1q-dependent pathway, thus promoting immunosuppression. Moreover, C1q deficiency in mice impairs tumor growth. Notably, C1q is upregulated in human breast cancer and is associated with poor prognosis. Our results suggest that targeting C1q could be an effective method for breast cancer treatment.

#7462 Interventional dietary saffron drives antitumor immunity inInterventional dietary saffron drives antitumor immunity in high risk colorectal cancer IBD Patients, A Multisite Clinical Trial Study.

H. Ashktorab[1], R. Salmanroghani[1], H. Salmanroghani[2], R. Oskrochi[3], M. Rashid[1], A. Laiyemo[1], S. Challa[1], P. Oppong-Twene[1], N. Farjana[1], A. Kibreab[1], H. Maeker[4], A. Amin[5], A. Ahmed Mohamed[6], A. Elsayed[7], Z. Mohamed Zaki[8], O. Mohamed[7], A. Hassnine[7], S. Saed[9], S. Hassanin[10], F. Aduli[1], L. Gayathri Chirumamilla[1], H. Brim[1];

[1]Howard University, Washington, DC, [2]Yazd University, Yazd, Iran, Islamic Republic of, [3]Kuwait, American Middle School University, Kuwait, [4]Stanford University, Palo Alto, CA, [5]University of Sharjah, Sharjah, United Arab Emirates, [6]National Hepatology and Tropical Medicine Institute, Cairo, Egypt, [7]Minia University, Minia, Egypt, [8]Howard University, Minia University, Egypt, [9]University, Cairo, Cairo, Egypt, [10]Modern University for Technology and Information, Cairo, Egypt

Background: Inflammatory polyps in patients with Inflammatory Bowel Disease (IBD) pose a significant risk for colorectal cancer (CRC). Dietary interventions targeting anti-tumor immunity are crucial in mitigating this risk.

Aim: We investigated saffron's anti-inflammatory effects in IBD patients due to the high prevalence of polyps, aiming to prevent CRC.

Methods: The study retrospectively evaluated 485 colitis patients (70 IBD, 415 NIC) from Howard University Hospital, through colonoscopy, pathology, and clinical reports evaluations. At Howard University, three UC patients received 50mg of saffron twice daily for 8 weeks, with two cycles. Inflammatory markers, stool calprotectin, and cytokines were assessed. Similar saffron trials were conducted at Yazd University (30 UC patients) and Egypt University (11 UC patients).

Results: Patients with inflammatory bowel disease (IBD) were found to have a 15.7% prevalence of polyps compared to 8.2% in Non-inflammatory colitis patients. Among IBD patients, those with ulcerative colitis had more polyps (27%) than those with Crohn's disease (5%). In a multisite clinical trial, Saffron treatment improved various health indicators, including Partial MayoScore and quality of life. In the study (HU site), pro-inflammatory cytokines decreased, anti-inflammatory markers increased, and fecal calprotectin levels dropped significantly after saffron treatment. Saffron also led to changes in gut bacteria composition. Importantly, no adverse events were reported in the study participants. In one group of patients (Yazd study), saffron treatment led to significant improvements in depression scores, disease severity, and inflammation markers. In another site (Egypt study), 50% of saffron-treated patients showed improvement in markers related to disease severity, inflammation, and quality of life.

Conclusion: Saffron supplementation, alongside standard treatments, shows promise in reducing local and systemic inflammation in IBD patients and may reduce the risk of developing inflammatory polyps and hence CRC. This safe and feasible intervention warrants further exploration as an inflammation-driven CRC preventive strategy.

#7463 Chromosomal instability elicits anti-tumor immunity in pancreatic cancer.

D. Bronder, R. K. Sriram, M. Duran, M. Di Bona, S. McElduff, S. F. Bakhoum;
Memorial Sloan Kettering Cancer Center, New York, NY

Chromosomal instability (CIN) is a hallmark of solid cancers and an established driver of disease progression, therapy resistance, metastasis and on the whole poor patient outcome. Pancreatic cancer is particularly devastating, defined by dismal survival rates with many patients presenting with metastatic disease upon diagnosis, and 5-year survival only reaching ~10%. Despite recent efforts to improve prognosis for pancreatic cancer patients with immunotherapies alone and in combination with other therapeutics progress remains limited. Despite CIN's established role as a driver of disease progression, we have made the paradoxical observation that chromosomally unstable, murine pancreatic cancer cells elicit an anti-tumor immune response. CIN was induced experimentally in a chromosomally stable, metastatic model of pancreatic cancer. Modeling metastatic dissemination by injection of cells into the tail vein of mice led to robust tumor formation in the lungs where CIN-low cells formed many small lesions while CIN-high cells formed fewer but larger tumors. We investigated if the tumors were infiltrated differentially by immune cells by immunofluorescence and found that CIN-high tumors were more readily infiltrated by effector T-cells. This observation motivated us to test immunotherapy response in CIN-low and CIN-high cells. Subcutaneously implanted tumor cells were treated with an immune checkpoint inhibitor and isotype control antibody which revealed that CIN-high cells responded to immunotherapy while CIN-low cells did not. To put forward potential mechanisms explaining CIN-driven anti-tumor immunity, we performed molecular analyses of CIN-low and CIN-high tumors. First, we found that inflammatory pathways were significantly up-regulated in CIN-high tumors compared with CIN-low tumors. These findings were validated by cytokine measurements and RNA *in situ* hybridization. To dissect inflammatory pathway activation mechanistically, we engineered CIN-high cells using CRISPR/Cas9 that were deficient for key inflammatory cytokines and transcription factors. These experiments suppressed cell-intrinsic and ligand-induced inflammation. Yet, we failed to determine singular cytokine expression as mediator of anti-tumor immunity. To rule out the contribution of ligand-induced inflammation in the tumor microenvironment, we probed immune checkpoint blockade in combination with antibodies blocking inflammatory ligand receptors in CIN-high cells. We found that immune checkpoint blockade was cancer cell-intrinsic and independent of blocking antibodies. In summary, our data implicates CIN as a determinant of therapeutic and genetic anti-tumor immunity in a preclinical model of pancreatic cancer.

#7464 Tertiary lymphoid structures in pancreatic cancer: Biomarkers of immunogenic patients or direct contributors to anti-tumor immunity?.

S. Khanal[1], O. Harder[1], E. Kirschstein[1], M. Mack[1], C. Ware[2], M. Gough[3], K. Young[3], **A. J. Gunderson**[1];

[1]The Ohio State University Wexner Medical Ctr., Columbus, OH, [2]Sanford Burnham Preybus Medical Discovery Institute, San Diego, CA, [3]Providence Cancer Institute, Portland, OR

Pancreatic ductal adenocarcinoma (PDAC) is a cancer with low survival rates and currently no immunotherapy options. However, many tumors from PDAC patients can be heavily infiltrated with T and B cells associated with favorable survival outcomes indicating anti-tumor immunity is functional in certain patients. In some of these lymphocyte-inflamed PDAC tumors, spontaneous organization of tertiary lymphoid structures (TLS) is evident upon surgical resection and these patients have a clear survival advantage. TLS are predictive of immune checkpoint blockade response in some cancer types, yet PDAC patients, with or without TLS, are still insensitive to these strategies. To address this paradox, we evaluated surgically resected PDAC tumors from previously untreated patients and discovered that tumors with TLS (TLS+) recruited T and B cells with specific anti-tumor and memory phenotypes suggesting immunosurveillance of disease was enhanced. Furthermore, a subset of TLS+ patients contained germinal centers and improved humoral immune function corresponding to an increased neoantigen burden and long-term survival. When assessing gene expression differences between TLS+ and TLS- patients, operable inflammatory and immunosuppressive pathways emerged that could be therapeutically exploited to activate TLS neogenesis. To address these mechanistic questions, we have developed a method for inducing TLS formation in implantable mouse PDAC tumors in the orthotopic setting utilizing an antibody that agonizes the lymphotoxin beta receptor (LTBR) in mice bearing established PDAC tumors. These TLS are complexed with T cells, B cells, CXCL13^{+} cells, and PNAd^{+} HEV associated with reduced tumor growth, presence of lymphocyte-recruiting cancer associated fibroblasts and increases in anti-tumor T and B cell phenotypes. Interestingly, some mouse PDAC cell lines are resistant to TLS formation by LTBR agonism while others are susceptible offering a model to study patient heterogeneity. We will use this TLS+ PDAC mouse model to address how TLS may directly improve antigen-specific T cell and B cell immunity and elucidate the pathways that regulate TLS formation. These data will offer new strategies to overcome immunotherapy resistance in cancer patients.

#7465 Leukemia inhibitory factor creates an immune suppressive tumor microenvironment and fosters tumor growth in KRAS-driven pancreatic ductal adenocarcinoma.

L. Miller-Phillips[1], I. Boukhalfa Hanafi[1], A. J. Combes[1], S. Bano[1], L. Hysenaj[1], J. P. Roose[1], A. Olshen[1], A. Kiemen[2], S. Umetsu[1], M.-T. Wang[1], E. A. Collisson[1];

[1]UCSF - University of California San Francisco, San Francisco, CA, [2]The Johns Hopkins University, Baltimore, MD

Immune checkpoint blockade revolutionized cancer treatments by activating anti-tumor immunity. Pancreatic ductal adenocarcinoma (PDA) patients have not benefited from these advances due to an immune suppressive tumor microenvironment. Identifying PDA cell-encoded factors that drive immune evasion is necessary to unlock new immunologically active treatment options in PDA. We have recently demonstrated that the cytokine Leukemia inhibitory factor (LIF) is highly upregulated in PDA compared to the normal healthy pancreas. LIF is known for its immune suppressive qualities, but data on LIF in PDA is currently limited. We generated a conditional *Lif* ^{flox}(*L*) allele and crossed it into the well-established *Kras*$^{LSL\text{-}G12D/+}$, *Trp53*$^{flox/flox}$, *Pdx1*-Cre *(KPC)* mouse model. *LKPC* mice (n=29) had longer overall survival (69 days) than control *KPC* mice (n=29) (59 days), (p<0.05). *LKPC* mice harbored significantly smaller tumors with an average tumor weight of 0.6g compared to *KPC* control animals with an average tumor weight of 1.0g (p<0.005). Immunohistochemical evaluation of tumor proliferation measured by Ki-67 positivity in *LKPC* and *KPC* tumors at endpoint showed comparable results. Tumor-derived cell lines from *KPC* and *LKPC* mice showed no growth differences *in vitro* nor when reimplanted subcutaneously (sc) in immunodeficient mice. In contrast, we observed a significant decrease in tumor growth and weight in *LKPC* sc tumors (p<0.05) compared to the *KPC* sc tumors in syngeneic mice. *LKPC* sc tumors had significantly fewer neutrophils and more macrophages, particularly MHC II-high macrophages, known for their anti-tumor qualities when compared to KPC sc tumors using flow cytometry. A trend towards more CD8+ T-cells in sc LKPC tumors was also observed. Our genetically engineered mouse model confirmed this finding by immunohistochemical evaluation of tumors at endpoint, which demonstrated a significant increase of CD8+ T-cells in the *LKPC* animals compared to the *KPC* controls. In summary, we find that cancer-cell-expressed LIF augments tumor growth and shortens overall survival by changing the immune tumor microenvironment, nominating leukemia inhibitory factor depletion as a promising therapeutic immune target in KRAS-driven pancreatic cancer.

#7466 Exploring tertiary lymphoid structures and immune cell interactions in gastric cancer prognosis.

Zheng Zeng[1], Yee Man Au-Yeung[1], Jiandong Huang[1], **Chunxia Du**[2]

[1]The University of Hong Kong, Pokfulam, Hong Kong,[2]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, Hong Kong

Tertiary lymphoid structures (TLSs) are ectopic lymphoid aggregates found in chronically inflamed, infected, and tumor tissues. Prior research indicates that the presence of TLS and tumor-infiltrating lymphocytes (TILs) correlates with a more favorable prognosis in several cancers. Our study investigates the role of TLSs and TILs in gastric cancer, the 4th leading cause of cancer-related death worldwide. We analyzed tumor samples from 107 late-stage gastric cancer patients from mainland China, with a 5-year follow-up period. We performed H&E and multiplex immunofluorescence staining to assess the tumor area and infiltrating immune cells, and we evaluated potential relationships between TILs, clinicopathological features, and patient prognosis. Immunohistological analysis showed that CD4 T cells may have a more significant impact on patient prognosis than CD8 T cells. Notably, the presence of PDL1 and CD4 co-expressing cells was associated with better disease outcomes. We observed PDL1 expressing cells surrounding the tumor margin in a subset of cases, a distribution pattern that could lead to delayed recurrence or complete remission in gastric cancer. In the context of cancer-related TLS, we found that CD20 and CD86 co-expression in the center of the structures may indicate a higher maturation level. Additionally, the ratio and spatial distribution of CD86 and CD163 macrophages appear to play a crucial role in prognosis. We extracted the expression levels of markers from representative samples to examine the spatial relationships between cancer cells and each immune cell type. We then visualized these cellular interactions in the tumor microenvironment using topographic plots. This study broadens our understanding of tumor and immune cell interactions in gastric cancer, with the potential to inform future directions in immunotherapy treatments.

#7467 Multi-omics analysis reveals high chronic inflammation in African Americans compared to Native African Men with prostate cancer.

I. Elhussin[1], E. Baraban[1], T. L. Lotan[1], C. Handy Marshall[1], E. Antonarakis[2], M. J. Campbell[3], M. Davis[4], M. Dixon[5], I. Kim[6], S. Ambs[7], R. Kittles[4], A. B. Murphy[5], C. Yates[1];

[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Minnesota, Minneapolis, MN, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Morehouse School of Medicine, Atlanta, GA, [5]Northwestern University Feinberg School of Medicine, Chicago, IL, [6]Yale School of Medicine, New Haven, CT, [7]National Cancer Institute (NCI), National Institutes of Health (NIH), Bethesda, MD

Men of African descent have the highest prostate cancer (PCa) mortality rates in the United States and globally. Studies suggested that tumor subtypes or gene expression profiles had the greatest influence on overall racial/ethnic survival, accounting for 24% of the disparities in PCa and remains even when controlled for access to care and stage at presentation. Moreover, the tumor microenvironment plays an essential role in tumor progression, aggressiveness, therapeutic response, and patient outcomes. Additionally, the association of the genomic findings with patient ancestry and other characteristics, such as tumor biology and transcriptomic alterations, remains poorly understood. Here, we performed a multi-Omics approach (N=447) to unravel the complexity of tumor heterogeneity and understand disease progression & distinct tumor biology influenced by genetic ancestry. We performed Whole Exome (Normal/tumor paired) Sequencing matched with Methyl Seq and Whole transcriptomic Sequencing for three datasets of our African, African American Men (AAM), and European Men (EAM). Additionally, we ran Spatial NanoString high-plex GeoMx-DSP at the protein and RNA levels for a total of 118 treatment-naive PCa patients (around 500 ROIs). Simultaneously, we added matched genome-wide Sequencing (whole transcriptome) for these patients. The cohort comprised 87 AAM, 3 unknown, and 28 EAM self-reported individuals. To verify the self-reported race, the genomic ancestry was qualified using genotype and Admixture analysis. To further validate differentially expressed genes at the protein level, we performed multi-plex histological staining of 40 markers to determine the spatial resolution and neighborhood clustering within the tumor and the microenvironment. In parallel, we performed scMultiOmics sequencing (scRNA & scATAC-Seq) at a single-cell resolution (6000 cells/sample at 25K reads per cell) from an additional 12 patients (9 AAM & 3 EAM). Our results demonstrate that patients who self-report as AAM or Nigerian are assigned to high African (> 70%) Ancestry with either Yoruba (Nigeria) and/or Bantu subpopulation in the Sub-Saharan area. Additionally, high African Ancestry patients are diagnosed at a younger age and show advanced pathology stages compared to patients with European Ancestry. AAM with Yoruba descent express significantly higher immune-inflammatory signatures (IFNG-signaling pathway) compared to the Nigerian-Yoruba subpopulation. Our scRNA-Seq analysis shows that AAM has myeloid cells that infiltrate within the tumor cells. The infiltrations of these cells change with age, Gleason Grade, and pathology stage. Our study provides new insight into how genetic ancestry impacts immune signatures in AAM/African and contributes to PCa racial disparities.

#7468 Development of a high complexity flow cytometry panel to assess minimum residual disease in acute myeloid leukemia.

J. Pearl, E. Bruni, H. Hsu, **B. Walling**, K. Abarca-Heidemann;
Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

Acute Myeloid Leukemia (AML) is a highly heterogeneous disease with a diverse range of abnormal myeloid subpopulations resulting in challenges in clinical diagnosis and treatment. Many methods such as flow cytometry are used to provide precise information for risk stratification and treatment methods. Flow cytometry utilizes the expression patterns of cellular markers to characterize the high diversity in AML subpopulations with high sensitivity and specificity. This coupled with rapid analysis timelines allows for flow cytometry to be an excellent tool for the identification of AML lineage and progression through both phenotypic analysis and difference from normal. As AML lineage and disease progression are predictors of residual disease and relapse; the need for effective and accurate characterization of AML populations is critical. Here, Champions Oncology has developed a high-complexity 18-color flow cytometry panel to identify AML subpopulations at high resolution. We have characterized AML samples to evaluate the expression of phenotypic markers and their heterogeneity. Utilizing primary AML samples, we have evaluated the stability of AML subpopulations to understand how delayed analysis, such as what is seen in clinical trials, may impact marker expression and observed key populations were stable for up to 72 hours after collection. In addition to stability, understanding the lower limits of detection is critical for AML patients, particularly for minimum residual disease and relapse screening. The use of a flow cytometric panel again provides an excellent tool for these tests due to the single cell nature that allows for the interrogation of individual populations with primary AML subpopulations detected at a range of 10^{-3} to 10^{-4}. Finally, with hundreds of never-passaged AML models characterized and cryopreserved by both flow cytometry and sequencing at Champions Oncology, we investigated how the cryopreservation processes impacted the expression of AML subpopulations. We have observed similar expression and detection of AML populations following cryopreservation indicating that these models can be utilized as an excellent tool for further studies. Collectively, our data indicates that the panel developed at Champions Oncology provides robust data analysis of AML subpopulations and can be an excellent tool for the tracking of AML disease progression in the clinic.

#7469 Inflammation plays an important role in the progression of chronic myeloid leukemia.

M. Langhammer[1], J. Schopf[1], T. Jaquet[2], K. Horn[3], M. Angel[1], D. Mohl[1], S. Lagies[1], C. Spohr[1], D. Christen[1], F. Uhl[1], T. Maie[3], H. Jacobi[2], T. Feyerabend[4], J. Huber[1], M. Panning[1], C. Sitaru[1], I. Costa[3], R. Zeiser[1], K. Aumann[1], H. Becker[1], T. Braunschweig[3], S. Koschmieder[2], B. Kammerer[1], K. Shoumariyeh[1], M. Huber[3], M. Schemionek-Reinders[2], T. Brummer[1], S. Halbach[1];

The development of Tyrosine Kinase Inhibitors (TKIs) resulted in a significant increase in the life expectancy of patients with chronic myeloid leukemia (CML). Nevertheless, TKIs still fail in a significant proportion of therapy-naïve patients, or their effectiveness is hampered by secondary resistance. It is therefore urgent to explore the underlying mechanisms in order to develop new therapeutic approaches to cure CML instead of controlling the disease with a lifelong TKI therapy. Using the ScltTA/TRE-BCR::ABL1 mouse model for chronic phase CML we show that BCR::ABL1 leads to the elevation of pro-inflammatory cytokines, known to be important in disease initiation and progression. This is supported by our data from CML patients, where we also observe higher levels of pro-inflammatory cytokines in the serum compared to healthy individuals. Furthermore, we demonstrate that BCR::ABL1 drives the expansion of bone marrow derived mast cells (BMMCs) and sensitizes them for FcεRI triggered degranulation. Interestingly, these BMMCs show differences in their lipid metabolism. Hence, sphingomyelin and lysophosphatidylcholine, both known to be involved in inflammation and cancer progression, are upregulated in BCR::ABL1-positive mast cells compared to their negative counterparts. By crossing in the Cpa3Cre mediated model for mast cell deficiency, we demonstrate for the first time that the lack of mast cells prevents the BCR::ABL1 induced upregulation of pro-inflammatory cytokines and also the development of splenomegaly. In addition, we were able to show that splenomegaly in CML patients is associated with high bone marrow mast cell counts and that an upregulation of pro-inflammatory cytokines in patient serum samples correlated with tryptase levels. In summary, our study identifies mast cells and their inflammatory cytokines as important factors in disease progression and suggests considering them as additional targets in CML therapy.

#7470 Leukemia inhibitory factor promotes tumor progression in KRAS-driven lung cancer.

I. Boukhalfa Hanafi, L. Miller-Phillips, O. Zakraoui, K. D. Marini, S. Umetsu, M.-T. Wang, E. A. Collisson;
UCSF - University of California San Francisco, San Francisco, CA

Leukemia inhibitory factor (LIF) displays complex effects in different types of cancer but its role in lung cancer remains unknown. Since KRAS mutation is an initial validated oncogenic event in near 30% of non-small cell lung cancer (PanCancer Atlas), we were interested in studying how LIF would influence tumor initiation and progression in KRAS-driven lung cancer.To properly study the roles of LIF throughout KRAS-driven tumorigenesis, we generated a novel genetically engineered mouse model (GEMM), where expression of LIF can be conditionally knocked out by Cre recombinase. Conditional deletion of the Lif allele in oncogenic KRAS-induced lung tumors is achieved by crossing *Lif* $^{flox/flox}$ mice with *Kras*$^{LSL\text{-}G12D/+}$, *Trp53*$^{flox/flox}$ *(KP)* mouse model. In our lung cancer model, induction of oncogenic KRAS and depletion of LIF is attained through intratracheal infection of adeno-Cre virus.When our *Lif* $^{flox/flox}$*KP (LKP)* and *KP* mice were infected by adeno-Cre virus, they developed lung tumors at reasonable frequencies within 4-8 months. We generated cell lines from tumors and used ELISA and RT-qPCR analysis to validate the efficiency of the knockout. While control *KP* tumor cell lines (n=3) showed *Lif* expression and LIF protein secretion, cell lines from *LKP* tumors (n=3) presented with undetectable *Lif* expression and no LIF secretion validating the successful deletion of *Lif* and functionality of our new mouse model. We generated H&E slides from the tumors and with the help of our pathologist we confirmed the subtype of lung adenocarcinoma. The effects of LIF on cell lines proliferation were evaluated *in vitro* and we found that *LKP* cell lines grow significantly slower than the *KP* lines ($p<0.05$).Mice in both groups were monitored for their overall survival (OS) rate. *LKP* mice (n=5) tend to have an increased median overall survival at 176 days when compared to control *KP* mice (n=7) at 152 days ($p=0.07$). To estimate the tumor initiation and progression, mice in each group were sacrificed at early endpoints (10- and 15-weeks post adeno-cre infection) and ratios of lung weight/mouse weight were measured as an indicator of tumor burden. At 10 weeks, *LKP* mice (n=5) presented with significantly smaller ratios with an average of 0.014 compared to *KP* animals (n=4) with an average of 0.019 ($p=0.027$).We found that LIF tends to shorten overall survival and augments tumor burden in lung cancer. These data suggest that LIF has a pro-tumorigenic role in KRAS-driven lung cancer proposing this cytokine as a potential prognostic biomarker and its depletion as a promising therapeutic target.

#7471 Cancer-associated fibroblasts drive T cell infiltration and resistance to immunotherapy in non-small cell lung cancer with mature tertiary lymphoid structures.

F. Peyraud[1], J.-P. Guegan[2], L. Vanhersecke[1], C. Rey[2], O. Lara[2], O. Odin[2], E. Clot[1], M. Brunet[1], T. Grellety[3], M. Del Castillo[4], S. Le Moulec[5], F. Le Loarer[1], A. Bessede[2], A. Italiano[1];

[1]Institute Bergonie, Bordeaux cedex, France, [2]Explicyte, Bordeaux cedex, France, [3]Centre Hospitalier de la Cote Basque, Bayonne, France, [4]Atlantic Pathologie, Saint Pierre d'Irube, France, [5]Clinique Marzet, Pau, France

Background: The presence of mature tertiary lymphoid structures (mTLS) within the tumor microenvironment (TME) has been linked to the effectiveness of PD-L1 blockade in non-small cell lung cancer (NSCLC). However, only a subset of patients experiencing clinical benefit. Our study aims to delve into the determinants of immunotherapy response in mTLS-positive NSCLC.

Methods: We included 77 TLS-positive NSCLC from the BIP study (NCT02534649). First, we employed the GeoMx whole-transcriptome atlas (WTA) assay to spatially profiled the expression of >18,000 protein-coding in patients exhibiting extreme responses (3 responders [R] and 3 non-responders [NR]). To target regions of interest (ROIs), we selected areas that encompassed TLS ($CD3^{+}$/$CD20^{+}$) as entire areas of illumination (AOIs). Additionally, we segmented areas outside TLS into 'tumor' ($PanCK^{+}$/$CD45^{-}$) vs 'stroma' ($PanCK^{-}$/$CD45^{+}$) AOIs. To validate our findings, we conducted multiplex immunofluorescence (mIF) and complemented our results with bulk gene expression analysis using the HTG whole human transcriptome panel.

Results: Spatial transcriptomic analysis pinpointed significant differences in gene expression within the stromal compartment between R and NR. Notably, a subset of cancer-associated fibroblasts (CAFs) expressing both FAP and αSMA markers emerged as the most differentially expressed genes. Subsequently, we used FFPE tissue mIF to delineate the histological profile CAF subsets and the spatial distribution of T cells. Notably, the stromal density of $FAP^{\pm}$αSMA$^{\pm}$ CAFs and $MYH11^{\pm}$αSMA$^{\pm}$ CAFs were significantly higher in NR compared to R. Correspondingly, tumors enriched in $FAP^{\pm}$αSMA$^{\pm}$ CAFs and $MYH11^{\pm}$αSMA$^{\pm}$ CAFs exhibited significantly lower overall response rates (ORR) and progression-free survival (PFS) than those with a low abundance of CAFs. Interestingly, tumors with elevated $FAP^{\pm}$αSMA$^{\pm}$ CAFs and $MYH11^{\pm}$αSMA$^{\pm}$ CAFs were associated with a higher infiltration of $CD8^{\pm}$ T cells. To delve deeper into the $CD8^{\pm}$ T cell infiltrate, we conducted a comparative bulk transcriptomic analysis. Both $FAP^{\pm}$αSMA$^{\pm}$ CAFs High and $MYH11^{\pm}$αSMA$^{\pm}$ CAFs High demonstrated significant associations with regulatory T cells (Treg), exhaustion signatures, and inflammatory processes. To validate the $CD8^{\pm}$ T cell phenotype, we performed complementary mIF. Consistently, the $CD8^{\pm}$ T cell infiltrate in tumors featuring $FAP^{\pm}$αSMA$^{\pm}$ CAFs High and $MYH11^{\pm}$αSMA$^{\pm}$ CAFs High exhibited higher levels of exhaustion markers (PD1, LAG3, TIM3, TIGIT) and Treg infiltration, underscoring an immunosuppressive TME.

Conclusions: $FAP^{\pm}$αSMA$^{\pm}$ CAFs and $MYH11^{\pm}$αSMA$^{\pm}$ CAFs play a pivotal role in driving T cell exhaustion and Treg cell infiltration, contributing to the resistance to immune checkpoint inhibition. Targeting these specific CAF subsets may hold significant promise in overcoming resistance in mature TLS-positive NSCLC.

#7472 Melanoma-intrinsic expression of signal-regulatory protein alpha (SIRPα) confers tumor cells resistance to anti-tumor adaptive immunity.

C.-H. Weng[1], C. Schochet[1], L. Hamadene[1], S. Eghbali[1], S. Monette[2], L. Mangarin[1], C. Liu[1], F. Samaan[3], J. D. Wolchok[1], T. Merghoub[1];
[1]Weill Cornell Medicine/Sandra and Edward Meyer Cancer Center, New York, NY, [2]Laboratory of Comparative Pathology, Memorial Sloan Kettering Cancer Center, The Rockefeller University, Weill Cornell Medicine, New York, NY, [3]PSU College of Medicine, Pennsylvania, PA

Introduction: Melanoma patient survival rates have significantly improved recently owing to the development of both targeted therapies and immunotherapies. However, there are still around 50% of patients relapse. The limited response to immunotherapies and global rise in melanoma incidence, with around 290,000 cases newly diagnosed each year, highlight the need for identifying new biomarkers, modulatory pathways, and risk factors for melanoma development. Earlier studies have characterized that aberrant expression of CD47 (a.k.a. “don’t eat me” signal) is one of the mechanisms that tumors exploit to avoid innate immune surveillance. CD47 blockade has been demonstrated to restore myeloid effector function by reinvigorating phagocytosis of tumor cells, which further enhances anti-tumor T cell responses. However, melanoma tumors are resistant to CD47 blockade. Interestingly, we and others have discovered that human and mouse melanoma cells express high levels of SIRPα, the receptor for CD47, which is typically expressed in myeloid compartments.

Experimental Procedure: To investigate the role of tumor SIRPα, we designed gRNAs to CRISPR out the SIRPα N-terminal region, where it interacts with CD47, in B16 melanoma and generated SIRPα+/+ (WT) and SIRPα-/- (KO) B16 tumors. We conducted multiple *in vitro* and *in vivo* experiments to investigate whether tumor SIRPα played a role in tumor growth and modulated anti-tumor immunity. The preclinical tumor model we used is B16-F10 melanoma and the murine strains we used are the immune-competent (C57BL/6j; B6) and the immune-deficient (RAG^{null}) mice. For phenotypic and functional assessments, we performed analysis using flow cytometry, immunohistochemistry (IHC) and single cell RNA-sequencing (scRNA-seq) derived from live-sorted CD45+ tumor infiltrating lymphocytes (TILs) of SIRPα-WT and SIRPα-KO B16 tumors.

Summary of Unpublished Data

Our preliminary data in a preclinical B16-F10 melanoma model revealed that surface SIRPα expression is necessary for optimal B16-F10 melanoma growth in immune-competent mice, but not in immune-deficient RAG^{null} mice, suggesting a potential crosstalk between tumor SIRPα and the host adaptive immune system. Intriguingly, we found that selective SIRPα deletion in melanoma cells results in a significant increase of immune infiltrates within melanoma tumors that further suppresses tumor growth.

Concluding Remarks: SIRPα is required for optimal melanoma development by suppressing anti-tumor adaptive immunity.

Ethics Approval: All mice were maintained in microisolator cages and treated in accordance with the NIH and American Association of Laboratory Animal Care regulations. All mouse procedures and experiments for this study were approved by the Weill Cornell Medicine Institutional Animal Care and Use Committee.

#7473 Flotillin-2 ablation in T cells enhances antigen sensitivity and functionality.

S. Moon, P. W. Karmaus, M. B. Fessler;
NIH-NIEHS (National Institute of Environmental Health Sciences), Durham, NC

The membrane scaffolding protein flotillin-2 (Flot2) has been proposed to support receptor signaling, but its involvement in T cell receptor (TCR) signaling and T cell responses remains unclear. Here, we show that the deletion of Flot2 increases antigen sensitivity along with changes in surface TCR clustering, resulting in enhanced TCR signaling and effector function to weak TCR stimulation. T cell-specific Flot2-deficient mice showed enhanced proliferation and effector cytokine production in both $CD4^{\pm}$ and $CD8^{\pm}$ T cells, resulting in better control of tumor growth and infection. However, in vitro TCR stimulation with plate-bound anti-CD3 and soluble anti-CD28 showed increased TCR signaling and early activation of $CD4^{\pm}$, but not $CD8^{\pm}$ Flot2-deficient T cells upon weak stimulation. In addition, Flot2-deficient $CD4^{\pm}$ T cells showed better in vitro polarization toward T helper 1 cells upon weak TCR stimulation, likely due to increased sensitivity of the TCR-triggering threshold. Changes in TCR clustering on the membrane have been suggested to influence the early detection of foreign stimuli and the formation of immune synapses. Flot2 ablation indeed increased the number of membrane TCR nanoclusters on naïve $CD4^{\pm}$ T cells. Collectively, this study suggests a mechanism for increasing T cell functionality to weak TCR stimulation by modulating the membrane protein Flot2, which affects surface TCR clustering. These results may have important implications for improving T cell reactivity in diseases with poor antigenicity, such as anti-tumor immune responses.

#7474 T-cell responses across heart, blood, and tumor in patients with immune checkpoint inhibitor-related myocarditis (irMyocarditis).

S. Blum[1], D. A. Zlotoff[1], N. P. Smith[1], I. J. Kernin[1], S. Ramesh[1], G. Oliveira[2], L. Zubiri[1], J. Caplin[1], N. Samanta[1], S. Martin[1], M. Wang[1], A. Tirard[1], P. Sen[3], Y. Song[1], K. Xu[1], J. L. Barth[1], K. Slowikowski[1], M. Nasrallah[1], J. Tantivit[1], K. Manakongtreecheep[1], B. Y. Arnold[1], J. McGuire[1], A. B. Afeyan[2], C. J. Pinto[1], D. McLoughlin[1], M. Jackson[1], P. Chan[1], A. Lawless[1], W. A. Michaud[1], T. Sharova[1], L. T. Nieman[1], J. F. Gainor[1], D. Juric[1], M. Mino-Kenudsen[1], R. J. Sullivn[1], G. M. Boland[1], J. R. Stone[1], C. J. Wu[1], M. F. Thomas[1], T. G. Neilan[1], K. L. Reynolds[1], A.-C. Villani[1];

[1]MGH/Harvard Medical School, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA

Introduction: Immune checkpoint inhibitor (ICI)-related myocarditis (irMyocarditis) is a potentially lethal complication of ICI use that is characterized by the presence of clonally expanded T cells in the heart. The antigens recognized by these expanded intracardiac T-cell clones and their relationships to T-cell clones in the blood and tumors of irMyocarditis patients are poorly understood.

Methods: Paired single-cell RNA sequencing (scRNA-seq) and T-cell receptor (TCR) sequencing was performed on heart tissue (n = 13) and peripheral blood from patients with irMyocarditis (n = 25) and ICI-treated controls (n = 28) using the 10X Chromium (10X Genomics) system. TCR-β chain sequencing was performed (Adaptive Biotechnologies) on four autopsy cases of patients with available scRNA-seq data and irMyocarditis heart, tumor, and histologically normal tissue. An established high-throughput protocol was used to screen expanded intracardiac TCRs against candidate antigens (Oliveira G, et al. Nature 2021). Briefly, full-length TCRs were cloned, transduced into donor T cells, and screened against autologous or major histocompatibility complex (MHC) Class I-matched antigen presenting cell lines pulsed with peptide pools that covered the full length of the α-myosin, troponin-I, and troponin-T proteins alongside pools of common viral antigens and appropriate controls.

Results: scRNA-seq data showed that TCRs shared between heart and blood are predominantly found in circulating CD8 T cell subsets as compared to circulating CD4 T cell subsets. The gene expression patterns of these shared T-cell clones in circulation appear distinct in fatal and non-fatal irMyocarditis patients, with shared T-cell clones in fatal cases expressing cycling markers (*MKI67*, *STMN1*) and the chemokine receptor *CXCR3*. TCR-β chain sequences most enriched in irMyocarditis tissue relative to control tissues were distinct from those enriched in tumor tissues, and their full-length TCR sequences could be recovered from scRNA-seq data. In total, 52 cardiac-expanded TCRs across eight donors were screened against candidate antigens. None of the screened TCRs recognized the putative cardiac autoantigens.

Conclusions: T-cell clones expanded in irMyocarditis are shared in circulation, where the gene expression of these clones may help to distinguish fatal from non-fatal irMyocarditis. TCRs enriched in irMyocarditis appear to be largely distinct from those enriched in tumor and likely recognize currently unknown cardiac autoantigens.

#7475 The contribution of the oral bacteriome and mycobiome in cancer risk in people with HIV in Puerto Rico.

V. S. Sanchez Gonzalez[1], Y. N. Ortiz-Maldonado[1], G. Borges-Velez[1], T. L. Shull[2], J. L. Salgado-Montilla[1], **J. Perez-Santiago1**[1];
[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR, [2]Rush University, Chicago, IL

Although under highly effective antiretroviral therapy, people with HIV (PWH) still experience an increased risk of developing cancer compared to people without HIV (PWOH). Dysbiosis of the oral microbiota in PWH can contribute to persistent inflammation and cancer risk. We previously showed higher levels of inflammation in saliva of PWH measured by TGF-β1 and IL-2. In addition, microbial products such as short-chain fatty acids (SCFA) can regulate the transcription of immune-related genes, particularly those necessary for the innate immune response to pathogens. In this study, we characterized the composition of the oral bacteriome and mycobiome in saliva of Puerto Rican PWH and PWOH, and analyzed these data in relation to markers of inflammation and cancer risk in saliva.

Saliva, sociodemographic, and clinical data from 100 adults were collected (50 PWH and 50 PWOH). PWH were virally suppressed (<50 copies/mL) and had a median CD4 count of 699.8 cells/µL. We sequenced the 16S rDNA and the ITS in extracted DNA from saliva to characterize and quantify the bacterial and fungal communities, respectively. Furthermore, measurement of inflammatory markers (TGF-β1, IL-2, and IL-8) in saliva was performed using quantitative immunoassays. Microbiome data was processed using Qiime2, and statistical analysis was carried out using R-statistical software. Biological pathways associated to changes in the microbiome were inferred using PiCRUST2.

PWH showed lower alpha diversity in the oral bacteriome (Observed OTUs: p=0.02, Faith: p=0.03) and oral mycobiome (Shannon: p=0.02) when compared to PWOH. In a multivariate analysis, lower alpha diversity in the bacteriome was associated with biological sex and HIV status. Lower alpha diversity in the oral bacteriome was associated with higher levels of acetate (r=-0.38, p<0.001) and lower levels of IL-8 (r= 0.21, p= 0.056) in saliva independent of HIV status. Taxonomic analyses showed PWH had a significantly lower abundance of *Porphyromonas*, *Peptostreptococcus*, *Oribacterium*, *Parvimonas*, *Leptotrichia*, *Fusobacterium*, *Eubacterium*, *Dialister*, and *Alkalibacter* genera of bacteria but there not significant changes in taxonomy in the oral mycobiome. Biological processes significantly affected by dysbiosis of the oral mycobiome include cytosolic and mitochondrial NADPH production, amino acid and sugar degradation, and phospholipid remodeling.

Dysbiosis of both the oral bacteriome and mycobiome occur in HIV infection, which can contribute to chronic inflammation. However, the bacteriome and mycobiome may have different biological mechanisms, which suggest different roles in increasing cancer risk in Puerto Rican PWH. These findings provide more information regarding the oral health in people with HIV and may contribute to innovative cancer prevention strategies and screening guidelines for this high-risk population.

#7476 Obtusifolin attenuates LPS-induced inflammation and NLRP3 inflammasome activation by suppressing the MAPK/NF-κB signaling pathway and ROS production in BV2 cells.

H. Lin[1], C.-H. Lee[1], C.-Y. Li[2],
[1]National Sun Yat-sen University, Kaohsiung City, Taiwan, [2]Kaohsiung Medical University, Kaohsiung City, Taiwan

Neuroinflammation, along with activation of microglia and oxidative stress, plays an important role in the development and progression of neurodegenerative diseases. During the inflammation process, immune cells release inflammatory mediators such as cytokines and chemicals that may promote the formation and growth of cancer cells. Obtusifolin, an anthraquinone extracted from the seeds of *Senna obtusifolin*, has anti-inflammatory properties. However, the effect of obtusifolin on neuroinflammation and its regulatory mechanism have not been yet investigated. In the present study, BV2 microglial cells were used to investigate the effects of obtusifolin on LPS-induced inflammatory responses, NLRP3 inflammasome activation, and reactive oxygen species (ROS) production. The secretion of nitric oxide (NO) was analyzed by Griess reagent assay, and the cell viability was detected by the CCK-8 assay. The expressions of iNOS, COX-2, STAT3, ERK, JNK, and p38 were examined using Western blotting, and the production of IL-6 and TNF-α was measured by ELISA. To examine whether obtusifolin affected NLRP3 inflammasome activation, BV2 cells were pretreated with LPS and then stimulated with ATP or nigericin. The secretion of IL-1β was measured by ELISA, whereas the expression of NLRP3 inflammasome-related proteins was detected using Western blotting. The production of ROS was analyzed by flow cytometry. Our experimental results showed that obtusifolin suppressed the production of NO and the secretion of proinflammatory cytokines by LPS-induced BV2 cells under noncytotoxic concentrations. In addition, obtusifolin decreased the expression of iNOS, COX-2, phospho-STAT3, phospho-ERK, phosphor-JNK and phospho-p38, and also attenuated the expression of NLRP3 and ASC, cleaved caspase-1 and cleaved IL-1β by LPS- induced BV2 cells. Moreover, obtusifolin reduced the production of both intracellular and mitochondrial ROS by LPS-induced BV2 cells. Overall, these results demonstrated that obtusifolin attenuated LPS-induced inflammation by suppressing the activation of MAPK and NF-κB signaling pathways, inhibiting NLRP3 inflammasome activation, and reducing the production of ROS in microglia, suggesting that obtusifolin might have benefits in the treatment of neurodegenerative diseases.

#7477 Isoxanthohumol inhibits LPS-induced inflammatory responses in macrophages.

T.-H. Kao, C.-y. Li;
Kaohsiung Medical University, Kaohsiung City, Taiwan

Background: Pathogen infection, such as bacteria, viruses, and fungus, frequently leads to septicemia through a series of inflammatory responses that have very high fatality rates. And, servere inflammation may cause gene mutation which is beginning of cancer. Macrophages are a critical type of antigen-presenting cells that control both innate and adaptive immune responses. During pathogen infection, activated macrophages secret many proinflammatory mediators and cytokines, including nitric oxide (NO), TNF-α and IL-6 against pathogens; however, an overwhelming inflammatory response provokes abundant cells to undergo apoptosis. In the present study, we aimed to examine the anti-inflammatory effect of isoxanthohumol, a prenylflavonoid from hops and beer.
Method: We used lipopolysaccharide (LPS) as a pathogenic stimulus to induce inflammatory responses by J774A.1 macrophages. MTT assay was used to detect cell viability. The secretion of NO was analyzed by Griess reagent assay, while the production of TNF-α, IL-6, IL-1β was measured by enzyme-linked immunosorbent assay (ELISA). The expression of iNOS, COX-2, and MAPKs was examined by Western blotting. The activity of NF-κB was analyzed by promotor reporter assay. The activation of NLRP3 inflammasome was examined by ELISA and immunofluorescence staining. In addition to that, we explored the secretion of cytokines, IL-1β, in THP-1 cell.
Result: We found that isoxanthohumol significantly suppresses the secretion of NO and attenuates the production of TNF-α and IL-6 by LPS-induced macrophages. In addition, isoxanthohumol also inhibits the expression of iNOS and COX-2, suppresses the phosphorylation of JNK, and attenuates the activity of NF-κB by LPS-induced macrophages. Moreover, isoxanthohumol decreases the activation of NLRP3 inflammasome by reducing the production of IL-1β and repressing the ASC speck formation of NLRP3 inflammasome in LPS/ATP-induced macrophages.
Conclusion: Our experimental results demonstrated that isoxanthohumol effectively inhibits LPS-induced inflammatory responses in macrophages, suggesting that isoxanthohumol might have benefits for attenuating inflammation.

#7478 Unveiling the role of two-pore channel 2 (TPC2) in cancer immunity from monocyte differentiation to cytokine production.

A. Alharbi, J. Parrington;
University of Oxford, Oxford, United Kingdom

Background: The study of TPC2 is of great interest in the field of cancer and immune diseases, as it plays a crucial role in various cellular processes, and there is substantial evidence that TPC2 sustains several cancer hallmarks (angiogenesis, autophagy, and metastasis). The expression and role of TPC2 and its relevance to cancer in the innate immune system remain unknown.

Methods: U937 TPCN2 knockdown (KD) cells were developed by nucleofection-based transfection of CRISPR-Cas9 gene editing tools. sgRNA (single guide RNA): CGUGCUGGUGAGUGAGGAUG was designed to target the fourth exon of the TPCN2 gene (Transcript ID: ENST00000294309). The model was used in tandem with pharmacological modulators of TPC2 channel activity to underpin its function in monocyte differentiation, macrophage development, and IL-8 production. Molecular biology techniques, including Sanger sequencing, qPCR, ELISA, and WB, were utilized. Proteins of murine TPC2 WT and TPC2 KO cells were extracted and sent to the Discovery Proteomics Facility of the Target Discovery Institute for label-free quantification and proteomics analysis using mass spectrometry.

Results: We developed TPC2-deficient human monocytes (U937 cells) with a 75% reduction in TPCN2 expression levels, and we demonstrated that TPCN2 genetically modified U937 monocytes were resistant to monocyte differentiation after treatment with increasing concentrations of PMA ranging from 100 ng/mL to 400 ng/mL. TPC2-deficient U937 monocytes were not differentiated into Mϕ. TPC2 acts as a major regulator of monocyte differentiation by modulating PKC-alpha via calpain. In addition, the levels of IL-8 were significantly reduced after treating U937 cells with Ned 19 (an NAADP antagonist) or TPC2 KD. Keratinocyte-derived chemokine (KC) and Macrophage inflammatory protein-2 (MIP-2) are the murine IL-8 homologues. Notably, the levels of MIP-2, but not KC, were significantly reduced in the TPC2 KO murine cells compared to the WT controls. Thus, TPC2 appears to be involved in IL-8 secretion in both humans and mice. In contrast to KC at the protein level, the KC expression level was significantly reduced in TPC2-deficient murine cells. TPC2 in EE/RE is involved in lipopolysaccharide (LPS)-mediated IL-8 production in U937 cells. TPC2 modulates immune targets involving CD38, PKC-alpha, and AKT.We found that 28 different proteins that play roles in cancer immunity showed significant changes in expression in TPC2-deficient murine cells (three overexpressed proteins and 25 down-expressed proteins), compared to WT.

Conclusion: Our data provide the first preclinical proof of concept for TPC2 as a potential target for blocking macrophage development and modulating CD38/IL8 levels as therapeutic strategies for cancer patients, raising questions regarding the clinical utility of TPC2 as a biomarker or immunotherapy target to modulate immune responses.

#7479 Targeting the lipid kinase PIKfyve upregulates surface expression of MHC class I to augment cancer immunotherapy.

P. Borker, Y. Bao, Y. Qiao, A. Chinnaiyan, J. Choi, Y. Zhang, R. Mannan, C. Cheng, T. He, Y. Zheng, J. Yu, M. Gondal, G. Cruz, S. Sara Grove, X. Cao, F. Su, R. Wang, Y. Chang, I. Kryczek, M. Cieslik, M. D. Green, W. Zou;
Rogel Cancer Center, Ann Arbor, MI

The widespread success of cancer immunotherapies suggests a promising future - but has been subverted by unresponsiveness and resistance. Current research has furthered the understanding of immunotherapy resistance through the findings of “hot” (responsive) and “cold” (unresponsive) tumors. Here, we focus on the genetic and pharmacological inhibition of PIKfyve, a lipid kinase regulator of autophagic flux and lysosomal biogenesis. We find that inhibition of PIKfyve results in the upregulation of major histocompatibility complex class I (MHC-I) surface expression in cancer cells (through inhibition of autophagic flux), resulting in increased CD8+ T cell-mediated cancer cell death. These findings were corroborated in multiple syngeneic mouse models, which also displayed increased intratumoral functional CD8+ T cells. In addition, the Pikfyve-depletion antitumor responses are CD8+ T cell and MHC-I dependent - as CD8+ T cell and B2m knockout rescued tumor growth - resulting in improved response to immune checkpoint blockable (ICB), adoptive cell therapy, and a therapeutic vaccine. Further, high PIKfyve expression predicts poor ICB response and is prognostic of poor survival in ICB-treated cohorts. Ultimately, these findings collectively suggest PIKfyve as an effective target to enhance immunotherapies through elevation of MHC-I surface expression in cancer cells, and accordingly, PIKfyve inhibitors have novel potential to increase immunotherapy response in cancer patients.

#7480 Human LINE-1 ORF1p retrotransposition independent function in pancreatic cancer.

E. You[1], B. Patel[1], A. Rojas[1], N. Ho[1], S. Sun[2], M. Raabe[1], Y. Song[1], I. Phillips[1], K. Xu[1], P. Richieri[1], L. Nieman[1], B. Greenbaum[2], D. Ting[1];
[1]Harvard Medical School/Massachusetts General Hospital, Boston, MA, [2]Memorial Sloan Kettering Cancer Center, New York, NY

The aberrant expression of repeat elements is a common feature found in both mouse models and human pancreatic ductal adenocarcinoma (PDAC). The majority of these are non-coding RNAs that have shown the ability to stimulate a viral-like innate immune response. The long interspersed nuclear element 1 (LINE-1) retrotransposon is one of the few protein coding repeat elements in the human genome. LINE-1 has two open reading frames, ORF1 and ORF2. The former (ORF1p) encodes a ribonucleotide protein and the latter (ORF2p) a reverse transcriptase and endonuclease. Although nuclear ORF1p and ORF2p is required for retrotransposition, ORF1p is primarily localized in the cytoplasm, which suggests the possibility of ORF1p function independent of LINE-1 retrotransposition. Here, we show that ORF1p has a function to shield repeat RNAs from activating pathogen recognition receptor (PRR) mediated antiviral response in PDAC cells. LINE-1 ORF1p-targeting shRNA significantly inhibits patient-derived PDAC tumor growth both *in vitro* and *in vivo*. Total RNA sequencing (RNA-seq) reveals distinct transcriptional profiles with ORF1p deficiency. Gene set enrichment analysis (GSEA) identified high enrichment of innate immune response-related pathways including IL6-JAK-STAT3 signaling, inflammatory response, interferon response, and apoptosis in ORF1 knockdown PDAC cell lines. These immune related pathways are suppressed by deletion of RIG-I and MAVS, two components of viral RNA sensing. Mechanistically, we demonstrated that ORF1p is associated with repeat RNAs including LINE-1 RNA (*L1HS*) in processing bodies (PBs), which are cytoplasmic membraneless ribonucleoprotein (RNP) granules. In the PBs, ORF1p interacts with MOV10 RNA helicase, an essential enzyme for dsRNA unwinding. Using MOV10 truncated mutants, we found that the ORF1p-MOV10 interaction is important in attenuation of PRR sensing and apoptosis upon repeat RNA exposure. Finally, we evalulated the activation of the innate immune response in the tumor microenvironment by ORF1p depletion. These results suggest that ORF1p loss induces a desmoplastic reaction driven by *Acta2*$^{+}$ myofibroblastic CAFs in response to inflammatory cytokines. Collectively, our results demonstrate a critical and previously uncharacterized role of ORF1p in evasion of endogenous repeat RNA-triggered antiviral immune response in PDAC cells with implications in the tumor microenvironment.

#7481 The allosteric STING agonist CRD3874 is systemically tolerated demonstrates systemic tolerability.

M. Banerjee[1], S. Middya[1], R. Shrivastava[1], A. Middya[1], N. Mane[1], N. Rawat[1], T. Soram[1], D. Chakraborty[1], R. Ghosh[1], R. R. Mansuri[1], D. Yadav[1], A. Gautam[1], A. Singh[1], K. Puniya[1], D. Pryde[2], S. Basu[1], F. Sonego[3], G. H. Martin[3], K. Thiam[3], A. Surya[1];

[1]Curadev Pharma, Noida, India, [2]Curadev Pharma, Sandwich, United Kingdom, [3]genOway, Lyon, France

Background: The activation of STING by CDN bind site targeting ligands leads to the generation of Type I interferons as well as pyroptosis and autophagy of the cell expressing STING due to STING's ability to transport protons across the endoplasmic reticulum. CDN site targeting STING agonists tested in the clinic thus far have shown limited systemic tolerability as well as a tendency to kill the very immune cells that they are designed to activate. CRD3874 is an allosteric small-molecule human STING agonist with a unique binding mode that generates robust Type I interferon responses while simultaneously blocking STINGs proton transport activity that is associated with pyroptosis and autophagy.

Methods: Allosteric binding was established using radioligand binding assays. Anti-cancer activity of CRD3874-SI by the IV route was evaluated in human STING KI C57/BL6 mice (genOway, France). Inflammasome and autophagy markers were studies in human and mouse cells.

Results: In contrast with competitive STING agonists, CRD3874 potentiates the binding of radiolabeled cGAMP to STING. Treatment of immune cells with CRD3874 or other STING agonists, led to dose dependent increases in Type1 interferons and other pro-inflammatory cytokines. However, unlike other STING agonists, activation of STING by CRD3874 did not lead to induction of autophagy or Inflammasome markers in cells or mice. Intravenous administration of CRD3874-SI in human STING knock-in mice caused tumor regression and survival benefit in multiple murine tumor models. The compound was well tolerated at high doses in the primate GLP study when administered intravenously and caused dose and exposure dependent increases in cytokines. This profile of retaining the high efficacy of a STING agonist while demonstrating systemic safety is unique to CRD3874-SI.

Conclusions: CRD3874 is a systemically administered STING agonist with promising single agent activity and an excellent IV safety profile in NHP. An investigator sponsored FIH Phase 1 trial with CRD3874-SI has been initiated at Memorial Sloan Kettering, NY, in sarcoma, MCC patients under the supervision of Dr. Ciara Kelly (NCT06021626).

#7485 Microfluidic detection of dual positive cells in whole blood of metastatic breast cancer patients.
J. Zhou, Q. Luan, C. Macaraniag, A. B. Guzman, M. Mantice, O. Danciu, K. F. Hoskins, I. Papautsky;
University of Illinois at Chicago, Chicago, IL

Background. Dual positive cells (DPCs) that express both epithelial markers and leukocytic markers have been observed in peripheral blood of breast cancer patients. DPCs acquire functional behaviors from both cell types which may drive tumor progression. However, the lack of reliable methods to isolate and identify DPCs has hindered the investigation of their origin and clinical implications in breast cancer patients. While microfluidic devices have been widely used for the detection of circulating tumor cells (CTCs) by liquid biopsy, DPC detection is underexplored in these devices. Herein, we demonstrate rapid onchip isolation and detection of DPCs in whole blood samples from metastatic breast cancer (MBC) patients using an integrated microfluidic device.
Methods. Our microfluidic device consists of a unique preconditioning component that concentrates targets in whole blood and a downstream cell immobilization component that captures target cells. We included 7 female patients with MBC, of which 29% are white (2), 57% are African American (4), and 14% are Latina (1). The median age is 50y (34y -75y). All patients were undergoing systemic breast cancer therapy at the time of blood collection. A total of 9 samples (4 mL each) were collected from either an antecubital vein (peripheral vein) or the subcutaneous port catheter (central vein) of these patients. All samples were processed within 5 hours of blood drawn in our novel microfluidic biochip. CTCs (EpCAM+/CK+, CD45-, DAPI+) and DPCs (EpCAM+/CK+, CD45+/CD66b+, DAPI+) were identified by immunofluorescence after cells were fixed.
Results. Processing of each sample was completed within 40 minutes using our microfluidic device. Both DPCs and CTCs were detected in all the samples (9/9). The average DPC count was 3 DPCs per 4 mL whole blood with a standard deviation of 1.9 cells. The average CTC count was 9 with a standard deviation of 5 per 4 mL whole blood. 89% of the samples (8/9) had > 5 CTCs after the sample volume is scaled to the standard 7.5 mL. No correlation was found between DPC count and CTC count (Pearson correlation coefficient r=0.08). While the blood collection location (central vs peripheral veins) had a significant impact on the CTC count (12.6 vs 4 on average with p<0.01), there was no statistical difference in DPC counts in the samples collected from central and peripheral veins.
Conclusions. Both DPCs and CTCs can be rapidly isolated and detected from MBC patient whole blood in our microfluidic device. Our preliminary results indicate no correlation between DPCs and CTCs, suggesting that DPCs might not originate in blood circulation of MBC patients. More work with a larger patient cohort will be needed to further investigate the clinical implications of DPCs on MBC patients.

#7486 Development and analytic validation of an ARv7/PSMA dual biomarker circulating tumor cell assay.

J. Ladd, E. Bayer, B. Bartels, E. Kaldjian, A. Ramirez;
RareCyte, Inc., Seattle, WA

Background Prostate cancer drug targets and biomarkers may be investigated non-invasively on circulating tumor cells (CTCs) obtained via liquid biopsies. PSMA is an important drug target in prostate cancer, and ARv7 is a splice variant that confers resistance to second-generation androgen receptor inhibitors. In this study, we describe the development and analytic validation of a novel assay to quantify ARv7 and PSMA protein expression on CTCs. The assay was validated with blood samples from patients with Stage IV prostate cancer to demonstrate clinical feasibility. To our knowledge, a PSMA/ARv7 dual protein assay for CTCs has not previously been reported.

Methods LNCaP (PSMA positive), PC3 (PSMA negative), 22Rv1 (ARv7 positive), and BT474 (ARv7 negative) cells were spiked into healthy donor blood to generate model CTCs. Nucleated cells were collected from these spike-in samples using the AccuCyte® sample preparation kit and spread onto microscope slides. Slides were fixed and stained with antibodies to cytokeratin, EpCAM, and CD45 to detect CTCs and exclude white blood cells (WBCs), and with PSMA and ARv7 to evaluate protein expression on identified CTCs. The slides were imaged with the CyteFinder® automated immunofluorescence scanning microscope that identifies CTCs for confirmation by trained reviewers based on machine learning algorithms and quantitatively measures biomarker signal mean fluorescence intensity (MFI).

Results For ARv7/PSMA expression classification of the model CTCs, the dual biomarker assay showed analytic sensitivity of 83%/97% and specificity 98%/99%, yielding accuracy of 90.2%/97.9%, respectively. The dynamic range of MFI for both biomarkers was approximately three orders of magnitude. Inter-run reproducibility CV was 13.6% (ARv7) and 6.9% (PSMA). Slide repeatability mean CV was 11.1% (ARv7) and 12.0% (PSMA). Clinical feasibility of the assay was investigated in 9 progressing Stage IV prostate cancer patient blood samples. CTCs were identified in all clinical samples (median 4, range 1 - 384). Thresholds for biomarker positivity were established based on MFI measurements of positive and negative control cell lines. ARv7 positivity in clinical samples ranged from 33% to 100%, and PSMA positivity ranged from 0% to 75%.

Conclusions We have developed a dual ARv7/PSMA assay that simultaneously measures protein expression of both biomarkers on individual CTCs. The assay is accurate and reproducible for the assessment of ARv7 and PSMA expression by liquid biopsy in clinical studies.

#7487 Construction of a reliable CTC detection method and validity evaluation of CTC markers in colorectal cancer.

Y. Takahashi[1], Y. Ijiri[1], S. Fujino[2], N. Elnaz[1], A. Kishimoto[1], K. Shirai[1], S. Iwanaga[1], M. Yanagida[1], A. A. Bhagat[3], N. Miyoshi[2];
[1]Sysmex Corporation, Kobe, Japan, [2]Osaka International Cancer Institute, Osaka, Japan, [3]Biolidics Ltd, Mapex, Singapore

Even in modern times when medical technology has advanced, cancer remains a life-threatening disease, and recurrence and metastasis are major issues in cancer treatment. The characteristics of cancer cells change with progression and treatment. Therefore, timely evaluation on their characteristics and decision on the treatment strategy are required. Circulating tumor cells (CTCs) are released into blood vessels in solid tumors and promote metastasis by circulating in the blood. CTCs are thus attractive targets for liquid biopsy and can provide useful information for selection of appropriate treatment. To obtain reliable results from CTC testing, it is important to prove that the detected cells are derived from cancerous tissue. In molecular tests targeting CTCs, it is still unclear whether the detected cells are derived from cancer tissue displaying genetic mutations. Aiming to establish reliable CTC testing, we have developed a simple method using molecular imaging flow cytometry to detect APC gene mutation together with Cytokeratin and Vimentin, which are epithelial-mesenchymal transition markers. Since, abnormalities in the APC gene are detected in 60-70% of colorectal cancer patients, detecting such mutations provides strong evidence that the detected cells are derived from cancerous tissue. Here, we show that upon evaluation of analytical performance of our method using cells isolated from cancerous tissue, our method showed high concordance rate against APC gene mutation. A clinical proof-of-concept using 5 mL of whole blood from colorectal cancer patients revealed that counts of cells with APC mutation in blood and cells with Cytokeratin and/or Vimentin expression in blood are highly correlated. Our results demonstrated a pathological stage-dependent increase in the count and frequency of Cytokeratin and/or Vimentin positive CTCs. We believe that our study not only establishes a practical approach for identifying CTCs in cancer patients but also provides potential implications in clinical practice, prognostic evaluation, and selection of treatment strategies.

#7488 Detection of *PD-L1* mRNA expression in circulating tumor cells (CTCs) from patients with metastatic NSCLC, HNSCC and melanoma using a novel highly sensitive commercially available CE-IVD kit.

A. Strati[1], M. Zavridou[1], S. Smilkou[1], V. Tserpeli[1], E. Tzanikou[2], D. Stergiopoulou[2], E. Efthimiadou[1], E. Tsaroucha[3], A. Psyrri[4], A. Sfika[5], E. Bournakis[5], I. Balgkouranidou[6], S. Kakolyris[6], I. Boukovinas[7], C. Papadimitriou[8], L. Kaklamanis[9], I. Koukli[2], **E. Lianidou[1]**;
[1]National & Kapodistrian University of Athens, Athens, Greece, [2]Pharmassist Ltd, Athens, Greece, [3]"SOTIRIA" General Hospital of Athens, Athens, Greece, [4]Attikon University Hospital, Athens, Greece, [5]Aretaieio University Hospital, Athens, Greece, [6]University General Hospital of Alexandroupolis, Athens, Greece, [7]BIOCLINIKI Hospital, Athens, Greece, [8]Araiteio University Hospital, Athens, Greece, [9]Onassis Cardiac Surgery Center, Athens, Greece

Background: We have previously reported the development of an RT-qPCR assay for *PD-L1* expression in CTCs (Strati et al, Ann Oncol, 2017). This assay is now commercially available as Oncolipsy *PD-L1* kit (CE-IVD, Pharmassist, Greece) and we report here it's application in size-based enriched CTCs from patients with metastatic NSCLC, HNSCC and melanoma, before and during PD-1/PD-L1 blockade therapies.
Patients and Methods: The Oncolipsy *PD-L1* kit was analytically validated using Mini-Genes as positive controls (IDT, USA). The analytical sensitivity was tested by spiking known numbers of H1975 cells in peripheral blood (PB) samples from healthy donors (HD). In total 95 patients were enrolled in the study: 69 patients with metastatic NSCLC, 19 patients with metastatic HNSCC and 7 patients with metastatic melanoma. 40 PB samples from HD were used as a control group. 10 ml of PB was collected at baseline (V0), two months after immunotherapy (V1) and at the time of disease progression (PD) or 18 months after initiation of immunotherapy (V2). *PD-L1* and *B2M* transcripts were quantified in cDNAs obtained from CTCs isolated with the size-based PARSORTIX (ANGLE, UK) device. A sample was considered as CTC-positive when cDNAs were positive for *CK-8, CK-18* or *CK-19* expression.
Results: Spiking experiments have shown that 10 H1975cells/10ml PB can be detected using the kit. In CTC-positive samples, overexpression of *PD-L1* was detected in 15/58(25.8%) patients at V0, in 6/34(17.6%) patients at V1 and in 3/11(27.3%) at V2. Patients with elevated expression of *PD-L1* at V1 in respect to V0 and detectable CTCs had longer PFS (18.5mo vs. 13.2mo, p=0.033) and longer OS (24.8mo vs. 12.8mo, p = 0.071) after initiation of immunotherapy. Patients with elevated *PD-L1* at V1 compared to V0 benefited from immunotherapy, with a longer DFS (17.8mo vs. 13.4mo) and OS (29.4mo vs. 26.9mo).
Conclusions: The commercially available Oncolipsy *PD-L1* kit can be used for the quantification of *PD-L1* transcripts in CTCs. Expression of *PD-L1* in size-based enriched CTCs can predict response to PD-1/PD-L1 blockade therapy.

#7489 Peripheral blood liquid biopsy for the screening of lung cancer.

J. Seo[1], S. N. Shishido[1], J. Mason[1], C. R. Velasco[1], A. Chen[1], D. Rothwell[2], P. Crosbie[2], J. Hicks[1], C. Dive[3], P. Kuhn[1];
[1]USC - University of Southern California, Los Angeles, CA, [2]University of Manchester, Manchester, United Kingdom, [3]University of Manchester and University College London, Manchester, United Kingdom

Lung cancer is the second most common type of cancer in both men and women and the leading cause of cancer-related mortality. Unfortunately, most patients have advanced stages (stage III or IV) at the time of diagnosis and the only U.S. Preventive Services Task Force-recommended screening test, Low Dose CT scan (LDCT), has a high false-positive rate. Therefore, there is an urgent need for the early detection of lung cancer with better discrimination between individuals with lung cancer and those without. In this study, we demonstrate the capability of a non-enrichment-based liquid biopsy workflow, the High Definition Single Cell Assay (HDSCA) to be used as a complementary tool to the current screening methodology. The HDSCA workflow can detect circulating cells of epithelial, mesenchymal, endothelial, and hematological origin, as well as acellular events such as oncosomes. This allows the investigation of the broad spectrum of circulating rare events for the potential identification of biomarkers associated with lung cancer. We investigated 52 peripheral blood samples collected from the second annual screening round of Manchester's 'Lung Health Check' pilot of a community-based lung cancer screening cohort. Of these, 7 were subsequently diagnosed with non-small cell lung cancer, 2 with small cell lung cancer, and 43 were deemed at high risk of developing lung cancer. We additionally investigated 60 peripheral blood samples from individuals with no known pathology to use as controls. Within the screening cohort, a number of single rare analytes were found to have statistically significant differences between the lung cancer, high-risk cohort, and normal blood donor samples, which can potentially be biomarkers used to differentiate the cohorts. We also built a multi-analyte patient-level classification model utilizing the rare cellular and acellular events that stratified lung cancer patients from the normal donor individuals and high-risk cohort with high accuracy. Our results demonstrate the potential of liquid biopsy as a complementary screening approach for lung cancer.

#7490 Clinical utility of liquid biopsy in early stage lung cancer: A single institution experience.

K. Beshiri[1], A. Marinello[1], D. Vasseur[1], L. Zullo[1], M. V. Sanchez Becerra[1], A. Pagliaro[1], M. Cani[1], C. Parisi[1], P. Lavaud[1], M. Frelaut[1], P. Abdayem[1], A. Gazzah[1], A. Botticella[1], A. Levy[1], C. Le Pechoux[1], O. Mercier[2], S. Ponce[1], F. Barlesi[1], D. Planchard[1], A. Italiano[1], B. Besse[1], J. Remon[1], M. Aldea[1]; [1]Gustave Roussy Institute, Villejuif, France, [2]Marie Lannelongue Hospital, Le Plessis-Robinson, France

INTRODUCTION

Liquid biopsy (LB) proved its clinical utility in advanced non-small cell lung cancer, but its role in early-stage disease is less clear. Here, we investigated the clinical utility of LB for molecular diagnosis in early-stage lung cancer and its correlation with cancer relapse.

METHODS

This retrospective, monocentric study collected results from LB performed in patients (pts) with an early-stage lung cancer between January 2021 and May 2023, within the prospective STING study (NCT04932525). LBs were executed at different time points (before, after curative treatment, or under treatment), by using the Foundation One Liquid Dx panel. All patients had tissue molecular testing for at least *EGFR, ALK* and *KRAS* alterations. LB was considered positive (ctDNA+) if ≥ 1cancer-related alteration was identified and negative (ctDNA-) in the absence of somatic alterations or the presence of clonal hematopoiesis (CH) only. Disease-free survival (DFS) was calculated from diagnosis to cancer relapse or last follow-up, and correlated with LB results.

RESULTS

A total of 52 pts were included and 52 LBs were conducted. Pts had a median age of 63 years, 40% (25/52) were females, and 84% (43/51) had a smoking history with a median pack-years of 37.5 [4-100]. Adenocarcinoma was the most common histology (48% 25/52), followed by squamous carcinoma (23% 12/52), undifferentiated (20% 10/52) and other hystologies (9% 5/52). Patients had stage I disease in 10% (5/52), stage II in 11% (6/52) and stage III in 79% (41/52). LB was performed before curative treatment in 35/52 (67%), after curative treatment in 6/52 (11.5%) and during curative treatment in 12/52 (23%). Overall, LB was positive in 57% (30/52) of cases: 63% (26/41) in stage III and 36% (4/11) in stage I/II. Major driver mutations identified in tissue were then found in 61.5% (8/13) of LBs. The concordance between LB and tissue findings was 100% in pts with ctDNA+ (7 KRAS, 4 EGFR, 1 ALK, 1 HER2 ampl). CH was present in 66.7% (20/30) of ctDNA+ LB and 47.8% (11/23) of ctDNA- LB. Median tumor mutational burden (TMB) in ctDNA+ LB was 5.5 mut/Mb, with 4 cases of TMB >16. Median follow-up was 12.6 months (mo). In pts with ctDNA+ versus ctDNA- LB, mDFS was 12.9 mo (95% 6.3-18.6) versus 27.7 mo (95%CI 12.7- NR), p=0.07, in the overall population and 12.9 mo (95%CI 7.8-19.2) versus 27.2 mo (12.7-NR) respectively, p=0.19, in pts with stage III disease.

CONCLUSIONS

LB has informal results for molecular diagnosis in nearly half of pts with an early-stage lung cancer. The high frequency of CH may lead to LB misinterpretation as false positive and requires caution. The potential association of positive LB with earlier relapse requires further investigation in larger cohorts with a longer follow-up. Results will be updated by the time of meeting.

#7491 ctDNA liquid biopsy result among gynecologic cancer patients: Does it give additional information?.

M. Kim;
Samsung Changwon Hospital, Changwon-si, Korea, Republic of

Objectives: There are many target molecules for precisional cancer therapy Precision diagnosis-based target treatment is believed to be better survival approach compared than conventional treatment. Predictive markers are variant and vast. This study evaluated the initial experience of ctDNA liquid biopsy as a precision tumor marker for gynecologic cancer patients?
Methods: we retrospectively identified ovary/endometrial and cervical cancer patients who approved ctDNA test for various purpose. Two methods were used. Guardant 360 and Foundation One Liquid CDx.
Results: There were 31 cases. Median age was 60(46-84). Half of cases were ovarian cancer(17/31 55%).Cervix and endometrial cancer are 12(39%) and 2(6%).We found about ten percentages of actional genetic mutation patients(3/31).Two BRCA1 mutation(each patients have variant allele frequency(VAF) percentages are 50.4,49.6).One high bTMB(blood tumor mutational burden)was 21.There was no mutation in 6/31(19 %).
Conclusions: It seems additional supportive information may be acquired through well-established ctDNA liquid biopsy test among this population. Role of ctDNA liquid biopsy test for precision tumor marker should be investigated for future study.

#7492 Automated identification and enumeration of CELLSEARCH Circulating Tumor Cells (CTC) with a deep learning algorithm.

L. Biasiolli, P. Ansaloni, N. Gentili, D. Giardiello, F. Montanari, R. Miserendino, G. Signorini, G. Medoro;
Menarini Silicon Biosystems, Bologna, Italy

Introduction: CTC enumeration in blood samples with CELLSEARCH® is a prognostic biomarker in metastatic breast, prostate and colorectal cancer (full intended use documents.cellsearchctc.com). Currently, CTC identification is performed by visual assessment, which is time-consuming and potentially affected by subjective interpretations. Recently, we developed a Deep Learning (DL) algorithm for automated CTC identification in CELLSEARCH images (CellFind®, Menarini Silicon Biosystems, research use only). This study aims to assess the CTC identification performance of CellFind on 2 different datasets: the first for comparison with human reviewers, and the second for validation with much higher number of images.
Methods: CellFind is composed of an image segmentation followed by a classification network, which was trained using 13067 CTC and 52890 non-CTC images from 215 breast, 123 prostate and 180 colorectal cancer samples. The performance of CellFind was tested on 2 separate datasets. 1) The first dataset was made of CELLSEARCH gallery images from 26 breast cancer, 68 prostate cancer, and 40 benign samples. 8 human reviewers, qualified for CTC image analysis, performed blind labeling. The Ground Truth (GT) was generated by the classification of the 3 most experienced reviewers by majority voting (1621 CTCs out of 17080 images). Accuracy and F1 metrics were used to rank the performance of DL and 5 reviewers against the GT. 2) The second dataset was made of CELLSEARCH gallery images from 63 breast, 66 prostate and 32 colorectal cancer samples. 3 experienced reviewers created the GT classification by majority voting, identifying 20052 CTCs out of 117447 images.Finally, each patient was assigned to the favorable or unfavorable group by applying the validated cutoff on CTC enumeration per sample (CTC≥5 for breast and prostate cancer, CTC≥3 for colorectal cancer).
Results: 1) On 17080 gallery images from 134 samples, CellFind reached top human-level performance, as ranked both by accuracy (97.8% for DL vs. 96.8-98.0%) and F1 (88.6% for DL vs. 83.3-89.9% for reviewers). On the 94 cancer samples, DL accuracy on favorable/unfavorable prognosis was 98.9% vs. 95.8-97.9% for reviewers. 2) On the bigger dataset with 117447 gallery images from 161 cancer samples, CellFind obtained accuracy = 96.0% and F1 = 87.8% for CTC identification (TP = 17039, FP = 1735, FN = 3013, TN = 95660). For favorable/unfavorable prognosis the DL accuracy was 95.4%.
Conclusion: Automated identification and enumeration of CTCs in CELLSEARCH images with CellFind can remove human subjectivity from the review process and maximize standardization among different research centers. CellFind performed better than most operators and reduced the data processing time required for each blood sample by the operator.

#7493 Real-time monitoring of CTC number, biomarker expression, and kinetics as prognostic and predictive markers in patients with GI malignancies.

E. G. Bayer[1], B. M. Bartels[1], R. N. Ponting[1], A. Lutfi[2], M. K. Afghan[2], A. B. Ramirez[1], P. M. Kasi[2];
[1]RareCyte, Inc., Seattle, WA, [2]Weill Cornell Medicine, Cornell University, New York, NY

Background: Most of the utility in the clinic regarding liquid biopsies has been around circulating tumor DNA (ctDNA). ctDNA analysis provides valuable insight into mutational burden and therapeutic targets, but the speed and cost of analysis are prohibitive especially when it comes to serial testing. Using a cohort of patients with advanced or metastatic gastrointestinal (GI) cancers, we herein show the feasibility of using circulating tumor cell (CTC) enumeration, biomarker analysis, and kinetics as complementary to or as an alternative to ctDNA testing.
Methods: Using the RareCyte platform, nucleated cells from blood were collected, spread on slides, stained, and imaged with CyteFinder® for CTC identification (CK/EpCAM+, CD45-) and quantification of biomarkers (PD-L1/HER2 or Ki67/EGFR). CTC enumeration (CLIA-accredited CTC test) and biomarker status for each patient were tracked over time and compared with ctDNA mutational analysis and tumor burden.
Results: CTCs were detected in 60/70 samples (86%) and in 36/38 unique patients (95%). On average, more CTCs were detected in baseline samples from colorectal cancer patients compared to other subtypes (Table 1). Moreover, multiple patients showed pronounced changes in CTC number that correlated with treatment response, as well as strong correlation between CTC and tissue biomarker expression e.g. HER2. Rapid decline and/or CTC clearance was seen as early as a few days into starting effective systemic therapy. The average turnaround time for CTC testing was 5-7 days.
Conclusions: Our study emphasizes that real-time monitoring of CTCs is complementary to traditional tumor burden monitoring via imaging and ctDNA analysis. CTCs offer multiple unique advantages vs ctDNA including early response assessment within days of initiating therapy, a substantial decrease in cost of serial testing, and the ability to assess clinically relevant cell surface protein biomarkers e.g. HER2 and PD-L1.

Table 1. CTC values in initial baseline blood draw sample

Gastrointestinal cancer subtype	# of patients	Average # of CTCs per 7.5mL blood	Median # of CTCs per 7.5mL blood	Minimum # of CTCs per 7.5mL blood	Maximum # of CTCs per 7.5mL blood
Colorectal carcinoma	27	84	3	0	1378
Cholangiocarcinoma	3	8	3	1	23
Pancreatic cancer	3	2	2	0	3
Hepatocellular carcinoma	2	4	5	0	10
Gallbladder cancer	1	6	6	3	8
Appendix cancer	1	2	2	1	3
Anal cancer	1	0	0	0	0

#7494 Pan-cancer analysis of circulating tumor organoid drug sensitivity revealed differential distribution of viability dependence among cancer hallmark modules.

Y. Chen[1], **S.-P. Wu**[2], Y.-J. Chen[3], L.-S. Lu[4];

Background: Patient-derived organoids represent an opportunity into deciphering human cancer biology at the personal-level resolution. Phenotyping living cell properties, such as drug sensitivity, complements deep sequencing to improve the prediction of cancer treatment response and holds promises for functional precision medicine. Modern cancer therapeutics target genetic alterations in modular networks, also known as cancer hallmarks, which drive biological essentialities for cancer progression. However, it remains elusive the relative robustness of each module among the naturally occurring solid tumors.
Methods: In order to explore this issue, we analyzed a drug sensitivity database of a collection of circulating tumor cells-derived organoids (CDO) from 532 patients with advanced/metastatic solid tumors to 15 chemicals. In this collection, each CDO was derived from 20 ml peripheral blood on a binary colloid crystal cell culture system over 4 weeks. CDO were tested for survival fraction at the Cmax of the designated chemicals. Cell viability was measured with ATP abundance normalized to vehicle controls. For each chemical tested, the probability density function (PDF) of drug sensitivity was fitted to log normal distribution and goodness of fit was analyzed with Kolmogorov Smirnov test with the significance cut-off set to 0.05. The targeted biological pathway of each chemical was mapped to canonical human pathways in the Gene Ontology and KEGG databases. Strength of the specific evolution conserved module (ECM) was evaluated with the published analysis using clustering by inferred models of evolution (CLIME) algorithm.
Results: There were 25 types of tumors in the database. The top 3 tumor types were soft-tissue sarcoma, breast cancers, central nervous system tumor. The average number in each tumor type was 21. The PDF of commonly known chemotherapeutic agents, such as gemcitabine, doxorubicin, docetaxel followed log normal distribution. In contrast, the PDF of commonly known biological targeted agents such as everolimus, cabozantinib or enzalutamide do not. For chemicals whose PDF followed a log normal distribution, the biological pathways that were affected tend to have a higher strength of ECM value.
Conclusions: Our early analysis revealed the feasibility to quantitatively estimate the robustness of biological pathways in the cancer hallmark modules with a CDO bank. The biological implication of deviation from classical log normal distribution for biologically targeted agents warrants further investigation.

#7495 Validation of microfluidic isolation of circulating pancreatic tumor cells from blood.

C. Macaraniag, I. Khan, J. Zhou, P. C. Giulianotti, A. Borgeat, G. Votta-Velis, I. Papautsky;
University of Illinois at Chicago, Chicago, IL

Background. Pancreatic ductal adenocarcinoma (PDAC) has a poor prognosis and is the fourth leading cause of cancer-related deaths in the US. PDAC is diagnosed in the late stages, which limits treatment options and yields poor clinical outcomes. Recurrence is a significant issue for patients undergoing surgery for PDAC. Circulating tumor cells (CTCs) are thought to be a potential mediator of recurrence, facilitating the formation of secondary tumor sites after surgery. Thus, there is a need to isolate CTCs to improve understanding of disease recurrence, to ultimately improve outcomes. Herein, we aim to validate our inertial microfluidic (iMF) system for isolating pancreatic CTCs from blood. We also benchmark our iMF system to a commercially available immunomagnetic negative selection system, EasySep™, and quantify target cell recovery and cell enrichment.

Methods. Our iMF system employs the differential cell sizes of CTCs from blood cells and inertial migration of such cells in a straight microchannel (150 µm × 50 µm × 24 mm) to enrich CTCs from blood. The iMF system sample flow rate used is 100 µL/min, with a 200 µL/min PBS buffer flow rate. The EasySep™ Direct Human CTC Enrichment kit targets CD2, CD14, CD16, CD19, CD45, CD61, CD66b, and Glycophorin to remove blood cells from the sample using magnetic particles, thereby separating them from CTCs. We spiked low cell concentrations of 50, 100, and 500 Hoechst-stained pancreatic carcinoma cells, PANC1, in 1 mL of healthy blood then captured using either EasySep™ or iMF. Cell enumeration was performed after centrifugation or Cytospin.

Results. PANC1 cells and WBCs have average sizes of 18 µm and 8.4 µm, respectively. We characterized our iMF device to capture cells ≥ 12 µm, which yields capture of most PANC1 cells. Indeed, our iMF system achieved 82.8±19.2%, 72.5±16.3%, and 59.3±3.8% recovery for 50, 100, and 500 cell-spikes in lysed blood, respectively. For the same 50, 100, and 500 cell-spikes, the total iMF CTC yields after Cytospin were 46.3±11.8, 44.3±9.1, and 32.7±2.1%, while the total CTC yields from EasySep™ were 4.6±3, 5.3±2.1, 8.3±1%, respectively. When we processed whole blood directly, EasySep™ had lower cell recovery, 3.8±0.2, 4.6±1, and 3.3±0.4%, respectively. Our system also demonstrated 8× higher target cell enrichment compared to EasySep™. Blood lysis before iMF separation did not drastically affect the recovery of target cells.

Conclusions. We determined that our system has improved performance over the commercial isolation system, EasySep™, thereby validating the effectiveness of microfluidic isolation for PDAC. In future studies, we can then use our iMF system in CTC isolation from routine blood draws from PDAC patients undergoing surgical resection. We may then isolate real patient samples and study relevant phenotypes of PDAC CTCs which may therefore be used for identifying certain mechanisms of PDAC progression.

#7496 The piritramide-based perioperative analgesia can affect the cancer dissemination in colorectal cancer patients.

J. Srovnal[1], E. Berta[1], M. Vidlarova[1], A. Rehulkova[1], K. Jecmenova[1], M. Popper[1], A. Srovnalova[1], P. Prasil[2], P. Skalicky[3], T. Gabrhelik[4], J. Maca[5], P. Michalek[6], M. Hajduch[1];

[1]Faculty of Medicine, Palacky University, Olomouc, Czech Republic, [2]Landesklinikum in Amstetten, Amstetten, Austria, [3]University Hospital in Olomouc, Olomouc, Czech Republic, [4]The Tomas Bata Regional Hospital, Zlin, Czech Republic, [5]University Hospital in Ostrava, Ostrava, Czech Republic, [6]General University Hospital, Charles University, Prague, Czech Republic

Introduction: Colorectal cancer (CRC) stands as a prominent contributor to global cancer-related mortality. Post-surgical management of CRC patients often involves the administration of opioid analgesics. These analgesics operate through opioid and cannabinoid receptors, pathways implicated in tumor progression and metastasis, potentially impacting patient survival adversely. This investigation delves into the influence of piritramide and morphine on cancer dissemination, encompassing in vitro and in vivo assessments, cytotoxicity analyses, and elucidation of their mode of action.

Methods: The presence of circulating tumor cells (CTCs) in the blood of 131 CRC patients was quantitatively assessed using the real-time polymerase chain reaction (qPCR) method. Cytotoxic effects of morphine and piritramide were evaluated via colony-forming assays (CFA) utilizing HCT116 and HT29 cell lines. The impact of piritramide and morphine on opioid receptor activity was gauged through transfected reporter cell lines and fluorescence imaging plater reader (FLIPR) calcium assays. *In vivo* models involving subcutaneous and intrasplenic administration in SCID and BALB mice, respectively, utilizing HCT116 and HT29 cell lines, were conducted. Morphological profiling, employing the cell painting assay, facilitated high-content image-based analysis on both cell lines.

Results: Perioperative analgesia with piritramide exhibited a tendency towards longer time to recurrence (TTR) survival in CRC patients (HR=1.8, p=0.104). Conversely, morphine-treated patients demonstrated a twofold increase in TTR events (HR=4.7, p=0.011). Piritramide, but not morphine, significantly inhibited colony growth in HCT116 and HT-29 cell lines in the CFA, consistent with cytotoxicity test results. Functional assays revealed agonistic effects of both piritramide and morphine on opioid receptor kappa 1 (OPRK1) and mu 1 (OPRM1), with piritramide exhibiting greater potency as an OPRK1 agonist. In the SCID mice model, subcutaneous application of HT29 cell lines resulted in significantly reduced tumor growth in piritramide-treated mice. In the intrasplenic model utilizing BALB mice, mice treated with piritramide exhibited diminished tumor growth and a reduction in both the number and size of metastases. Comparative analysis with reference compounds revealed a distinct phenotypic profile of piritramide affecting the endoplasmic reticulum.

Conclusion: Piritramide, as opposed to morphine, demonstrated cytotoxic effects on both *in vitro* and *in vivo* CRC cell lines, resulting in reduced tumor growth and dissemination. Perioperative analgesia with piritramide exhibited potential in improving time to recurrence survival in CRC patients.

Corp, Seoul, Korea, Republic of, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [6]Cichlid. Inc, Seoul, Korea, Republic of

Introduction: The successful outcomes observed in clinical trials emphasize the effectiveness of therapeutic approaches relying on biomarker tests, particularly in the development of cancer drugs. The parallel development of a drug and its associated predictive biomarker is considered an ideal strategy for achieving rapid and successful drug development in precision medicine. In this context, we employ an automated circulating tumor cell (CTC) isolation platform, known as GenoCTC, to facilitate the development of biomarker-driven CTC assays, with the ultimate goal of developing companion diagnostic (CDx) tests. Method: This study employed the 5th generation GenoCTC device, a fully automated system designed for marker-based CTC enrichment using immune magnetophoresis. We confirmed the isolation of CTCs through spiking tests, utilizing cancer biomarkers such as cMET, Mesothelin (MSLN), and Claudin 3 (CLDN3). cMET is a biomarker extensively studied in various cancers, particularly non-small cell lung cancer. We previously showed the prognostic significance of cMET expressing CTCs in HR+ and HER2- metastatic breast cancer patients. MSLN and CLDN3 are tumor-associated proteins showing overexpression across diverse cancer types, with a potential for the development of antibody-based cytotoxic drugs. The GenoCTC device allows efficient separation of CTCs expressing these biomarkers, ensuring high accuracy, precision, specificity, and sensitivity. Simultaneously, therapeutic drugs directed at these markers are progressing through phase trials or preclinical studies. Conclusion: Our results show that cMET, MSLN, and CLDN3 are potential markers for the development of biomarker tests, that can improve the patient selection process for personalized therapy targeting these biomarkers.

#7498 Acoustophoresis enriches tumor cell clusters from patients with metastatic prostate cancer.

C. Magnusson[1], P. Augustsson[1], A. Lenshof[1], A. Josefsson[2], A. Bjartell[1], Y. Ceder[1], H. Lilja[3], T. Laurell[1];
[1]Lund University, Lund, Sweden, [2]Umea University, Umea, Sweden, [3]MSKCC, New York, NY

Purpose: A subset of aggressive prostate cancers (PCa) progress to invade surrounding tissue to form distant metastases by shed of circulating tumor cells (CTCs). However, due to the scarcity of CTCs among the millions of nucleated blood cells, there is an unmet need to improve CTC isolation assays. Our technique *Acoustophoresis* uses standing ultrasound waves in a flow-through microfluidic chamber to discriminate cells based on their size, density, and compressibility.

Method: We analyzed the effectiveness of acoustophoretic circulating tumor cell (CTC) isolation from 6 mL PFA fixed red blood cell lysed blood from 12 metastatic prostate cancer patients and 20 healthy control subjects and compared it to the golden standard CellSearch. For acoustic cell separation, cells were diluted in 12 mL PBS based buffer and separated by acoustophoresis and analyzed by imaging flow cytometry using a standardized antibody panel (EpCAM, cytokeratin, CD45, CD66b, DAPI). Generally, CTCs, and clusters migrate faster than white blood cells (WBCs) when exposed to ultrasound in the microchannel during acoustophoresis and can therefore be separated from nucleated blood cells.

Major findings: Our pilot study shows that acoustophoresis finds both singlets and clusters of CTCs in patients as well as aggregates of CTCs and WBCs. In total, 67 cancer cell containing cell clusters were identified. Most identified cell clusters were small, containing less than 4 cells. In addition, acoustophoresis is a label-free separation technique, and could therefore identify additional subclasses of CTCs among the detected CTCs with e.g., EpCAM low/- expression. Further, we provide extensive data for the effect of storage time on acoustophoretic separation performance for fixed prostate cancer cell line cells and WBCs. Demonstrating that sample processing can be done up to 72 hours after blood sampling. We believe this is to date the most comprehensive study of acoustic separation of CTCs in patients and control subjects.

Conclusion: Label-free acoustophoresis is a potential method for future non-invasive molecular interrogation of metastatic cancers. We believe Acoustophoresis is a promising technology for CTC enrichment with the possibility to detect new subclasses of CTCs as well as cell clusters not detectable with CellSearch. CTC-clusters has previously been proposed as a promising and potent predictor to monitor progressive disease and is associated with earlier onset of metastatic disease and poor prognosis, which makes acoustophoresis ability to identify clusters of high interest.

#7499 Circulating tumor cell enumeration and protein expression by CapioCyte and Allegro Plus imaging.

J.-h. Lim[1], C. Johnson[2], T. Kaplan[2], M. J. Poellmann[3], Y. Harari[2], E. Kfir[2], A. Z. Wang[3], S. Hong[3];
[1]CAPIO BIOSCIENCES KOREA, Incheon, Korea, Republic of, [2]BioView Ltd., Rehobot, Israel, [3]CAPIO BIOSCIENCES, INC, MADISON, WI

Radiation or chemoradiation followed by surgical resection is the current standard of therapy for many diseases. These treatments are increasingly supplemented with monoclonal antibodies, such as epidermal growth factor receptor (EGFR)-targeting and programmed death ligand 1 (PD-L1) checkpoint-blocking antibodies. The use of these therapies is typically dependent on solid tissue biopsy to confirm elevated expression of these markers in the solid tumor, which carries complications and may only be sampled at diagnosis. In contrast, a liquid biopsy may detect these markers with minimal invasiveness and at multiple points throughout treatment and recovery. Here, we describe the development of an automated and integrated workflow for circulating tumor cell (CTC) analysis. We previously demonstrated that the CapioCyte method is a highly sensitive approach for enrichment of CTCs using a combination of biomimetic rolling on recombinant E-selectin and antibody-mediated capture on a nanostructured polymer surface within a flow chamber for capture. Here we report a fully automated CapioCyte instrument for CTC purification and immunofluorescence staining using epithelial, white blood cell and nuclear makers to identify and distinguish CTCs from WBCs while also quantifying EGFR or PD-L1 presence on respective CTCs. The immunostaining conditions were developed and validated for high analytical sensitivity and specificity using cell lines and health donor white blood cells with known biomarker status. The final assay conditions were transferred to the CapioCyte for automated immunostaining. CapioCyte enriched and stained CTC samples are paired with the BioView Allegro Plus platform, an imaging and analysis solution using machine learning and customized algorithms for automated imaging and CTC candidate identification based on high-resolution Z-stack images. The reported comprehensive and automated workflow was used to enumerate CTCs in patients with non-small cell lung carcinoma (NSCLC) in a feasibility cohort. Median CTC counts from NSCLC patients was 7.5 CTC/ml (n=26, mean 51.7, range 0.3 - 406.2). Studies are on-going to expand the cohort including testing blood from head and neck cancer patients and respective EGFR and PD-L1 status. The combined and automated CapioCyte-Allegro Plus workflow shows great potential for routine quantification of CTCs and EGFR and PD-L1 status.

#7500 Distribution and prognostic significance of circulating tumor cells (CTCs) and tumor-derived extracellular vesicles (tdEVs) in patients (pts) with lobular metastatic breast cancer (MBC).

E. Nicolo[1], L. Gerratana[2], L. Foffano[2], L. Munoz-Arcos[1], M. S. Serafini[1], M. Manai[1], L. Pontolillo[1], N. Bayou[1], E. Molteni[1], A. K. Strickland[1], C. Gianni[1], Y. Zhang[3], P. D'Amico[3], A. A. Davis[4], J. Donahue[1], H. Liu[3], W. J. Gradishar[3], A. N. Shah[3], G. Curigliano[5], C. Reduzzi[1], M. Cristofanilli[1];
[1]Weill Cornell Medicine, New York, NY, [2]Centro di Riferimento Oncologico di Aviano (CRO) IRCCS, PN, Aviano, Italy, [3]Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL, [4]Washington University in St. Louis, St. Louis, MO, [5]European Institute of Oncology, Milan, Italy

Background

Invasive lobular carcinoma (ILC) has distinctive clinical and molecular features compared with invasive ductal carcinoma (IDC). CTCs and tdEVs are independent prognostic factors in MBC, however, liquid biopsy studies focusing on ILC are to date scarce. Higher CTC levels have been observed in ILC than IDC. One study including 28 ILC pts suggested the use of higher CTC cutoff for prognosis stratification. The clinical significance of tdEVs in ILC is unexplored. This study aimed to assess differences in the distribution and prognostic value of CTCs and tdEVs between ILC and IDC.

Methods

Blood samples were collected from 304 pts with MBC before starting a new line of therapy at Northwestern University (Chicago, IL) between 2016 and 2021 (NU16B06 trial). Blood was processed with the CellSearch® system. The ACCEPT software was applied to CellSearch® images to automatically enumerate CTCs and tdEVs. Association of CTCs and tdEVs with overall survival (OS) was tested in ILC and IDC pts. A count of CTCs ≥ 5 was considered high. The cutoff levels for tdEVs were < 20 (low), 20-79 (intermediate), and ≥ 80 (high), as previously reported. Additional exploratory cutoffs for CTCs (≥ 20, ≥ 50, ≥ 80, and ≥ 100) and tdEVs (based on quartiles of tdEV distribution in the overall population and ILC) were also evaluated.

Results

Of the 304 pts, 47 had ILC while 257 had IDC. 56% of pts received first-line therapy. Median CTC count was 8 [interquartile range (IQR) 2-35] in ILC and 1 (IQR 0-8) in IDC pts (P <.001). A significantly higher median tdEVs count was observed in ILC (36; IQR 18-115) than in IDC (11; IQR 2-86) pts (P =.002). High levels of CTCs (≥5) were not associated with OS in ILC (P =.88), even when higher cutoffs (≥ 20, ≥ 50, and ≥ 80) were used. Only the detection of ≥ 100 CTCs was significantly associated with OS in ILC pts (median OS 36 vs 10 months; HR 3.4; P =.028). In contrast, the prognostic effect of CTCs ≥ 5 was strong in IDC and maintained for all cutoffs. Similarly, while the prognostic value for tdEVs was confirmed for IDC using both 20-80 and exploratory cutoffs (3-105 and 18-155), no association between tdEV levels and OS was observed in ILC regardless of the cutoffs used.

Conclusion

ILC is associated with higher CTCs and tdEVs compared to IDC, probably due to the impaired cell-cell adhesion that characterizes ILC. Unlike IDC, the prognostic effect for the established cutoff of ≥ 5 CTC was not observed in ILC. A higher CTC cutoff could be considered for this subtype of BC. For tdEV no association with OS was observed, regardless of the cutoff used. These findings emphasize that ILC is a distinct entity also in the liquid biopsy features. Because of the low prevalence of ILC, research efforts should be directed at combining data from ILC pts to better characterize this subtype of BC and understand the reason behind the different associations with OS as compared to IDC.

#7501 Gene expression profiling of rare cells captured from liquid biopsy using the genesis cell isolation system.

S. Perike[1], A. Olcott[1], C. Jiang[1], N. Kumar[1], N. Knapp[1], J. Placek[1], C. Cox[1], Y.-T. Kang[2], L. Lingelbach[1], E. Dreskin[1];
[1]Bio-Rad Laboratories, Hercules, CA, [2]Bio-Rad Laboratories, Ann Arbor, MI

Background: Targeting rare cell types such as circulating tumor cells (CTCs), considered to be metastatic precursors in cancer progression, may provide long-term clinical benefits by enhancing patient outcomes. The study of CTCs comes with technical challenges due to their heterogeneity and low cell numbers, leading to difficulties in genomic characterization. This study aims to overcome these technical challenges by developing a comprehensive gene expression profiling workflow using qPCR and RNA sequencing (RNA-Seq) on rare cells enriched with Genesis System with Celselect Slides™.
Methods: To mimic CTCs in blood, we created a rare cell model sample by spiking A549 non-small cell lung cancer cells at concentrations of 50, 100, 500 and 1000 cells/ml in whole blood from healthy donors. The Genesis System, which can capture rare cells of 8µm-30µm, isolated 83.73% of spiked A549 cells in whole blood. Using the same blood samples without A549 spiked in, we enriched cells using the Genesis and it was used as a baseline for gene expression controls. High quality RNA was extracted from each of the enriched samples and used for both qPCR and RNA-Seq to detect the gene expression signature of the non-small cell lung cancer cells.
Results: Our analyses revealed significant differential expression of cancer-related genes ($p < 0.05$) in all A549-spiked samples when compared to the blood-only controls. Notably, in the 50 cells/ml dilution, RNA-Seq analysis identified over 3,000 differentially expressed genes, encompassing protein-coding genes, long non-coding RNAs, and small non-coding RNAs. Among these, 759 genes were consistently present across all enriched samples, suggesting a common expression pattern. To investigate the potential utility of these genes as non-small cell lung cancer biomarkers, we constructed a custom qPCR array comprising 38 of these genes and pre-amplified their targets using 50pg of RNA from the enriched cell samples. Notably, six genes from this panel (MET, TOP2A, NF1, SPP1, GAPDH, and ANXA5) exhibited significant differential expression (+/- 4-fold, $p<0.05$) in the enriched samples. MET and TOP2A, in particular, are well-known biomarkers for non-small cell lung cancer.
Conclusion: Our liquid biopsy workflow demonstrates the recovery of high-quality RNA from enriched rare cells, including CTCs. It enables comprehensive profiling of the tumor transcriptome, encompassing RNAs of various sizes, including miRNAs. Our approach has the potential to facilitate the identification of patient-specific biomarkers, enabling swift monitoring using preamplification and qPCR in advancement of targeted oncology therapy and research.

#7502 MCT1 and MCT4 on circulating tumor cells isolated from non small cell lung cancer patients.

K. Mangani[1], E. Pantazaka[1], E. Lianidou[2], V. Gerogoulias[3], A. Kotsakis[4], A. Markou[2], **G. Kallergi**[1];
[1]University of Patras, Patras, Greece, [2]University of Athens, Patras, Greece, [3]Hellenic Oncology Research Group, Athens, Greece, [4]University of Thessaly, Larisa, Grenada

Background: Lung cancer is the leading cause of cancer-related deaths. Non-small-cell lung cancer (NSCLC) is the most common subtype of lung cancer and is characterized by poor prognosis and survival rate. This is associated with the fact that most patients are diagnosed at advanced stages of the disease and the possibility of recurrence after treatment remains high. Monocarboxylate transporters 1 and 4 (MCT1 and MCT4) play a crucial role in cellular metabolism, as they are responsible for the transport of lactate and other monocarboxylic acids across the plasma membrane. Their function can further regulate cell survival and proliferation, especially under hypoxic conditions. To elucidate the relationship between CTCs and the metabolic aspect of cancer, we aimed to investigate the expression of MCT1 and MCT4 in CTCs derived from NSCLC patients and its potential association with patients' outcome.
Methods: Fifty-three NSCLC patients at baseline were enrolled in the current study. CTCs were isolated using the ISET system and triple immunofluorescence experiments were performed, using CK, MCT1, MCT4, and CD45 antibodies. The expression of MCT1 and MCT4 in CTCs was assessed by confocal laser scanning microscopy and statistical analysis was performed using SPSS software.
Results: CTCs were detected in 29 out of 53 (55%) NSCLC patients. CK expression was characterized as high or low, with the predominant phenotypes among CK-positive patients being the CK_{high}/MCT1+/CD45-and CK_{low}/MCT4-/CD45- (63% and 66%, respectively). Whereas the phenotype CK_{high}/MCT4+/CD45- was detected in 52% of the patients. The phenotypes with the lowest frequency were the CK_{low}/MCT4+/CD45- (7%), CK_{low}/MCT1+/CD45- (15%), and the CK_{high}/MCT1-/CD45- (15%). Most of the isolated CTCs had the CK_{high}/MCT1+/CD45- and CK_{low}/MCT4-/CD45- phenotypes with a mean percentage of 48% and 51% respectively, while only a small number of CTCs per patient were CK_{low}/MCT1+/CD45- or CK_{low}/MCT4+/CD45- (8%and 5%, respectively). The phenotype CK_{low}/MCT1-/CD45- was associated with poorer overall survival (OS) [p = 0.005, (15 vs 33 months respectively)], HR=0.351), while the presence of more than 3 CK_{high}/MCT4+/CD45- CTCs was related to poorer progression-free survival (PFS) [p = 0.042 (4 vs 17 months respectively)].
Conclusions: MCT1 and MCT4 were expressed in a high proportion of NSCLC patients at baseline and may constitute interesting biomarkers relevant to cancer progression. However, further analysis in a larger cohort of patients is required to clarify their potential significance in clinical practice.

#7503 Non-clinical study of circulating tumor cells in humanized mice: Post-xenograft effects in immunodeficient mice.

S. Pak, H. Pak, H. Yoo, S. Min, H. Kim, J. Lee, M.-J. Song, J. Choi, A. Jeong, H. Kim, J. Kim, H.-C. Lee;
Cytogen, Inc., Seoul, Korea, Republic of

Circulating tumor cells (CTCs) possess the potential to serve as innovative markers in clinical trials, contributing to the understanding of cancer metastasis mechanisms, diagnosis, prognosis, the development of personalized treatment strategies, and enabling the monitoring of treatment efficacy. NSG mice, which are a strain of immunodeficient mice frequently utilized as a non-clinical model for cancer research, exhibit diminished levels of natural killer (NK) cells and abnormal monocytes in their bloodstream. In a previous study, a positive correlation was observed between the duration of injection and the levels of white blood cells (WBC) in mice that were injected with various cancer cell lines derived from humans. To evaluate the correlation among the primary tumor and circulating tumor cells (CTCs), as well as the impact on immune cells, we assessed changes in immune cell composition, primary tumor size, and enumeration of CTCs in xenografted mice over a period of time. This investigation was carried out using CytoGen's Smart Biopsy™ systems. The results, which were obtained using equipment including CytoGen's Smart Biopsy™ Systems, showed that the distribution of white blood cell (WBC) components exhibited variations based on age, primary tumor burden, and circulating tumor cell (CTC) count following injection. A notable association was observed between the augmentation of immune cells and the quantity of circulating tumor cells (CTCs) present in the bloodstream. Therefore, alterations in immune cells may potentially impact the potential to affect the ability to influence the efficacy of cancer immunotherapy, metabolic therapy, and anti-metastatic therapy. When conducting non-clinical investigations with the objective of developing cancer treatment protocols, it is crucial to meticulously select humanized or immunodeficient mice that are appropriate for the study. Therefore, it is advisable to perform regular monitoring of murine blood samples in order to observe any variations in the counts of circulating tumor cells (CTCs), while considering a standardized blood volume per individual. In the immunodeficient mouse model, the existence of circulating tumor cells (CTCs) results in an increase in the quantity of cells present in the bloodstream. The observed rise in circulating tumor cells (CTCs) is found to be concurrent with the progression and development of the primary tumor. The consideration of this aspect is of utmost importance in the formulation of non-clinical studies aimed at the development of cancer treatment protocols.

#7504 Longitudinal multi-omics characterization of circulating tumor cells from ALK positive NSCLC patients.

Yuru Chen, Shamileh Fouladdel, Harrison Ball, Zhaoping Qin, Albert Liu, Xu Cheng, Liwei Bao, Habib Serhan, Bryce Vandenburg, Varun Kathawate, Larua Goo, Peter Ulintz, Nathan Merrill, Aaron Udager, Angel Qin, Sofia D. Merajver, Sunitha Nagrath

University of Michigan, Ann Arbor, MI

Introduction:

Anaplastic lymphoma kinase positive non-small cell lung cancer (ALK+NSCLC) represents a distinct subtype of NSCLC characterized by oncogenic ALK gene mutations leading to ALK overexpression and activation in tumor cells. ALK+ NSCLC will frequently develop mutations during treatment, leading to nonresponse and eventually cancer relapse. Therefore, there is a critical need for sensitive technologies to monitor ALK+ NSCLC disease status in patients over time.

To facilitate longitudinal monitoring, there has been a rapid evolution in diagnostic technologies leveraging circulating tumor cells (CTCs) as a liquid biopsy tool. CTCs can be collected non-invasively at various intervals throughout patient treatment. Moreover, they shed from solid tumors and disseminate into the bloodstream, which makes isolating CTCs a valuable source of genomic, transcriptomic, and proteomic insights pertaining to the primary tumor. In this study, we present a comprehensive workflow for conducting multi-omic analysis on CTCs derived from ALK+ NSCLC patients.

Methods:

Blood samples were collected from a cohort of ALK+ NSCLC patients, and CTCs were isolated using a high throughput, label free microfluidic device, Labyrinth. Enriched CTCs were immunofluorescently stained for cytokeratin, CD45, DAPI, epithelial cell adhesion molecule (EpCAM), and vimentin markers. Heterogeneous CTC populations with hybrid epithelial/mesenchymal (EM) phenotypes are reported. Fluorescence in situ hybridization (FISH) was performed on enriched CTC samples. DNA was extracted and sequenced using a 523 gene targeted sequencing panel. Single cell RNA-seq technology was performed in parallel on CTC samples to investigate the gene expression throughout treatment.

Results:

The median concentration of CTCs in the ALK+ NSCLC cohort (n=33) is 137 CTCs per ml of blood, and 64% of CTCs are in an EM hybrid state. In ALK+ NSCLC patients (n=3) with an average of 4.6 visits per sample, we observed a trend of decreasing CTC concentration for patients with partial response to the treatment. The presence of ALK fusion in ALK+ NSCLC patient's CTC is confirmed by FISH. Oncogenic mutations (JAK1, SPEN, ERBB4, NTRK3) are observed in bulk CTC samples from two NSCLC patients. Single cell RNA sequencing was performed on three ALK+ NSCLC patients; 58, 199, and 700 potential CTCs were detected with positive cytokeratin expression and no white blood cell marker expression.

Conclusions:

This study examined the feasibility of using CTCs for studying and monitoring the clinical status of the ALK+ NSCLC patients as well as the genomic and transcriptomic signatures within their tumors. More patients will need to be processed in order to validate our workflow and reinforce our conclusions.

#7505 Detection validation of androgen-receptor splice variant 7 in circulating tumor cells of prostate cancer by double-check assays.

Hoin Kang, Jihyun Lee, Min Hyung Kim, Soee Kim, Hyoyong Kim, Jubi Lee, Hae Ung Lee, Hai-Chon Lee, Jung Won Kim

Cytogen, Inc., Seoul, Korea, Republic of

Introduction: Androgen-receptor splice variant 7 (AR-V7) is constitutively activated isoform of AR and has been associated with resistance towards AR targeting therapies and development into mCRPC. Confirmation of AR-V7 expression is important step in prostate cancer diagnosis and determining the drug, but the detection of AR-V7 with tissues has limitations such as clinical challenge to poorly accessible tumor tissues before and after treatment. Here, we developed the method of AR-V7 detection in circulating tumor cells (CTC) after isolation with CytoGen's Smart Biopsy™ CTC isolator by in vitro assays of qPCR and immunofluorescence (IF) with high sensitivity and specificity, overcoming the limitations of tissue biopsy.

Method: qPCR and IF methods were developed for high sensitivity and specificity of AR-V7 detection. Sensitivity and specificity were tested using AR-V7 positive cells (VCaP and 22Rv1) and negative cells (PC-3 and Raji). Limit of detection (LOD) test of AR-V7 expression was performed with AR-V7 positive cells (200 cells to 50 cells, 3 points) mixed with Raji cells (1x10^5cells). Then, AR-V7 positive cells (200 cells to 50 cells, 3 points) were spiked into peripheral blood mononuclear cells (PBMC) of blood sample (5mL, healthy donor) to mimic CTC after isolation by CytoGen's Smart Biopsy™ CTC isolator, subsequently AR-V7 expression was tested with qPCR and IF assay.

Results: AR-V7 expression was clearly detected by qPCR and IF in the LOD test of AR-V7 positive cells mixed with Raji cells and was not detected at all in the negative controls. The similar clear results were also observed in the spiking test of AR-V7 positive cells into PBMC isolated by CytoGen's Smart Biopsy™ CTC isolator, suggesting that clinical samples of prostate cancer could be applied with excellent sensitivity and specificity for AR-V7.

Conclusions: AR-V7 expresses only a part of cancer tissue, so it is difficult to accurately diagnose with traditional histological assays. Detection of AR-V7 in intact live CTC isolated by CytoGen's Smart Biopsy™ CTC isolator might overcome limitations of tissue biopsy. In this study, we developed the method to detect AR-V7 in CTC with high sensitivity and specificity with qPCR and IF assay, and presented the results of verifying AR-V7 expression by double check using two kinds of assays. We plan to conduct clinical validation of the developed method through additional study using patient samples.

#7506 Comprehensive mutational profile of true single circulating tumor cells compared with CtDNA in advanced pancreatic adenocarcinoma.

J. Khandare[1], A. Bharde[2], G. Khutale[2], S. Andhari[2], R. Deshpande[2], K. Hariramani[3], M. Basavalingegowda[2], V. Jadhav[2], M. Uttarwar[1], G. Shafi[1]; [1]OneCellDx, Cupertino, CA, [2]OneCellDx, Pune, India, [3]IndxTechnology, Pune, India

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is aggressive malignancy characterized by 5-year survival rate of <10%. Comprehending PDAC's mutational landscape through NGS-based assays, acquiring representative tumor tissue biopsies remains arduous. Single circulating tumor cell (sCTC) genomics could provide clinically relevant personalized diagnostics. Here we demonstrate comparative analysis of sCTCs genomics and ctDNA outcomes in paired advanced PDAC patients.

Methods: Retrospectively, 25 live sCTCs and sCTC clusters were isolated from 10 advanced PDAC patients' blood using OncoRadar platform consisting glass beads conjugated with antiEPCam antibodies, tuned for releasing CTCs, without cell fixing, an assay in 96 well plate. Whole genomes from sCTCs were amplified using random degenerate primer-based PCR. Amplified genomes and paired ctDNA were subjected to CGP using clinical assay OncoIndx® to identify patient-specific genomic alterations in sCTC and paired ctDNA samples. The raw sequence alignment and variant calling was performed using iCare software®.

Results: Live 25 sCTCs and 8 CTC clusters were isolated (≥2 CTCs). Mutational profiling revealed multiple pathogenic (P) and likely pathogenic (LP) variants. sCTCs exhibited at least twice as many P variants compared to paired ctDNA samples, with CHD4, FGFR2, and HNF1α being the most common. The mutational profile of sCTCs showed concordance with at least one variant in paired ctDNA, and was enriched in dysregulated cytoskeleton and cell migration machinery. Specifically, COL7A, KIF5B, and RHOA mutations were prevalent in almost all sCTCs, with exclusive mutations (KIF5B and RHOA) in some cases. KRAS P variants were exclusive to 50% of ctDNA samples, paired sCTCs exhibited NRAS P variants. RAS isoforms were observed in 70% of sCTCs. Gene amplification occurred in CCND1/2, FGFR2, and ERBB2 in 90% of sCTCs, with CCND1 amplification more prevalent in sCTC clusters. Mutations in epigenetic repressors (HDAC1, KDM2B) were ubiquitous in sCTCs, co-occurring with DDR pathway mutations (F test, P 0.003, OR 11). Loss-of-function BRCA mutations were detected in 60% of sCTCs, and were absent in paired ctDNA. Additionally, 70% of sCTCs exhibited therapy-resistant variants (NF1, STK11, ARID1A, and PIK3CA), contrasting with a 10% frequency in paired ctDNA.

Conclusions: Genomic profile of sCTCs in advanced PDAC patients revealed a complex mutational landscape, providing additional clinically relevant insights that complemented ctDNA findings. sCTCs exhibited greater tumor mutational heterogeneity compared to paired ctDNA samples, and detected additional actionable pathogenic variants. Results suggest that sCTCs may offer therapeutically relevant molecular information for advanced PDAC patients for whom tissue is unavailable and ctDNA fails to provide actionable therapy options.

#7507 Capturing live single circulating tumor cells platform for comprehensive genomic profiling with paired ctDNA in breast cancer patients.

G. Shafi[1], A. Bharde[2], G. Khutale[2], S. Andhari[2], R. Deshpande[2], B. Jadhav[2], S. Prajapati[2], M. Fauzul[2], K. Hariramani[2], M. Basavalingegowda[2], J. Khandare[1]; [1]OneCellDx, Cupertino, CA, [2]OneCellDx, Pune, India

Background: Single circulating tumor cells (sCTC) capture without cell fixation with no blood contaminants like leukocytes are highly challenging. sCTC genome transcriptomics anticipates new avenues in new discovery, targeted therapies, and inclusion of patients in clinical trials where the tissue is inaccessible. We report, an assay to selectively capture live sCTCs at singularity with NGS-based comprehensive mutational profiling in breast cancer (BC) patients. Further, paired ctDNA outcomes using blood with mutational heterogeneity scores of sCTCs adds comprehensive genomics for establishing an accelerated treatment outcomes and resistance signatures.

Methods: Retrospectively, sCTC were isolated from 70 breast cancer (BC) patients using OncoRadar platform consisting affinity-based glass beads mediated by anti EpCAM antibody. CTCs were selectively captured and released without fixing and contamination of any leukocytes. Platform possess cleavable disulfide spacer at pH 8.0, between glass beads (diam. 2 mm, area 12.57 mm2) and a ligand. Sensitivity, specificity, positive predictive value (PPV), negative prediction value (NPV), and accuracy were evaluated using MCF-7 cells and CTCs. Assay to isolate CTC has been developed in 96 well plate, for downstream NGS-based comprehensive gene panel analysis using hybridization-based target enrichment. Interestingly, no mutations detected in blood samples (~20%) for CtDNA versus CTC DNA offered non-chip implicated mutations.

Results:. Analytical validation using OncoRadar showed higher cell capture efficiency (99%) with spiked MCF-7 cells/ml of blood. Sensitivity and specificity values were 97% and 98% respect, while PPV was 99% and NPV was 7.5% with the accuracy parameter of 99%. Sensitivity, specificity, PPV, and NPV parameters when assessed for CTC isolation from 70 BC patients. NGS-based mutational analysis, sCTC showed the presence of PIK3CA, ESR1, and NF1 mutations, which were absent from paired ctDNA samples.

Conclusion: Detection of ctDNA obscure mutations in paired sCTC samples suggests high sensitivity of sCTC-based genomic assays compared to current standard of practice. Heterogeneity scores amongst inter and intra CTCs with MATH scores offer new dimensions in genomics. Combination of ctDNA and sCTC DNA assay offers a comprehensive realistic genomic outcome for more significant therapy decisions, especially when guideline based options may exhausts.

#7508 Distribution prophecy of circulating tumor cell clusters in CTC populace patients of epithelial cancers.

J. Khandare[1], G. Aland[2], G. Khutale[2], S. Andhari[2], P. Patil[2], M. Garbhe[2], M. Dongare[2], T. Deshpande[2], V. Jadhav[2], N. Raut[3], G. Shafi[4], A. Bharde[2], A. Vasudevan[2], S. Jayant[2];

[1]Actorius Innovation and Research Pvt Ltd, Simi Valley, CA, [2]Actorius Innovation and Research Pvt Ltd, Pune, India, [3]Bhaktivedanta Hospital And Research Institute, Mumbai, India, [4]OneCelldDx, Pune, India

Background: Role of CTCs in metastatic cancers to predict the % prediction of overall survival has been well-established. The effectiveness of three- or six-months adjuvant therapy in colorectal cancer estimation showed association of CTCs with the emergence of resistant cell clones. The presence of CTCs with clusters indicates an aggressiveness of the epithelial cancers. However, the presence of CTC clusters has not been evaluated in large populations. Here, we demonstrate the distribution prophecy of CTCs and CTC clusters in epithelial cancer patients.

Methods: Retrospectively, 3458 patients' blood sample was analyzed for the presence and distribution of CTCs and CTC clusters using DCGI approved OncoDiscover platform having immunomagnetic multicomponent system mediated by anti EpCAM antibody. 1.5 mL of peripheral blood was analyzed to capture cells and clusters from Head & Neck, breast, and lung cancer patients. Earlier the sensitivity, specificity and accuracy of OncoDiscover assay was presented. CTCs and clusters were identified with CK 18 +ve, DAPI + ve and CD45 -ve staining using automated motorized fluorescence microscopy. CTCs clusters were defined by the presence of two or more CTCs bound together.

Results: .Out of 3458 epithelial cancer patients, 65.52 % patients showed the distribution of CTCs ~ 2262 (CTC numbers varied from 1-9/ 1.5 mL), while 7.54% patients showed CTC clusters (261 clusters). Total number of captured CTCs and clusters were 19345 (mean CTCs and cluster distribution was 5.59), while CTC were predominantly in 19037 numbers (98.41%) and clusters were 308 (1.59 %). Highest number of CTS were observed in HNC (52.98%) and breast cancers (22.75%), followed by lung cancer (5.65%). While, prophecy clusters were observed in breast cancers (26.95%), followed by lung (16.23%).

Conclusions: The frequency and distribution of CTCs and CTC clusters was evaluated in epithelial cancers. Patients with CTC alone and patients having CTCs as well CTC clusters represent more aggressive disease and the progression of disease. The effectiveness of adjuvant therapy in epithelial cancers can be estimated with CTC and cluster for association of treatment outmoded with an emergence of resistant cell clones.

#7509 Evaluation ofHER-2 expression on circulating tumor cells as a real time biomarker in advanced breast cancer.

J. Khandare[1], G. Aland[2], S. Andhari[1], G. Khutale[1], P. Patil[1], T. Deshpande[1], M. Garbhe[1], V. Jadhav[1], A. Vasudevan[1], S. Jayant[1];
[1]Actorius Innovation and Research, Simi Valley, CA, [2]Actorius Innovation and Research, Pune, India

Introduction: Breast cancer accounts for 12.5% of all new annual cancer cases worldwide. Cases classified as HER2-positive tend to proliferate, metastasize, and often lead to relapse. HER-2 is the most valid tumor marker, used as a diagnostics and prognostic biomarker in metastatic breast cancer (MBC). Thus, analysis of expression of HER-2 on CTCs can offer a real time dynamic biomarker for treatment options between endocrine therapy versus chemotherapy in advanced breast cancer. Functional assays on CTCs with HER-2 biomarker offer evolving biomarkers especially when the tissue is not accessible and inadequate.
Methods: Retrospectively, 179 breast cancer patients' blood was analyzed for the presence of CTCs using the OncoDiscover® platform approved by Drug Controller General of India (CDSCO). Consisting of immunomagnetic multi-components mediated by anti EpCAM antibodies. The isolated cells were immunostained consisting of a nuclear dye DAPI, CK-18, CD45 and HER-2 antibodies. CTCs were identified by the presence of HER-2 + ve, CK 18 + ve, DAPI + ve and CD 45 -ve staining. Validation of HER-2 expression on the CTCs was analyzed based on the linear intensity gradients of the fluorescence signals. CTCs were termed as HER-2 -ve based on weak or no detectable fluorescence signal and termed +ve based on high fluorescence signal.
Results: Among the cohort of 179 patient samples, 63.68 % samples showed the presence of CTC (CTC ranged from 1-7). 47.84% of these CTCs showed the expression of HER-2 signal. The mean value for fluorescence intensity for expression of HER-2 in CTCs was found to be 3.23. The observed mean fluorescence intensity for HER-2 expression further emphasizes the robustness of CTCs as a viable source for molecular characterization.
Conclusion: Integration of HER-2 analysis on CTCs into the clinical assessment of metastatic breast cancer, may offer a non-invasive, real-time strategy for profiling and possibly paving the way for more precise and tailored therapeutic interventions.

CLINICAL RESEARCH: Immune Checkpoint Inhibitor Therapy
Poster Session

#7513 Tumor treating fields (TTFields) can induce immunogenic cell death in GBM resulting in enhanced immune modulation.
R. T. Nitta, S. Lee, M. Lim, G. Li;
Stanford University, Stanford, CA

Glioblastoma (GBM) is the most common and aggressive form of malignant primary brain tumors. Despite current standard of care, the overall survival for GBM is ~15 months. While immunotherapy using immune checkpoint inhibitors such as anti-PD-1/PD-L1 have been efficacious for solid malignancies, very little progress has been made in a clinical setting for GBM. This is mainly due to GBM being known as a “cold” and non-immunogenic tumor. It has been previously established that a tumor may become “hot” if the T cell responses can be enhanced by increasing the presentation of tumor-specific antigens to the immune system. Tumor Treating Fields (TTFields) are alternating electric fields in a specific frequency range (100-500 kHz) delivered to the human body through transducer arrays. Treatment with TTFields have been approved and have shown efficacy in GBM. TTFields have induced immunogenic cell death in GBM, which in turn can elicit anti-tumoral immunity by inducing damage-associated molecular patterns (DAMP). These patterns are important for promoting engulfment of lung cancer cells by dendritic cells and recruitment of immune cells. These findings suggest that TTFields may enhance the immune response in GBM by increasing tumor specific antigens. In this study we show *in vitro* that TTFields enhanced the immune response to GBM. We initially demonstrated that GBM cells (GL261 or CT2A) treated with TTFields (200 kHz) can elicit DAMP emissions as evident by the increase in secretion of ATP and HMGB1 and the enhanced translocation of calreticulin to the cell surface. Additionally, TTFields stimulated the phagocytotic activity of antigen presenting cells (Raw264.7) and increased T-cell early activation (CD69/CD4+, CD69/CD8+) and activity (IFNγ and perforin). Since our findings *in vitro* indicate TTFields enhanced the immune response to GBM, we studied the therapeutic potential of using TTFields together with anti- PD1 in a syngeneic mouse model. We applied TTFields to GBM cells prior to intracranial injections. While our survival studies are preliminary, our findings suggest that systemic anti-PD1 and TTFields may result in a myeloid and T-cell mediated anti-tumor response and enhanced survival. Our findings indicate that TTFields treatment may help transform GBM into a “hot” tumor thereby making it an attractive target for immunotherapy.

#7514 Tumor intrinsic CDC42BPB confers resistance to anti-PD-1 immune checkpoint blockade in breast cancer.

R. P. Deshpande, K. Wu, S.-Y. Wu, A. Tyagi, J. Hunting, J. Ruiz, W. Li, K. Watabe;
Wake Forest Baptist Comprehensive Cancer Ctr., Winston-Salem, NC

Immune checkpoint blockade has been used to treat breast cancer, but the clinical responses remain relatively poor, especially for the triple-negative subtype. The weak responsiveness is attributed to tumor intrinsic as well as tumor extrinsic factors, suggesting a need for novel approaches. We have used the CRISPR Cas9 kinome knockout library consisting of 763 kinase genes to identify tumor intrinsic kinase conferring resistance to anti-PD-1 immune checkpoint blockade and identified the CDC42BPB kinase as a potential target to overcome the resistance to anti-PD-1 immunotherapy. We found that CDC42BPB is highly expressed in breast cancer patients who are non-responsive to immunotherapy. Importantly, a small molecule pharmacological inhibitor, BDP5290, which targets CDC42BPB synergized with anti-PD-1 and enhanced tumor cell killing by promoting T-cell proliferation in both in vitro and in vivo assays. Moreover, anti-PD-1 resistant breast cancer cells showed higher expression of CDC42BPB, and its inhibition rendered the resistant cells more susceptible to T cell killing in the presence of anti-PD-1. We also found that CDC42BPB phosphorylated AURKA which in turn upregulated PD-L1 through cMYC. Our results have revealed a robust link between tumor intrinsic kinase and immunotherapy resistance and provided a rationale for a novel combination therapy of CDC42BPB inhibition and anti-PD-1 immunotherapy for breast cancer.

#7515 Enhancing immune checkpoint inhibitor efficacy with fulvestrant in estrogen receptor-positive breast cancer.

J. Arima[1], K. Chida[1], M. Oshi[1], A. M. Roy[1], K. Taniguchi[2], S.-W. Lee[2], K. Takabe[1];

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Osaka Medical and Pharmaceutical University, Takatsukishi, Osaka, Japan

Introduction: Breast cancer (BC) recurs decades after initial treatment that consists majority of the annual 43,000 BC deaths. Thus, Immune Checkpoint Inhibitor (ICI) therapy that bolster anti-cancer immunity is expected to improve long-term survival with reduced recurrence. Neoadjuvant ICI revolutionized management of triple negative breast cancer (TNBC); however, this represents only 5-7% of all BC cases, where estrogen receptor (ER)-positive subtype that consists of 70% of all BCs is not indicated due to less tumor-infiltrating lymphocytes (TILs). Using I-SPY2 trial we aim to investigate the potency of ER-alpha gene (ESR1) expression as a predictive biomarker, and whether the inhibition of the ER with fulvestrant enhances the efficacy of ICIs in ER+ BC.

Methods: Total of 1157 BC patients from two independent cohorts (ISPY2 trial; n= 73, TCGA; *n* = 1084) were included, encompassing both clinical and transcriptomic profiles. The TIL score was determined using the xCell algorithm.

Results: Using the transcriptome of the ISPY2 trial, we found that compared to ESR1 low expression patients, ESR1 high patients were associated with significantly lower pCR rates after neoadjuvant immunotherapy with ICI in whole cohort (n=71, pCR rate=30%, p<0.05) and HR+ subtype (n=50, pCR rate=20%, p<0.001), but not in triple-negative breast cancer (TNBC). ESR1 expression outperformed PD-1, PD-L1, and CTLA4 in Area Under the Curve (AUC) of the whole ISPY2 cohort (AUC=0.75, 0.68, 0.48, and 0.62, respectively), and further pronounced in HR+ BC (AUC=0.88, 0.73, 0.55, and 0.65, respectively), suggesting the potency of ESR1 expression as a predictive biomarker for ICI in HR+ BC. In agreement, ESR1 expression inversely correlated with the amount of intratumoral TILs consistently in both ISPY2 and TCGA cohorts in HR+ BC, but only in TCGA in whole cohort (all p<0.05). Among the intratumoral TILs, CD8+ T cell and M1 Macrophages were found to be less infiltrated in HR+ BC in TCGA. Given that ESR1 expression was associated with less intratumoral TILs and a poor response to ICI, we hypothesized that suppression of ER-alpha would enhance the effectiveness of ICI in HR+ BC in vitro. ER-alpha positive MCF7 cells were incubated with activated peripheral blood mononuclear cells with 1:1 ratio, and treated with 0.1 microgram of anti-PDL1, and 1nM of ER antagonist, fulvestrant, which demonstrated minimum cell killing. We found that ICI therapy with anti-PDL1 significantly decreased the cell viability of the MCF7 cells when ER-alpha expression was suppressed by fulvestrant, while activated peripheral blood mononuclear cells or anti-PDL1 alone or the combination did not exhibit any significant cell killing.

Conclusion: We found that ESR1 expression is a predictive biomarker of ICI, and ER antagonist fulvestrant enhances the response of HR+ BC to ICI, suggesting that this combination could expand ICI indications to HR+ BC.

#7517 Integrating in situ proximity ligation assay for PD1-PDL1 interaction with multiplexed immunofluorescence imaging.

T. Ullman[1], D. Krantz[2], H. Elofsson[3], C. Oses Sepulveda[1], A. Zieba-Wicher[3], P. Ostling[2], A. Ullen[2], S. Basu[3], **C. Stadler**[1];
[1]KTH Royal Institute of Technology, Stockholm, Sweden, [2]Karolinska Institute, Stockholm, Sweden, [3]Navinci Diagnostics, Uppsala, Sweden

Background: Programmed cell death protein 1 (PD1) and its ligand PD-L1 are pivotal components of the immune checkpoint machinery, playing a crucial role in the regulation of immune responses in cancer. The interaction between PD1 and PD-L1 is a significant therapeutic target in oncology, as its inhibitors have shown improved outcomes across a variety of malignancies. However, the treatment response to immunotherapies such as pembrolizumab has shown a modest response (~30%) in previous studies. This could be explained by the lack of molecular insight pertaining to the interaction of PD1 on T-cells and PD-L1 in the tumor cells in malignant tissues at the time of clinical diagnosis. The recent development of *in situ* Proximity Ligation Assay (*is*PLA), marks a significant advancement in the field. This method allows for the visualization of direct protein interactions within tissues, for example between PD1 and PD-L1. This adds an important layer of information compared to multiplexed immunofluorescence, which is useful for deep phenotyping of cell types in a tissue but lacks the ability to detect direct interactions between specific cells.
Methods: PD-L1-PD1 interactions in human FFPE tonsil and bladder cancer tissue were identified using the NaveniFlex Tissue Atto647N kit, following the guidelines provided by the manufacturer. This method is capable of detecting proteins within a proximity of less than 40 nm, utilizing oligonucleotide-antibody conjugates that generate an enhanced fluorescent signal. After completing the Naveni® detection process, we performed multiplexed immunofluorescence (IF) using the Phenocycler platform and a panel of 14 barcoded antibodies, to generate *is*PLA and multiplexed IF data on the same tissue section.
Results & Discussion: We have successfully established an automated workflow for the *is*PLA protocol. In this work, we aim to continue this effort and combine the *is*PLA, with downstream highly multiplexed immunofluorescence using the Phenocycler platform. We have generated proof of concept data for the successful integration of the two methods, using tonsil and bladder cancer tissue to detect protein interactions between PD1 and PD-L1, as well as phenotypic profiling of the tumor microenvironment with a 14 plex panel. This panel allows us to phenotype the relevant cell types (B cells, dendritic cells, T cells, macrophages, tumor cells and their proliferation status) and subsets of T-cells like cytotoxic CD8+ cells. The integration of the *is*PLA and multiplexed IF is poised to significantly advance our understanding of the TME and hopefully aid in patient stratification for immune checkpoint inhibition therapy. The clinical significance of this method integration will later be explored in a retrospective cohort of muscle invasive bladder cancer, receiving immune checkpoint inhibition therapy with pembrolizumab as a second line treatment.

#7518 Neoadjuvant-adjuvant pembrolizumab in resectable advanced basal cell carcinoma of the head and neck: An open-label, single-arm, phase 1b trial.

Grace M. Jones[1], James Isaacs[2], Lucy Boyce Kennedy[2], Jennifer Ko[3], Allison Vidimos[4], Alok Vij[4], Christine Poblete-Lopez[4], Jennifer Lucas[4], Yee Peng Phoon[1], Melissa McEnery-Stonelake[4], Jon Meine[4], Thach-Giao Truong[2], Pauline Funchain[5], Brian Gastman[6]

[1]Center for Immunotherapy & Precision Immuno-Oncology, Cleveland Clinic Lerner Research Institute, Cleveland, OH,[2]Hematology and Medical Oncology, Cleveland Clinic, Cleveland, OH,[3]Anatomic Pathology, Cleveland Clinic, Cleveland, OH,[4]Dermatology, Cleveland Clinic, Cleveland, OH,[5]Stanford Cancer Institute, Stanford, CA,[6]Plastic Surgery, Cleveland Clinic, Cleveland, OH

Introduction: BCC is a common form of skin cancer that shares treatment-related aspects with the more well-studied skin malignancy, melanoma, including sensitivity to anti-PD-1/PD-L1 immunotherapy. However, despite major advances in peri-operative immunotherapy for melanoma, little is known regarding these strategies in BCC. This phase 1B, single-arm study evaluated neoadjuvant-adjuvant treatment with pembrolizumab (PEMBRO) together with standard of care (SOC) resection in advanced BCC of the head and neck.

Methods: Eligible patients had resectable, locally advanced BCC of the head and neck, defined by at least one of the following high-risk characteristics: a measurement of ≥ 20 mm, indication for post-operative radiation, or perineural invasion (PNI) in multiple nerves. Patients were naive to hedgehog inhibitors (HHI) and had an ECOG of 0 or 1. All patients received IV PEMBRO at a dose of 200 mg every 3 weeks for a total of 4 cycles, then within 4 weeks underwent a SOC resection followed by adjuvant PEMBRO until a total of 17 cycles was completed. After the 30-day post treatment safety follow-up visit, patients were followed for up to 5 years post-operatively. The primary endpoint was pathological response rate. Secondary endpoints included RECIST response by radiographic or physical exam, adverse events (AE), and recurrence-free survival (RFS).

Results: 13 patients were enrolled in the trial from July 2020 to May 2023, and received at least one dose of PEMBRO. Two patients withdrew from the trial after one dose of PEMBRO, one following treatment-related G3 hepatitis and a second due to an unrelated medical complication (cholecystitis). Out of 11 patients undergoing surgical resection, 10 patients received 4 out of 4 and 1 patient received 3 out of 4 planned cycles of neoadjuvant PEMBRO (investigator preference without new related AE). Pathological complete response (pCR) was observed in 3 patients (23%). For those with RECIST measurable disease, 2 patients demonstrated a complete response (CR), 1 patient a partial response (PR), and 5 patients showed stable disease (SD). Two patients had progressive disease (PD). One patient with a complete pathologic response had a discordant RECIST response with PD noted radiographically. All 13 patients experienced at least one AE of G1 or 2. The highest grade of related AEs were noted in 2 patients with grade 3 hepatitis and pruritus respectively that resolved with supportive therapy. As of November 2023, the median follow-up time is 17.6 months with no recurrences noted.

Conclusions**:** Neoadjuvant-adjuvant PEMBRO shows promising efficacy and an acceptable safety profile in resectable advanced BCC of the head and neck. Given these positive results and the healthcare burden BCC accounts for, these findings warrant further study.

#7519 Elucidation of the mechanism of acquisition of immune checkpoint inhibitor resistance by chronic inflammation.

S. Yumoto, H. Horiguchi, H. Baba, Y. Oike;
Kumamoto Univ Graduate School of Medical Sci, Kumamoto, Japan

Introduction: Eight molecules that are structurally similar to angiopoietin but do not bind to angiopoietin's specific receptor Tie2 were identified and named angiopoietin-like factors (ANGPTL). ANGPTL2, particularly abundantly expressed in adipose tissue, promotes damage repair through tissue remodeling, and contributes to tissue homeostasis; however, in severe obesity, ANGPTL2 is overexpressed, resulting in irreversible tissue remodeling, which induces chronic inflammation and is involved in systemic insulin resistance and diabetes development. On the other hand, it is unclear how systemic chronic inflammation controlled by ANGPTL2 is involved in cancer progression and acquisition of immune checkpoint inhibitor (ICI) resistance. Therefore, we aimed to elucidate the mechanisms in the acquisition of ICI resistance by systemic chronic inflammation from the perspective of ANGPTL2.
Materials and Methods: 1. To induce chronic inflammation in adipose tissue, BALB/c mice were fed high-fat-diet (HFD) for 6 weeks. CT26 cells, a mouse colon cancer cell line, were subcutaneously implanted in normal diet (ND) and HFD mice and anti PD-1/PD-L1 antibody was administered intraperitoneally. Immune cell fractions in tumor tissue and bone marrow were analyzed by flow cytometry. 2. CT26 was subcutaneously implanted in WT and systemic ANGPTL2-deficient (*Angptl2*$^{-/-}$) mice, and anti PD-1/PD-L1 antibody was administered intraperitoneally. Tumor size and survival time were analyzed. Bone marrow cells were isolated and the immune cell fractions were analyzed by flow cytometry, and the expression of inflammatory cytokines in adipose tissue were also analyzed. 3. Bone marrow cells were isolated from BALB/c mice, and myeloid-derived suppressor cells (MDSCs) were established *in vitro* by GM-CSF and IL-6. Recombinant ANGPTL2 protein was added, and MDSC differentiation and function were evaluated by flow cytometry and qRT-PCR.
Results: 1. HFD mice had larger tumor size and poorer response to ICI treatment compared to ND mice. In tumor microenvironment, MDSCs were increased in HFD mice. HFD mice had significantly increased MDSCs, especially polymorphonuclear MDSCs (PMN-MDSCs) in bone marrow. 2. ICI-treated *Angptl2*$^{-/-}$ mice showed higher treatment efficacy and prolonged survival compared to WT mice. In bone marrow, MDSCs were reduced in *Angptl2*$^{-/-}$ mice under ICI treatment. In adipose tissue, the expression of chronic inflammatory markers was increased. 3. *In vitro*, addition of recombinant ANGPTL2 protein to MDSCs induced differentiation from mouse bone marrow cells did not significantly increase the cell ratio of MDSCs. No changes in the expression of MDSCs markers were observed in qRT-PCR.
Conclusions: Chronic inflammation induced by ANGPTL2 promotes MDSCs differentiation and maturation in the bone marrow, which may suppress anti-tumor immunity and contribute to ICI resistance.

#7520 NRT-YHD_001, targeting CD47 for liver cancer immunotherapy.

S. Nam[1], S. Kim[1], M. Na[1], E. Shin[1], J. Ha[1], S. Jeon[1], S. Yoon[2];

[1]Catholic University of Korea, College of Medicine, Seoul, Korea, Republic of, [2]NEORNAT, Seoul, Korea, Republic of

Previously, we demonstrated that recovery of histone deacetylase 6 (HDAC6) suppressed let-7i-5p expression to de-repress the thrombospondin-1 (TSP1) expression, and thereby it occupied CD47 receptor to block CD47-SIRPα mediated anti-phagocytosis of macrophage in liver cancer. NRT-YHD_001 is a modified antisense miRNA of let-7i-5p for liver cancer treatment. In addition, N-acetylgalactosamine was attached to NRT-YHD_001 for specific delivery to the liver. *In vitro* phagocytosis assay showed better macrophage phagocytosis activity than non-modified antisense let-7i-5p. To investigate the *in vivo* efficacy of NRT-YHD_001, spontaneous (Ras-transgenic) mouse liver cancer model was used and compared with that of sorafenib treatment. This mouse liver cancer model usually develops spontaneous liver cancer mass after 15 ~ 20 weeks of birth. We confirmed that both weekly i.v. injection of 1mg/kg and biweekly i.v. injection of 2mg/kg NRT-YHD_001 showed more significant therapeutic efficacy than the sorafenib-treated group. Furthermore, xenograft assay with Hep3B human liver cancer cells in athymic-nude mouse also showed that weekly i.v. injection of 1mg/kg NRT-YHD_001 exhibited better survival and tumor growth inhibition compared to non-treated group. In mouse and cynomolgus monkey maximum tolerated dose (MTD) studies, no toxicity of NRT-YHD_001 was found at doses up to 500 mg/kg intravenously. These results showed that NRT-YHD_001 had a robust anticancer effect by converting the macrophage of “don't eat me” into “eat me signal” in the tumor microenvironment of liver cancer, thereby removing or inhibiting liver cancer cells.

#7521 Tumor NLRP3 inflammasome activity mediates resistance to Anti-PD-1 immunotherapy in advanced gastroesophageal cancer.

N. Yarla, K. Howell, Y.-V. Nguyen, D. Niedwiecki, H. Uronis, J. Strickler, N. C. DeVito, B. Theivanthiran, **B. A. Hanks**;
Duke University, Durham, NC

The addition of anti-PD-1 immunotherapy to the therapeutic armamentarium of advanced gastroesophageal (GE) cancer patients has resulted in modest improvements in clinical outcomes for a subset of patients. More robust predictive biomarkers to guide patient management and to select optimal combination immunotherapy strategies for the individual patient are needed. Our previous studies indicate that the tumor-intrinsic NLRP3 inflammasome-HSP70 signaling axis promotes the recruitment of granulocytic myeloid-derived suppressor cells (PMN-MDSCs) and drives resistance to anti-PD-1 immunotherapy.
The KEYLargo phase II clinical trial evaluated the efficacy of pembrolizumab (pembro) in combination with capecitabine/oxaliplatin (CAPOX) in HER2-negative advanced GE cancer patients. An 8-day lead-in period of pembro monotherapy in 36 advanced GE cancer patients allowed for the acquisition of blood and tumor tissue specimens to determine which immune-mediated alterations within the tumor microenvironment correlated with resistance to anti-PD-1 immunotherapy. Baseline and on-treatment specimens were collected for HSP70 ELISA, immunofluorescence microscopy, spatial transcriptomics, *NLRP3* FISH, IHC, and NLRP3-ASC proximity ligation assays (PLA) to measure NLRP3 pathway activity levels. All data was correlated with best objective response, progression-free survival (PFS), and overall survival (OS). Tumor-infiltrating $CD8^{\pm}$ T cells and PMN-MDSCs were increased in responders and non-responders, respectively. While PD-L1 CPS failed to associate with response, elevated baseline NLRP3 PLA activity correlated with increased tumor-infiltrating PMN-MDSCs ($P = 0.001$) and resistance to pembro/CAPOX therapy ($P = 0.01$). Only non-responding tumors exhibited an increase in NLRP3 PLA activity and *NLRP3* amplification. Transcriptional studies revealed tumors with enhanced NLRP3 activity to exhibit decreased expression of the NLRC5 transactivator, MHC class I antigen presentation genes, and an increase in the NK cell negative regulator, HLA-G. Baseline plasma HSP70 levels correlated with tumor NLRP3 activity ($P = 0.043$) and with resistance to pembro/CAPOX therapy ($P = 0.001$). Elevated baseline NLRP3 PLA activity and amplification were associated with diminished PFS ($P = 0.008$) and OS ($P = 0.009$). In additional studies, pharmacologic inhibition of the NLRP3 inflammasome suppressed PMN-MDSC recruitment, upregulated MHC class I, and reversed anti-PD-1 resistance in an orthotopic model of GE cancer. Together, these findings implicate tumor-intrinsic NLRP3-HSP70 signaling as an important mediator of anti-PD-1 resistance in advanced GE cancer. The NLRP3-HSP70 pathway is a promising source of therapeutic targets and biomarkers capable of improving treatment outcomes for this patient population. Additional clinical studies are warranted.

#7522 Association between the *CNTN4* expression and responsiveness to pembrolizumab in gastric cancer.

M. Cha[1], **G. Kim**[1], C. Park[1], B.-N. Jeon[1], K. Park[1], H. Park[1], C.-Y. Ock[2];
[1]Genome & Company, Sungnam-si, Gyeonggi-do, Korea, Republic of, [2]Lunit, Seoul, Korea, Republic of

Even though numerous strategies for controlling malignant tumors have been established with immunotherapies, a solution for non-favorable responses to immunotherapy is still unclear. To address this unsolved problem, we previously suggested that a new immune checkpoint, CNTN4, is expressed on the tumor side and suppresses T cell-dependent immune activation. We further investigated the association between the clinical outcome of pembrolizumab and the expression of *CNTN4* in the gastric cancer cohort using bulk RNA sequencing data to establish a clinical strategy for targeting CNTN4. We split the patients into high- or low-group based on the expression of *CNTN4* and *CD274* (PD-L1) with the median of those two genes and analyzed for the responses. As a result, patients who had low-*CNTN4* expression and high-*CD274* expression were favorable to the pembrolizumab (Objective response rate, ORR; 64.3% [9/14]). However, patients who had high-*CNTN4* expression and high-*CD274* expression showed unfavorable responses (ORR; 0% [0/9], χ^2 = 5.951, *P* = 0.002). We also figured out that non-responders (NRs, N = 33) had a relatively lower expression of *CD274* (p = 0.0012) and a higher expression of *CNTN4* (p = 0.0015) compared to responders (Rs, N =12). Furthermore, in *CD274*-high patients, NRs showed significantly higher *CNTN4* expression than Rs (Fold change = 2.17. *P* = 0.0086). Immune-related cytokine genes, such as *IFNG*, *GZMA*, and *CXCL9*, were negatively correlated to *CNTN4* expression (*R* = -0.69, *P* = 2×10^{-4}; *R* = -0.52, *P* = 0.0108; *R*= -0.54, and *P* = 0.0077, respectively.). In addition to the cancer cells, cancer-associated fibroblast, important for immunotherapy, was deconvoluted from bulk RNA data and showed higher *CNTN4* expressions in NRs than Rs (Fold change = 3.3, *P* = 0.002). When classifying tumor tissue based on TCGA molecular subtypes, genomically stable (GS) type and chromosomal instability (CIN) were more observed in the NRs compared to the Rs with poor prognosis. CIN and GS type patients showed higher *CNTN4* and lower *CD274* expression than other TCGA subtypes. We also figured out that all *CNTN4*-high patients were composed of CIN or GS types. Similarly, higher *CNTN4* expression and lower *CD274* expression were observed in CIN and GS gastric patients from the TCGA database. Moreover, overall survival (OS) and progression-free survival (PFS) were poorer in *CNTN4*-high patients (OS: median of *CNTN4*-high = 9.73 [95% CI= 4.77-NA] months, median of *CNTN4*-low = NA [95% CI= 9.03-NA] months, *P* = 0.072. Hazard ratio = 2.15 [95% CI = 0.917-5.037], *P* = 0.078) (PFS: median of *CNTN4*-high = 2.10 [95% CI= 1.33-3.97] months, median of *CNTN4*-low = 5.47 [95% CI= 2.80-NA] months, *P* = 0.0004. Hazard ratio = 3.303 [95% CI = 1.647-6.624], *P* = 0.0008).Together, we suggest that *CNTN4* is a potential ICP candidate for gastric cancer patients unfavorable to pembrolizumab treatment. The anti-CNTN4 antibody GENA-104A16 is under the IND submission stage for clinical studies.

#7523 An integrated analysis of radiologic and pathological responses in patients with metastatic renal cell carcinoma who presented with primary renal tumor in situ and received first-line nivolumab plus ipilimumab followed by cytoreductive nephrectomy.

L. Campos Clemente, O. Alhalabi, M. T. Campbell, G. Corredor Alonso, K. Hara, P. Msaouel, A. C. Johns, C. Tang, J. A. Karam, P. Rao, N. M. Tannir; The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The decision to perform cytoreductive nephrectomy (CN) and timing of CN in patients (pts) with metastatic renal cell carcinoma (mRCC) and primary who respond to immune checkpoint therapy (ICT) is a matter of debate. In CheckMate-214, nivolumab plus ipilimumab (N+I) yielded a 35% objective response rate in the primary; however, there is a paucity of pathological data from nephrectomy specimens (Nx) after treatment with N+I. We sought to investigate the radiologic and pathological responses and correlate the findings with outcomes in pts receiving 1L N+I followed by CN.

Methods: We reviewed the medical records and Nx of pts with mRCC who received N+I followed by CN at our institution (2016-2021). H&E slides were reviewed to determine the % of residual viable malignant cells. Pathological response was defined as tumor viability ≤20%, and pathological complete response (pCR) defined as absence of residual cancer. Radiologic response was defined as ≥30% reduction in primary size. Progression-free survival (PFS) and overall survival (OS) were determined from date of CN.

Results: 22 pts (median age 59) are included: 18 (81.8%) males, 19 (86%) Caucasian, 20 (91%) had clear-cell histology, 20 (91%) had ECOG Performance Status 0-1, 10 (45%) had intermediate-risk disease and 12 (55%) had poor-risk disease by IMDC. Median ICT duration before CN was 6.5 months (mo) (range, 2-19 mo). 17 (77%) completed 4 cycles of N+I, and 16 (73%) received N maintenance before CN. 5 pts (23%) had grade 3/4 immune-related adverse effects; 1 pt did not complete 4 cycles of N+I due to hepatitis. There were no therapy-related deaths. 12 pts (54.5%) had progressive disease (PD); 3 pts (14%) died of RCC. Median PFS was 22 mo, median OS not reached (NR). Pts with pathological response had greater radiologic reduction in primary size compared to pts without pathological response (median reduction 38% vs. 15% p-value 0.01), smaller final primary pathological size (median 5.7 cm vs. 10.65 cm p-value 0.002), and lower pathological yT stage (pT0: 1, pT1: 6, pT2: 2 pT3: 3, pT4: 0 vs. pT0: 0, pT1: 1, pT2: 0, pT3: 8, pT4: 1 p-value 0.045); ICT duration was similar between groups (median 5.5 mo vs. 7 mo p-value 0.733). 6 pts achieved low viability within 5 mo of ICT. In 9 pts with optimal radiopathological response [viability ≤20% and ≥30% primary size reduction], PFS was longer compared to PFS in pts with suboptimal radiopathological response: median PFS NR vs. 17 months (HR 0.23, 95% CI 0.076 - 0.741; p-value 0.041). In 13 pts with suboptimal response, 10 (77%) had PD, the most common sites of PD were lymph nodes [6 pts (60%)] and brain [3 pts (30%)].

Conclusions: In this small cohort, N+I yielded a low pCR in Nx of pts with mRCC. Radiologic response but not ICT duration was associated with low tumor viability.

#7524 Targeting siglec-7/9 glyco-immune checkpoints in prostate cancer for enhanced immune responses and tumor suppression.

R. Wen, G. Marti, J. Stark, F. Marques, N. Riley, A. Bermudez, H. Zhao, C. Bertozzi, S. Pitteri, J. Brooks;
Stanford University, Stanford, CA

Prostate cancer is one of the leading causes of death in men worldwide. Despite significant advancements in the fight against cancer, immune checkpoint inhibitors have limited effectiveness in treating prostate cancer. Evidence shows that disrupting the interactions between Siglec-7/9 and sialic acids can enhance immune responses and effectively inhibit tumor growth in several cancers. However, the understanding of Siglec-7/9-sialic acid interactions in prostate cancer remains limited. Here, we found that tumor-infiltrating immune cells derived from prostate cancer patients exhibited high levels of Siglec-7 and Siglec-9. TCGA data analysis suggests that high levels of Siglec-7/9 are correlated to worse patient survival. Elevated levels of Siglec-7/9 ligands were found in prostate tumor tissues compared to adjacent normal tissues. Prostate cancer cell lines exhibited significant expression levels of Siglec-7 and Siglec-9 ligands, and cell surface sialic acids. Proteomic analysis suggests that increased sialylation was observed in tumor tissues in comparison to adjacent normal tissues. Disrupting interactions between Siglec-7/9 and sialoglycans enhanced T cell-mediated cytotoxicity against prostate cancer cells. Treatment with anti-Siglec-7/9 antibodies effectively suppressed the growth of PC3 and 22Rv1 tumors in a humanized mouse model. Immunohistochemistry analysis of tumor tissues showed that PC3 and 22Rv1 tumors treated with anti-Siglec-7/9 exhibited reduced proliferation, decreased vascularization, increased apoptosis, and enhanced immune cell infiltration. The CRISPR screen and mass spectrometry analysis suggested CD59 as a potential ligand for Siglec-9. Knockout of CD59 in prostate cancer cells decreased their binding activity of Siglec-9-Fc chimera proteins and promoted T cell-mediated killing ability. These findings provide valuable insights into the potential therapeutic strategy of targeting Siglec-7/9 and their ligands for prostate cancer treatment.

#7525 Investigating B7-H3 as a checkpoint and antibody drug conjugate target across prostate cancer variants- both androgen receptor dependent and independent.

N. Mundhara[1], S. Sharma[1], E. Tekoglu[2], E. G. Baraban[1], N. A. Lack[3], E. Shenderov[1];
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]School of Medicine, Koc University, Istanbul, Turkey, [3]Vancouver Prostate Center, University of British Columbia, Columbia, DC, Canada

Background: *CD276* (B7-H3) has recently emerged as a promising presumptive immune checkpoint inhibitor (ICI) and antibody-drug conjugate (ADC) target for PCa. Unfortunately, current immunotherapy trials have yielded few objective responses in PCa and hormonal therapy seldom cures necessitating the need to develop new immunotherapy or targeted antibody-drug conjugate (ADC) treatment options for PCa, including B7-H3 targeted approaches.
Method: In this work, we evaluated important ADC targets and immune checkpoints (PD-1, PD-L1, PD-L2, LAG3, TIGIT, OX40, 4-1BB, CTLA4, STEAP1, STEAP2, PSMA, NECTIN1, TROP-2, DLL3 and B7-H3) in various PCa cell lines and multiple patients spanning various subtypes of PCa using publicly available bulk RNA sequencing data and single-cell RNA sequencing (scRNA-seq) data respectively. The results were validated at RNA and protein levels in listed cell lines. Further, the impact of androgen receptor (AR) signaling on B7-H3 expression was quantified using charcoal stripped media, AR agonist (R1881) and antagonist (enzalutamide) using real-time PCR and flow cytometry at RNA and protein levels respectively.
Results: We found that B7-H3 shows high expression and very low variability compared to other ADC targets and immune checkpoints in AR-positive (LnCAP), hormone-refractory (VCAP), Castrate resistant (22RVI), AR negative (PC3, DU145), and neuroendocrine (H660) cell lines, as well as in—PCa cells and tumor microenvironment (TME) myeloid cells—of multiple patients spanning various subtypes of PCa. Western blotting confirms the ubiquitous presence of B7-H3 in all these cell lines, even when PSMA is absent. Furthermore, B7-H3 expression was modifiable via androgen depletion, R1881 supplementation, or addition of the AR antagonist enzalutamide. These changes were significant in AR-positive LnCAP cells compared to AR-negative DU145 cells further endorsing the crosstalk between AR and B7-H3 signaling pathways, which will be presented in greater detail.
Conclusion: This work explores the therapeutic relevance of important ADC targets and immune checkpoints for Prostate Cancer (PCa), highlighting B7-H3 as a unique therapeutic ADC and ICI candidate across the continuum of PCa—androgen sensitive, castration resistant, and neuroendocrine—due to its stable expression across various subtypes and on TME myeloid cells. The relationship between AR and B7-H3 opens the possibility of future combination therapies based on this interaction.

#7526 Landscape of TIGIT and PD-L1 co-expression in solid tumors.

Sarabjot Pabla[1], Maria-Fernanda Senosain[1], R.J. Seager[1], Hardik Parikh[1], Erik Van Roey[1], Shuang Gao[1], Yamuna Pulivendula[1], Paul DePietro[1], Mary Nesline[1], Durgapras Dash[1], Jeffrey M. Conroy[1], Stephanie Hastings[2], Heidi Ko[2], Kyle C. Strickland[2], Rebecca A. Previs[2], Eric Severson[2], Marcia Eisenberg[3], Brian Caveney[3], Taylor J. Jensen[2], Shakti Ramkissoon[2]

[1]OmniSeq Inc. (Labcorp), Buffalo, NY,[2]Labcorp Oncology, Burlington, NC,[3]Labcorp, Burlington, NC

Background: Combination treatment of solid tumors with anti-PD-1/PD-L1 and anti-TIGIT agents have shown promise in recent clinical trials. However, TIGIT co-expression with other checkpoints has not been comprehensively characterized to support identification and prioritization of patients most likely to benefit from anti-TIGIT drugs and guide clinical trial design. In this study, we investigate TIGIT and other PD-1/PD-L1 axis checkpoint targets across various solid tumors.
Methods: A discovery cohort (DC) of 24,186 solid tumors across 35 tumor types was evaluated by comprehensive immune profiling. TIGIT gene expression was normalized and ranked yielding a percentile rank values [0-100]. TIGIT rank was classified as high (rank >e 75) and low (rank < 25). We studied the distribution of TIGIT expression, cellular proliferation signature, and co-expression with PD-1/PD-L1 axis and other checkpoint targets using Spearman correlation(r_s). Kaplan-Meier analysis and Chi-squared assessed associations between TIGIT expression/checkpoint co-expression and overall survival (OS), progression free survival (PFS) and objective response rate (ORR) differences in a separate cohort of 72 pembrolizumab treated non-small cell lung cancer (LC) patients treated with pembrolizumab.
Results: The DC confirmed a large range of TIGIT expression with highest median expression observed in NSCLC (median = 61), head & neck (HNSCC) (median = 59), and cervical cancer (median = 55). Significant association between PD-L1 IHC positivity (TPS≥1%, CPS≥1) and TIGIT expression ($p<0.001$) was discovered, where 69% (n=3574) of TIGIT high cases were PD-L1 positive, whereas 66% (n=3606) of TIGIT low cases were PD-L1 negative. By RNA-seq measurements, significant TIGIT co-expression ($p<0.001$) with various checkpoint blockade targets including PD-1 (r_s=0.5), PD-L1 (r_s=0.5), and TIM3 (r_s=0.6) was confirmed. In the LC, patients with TIGIT high tumors had significantly improved OS (median OS = 44 months; p=0.01) and PFS (median PFS = 35 months; p=0.006) compared TIGIT low group (median OS = 23 months; median PFS = 18 months). Similar results were observed for response to pembrolizumab, where TIGIT high cases had significantly higher response (ORR=60%, p= 0.001) vs. TIGIT low cases (ORR=39%). This was confirmed in TIGIT high and PD-L1-IHC positive group with improved OS (p=0.013), PFS (p=0.017) and ORR (p=0.016).
Conclusion: In an ultra-large cohort of clinically tested solid tumors, TIGIT was differentially expressed across tumor histologies of solid tumors. TIGIT expression was strongly co-expressed with PD-1/PD-L1 axis, supporting the improved outcomes for patients with NSCLC treated with a combination of TIGIT and PD-1/PD-L1 inhibitors from recent clinical trials. This finding of co-expression pattern of TIGIT and PD-1/PD-L1 axis highlights the potential use of immune profiling for combination therapy strategies and clinical trial design in solid tumors.

#7527 Investigating biomarkers for immune-related adverse events following immune checkpoint inhibitor therapy in recurrent lung cancer patients.

Y. Kudo, J. Matsubayashi, S. Takahashi, M. Hagiwara, M. Kakihana, T. Nagao, T. Ohira, N. Ikeda;
Tokyo Medical Univ., Tokyo, Japan

Background: The application of immune checkpoint inhibitors (ICIs) as adjuvant therapy post-lung cancer surgery is expected to confer significant benefits. However, the risk factors for severe immune-related adverse events (irAEs) remain incompletely understood, and managing irAEs may require long-term steroid use. The identification of biomarkers for irAEs in patients with surgically resected lung cancer is an urgent need.
Methods: We analyzed 43 lung cancer patients who received ICI treatment for recurrence postoperatively. Macrodissection of lung cancer lesions was performed on FFPE specimens from resected lungs, from which total RNA was extracted. We conducted gene expression analysis of 770 immune-related genes using the PanCancer Immune Profiling Panel (NanoString Technologies, Inc., Seattle, WA, USA). The relationship between gene expression changes and irAEs or the efficacy of ICI treatment was examined. For validation, immunostaining of proteins strongly associated with irAEs was performed to determine their expression status in tissue specimens.
Results: Among the 43 patients (30 males, 13 females, median age 68), 28 had adenocarcinoma, and 15 had squamous cell carcinoma. PD-L1 positivity was observed in 36 patients. The treatment regimens included pembrolizumab monotherapy for 18 patients and combination immunotherapy for 25 patients, with 25 patients responding to treatment and 7 developing irAEs. There was a marked difference in gene expression between adenocarcinoma and squamous cell carcinoma, with a notably higher number of tumor-infiltrating lymphocytes (TILs) in adenocarcinoma. An increase in TILs was observed in cases with irAEs across both cancer types. Additionally, an increased CD8/Treg ratio and CD8/exhausted T cell ratio were noted in adenocarcinomas with irAEs. A strong correlation between IRF5 gene expression and the occurrence of irAEs in adenocarcinoma was also confirmed by immunohistochemistry.
Conclusion: We have identified tumor immune microenvironments correlated with the onset of irAEs following ICI treatment in patients with postoperative recurrence of lung cancer. This discovery could contribute to perioperative treatment strategies and improve our understanding of tumor immune mechanisms.

#7528 Coordinated regulation of critical immune checkpoint proteins by the integrated stress response (ISR) pathway in lung cancer.

S. E. Thomas-Jardin, S. Suresh, C. Lewis, C. Ahn, B. M. Evers, J. D. Minna, K. A. O'Donnell;
UT Southwestern Medical Center, Dallas, TX

Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related deaths worldwide. Despite recent advances, high rates of recurrence highlight the need for novel treatment options. Groundbreaking discoveries in identifying and exploiting the PD-1/PD-L1 (Programmed Death 1/ Programmed Death Ligand 1) immune checkpoint have resulted in the approval of monoclonal antibodies that disrupt this interaction as a first-line therapy for lung cancer patients. However, only ~20% of NSCLC patients benefit from checkpoint blockade. A critical question remains as to what mechanisms facilitate resistance to PD-1/PD-L1 therapy and whether other immune checkpoints or pathways can be pursued clinically in combination with this therapy. The integrated stress response (ISR) pathway represents an emerging therapeutic vulnerability. The ISR is a generalized response to maintain cellular homeostasis, and is known to be activated by hypoxia, heme deprivation, amino acid starvation, and oncogenic activation. We previously demonstrated that ISR activation potently induces PD-L1 in NSCLC and suppression of anti-tumor immunity (Suresh et al, *Nature Cancer*, 2020). We discovered that ISR pathway activation enhances PD-L1 translation through the bypass of inhibitory upstream open reading frames (uORFs) in the *PD-L1* 5' UTR and a mechanistic link to the translation initiation factor eIF5B. Our latest studies demonstrate that the immune checkpoint protein, CD155 (Cluster of Differentiation 155), is induced by ISR activation. We find that both PD-L1 and CD155 are induced by multiple arms of the ISR pathway, and CD155 harbors inhibitory uORFs in its 5' UTR. Importantly, we observed a significant correlation between PD-L1 and CD155 expression in a panel of primary human lung adenocarcinomas. We further demonstrated that ISR activation inhibits T cell function *in vitro* and promotes tumor growth in the CMT167 syngeneic mouse model. Analysis of immune cell infiltration using mass cytometry in this *in vivo* model is ongoing. Currently, we are determining the extent to which ISR inhibition suppresses tumorigenesis by promoting anti-tumor immunity and whether this may synergize with existing immune checkpoint therapies. Overall, these studies will set the stage for determining whether inhibition of the ISR pathway alone or in combination with immune checkpoint blockade will benefit lung cancer patients. Our studies may also lead to new therapeutic approaches to trigger anti-cancer immune responses and improve current strategies.

#7529 Harmonization radiomics model to predict immune checkpoint inhibitor-related pneumonitis (CIP) in non small cell lung cancer (NSCLC) in patients treated with immunotherapy.

M. Yadav[1], J. Lee[2], P. Kim[3], S. Lee[2], T. Um[1], S. Lee[4], M. J. A. Chuchuca[1], T. Djunadi[5], L.-Y. Chung[1], J. Yu[6], D. Rodrigues[1], N. Gennaro[1], L. Kim[7], M. Nam[8], Y. Oh[9], S. Yoon[1], Z. Shah[10], Y. Kim[1], I. Hong[11], J. Jang[11], G. Kang[11], A. Cho[11], S. Lee[12], T. Hong[11], C. Nam[11], Y. Velichko[1], Y. Chae[1];
[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, [2]Kyungpook National University, Daegu, Korea, Republic of, [3]The University of Texas at Austin, Austin, TX, [4]School of Medicine at UCI, Irvine, CA, [5]Richmond University Medical Center, Staten Island, NY, [6]Dignity Health - St. Rose Dominican Hospital, Henderson, NV, [7]Ascension Saint Francis Hospital, Evanston, IL, [8]Lincoln Medical Center, Bronc, NY, [9]John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, [10]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [11]Northwestern University, Evanston, IL, [12]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: With the increasing use of immunotherapy in advanced non-small cell lung cancer (NSCLC), managing adverse events, particularly checkpoint inhibitor-associated pneumonitis (CIP), poses a significant challenge. CIP often necessitates discontinuation of immunotherapy, even in cases of tumor response. Currently there are no effective models in predicting CIP. This study leverages artificial intelligence (AI) algorithms and the use of harmonization models to analyze radiomic features from chest CT scans, aiming to predict the occurrence of CIP in patients with NSCLC.
Methods: This retrospective study examined data from 152 stage III-IV NSCLC patients undergoing immunotherapy. Tumor segmentation was performed using LIFEx software (IMIV/CEA, Orsay, France). 3D-radiomic features were extracted from both the tumor and the surrounding 1 cm thick peritumoral regions. The Random Forest (RF) algorithm was employed to develop a classification model to differentiate between CIP and non-CIP. A harmonization model was deployed to account for the scanner-related differences by using spleen and normal lung signals. The dataset was divided into a training set (75%) and a test set (25%). Bootstrapping with 1,000 iterations was performed to estimate the model's performance by calculating the median and 95% confidence interval (CI) estimate. The accuracy of the model's predictions was evaluated by creating a confusion matrix. The model's performance was assessed by calculating the sensitivity, specificity, positive predictive values (PPV), negative predictive values (NPV), and area under the ROC curve (AUC) for CIP prediction.
Results: Among 152 patients, 87 (57.23%) are female and 65 (42.76%) are male. The median age was 59 years. Histology types included were Adenocarcinoma 111 (73%), Squamous cell carcinoma 27 (17.8%), and others 14 (9.2%). CIP was seen in 30 (19.73%) patients. Among the 30 patients with CIP, 17 (56.7%) patients had grade 1 pneumonitis, 11 (36.7%) patients had grade 2 pneumonitis, 2 (6.6%) patients had grade 3 pneumonitis, and none had grade 4 or grade 5 pneumonitis. The model achieved a sensitivity of 0.57, a specificity of 0.67, a PPV of 0.48, and NPV of 0.38 for predicting CIP. The AUC of 0.59 indicates that the model may predict checkpoint inhibitor-associated pneumonitis with an accuracy of 59%.
Conclusions: The study provides insights into the potential of radiomic analysis coupled with AI algorithms and the use of harmonization model in predicting CIP among NSCLC patients treated with immunotherapy. Larger studies are needed to validate our findings and the utility of harmonization models in predicting CIP.

#7530 Harmonization radiomics models to predict tumor response in non-small cell lung cancer (NSCLC) patients treated with immunotherapy.

M. Yadav[1], J. Lee[2], P. Kim[3], S. Lee[2], T. Um[1], S. Lee[4], M. J. A. Chuchuca[1], T. Djunadi[5], L.-Y. Chung[1], J. Yu[6], D. Rodrigues[1], N. Gennaro[1], L. Kim[7], M. Nam[8], Y. Oh[9], S. Yoon[1], Z. Shah[10], Y. Kim[1], I. Hong[11], J. Jang[11], G. Kang[11], A. Cho[11], S. Lee[12], T. Hong[11], C. Nam[11], Y. Velichko[1], Y. Chae[1];

[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, [2]Kyungpook National Univeristy, Daegu, Korea, Republic of, [3]The University of Texas at Austin, Austin, TX, [4]School of Medicine at UCI, Irvine, CA, [5]Richmond University Medical Center, Staten Island, NY, [6]Dignity Health - St. Rose Dominican Hospital, Henderson, NV, [7]Ascension Saint Francis Hospital, Evanston, IL, [8]Lincoln Medical Centre, Bronx, NY, [9]John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, [10]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [11]Northwestern University, Evanston, IL, [12]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: Precise prediction of immunotherapy response in non-small cell lung cancer (NSCLC) is crucial for personalized treatment. This study investigates the application of pretreatment CT-based radiomics and use of harmonization model in predicting these outcomes in NSCLC patients receiving immunotherapy.
Methods: This retrospective study examined data from 152 stage III-IV NSCLC patients undergoing immunotherapy. Patient responses were categorized using immune-related RECIST (irRECIST) criteria into durable responders (complete response [CR], partial response [PR], or stable disease [SD]) for at least 24 weeks and non-responders. Tumor segmentation was performed using LIFEx software (IMIV/CEA, Orsay, France). 3D-radiomic features were extracted from both the tumor and surrounding 1 cm thick peritumoral regions. The Random Forest (RF) algorithm was employed to develop a classification model to differentiate between responders and non-responders. A harmonization model was deployed to account for the scanner-related differences by using spleen and normal lung signals. The dataset was divided into a training set (75%) and a test set (25%). Bootstrapping with 1,000 iterations was performed to estimate the model's performance by calculating the median and 95% confidence interval (CI) estimate. The accuracy of the model's predictions was evaluated by creating a confusion matrix. The model's performance was assessed by calculating the sensitivity, specificity, positive predictive values (PPV), negative predictive values (NPV), and area under the ROC curve (AUC) for response prediction.
Results: A total of 152 patients were analyzed. 87 (57.23%) were female and 65 (42.76%) were male. The median age was 59 years. Histology types included were: 111 Adenocarcinoma (73%), 27 Squamous cell carcinoma (17.8%), and 14 other types (9.2%). The model achieved a sensitivity of 0.63, a specificity of 0.59, a PPV of 0.51, and NPV of 0.7 for response prediction of NSCLC patients receiving immunotherapy. The AUC of 0.61 indicates that the model may discriminate between responders and non-responders with an accuracy of 61%.
Conclusion: This study demonstrates the potential of radiomics and the use of harmonization models to predict immunotherapy responses in NSCLC patients, offering insights into personalized treatment approaches. Larger studies are needed to validate our findings and the utility of harmonization models in predicting a tumor response.

#7531 Mechanisms of response to anti-PD1 (PD1) combined with Ipilimumab (IPI) in patients (pts) with PD1-resistant metastatic melanoma (MM).

I. Pires da Silva[1], J. Conway[1], J. Edwards[1], F. Marsh-Wakefield[2], C. Quek[1], A. Ferguson[2], P. Johnansson[3], M. Carlino[1], A. Menzies[1], J. Wilmott[1], U. Palendira[2], R. Scolyer[1], G. Long[1];

[1]Melanoma Institute Australia, Wollstonecraft, Australia, [2]The University of Sydney, Sydney, Australia, [3]QIMR Berghofer Medical Research Institute, Brisbane, Australia

Background: Approximately 1 in 3 pts with PD1-resistant MM will benefit from IPI+PD1, but the role of adding IPI in this context is unclear. We sought to (a) identify biomarkers and (b) determine mechanisms of response to IPI+PD1 in PD1 resistant pts.

Methods: Pts with PD1-resistant MM subsequently treated with IPI+PD1 were included. We performed multiplex immunofluorescence (mIF), imaging mass cytometry (IMC) and RNA sequencing (RNAseq) on melanoma samples, and cytometry by time of flight (CYTOF) on peripheral blood mononuclear cells (PBMCs), at 3 timepoints (before PD1 [T1], before IPI+PD1 [T2], and after IPI+PD1 [T3]).

Results: 34 pts with PD1-resistant MM (82% innate resistance) who received IPI+PD1 were included: 16 (47%) responders and 18 (53%) non-responders to IPI+PD1. Median age was 66yo (37-86) and 19 (56%) were male. Six pts (18%) were ECOG PS ≥1, 18 (53%) were stage M1C/D and 11 (32%) had elevated LDH at the start of IPI+PD1.Gene expression analysis (RNAseq) on T1 and T2 tumor samples revealed higher expression of cancer testis antigens (CTA; MAGE-A3 and MAGE-C1; $p<0.05$) and immune regulatory genes (ILR2; $p<0.2$), but lower expression of fibrosis regulation genes (FABP3 and MMP7; $p < 0.2$) in responders vs non-responders. We then examined whether the addition of IPI led to expansion of CTA-specific T cells, and CyTOF analysis of MAGE-A3 tetramers on PBMCs showed a decrease in peripheral MAGE-A3-specific CD8+ T cells with PD1 (T1 to T2; $p=0.03$); and expansion of this T-cell subset with subsequent IPI+PD1 (T2 to T3) was seen in 7/12 HLA-A2+ pts. Further analysis on PBMC longitudinal samples showed an increase in regulatory T cells (Tregs) in responders ($p=0.04$), between T1 and T3, and a decrease in % of TCF7+ CD8+ & CD4+ T cells in non-responders ($p<0.05$) with the addition of IPI (T2 to T3). On baseline (T1) tumor samples (mIF), IPI+PD1 responders had a higher % of stem cell-like TCF7+ CD8+ T cells ($p=0.0004$), lower % of well-differentiated Tbet+ CD8+ T cells ($p=0.07$), and higher % of CD4+ T cells ($p=0.006$), compared with non-responders; but no difference in Tregs. On longitudinal tumor samples, there was a decrease in the % of stem cell-like TCF7+ CD8+ T cells but an increase in the % of tumor-reactive CD39+ CD103+ CD8+ T cells with PD1 (T1 to T2; $p<0.05$), mainly seen in responders ($p=0.06$). There were only 3 T2 to T3 IHC paired samples, precluding further analysis. IMC analysis on longitudinal samples (T1, T2 and T3) is underway to characterize the interaction between Tregs and T effector cells.

Conclusions: We identified potential mechanisms of response to IPI+PD1 in PD1-resistant MM pts. Our data suggests that response to IPI+PD1 requires baseline stem cell-like TCF7+ T cells with the potential to differentiate to an effector phase (CD39+ CD103+ CD8+ T cells), and that IPI facilitated expansion of antigen-specific T cells in a CTA-expression context, that PD1 alone is unable to do.

#7532 NB005.1, a fully humanized anti-KLRG1 blocking mAb enhances effector function of human CD8 T-cells.

B. P. Nayak[1], M. Xiong[2], Y. Xue[2], B. Wang[2], S. Lighvani[1], S. Sharma[1], D. Wang[2], H. Wang[2], B. Wang[2], Y. Zhang[2], X. Dong[2];
[1]Neologics Bioscience, San Diego, CA, [2]Neologics Bioscience, Suzhou, China

Introduction: Immune checkpoint blockers (ICBs) have revolutionized treatment, enhancing survival and benefiting many patients. However, many patients fail to respond to the treatment, necessitating research for new targets and improved approaches. The Killer cell Lectin-like Receptor G1 (KLRG1), expressed on a subset of NK and T-cells harbors an immune receptor tyrosine-based inhibitory motif (ITIM) within its cytoplasmic domain, indicating its inhibitory function. On $CD8^{\pm}$ T-cells, KLRG1 is expressed on highly differentiated antigen-specific effector memory T-cells (TEMs) and $CD45RA^{\pm}$ effector memory T cells (TEMRA). These cells are known to exhibit strong cytotoxicity potential and display developmental plasticity following KLRG1 blockade. And 16-48% of $CD8^{\pm}$ T-cells that infiltrate the tumor microenvironment (TME) are KLRG1 positive. We hypothesize that the blockade of KLRG1 should enhance the effector function of $KLRG1^{\pm}$ CD8 T-cells in the TME and provide therapeutic benefit as a standalone or in combination with existing ICBs.

Methods: Monoclonal antibodies (mAbs) targeting the human KLRG1 extracellular domain (ECD) were generated through mouse immunization and hybridoma technology. Purified mAbs from positive clones were screened using CHO-K1 and Jurkat cells overexpressing human or cynomolgus KLRG1 and human primary CD8 T-cells (n=3) to determine EC_{50} values. Epitope binning was performed, and high-affinity clones from each bin with cyno cross-reactivity were humanized to IgG1-Fc LALA variant. The Abs were evaluated for ligand blocking and enhancement of CD8 T-cell effector function through multiple functional assays. The assay measured enhancement of IFNγ or TNFα by $KLRG1^{\pm}$ human $CD8^{\pm}$ T-cells co-cultured with CHO-K1 expressing OKT3 and E-cadherin as artificial antigen-presenting cells (aAPCs) or PBMCs stimulated in with anti-CD3 and anti-CD28 Abs in presence of soluble E-cadherin. A human IgG1-LALA antibody (Ab) served as a negative control. PD-1 and KLRG1 synergy was evaluated in hPBMC assays.

Results: NB005.1 demonstrated single digit nanomolar (nM) binding potency on human primary CD8 T-cells and Jurkat cells expressing human KLRG1 as identified by its EC_{50} value. Blocking of KLRG1 with NB005.1 on purified human CD8 T-cells in co-culture assay with aAPC expressing E-cad and OKT3 led to CD8 T-cell activation and increase in IFNγ production confirming inhibitory function of KLRG1. Similar result was obtained when the Ab was tested on hPBMCs stimulated with anti-CD3 and anti-CD28 Abs in presence of soluble E-cadherin.

Conclusion: NB005.1, a fully humanized mAb, binds to human KLRG1 in the single digit nM range and effectively blocks the interaction with its ligand. This blockade enhances T-cell effector function as measured by IFNγ production, supporting the advancement of NB005.1 for preclinical testing, either as a standalone therapeutic or in combination with existing ICBs.

#7533 PVRIG is uniquely expressed in tumor dendritic cells-rich niches on stem-like memory T cells and its blockade may induce immune infiltration and activation in non-inflamed tumors.

Z. Alteber[1], G. Cojocaru[1], R. Granit[1], I. Barbiro[1], A. Wool[1], M. Frenkel[1], A. Novik[1], A. Shuchami[1], Y. Liang[2], V. Daniel Carmi[1], N. Sabath[1], R. Foreman[3], N. Petrenko[3], J. He[3], Y. Kliger[1], H. Adewoye[2], P. Ferre[1], Z. Levine[1], **E. Ophir**[1];

[1]Compugen Ltd., Holon, Israel, [2]Compugen USA Inc., San Francisco, CA, [3]Vizgen Inc., Cambridge, MA

Poorly immune infiltrated cancers pose a significant challenge, with current immunotherapies yielding limited clinical success. Stem-like memory T cells (T_{SCM}) have been identified as a T cell subgroup which possess enhanced proliferative capacity that could expand and differentiate upon dendritic cells (DCs) priming. In this study we investigated the expression of the recently discovered inhibitory receptor PVRIG and its ligand, PVRL2, in the tumor microenvironment (TME). Leveraging single cell RNA sequencing (scRNAseq) data from diverse cancer indications, we found that in $CD8^{\pm}$ T cells, PVRIG clusters with early differentiation/T_{SCM} genes, unlike other immune checkpoints that cluster with genes related to T cells exhaustion. In agreement with the scRNAseq data, PVRIG protein expression was markedly increased on $CD28^{\pm}CD8^{\pm}$ early-memory T cells across cancer indications. PVRL2, was dominantly expressed on intratumoral DC subsets on both scRNA and protein levels. The observation that PVRIG is uniquely expressed by T_{SCM} cells, and PVRL2 by DCs, led us to evaluate whether these cell populations physically co-localize in the TME, thus potentially allowing PVRIG/PVRL2 interaction. Employing spatial transcriptomic analysis in surgically resected CRC lesions we showed that while CTLA4, PD1, and TIM3 were mainly expressed by tumor infiltrating T cells, PVRIG and other genes of the DNAM-1 axis were intensely expressed by T_{SCM} in specialized immune aggregates, as well as by T cells in tumor bed. High resolution spatial mapping of interacting immune and adjacent cells revealed pairs of activated $LAMP3^{\pm}PVRL2^{\pm}$ DCs interacting with $CD28^{\pm}PVRIG^{\pm}$ CD8 T cells in the intratumoral immune aggregates. Thus, PVRIG/PVRL2 interaction may limit T_{SCM} priming by DCs and blocking this interaction may unleash potent T_{SCM} proliferation, differentiation, and infiltration into the tumor regions. To gain a more comprehensive understanding on the intratumor effects induced by PVRIG blockade, we evaluated the immune response in the TME of patients with poorly immune infiltrated tumors, platinum resistant ovarian cancer and MSS-CRC, indications typically less responsive to immune checkpoint inhibitors. Treatment with COM701, anti-PVRIG antibody, as monotherapy or in combination with nivolumab resulted in an increased tumor T cell infiltration, accompanied by TCR clonality expansion, which were associated with clinical benefit. In summary, our study identifies PVRIG as uniquely expressed on T_{SCM} in the TME, with its ligand PVRL2 expressed on activated DCs. Blockade of PVRIG/PVRL2 interaction by COM701 antibody emerges as a promising strategy to induce potent T cell responses, providing a novel approach overcoming resistance to immunotherapy in immune excluded tumors.

#7534 Tobemstomig, a novel bispecific checkpoint inhibitory antibody to preferentially block PD-1 and LAG-3 on CD8 TILs over Tregs.

L. Codarri-Deak[1], P. A. A. Weber[1], V. Nicolini[1], C. Klein[1], P. Umana[1], S. Seeber[2], M. Perro[1], S. Leclair[2];
[1]Roche Glycart, Schlieren, Switzerland, [2]Hoffman La Roche, Penzberg, Germany

Checkpoint inhibitors targeting PD-1 have shown unprecedented clinical efficacy in several cancer indications and therefore have, revolutionized the standard of care. However, despite this advancement, only ~20-30% of the patients derive durable benefit from such a treatment. One of the suggested reasons for this limited success is the expression/activation of compensatory inhibitory pathways such as LAG-3 on tumor-reactive T cells. Therefore, it is envisioned that simultaneous antagonism of PD-1 and LAG-3 receptors would overcome this adaptive resistance mechanism and allow a more profound reinvigoration of tumor-reactive T cells. LAG-3 is constitutively expressed by regulatory T cells (on Tregs) and it has been reported that its blockade increases Treg suppressive function which could potentially off-sets the benefit of blocking LAG-3 on tumor-reactive CD8 T cells.We therefore developed a 1+1 PD1-LAG3 bispecific antibody, Tobemstomig, with a unique PD-1 binder recognizing a glycoepitope and more than 20 fold higher affinity than the LAG-3 binder which recognizes a novel and differentiated binding epitope (E3). This difference in affinities allows for an avidity driven selectivity gain to PD-1 and LAG-3 double positive T cells over and the following advantages over monospecific and other bispecific aPD-1/-L1 and aLAG-3 antibodies:1.improved targeting to tumor-reactive T cells rather than Tregs due to the selectivity gain and different expression patterns of PD-1 and LAG-3 on these two T cell types, 2.reduced internalization, 3.resistance to drug-shaving by macrophages due to Fc -silencing via P329G LALA,4.increased *in vitro* T cell effector functions even in the presence of Tregs, 5.in-vivo targeting and expansion of CD8 TILs, including stem-like T cells, and increase in T cell effector functions and6.superior *in vivo* tumor control/eradication compared to combination of monospecific anti-PD1 and anti-LAG3 antibodies,in several mouse models including Panc02 in syngeneic huPD-1xhuLAG3 dtg mice and BXPC3, WSU, OCI-Ly18 and BC004 in humanized mice Tobemstomig has completed dose escalation and is currently tested in a composite proof of concept Ph2 trial in several solid tumor indications.

#7535 First-in-human phase 1 clinical trial of ZM008, a monoclonal IgG1 targeting LLT1, monotherapy and in combination with pembrolizumab in advanced solid tumors.

Maloy Ghosh[1], Anurag Tiwari[1], Ashvini Kumar Dubey[1], Sanghamitra Bhattacharjee[1], Yogendra Manjunath[1], Shalini Kashipathi[1], Subith Krishna[1], Tirtha Mandal[1], **Jyotsna Fuloria**[2], M. S. Madhusudhan[3], Golding Rodrigues[3]

[1]Zumutor Biologics Pvt. Ltd., Bangalore, India,[2]Fuloria Clinical Research Solutions, New Orleans, LA,[3]Indian Institute of Science Education and Research (IISER), Pune, India

Lectin-like transcript 1 (LLT1) interaction with CD161 receptor on NK cells facilitates tumor immune escape. Hence, blocking LLT1-CD161 interaction could potentially activate NK cells and resulted tumor cell cytotoxicity. ZM008 is a first-in-class anti LLT1 monoclonal antibody with promising pre-clinical safety, efficacy data and received IND approval from USFDA. Clinical study will start soon at multiple US sites. TCGA data analysis revealed high LLT1 gene expression in multiple solid cancers BRCA, CHOL, ESCA, GBM, HNSC, KIRC, KIRP, LIHC, LUAD, STAD, SARC. Several immune checkpoint genes PDL1, LAG3, TIM3, TIGIT, ICOS, B7-H3, are positively correlated ($p<0.05$) with high LLT1 expression. CIBERSORT analysis of immune cells revealed significant presence of Treg and CD33+ immune cells along with IL4, IL10, Arg1 and IDO1 in the TME with high LLT1 expression. Cox regression analysis suggests high LLT1 is a risk factor for survival ($p<0.05$) in patients with COAD, KICH and KIRC. High TMB and MSI scores were significantly correlated ($p<0.05$) with LLT1 expression in Colon and Kidney cancers, suggesting plausible biomarker application. Overall, transcriptome data analysis strongly suggests immune repressive gene signatures are prevalent with high LLT1 TMEs in multiple solid cancers. *In vitro* studies with human PBMC revealed ZM008 activates immune cells by inducing expression of CD69, NKG2D, CD107a, proinflammatory cytokines (IFN-γ, IL2, etc.,) secretion, and tumor cytotoxicity. In MLR assay, ZM008 as a single agent or in combination with Pembrolizumab primed DCs to secrete IFNγ and IL-2 which results in effector NK and T cells activation/proliferation *Ex vivo* studies with biopsy samples from NSCLC and Bladder Cancer patients showed significant tumor reduction and infiltration of patients' immune cells with ZM008 monotherapy and ZM008 + pembrolizumab combination. An open label, 3+3 design, multicenter dose escalation phase 1 trial for ZM008 is planned in patients with advanced/metastatic solid tumors with no therapeutic standard alternative to evaluate the safety, tolerability and efficacy of ZM008, as monotherapy and in combination with Pembrolizumab. FIH dosing of 0.15mg/Kg was determined based on MABEL strategy. *In silico* data analysis showing high LLT1 expression in patients non-responsive to immune checkpoint inhibitor treatments indicate the potential benefit to the patients from ZM008 + pembrolizumab combination treatment. ZM008 treatment will release the immune break, activate the infiltrated immune cells and provide anti tumor effects in solid cancers either as a standalone treatment or combination therapy. Retrospective analysis of patient samples pre and post ZM008 treatment will identify relevant biomarkers for patient recruitment and better prediction of prognosis.

#7536 CD4$^{\pm}$T cell exhaustion in the tumor microenvironment and antitumor immunity.

J. Nagasaki[1], W. Zhou[1], S. Kawashima[2], T. Ishino[1], K. Kawase[3], Y. Ueda[1], K. Yamashita[4], T. Watanabe[1], T. Inozume[2], Y. Togashi[1]; [1]Okayama University Graduate School of Medicine, Okayama, Japan, [2]Chiba University Graduate School of Medicine, Chiba, Japan, [3]Chiba Cancer Center, Chiba, Japan, [4]KOTAI Biotechnologies, Osaka, Japan

Background: Immune checkpoint inhibitors (ICIs) exert clinical efficacy against various types of cancer through reinvigoration of exhausted CD8$^{\pm}$ T cells that attack cancer cells directly in the tumor microenvironment (TME). However, compared to CD8$^{\pm}$ T cell exhaustion, the role of CD4$^{\pm}$ T cell exhaustion in antitumor immunity remains unclear.

Methods and Results: From single-cell sequencing for tumor-infiltrating lymphocytes (TILs) from patients with melanoma and mouse models, we found that *CXCL13*, which is highly expressed in tumor-infiltrating exhausted CD8$^{\pm}$ T cells, induces PD-1$^{\pm}$CXCR5$^{\pm}$CD4$^{\pm}$ follicular helper T (T_{FH})-like cell infiltration, which could contribute to antitumor immunity. Furthermore, a part of the T_{FH}-like cells in the TME exhibits cytotoxicity and directly attacks MHC-II-expressing tumors. RNA velocity and latent time analysis in single-cell sequencing for melanoma TILs showed that the differentiation of T_{FH}-like cells from the naive CD4$^{\pm}$ T cells were different from that of other CD4$^{\pm}$ T cells. In addition, the T_{FH}-like cytotoxic CD4$^{\pm}$ T cells were at the late stage of differentiation and some non-cytotoxic T_{FH}-like cells might differentiate into T_{FH}-like cytotoxic CD4$^{\pm}$ T cells. We additionally found considerable overlapped clonotypes between the cytotoxic and non-cytotoxic clusters. T_{FH}-like cytotoxic CD4$^{\pm}$ T cells have high LAG-3/BLIMP1 and low TCF1 expression without self-renewal ability, whereas non-cytotoxic T_{FH}-like cells express low LAG-3/BLIMP1 and high TCF1 with self-renewal ability, closely resembling the relationship between terminally differentiated and stem-like progenitor exhaustion in CD8$^{\pm}$ T cells, respectively.

Conclusion: Our findings provide novel insights into T_{FH}-like CD4$^{\pm}$ T cell exhaustion with helper progenitor and cytotoxic differentiated functions, which mediates antitumor immunity orchestrally with CD8$^{\pm}$ T cells.

#7537 “Cross-over Effect” in survival curves with immune-checkpoint inhibition: Identifying ideal candidates for immunotherapy-only approaches in specific tumor histologies.

Shubhank Goyal[1], Anish Thomas[1], **Parth Anil Desai**[2]

[1]Developmental Therapeutics Branch, National Institutes of Health, Bethesda, MD, [2]Hematology & Medical Oncology, Fox Chase Cancer Center, Philadelphia, PA

Immune checkpoint inhibition (ICI), a cornerstone of modern immunotherapy (IO), has revolutionized cancer treatment, offering significant survival benefits across various malignancies. Initial trials with ICI in refractory cancers demonstrated remarkable efficacy compared to standard-of-care (SOC) treatments. With the integration of ICI into combination therapies, including chemotherapy and multi-tyrosine kinase inhibitors (TKI), its role in frontline, early-stage, and locally advanced cancers has grown. However, the potential of an immunotherapy-only strategy, especially in advanced malignancies, warrants better biomarker selected approaches given the inconsistencies with existing biomarkers. This study investigates the "cross-over” effect observed in Kaplan-Meier survival curves from randomized trials comparing ICI with non-ICI agents where the survival curves, assumed to be proportionally constant distinctly cross over each other during the on-treatment monitoring period. We initiated a meta-analysis investigating randomized trials comparing ICIs with non-ICI historical SOC agents and finally analyzed data from 38 large clinical trials. Trials were selected based on their comparative nature with overall survival (OS) and progression-free survival (PFS) data as outcomes. A positive “cross-over” in Kaplan-Meier curves was identified when divergence occurred for at least three consecutive months. Cross-over in PFS and OS curves were observed in 53% (20/38) and 43% (16/37) of trials, respectively. All cross-overs were one-sided with the ICI arm crossing over the non-ICI arm with a superior tail. Notably, 100% of trials with OS curve cross-over involved ICIs against chemotherapy. A significant association (Fischer’s exact test, p=0.01) was found between OS curve cross-over and adenocarcinoma histologies, in contrast to trials with no cross-over effect, predominantly featuring squamous cell carcinomas. This pattern persisted within various organ sites such as the lung, esophagus, and cervix where both adenocarcinomas and squamous histological patterns are seen. Cross-over of Kaplan-Meier curves blatantly violates the cox-proportional hazard assumption, potentially underestimating the impact of the ICI-only approach compared to alternative therapies. These observations highlight substantial biological heterogeneity in tumor responses to ICI versus chemotherapy. The cross-over effect, particularly pronounced in gland-forming tumors (adenocarcinomas), underscores the urgent need to investigate mechanisms of ICI resistance in these tumor types and incorporate tumor histology and longitudinal tumor growth dynamics into existing predictive models for biomarkers for IO response and help identify patients who would benefit the most from immunotherapy-only approaches.

#7539 First-in-class anti-PVR mAb NTX1088 advancing through Phase I: Safe and potent in restoring DNAM1 expression to enhance antitumor immunity.

A. Atieh[1], A. Obeidat[1], A. Vitenshtein[1], G. Cinamon[1], **K. Paz**[2], T. Rovis[3], P. Brilc[3], O. Mandelboim[4], S. Jonjic[3], P. Tsukerman[1];
[1]Nectin Therapeutics, Ltd., Jerusalem, Israel, [2]Nectin Therapeutics, Ltd., Fort Lee, NJ, [3]MEDRI, Rijeka, Croatia, [4]Hebrew University, Jerusalem, Israel

NTX1088, a first-in-class anti-PVR (CD155) mAb, is currently evaluated in a Phase 1, open-label, multi-center study (NCT05378425). The trial initiated at MD Anderson Cancer Center, and was expanded into additional sites, including City of Hope, Ochsner Health, Sheba Medical Center and Hadassah Medical Center. Study objectives are safety, dose-finding, and efficacy with focus on pharmacokinetics, pharmacodynamics, and biomarker discovery. NTX1088 is investigated as a single agent and in combination with the anti-PD1 mAb, pembrolizumab (Keytruda) in patients with advanced solid malignancies. Ongoing dose escalation demonstrates a safe profile across ascending dose levels. NTX1088 is a high affinity humanized IgG4-S228P mAb that binds PVR and blocks all known interacting receptors at a single nM EC_{50}. PVR, is a highly upregulated membrane protein on numerous tumor cells. PVR expression has been associated with worse patient outcome, due to its central role in immune suppression. PVR's impact is mediated through interaction with the key stimulatory receptor, DNAM1 (CD226), on T and NK cells, leading to internalization and degradation of DNAM1. PVR also interacts with the inhibitory immune checkpoint receptors, TIGIT, CD96 and KIR2DL5A. Blocking PVR by NTX1088 has multiple immune-stimulating roles, through restoration of DNAM1 immune activation function, while simultaneously neutralizing TIGIT, CD96 and KIR2DL5A inhibitory signals in immune cells. Importantly, DNAM1 downmodulation was recently identified as a key resistance mechanism to approved immune checkpoint inhibitors, and its restoration by NTX1088 is a novel MoA, not demonstrated previously by other therapies.In vitro, as a monotherapy, NTX1088 significantly increased immune cell activation, superior to TIGIT, CD112R, and PD1 antibody blockade, leading to a greater immune-mediated tumor cell killing, IFNγ secretion, and CD137 induction. Importantly, only NTX1088 was able to restore DNAM1 to the surface of immune cells. Synergy was obtained when NTX1088 was combined with PD1 blockers, or with the anti-CD112R mAb, NTX2R13.Syngeneic models of $PVR^{K.O}$, demonstrated a complete immune-mediated tumor regression. Numerous humanized murine xenograft models were investigated whereby NTX1088 exhibited robust tumor growth inhibition as a standalone and in combination with PD1 blockade.In conclusion, PVR blockade by NTX1088 has a remarkable pre-clinical efficacy, suggesting a potential clinical breakthrough, based on its ability to simultaneously overcome multiple tumor escape mechanisms. First-in-human (FIH) trial is currently ongoing and biomarker analysis is showing initial mechanistic proof of concept for NTX1088 mode of action, including the restoration of DNAM1 surface expression on patients' immune cells. This is the first case of surface DNAM1 elevation in clinical settings.

#7540 Impact of IL-2 and IL-7 on human regulatory T cell suppression and pembrolizumab-mediated reversal of human T cell exhaustion.

Gokhan Tut, Neale Harrison, Leila Sallie, Emma Welsh Welsh, Ashley Pegg, Arshpreet Kaur, Zhi Li, Ines Morano, Hujo Chan, Jamie Cowley, Catherine Brady, John Gordon, Mark Bryant, **Omar Qureshi**, Nicholas M. Barnes

Celentyx Ltd, Birmingham, United Kingdom

Inhibitory pathways within the tumour microenvironment limit the anti-cancer immune response. Two central mechanisms limiting the T cell response in the tumour are suppression of effector T cells responses by regulatory T cells, and chronic exposure to tumour antigens that may bestow T cell unresponsiveness or exhaustion. Restoring exhausted T cell responsiveness through blockade of inhibitory immune checkpoints such as the PD-1/PDL-1 interaction is an established therapeutic modality leading to durable responses and improved survival rates in some patients.We have modelled suppressive mechanisms *in vitro* using purified human T cells and investigated the impact of the cytokines IL-2 and IL-7. A comparison of *in vitro* assay systems for T cell exhaustion including T cell/allogeneic dendritic cells, a recall response to a viral antigen, prolonged stimulation of T cells to generate an ‘exhausted’ phenotype followed by a secondary stimulation with allogeneic DCs, revealed in some donors, the greatest impact of pembrolizumab was with exhausted T cells, a finding consistent with our studies using a dissociated tumour cell response with primary cells from patients with lung or colon carcinomas. Quantifying a range of cytokines (e.g. IFNγ, TNFα and IL-10) and flow cytometry activation markers (e,g, CD69, CD25, CD71, OX40 and CD137) established that in general pembrolizumab was effective at restoring the IFNγ response, although some donors were not responsive, and there was a more modest impact on other readouts indicating not all T cell functionality is restored. We therefore tested the impact of IL-2 and IL-7 on the reversal of the ‘exhausted’ phenotype and identified further improved functionality and donor responsiveness. We subsequently tested the impact of these cytokines in another ‘inhibitory’ context, that of regulatory T cell suppression; we identified that high-levels of IL-2 overcame regulatory T cell suppression and IL-7 led to an overall enhancement of response.These findings highlight how multiple suppressive mechanisms may need to be overcome to maximally restore anti-cancer immune responses, and that the combination of cytokines, such as IL-2 and IL-7, and checkpoint inhibitors, such as pembrolizumab, may enhance T cell responses.

CLINICAL RESEARCH: Molecular Biology in Clinical Oncology: Characterizing and Modulating Epigenetics and Gene Expression
Poster Session

#7544 Bromodomain and extra-terminal protein inhibitors deplete nuclear factor 1C and reduce stemness and growth of human small cell lung cancer cells in vitro and in vivo.

H. Wang, R. Wang, F. Villa-Hernandez, V. Shukla, L. Varticovski, S. Baek, F. Echtenkamp, S. Gara, M. R. Zhang, S. Shiffka, R. Raziuddin, L. M. Neckers, W. Linehan, G. L. Hager, S. R. Carr, C. D. Hoang, H. Chen, D. S. Schrump;
Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Objectives: Recent insights regarding mechanisms mediating stemness, heterogeneity, and metastatic potential of lung cancers have yet to be fully translated to effective regimens for the treatment of these malignancies. This study sought to examine complex epigenetic mechanisms underpinning the aggressiveness of SCLC, with a focus on understanding those mediating stemness in these highly lethal cancers.
Methods: Normal small airway epithelial cells (SAECs) were reprogrammed into iPSCs, validated by various assays, such as spectral karyotyping and teratoma formation. Genome-wide chromatin landscapes of lung iPSCs (Lu-iPSC) and SAECs, as well as NSCLC and SCLC lines were characterized using RNA-seq, DNA methylome, and DNase-hypersensitivity sequencing (DHS). Gene knock-downs were established using siRNA/shRNA techniques, along with qRT-PCR, immunoblotting, proliferation, and tumorigenicity assays. Glycolysis was analyzed using Seahorse assays. In-silico analysis of the NFIC promoter was performed using TFmapper. NFIC and related gene expression in human SCLC cells following NFIC or Bromodomain-containing protein (BRD) knockdown or exposure to BET inhibitors (BETi) were evaluated. Stemness scores were calculated using established RNA-seq criteria, and gene set enrichment analyses were conducted. Proliferation assays and xenograft models were used for in-vitro and in-vivo SCLC growth assessment.
Results: RNA-seq ,DNA methylome and DHS analyses revealed shared characteristics among SAEC, Lu-iPSC, SCLC, and NSCLC, whereas SOXs and POUs showed strong activity in Lu-iPSC but not SCLC. NFIC, with elevated chromatin occupancy in SCLC, exhibited increased expression compared to SAEC. NFIC KD in SCLC significantly curtailed cell growth in-vitro and in-vivo, affecting multiple pathways, including glycolysis and stem cell signaling etc, confirmed by Seahorse assays. Furthermore, we identified occupancy sites for BRD4 in the NFIC promoter, and knockdown of BRD4, but not BRD2 or BRD3, reduced NFIC expression in SCLC cells. BET inhibitor (BETi) treatment dose-dependently decreased NFIC expression in SCLC lines and human SCLC PDXs, irrespective of subtype. BETi treatment also reduced SCLC stemness and showed a significant overlap in gene regulation with NFIC knockdown, affecting pathways related to gluconeogenesis, neuronal differentiation, and embryonic organ morphogenesis. Importantly, BETi treatment effectively reduced SCLC cell growth in-vitro and in-vivo, suggesting the potential therapeutic value of targeting NFIC via BET inhibition in SCLC.
Conclusions: NFIC, a unique transcription factor in SCLC, emerges as a key downstream target of BRD4. These findings underscore the potential druggability of NFIC in clinical settings, provide compelling rationale for evaluating BETi for SCLC therapy.

#7545 Epigenetic plasticity in rewiring DNMT1/UHRF1-RB1- NFkB signaling circuit regulates asbestos-induced mesothelial malignant transformation.

S. Xi, X. Wu, D. Straughan, E. Payabyab, H. Wang, R. Wang, M. Zhang, S. Carr, C. Hoang, D. Schrump;
NIH-NCI, Bethesda, MD

The exact mechanisms underlying the causal relationship between asbestos exposure and malignant mesothelioma (MM) have yet to be elucidated. Widespread genomic and epigenomic alterations are being implicated in rewiring of oncogenic signaling networks which may contribute to initiation and progression of MM. In the present study, we examined the molecular profiles of mesothelial cells exposed to asbestos in-vitro and found that asbestos-induced activation of DNMT1/UHRF1 mediated epigenetic repression of RB1 in normal mesothelial cells as well as mesothelioma cells via promoter-specific methylation mechanisms. RB1, as a noncanonical transcription factor, was capable of also negatively modulating the transcriptional activities of DNMT1/UHRF1 mesothelium and mesothelioma. Functioning as one of the downstream effectors of RB1, NFkB was also involved in the transcriptional regulation of DNMT1/UHRF1 directly in a promoter-selective manner and played a pivotal role in the acute as well as chronic functional and phenotypic changes of mesothelial cells following asbestos exposure. Pharmacological interference of the dysregulated RB1-DNMT1/UHRF1- RB1-NFkB signaling circuit constitutively arrested the invasive growth of MPM cells. In-vivo studies using FVB genetic background wild-type and Bap1+/- mice further revealed involvement of epigenetically dysregulation of the RB1-DNMT1/UHRF1- RB1-NFkB signaling circuit during asbestos-induced malignant transformation of mesothelial cells. Taken together, our data are the first to describe that asbestos epigenetically rewires the RB1-DNMT1/UHRF1- RB1-NFkB signaling circuit during mesothelioma development and suggest potential novel strategies to reverse these epigenetic perturbations for MPM treatment in the clinic.

#7546 Targeting NSD2 to reverse lineage plasticity and drug resistance in neuroendocrine prostate cancer and subtypes of mCRPC.

J. J. Li[1], A. Vasciaveo[1], D. Karagiannis[1], X. Chen[1], C. Yu[2], A. Califano[1], C. Lu[1], M. M. Shen[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Treatment with highly potent anti-androgens, such as enzalutamide and abiraterone promotes lineage plasticity in metastatic castration-resistant prostate cancer (mCRPC), which results in intra-tumor heterogeneity and emergence of mCRPC subtypes. The histological transformation from adenocarcinoma to aggressive neuroendocrine prostate cancer (CRPC-NE) has been associated with a loss of dependency on lineage-survival signals, leading to targeted drug resistance. Epigenomic reprogramming might be a fundamental driver of lineage plasticity. To determine CRPC-NE vulnerabilities, we have performed image-based screening using a small library of antibodies targeting different histone marks on CRPC-NE organoids derived from genetically engineered mice. We find that the histone mark H3K36me2 and the histone methyltransferase NSD2 play important roles in maintain the CRPC-NE epigenetic state. Knockout of NSD2 or ablation of H3K36me2 using an oncohistone mutant H3.3K36M reverted CRPC-NE to an adenocarcinoma phenotype. Simultaneous profiling of the transcriptome and epigenome from single cells verified this lineage conversion and the generation of cell states with canonical AR signaling. Moreover, H3K36me2 or NSD2 depleted mouse and human CRPC-NE organoids responded to enzalutamide treatment *in vitro* and *in vivo*, suggesting a reversal of castration-resistance. Most importantly, a small molecule inhibitor of NSD2 (NCT05651932), in combination with enzalutamide leads to growth suppression or apoptosis of mouse and human CRPC-NE organoids, organoids of other CRPC subtypes and xenografts *in vitro* and *in vivo*. In conclusion, inhibition of NSD2 reverts the epigenomic state of CRPC-NE, reversing lineage plasticity and restoring anti-androgen sensitivity. Thus, we suggest that the combination of NSD2 inhibition with AR inhibition may represent a novel therapeutic approach for patients with CRPC-NE or even other CRPC subtypes.

#7547 Enhancers as targets for improvements in immunotherapy.

A. Singh, V. Kochat, E. Arslan, S. Satpati, W. Deng, S. Yadav, E. Bataki, C. Yee, **K. Rai**;
UT MD Anderson Cancer Center, Houston, TX

Role of epigenetic elements in mediating tumor immune interaction remains poorly understood. We previously identified enrichment of active enhancer states on a set of genomic loci in non-responders to immune checkpoint blockade (ICB) therapy. We noted that the activated non-responder enhancers marked a group of key regulators of in melanoma cells that are known to mediate resistance to ICB therapy and several checkpoint receptors in T cells. Through spatial epigenomics (Spatial ATAC and CUT&Tag) approaches, we identified the tumor-immune niches harboring unique gene regulatory elements and transcription factors that could mediate melanoma-T cell interaction. Further, we aimed to identify functional epigenetic elements through custom CRISPRi screening of enhancers in patient tumor-derived melanoma and T cells. CRISPRi approaches identified novel functional enhancers that mediate T cell mediated killing. For example, we identified distal c-MET enhancers as important contributors to T cell mediated killing. In T cells, we identified enhancer hubs that target multiple genes. These hubs could be targeted to activate interferon gamma, reduce T cell exhaustion, and improve T cell mediated killing of melanoma cells. Such enhancer hubs could serve as targets in the ex vivo setting to improve adoptive T cell therapy. Overall, our results suggest that enhancers with unique spatial patterns in melanoma tumors contribute to the response to immunotherapy and could be novel targets for therapy.

#7548 Role of bromodomain extra terminal inhibitor (BETi) in combination with radiotherapy for the treatment of NF1-associated malignant peripheral nerve sheath tumor.

A. A. Gingrich[1], S. Landers[1], A. Bhalla[1], C. Rodriguez-Aguayo[1], R. Lazcano[1], S. Satpati[1], A. Lebron-Torres[2], E. Z. Keung[1], C. P. Scally[1], C. L. Roland[1], K. K. Hunt[1], H. Lyu[1], H. Lillemoe[1], A. Guadagnolo[1], A. Lazar[1], J. Slopis[1], I. McCutcheon[1], J. A. Livingston[1], A. Farooqi[1], K. Rai[1], K. E. Torres[1];
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Davidson College, Davidson, NC

Introduction: Neurofibromatosis Type 1 (NF-1) associated malignant peripheral nerve sheath tumors (MPNST) harbor mutations in the polycomb repressive complex 2 (PRC2) in 70% of tumors. PRC2 loss results in epigenetic changes, which increase histone acetylation and make the DNA vulnerable to binding by bromodomain proteins. This interaction could be targeted to uncouple histone acetylation from transcription using bromodomain extra terminal inhibitors (BETi). As radiation therapy (RT) is a cornerstone of MPNST treatment, we analyzed the effects of BETi with and without RT.
Methods: Mice were implanted with patient-derived xenografts (PDX) of PRC2-wildtype model developed in the Torres laboratory, MPNST007. Mice were segregated into vehicle and I-BET 762 treatment groups and treated with either vehicle or drug for one week before the RT was initiated. Half of the mice in each treatment group (n = 10) received radiation (2 Gy per fraction for 5 days for a total of 10 Gy). The study endpoints were (1) tumor growth rates, (2) tumor size and weight at study termination, (3) immunohistochemical (IHC) staining for biomarkers of proliferation (Ki67), apoptosis (cleaved caspase 3, CC3), and DNA damage (γH2AX), and (4) RNA sequencing of PDXs from each experimental arm.
Results: Significant tumor regression was observed in PRC2-mutant PDX tumors treated with I-BET 762 based on tumor growth kinetics over 45 days of treatment ($p < 0.001$). Tumor volume was significantly reduced by I-BET 762 compared to vehicle ($p < 0.01$). Combining I-BET 762 and RT resulted in significant tumor volume reduction ($p < 0.001$). RNA sequencing and intersection of differentially expressed genes related to “DNA damage repair” and those repressed by I-BET 762 was performed for the MPNST007 PDXs. The expression of 259 genes related to DNA damage repair decreased after I-BET 762 treatment, including XRCC1, ERCC4, RAD50, RAD51D, and LIG4 (data not shown). IHC analysis prompted by the RNA sequencing results of the I-BET 762-treated PDXs revealed higher levels of γH2AX. An increase in necrotic and fibrotic tissue with increased CC3 in the BETi plus radiation group was observed.
Conclusions: Genetic mutations in NF-1-associated MPNST tumors result in susceptibility to BETi treatment. In a PDX model of PRC2 wild-type tumors, BETi treatment resulted in tumor regression and sensitized MPNST xenografts to RT. Combining BETi and RT enhanced tumor death and increased expression of genes associated with DNA damage and apoptosis.

#7549 Overcoming resistance to anti-VEGF therapy via epigenetic regulation of BARD1.

E. Bayraktar[1], C. Rodriguez-Aguayo[1], E. Stur[1], S. Kumar[2], L. S. Mangala[1], N. N. Bayram[1], P. Hanjra[1], S. Corvigno[1], S. Baylin[1], G. Lopez-Berestein[1], A. K. Sood[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Department of Obstetrics and Gynecology, Medical College of Wisconsin, Milwaukee, WI 53226, USA, WI, TX

DNA methylation inhibitors such as 5-azacytidine (Aza) and 5-aza-2′-deoxycytidine have been extensively used in patients with hematologic disorders and other neoplasms since their approval by the FDA. However, global DNA demethylating agents can result in intolerable toxicities; therefore, targeted epigenetic modulation is needed. Here, we searched for epigenetic changes with adaptive resistance to anti-VEGF antibody (AVA) in the TME and a novel strategy for targeted demethylation.

Methods: We examined methylation and transcriptional changes in orthotopic ovarian cancer models with emergence of AVA resistance. We developed a targeted demethylation strategy for BARD1 to enhance the effectiveness of AVA. We used a novel dCas9-CRISPR-based system for targeted BARD1 CpG demethylation (derived by fusing the deactivated Cas9 [dCas9] with the TET1 catalytic domain) delivered *in vivo* using a nanoliposomal carrier.

Results: We identified BARD1 methylation and reduced expression as lead candidate with AVA resistance; multiple CpG island sites in the BARD1 gene from adaptive AVA-resistant tumors were methylated. Next, we investigated the biological effects of global and targeted DNA methylation. Azacytidine along with AVA therapy was tested in a series of models (fibrosarcoma, PDX and orthotopic ovarian cancer models) and resulted in reduced tumor burden compared with the control and monotherapy groups ($p<0.01$). Next, to determine whether targeted demethylated BARD1 would have antitumor effects *in vivo*, we used an orthotopic SKOV3ip1luc ovarian cancer mouse model. Mice were treated with DOPC-dCas9-TET1-sgcontrol- (control) and DOPC-dCas9-TET1-sgBARD1 (sgBARD1). Tumor weight in the sgBARD1-3 group was significantly ($p<0.01$) reduced compared with the control group with no significant change in mouse body weight. We found that BARD1 expression was significantly increased in sgBARD1-treated group compared with control ($p<0.001$). Next, to determine whether demethylated BARD1 would combine well with AVA therapy in the SKOV3ip1 model, we combined sgBARD1-3 with bevacizumab (bev); sgBARD1-3 alone led to a significant decrease in tumor burden compared with control groups. Moreover, tumor burden was significantly reduced in the sgBARD1-3 and bevacizumab combination group compared with the sgcontrol group and bev alone group. BARD1 expression was significantly increased in sgBARD1-3-treated and in combination tumor samples compared with controls. To check for potential off-target effects, we tested the efficacy of another sgBARD1 and found that tumor burden in the sgBARD1-1 group was significantly reduced compared with control group.

Conclusion: Our novel targeted approach results in robust antitumor effects when combined with AVA therapy in multiple cancer models. Collectively, our findings provide a novel approach for gene targeted demethylation and could have implications for epigenetic therapies.

#7550 KB-0742, an oral highly selective CDK9 inhibitor, demonstrates preclinical activity in transcription factor fusion driven adenoid cystic carcinoma patient-derived models.

M. R. McKeown[1], **L. A. Carvajal**[1], T. R. Hood[1], N. S. Burr[2], J. Kaufman[2], A. Boynton[1], K. Mori[1], T. DesRochers[3], M. Wick[4], C. Y. Lin[1], J. F. DiMartino[1]; [1]Kronos Bio, Inc., Cambridge, MA, [2]Adenoid Cystic Carcinoma Research Foundation (ACCRF), Needham, MA, [3]Kiyatec, Greenville, SC, [4]XenoStart, San Antonio, TX

Adenoid Cystic Carcinoma (ACC) is an aggressive rare type of cancer of the secretory glands with no approved targeted therapy and high unmet clinical need. Deregulated transcription driven by MYB-NFIB or MYBL1-NFIB transcription factor (TF) fusions are a hallmark of ACC pathogenesis. More aggressive disease and resistance to therapy has been associated with co-mutation in NOTCH. Although direct targeting of oncogenic TF fusions has remained challenging, targeting of their activity via transcriptional cofactors has emerged as an attractive and clinically actionable strategy. Cyclin-dependent kinase 9 (CDK9) is a key potentiator of TF activity via its ability to act both as an upstream regulator of TF expression and a downstream cofactor. KB-0742 is a potent, selective, and orally bioavailable inhibitor of CDK9 with a long plasma half-life. KB-0742 is being studied in an ongoing Phase 1/2 study (NCT04718675) in advanced solid tumors including ACC. KB-0742 has demonstrated on-mechanism, single agent anti-tumor activity and a manageable safety profile in heavily pre-treated patients (0-11 prior lines of therapy) with transcriptionally addicted solid tumors. Here we present the preclinical rationale for targeting of oncogenic fusion TF activity in ACC. XenoSTART Patient-Derived Xenograft (XPDX) models were established from viable human tumor tissue for in vivo and ex vivo testing. Cell viability was assessed by CellTiter GLO reagent and phase imaging. Changes in MYB-fusion transcripts were assessed by RNA-Seq. Tumor Fragments (~70 mg) from ACCx5M1, ACCx6, ACCx9, ACCx11 models were implanted into athymic nude mice. Animals were treated with either vehicle (normal saline) or 60 mg/kg KB-0742 on a Q3D/week until tumors reached 2500 mm^3 or up to 60 days post start of treatment. In a retrospective analysis using real world data, ACC has a low incidence of genomic instability and high rates of MYB fusions detectable by RNA-seq, making immunotherapy challenging but creating an opportunity for targeting MYB transcription. In primary MYB-fusion positive and NOTCH co-mutated patient-derived spheroid models, KB-0742 treatment induced strong antiproliferative activity and cytotoxicity. Importantly, KB-0742 demonstrated stronger cytotoxic effects when compared to historical control agents. In XPDXs, CDK9 inhibition with KB-0742 resulted in antiproliferative activity and stronger tumor growth inhibition in MYB-fusion positive and NOTCH co-mutated tumor models compared to MYB-fusion positive only models.These data demonstrate KB-0742 is effective in preclinical models of ACC suggesting KB-0742 may be a promising therapeutic option for ACC patients. KB-0742 is currently being evaluated in a phase 1/2 dose-escalation and cohort expansion trial in patients with ACC and other transcriptionally addicted tumors (NCT04718675).

#7551 Combined epigenetic therapy and immune checkpoint blockade drive reshaping of the tumor microenvironment of platinum resistant ovarian cancer.

B. V. Landon[1], G. Kaleka[2], A. Balan[1], J. L. Boland[2], C. Cherry[1], G. Pereira[1], C. Zahnow[1], B. Winterhoff[3], S. Baylin[1], V. E. Velculescu[1], G. E. Konecny[2], J. A. Glaspy[2], V. Anagnostou[1];

[1]Johns Hopkins University, Baltimore, MD, [2]University of California, Los Angeles, Los Angeles, CA, [3]University of Minnesota, Minneapolis, MN

Introduction: Immunotherapy has demonstrated modest effectiveness for patients with platinum-resistant ovarian cancer, which is in part related to the immunosuppressive tumor microenvironment (TME) of ovarian cancers. Epigenetic modulators in combination with immune checkpoint inhibitors (ICIs) may represent a potential way to sensitize ovarian cancer to immunotherapy by TME reprogramming.

Methods: We evaluated the effect of epigenetic modulation in combination with ICI by comprehensive transcriptomic analyses of serially biopsied platinum-resistant/refractory ovarian cancer. Leveraging serial tumor samples from 30 patients that received oral azacitidine and pembrolizumab in the TRIO026 phase II clinical trial (NCT02900560), we performed bulk RNA sequencing and direct digital counting of 770 target genes using molecular barcodes (nCounter, NanoString) for 72 serial tumor samples, prior to treatment initiation and 6 weeks on-therapy. RNA sequencing of ~200 million reads for each sample was used for differential gene expression and gene set enrichment analysis (GSEA) and cell type deconvolution. Target gene expression data was normalized and analyzed for differential gene and pathway expression.

Results: Differential gene expression analyses revealed an upregulation of inflammatory and cytolytic genes (IFNG, GZMA and GZMH; FDR-adjusted p=0.0184) as well as the co-inhibitory molecule CTLA-4 (FDR-adjusted p=0.0184). GSEA revealed an enrichment of IFNG response, natural killer cell mediated cytotoxicity, neutrophil degranulation, inflammatory response, and antigen processing/presentation related gene sets on-therapy (FDR-adjusted $p < 0.001$). Target gene expression analyses orthogonally confirmed these findings, which were also concordant with pathway scoring analyses showing an increased score for immune inflammatory pathways such as INFG signaling (Wilcoxon rank sum test p=0.01). Immune cell subset deconvolution suggested TME reshaping driven by a greater density of intra-tumoral T cells on-therapy (Wilcoxon rank sum test p=0.012). Higher IFNG, CXCL13, CXCR5 expression, CD8 T cell and NK cell density were associated with longer time on treatment, both at baseline and at the on-therapy timepoint. GSEA revealed an upregulation of interferon gamma, adaptive immunity, antigen presentation as well as conserved immune response gene sets on-therapy, for the patients attaining longer time on-treatment.

Conclusion: Combination epigenetic and immunotherapy induces an inflammatory response and reshaping of the tumor microenvironment that may enhance their clinical efficacy, highlighting the therapeutic potential of utilizing epigenetic modulators as a way to sensitize platinum-resistant ovarian cancer to immune checkpoint inhibition.

#7552 Inhibition of histone methyltransferase EZH2 for immune-interception of colorectal cancer in Lynch syndrome.

F. Duzagac[1], C. M. Bowen[1], L. Reyes-Uribe[1], M. Zaheer[1], J. Thompson[1], N. Deng[1], M. Taggart[1], A. Jain[1], W. Edelmann[2], K. M. Sinha[1], E. Vilar[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Albert Einstein College of Medicine, Bronx, NY

Introduction: Colorectal pre-cancers in Lynch Syndrome (LS) display a distinct immune profile thus presenting a unique opportunity to develop novel immune-interception approaches to halt carcinogenesis. Epigenetic modulation by EZH2 of immune-related genes has been implicated in many cancers including colorectal but it has yet to be explored in LS carcinogenesis. The main objective of this study is to test the effect of EZH2 inhibition on immune cell profiling, colorectal carcinogenesis, gene expression, and histone methylation, using ex vivo organoids and a LS mouse model.

Methods: A mouse model of LS colorectal carcinogenesis (*Villin-Cre*;*Msh2*$^{fl/fl}$;*TgfβRII*-KI; herein referred to as *VCMsh2T*^{Hu}) and e*x vivo* colonic organoids were utilized to assess the effects of the EZH2 inhibitor GSK503. Mice were treated for 9-weeks with GSK503 with downstream studies exploring polyp multiplicity, changes to the immune landscape, and epigenetic analyses to derive mechanistic insights into EZH2 regulation in LS.

Results: GSK503 significantly altered transcriptomic changes in *VCMsh2T*^{Hu} organoids with tissue-specific tropism for dysplastic organoids as compared to organoids prepared from adjacent normal mucosa. GSK503 significantly increased CD4$^{\pm}$and CD8$^{\pm}$ T cells in splenocytes and colonic mucosa of treated mice compared to controls in vitro and in vivo. A preventive-dose (200µg/kg) of GSK503 for 9 weeks significantly reduced adenoma multiplicity in the large intestine of *VCMsh2T*^{Hu} mice with significant changes in the immune landscape of treated mice compared to controls. The data suggests GSK503 significantly enriched both total and activated cytotoxic T-lymphocytes CD8$^{\pm}$/CD137$^{\pm}$), stromal macrophages (CD68$^{\pm}$), and activated helper T-lymphocytes (CD4$^{\pm}$/CD134$^{\pm}$) in the large intestine of *VCMsh2T*^{Hu} mice. Transcriptome and molecular analyses using IHC, Western blots, and computational tools showed activation of immune and apoptotic markers with concomitant reduction of H3K27 methylation levels in colonic crypts. ChIPseq analyses revealed decreased levels of H3K27me3 and H3K4me1 (enhancer), a slight increased levels of H3K27ac (enhancer) marks with no changes in levels of H3K4me3 in treated mice, indicating that EZH2 inhibition yields global reprograming of poised promoters and active enhancers in the LS mouse genome.

Conclusions: Collectively, our findings reveal that GSK503 has a promising potential as an immuno-interception modality establishing the framework for launching phase I clinical trials with EZH2 inhibitors for LS carriers.

#7553 Dual inhibition of chromatin remodeling and DNA methylation as a novel treatment for triple negative breast cancer.

J. W. Landry, j. Kang, C. Morecock, H. Bear, R. Martin;
Virginia Commonwealth University, Richmond, VA

Epigenetics plays a central role in the initiation, establishment, and progression of cancer. In this capacity, epigenetics regulates several abnormal nuclear processes in the cancer cell including DNA replication, DNA damage repair and most prominently transcription. Because of their reversibility, epigenetic modifications have been aggressively pursued pharmacologically to correct abnormal cancer biology in the hopes of reversing cancer phenotypes. To develop novel epigenetic based therapeutic strategies for triple negative breast cancer (TNBC) we combined the DNA methyltransferase inhibitor (DNMTi) guadecitabine (Gua) with a genetic CRISPR/Cas9 mediated knockout (KO) of the chromatin remolding protein Bromodomain PHD-finger Transcription Factor (BPTF). Using the E0771 and 4T1 mouse TNBC models we show that BPTF depleted tumor cells are more susceptible to the antitumor effects of Gua. These antitumor effects are not observed in culture, or in immune compromised NSG mice, suggesting that their effects on cancer cell growth are not cancer cell intrinsic. RNA-Seq, ATAC-Seq and MBD-Seq analysis from FACS purified cancer cells shows that the combination of BPTF inhibition and Gua alters immune regulatory cytokine expression (BMP4 and CSF3) in the cancer cell, and it is theorized that these changes alter the tumor microenvironment to become less immune suppressive and permissive to the antitumor effects of immune cells. This hypothesis is supported by Cytek phenotyping of tumor resident and peripheral immune cells from treated mice showing reduced levels of immune suppressive myeloid derived suppressor cells (MDSC). Inhibiting BPTF pharmacologically using the bromodomain inhibitor AU1 does not recapitulate the effects of the genetic inhibition suggesting that the benefits of BPTF depletion to sensitization to Gua are not captured by inhibition of its bromodomain. To model the effects of pharmacologic BPTF inhibition we created a BPTF mouse KO genetically modified mouse model (GEMM). We show using this GEMM that BPTF KO in the adult mouse (a tamoxifen inducible Cre) is not lethal and has beneficial effects to the control of E0771 tumors, possibly through depleting tumor resident naïve T cells, and that transplanting BPTF KO E0771 tumors into BPTF KO adult mice further improves tumor growth control. These benefits in tumor growth control are prevented with CD8 depletion. These results in total suggests that a combination therapy regimen including BPTF inhibition (a PROTAC degradation approach) with a DNMTi could provide clinical benefits to patients with TNBC through both tumor cell intrinsic and extrinsic mechanisms.

#7554 The histone deacetylase inhibitor romidepsin is a potential therapeutic for metastatic osteosarcoma.

E. E. Seiden, S. M. Richardson, S. Ramnath, T. Whiteside, K. L. Coy, A. L. Sinn, M. L. Capitano, K. E. Pollok, C. D. Collier, E. M. Greenfield;
IU Simon Comprehensive Cancer Center, Indianapolis, IN

Osteosarcoma predominately affects adolescents, young adults, and canines. For human patients, the five-year survival rate of those with detectable lung metastases is only 30% while most canine patients with metastatic disease die within 1-2 years. Standard therapy is not effective for this patient group, so it is therefore necessary to identify novel therapies that target the progression of lung metastases. Our lab previously screened 114 FDA-approved anti-cancer drugs to identify agents that decrease the growth of 3D spheroids (sarcospheres) generated from highly metastatic osteosarcoma cell lines. The top hits included both histone deacetylase inhibitors (HDIs) that were tested. In follow-up experiments measuring potency on sarcospheres and toxicity on non-transformed cells, romidepsin was the top hit of the 114-drug panel as well of the two additional FDA-approved HDIs and seven HDIs that are in clinical oncology trials. Our goal was therefore to further evaluate romidepsin as a potential therapy for metastatic osteosarcoma. Romidepsin potently decreased viability in sarcospheres from established highly metastatic osteosarcoma cell lines (relative ED50s = 3-36nM). About 50% of the patients (both canine and human) had similar responses to romidepsin (relative ED50s = 1- 18nM) suggesting that those patients might be good candidates for romidepsin therapy. This includes patients who had been heavily pretreated with standard-of-care osteosarcoma chemotherapeutics. Mechanistically, romidepsin blocks proliferation and causes a G2/M cell cycle arrest in fast growing sarcospheres (143B and MG63.3) while in slow growing sarcospheres (LM7 and K7M2) where primarily induces cytotoxicity and there is no cell cycle arrest. Patient-derived sarcospheres are slow growing, so we predict that the primary mechanism will be cytotoxicity. Using a tail vein injection model of osteosarcoma lung metastases, romidepsin dose dependently prolonged survival and reduced the area and number of lung metastases in immunodeficient mice injected with 143B cells and a syngeneic model using K7M2 cells. Romidepsin will be evaluated in mice with metastases from patient-derived cells and if effective, will be repurposed for canine and human clinical trials to improve outcomes in metastatic osteosarcoma without the associated costs and extensive timeframe of traditional drug discovery.

#7555 Selective inhibition of the CoREST complex as a novel therapeutic target of atypical teratoid rhabdoid tumors.

Anupa Geethadevi[1], Marianne Collard[2], Tyler Findlay[1], Yiming Deng[1], Robert Fisher[2], Nikhil Vaidya[2], Charles Eberhart[1], Philip A. Cole[3], Rhoda Alani[2], Jeffrey Rubens[1], Eric Raabe[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Boston University, Boston, MA,[3]Harvard Medical School, Boston, MA

Atypical teratoid/rhabdoid tumors (AT/RT) are deadly infantile brain tumors, primarily arising from a single recurring biallelic loss-of-function mutation in SMARCB1 which is a member of the SWI-SNF chromatin remodeling complex. The partially functional SWI-SNF complex (without SMARCB1) is able to inhibit EZH2 at most locations of the genome except at gene promoter regions where EZH2 co-localizes with the REST complex. This results in hypermethylation and subsequent repression of genes coding for neuronal differentiation and tumor suppressors. CoREST is an important transcriptional repressor and consists of LSD1 and HDAC1/2 bound together by the scaffolding protein RCOR. Increased activity of EZH2 and the CoREST complex may help AT/RT cells maintain a stem cell-like state, driving its aggressive growth and therapy resistance. We hypothesize that functional inhibition of the CoREST complex by targeting LSD1 and HDAC1/2 might help restore the epigenetic balance lost in AT/RT cells.We selectively inhibited the CoREST complex in AT/RT cells (BT37, CHLA05 and CHLA06) by using a bi-functional LSD1 and HDAC1/2 inhibitor, Corin, which has previously been shown to be effective against melanoma and diffuse midline glioma. Administration of corin to AT/RT cells significantly increased H3K4me1, H3K9Ac and H3K27Ac histone marks ($p < 0.001$, Western blotting). Corin inhibited AT/RT cell growth and proliferation (MUSE Viacount $p<0.05$, BrdU immunofluorescence compared to control), and increased apoptosis (cPARP Western blotting, CC3 immunofluorescence, MUSE Annexin V assay, $p<0.05$ compared to control). Corin appears to be specific in targeting AT/RT as it did not affect brain organoids derived from iPSCs (cPARP Western blotting). Corin induced neuronal differentiation in AT/RT as seen by the increased expression of Beta-3-tubulin, MAP2 and Synaptophysin (Immunofluorescence). Enrichment analysis of differentially expressed genes after whole mRNA sequencing of AT/RT cells treated with corin for 24 h revealed upregulation of pathways related to neuronal differentiation and axonal development and downregulation of pathways related to proliferation and cell cycle ($pFDR < 0.05$, $FC>2$). In mice bearing orthotopic CHLA06 tumors, intratumoral delivery of a single dose of corin for 24 h increased H3K27me3 and H3K27ac, demonstrating that corin engaged its target in vivo, reduced growth and induced apoptosis (Ki67, cPARP). Survival studies show a trend toward single agent activity against the very aggressive CHLA06 orthotopic xenograft (increased in median survival from 14 to 35 days compared to control). These studies demonstrate that targeting the CoREST complex disrupts AT/RT epigenetic abnormalities, reversing their stem cell-like state, slowing tumor cell growth, and inducing apoptosis, that may translate into the clinical setting to help improve AT/RT's dismal survival.

#7557 Hypoxia-induced downregulation of MUC16: A key player in bispecific T-cell engager resistance in ovarian cancer.

M. Xu[1], S. K. Barakzai[2], A. Kononenko[1], R. Kumar[1], I. Veillard[1], E. Kim[2], T. S. Bond[1], D. R. Spriggs[1], B. R. Rueda[2], O. Yeku[1];
[1]Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA, [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Ovarian cancer (OC) is a lethal disease due to limited treatment options and the development of multidrug resistance. Bispecific T-cell engager (BiTE) therapy represents a promising immunotherapeutic approach to OC. Our previous findings suggest that resistance to BiTE therapy in OC is a complex interplay of factors including loss of tumor-associated antigens and epithelial-mesenchymal transition (EMT). Since the peritoneum is a relatively hypoxic (HX) tumor microenvironment, we hypothesized that HX plays a role in the modulation of MUC16 and potential resistance to BiTE therapy.
Methods: After informed consent, samples were collected from patients with recurrent OC undergoing treatment with MUC16 BiTEs. For HX studies, we used OVCAR3 tumor cell lines which express full-length MUC16. Tumor cells were cultured under normoxic (NX) or HX conditions. The effect of HX on cell death was analyzed using an apoptosis assay. Cells were evaluated for changes in cell surface MUC16 expression by flow cytometry. MUC16 protein expression and EMT markers were analyzed by western blot. Proteasome inhibitors were used to stabilize MUC16 expression under HX conditions. Antibody internalization assays were conducted to assess MUC16 endocytosis and recycling.
Results: In patients who progressed on MUC16 BiTEs, we found decreased MUC16 expression on tumor samples isolated from ascites samples. Using OVCAR3 cells, we found significantly decreased MUC16 expression on ovarian cancer cells grown under HX conditions (Fold change: 0.4 vs NX, $p<0.001$). Flow cytometry analysis revealed a time-dependent loss of MUC16 expression on the cell surface under HX (64.22% after 9 days HX vs 88.26% NX), highlighting the susceptibility of MUC16 to HX-induced downregulation. Treatment with proteasome inhibitors partially rescued MUC16 expression under HX conditions (Fold change: 1.4 vs NX, $p<0.001$). Notably, HX did not induce necrotic cell death in these tumor cells. In addition to the loss of MUC16, tumor cells under HX conditions showed alterations in EMT markers. E-cadherin was downregulated with prolonged HX exposure (Fold change: 0.3 vs NX, $p < 0.001$), while Vimentin (Fold change: 7.1 vs NX, $p < 0.001$) and Snail (Fold change: 2.8 vs NX, $p < 0.001$) were upregulated, indicating a potential shift towards a more aggressive phenotype. Epidermal growth factor receptor (EGFR) was also upregulated (Fold change: 4.9 vs NX, $p < 0.001$), potentially contributing to enhanced survival and invasion of OC cells under HX stress. Finally, under HX conditions, MUC16 internalization was slower in response to antibody binding over time due to reduced cell antigen expression, corroborating the observed MUC16 loss.
Conclusion: Understanding hypoxia-induced MUC16 downregulation and its downstream effects on EMT markers and CA125 expression provides crucial insight into the mechanisms of BiTE therapy resistance in ovarian cancer.

#7558 Novel liquid biopsy based determination of lung cancer histology using a comprehensive epigenomic platform reveals enhancer activity as a key determinant for accurate classification.

J. Guess, A. Gorthi, A. D'ippolity, J. Beagan, T. Clark, M. Coyne, T. Tamakloe, B. Tran, H.-H. Jeong, K. Cibulskis, H. Sawaengsri, J. Chmielecki, C. A. Painter, J. Barrett, M. Eaton;
Precede Biosciences, Inc., Boston, MA

BACKGROUND: Accurate molecular characterization of lung cancer including histology classification and therapeutic target profiling is critical for treatment planning and resistance monitoring. For example, detecting lineage transformation from lung adenocarcinoma (LUAD) to small cell lung carcinoma (SCLC) following treatment, an established resistance mechanism, is challenging due to deteriorating patient health and complicated invasive procedures. Here, we describe an accurate lung cancer histological classification using an innovative, multimodal epigenomic liquid biopsy method that comprehensively profiles tumor-specific transcription activation from 1 mL of patient plasma.

METHODS: 37 LUAD, 34 SCLC patient plasma samples collected from commercial biobanks, and reference cell lines were profiled for enhancer, promoter and DNA methylation activity to identify epigenomic loci characteristic of LUAD and SCLC. The resulting map of select quantified loci was used as input to a machine learning algorithm that distinguishes SCLC from LUAD, in a cross validated training and testing approach.

RESULTS: The epigenomic maps derived from lung cancer patient plasma were highly informative of the regulatory programming of the tumor cells. The enhancers and promoters most strongly linked to lung cancer profiles across the patient population include key, histology-specific driver genes such as NKX2-1, FOXA1, FOXA2, ONECUT2, DLL3, and ASCL1. The resulting classifier was able to accurately predict histology with a cross validated AUC greater than 0.94. In silico simulation results suggest that accurate classification can be achieved with ctDNA content below 1%. Further correlative examination of the SCLC enhancer landscape revealed a partitioning of SCLC patients into molecular subtypes characterized by active enhancer marks at subtype-specific transcripts, including ASCL1, POU2F3, NEUROD1, and YAP1. The transcriptional regulation of ADC targets is apparent through comprehensive epigenomic profiling of plasma in both SCLC and LUAD, with the expression of Claudin 18.2, SEZ6, and others showing a strong dynamic range independent of ctDNA levels. This represents a novel liquid biopsy approach to distinguish LUAD from SCLC and provide simultaneous insight into expression of key targets at clinically relevant ctDNA levels.

CONCLUSION: These data demonstrate the feasibility of epigenomic mapping from 1mL of plasma in lung cancer patients to distinguish lung cancer histology. The resulting data is biologically interpretable through the lens of transcriptional activation of key histology specific genes. This liquid-biopsy based approach may provide a non-invasive alternative to invasive and challenging tissue biopsies for biomarker investigation and therapeutic decision making.

#7559 Multi-state gene cluster switches determining the adaptive mitochondrial and metabolic landscape of breast cancer.

M. Menegollo[1], R. Bentham[2], N. Patani[2], R. C. Stein[2], M. Yuneva[2], **G. Szabadkai**[2];
[1]University of Padua, Padua, Italy, [2]University College London, London, United Kingdom

Adaptive metabolic switches are proposed to underlie conversions between cellular states during normal development as well as in cancer evolution, where they represent important therapeutic targets. However, the full spectrum, characteristics and regulation of existing metabolic switches are unknown. We propose that metabolic switches can be recognised by locating large alternating gene expression patterns and associate them with specific metabolic states. We developed a method to identify interspersed genesets by massive correlated biclustering (MCbiclust) and to predict their metabolic wiring. Testing the method on major breast cancer transcriptome datasets we discovered a series of gene sets with switch-like behaviour, predicting mitochondrial content, activity and central carbon fluxes in tumours associated with different switch positions. The predictions were experimentally validated by bioenergetic profiling and metabolic flux analysis of 13C-labelled substrates and were ultimately extended by geneset analysis to link metabolic alterations to cellular states, thus predicting tumour pathology, prognosis and chemosensitivity. The method is applicable to any large and heterogeneous transcriptome dataset to discover metabolic and associated pathophysiological states.

#7560 Microsatellite instability (MSI) detection using flow-based sequencing.

G. Lithwick-Yanai[1], H. Benjamin[1], J. Cano-Nistal[2], S. Geisler[2], A. Jaimovich[1], N. Iremadze[1], D. Kessler[1], I. Soifer[1], D. Lebanony[1], K. Ben Simhon[1], S. Gilad[1], E. Meiri[1], D. Lipson[1], Y. E. Maruvka[2];

[1]Ultima Genomics, Fremont, CA, [2]Technion - Israel Institute of Technology, Haifa, Israel

Background: Microsatellite instability (MSI) is an important genomic biomarker associated with various cancers and hereditary conditions. Accurate and efficient classification of MSI status is essential for diagnosis, prognosis, and treatment decisions. Different approaches for testing MSI have been presented in the literature, including NGS-based methods which either rely on comparison with a matched control sample, a set of reference control samples, or the reference genome (no control). In this study, we explore the feasibility of accurately identifying MSI status using the UG100 platform, which utilizes flow-based sequencing chemistry. Since MSI detection is typically based on long homopolymers, we examined here whether the flow-based sequencing data can be effectively used for MSI classification.

Methods: We performed whole genome sequencing (WGS) on a cohort of 24 cell lines with known MSI status, as well as on 15 tumor tissue samples, encompassing various cancer types, including colon, lung, bladder, and endometrial cancer. To determine the MSI status, polyA/T homopolymer loci were considered. We measured the MSI status in these loci using two methods: 1) Counting short indel variants detected using somatic Deep Variant, in comparison with matched blood normal, and 2) a novel MSI score based on the difference of the polyA/T homopolymer length, in comparison to the reference genome. We assessed the ability to evaluate the score for the full sequenced coverage (~100X) as well as when limiting to exome boundaries, and when sampling down to 1X coverage.

Results and Conclusions: We established the performance of the MSI score on the cell lines with known MSI status. The score was verified on cell line mixtures (simulating lower tumor purity) as well as on clinical samples from various tissue sources, including colon samples annotated as mismatch-repair deficient. We demonstrate the ability to use the cost-effective UG100 sequencing combined with the two methodologies to identify MSI-high samples in these scenarios.

#7561 Standardized conditions for growth of lung cancer tumoroids cultured reproducibly in 3D-cultures.

K. Malmros[1], D. Carlsen[1], H. Brunnstrom[2];

[1]Lund University, Lund, Sweden, [2]Lund University and Skane University Hospital Lund, Lund, Sweden

Background: Lung cancer is the most common cause of cancer-related death in Sweden with an estimated mortality of 3500 persons in 2021. Late diagnosis and heterogeneity of the disease lead to difficulty in predicting optimal treatment regime for each case. Further development of personalized therapy would be facilitated by reliable and efficient cultivation of cancer cell samples from patients in a clinical setting. A promising method is to grow the cells as 3D structures known as tumoroids, though the choice of extracellular matrix substrate or solid support most suitable for this purpose should be elucidated.

Aim: To assess which extracellular matrix substrates or solid supports which enable lung cancer tumoroid generation reproducibly without affecting the status or detection of genetic alterations and protein expression, using lung cancer cell lines.

Methods: Eight lung cancer cell lines, where of three adenocarcinoma and five squamous cell carcinomas, were included in this project. Each cell line was characterized with immunohistochemistry (IHC) for commonly expressed antigens in the two lung cancer types. Also, protein detection with Western Blots was performed. Cell lines found not expressing relevant antigens associated with the specific lung cancer variant were discarded. The remaining cell lines were cultivated in BIOFLOAT TC-Platte 96 well plate, Nunclon Sphera flasks, or GrowDex-T hydrogel, later transferred to a Corning Elplasia 6 well plate, and monitored for tumoroid generation.

Results: The lung squamous cell carcinomas HCC-95 and HCC-1588 were both positive for CK5 and p40, while H1703 was negative for both markers. The adenocarcinoma H1975 was positive for TTF-1, also, unexpectedly, seen for NCI-H1703, earlier defined as squamous cell carcinoma. The tested cell lines were successfully cultured as tumoroids in the BIOFLOAT TC- 96 well plate, Nunclon Sphera flasks, and GrowDex-T hydrogel. The mutational status of the tumoroids as compared to the original tumors is currently under evaluation.

Conclusion: We here show successful 3D culturing of cell lines with alternative substrates. Further fine-tuning of the chosen reproducible system's simplicity and cost is required before culturing tumoroids from lung cancer patients can be launched.

#7563 Efficacy of JPI-547, novel dual PARP inhibitor, in endometrial cancer cell line.

S.-W. Lee[1], S.-H. Nam[1], S.-B. Park[2];

[1]Asan Medical Center, University of Ulsan, Seoul, Korea, Republic of, [2]Asan Institute for Life Science, Seoul, Korea, Republic of

Objectives: PARP inhibitor is effective in treating DNA repair deficiency endometrial cancer. Endometrial cancer (EC) is one of the most common gynecological cancers in developed countries and its incidence is increasing, and the prognosis of patients with early stage and low-risk EC is very good, but the prognosis of progressive and recurrent EC is poor. Novel PARP inhibitor JPI-547 is a PARP and tankyrase dual inhibitor, and in cancer cells, tankyrase inhibitor plays an important role in DNA repair, telomere maintenance, and cell survival. This experiment was conducted to determine whether the reactivity of the PTEN mutant EEC was increased by using the Novel PARP inhibitor.

Method: Human endometrioid endometrial cancer cell lines, Hec-1A, Hec-1B and Ishikawa were obtained. Cell viability assay for the drugs Olaparib and JPI-547 were assessed. Colonies consisting of at least 50 cells were counted. The number of dead cells was counted in five different areas of the hemocytometer, and the experiment was performed three times. The percentage of dead cells was analyzed compared to the untreated group. We confirmed the efficacy by siRNA transfection and immunofluorescence.

Result: When treated with Olaparib, there was no change in cell viability in the rest of the cells except for Ishikawa cells, which are PTEN mutations. It decreased by 35.4% in Ishikawa cells, whereas when treated with JPI-547, all cell lines Hec-1A, Hec-1B, and Ishikawa cell viability decreased by 28%, 34.3%, and 48.7%, respectively. PTEN knock-down reduced cell visibility by 28% when treated with olaparib, whereas when treated with JPI-547, Hec-1A (siCont) and Hec-1A (siPTEN) decreased by 26% and 42%, respectively, in all cells regardless of whether PTEN knock-down is present. When treated with Olaparib, dead cells were identified only in PTEN knock-down cells, increasing by 22%. When treated with JPI-547, dead cells increased by 25.5% and 33% in all cells of Hec-1A (siCont) and Hec-1A (siPTEN), respectively. It was confirmed that JPI-547 can reduce cell viability regardless of the formation of Rad51 according to PTEN.

Conclusion: JPI-547, a novel PARP inhibitor, showed good efficacy in PTEN mutation and PTEN-wild-type EEC cell lines than in conventional PARP inhibitor. The effect of reducing survival of ECC cell line with JPI-547 was confirmed with or without PTEN mutation. Further evaluation and in vivo experiments are needed to prove the efficacy of JPI-547 in EC.

#7564 DNA methylation profiling identifies two distinct groups of oligosarcoma, IDH-mutant with distinct genetic alterations and clinical outcomes.

K. Zhang[1], L. Liu[2], X. Liu[3], T. Jiang[2];
[1]Duke University, Durham, NC, [2]Beijing Neurosurgical Institute, Beijing, China, [3]Beijing Tiantan Hospital, Beijing, China

DNA methylation has been extensively adopted for the classification of brain tumors and is endorsed by current neuropathology guidelines. Recently, oligosarcoma, IDH-mutant has been characterized as a distinct group of *IDH* mutant gliomas by DNA methylation classification. However, emerging studies revealed the variety in this group. Here, we employed DNA methylation-based t-SNE analysis to characterize oligosarcomas identified by the dkfz brain tumor classifier (v12.5). Thereby, we uncovered that oligosarcomas were segregated into two distinct groups, namely, subgroup A and subgroup B, which were further validated by genetic alterations and clinical outcomes. Next-generation Sequencing revealed subtype A tumors enriched with chr 1p/19q co-deletion, chr 6q loss, CDKN2A/B homogeneous deletion, TERT promoter mutation, and NF1 mutation, while subtype B tumors showed chr7 gaining and TP53 mutation. RNA sequencing and gene set enrichment analysis (GSEA) revealed that neuronal-tumor interaction and muscular progression pathways were more enriched in subtype A tumors. In contrast, subtype B tumors showed enrichment for angiogenesis and mTOR pathways. Additionally, inter-chromosomal fusion genes were more frequently found in subtype A tumors. Clinically, patients with subgroup A oligosarcomas manifested poorer survival and distinct imaging features in magnetic resonance imaging (MRI) compared to those with subgroup B. Collectively, we provided more cases of oligosarcoma, IDH-mutant, confirming the existence of this newly identified group, and revealed the subgroups harboring different genetic alterations and suffering different prognoses, providing new evidence for the molecular pathology in diffuse glioma.

#7565 Tumor classification and deconvolution in liquid biopsy using enriched methylation sequencing.

J. Yu[1], L. S. Ahmann[1], Y. Y. Yao[2], A. Toland[3], A. Snowden[4], C. Ho[5], B. A. Pinsky[1], H. Vogel[1], R. Y. Luo[1], L. Wang[6], B. Howitt[1], B. Holmes[1], A. C. Lowe[1], W. Gu[1];

[1]School of Medicine, Stanford University, Palo Alto, CA, [2]School of Medicine, University of Calgary, Calgary, AB, Canada, [3]Children's Hospital Colorado, University of Colorado Anschutz Medical Campus, Aurora, CO, [4]Howard University College of Medicine, Washington DC, WA, [5]Clinical Laboratories, Stanford Health Care, Palo Alto, CA, [6]School of Medicine, University of California San Francisco, San Francisco, CA

Background: Cell-free DNA (cfDNA) detected in proximal body fluids has demonstrated potential for cancer detection using minimally invasive methodology. Our past work showed that tumor cfDNA is present in the cerebrospinal fluid (CSF) and other body fluids of patients with inconclusive standard of care testing. However, past work measuring copy number aberrations or somatic mutations was limited in cancer classification. To facilitate reliable classification, even at low tumor fractions and with fragmented DNA, we developed XR-methylSeq, a methylation sequencing platform to enrich for cell type-specific markers.
Methods: We benchmarked XR-methylSeq with the K562 cell line and correlated the methylation values with gold standard measurement − whole genome bisulfite sequencing (WGBS). Methylation classifiers were applied for at least 22 cytology-positive body fluids, incorporating methylation array data from public references. T-distributed stochastic neighbor embedding (t-SNE) analysis was used for visualization in R. Deconvolution of cell type fractions for at least 29 (seven cytology-negative) body fluids and plasma samples was conducted using wgbstools. Cell type-specific markers were identified from a human DNA methylation atlas.
Results: Benchmarks: XR-methylSeq has a 5-fold enrichment of the cell type-specific markers compared with WGBS. XR-methylSeq at 20 ng input highly correlates with WGBS at 2 µg (Pearson’s r = 0.97). Body Fluids: Thirteen cytology-positive CSF samples had copy number aberrations, 77% of them had concordant tumor classification, while the remaining 23% clustered with low tumor fraction samples. All nine lung primaries, including a low tumor fraction case that did not originally classify, showed a consistent cell-of-origin through deconvolution, as indicated by increased contributions from lung alveolar epithelial cells. Among six other body fluids, three exhibited the highest fractions aligning with the clinically identified cancer cell-of-origin. Additionally, the plasma cfDNA of a patient with acute liver injury had a higher fraction of hepatocyte signatures (22%) than the healthy control (8%).
Conclusions: This research highlights the potential of XR-methylSeq as an enriched methylation profiling method useful for liquid biopsy applications.

#7566 Identification of cancer subtypes with a ctDNA-based targeted methylation assay.

T. Nance[1], T. Shaver[1], Y. Zhou[1], M. Antonio[1], Y. Gao[1], J. Heiss[1], R. Calef[1], J. Hiatt[1], O. Venn[1], J. Bredno[1], J. Beausang[1], L. Newman[2], C. Swanton[3], C. Zhang[1];

[1]GRAIL, LLC, Menlo Park, CA, [2]Weill Cornell Medicine, New York, NY, [3]The Francis Crick Institute, London, United Kingdom

Introduction: Identifying cancer subtypes is necessary for cancer diagnosis, prognosis determination, and treatment selection. Furthermore, as transformation between subtypes is increasingly recognized as a key resistance mechanism to targeted therapies, serial subtype reassessment is likely to gain adoption. Cancer subtypes have traditionally been determined by pathologists based on histology; more recently, molecular subtyping has been performed using IHC, RNAseq, or assays that detect genetic alterations. However, these methods have significant limitations, including tissue biopsy requirement (IHC and RNAseq), low discriminative resolution for distinct transcriptional programs (IHC and mutation detection), and poor reproducibility and feasibility (RNAseq). The GRAIL plasma-only, ctDNA-based targeted methylation platform is a robust, biopsy-free, scalable assay that can distinguish cancer methylation patterns between different cancer signal origins through the use of a proprietary classifier. Here, we explore the GRAIL platform's potential to detect finer-scale differences in cancer biology by developing classification algorithms for subtyping of three common cancer types.

Methods: As part of the Circulating Cell-free Genome Atlas (NCT02889978) and STRIVE (NCT03085888) studies, clinical data were recorded and plasma samples were collected, accessioned, stored, and processed through GRAIL's targeted methylation assay from 3,989 cancer and 6,013 non-cancer participants. We developed algorithms to predict cancer status and subtype for breast (triple negative breast cancer [TNBC] model; 531 cancer training participants), lung (lung histology model; 334 cancer training participants), and head and neck (HPV model; 3090 cancer training participants) cancers. Dimensionality reduction of methylation data was performed to illustrate subtype separation within these cancer types. Performance of these three algorithms was assessed on a held-out cohort of cancer samples (184 breast, 241 lung, 67 head and neck) with detectable ctDNA.

Results: The lung histology model correctly classified 95% (105/111) of adenocarcinomas, 88% (68/77) of squamous cell carcinomas, and 94% (59/63) of lung neuroendocrine carcinomas and tumors. The TNBC model correctly classified 84% (58/69) of TNBCs and 82% (94/115) of non-TNBCs. The HPV model correctly identified 98% (48/49) of HPV-positive head and neck cancers, and 89% (16/18) of HPV-negative head and neck cancers.

Conclusions: GRAIL's proprietary ctDNA-based targeted methylation platform demonstrates the ability to accurately predict cancer subtypes in multiple cancers using only a plasma sample without the need for tumor biopsy. Future efforts will be directed towards generalizing the GRAIL subtyping method to additional cohorts and cancer types.

#7567 In-depth mass cytometry analysis reveals different immune cell composition of unique molecular subtypes in extensive stage small-cell lung cancer.

Y. Li, J. Qu, B. Wu, Q. Shen, W. Sun, L. Chen, B. Wang, L. Ying, J. Zhou, J. Zhou;
The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: A novel molecular subtype classification was fashionable for small cell lung cancer (SCLC). However, the distribution of SCLC molecular subtype classification in Chinese patients were unknown, especially extensive stage (ES)-SCLC. It should validate and define their associated microenvironments across subtypes in ES-SCLC.
Method: We used immunohistochemical (IHC) to evaluate SCLC markers of the subtypes including ASCL1, NEUROD1, POU2F3, SCLC-A/N/P in 135 ES-SCLC tumors. Peripheral blood of 24 ES-SCLC patients was test by mass cytometry using time-of-flight (CyTOF) to evaluate the differences in immune subsets regard to the subtype tumor microenvironment (TME). Validation was performed using flow cytometry and multiplex IF.
Results: ASCL1, NEUROD1, POU2F3, and Inflamed were account for 60.7%, 28.9%, 7.4%, and 18.5% of SCLC tumors, respectively. Significant intratumoral heterogeneity was observed with 15.6% of the tumors being both positive for SCLC-A and -N subtype markers, respectively. The SCLC-I type possessed more CD8+ T-cells infiltration and had higher frequency an ‘inflamed’ immunophenotyped. CyTOF data showed greater CD161+CD127+CD8+T cells proportion in SCLC-I than SCLC-N subtypes before and after anti-immunotherapy. Furthermore, we validated that lung tissue of SCLC-I were infiltrated more CD161+CD127+CD8+T cells compared to SCLC-N subpopulation(P=0.0281). Flow cytometry further showed the stronger immune activation of CD161+CD127+CD8+T cells in SCLC-I types induced higher expression of GZMB and GNLY and lower-expression of T-cell exhaustion markers PD-1,TIGIT and LAG3 in comparison with SCLC-N types. We further confirmed that the high level of CD161+CD127+CD8+T associated with a favorable treatment response and prolonged overall survival.
Conclusion: The present study validated the molecular subtypes in ES-SCLC patients. Furthermore, SCLC-I subtype has longer PFS and OS than SCLC-A, -N and -P patients. Our research not only provides an insight into the immune landscape of ES-SCLC but also sheds light on a special subset of CD161+CD127+CD8+T cells with prognostic and therapeutic significance.

#7568 Molecular effects of neo-adjuvant hormone therapy for locally advanced prostate cancer: An ancillary study of the ARNEO phase 2 trial.

M. Ismail[1], W. Devlies[2], M. Parry[1], G. Devos[2], S. Friedrich[1], C. Parker[1], L. Mendes[1], E. Davicioni[3], M. Linch[1], F. Claessens[2], S. Joniau[2], G. Attard[1]; [1]UCL Cancer Institute, London, United Kingdom, [2]KU Leuven, Leuven, Belgium, [3]Veracyte, San Diego, CA

Intensified hormone therapy in combination with radiotherapy improves outcome for very high-risk locally advanced prostate cancer. The impact of hormone therapy with surgery, however, is uncertain. In order to understand this better, we ran an ancillary translational study on ARNEO (NCT03080116), a Phase 2 clinical trial, which randomized 89 locally-advanced prostate cancer patients to 12 weeks LHRHa +/- apalutamide (APA) followed by prostatectomy.

We performed clinical-grade transcriptome-wide expression array analysis (Veracyte, Inc. San Diego, CA) of FFPE diagnostic core biopsies (N=89) and tumors removed at prostatectomy (N=32 LHRHa, N=23 LHRHa + APA). We also performed RNASeq on fresh frozen biopsies of prostatectomy tumors (N=42 LHRHa, N=45 LHRHa + apalutamide) and LHRHa-naive control cases (N=61) matched for clinical and pathological risk factors.

Pre-surgery serum PSA decreased by a median of 98% (IQR:90.2-99.3) after hormone treatment. This decrease was better associated with tumor AR signaling (r^2=0.11) versus pre-treatment serum PSA (r^2=0.0005), or between pre-treatment serum PSA with diagnostic biopsies (r^2=0.008). We confirmed APA more potently suppressed AR signaling than LHRHa alone, with no detectable difference in direction of effect for differentially regulated genes/pathways. LHRHa + APA had less residual tumor (median Residual Cancer Burden, RCB=0.48cm^3) than in LHRHa (median RCB=1.7cm^3) but in cases with sufficient tumor, we observed residual active AR signaling pathways at prostatectomy in both treatment arms. To orthogonally confirm this, we selected 28 ERG positive cases (by IHC pre-treatment) and found retained ERG expression in 12/13 on LHRHa and 10/15 on LHRHa + APA.

Using pathway analysis in the RNAseq data, we identified LHRHa +/- APA induced down-regulation of AR, metabolic pathways, as well as DNA repair, and up-regulation of hallmark NOTCH, Hedgehog, TGF-beta, WNT and immune signaling (adjusted p-value cutoff=0.001). Comparing differentially expressed genes on RNASeq between treatment-naïve versus LHRHa +/- APA treated tumors, we observed STING1 as significantly higher in LHRHa +/- APA vs control (Wilcoxon rank sum test p-value <0.001). We found that expression of STING1 was positively correlated with hallmark interferon alpha response (r=0.7, r_s=0.6) that was correlated with apoptosis (r=0.5, r_s=0.5).

Whilst we show that adding APA to LHRHa increases suppression of AR activity and ERG expression, we find that 12 weeks is insufficient to abrogate AR signaling in most tumors, despite ~98% decrease in serum PSA. We identify novel processes modulated in humans by potent suppression of androgen activity, including upregulation of STING1-type 1 interferon response as a potential key modulator of treatment effect.

#7569 Characterizing pathways for metastasis of retinoblastoma in forebrain organoids.

Y. Shtanko[1], S. Rodriguez[2], B. Schachner[3], E. Adis[2], S. McLaughlin[2], S. Borges[2], J. Dollar[2], A. Zuniga[2], G. Quintana[2], S. Lopez[2], D. Owens[4], C. Moulin[5], S. Braun[2], G. Yenisehirli[2], D. Pelaez[6], J. Harbour[7], S. Kurtenbach[2];

[1]Herbert Wertheim College of Medicine (FIU), Miami, FL, [2]Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Bascom Palmer Eye Institute, Interdisciplinary Stem Cell Institute, Miami, FL, [3]Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Bascom Palmer Eye Institute, Interdisciplinary Stem Cell Institute, Wake Forest Baptist Health, Miami, FL, [4]Nova Southeastern University, Fort Lauderdale, FL, [5]Bascom Palmer Eye Institute (BPEI), University of Miami Miller School of Medicine, Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL, [6]Bascom Palmer Eye Institute (BPEI), University of Miami Miller School of Medicine, Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicin, Miami, FL, [7]Department of Ophthalmology and Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, TX., Dallas, TX

Retinoblastoma (Rb) is a childhood cancer of the eye, which usually presents in children under the age of five. When detected early, Rb has favorable prognosis in developed countries, but metastasis into the central nervous system (CNS) through the optic nerve correlate with a high mortality rate. Even if detected early, the available harsh and unspecific treatments can cause serious side effects, and enucleations are still performed frequently. There is still uncertainty regarding the mechanism for metastasis into the central nervous system. We performed bioinformatic analysis of single cell sequencing data for retinoblastoma, retinal tissues, optic nerve, and brain, to identify potential pathways and cell-cell communications fostering Rb invasion into the optic nerve and brain. Our analysis revealed several potential metastatic drivers, including immune modulation involving MIF, secreted by the Rb cells, as well as cell-adhesion pathways promoting a change in cellular phenotype. Given that animal models do not faithfully recapitulate human Rb initiation and progression, we developed a novel human iPSC-derived forebrain organoid model to investigate mechanisms of Rb CNS metastasis. Microinjections of GFP-labelled Rb cells allow to track growth and spread. In this fully human model including microglial cells, we can, for the first time, study the Rb forebrain interactions and pathways involved. RNA-seq analysis of Rb cells growing in forebrain organoids shows increased activity in neuron projection development and neuron migration, overlapping with the observed phenotype switch of invading Rb. Together, we present a novel iPSC-derived human forebrain model to monitor growth and spread of metastatic Rb, and describe new pathways involved in invading and metastasizing Rb.

#7570 Molecular subtyping and immunohistochemistry validation identifies muscle Invasive bladder cancer subgroups with poorer overall survival.

J. Zhang[1], M. Feng[2], N. Beeharry[1], S. Thomas[1], R. Wirtz[3], A. Hartmann[4], M. Eckstein[4], W. Choi[5];
[1]Janssen Research & Development, Spring House, PA, [2]Greenberg Bladder Cancer Institute, Johns Hopkins Medical Institutions, Baltimore, MD, [3]STRATIFYER Molecular Pathology, Cologne, Germany, [4]Institute of Pathology, University Hospital Erlangen, Friedrich-Alexander University at Erlangen-Nurnberg, Erlangen, Germany, [5]Brady Urological Institute, Johns Hopkins Medical Institutions, Baltimore, MD

Introduction: Muscle-invasive bladder cancers (MIBC) are molecularly heterogeneous and have poor clinical outcomes, compared to non-muscle invasive disease. The molecular characterization of subtypes and immune status has shown prognostic value and the potential to guide precision intervention. However, a more comprehensive understanding of the association between subtypes and immune cells is still required. To this end, an integrative multi-omics analysis was performed on patients with MIBC.
Methods: From a cohort of 244 MIBC patients who did not receive neoadjuvant chemotherapy, cystectomy tissue was collected to assess molecular features associated with poor outcomes. Macro-dissected FFPE slides were used to perform whole transcriptome RNA sequencing (N=208, passing quality control) and both the consensus single-sample classifier and TCGA classifier were applied to the RNAseq data to determine molecular subtypes. Immunohistochemistry (IHC) staining for canonical markers of basal (KRT5, 14 and CD44), luminal (KRT20, GATA3, FOXA1) and immune cells (CD3, CD8, PD-L1 (SP263)) was performed, and scoring was assessed by two independent pathologists. Tumor subtypes derived from either RNAseq or IHC were compared and correlated with disease specific survival.
Results: Among the 244 MIBC patients 30.7% were T2, 47.6% were T3 and 21.7% were T4. The consensus molecular classification identified mRNA subtypes and showed agreement with the TCGA molecular classification. Correlations with disease specific survival revealed that luminal subtypes trended towards best outcome while stroma-rich subtype trended towards poorest outcomes compared to other subtypes. IHC markers associated with luminal-like and basal-like tumors recapitulated the molecularly defined luminal/basal subtype assignment. Stroma-rich subtypes were enriched with fibroblast signatures, implying high desmoplastic stromal cell infiltration and low immune cell infiltration. By integrating molecular classification and IHC immune markers (PD-L1, CD3, CD8 - serving as a proxy for ‘immune signature’), we found that the immune signatures themselves stratified the survival benefit, as previously shown. Interestingly, we observed heterogeneity of the IHC-immune signature within mRNA subtypes.
Conclusions: Integrating MIBC subtyping, IHC of immune markers and patient outcomes data provides a biological framework that allows for potential biomarker identification for this lethal disease. The studies presented here underscore the existence of heterogeneity in immune phenotypes within tumor subtypes. A deeper understanding of the association between these tumor subtypes and their immunological states is crucial to guide treatment decisions, particularly for patients facing worse prognostic outcomes.

CLINICAL RESEARCH: Other Targets
Poster Session

#7574 Exploring the therapeutic potential of proteasome inhibitors in targeting SOX2-driven LUSC and SCLC.
A. Mohanty, Linlin Guo, Sravani Ramisetty, Sharad Singhal, Erminia Massarelli, Prakash Kulkarni, Ravi Salgia;
City of Hope National Medical Center, Monrovia, CA

This study addresses the current lack of small molecules targeting SOX2, a pivotal protein in cancer, through an examination of the effectiveness of FDA-approved drugs and proteasome inhibitors. Building on prior research demonstrating the proteasome inhibitor CFZ's capacity to diminish the expression of ITGB4 and PXN in LUAD effectively, our investigation highlights CFZ and IXA as potent inhibitors at nanomolar concentrations. Notably, CFZ treatment enhances sensitivity to cisplatin by suppressing the expression of ITGB4 and the stemness-associated gene SOX2.At a mechanistic level, CFZ hinders histone acetylation at the SOX2 promoter site, leading to rapid and specific downregulation. RNA-seq analysis of COH2 cells treated with CFZ unveils substantial downregulation of genes related to transcription and DNA binding. Z score analysis further reveals a noteworthy inhibition of key transcription factors (TFs), including SOX2, NANOG, POU5F1, SALL4, and KLF4. This TF inhibition extends to neuroendocrine cell lines, identifying 16 overlapping targets of SOX2 associated with stemness. These findings suggest a potential therapeutic approach for targeting cisplatin-resistant cancer stem cells across various cancer types. Moreover, the study proposes a synergistic effect of cisplatin and CFZ in mitigating the growth of neuroendocrine phenotype, SCLC. Given the limited medical options currently available for this phenotype, this insight holds particular significance. In conclusion, our study unveils CFZ as a potent transcriptional suppressor of SOX2, providing a novel strategy to sensitize cisplatin-resistant cancer stem cells. The results underscore the interplay of genetic and non-genetic mechanisms in drug resistance, emphasizing the significance of repurposing drugs for other indications.

#7575 BPI-460372, a covalent, irreversible TEAD inhibitor in Phase I clinical development.

X. Han[1], J. Guo[2], X. Jin[2], L. Zhu[2], H. Shen[2], X. Xu[2], M. Zhang[2], X. Liu[2], Y. Liu[2], H. Cheng[2], S. Guo[2], L. Ding[2], J. Wang[2], **H. Lan**[2], M. Wang[1];
[1]Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing, China, [2]Betta Pharmaceuticals Co.,Ltd, Hangzhou, China

The Hippo signaling pathway is critical for the regulation of organ development, tissue homeostasis, and tumorigenesis by controlling the activation status of yes-associated protein (YAP) or its homolog PDZ-binding motif (TAZ). As a major downstream effector, the transcription factor TEAD is activated by forming a complex with YAP/TAZ. Hippo pathway aberrations leading to TEAD activation have been reported in many cancers. Inhibiting TEAD function by directly blocking the palmitoylation pocket of TEAD is a potential therapeutic approach for cancer treatment. Betta Pharma has discovered a selective, covalent and irreversible TEAD inhibitor known as BPI-460372. The discovery of BPI-460372 was first reported in AACR 2023. Here we present additional preclinical and clinical data characterizing BPI-460372 as a promising candidate drug. In the dose-escalating part of the Phase I study, the exposure of BPI-460372 increased proportionally over 10 to 80 mg dose range after oral administration and exhibited linear pharmacokinetics, with a clearance rate suitable for once-daily dosing. The compound is generally well tolerated, with no drug-related Grade ≥3 adverse event observed. Remarkably, we have not seen renal toxicities that was perceived as a potential risk associated with certain TEAD inhibitors. Preliminary efficacy was observed in a few subjects. In preclinical studies, we found that intermittent dosing schedule of 3 days on/4 days off, compared with continuous dosing at equivalent weekly exposure, can ameliorate kidney damage and improve early renal injury biomarkers while maintaining anti-
tumor activity. Thus, alternative dosing schedule could further improve the therapeutic window and enable combination studies in clinical development. Collectively, these results support further development of BPI-460372 for the treatment of cancers harboring Hippo pathway alterations.

#7576 Exemestane and its primary metabolite 17-hydroexemestane inhibit synergically the tumor growth of ER/AR positive breast cancer tumors.

G. Santacana-Font[1], D. Kedra[1], M. Garcia-Macias[2], L. Cornelus-Reitsma[3], M. Lyngra[3], T. Sauer[3], V. Kristensen[4], A. Hurtado[1], **J. Geisler**[5];
[1]CSIC-Centro de Investigacion del Cancer de Salamanca, Salamanca, Spain, [2]Centro de Investigacion del Cancer de Salamanca, Salamanca, Spain, [3]Akershus University Hospital, Oslo, Norway, [4]Oslo University Hospital, Oslo, Norway, [5]University of Oslo, Oslo, Norway

Exemestane, an aromatase inactivator of the third generation, plays a crucial role in breast cancer therapy by targeting the P450 aromatase enzyme and, thus, decreasing estrogen synthesis. Exemestane (Aromasin™) is currently the only steroidal aromatase inactivator widely used in clinical routine treatment of ER+ breast cancer in all phases of the disease in a global perspective. However, the complex mechanisms underlying its therapeutic effects, besides being an aromatase inhibitor, remain incompletely understood. In this study, we employed a combination of human samples and in vitro data to unveil a compelling insight: Exemestane (EXE) and its primary metabolite, 17β-hydroxyexemestane (HEXE), exhibit potent inhibitory effects on tumor growth when present together in patient serum. Our biochemical analysis establishes a critical threshold—20% HEXE metabolite of the total EXE in patient serum—to trigger a tumor growth inhibition exceeding 90%, as evidenced by Ki67 staining. Mechanistically, our data reveals that both HEXE and EXE bind to the Androgen Receptor (AR), triggering a synergistic activation that induces a transcriptional program leading to cell death while diminishing the intracellular signaling activated by the oncogene Ras. Notably, patients with tumors characterized by a minimum of 20% AR+ epithelial cancer cells stand to benefit the most from exemestane and HEXE. Intriguingly, the binding of AR to chromatin in tumors gives rise to a molecular signature capable of distinguishing responsive from non-responsive patients to both EXE and HEXE. Collectively, our findings elucidate a dual therapeutic role for Exemestane in selected patients: it not only restrains estrogen-driven proliferation by estrogen suppression but also stimulates cell death by establishing a specific interactome with the AR at the genomic level. These insights suggest that both EXE and HEXE are necessary to achieve the best therapeutic effects in ER+/AR+
breast cancer tumors. Moreover, our findings suggest that AR-expression and targeting should be investigated further to potentially add novel strategies to our existing algorithms in ER+/AR+ MBC.

#7578 BRD4 protein degradation for p53 mutant diffuse intrinsic pontine glioma (DIPG) via various delivery approaches for ARV-825 by using camel milk exosomes.

A. Nathani[1], M. Aare[1], L. Sun[2], Y. Li[3], M. Singh[1];

[1]Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL, [2]Florida State University, Tallahassee, FL, [3]FAMU-FSU College of Engineering, Tallahassee, FL

DIPGs (diffuse intrinsic pontine gliomas) are a particularly aggressive and malignant type of pediatric brain tumor. Given the tumor's location, surgery has a restricted role, and it is insensitive to most chemotherapies. Although fractionated radiation is the standard of therapy for DIPG, the cancer invariably worsens in 6-12 months. TP53 tumor suppressor protein mutations are found in 70-80% of DIPG tumors. These TP53 mutations have been linked to radiation resistance in DIPG patients. Our goal was to find new pharmacological compounds that would improve the radiation sensitivity of p53 mutant DIPG cell lines and to determine their molecular mechanism of action. Numerous bromodomain-containing protein 4 (BRD4) inhibitors have entered clinical trials in recent years, yielding promising outcomes in tumor treatment since BRD4 expression in DIPG is substantially higher than in neighboring normal brain tissue. So consequently, BRD4 is a target for DIPG treatment. ARV-825 is an emerging PROTAC (Proteolysis Targeting Chimera) compound which can cause rapid and persistent BRD4 protein degradation. However, delivering ARV-825 to pons is a major challenge owing to poor oral bioavailability of PROTACS. In this study, we used camel milk derived exosomes (CME) for delivery of ARV-825 to pons by both nasal and oral routes. To begin with, goat milk exosomes were also considered but CME was chosen because of its innate cytotoxicity against DIPG cell lines. CME were isolated using ultracentrifugation and nanoparticle tracking analysis and revealed a size distribution of 112.5 ± 2.8 nm, zeta potential of -26.38 ± 0.12 mV. CME ($1*10^{11}$) were cytotoxic to both SF8628 (with a H3.3 K27M mutation) and SF188 (grade IV pediatric glioblastoma with wild type H3.3) cell lines and had 51% and 44% cell viability respectively. ARV-825 showed IC_{50} of 546.58 ± 22.14 nM and 608.94 ± 30.04 nM in SF8628 cells and SF188 cells respectively. ARV-825's IC_{50} was lowered when ARV-825 loaded CME were used. ARV-825 was loaded using sonication and entrapment efficiency was found to be 42.96 ± 2.14 % by HPLC analysis. CME were labelled with Vybrant DiO (CME-DIO) and instilled into each nostril of Sprague Dawley rats daily. Brain sections were viewed with fluorescent microscope and CME-DIO were seen in olfactory region after 3 days and in the pons region after 5 days demonstrating the ability of CME to reach the target site. *In-vitro* permeability studies using MDCK cells showed approximately 9µg/mL (60%), 15µg/mL (80%) and 16µg/mL (100%) of ARV-825 permeation in 2, 4 and 24 hours respectively when loaded into CME. The results of the present study suggest the possibility of using CME as a viable delivery strategy for ARV-825 against DIPG. Further in vitro and in vivo studies are currently undergoing to validate the results and understand kinetics and the molecular mechanisms of ARV-825 loaded CME.

#7579 Dual inhibition of enhancer of zeste homolog 1 2 induces pyroptosis, modulates oncogenic signaling pathways & sensitizes hepatocellular carcinoma to valemetostat & docetaxel treatments.

A. E. Harira, A. Maher, A. Sultan;
Alexandria University, Alexandria, Egypt

HCC is a global health concern, with chemotherapy resistance and patient recurrence posing significant challenges to liver cancer treatment. EZH2 is a crucial part of the polycomb repressive complex 2 (PRC2). It, along with its homolog EZH1, is a focus for cancer therapeutic targets. Dysregulation of EZH1/2 can cause cancer development due to significant changes in geneexpression. The current study aims to investigate the interaction between EZH1/2 and oncogenic signals responsible for HCC progression and pyroptosis induction. Two cell lines, HepG2 and SK-Hep1, were subjected to two FDA-approved drugs, Valemetostat (Val) and Docetaxel (Doc), to determine the impact of EZH1/2 on tumorigenicity and drug resistance. The WST-1 assay was utilized to gauge cell proliferation. The results indisputablydemonstrated a synergistic effect of the drugs after 48 h of treatment. The inhibition of viability was attributed to apoptosis induction in both tested cell lines, and the maximum effect was observed in the combined treatment as compared to either the control or each drug alone. Furthermore, our datashowed activation of caspase-3, upregulation of BAX, indicating apoptotic induction, and downregulation of Bcl-2, Bcl-XL, AKT, S6k, oncogenic β-catenin, and Stat3 protein expression levels, suggesting a modulation of oncogenic signaling pathways at the protein level. After 24 h of Val/Doc treatment, pyroptosis was observed, characterized by cell swelling and bubbles on themembrane and a significant release of lactate dehydrogenase, indicating pyroptotic cell cytotoxicity. The antitumor effects and pyroptosis were enhanced by using a dual inhibitor, UNC1999, for EZH1/2, resulting in a marked increase in the sensitivity of tested cells to the Val/Doc treatment invitro. The present study unequivocally demonstrated that dual inhibition of EZH1/2 acts as a potent sensitizer of HCC cells to Val/Doc treatment, which might be a promising therapeutic approach for inducing cellular pyroptosis in HCC cell lines.

#7580 The antihistamine terfenadine inhibits TFE3 dimerization, has antitumor activity and synergizes with tyrosine kinase inhibitors in translocation renal cell carcinoma.

I. Delle Fontane[1], R. Cordova[2], C. Rupert[1], S. Orsi[1], A. Jawadwala[1], D. E. Heppener[1], R. Pili[1];

[1]University at Buffalo, Buffalo, NY, [2]Indiana University, Indianapolis, IN

Translocation renal cell carcinoma is a subtype of kidney cancer characterized by gene fusions involving MiT transcription factor family, TFE3 and TFEB, with various gene partners. In general, these tumors do not respond to conventional therapies, which stresses the importance of developing new therapeutical approaches. To date, several TFE3 fusion gene partners have been identified. However, the mechanism driving TFE3 cooperation with various gene partners remains to be elucidated. We have previously shown the vulnerability of dimerization domain of multiple TFE3-fusion proteins, and we have screened the FDA approved drugs library LOPAC and a small molecule library (Microsource) to identify compounds that inhibit TFE3 dimerization. The antihistamine terfenadine was found to inhibit TFE3 dimerization and had antiproliferative activity in different models of tRCC, both *in vitro* and *in vivo*. Interestingly, our more recent data show that terfenadine reduced the amount of TFE3 in the nuclei. We have also observed enhanced antiproliferative activity of terfenadine in HEK293 cells overexpressing PRCC-TFE3, SPFQ-TFE3 or NONO-TFE3 compared to TFE3 alone or vector control, suggesting a targeted effect of terfenadine on cells driven by these TFE3-SF fusions. In addition, knock-down of SFPQ-TFE3 in HEK293 partially reversed this enhanced sensitivity to terfenadine. Cell proliferation and combination index analysis were performed in cell lines endogenously expressing the most common TFE3-fusion proteins cells to determinate the combination with different tyrosine kinase inhibitors. Immunofluorescence and confocal microscopy were performed to assess the impact on TFE3 fusion protein levels. The combination of terfenadine with sunitinib showed a synergistic effect in cells endogenously expressing PRCC-TFE3 (IC50=1.5μM; Fraction Affected > 0.05) and NONO-TFE3 (IC50=1.8μM; Fraction Affected<0.7) fusions. The combination of terfenadine with crizotinib showed a synergistic effect in cells expressing SFPQ-TFE3 fusion (IC50=0.7μM; Fraction Affected>0.7). The combination of terfenadine with dovitinib showed a synergistic effect in cells expressing PRCC-TFE3 fusion (IC50=1μM; Fraction Affected>0.4). These preliminary data suggest a different response to the combination with different TKIs. This observation underlines the importance of identifying the TFE3 partner gene for targeted therapy. Overall, our results suggest that targeting the dimerization domain along with different oncogenic pathways activated in tRCC cells may represent a new therapeutic approach for this disease.

#7581 Nicotine promotes the proliferation and metastasis of non-small cell lung cancer through c-Myc/EZH2 pathway.

C. Ding[1], H. Huang[1], C. Chen[2], Y. Li[2], H. Liu[2], **J. Chen**[1];

[1]Department of Lung Cancer Surgery, Tianjin Medical University General Hospital, Tianjin 300052, People's Republic of China, Tianjin, China, [2]Tianjin Lung Cancer Institute, Tianjin Key Laboratory of Lung Cancer Metastasis and Tumor Microenvironment, Tianjin Medical University General Hospital, Tianjin 300052, People's Republic of China, Tianjin, China

Objective: Lung cancer, particularly non-small cell lung cancer (NSCLC), continues to be a predominant contributor to global cancer-related mortality, with smoking emerging as a significant risk factor. Nicotine, which is one of the main chemicals from the tobacco smoke, is identified as carcinogen for lung cancer, especially for squamous carcinoma (LUSC). This study aims to investigates the intricate molecular mechanisms by which nicotine facilitates proliferation and migration in NSCLC through the c-Myc/EZH2 signaling pathway.

Methods: Clinical tissue specimens were procured from surgical patients with lung cancer for immunohistochemical staining. Additionally, public databases were scrutinized to compare EZH2 expression between smokers and non-smokers. NSCLC cell lines underwent treatment with nicotine in a time- and concentration-dependent manner, and the impact on EZH2 was corroborated through Western Blot, Real-time PCR, and immunofluorescence staining. Proliferation and migration assays, encompassing CCK8 experiments, colony formation assays, EdU staining, and Transwell assays, were conducted to discern the effects of nicotine on NSCLC. Experimental techniques such as si-RNA and CHIP were deployed to investigate changes in c-Myc-mediated regulation of EZH2, elucidating the intricate role of the c-Myc/EZH2 pathway in nicotine-induced NSCLC proliferation and migration.

Results: Smokers exhibited heightened EZH2 expression in tumor tissue compared to non-smokers. Nicotine treatment induced a concentration- and time-dependent upregulation of EZH2 in NSCLC cell lines. In 10 μM nicotine-treated NSCLC cells, concurrent treatment with 10 μM DZNep (EZH2 inhibitor) or si-EZH2 significantly augmented proliferation and migration. Moreover, the upregulation of EZH2 correlated with increased c-Myc expression, and siRNA-mediated c-Myc inhibition resulted in a corresponding reduction in EZH2 expression. Nicotine was identified as a promoter of NSCLC proliferation and migration through the c-Myc/EZH2 signaling pathway. This study establishes a robust association between nicotine and EZH2 in NSCLC cells, unveiling the novel regulatory axis of c-Myc/EZH2. Combined treatment with c-Myc and EZH2 inhibitors demonstrated efficacy in suppressing nicotine-induced promotion of NSCLC proliferation and migration.

Conclusion: In summary, this study elucidates the mechanisms through which nicotine propels NSCLC development via the c-Myc/EZH2 pathway, providing a theoretical underpinning for future NSCLC treatment paradigms. The combined use of c-Myc and EZH2 inhibitors emerges as a promising therapeutic strategy, poised to inhibit nicotine-induced NSCLC proliferation and migration, offering enhanced treatment modalities for patients.

#7582 Descriptive analysis of patients with mCRPC and liver metastases receiving alpha and beta PSMA targeted radionuclide therapy (PSMA-TRT).

S. Ruder, M. Sun, A. Ricaurte Fajardo, J. Nauseef, Z. Davidson, J. Thomas, S. Huicochea Castellanos, A. Molina, C. Sternberg, A. Patel, E. Fernandez, S. Yuan, E. Fung, V. Avlonitis, E. O'Dwyer, D. Nanus, J. Osborne, N. Bander, S. Tagawa;
New York Presbyterian Hospital Weill Cornell University Medical Center, New York, NY

Introduction: Predictors of outcomes after PSMA-TRT are still being established. Liver metastases (mets) have been associated with poor response. Mutations in genes encoding DNA damage repair (DDR) and TP53 affect radiosensitivity. Here we describe a cohort of patients with mCRPC and liver metastases treated on clinical trials of PSMA-TRT.

Methods: 39 patients with liver mets were enrolled on phase I/II PSMA-TRT studies between Jan 2006 to Apr 2022. Patients received alpha therapy (225Ac-J591), beta therapy (fractionated 177Lu-PSMA-617, single-dose and fractionated 177Lu-J591) or a combination of both (225Ac-591 and 177Lu-PSMA-I&T). All patients included in this analysis had CT imaging; patients enrolled after 2017 had PSMA-PET imaging. 15 patients also had genomic analysis completed.

Results: Median age was 69 (range 55-93), PSA 85.7 (2.45-9614). 39 (100%) bone mets, 33 (84.6%) LN, 9 (23.1%) lung. 22 (56.4%) greater than 1 ARPI, 23 (59.0%) greater thanc 1 chemo, 13 (33.3%) sip-T, 7 (17.9%) Ra-223, 4 (10.2%) prior TRT (with concurrent liver mets). Of the 19 with both CT and PSMA PET, 18 (94.7%) were identified on PSMA PET (including 8 PET only), 10 (55.6%) on CT (1 CT only, i.e. non-PSMA PET avid). Median whole body PSMA-imaging score (PSMA-IS) was 4 (range 1-4), with 7 (17.9%) 1-2 and 32 (82.1%) 3-4. 9 (23.0%) received alpha-TRT, 26 (66.7%) beta-TRT, and 4 (10.3%) combo-TRT. Somatic or germline analysis was completed in 15 (38.5%) of 39 patients. 8 (53.3%) had mutations in DNA repair pathways (3 in BRCA2, 3 in CHEK 2, 1 in FANC, 1 in MSH2). 7 (46.7%) had mutations in TP53. 31 patients (79.5%) had PSA decline, with 15 (38.5%) achieving PSA 50. 26 (66.7%) had baseline CTC measured; 19 (73.0%) had detectable CTC at baseline. Of these 19, 3 (15.8%) converted to undetectable after therapy and 2 (10.5%) converted to favorable CTC. PSA50 rate in alpha-TRT was 4 (44.4%), beta-TRT 8 (30.7%), combo-TRT 3 (75%). PSA50 in patients with PSMA-IS 1-2 was 1 (14.2%) compared to 14 (43.9%) in PSMA-IS 3-4. 3 (37.5%) of 8 patients with mutDDR achieved PSA50, compared to 3 (42.9%) with mutTP53.

Conclusions: This dataset adds to the collective literature of two subgroups of patients with mCRPC receiving TRT: those with liver disease and those with mutations in DNA repair pathways. The results of this study suggest higher rates of response in patients receiving alpha therapy, either alone or in combination with beta therapy, and in patients with high radiotracer uptake on PSMA-PET, based on PSMA-imaging score of 3 or 4. Genomic alterations in DRR proteins did not have clear implications.

#7583 Discovery of a potent small molecule MALT1 protease inhibitor for the treatment of cancer.

Y. Zhou, B. Fu, J. Chen, W. Cai, X. Sun, Y. Li, W. Ren, Q. Shen, G. Du, X. Zhou, Z. Zou, H. Chen, X. Liu, C. Yang, X. Liu, J. Guo, H. Wu, L. Ding, J. Wang, **H. Lan**;

Betta Pharmaceuticals Co.,Ltd, Hangzhou, China

The paracaspase mucosa-associated lymphoid tissue lymphoma translocation protein 1 (MALT1), as the core component of CBM complex (CARD9/10/11/14-BCL10-MALT1), plays an essential role in activating the NF-κB pathway and regulating the cell proliferation, differentiation and immunity. Inhibiting of MALT1 is considered a promising therapeutic approach for the treatment of several non-Hodgkin B-cell lymphomas, chronic lymphocytic leukemia (CLL), solid tumors and autoimmune diseases. Herein, we report the discovery of a novel potent MALT1 allosteric inhibitor, BPI-530616, which strongly inhibited MALT1 protease activity with subnanomolar IC_{50}, and low off-target activity on other proteases. BPI-530616 can inhibit the proliferation of B-cell diffuse large B-cell lymphoma (ABC-DLBCL) cell line, OCI-ly3, bearing CD79b and CARD11 mutations. The cell line is intrinsically resistant to covalent and non-covalent Bruton's Tyrosine Kinase (BTK) inhibitors. Meanwhile, BPI-530616 suppressed the cellular cytokine secretion (e.g.IL-10, IL-2) or MALT1 direct substrate cleavage (e.g. CYLD). *In vivo*, BPI-530616 dose-dependently suppressed tumor growth and inhibited the cleavage of CYLD in OCI-ly3 xenograft mouse model. To address the role of MALT1 inhibitor in the contest of immune-oncology, a CT26 syngeneic mouse model was set up. Oral administration of BPI-530616 exhibited a good antitumor effect comparable to that of the anti-PD1 antibody, with no observable adverse effects. Additionally, BPI-530616 displayed desirable drug-like properties, including low clearance and good oral bioavailability across multiple pre-clinical species. Taken together, our research has led to the discovery of a novel, potent, selective, and orally bioavailable small molecule MALT1 inhibitor, BPI-530616. It demonstrated anti-tumor efficacy in the DLBCL animal model and showed promising effects in an immune-oncology animal model.

#7584 The solute transported xCT (SLC7A11) modulates lysosome biogenesis and microRNA trafficking in drug resistant renal cell carcinoma.

A. Jawadwala, C. Rupert, R. Adelaiye-Ogala, R. Pili, Sreenivasulu Chintala, Ashley Orillion, May Elbanna, Nur Damayanti, I. Delle Fontane;
SUNY Buffalo, Buffalo, NY

Multi-tyrosine kinase inhibitors (TKIs) like sunitinib bind to over 50 kinases and inhibit several receptors such as VEGFR-1, VEGFR-2, and VEGFR-3 receptors, PDGFRa and PDGFRb, RET, cKIT, and FLT3. TKIs are effective drugs for the treatment of renal cell carcinoma (RCC) but intrinsic/acquired resistance remains a major hurdle. One of the proposed models for TKI resistance is drug sequestration by lysosomes. The solute transporter xCT is a cystine/glutamate antiporter that plays a role in the production of antioxidants in cancer cells. Our lab has found that SLC7A11, the gene that encodes xCT, is overexpressed in sunitinib resistant RCC cells. LAMP1 expression was also increased in sunitinib resistant RCC cells, suggesting an upregulation of lysosome biogenesis. The biochemical knock down of SLC7A11 by shRNA showed a decrease in LAMP1 expression, suggesting a decrease in lysosome biogenesis. SEC24D is a key catalytic component of COPII complex involved in formation of exosomes and secretory pathways. Our preliminary data showed that reduction in xCT expression was associated with a decrease in SEC24D protein levels which was associated with a reduction in the extracellular export and, consequently, an increase in intracytoplasmic levels of miRNA 605, a known tumor suppressor. We are currently testing the hypothesis that xCT may modulate lysosomes biogenesis and micro-RNA trafficking in several clear cell and translation renal cell carcinoma models. In summary, a better understanding of the role of xCT in the regulation of intracytoplasmic organelles may lead to the identification of a novel therapeutic strategy to overcome TKI resistance in RCC.

#7585 Targeting of 7 or 24 dehydrocholesterol reductase decreases cancer progression in head and neck cancer.

Bok-Soon Lee[1], Ji-Hye Choi[2], Hyo Jeong Kim[1], Jin Roh[3], Joselyn Padilla[4], Kennedy Davis Brock[4], Jeon Yeob Jang[1], Hyun Goo Woo[2], Chul-Ho Kim[1], Jiyoung Lee[4]

[1]Department of Otolaryngology, Ajou University School of Medicine, Suwon, Korea, Republic of,[2]Department of Physiology, Ajou University School of Medicine, Suwon, Korea, Republic of,[3]Department of Pathology, Ajou University School of Medicine, Suwon, Korea, Republic of,[4]Department of Biochemistry and Molecular Medicine, The George Washington University, School of Medicine and Health Sciences,, Washington, DC

The elevated expression of cholesterol metabolism has been associated with many cancer including head and neck squamous cell carcinoma (HNSCC). However, the molecular mechanisms between cholesterol biosynthesis and head and neck cancer have not yet been studied. In this study, we identified upregulation of dehydrocholesterol reductase such as DHCR7 or DHCR24 in HNSCC compared with adjacent normal tissues from the same patients using RNA sequencing data. We observed protein expression level of DHCR7 or DHCR24 in head and neck cancer cell lines through Western blotting. We also checked high expression of DHCR7 or DHCR24 in HNSCC tissues from patients using immunohistochemistry assays. Yet, when DHCR7 or DHCR24 was knocked down using siRNA, the viability of HNSCC cells was decreased in MTT assays. In parallel, we adapted small inhibitory drugs; AY9944 for DHCR7 inhibition and Triparanol or SH-42 for DHCR24 inhibition. Treatment of AY9944, Triparanol, or SH-42 also resulted in decreased viability of HNSCC cells. Moreover, when we used a cholesterol blocker, MCD, the cell viability was decreased, whereas the cells overcame cell death by adding the combination of cholesterol and LDL. Taken together, we concluded that head and neck cancer requires DHCR7 and DHCR24 activity involved in cholesterol metabolism for cancer growth. Our data suggest that targeting DHCR7 or DHCR24 using AY9944, Triparanol or SH-42 is one of the potential strategies that will definitely help with cancer treatment for head and neck cancer.

#7586 TOX loss-of-function(TOX^{LOF})results in BCR hyperactivation andenhanced responses to BCR-targeting in diffuse large B cell lymphomas (DLBCL).

Eloisi Caldas Lopes, Maria Victoria Revuelta, Rossella Marullo, Leandro Cerchietti

Weill Cornell Medicine, New York, NY

DLBCL originate from germinal center B cells (GCB). The ABC-DLBCL subtype, characterized by activation of B-cell receptor (BCR) signaling and downstream NF-kB pathway, carries a poor outcome. Up to 30% of ABC-DLBCL present TOX^{LOF} mutations, suggesting that TOX function as a tumor suppressor. Our analysis of TOX expression along the germinal center B-cell differentiation program (naïve → GCB → plasma cells) showed that TOX expression paralleled NF-kB activity with highest levels in plasma cells (P<0.001, vs. either naïve and GCB). We thus propose that TOX acts as a transcriptional gatekeeper in GCB cells to prevent early activation of NF-kB thus enabling differentiation into plasma cells while restraining lymphomagenesis. We generated a conditional GCB TOX KO mouse model, induced the GC reaction with a T-cell antigen and found that TOX KO (vs. TOX WT, 10 mice per condition) had impaired differentiation of plasma cells (p<0.001) and hyperproliferative Ki67+ GCB cells (p<0.05). We then generated (by CRISPR) an isogenic TOX^{LOF} ABC-DLBCL cell line (TMD8) and found upregulation of genes in the NF-kB pathway (q-value <0.05, vs. TMD8). Furthermore, TMD8-TOX^{LOF} cells showed increased secretion of autocrine cytokines IL6 and IL10, and higher STAT3 phosphorylation (p<0.05 for all comparisons, vs. TMD8-TOX^{WT} cells) all compatible with NF-kB activation. Tumor microenvironmental cues can hyperactivate BCR and downstream NF-kB in ABC-DLBCL. We thus implanted isogenic TMD8 cells in mice (n = 10) and determined pathway activation by phospho-flow. We found massive activation of SYK, BTK, PLCG2 (from the BCR) and p65 (from NF-kB) in TMD8-TOX^{LOF} vs. TMD8-TOX^{WT} tumors (all p<0.01), and vs. these cell lines cultured in vitro (all p<0.01). To determine whether these features can be therapeutically exploited, we conducted a viability screening using a panel of 20 clinical-phase targeted therapies relevant to ABC-DLBCL. We found that BTK inhibitor acalabrutinib (BCR pathway) and MALT1 inhibitor JNJ67690246 (NF-kB pathway) were 2-3 fold more active in TMD8-TOX^{LOF} vs. TMD8-TOX^{WT} cells (all p<0.05). We then xenografted isogenic TMD8 cells (n = 10 mice per condition) and, when tumors reached 150 mm3, we randomized mice to vehicle vs. acalabrutinib 30 mg/kg/day by oral gavage (human dose equivalent). Acalabrutinib was significantly more active in TMD8-TOX^{LOF} tumors (vs. TMD8-TOX^{WT}, p=0.0008), which translated into significantly prolonged survival (p<0.05). This acalabrutinib effect was accompanied by significant reduction of BTK, SYK and PLCG2 phosphorylation in TMD8-TOX^{LOF} tumors (p<0.0001, all comparisons). Thus, TOX^{LOF} leads to hyperactivation of the BCR and NF-kB signaling pathways in ABC-DLBCL cells, rendering them hypersensitive to BCR-targeted therapies, delineating a potential mechanism-based therapeutic approach for ABC-DLBCL TOX^{LOF} patients.

#7587 Fascin1 might be a promising molecular target for colorectal cancer patients at advanced stage.

Canfeng Fan, Qiang Wang, Rika Aoyama, Hinano Nishikubo, Kyouka Kawabata, Imanishi Daiki, Takashi Sakuma, Koji Maruo, Gen Tsujio, Yurie Yamamoto, Tatsunari Fukuoka, Masakazu Yashiro

Osaka Metropolitan University, Sakai, Japan

Background: Colorectal cancers (CRC) show high morbidity and mortality. Especially, the consensus molecular subtypes 4 (CMS4)-CRC shows extremely poor prognosis and high chemo-resistance rate, in compared with the other types of CRC. CMS4-CRC is histologically characteristic for the extensive stromal infiltration with poorly differentiated cancer cells in the tumor microenvironment. Several studies have reported that sessile serrated adenomas, which is characterized by disorganized crypt architecture and irregular serrations with high malignant potential such as epithelial-mesenchymal transition and TGFβ signaling, might be closely associated with CMS4-CRC. Fascin-1 is an actin-binding protein supposed to be associated with sessile serrated adenomas. However, the expression and clinical significance of fascin-1 in CMS4 CRC remains to be unclear.
Aim: The aim of this study was to clarify the clinic-pathological significance of fascin-1 in colorectal cancer, and to evaluate the effects of fascin-1 inhibitors on the invasion and migration ability of CMS4 cancer cell lines.
Materials and Methods: We conducted an immunohistochemical study on 351 colorectal cancer patients, where we examined the expression levels of Fascin-1 and analyzed their correlation with the patients' clinicopathologic features. Using two human CMS4-CRC cell lines, SW480 and HCT116, we investigated the effects of the fascin-1 inhibitors, NP-G2-044 and BDP-13176, on the proliferation and the migration activity of CMS4-CRC cells via MTT assay and a wound-healing assay.
Results: Fascin-1 is expressed both on cancer cells and on stromal cells, but mainly expressed on cancer cells. Significance of fascin-1 expression on cancer cells was evaluated in this study. Fascin-1 expression is significantly associated with histologically poorly differentiation ($p < 0.001$), deeper T invasion ($p = 0.003$), and proximal colon cancer ($p < 0.001$). High fascin-1 expression is significantly associated with worse prognosis ($p = 0.0085$, log-rank) and higher recurrence rates ($p = 0.018$). Univariate analysis demonstrated that overall survival of patients was significantly associated with Fascin1 expression in cancer cells, age ≥65 years old, poor histological type, lymphatic invasion, lymph node metastasis, and venous invasion. Multivariate analysis revealed that fascin1 expression ($p = 0.037$), poor histological type ($p = 0.022$), venous invasion ($p = 0.078$), and lymph node metastasis ($p = 0.009$) were significantly correlated with the overall survival rate of CRC patients. Both fascin-1 inhibitors significantly reduced the invasion and migration of colorectal cancer cells at the concentration of 100 nM.
Conclusions: Fascin-1 is one of key molecules for the development of CRC. Fascin-1 might be a promising molecular target for CMS4-CRC patients at advanced stage.

#7588 Discovery of NSP-5033: A novel and potent PARP7/12 dual inhibitor.

Q. Chen, Q. Huang, K. Zhang, Y. Hao, Z. Wang, B. Li;
Novostar Pharmaceuticals, Ltd., Shanghai, China

PARP7 is a mono-ADP-ribosyl transferase that catalyzes the transfer of single units of ADP-ribose onto substrate proteins to regulate their functions. One of its substrates is TANK binding kinases 1 (TBK1), whose MARylation by PARP7 inhibits its activation and thereby represses the type I IFN response to cytosolic nucleic acid. PARP7 is upregulated in many kinds of cancers and acts as a brake in cytosolic nucleic acid sensing, which leads to the suppression of type I IFN signaling and immune response. Therefore, PARP7 is a novel and promising target in cancer immunotherapy. Herein, we describe the discovery of a novel small molecule NSP-5033 as a dual PARP7/PARP12 inhibitor, which potently inhibits PARP7 and PARP12 enzymes with sub-nanomolar and low nanomolar activities, respectively. It displayed potent anti-proliferative activities against a number of cancer cell lines *in vitro*. NSP-5033 also increased the mRNA level of IFNβ and CXCL10 and stimulated STAT1 phosphorylation, suggesting that it restored the type I IFN response in tumor cells. With excellent ADME and pharmacokinetic properties, NSP-5033 demonstrated potent *in vivo* efficacy in human lung cancer xenografts with tumor regression and induced antitumor immunity in tumor-bearing immunocompetent mice. NSP-5033 has been nominated as a preclinival candidate for treatment of solid tumors and is undergoing IND-enabling studies.

#7589 The novel complex delivery system of C-phycocyanin-loaded *klebsiella pneumonia*bacterial ghost induces apoptosis and sensitizes non-small cell lung cancer cell lines to doxorubicin.

B. A. Abdelaziz[1], H. E. Mahmoud[2], O. M. Sadek[3], A. S. Sultan[4],
[1]Pharos University in Alexandria / Alexandria University, Alexandria, Egypt, [2]Institute of Graduate Studies and Research, Alexandria University, Alexandria, Egypt, [3]Faculty of Science, Alexandria University, Alexandria, Egypt, [4]Georgetown University / Alexandria University, Alexandria, Egypt

Lung cancer is a significant cause of cancer-related deaths worldwide, with a high incidence rate, poor prognosis, aggressiveness, and a lack of effective treatment options. The present study has brought together two FDA-approved drugs with antineoplastic properties to create a complex that promises to revolutionize the treatment of Non-Small Cell Lung Cancer (NSCLC). By combining C-Phycocyanin extract (PCE), a pigment-protein complex synthesized by blue-green microalgae *platensis*, with the immunostimulatory doxorubicin (DOX) loaded Bacterial Ghosts (BGs), the present study aims to achieve enhanced dual-chemotherapy and remarkable inhibition of DOX-chemoresistance. The BG delivery system uses purified bacterial cell evacuation and safe confirmed *Klebsiella pneumoniae* BGs (KPBG) for safe and effective delivery, overcoming issues with resistance and poor delivery. The complex delivery system of KPBG-PCE/DOX was tested on two NSCLC cell lines, wild-P53, A549, and mutant-P53, NCI/H358, respectively. Our data showed that the loaded combined treatment significantly induced morphological changes with signs of apoptosis induction in the tested cell lines compared with the control. The WST-1 assay was used to evaluate cell proliferation. Data indicates that PCE and DOX have a synergistic effect at low concentrations when loaded on KPBGs for a constant count of BGs CFU/ml after 48 h of treatment. The viability inhibition and apoptosis induction of A549 and NCI/H358 cells were amplified in the combined treatment of 48 h compared to the control or either each drug alone. At the protein levels, our data showed activation of caspase-3, upregulation of BAX, and downregulation of Bcl-2, Bcl-XL, m-TOR, S6k, oncogenic β-catenin, and cyclin-D1 protein expression levels after treatment with (KPBG-PCE/DOX) for 48 h, indicating apoptotic induction and modulating oncogenic signaling pathways. In conclusion, the current study presents a promising outcome of a synergistic delivery system of KPBG-PCE/DOX that can inhibit lung cancer cell line proliferation, induce apoptosis, and increase cell sensitivity to DOX. The KPBG delivery system offers an appealing approach for a successful combination of targeted therapy for lung cancer.

#7590 Novel therapeutic approach for targeting p53 mutant colorectal cancers by affecting post-replicative DNA repair.

M. M. Alruwaili[1], N. Naranjo[1], P. Rajan[1], K. Jo[1], D.-K. Kim[1], T. Melendy[2], R. Straubinger[3], C. Fountzilas[1], A. Bakin[1];
[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]University of Buffalo, Buffalo, NY, [3]University at Buffalo, Buffalo, NY

Colorectal Cancer (CRC) is the third most common cause of cancer mortality in the US. A major problem in CRC management is relapse and progression to metastatic disease leading to poor overall survival. The tumor suppressor p53 is mutated in most CRCs and often drives metastasis and therapy resistance. Current therapeutic options targeting p53 mutant cancers show poor efficacy and frequently exhibit high toxicity. To address this clinical problem, we developed a novel therapeutic strategy for selective targeting of p53 mutant cancers. The strategy combines a thymidine analogue (e.g., trifluorthymidine/TFT, a component of TAS102) and poly (ADP-ribose) polymerase inhibitor (PARPi). We observed that TAS102 does not block DNA replication, but rather prompts post-replicative base-excision DNA repair (BER), and PARPi increases double-strand DNA breaks (DSBs) in p53 mutant cancer cells. Normal p53 wild type (p53wt) cells are arrested in the G1 phase and repair DNA. Thus, the TAS102-PARPi combination selectively targets p53-mutant cancer cells, resulting in the accumulation of DSBs and cell death. This novel strategy was examined in p53wt and p53-mutant tumor cell-derived xenograft (CDX) and patient-derived xenograft (PDX) models. The drug combination was significantly more effective in inhibiting p53 mutant tumor growth and in prolonging survival compared to monotherapies. This strategy is currently being tested in a first-in-human dose-escalation Phase I study (NCT04511039) in patients with advanced CRC. Further investigation revealed that the TAS102-PARPi combination induced DNA damage response (DDR) and the G2 checkpoint, leading to G2 arrest in p53 mutant cancer cells. We observed that TAS102-PARPi induced phosphorylation of CDC2 (also known as CDK1) but did not increase phosphorylation of histone H3 (a marker of mitosis), therefore indicating activation of the G2 checkpoint. Furthermore, the roles of ATM and ATR kinases in the DDR and G2 responses were clarified using highly specific kinase inhibitors. The analysis of the DDR/G2 signaling response in isogenic p53wt and mutant CRC cell lines showed that inhibition of WEE1 kinase can selectively abrogate the G2 checkpoint in p53-mutant cells, resulting in marked DNA damage and cell death. Importantly, the blockade of WEE1 strongly synergized with the TAS102-PARPi combination, further enhancing its potency and efficacy against p53-mutant cancer cells. In summary, our research provides a foundation for a novel therapeutic strategy for p53 mutant cancers that may provide a paradigm shift in the treatment of these deadly cancers, increasing efficacy while minimizing toxic adverse effects.

#7591 Tumor Treating Fields (TTFields) show efficacy in Triple-Negative breast cancer (TNBC) cells alone and in combination with PARP inhibitor Talazoparib.

M. Ghandali, P. Srinivasan, Y. Xia, E. T. Wong, R. W. Sobol, L. zhou, B. A. Carneiro, S. L. Graff, W. S. El-Deiry;
Legorreta Cancer Center at Brown University, Providence, RI

Breast cancer is the most common cancer in women worldwide, and the fifth leading cause of cancer-related deaths globally. Triple-negative breast cancer (TNBC), the most aggressive form of breast cancer, is usually treated with surgery, chemotherapy, and radiation. Tumor Treating Fields therapy are FDA-approved for the treatment of glioblastoma (GBM) and malignant pleural mesothelioma (MPM).TT Fields use alternating electric fields to inhibit tumor growth through mitotic disruption, cellular damage, integrated stress response activation, and immune mechanisms and inhibit cell proliferation, induce cell death, and cause cell cycle arrest.TT Fields can induce BRCAness and when combined with PARP inhibition, this combination may result in synthetic lethality. We explored the effect of TTFields on two TNBC cell lines MDA-MB436 (BRCA1-mutant, p53-null) and MDA-MB468 (BRCA1 wild-type, p53-mutant) treated with TTFields (150 kHz) for 24 hours. Western blot analysis showed elevation of p21 independent of p53 mutational status. We examined the combination of PARP inhibitor (Talazoparib) with TTFields in MDA-MB468 cells to determine the effect of the combination in BRCA wild-type cancer cells. Western blot analysis showed p21 upregulation after 24 hours in combination without an increase in p53. p21 acts as a G1-checkpoint protein and loss of p21 expression has been observed in a high percentage of human breast cancer cells. Our results suggest a rational and potentially effective therapy that could be further developed and used for the treatment of breast cancer. Our ongoing studies are exploring potential mechanisms of synergy between PARP inhibitor Talazoparib and TTFields using various TNBC models, and the effect of the combination on cell cycle arrest in cell culture and in vivo.

#7592 Combined inhibition of CDK4/6 and AKT is highly active against the luminal androgen receptor (LAR) subtype of triple negative breast cancer (TNBC).

R. Chica-Parrado, G. Kim, Y. Uemoto, D. Ye, F. Napolitano, C.-C. Lin, E. Bikorimana, K.-m. Lee, S. Mendiratta, A. B. Hanker, C. L. Arteaga;
UT Southwestern Simmons Comprehensive Cancer Center, Dallas, TX

The LAR subtype of TNBC is enriched for targetable biomarkers such as androgen receptor (AR) expression, PIK3CA mutations, and intact Rb. The purpose of this study was to investigate the most effective combination of CDK4/6, AR, and PI3K-AKT inhibitors in preclinical models of LAR TNBC. The MDAMB453 and MFM223 (AR positive/Rb intact/PIK3CAmutant) LAR TNBC cells were treated with each inhibitor alone or in combination. Drug sensitivity was assessed using colony formation, cell viability, and live-cell analysis. The Loewe additivity equation was used to measure the additive drug effects. Immunoblot analysis was used to evaluate cell cycle and PI3K-AKT signaling and ARE luciferase assay was used to assess AR transcriptional activity. MDAMB453 and MFM223 cells were sensitive to the single agents palbociclib, alpelisib, and capivasertib (IC50, ~500 nM), which inhibited CDK4/6, PI3Kα, and AKT, respectively. Enzalutamide, an AR antagonist, exerted no growth inhibitory activity (IC50, 15-25 μM). Treatment with palbociclib, alpelisib, or capivasertib did not alter the AR protein levels or transcriptional activity. The combination of palbociclib+capivasertib synergistically inhibited the proliferation of MDAMB453 and MFM223 cells (synergistic scores 7.34, p=5.81-11, and 4.78, p=0.012, respectively) better than palbociclib+alpelisib. Enzalutamide did not enhance either combination. Palbociclib+capivasertib inhibited PI3KCA-mutant and Rb-intact LAR TNBC PDX growth more potently than palbociclib+alpelisib (p=0.046). Treatment of LAR TNBC cells with palbociclib suppressed Rb phosphorylation and resulted in adaptive activation of P-AKT$^{S473/T308}$ and the AKT substrates GSK3β, PRAS40, and FoxO3a after 24 h. Capivasertib inhibited the phosphorylation of AKT and AKT substrates, following CDK4/6 blockade with palbociclib, more potently than alpelisib. PI3Kβ inhibitors (TGX221, GSK2636771) did not block AKT substrate upregulation, suggesting PI3Kβ does not mediate adaptive responses. Rictor knockdown failed to reduce AKT activation following palbociclib treatment, suggesting an mTORC2-independent mechanism. Human Phospho-kinase Array of MDA-MB-453 cells treated with palbociclib showed time dependent upregulation of GSK3β^{S9}, STAT3^{Y727} and PDFGRβ^{Y751}. PDGFRβ activation after palbociclib treatment was confirmed in MFM223 cells. PDGFRβ siRNAs in MDAMB453 cells blocked P-AKT^{S473} upregulation after palbociclib treatment. Treatment with palbociclib and the PDGFRβ small-molecule antagonist CP673451 arrested LAR TNBC growth similar to palbociclib+capivasertib, suggesting an adaptive response involving PDGFRβ signaling. In conclusion, this study supports the clinical testing of the palbociclib and capivasertib combination for LAR TNBC patients and reveals adaptive responses after palbociclib treatment through PDGFRβ signaling.

#7593 Photodynamic therapy improves therapeutic management of glioblastoma.

N. Vasyliv[1], K. Williams[2];

[1]University of Edinburgh, Edinburgh, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom

Glioblastoma (GBM) remains a formidable challenge in the realm of oncology, primarily due to the limitations of the standard of care therapies. Photodynamic therapy (PDT), which exploits the light-activated potential of 5-aminolevulinic acid (5-ALA), emerges as a promising avenue to combat GBM. In this study, primary patient-derived cell lines, Ox5 core, and G7, served as critical subjects, exposed to light excitation at wavelengths of 410 nm, 528 nm, and 810 nm, both with and without 5-ALA (protoporphyrin IX). The central objective was to rigorously assess the efficacy of PDT, either with or without 5-ALA, in reducing cell viability and curtailing clonogenic expansion. This evaluation was performed within the context of the existing standard of care for GBM, encompassing Temozolomide (TMZ) and Radiotherapy. Our results unveiled striking insights into the potential of PDT as an innovative therapeutic strategy. Notably, Ox5 cells exhibited a remarkable reduction in viability, exceeding 70%, following exposure to PDT with 410 nm light and 5-ALA at a concentration of 50µM. A similar, albeit slightly less profound, effect was observed in G7 cells, with a viability decrease of more than 53%. These outcomes, meticulously quantified through the MTT viability assay (n=4), were reinforced by statistical significance, as indicated by p-values falling below 0.05 and, lower 0.001. Furthermore, clonogenic assays employing G7 cells provided an additional layer of evidence, demonstrating a substantial inhibition of clonogenic potential following PDT treatment with 410 nm light and 5-ALA. Immunohistochemistry techniques, particularly focusing on the cleaved caspase-3 marker, in both Ox5 core and G7 cells, underscoring the mechanistic basis of the observed cell death. In stark contrast, the conventional standard of care, involving TMZ monotherapy, was tested, and the results across four biological replicates were less significant. The relative viability of Ox5 and G7 cells exhibited no statistical significance, with p-values exceeding 0.05, implying a limited impact of this regimen on cell viability. Moreover, clonogenic assays conducted under the standard of care protocol (TMZ+/-Radiotherapy) unveiled the persistence of colonies, even at higher radiation doses of 4 and 6 Gy.In summary, PDT, specifically when implemented with 410 nm light and 5-ALA, represents a breakthrough strategy that leads to substantial cell death in both Ox5 and G7 cells. This compelling alternative therapy shines a hopeful light on the horizon of GBM treatment, providing a potentially transformative approach that can augment the current standard of care.

#7595 PRMT5 inhibitor synergizes with PARP inhibitors in triple-negative breast cancer cells.

S. Suresh, L. A. McPherson, J. M. Ford;
Stanford University School of Medicine, Stanford, CA

Background: Treating triple-negative breast cancer (TNBC) patients, an aggressive subtype of breast cancer, is an ongoing clinical challenge. Small-molecule inhibitors targeting the poly ADP-ribose polymerase (PARP) DNA repair enzymes, have been approved for treating only a subset of TNBC patients with a specific genetic landscape (*BRCA1* mutation). However, TNBC patients with wildtype *BRCA1 (BRCA1^{WT})* are still lacking targeted therapy and chemotherapy remains their main treatment strategy. High expression of protein arginine methyltransferase 5 (PRMT5) is linked to poor prognosis in breast cancer and PRMT5 alone or via its interacting proteins plays an oncogenic role in breast cancer. Recent evidence suggests that PRMT5 is a key player in regulating the repair of DNA double strand breaks (DSBs) either through homologous recombination (HR) or non-homologous end joining (NHEJ) depending on the PRMT5 expression level within the cell. This dependency of cancer cells on PRMT5 expression levels in deciding the repair pathway of choice can be exploited for developing therapies. We hypothesize that in *BRCA1* wildtype TNBC cells, inhibiting PRMT5 activity will force the cells to rely on NHEJ rather than HR to repair DNA DSBs, and introducing PARP inhibitors in this setting will inactivate NHEJ as well, causing synthetic lethality and cell death. In this study, we evaluated the pre-clinical benefit of combining PARP inhibitors with a PRMT5 inhibitor in TNBC cells.

Methods: Human TNBC cell lines with wildtype *BRCA1* (MDA-MB-468, HCC1806) and mutant *BRCA1* (MDA-MB-436, SUM149-PT) were treated with varying doses of two PARP inhibitors (Olaparib, Talazoparib) and a PRMT5 inhibitor (GSK3326595) as single agents or in combination. MTT-based cell viability assay was used to determine cytotoxicity of the treatments. mRNA expression was determined by RT-qPCR after drug treatment.

Results and Conclusion: We report that PRMT5 inhibition synergizes with both Olaparib and Talazoparib, to potentiate cell death in two *BRCA1^{WT}* but not in *BRCA1^{mut}* TNBC cell lines. Furthermore, we show that inhibiting PRMT5 in *BRCA1^{WT}* cells upregulates the mRNA expression of *RAD50*, a DNA damage sensing gene in the HR pathway. Our ongoing study is to delineate the molecular mechanism of action for the observed synergy and whether PRMT5 inhibition can overcome resistance to PARP inhibitors. Through this study, we will identify a novel treatment strategy for the majority of TNBC patients (*BRCA1^{WT}*) who currently lack targeted therapies.

#7596 (TTFields) and imipridone ONC206 co-treatment inhibits p-AKT and spheroid growth and upregulates caspase-10 in human GBM cell lines.

V. Tajiknia, P. Srinivasan, M. Pinho-Schwermann, W. MacDonald, C. Purcell, W. El-Deiry;
Legorreta Cancer Center at Brown University, Providence, RI

Background: Glioblastoma (GBM) is the most common primary brain malignancy with dismal prognosis. Tumor Treating Fields (TTFields) therapy is available for the treatment of both newly diagnosed and recurrent glioblastoma and represents a new category of treatment modalities in oncologic therapy. Despite decades of study, few FDA approved modalities are available for GBM and provide limited survival improvements for patients. AKT functions as a key serine/threonine kinase in the RTK/PTEN/PI3K pathway, and extensive genomic analysis of GBM has revealed that this pathway is mutated in a significant majority of GBM cases. Activation of this pathway ultimately leads to the activation of AKT, and p-AKT levels are elevated in the majority of GBM tumor samples and cell lines. Studies have shown that increased p-AKT levels contribute to uncontrolled growth, resistance to apoptosis, and enhanced invasive capabilities of glioma cells, which are characteristics of tumor progression in GBM. AKT serves as a critical hub in this pathway, enabling the amplification of growth signals, thereby making the inhibition of AKT an appealing and promising therapeutic target for treating GBM. Imipridone ONC206 is under clinical development for treatment of pediatric and adult patients with primary brain tumors (NCT04732065 and NCT04541082). Here we show inhibition of p-AKT as well as upregulation of CHOP and caspase-10 following cotreatment of ONC206 and TTFields.
Materials & Methods: We investigated the effect of ONC206 (at IC50s) plus TTFields in U251 and T98G human GBM cell lines at different time points. Effect of treatment on cPARP, BCL-2, CHOP, caspase-10, and p-AKT were investigated using western blot. Neurospheres were generated using mentioned cell lines and used for investigating effect of co-treatment on 3D structure.
Results: Treatment with ONC206 at the IC50 in T98G cells with TTFields at 24h showed synergistic upregulation of cPARP as well as inhibition of BCL-2. At 96hour time point, inhibition of p-AKT was observed following all treatments (ONC206, TTFields, and co-application compared to control. In U251 cells, following treatment of ONC206 and TTFields, inhibition of BCL-2 was observed at 24h time point at all treatment conditions. Upregulation of CHOP and Casapse-10 at 96h time point was seen, as well as inhibition of p-AKT. Spheroid models showed structure disruption and growth arrest following combination treatment.
Conclusion: Here we showed cotreatment results in inhibition of p-AKT, the key node in GBM growth pathway. Also, the upregulation of CHOP and caspase-10 that has not been discussed before can be the key to focus on novel therapeutic targets for GBM More studies are needed to elaborate the exact mechanism of synergy but these new findings can be used to develop novel treatment combination

#7597 Therapeutic potential of ketogenic diet as an adjuvant to lenvatinib treatment in hepatocellular carcinoma.

M. Zhang[1], T.-W. Lee[2], S. Ma[3], M. Tong[1];

[1]Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong, [2]The Hong Kong Polytechnic University, Hong Kong, Hong Kong, [3]The University of Hong Kong, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) has been a major public health concern worldwide for decades because of its high mortality rates and poor prognosis, which are attributable to frequent tumor relapse and limited treatment regimens. Lenvatinib is one of the tyrosine kinase inhibitors approved for first-line treatment of advanced HCC, but its efficacy remains modest. Growing evidence suggest that the unsatisfactory survival benefits of lenvatinib could be attributed to the acquired drug resistance developed in HCC patients. In this study, we aim to explore the intrinsic metabolic vulnerability which could be exploited to enhance the treatment efficacy of lenvatinib in HCC. Our previous study showed that loss of tyrosine catabolism accompanied with a reduced downstream ketone metabolite beta-hydroxybutyrate (BHB) supports HCC initiation. To explore the therapeutic value of BHB in potentiating lenvatinib treatment in HCC, tyrosine catabolism-suppressing HCC cells were treated with BHB. We found that BHB treatment suppressed cell proliferation, increased cellular reactive oxygen species and potentiated the efficacy of lenvatinib treatment. Similar tumor-suppressive effect was observed when BHB was administered in vivo in mice bearing HCC patient derived xenograft. Combination treatment of lenvatinib and ketogenic diet which induces BHB level could drastically attenuate tumor development in immunocompetent mice bearing hepatic tumors. This study presents a potentially translatable combination treatment regimen to potentiate the therapeutic efficacy of lenvatinib in advanced HCC.

#7598 The novel eIF4A inhibitor potently synergizes with BCL2 inhibitor in high grade B-cell lymphoma with MYC and BCL2 rearrangements through regulating UPR.

So-Young Seol[1], Chung Hyun Park[2], Soo Jeong Kim[2], Haerim Chung[3], Hyunsoo Cho[3], Jin Seok Kim[3], Yu Ri Kim[1]

[1]Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Yongin Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Double hit lymphoma(DHL) is defined to be a chromosomal break with MYC gene combined with BCL2 or BCL6. MYC is an oncogene which proliferation the cells and BCL2 inhibit cell death. These combinations could be a cause of highly aggressive clinical features and poor survival of DLBCL. The WHO-HAEM5 renames the entity DLBCL/high-grade B-cell lymphoma with MYC and BCL2 rearrangements. Despite the dismal prognosis, no widely accepted standard treatment exists to the management of DHL. Therefore, new therapeutic approaches for these patients are urgently needed. Previously, we looked at the eIf4A inhibition was shown to downregulate MYC expression in lymphoma cell lines. Venetoclax, a highly selective inhibitor of BCL2, shows clinical activity for patients with DLBCL although there are concerns about increasing toxicity. Our hypothesis in the following: If eIF4A inhibitor preferentially inhibit the translation of oncogenes such as cMyc and venetoclax inhibit the BCL2 in DHL, then the combination of eIF4A inhibitor and BCL2 inhibitor will be highly effective for DHL and potentially safe for animals and humans. We tested the anti-lymphoma effect of CR-1-31-B, in combination with Venetoclax in lymphoma cell lines using flow cytometry. We performed cell apoptosis assays in increasing concentrations of Venetoclax, CR-1-31-B and a combination of the two drugs at 48 hours. To better understand molecular mechanisms underlying the observed synergistic effect in DLBCL-DHL, RNA-seq profiling was performed on cells treated with single drugs and their combinations, respectively. Venetoclax and CR1-31-B exhibited concentration and time dependent cytotoxicity in lymphoma cell lines at low nanomolar concentrations. Overall, the combination of eIF4A inhibitor and BCL2 inhibitor showed synergy in all kinds of DLBCL cell lines. Especially DHL cell lines were more sensitive to the drug combination and showed enhanced synergy compared to the non-DHL cell lines(p<0.0001). We analyzed RNA-seq profiling of cells treated with single drugs and their combinations and found that the transcriptional signature of the synergistic combination was unique relative to that of either constituent monotherapy. Gene set enrichment analysis was performed in the DHL and non-DHL group. The analysis demonstrates that known Unfolded protein response(UPR) part and metabolism, are enriched in DHL groups. This suggests that the UPR and metabolism pathway are closely related to the combination effect in DHL. These findings suggest that the combination of eIF4A inhibitor and BCL2 inhibitor have potent pharmacological activity in DHL lines, it was closely related with UPR. These combination is promising and novel treatment for high-grade B-cell lymphoma with MYC and BCL2 rearrangements. Further pre-clinical investigations of this combination for these patients are needed.

#7599 Evaluate the treatment efficacy of magnolol combined with cisplatin in non-small cell lung cancer.

R.-E. Lu[1], B.-X. Chen[1], F.-T. Hsu[1], I.-T. Chiang[2];
[1]China Medical University, Taichung, Taiwan, [2]Show Chwan Memorial Hospital, Changhua, Taiwan

Lung cancer is one of the five most common cancers in the world. Statistics indicate that approximately 80% to 90% of lung cancer cases fall under the classification of non-small cell lung cancer (NSCLC). For several decades, non-small cell lung cancer (NSCLC) has often been treated with chemotherapy drugs. However, lung cancer has high incidence and recurrence rates, mainly due to drug resistance and side effects during chemotherapy and radiotherapy. This is the hinder problem in the treatment of NSCLC, which highlight the necessity of developing new drugs or new treatments for NSCLC. Cisplatin is a chemotherapy drug that can treat about 50% of solid tumors, but the cisplatin-induced cytoprotective autophagy is the resistance to clinical treatment. It is urgent to elucidate the underlying molecular mechanisms regulating cisplatin resistance to improve its therapeutic value in lung cancer. Magnolol is a phenolic component isolated from the roots and bark of *Magnolia officinalis* and is used in traditional Chinese medicine. With a wide range of pharmacological activities, various studies have focused on the anti-cancer properties of magnolol in recent years. The effect of the drug is to keep cells in the G2/M phase, induce mitochondrial dysfunction and ROS production, affect the supply of cellular energy, and then lead to cell apoptosis. In this study, we investigated the ability of magnolol enhance cisplatin-induced cytotoxicity, showing dose dependence in NSCLC cell by MTT assay. We utilized the immunofluorescence staining and western blotting assay to confirm the downgrade expression of LC3B and the upregulate expression of p62 that define magnolol is able to suppress cisplatin-induced cytoprotective autophagy in NSCLC. We also detected the extrinsic/intrinsic apoptosis induction ability of magnolol combined with cisplatin in NSCLC. In the result, the cisplatin combined with magnolol have more significantly triggered the loss of mitochondrial membrane potential, and activate more protein cleaved caspase-3, -8 and -9 than monotherapy. We also used western blotting assay to confirm the expression of apoptosis inhibitory protein Bcl-2 and pro-apoptotic protein Bax to measure the degree of apoptosis. The migration and invasion effects of magnolol and cisplatin were identified by transwell invasion and wound healing on NSCLC. The magnolol combined with cisplatin extended the mouse survival rate and can inhibit tumor progression. These results suggest that combinational therapy of cisplatin and magnolol could be a promising treatment strategy for NSCLC. The potential regulation of magnolol on NSCLC is associated with triggering cisplatin-induced apoptosis and diminishing cisplatin-induce cytoprotective autophagy.

#7600 Synergy of ZEN3694 and VIP152 for dual transcriptional targeting of BET and CDK9 in patient derived organoid models of pancreatic cancer.

L. J. Koeppel[1], A. Stram[1], R. J. Millikin[2], E. Riedl[1], M. Hossan[1], E. Lin[1], R. Stewart[2], J. D. Kratz[1];
[1]UW Madison, Madison, WI, [2]Morgridge Institute, Madison, WI

Background: Pancreatic ductal adenocarcinoma (PDAC) remains a leading cause of cancer related mortality in the United States, largely due to ineffective systemic therapy. While novel KRAS target strategies are in development, few agents have been investigated to target the transcriptional machinery for global inhibition of expression. Recent small molecule inhibitors targeting transcription (i.e., CDK7) have shown preliminary evidence of disease control; however, combination therapies have lagged, likely due to uncertainty in clinical toxicity. Text mining analysis suggests combination BET and CDK9 inhibition may be promising against PDAC. Here, we present preclinical evidence of synergistic activity for the combination of bromodomain and extraterminal (BET) inhibitor (ZEN3694) and CDK9 inhibitor (VIP152) using patient derived cancer organoids (PCOs).
Methods: Dose response curves were generated for ZEN3694 and VIP152 to assess their single agent activity against PCOs using a low volume format. ZEN3694 was treated continuously while VIP152 was removed after 24h to mimic pharmacokinetics with assay endpoint at 144h. Synergy assays were designed using a combination dose titration grid. Viability was determined in all assays using 3D CellTiter Glo (CTG, 50% v/v). Synergy scores were produced using SynergyFinder 3.0 including Zero Interaction Potency (ZIP), Bliss Independence (Bliss), Highest Single Agent (HSA), and Loewe Additivity (Loewe). Western blot analysis was performed against global markers of active RNA polymerase II (phosphorylation at serine 2, 5, 7) and antiapoptotic protein, BCL xL, and MCL 1.
Results: ZEN3694 was observed to have a single agent IC_{50} in the single uM range across 3 independent PDAC PCO lines (PDAC1 3.7uM, PDAC2 1.1uM, PDAC3 2.9uM). VIP152 showed significant potency in the same 3 PDAC PCO lines (PDAC1 140.2nM, PDAC2 30.5nM, PDAC3 43.4nM). The combination of ZEN3694 and VIP152 was found to have increased therapeutic activity with double digit synergy scores across all reference models: PDAC1 (Loewe 17.3, HSA 19.8, ZIP 20.2, and Bliss 17.2) and PDAC2 (Loewe 34.7, HSA 28.3, ZIP 19.7, and Bliss 19.6). Western blots of protein collected from organoids treated for 48h showed on target activity, including decrease in the phosphorylation of Rbp1 (Ser 2, Ser 5, and Ser 7) compared to both control and single agents and decreased expression in antiapoptotic proteins (MCL 1 and BCL xL).
Conclusion: Here, we show the activity of dual transcription targeting with BET and CDK9 inhibition in patient derived pancreatic cancer organoid models. The combination of ZEN3694 and VIP152 has i*n vitro* synergy in PDAC PCO models with on target activity. Ongoing work is validating this combination in animal models to assess toxicity, *in vivo* activity, and RNA expression profiling to understand transcriptional pathway dependency and therapeutic resistance.

#7602 Discovery of GH1581, a potent and selective WRN inhibitor as a cancer therapy.

J. Li, G. Zhang, **J. Li**;
Suzhou Genhouse Bio Co., Ltd., Suzhou, China

Defects in DNA mismatch repair (MMR) proteins could induce damage of genome, resulting microsatellite instability (MSI). MSI is highly correlated with the occurrence of several types of cancers, mainly in colon, gastric, endometrial, and ovarian cancers. Despite advances in the treatment of MSI-high cancers, tumor evolution and drug resistance remain the leading causes of treatment failure and death in cancer patients. About 50% MSI cancers have no response to immune checkpoint inhibitors. There is still unmet needs to be fulfilled for MSI-high patients. WRN is a RecQ family helicase involves in genome stability maintenance, DNA repair, replication, transcription, and telomere maintenance. Recent studies have identified WRN as a synthetic lethal target of MSI-high cancers. Employing structure-based drug design strategy, we have discovered a potent and selective WRN inhibitor, GH1581. *In vitro*, GH1581 displayed specific < 10 nM potency in ADP-Glo assay and < 10 nM potency in cell proliferation assay using MSI cancer cell lines. *In vivo*, GH1581 demonstrated favorable pharmacokinetic properties in different species. In SW48 xenograft model, it inhibited the tumor growth with 100% TGI at QD dosing of 10 mg/kg without severe adverse effect on body weight. In summary, we discovered GH1581 as a novel inhibitor of WRN with high *in vitro* and *in vivo* efficacy.

#7603 Targeting MTAP-deleted tumor via synthetic lethality with a combination of a PRMT5i and an MAT2Ai.

G. Zhang, J. Li, **J. Li**;
Suzhou Genhouse Bio Co., Ltd., Suzhou, China

MTAP (methylthioadenosine phosphorylase) is located adjacent to the tumor-suppressor gene CDKN2A (cyclin-dependent kinase inhibitor 2A) and sometimes co-deleted in 10-15% of all cancers, especially in glioblastoma, mesothelioma, and pancreatic cancers. Recent studies shown that MTAP deletions in cancer create vulnerability to synthetic lethal with the MAT2A/PRMT5/RIOK1 axis. Herein, we report the discovery of a PRMT5 inhibitor GH56, and an MAT2A inhibitor GH31, both showed promising single agent efficacy and synergy in MTAP loss tumor models. GH56 is an MTA-Cooperative PRMT5 inhibitor. *In vitro*, GH56 showed potent SDMA inhibition in MTAP-deleted cancer cells with an IC_{50} from 0.8–3 nM. It also showed excellent selectivity with more than 100-folds in MTAP-WT cells. In a cell panel with more than 100 cell-lines, GH56 selectively inhibited the growth of cells with MTAP-deletion while separated the cells with MTAP-WT. In the safety panel and kinase panel, GH56 all showed good selectivity. In addition, GH56 had an IC_{50} > 10 μM for hERG. *In vivo*, GH56 showed dose-dependent efficacy in a series MTAP-deleted models and were well tolerated. In U87MG glioblastoma CDX model, NCI-H838 NSCLC CDX model, BXPC-3/HupT4 PDAC CDX models and RT112-84 BLCA model, TGI for GH56 at high dose were all >100%. On the other hand, GH31 is a potent and selective MAT2A inhibitor. GH31 also showed excellent selectivity with MTAP-deleted and MTAP-WT cell lines. The combination of GH56 and GH31 showed synergy both *in vitro* and *in vivo*. The low dose GH31 combination with low-dose GH56 achieved the similar efficacy as high dose GH56 and a more rapid tumor regression. In view of the delayed onset of the tumor response and high dose needed by PRMT5 inhibitor (reported by clinic stage compounds), the combination of PRMT5i and MAT2Ai will be advantageous. Furthermore, both GH56 and GH31 are brain penetrant, especially for GH31, with a K_{puu} > 0.6 and B/P > 2. The combination of GH56 and GH31 in a brain metastasis model and a glioblastoma *in situ* model all showed strong synergy, demonstrated the potential for the treatment of glioblastoma and other cancer with brain metastasis. In summary, we discovered potent, selective and brain penetrant PRMT5 inhibitor GH56 and MAT2A inhibitor GH31. Both compounds are currently under evaluation in IND-enabling studies and will provide more options for MTAP-deleted cancers.

CLINICAL RESEARCH: Predictive Biomarkers 7
Poster Session

#7607 Single-cell genomics study before and after neoadjuvant therapy for triple-negative breast cancer.
Y. Shao, K. Xu;
Zhejiang University School of Medicine, Hangzhou, China

Breast cancer has become the most common malignant tumor globally. Neoadjuvant chemotherapy (NAC) has become an important treatment option for locally advanced breast cancer, capable of eliminating circulating tumor cells (micrometastases) and achieving downstaging objectives. However, even after completing neoadjuvant chemotherapy or receiving local treatment, some patients may still have residual lesions, which are a key factor in distant recurrence and metastasis. The existing clinical biomarker tests such as CEA, CA-153, and imaging methods are unable to accurately assess the condition early on. Although tissue pathology biopsy of tumor specimens is the gold standard for clinical pathological diagnosis, it also has certain limitations. Traditional high-throughput sequencing technology for breast cancer primarily identifies "driver genes" associated with the occurrence and development of breast cancer. However, it has limitations in identifying genomic structural changes and subclones of breast cancer, and it overlooks the heterogeneity among tumor cells. The emergence of single-cell RNA sequencing (scRNA-seq) technology can detect these heterogeneous individuals, decode the heterogeneity of breast cancer cells, refine molecular subtypes, and open up new pathways to overcome drug resistance. We collected samples from 6 patients with locally advanced triple-negative breast cancer (ER-, PR-, HER2-negative, defined as HER2 immunohistochemistry 0, 1+ or 2+ but FISH-negative). We compared the cell subgroups and their gene expression in biopsy specimens before neoadjuvant chemotherapy with those in post-treatment specimens obtained during surgery, analyzing changes in cell composition in the tumor microenvironment before and after immunotherapy to identify specific cell types potentially contributing to the outcome of immunotherapy, particularly cell subtypes associated with T-cell clonal proliferation. We found that in the group with good neoadjuvant treatment response (Miller-Payne grade 4-5), B cells, CD4+ T cells, CD8+ T cells, and Tregs cells were all significantly downregulated, while endothelial cells and aSMA-positive fibroblast cells were significantly upregulated. By comparing changes in the immune microenvironment between patients with and without T-cell clonal proliferation before and after treatment, we revealed the differentiation patterns of various immune cells in immunotherapy and potential mechanisms of action.

#7608 Exploring the efficacy of atezolizumab plus bevacizumab for advanced hepatocellular carcinoma in relation to tumor-infiltrating lymphocytes.

H. Kanzaki[1], T. Ishino[1], S. Ogasawara[1], S. Yumita[1], M. Nakagawa[1], R. Kojima[1], K. Koroki[1], M. Inoue[1], K. Kobayashi[1], N. Kanogawa[1], S. Kiyono[1], M. Nakamura[1], T. Kondo[1], S. Nakamoto[1], T. Takayashiki[1], J. Lin[2], M. Kawazu[2], M. Komuta[3], J.-i. Ikeda[1], M. Ohtsuka[1], Y. Togashi[4], N. Kato[1];
[1]Graduate School of Medicine, Chiba University, Chiba, Japan, [2]Chiba Cancer Center Research Institute, Chiba, Japan, [3]International University of Health and Welfare, School of Medicine, Narita Hospital, Chiba, Japan, [4]Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan

Background and Aims: Bevacizumab, an anti-angiogenic agent, is reported to enhance antitumor immunity through various mechanisms, including the suppression of regulatory T (Treg) cells. Additionally, a combination therapy involving the anti-PD-L1 monoclonal antibody, atezolizumab, plus bevacizumab (AtezoBev) has emerged as a standard treatment for advanced hepatocellular carcinoma (aHCC). Given that more than half of treated patients do not respond effectively, identifying biomarkers predictive of clinical efficacy has become an urgent matter. However, the investigation into the tumor microenvironment (TME) has been lagging in aHCC compared to other malignancies due to the difficulty in obtaining tumor samples just before the commencement of systemic therapy.
Methods: We have established a scheme to analyze the TME by obtaining tumor samples immediately before AtezoBev administration, and explored the relevance to its efficacy, focusing on the tumor-infiltrating lymphocytes (TILs) within those samples. Tumor samples from 94 aHCC patients were collected before AtezoBev administration. TME was assessed in 54 patients via flow cytometry and in 72 patients through RNA sequencing, with certain samples undergoing both analyses.
Results: Predominant etiologies in 94 patients were HCV (n=22, 23%), followed by HBV (n=17, 18%), and alcohol abuse (n=16, 17%). The objective response (OR) and disease control rates were 17% and 81%, respectively, with a median progression-free survival (PFS) of 7.6 months. Groups exhibiting high PD-1 positivity of CD8+ T cells (median values as cutoffs) demonstrated superior AtezoBev treatment effects (PFS: 13.1 vs. 4.4 months, p=0.001). In contrast, PD-1 positivity of effector Treg (eTreg) cells in TILs, which reportedly can be one of resistant mechanisms to PD-1 blockade therapy (Togashi Y, et al. Nat Immunol 2020), was not correlated with efficacy. Gene set enrichment analysis highlighted the importance of antigen presentation for OR in groups exhibiting high PD-1 positivity of CD8+ T cells. Additionally, HLA class I expression was elevated in patients achieving an OR. Although previous studies suggest that immunotherapy efficacy could be reduced in non-alcoholic steatohepatitis-related HCC compared with viral-related HCC, no clear association was found between PD-1 positivity of CD8+ T cells or eTreg cells in TILs and etiology. Among the 94 patients, samples from 11 were analyzable at the point of AtezoBev refractoriness, revealing a trend toward reduction in PD-1 positivity of eTreg cells in TILs.
Conclusions: Our findings suggest a correlation between the efficacy of AtezoBev for aHCC and the presence of PD-1+CD8+ T cells within the tumor. In contrast, PD-1+ eTreg cells did not induce resistance along with a trend toward reduction after the treatment possibly due to combination with bevacizumab.

#7609 Potential gene expression meta-signatures predict neoadjuvant chemotherapy response in invasive breast cancer.

H. M. M. Guevara-Nieto[1], R. S. Parra-Medina[1], J. Zabaleta[2], L. Lopez-Kleine[3], A. L. Combita[1];

[1]Instituto Nacional de Cancerologia, Bogota, Colombia, [2]Louisiana State University Health Science Center, New Orleans, LA, [3]Universidad Nacional de Colombia, Bogota, Colombia

Early prediction of Neoadjuvant Chemotherapy (NAC) response is crucial for women with locally advanced breast cancer (BC), given their low response rates. This study aims to identify gene expression patterns and tumor microenvironment (TME) characteristics associated with resistance to NAC, which could significantly impact tumor progression and treatment outcomes. The study encompassed differential gene expression comparing non-responders and responders, enrichment analysis, tumor microenvironment estimation, and cytokines identification from a female patient's cohort with distinct molecular subtypes and candidates to NAC at the Colombian National Cancer Institute. Candidate differentially expressed genes validated with RT-PCR in a larger validation cohort and corroborated in several publicly available databases, including associated treatment drugs. Distinct gene expression profiles were observed between responders and non-responders, emphasizing immune system-related pathways such as IL-17 signaling, B cell receptor signaling, complement and coagulation cascades, natural killer cell-mediated cytotoxicity, and NF-kB signaling. Immune-related genes (AGTR1, APOD, CCL19, CGA, ECEL1, NPY1R, NTNG1, PCSK1, PFDN2, S100B, TPRG1, WDR5B, ZNF385B) were identified as biomarkers correlated with non-response and worse prognosis. Responders showed increased B cell populations, CD4+ and CD8+ effector memory T-cells in lymphoid groups, while non-responders displayed elevated levels of CD8+ naive T-cells. Additionally, responders revealed upregulated myeloid cell populations like macrophages and dendritic cells. Several cytokines like IL1B, IL-2, IL-4, IL-12, IL-21, IL-22, IL-36, and TWEAK showed elevated expression in non-responders. Dexamethasone, Vinblastine, and Streptozocin were candidate drugs that interacted with AGTR1, CGA, and S100B, respectively and are associated with progression and metastasis. Logistic regression revealed that overexpression of CGA showed a higher probability (OR:1.83, p=0.03) while ECEL1 had a lower probability (OR=0.44, p=0.04) in non-responders compared to responders who lacked expression of these genes. Immune-related genes and various subtypes of immune cells within the TME exhibit correlations with response to NAC, and several cell fractions significantly changed before and after NAC. These results suggest meta-signatures that warrant further evaluation as concordance assessment between immunohistochemistry (IHC) and gene expression profiling, in addition to an extensive validation to triage patients before NAC and target personalized interventions. Detection and evaluation of TME components are essential to predict NAC efficacy and avoid disease relapse. Finally, these findings emphasize the importance of assessing admixed populations to facilitate novel findings and alleviate disparities.

#7610 Predictive biomarkers for immuno-chemotherapy response in biliary tract malignancies.

Michele Zanoni[1], Tania Rossi[1], Martina Valgiusti[1], Giuliano La Barba[2], Michela Cortesi[1], Sara Bandini[1], Giulia Bartolini[1], Alessandra Dubini[3], Paolo Di Gioia[2], Chiara Gallio[1], Luca Esposito[1], Alessandra Virga[1], Giorgia Gurioli[1], Sara Bravaccini[1], Giovanni Martinelli[1], Paola Ulivi[1], Giovanni Luca Frassineti[1], Giorgio Ercolani[2], Ilario Giovanni Rapposelli[1]

[1]IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy,[2]Department of General and Oncologic Surgery, Morgagni-Pierantoni Hospital, Forli, Italy,[3]Department of Pathology, Morgagni-Pierantoni Hospital, Forli, Italy

Background: Biliary tract cancers (BTCs) refer to invasive malignancies of the biliary tree. Lack of specific symptoms in early-stages frequently leads to late-stage diagnosis, reducing therapeutic options. Surgical resection remains the only curative option for early-stage disease; instead, patients with advanced disease usually receive chemotherapy (cisplatin plus gemcitabine) in combination with durvalumab as first-line treatment and mFOLFOX-6 as second-line, but effects are limited and only a small proportion of patients respond to treatment. Recent advances in molecular characterization of BTCs allowed the identification of several alterations (e.g. IDH1/2 mutations, FGFR2 rearrangement) for which targeted agents are now available in second line setting but only for a small subset of patients. However, prognosis for patients with advanced stage disease remains poor. Treatment failure depends on several factors such as intra- and inter-tumor heterogeneity and the complex immunological landscape. Therefore, the identification of predictive biomarkers able to individuate patients that will benefit from immuno-chemotherapy will be crucial.

Methods: BTC patients at any stage were enrolled in two arms: A) BTCs undergoing surgery; B) advanced/relapsed BTCs. For this study, patients belonging to arm B were selected, in particular those who received first-line immuno-chemotherapy. Blood samples were collected before and after three months of therapy. Ascites samples were collected for patients with advanced disease who underwent paracentesis during therapy. DEPArray NxT (Menarini Silicon Biosystems) was used for phenotypic analysis and single ascites-derived cell isolation. The Ampli1 Lowpass kit was used for copy number aberration (CNA) profiling. Extracellular vesicles (EVs) were isolated from plasma at baseline and after three months of immuno-chemotherapy by size-exclusion chromatography and analyzed for size distribution and concentration using Nanosight NS300. Surface EV markers were analyzed by flow cytometry using the MACSPlex Exosome Kit human (MiltenyiBiotec).

Results: We enrolled 43 patients starting from August 2022: 14 in arm A and 29 in B. 23 patients from arm B received immuno-chemotherapy and 3 underwent paracentesis during therapy. Patient-derived organoids (PDOs) were successfully established from tumor cells recovered from ascites of these patients. Epithelial cells recovered from ascites displayed aberrant CNA profiles with gains in chromosomes 1q, 8q, 10, 12p, 20, and losses in 1q, 3q, 4, 8q, 9 and X. EV size distribution and concentration were similar before and after treatment as well as surface markers exposure. Further analyses in correlation with clinical features of patients will be performed.

Conclusions: Our approach will contribute to identify potential predictive factors associated with response/resistance to immuno-chemotherapy in BTCs.

#7611 Circulating blood RNAseq detects activation of immune system and predicts response to immunotherapy in bladder cancer.

C. Richard[1], S. Chevrier[1], A. Marabelle[2], **R. Boidot[1]**;
[1]Ctr. Georges-Francois Leclerc, Dijon, France, [2]Gustave Roussy Institute, Villejuif, France

Background: Anti-PD(L)1 immunotherapies have revolutionized oncology by getting durable tumor responses in advanced cancers. Nevertheless, currently approved biomarkers (PD-L1, MSI, TMB) have suboptimal positive/negative predictive values for tumor responses and survival.
Aims & Methods: We sought to assess the value of gene expression on circulating blood to predict responses to immunotherapy. We performed total paired-end RNAseq at 20-million reads and analyzed differential gene expressions according to cancer outcomes on baseline frozen whole blood from a cohort of 186 patients prospectively enrolled in the IOPREDI study, a French ancillary cohort of the international multi-center STRONG Phase III trial testing the anti-PD-L1 durvalumab in advanced bladder cancers (NCT03084471).
Results: One hundred and sixty four out of the 186 baseline samples generated valuable blood transcriptome data. Thanks to mathematical corrections, all samples were normalized, and the analysis was possible without introducing any bias despite the sample origin from 16 enrolling sites. We first observed that patients with a complete or partial response or a stable disease overexpressed 19 genes, 5 of which are markers of immune cell activation: *CXCL8*, *EOMES*, *GBP5*, *GZMA*, *and GZMH*. Conversely, patients with a progressive disease overexpressed 11 genes including *CD177*, a marker of neutrophil cells, recently associated to immunotherapy resistance. Next, patients with a PFS > 3 months showed an overexpression of 25 genes associated with immune cells activation such as *CD8A*, *CXCL8*, *EOMES*, *FASLG*, *GZM* genes, whereas patients with a shorter PFS highly expressed genes of immune cell inhibition: *CD177*, *CD300LG*, *CD99*, and *CST7*. Finally, patients with an OS > 7 months had also a higher expression of the same previous genes completed with 6 other genes, still indicators of immunity activation (*CD3D*, *CD3E*, *CD3G*, *GZMM*, *IL2RB*, *and PTGDS*).
Conclusion: Total RNAseq from RNA directly extracted from whole blood can detect baseline activation of T-cells in patients who will subsequently benefit from anti-PD-L1 immunotherapy. This work shows that RNAseq can detect an immune activation state in circulating blood without specific cell selection. This technique could be used in clinical trials to select for patients prone to benefit from cancer immunotherapies.

#7612 Genetic predictors of anti-PD(L)-1 therapy response in hepatocellular carcinoma.

S.-C. Chen, N.-J. Chiang, M. Chen, M.-H. Yang;
Taipei Veterans General Hospital, Taipei, Taiwan

Introduction: Immunotherapy targeting PD-1/PD-L1 shows promise in treating hepatocellular carcinoma (HCC), but standard predictors like PD-L1 expression are unreliable for gauging treatment response. RNA sequencing has identified a BMS 4-gene inflammatory signature that could more accurately forecast clinical outcomes. However, genomic alterations and tumor mutational burden (TMB) haven't consistently predicted anti-PD(L)-1 therapy response in HCC. Therefore, the aim of this research is to identify potential genetic alternation that could serve as predictive marker for anti-PD(L)-1 therapy responses in advanced HCC.
Methods: Formalin-fixed paraffin-embedded (FFPE) tumor tissues from 38 HCC patients were analyzed using targeted next-generation sequencing with the ACTOnco™ panel before anti-PD(L)-1 therapy. This analysis identified somatic variants across 440 genes and calculated TMB. In silico tools like NetMHC and IEDB predicted neo-peptide-HLA class I binding affinity. Additionally, peripheral blood mononuclear cells provided germline data for paired TMB calculations, with tumor responses assessed by RECIST criteria.
Results: Within a cohort of 167 patients with HCC undergoing ICI therapy, 35 (20.9%) responded to treatment, while 132 (79.1%) did not. Available formalin-fixed paraffin-embedded (FFPE) samples from this population included those from 14 responders and 30 non-responders. After conducting quality control measures, which assessed tumor purity, DNA quantity and integrity, as well as sequencing quality, 13 samples from responders and 25 from non-responders qualified for further analysis. Gene alteration analysis identified mutations in TP53 (47%), MUC16 (34%), CTNNB1 (32%), USH2A (16%), ARID1A (13%), NOTCH3 (13%), and ADAMTS16 (11%) of the cases. A TP53 mutation was linked to poor overall survival, whereas mutations in CTNNB1 and the RTK/RAS/RAF pathway did not correlate with clinical outcomes.
The median TMB, predicted at 3.2 ± 4.3 mutations per megabase (muts/Mb), was nominally higher in patients who achieved disease control compared to non-responders (4.6 vs. 3.7 muts/Mb, p=0.53). Utilizing paired TMB analysis, those with disease control exhibited a higher TMB trend than non-responders (6.0 vs. 2.2 muts/Mb, p=0.06). Notably, the 13 cases with MUC16 mutations were associated with a significantly higher predicted TMB (10.0 vs. 3.3 muts/Mb, p=0.0015).
Conclusions: This study suggests that certain genetic alterations, especially TP53 mutations, may have predictive value for the response to anti-PD(L)-1 therapy in HCC. Moreover, an elevated TMB, particularly when associated with MUC16 mutations, seems to be correlated with improved disease control.

#7613 Association of KAT6A expression with clinical outcomes in previously treated HR-positive and HER2-negative metastatic breast cancer.

M. Cristofanilli[1], L. Liu[2], S. Deng[2], X. Huang[2], F. Andre[3], S. Loibl[4], A. DeMichele[5], E. Gauthier[6], Y. Liu[2], N. C. Turner[7];
[1]Weill Cornell Medicine, New York, NY, [2]Pfizer Inc., San Diego, CA, [3]Institut Gustave Roussy INSERM and Universite Paris Saclay, Villejuif, France, [4]German Breast Group, Neu-Isenburg, Germany, [5]University of Pennsylvania, Philadelphia, PA, [6]Pfizer Inc., San Francisco, CA, [7]Royal Marsden Hospital and Institute of Cancer Research, London, United Kingdom

Background: KAT6A is a histone acetyltransferase that regulates gene transcription, cell cycle, senescence and cell differentiation. It is amplified and overexpressed in a subset of breast cancers and may positively regulate ER expression. Gene expression analysis in tumor samples from the PALOMA-3 study was conducted to explore potential associations of KAT6A and related biomarkers with enhanced benefit from the addition of palbociclib (PAL) to fulvestrant (FUL) in HR-positive, HER2-negative breast cancer. **Methods:** The PALOMA-3 trial randomly assigned 521 endocrine pretreated patients with metastatic breast cancer, including those with prior exposure to chemotherapy, to receive PAL+FUL or placebo (PBO) +FUL. Exploratory analysis was conducted on tumor gene expression levels of KAT6A and KAT6B to evaluate their association with the effect of PAL+FUL vs PBO+FUL on progression-free survival (PFS) using Cox proportional hazards regression analysis, with gene expression as a continuous variable or dichotomized by median. Treatment by biomarker interaction effect was also tested. **Results:** In the PALOMA-3 trial, the analyses were conducted in 214 patients (PAL+FUL, 137 patients; PBO+FUL, 77 patients) with baseline tissue profiled, which included 165 patients with prior chemotherapy (PAL+FUL, 101 patients; PBO+FUL, 64 patients). In patients with KAT6A data, a trend of better treatment effect (interaction p = 0.54) was observed in those with low KAT6A mRNA expression (median PFS on PAL+FUL was 11.04 months (m) and PBO+FUL was 3.65 m, HR = 0.52, 95% CI 0.32-0.85, log rank p = 0.008) versus high KAT6A expression (median PFS on PAL+FUL was 13.90 m and PBO+FUL was 11.20 m, HR = 0.66, 95% CI 0.39-1.13, p = 0.126). A treatment effect was observed in patients with prior exposure to chemotherapy who had low KAT6A expression (median PFS on PAL+FUL was 9.53 m and PBO+FUL was 3.66 m, HR = 0.55, 95% CI 0.33-0.94, p = 0.027), while this was not observed in those with high KAT6A expression (median PFS on PAL+FUL was 11.43 m and PBO+FUL was 11.33 m, HR = 1.13, 95% CI 0.61-2.09, p = 0.71), with the interaction p value of 0.12. No treatment difference was detected between treatment arms and expression levels of KAT6B (interaction p values of 0.48 and 0.36 in all patients and in those with prior chemo respectively). Potential interaction of KAT6A with other genes including ESR1 will be discussed. **Conclusions:** Low tumor KAT6A mRNA expression identified patients with relatively greater benefit from addition of PAL to FUL especially in those with prior exposure to both chemo- and endocrine therapies. The data support further investigation of KAT6A and its related biomarkers and their association with CDK4/6 inhibitors and/or endocrine therapy in HR+/HER2-breast cancer patients and to test if a KAT6 inhibitor can enhance CDK4/6 inhibitor and/or endocrine therapy efficacy in tumors with high KAT6A expression.

#7614 Mutations in *MEN1/DAXX/ATRX* are associated with improved progression-free survival in patients with gastroenteropancreatic neuroendocrine tumors receiving peptide receptor radionuclide therapy.

R. Gujarathi, S. Abou Azar, J. Tobias, X. Keutgen, C.-Y. Liao;
University of Chicago, Chicago, IL

Background: Peptide Receptor Radionuclide Therapy (PRRT) using ^{177}Lu-DOTATATE is an effective treatment for metastatic Gastroenteropancreatic Neuroendocrine Tumors (GEP-NETs). However, it remains unknown why some patients (pts) respond more favorably than others. Pre-clinical data suggests that mutations in the *MEN1*, *DAXX*, and/or *ATRX* genes influence DNA repair capabilities and increase radiation effect in cancer cells. We therefore thought to evaluate the association between response to PRRT and the presence of *MEN1*, *DAXX*, and/or *ATRX* mutations in patients with GEP-NETs.
Methods: We retrospectively analyzed CLIA certified tissue-based Next Generation Sequencing (NGS) assay results and clinicopathological data from 28 pts with GEP-NETs treated with PRRT at our center from 2017 to 2023. Genetic findings were correlated with progression-free survival (PFS) using Kaplan-Meier estimators and Cox proportional hazards regression modeling. Objective response was assessed per RECIST v1.1 by investigator review.
Results: Pts with mutations in *MEN1*, *DAXX*, or *ATRX* (n = 13, 46.42%) had a longer PFS [mPFS, 26.47 months (95% CI, 17.97 - NA) vs. 12.13 months (95% CI, 9.17 - NA); HR, 0.19; 95% CI, 0.06 - 0.68; p = 0.01] than wildtype (n = 15, 53.58%) pts, when adjusted for surgery prior to PRRT and tumor grade. Pts with mutations in *MEN1* along with a concurrent mutation in either *DAXX* or *ATRX* (n = 6) trended towards better PFS compared to patients without concurrent mutations [only $MEN1^{mt}$ or $DAXX^{mt}$/$ATRX^{mt}$, but not both; mPFS, 31.53 months (95% CI, 28.43 - NA) vs. 17.97 months (95% CI, 11.17 - NA); HR, 0.25; 95% CI, 0.05 - 1.29; p = 0.09]. Among evaluable pts, objective response rate was higher in pts with a mt in *MEN1*, *DAXX*, or *ATRX* compared to wild-type pts (41.67% vs. 15.38%; p = 0.09). In the pancreatic NET (PNET) subset, mutations in either *MEN1*, *DAXX*, or *ATRX* were found in 11/16 pts (68.75%) and were also associated with a better PFS compared to wild type patients [mPFS, 28.43 months (95% CI, 11.50 - NA) vs. 9.83 months (95% CI, 7.83 - NA); HR, 0.21; 95% CI, 0.05 - 0.95; p = 0.04).
Conclusions: Mutations in *MEN1*/*DAXX*/*ATRX* correlate with improved PFS in patients with GEP-NETs receiving PRRT. Concurrent mutations in *MEN1* and *DAXX*/*ATRX* may have additive effects on response to PRRT. If validated in larger studies, these findings may represent a novel biomarker to predict PRRT response.
Limitations: Limited sample size precludes generalization of results and might overestimate effect sizes.

#7615 Epithelial-mesenchymal-transition gene signature changes and poor oncological outcome in *Candida*-positive pancreatic ductal adenocarcinoma.

P. Ear[1], M. Hu[2], J. S. Shilyansky[1], N. H. Fei[1], S. Coleman[2], R. Hoyd[3], C. E. Wheeler[3], K. L. Steckly[1], M. L. Churchman[4], N. Denko[5], R. D. Dodd[1], S. Hardikar[2], N. Jin[3], Q. Ma[6], M. D. McCarter[7], A. Naqash[8], A. E. G. Osman[9], G. Riedlinger[10], L. A. Robinson[11], B. P. Schneider[12], E. A. Singer[3], A. A. Tarhini[11], G. Tinoco[3], C. M. Ulrich[2], Y. Zakharia[1], D. Spakowicz[3], A. Tan[2], **C. H. F. Chan**[1];

[1]University of Iowa Hospitals and Clinics, Iowa City, IA, [2]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, [3]The Ohio State University Comprehensive Cancer Center, Columbus, OH, [4]Aster Insights, Tampa, FL, [5]The Ohio State University Comprehensive Cancer Center, Columbus, UT, [6]The Ohio State University, Columbus, OH, [7]University of Colorado School of Medicine, Aurora, CO, [8]Stephenson Cancer Center of University of Oklahoma, Oklahoma City, OK, [9]University of Utah, Salt Lake City, UT, [10]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, [11]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [12]Indiana University Simon Comprehensive Cancer Center, Indianapolis, IN

Candida are commonly found in bile collected during surgery in pancreatic ductal adenocarcinoma (PDAC) patients. However, their significance in tumor biology and oncological outcome is unclear. PDAC patients receiving neoadjuvant therapy and pancreatectomy with intraoperative bile fungal culture were identified (N=40) in a prospective single-institution cohort. Tumor regression scores (TRS) were abstracted from pathology reports and correlated with bile fungal cultures. Bulk tumor RNASeq data were obtained from the Oncology Research Information Exchange Network (ORIEN). Tumor microbiome data of non-metastatic PDAC patients with upfront surgery were extracted using the {exotic} tool (Hoyd et al. *Cancer Res. Commun.*, 2023). Gene expression profiles were compared between *Candida*+ and *Candida*- tumors, defined by a cutoff microbial count of 0. Overall survival (OS) of resected PDAC patients with *Candida*+ and *Candida*- tumors was compared using Kaplan Meier survival analysis. From the single-institution PDAC cohort, *Candida*+ bile was associated with poor pathological response to neoadjuvant therapy (Table 1). Using the ORIEN cohort, *Candida* were detected in 67% (106/158) of the PDAC tumors. Patients with *Candida*+ tumors had worse OS (median 28 vs. 56 months, Log-Rank p<0.008). Gene Set Enrichment Analysis (GSEA) using Hallmark gene sets showed an enrichment of epithelial-mesenchymal-transition (EMT) gene set and a reduction of metabolic and DNA repair gene sets in *Candida*+ tumors. GSEA for Immune signature and Tumor Immune Microenvironment Deconvolution (TIMEx) cell types showed an enrichment of Stromal-Fibroblast and EMT signature in *Candida*+ tumors. Further investigations are underway to determine the causal and metabolic relationship between *Candida* and this tumor microenvironment with EMT and stromal fibroblasts which is a well-known contributor to poor chemotherapy response and oncological outcome of PDAC.

Table 1: Pathological Response to Neoadjuvant Therapy for PDAC

Bile Culture	**TRS0/1**	**TRS2**	**TRS3**
***Candida* -**	5 (25%)	15 (75%)	0 (0%)
***Candida* +**	1 (5%)	11 (55%)	8 (40%)

TRS: Tumor Regression Score (TRS0: complete response; TRS1: near-complete response; TRS2: partial response; TRS3: no response). Chi-Square Test, P=0.0035.

#7617 Quantitative continuous scoring of PD-L1 for superior patient selection for anti-PD-L1 treatment of locally advanced or unresectable NSCLC.

J. Lesniak[1], I. Bisha[1], S. Christ[1], L. Meinecke[1], T. Padel[1], L. Sebastian Monasor[1], P. Sontakke[1], T. Tan[1], D. Medrikova[1], A. Storti[1], A. Shumilov[1], H. Sade[1], G. Schmidt[1], R. Stewart[2], Y. Shrestha[3];

[1]AstraZeneca, Munich, Germany, [2]AstraZeneca, Cambridge, United Kingdom, [3]AstraZeneca, Gaithersburg, MD

Background: Immune checkpoint inhibitors (ICIs) targeting PD-(L)1 following concurrent chemoradiotherapy (cCRT) have shown clinical activity in locally advanced, unresectable NSCLC, e.g. with the PACIFIC regimen [1]. PD-L1 expression is typically assessed by pathologist scoring of immunohistochemically (IHC) stained tissue using the tumor cell (TC) score. In this work, we present PD-L1 Quantitative Continuous Scoring (PD-L1 QCS) to digitally assess PD-L1 expression (Ventana SP263 assay), and analyze its utility for identification of patient subgroups with higher likelihood of treatment response.

Method: 368 digitized whole slide images (WSI) of fresh biopsy and archival samples were obtained from the PACIFIC trial (NCT02125461), including 126 patients who received placebo and 242 patients who received Durvalumab post-cCRT [1]. WSI analysis included two deep learning models for epithelial TC segmentation followed by optical density (OD) quantification of membrane expression [2]. Initially, PD-L1 QCS was calibrated to compute the TC score at 1% cutoff by determining an optimal OD cell positivity threshold. Next, other scoring approaches were investigated, which included various OD thresholds and biomarker cutoffs.

Results: PD-L1 QCS-based TC scoring was able to maintain median overall survival (mOS) of 57.4 months in the biomarker positive (BM+) ICI cohort, while increasing prevalence to 191 out of 242 patients (78.9%) compared to 177 (73.1%) with manual TC score at 1% cutoff. Extending the scoring paradigm to the PD-L1+ TC density >= 542.5 cells/mm² lead to a more pronounced increase of prevalence to 200 patients (82.6%) in the ICI population, while mOS was not reached and additionally showed comparable hazard ratios (HR) when evaluating against the BM+ placebo cohort (HR=0.54 [0.39, 0.76] resp. HR=0.52 [0.37, 0.74]). Results further demonstrated that PD-L1 QCS density scoring of the ICI treated population allowed for a clearer separation of patients with less treatment benefit (34.2m mOS, N=42, log rank p=0.0067) compared to manual scoring (47.4m mOS, N=65, log rank p=0.2).

Conclusion: We investigated a computational pathology approach for selecting patients for treatment with the PACIFIC regimen and compared it against established manual pathology scoring. Results indicate that PD-L1 QCS TC proportion scoring can increase prevalence, while PD-L1 QCS TC density scoring has the potential to identify an even larger patient subgroup with increased survival benefit.

#7618 Genomic pathogenic alterations of the SWI/SNF complex genes compromise the outcomes to immunotherapy in Chinese *KRAS*-mutant non-small cell lung cancer by downregulated STING.

L. Gao, J. Jiang, Z. Xie, L. Zhu, Y. Chen, Z. Lv, Y. Chen, W. Zhou, J. Chen, Y. Zhong, L. Zhang, P. Zeng, X. Huang, W. Yan, D. Lu, S. Zhang, W. Guo, **X. Zhang**;

Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Guangzhou, China

Background: Immune checkpoint inhibitors (ICIs) have been standard of care in non-small cell lung cancer (NSCLC), but lack of response to ICIs remains a major hurdle in cancer immunotherapy. Switch/sucrose nonfermentable (SWI/SNF) chromatin-remodeling complex mutations have been reported in *KRAS*-mutant cancers with debated influence to clinical outcome of ICIs, which needs further investigation.

Methods: According to the OncoKB, COSMIC, and PolyPhen-2 databases, genomic pathogenic alterations (GPAs) of SWI/SNF are defined. Lung tumors were classified according to the presence or absence of mutations in six SWI/SNF genes (*ARID1A*, *ARID1B*, *ARID2*, *PBRM1*, *SMARCA4*, and *SMARCB1*). Lung cancer cell lines with different genotypes of SWI/SNF were used for differentially expressed genes analysis by RNA sequencing. Protein expression of STING was detected by immunohistochemistry (IHC) in tumor specimens.

Results: Out of 2660 NSCLC patients (NSCLCs), the GPAs of SWI/SNF were detected in 15.0% (401/2660) patients. 23.1% (69/299) $EGFR^{wt}ALK^{wt}$ and 27.8% (25/90) $STK11^{wt}KEAP1^{wt}KRAS^{mut}$ NSCLCs who received ICIs had SWI/SNF GPAs. Progression-free survival (mPFS) of SWI/SNF-wild type (wt) compared to SWI/SNF-mutant (mut) NSCLCs was not significantly different. However, GPAs of SWI/SNF in *KRAS*-mut ICI-treated NSCLCs associated with poorer clinical outcome. Patients with *ARID1A*, *ARID1B*, *ARID2* or *PBRM1* mutant tumors had a significantly shorter PFS (2.7 vs 6.5 months, HR=2.44 [95%CI: 1.31-4.54], *P*=0.004) as compared to SWI/SNF-wt patients. In $STK11^{wt}KEAP1^{wt}KRAS^{mut}$ NSCLCs, all SWI/SNF mutations (4.9 vs 9.1 months, HR=2.03 [95%CI: 1.07-3.86], *P*=0.029) or *ARID1A/ARID1B/ARID2/PBRM1* alterations (3.2 vs 9.1 months, HR=2.68 [95%CI: 1.33-5.41], *P*=0.004) significantly shortened the mPFS. In cell lines, SWI/SNF-mut cells had downregulated STING expression compared to SWI/SNF-wt cells. Downregulated STING protein were observed in *KRAS*-mut NSCLCs without benefit from the treatment of ICIs.

Conclusions: In *KRAS*-mut NSCLCs with or without *STK11/KEAP1* mutations, the presence of GPAs of DNA binding genes *ARID1A*/*ARID1B*/*ARID2* could compromise the clinical outcome of immunotherapy, which might be due to the downregulated STING.

#7619 Tissue-derived peripheral biomarkers that reflect activity of T-cells, macrophages, and neutrophils in patients with solid tumors.

N. Willumsen, N. I. Nissen, M. A. Karsdal;
Nordic Bioscience, Herlev, Denmark

Background: A toolbox of tissue-derived peripheral biomarkers that reflect the activity of T-cells, macrophages and neutrophils is a medical need for immuno-oncology drug development allowing non-invasive quantification of immune cell activity before - and during - treatment, both for predictive and pharmacodynamic purposes. By identifying and quantifying specific extracellular matrix fragments with neo-epitopes that are generated by proteases specific for T-cells, macrophages, and neutrophils, respectively, it is possible to develop peripheral biomarkers that reflect the activity of these immune cells. Such biomarkers have previously shown associations with outcome of patients treated with immune checkpoint inhibitors. Here we investigated the distribution of 3 such biomarkers in different cancer indications. Moreover, these data were compared to data from melanoma patients showing associations with response to cancer immunotherapy.

Methods: Tissue-derived biomarkers related to activity of T-cells (C4G: Collagen-4 degraded by Granzyme B), Neutrophils (CPA9-HNE: Calprotectin degraded by neutrophil elastase), Macrophages (VICM: citrullinated and MMP-degraded vimentin) were measured by validated ELISA/ECLIA in serum from patients with various solid tumor types (bladder-, breast- colorectal-, head and neck-, kidney-, lung-, ovarian-, pancreatic, stomach-, prostate- cancer, and melanoma, n=220) and compared to age-matched healthy controls (n=33) by ANOVA. The biomarker levels were compared to historical data.

Results: Median biomarker levels of CPA9HNE (neutrophil activity/NETosis) and VICM (macrophage activity) were significantly increased in all solid tumor types ($p<0.001$), respectively and with a ~5-fold inter-patient variation as well. Median C4G levels was only slightly elevated in a few indications ($p<0.05$) and with a 5-10-fold inter-patient variation across tumor types. All biomarker levels were independent of disease stage. Similar biomarkers levels were seen to those found to be associated with objective response rate and overall survival of melanoma patients treated with cancer immunotherapy.

Conclusion: Tissue-derived peripheral biomarkers that reflect the activity of T-cells (C4G), macrophages (VICM) and neutrophils (CPA9HNE) has biomarker potential in solid tumors and may serve as prognostic, predictive and pharmacodynamic biomarkers in clinical trials investigating cancer immunotherapy.

#7620 Immuno-transcriptomic profiling of blood and tumor tissue identifies gene signatures associated with immunotherapy response in metastatic bladder cancer.

P. J. Romero[1], E. Desponds[2], D. Croci[1], V. Wosika[3], N. Hadadi[1], S. Fonseca Cost[1], L. Ciarloni[1], M. Ongaro[1], H. Zdimerova[2], M. M. Leblond[2], S. Hosseinian-Ehrensberger[1], G. Verdeil[2];

[1]Novigenix, Epalinges, Switzerland, [2]University of Lausanne, Epalinges, Switzerland, [3]Lunaphore Technologies, Tolochenaz, Switzerland

Muscle-invasive bladder cancer (MIBC) accounts for 25% of bladder cancer cases. Despite the broader usage of immune checkpoint blockade targeting the PD-1/PD-L1 axis, the response rate and survival of patients remain low for this disease. Redirecting swiftly these patients toward alternative therapeutic strategies upon immunotherapy failure should be a priority. So far, no marker allows to precisely determine early outcome to the treatment.Blood-based biomarkers represent ideal candidates for the development of non-invasive immuno-oncology-based assays. However, to date, no blood biomarker has been validated to predict clinical response to immunotherapy. In this study, we used next generation sequencing (RNAseq) on bulk RNA extracted from whole blood and tumor samples in a pre-clinical MIBC mouse model. We aimed at identifying biomarkers associated with immunotherapy response and to assess the potential application of simple non-invasive blood biomarkers as therapeutic decision-making assay compared to tissue-based biomarkers. We established that circulating immune cells and the tumor microenvironment (TME) display highly organ-specific transcriptional responses to ICI. Interestingly, a common lymphocytic activation signature can be identified in both compartments associated with the efficient response to immunotherapy, including a blood specific CD8+ T cell activation/proliferation signature which predicts immunotherapy response.

#7621 Serum albumin and derived neutrophil-to-lymphocyte ratio are potential predictive biomarkers for immune checkpoint inhibitors in small cell lung cancer.

Z. Kuang, J. Miao, **X. Zhang**;
The Ohio State University Wexner Medical Ctr., Columbus, OH

Background: Immune checkpoint inhibitors (ICIs) have reshaped the treatment landscape of small cell lung cancer (SCLC), but only a minority of patients benefit from this therapy. Therefore, it is critical to identify potential risk factors that could predict the efficacy of ICI treatment in SCLC patients and identify patient subgroups who may benefit the most from ICI therapy.
Methods: Our study included a total of 183 SCLC patients who had received at least one dose of ICI treatment. We utilized both logistic regression and Cox proportional hazard regression to evaluate whether various patient clinical factors and serum biomarkers, could serve as predictors of patient response to treatment and overall survival (OS) during ICI therapy.
Results: Logistic regression showed that patients with a history of surgery (p=0.003, OR 9.06, 95% CI: (2.17, 37.9)) and no metastasis (p=0.008, OR 7.82, 95% CI: (1.73, 35.4)) exhibited a higher odds of response to ICI treatment. Cox regression analyses demonstrated that pretreatment blood albumin (p=0.003, HR 1.72, 95% CI: (1.21, 2.45)) and derived neutrophil to lymphocyte ratio (dNLR) (p=0.003, HR 1.71, 95% CI: (1.20-2.44)) were independent predictors for OS in SCLC patients. By establishing a pre-treatment prognostic scoring system based on baseline albumin and dNLR, we found that patients with high albumin and low dNLR exhibited a significantly better prognosis than those with low albumin and high dNLR in both the full (P<.0001, HR 0.33, 95% CI: 0.20-0.55) and the metastatic cohort (P<.0001, HR 0.28, 95% CI: 0.15-0.51). The better prognostic group also had younger age, higher BMI and lower systemic inflammatory biomarker values than the unfavorable group (P<.0001).
Conclusion: Our data reveals the significant role of metastasis status and treatment history in predicting the initial response of SCLC patients to ICI treatment. However, baseline serum albumin and dNLR provide a more precise prognostic prediction for patient OS. The scoring system based on albumin and dNLR enhances the ability to stratify patient prognosis and holds the potential to guide clinical decision-making for SCLC patients undergoing ICI therapy.

#7622 ASPYRE-Lung: Validation of a simple, fast, robust and novel method for multi-variant genomic analysis of actionable NSCLC variants in tissue.

R. T. Evans[1], E. Gillon-Zhang[1], J. Brown[1], K. Knudsen[1], C. King[1], A. S. Green[1], A.-L. Silva[2], J. M. Mordaka[2], R. N. Palmer[2], A. Tomassini[2], A. Collazos[2], C. Xyrafaki[2], I. Turner[2], C. Ho[2], D. Nugent[2], J. Jose[2], S. Andreazza[2], K. von Bargen[2], E. R. Gray[2], M. Stolarek-Januszkiewicz[2], A. Cooke[2], **W. J. Levin**[1], H. V. Reddi[1], B. W. Balmforth[2], R. J. Osborne[1];

[1]Biofidelity, Morrisville, NC, [2]Biofidelity, Cambridge, United Kingdom

Genomic variant testing of tumors is critical for patients to access the full potential of personalized oncology therapeutics. Current methods such as NGS are costly and challenging to interpret, while PCR assays are limited in the number of variants they can cover. We developed ASPYRE® (Allele-Specific PYrophosphorolysis REaction) technology to address the urgent need for rapid, accessible and affordable diagnostics informing actionable genomic target variants of a given cancer. The targeted ASPYRE-Lung® panel for NSCLC covers 114 variants in 11 genes (*ALK, BRAF, EGFR, ERBB2, KRAS, RET, ROS1, MET & NTRK1/2/3*) to robustly inform clinical management, based on practice guidelines. The assay detects single nucleotide variants, insertions, deletions, and gene fusions from tissue-derived DNA and RNA simultaneously. We tested the limit of detection, specificity, analytical accuracy and analytical precision of ASPYRE-Lung using FFPE lung tissue samples from patients with NSCLC, variant-negative FFPE tissue from tonsil tissue, and FFPE-based contrived samples with controllable variant allele fractions. The sensitivity of ASPYRE-Lung was determined to be ≤ 3% variant allele fraction for single nucleotide variants and insertions or deletions, ≤ 100 copies for fusions, and ≤ 200 copies for MET exon 14 skipping. The specificity was 100% with no false positive results. The analytical accuracy test yielded no discordant variants between ASPYRE-Lung and orthogonal testing (targeted enrichment NGS) or contrived samples, and results were replicable across operators, reagent lots, runs, and real-time PCR instruments with a high degree of precision. The technology is simple and fast, requiring only four reagent transfer steps using standard laboratory equipment (PCR and qPCR instruments) with analysis via a cloud-based analysis algorithm. ASPYRE-Lung has the potential to be transformative in facilitating access to rapid, actionable molecular profiling of tissue for patients with NSCLC.

#7623 Biomarker study to personalized neoadjuvant chemotherapy using preoperative gastric cancer specimens of biopsy from the COMPASS trial, a phase II randmazed controlled trial.

T. Oshima;
Kanagawa Cancer Ctr., Yokohama, Japan

Background and Aim: The results of COMPASS, a randomized phase II trial, suggest that preoperative adjuvant chemotherapy (NAC) regimen or course for locally advanced gastric cancer (GC) does not affect overall survival (OS). However, we hypothesized that some NAC regimens may be more effective for OS on a case-by-case basis. Furthermore, we searched for biomarkers, assuming that further improvement in the outcome of locally advanced GC could be expected if appropriate NAC regimens could be selected using biomarkers before treatment initiation.
Materials and Methods: RNA was extracted from endoscopic biopsy specimens of primary tumors collected prior to NAC administration in COMPASS patients, and real-time polymerase chain reaction (PCR) of 127 genes was performed to identify genes with significant ($P < 0.05$) interaction P values for survival with each regimen and stratified OS with each regimen. Genes were identified and biomarkers were searched at the protein level using immunohistochemical analysis.
Results: The THBS1, MSI1, and IGF2BP3 genes were identified as genes whose expression levels significantly ($P < 0.05$) stratified survival for each regimen and had significant ($P < 0.05$) interaction P values. Furthermore, a strong correlation was observed between each gene and THBS1, MSI1, and IGF2BP protein expression by immunohistochemical analysis, confirming that protein expression levels by immunohistochemical analysis are also useful as biomarkers.
Conclusion: Using endoscopic biopsy specimens prior to NAC for locally advanced GC, biomarkers were identified to select NAC regimens over predicted OS. The results of this study may guide the conduct of clinical trials of individualized treatment of NAC using biomarkers.

#7624 DNA checkpoint gene mutation as a biomarker of immune checkpoint inhibitor in advanced biliary tract cancer.

Ji Eun Shin[1], Seung Tae Kim[2], Dae-Ho Choi[2], Junho Lee[2], Jiyeon Hyeon[2]

[1]St. Vincents Hospital The Catholic University of Korea, Suwon, Korea, Republic of,[2]Samsung Medical Center, Seoul, Korea, Republic of

Introduction: The DNA checkpoint (DNACHK) pathway is engaged in signaling the need for cell cycle arrest. The G1 and S phase checkpoint allows for repair of damaged DNA, preventing damaged DNA from being copied. The G2 and M phase checkpoint prevents transmission of mutated DNA to the next generation. This pathway, along with mismatch repair (MMR), homologous recombination (HR), and base excision repair (BER), is being actively researched to assess its role in cancer immunotherapy.

Methods: Sixty-two patients participated in this study. These patients were treated with immune checkpoint inhibitors (ICIs) for advanced biliary tract cancers (BTCs) from Mar. 2020 to Aug. 2022 at Samsung Medical Center. DNACHK mutations were defined as genomic alterations such as SNVs, MNVs, and short insertion and deletions in seven genes These genes include checkpoint kinase 1 (CHEK1), checkpoint kinase 2 (CHEK2), BRCA1, DNA repair associated (BRCA1), the serine/threonine kinase ATM, the serine/threonine kinase ATR, and mediator of DNA damage checkpoint 1 (MDC1). We analyzed the effect of DNACHK mutations on the efficacy of ICIs in advanced BTCs.

Results: Patient median age at diagnosis was 68.0 years. Ten patients (16.1%) had gall bladder (GB) cancer; the remaining patients (n = 52, 83.9%) were diagnosed with cholangiocarcinoma. Among the 62 patients with advanced BTCs treated with ICIs, 37 (59.7%) were categorized into the DNACHK wild-type (WT) group and 25 (40.3%) into the DNACHK mutated (MT) group. The most observed DNA checkpoint mutations were ATM mutations (n=14). MDC1 mutations were found in seven patients, ATR mutations in three, BRCA1 mutations in four, and CHEK2 mutations in three. Patients in the DNACHK MT group had better disease control rates than patients in the DNACHK WT group (60.0% vs. 48.6%, p=0.53). Median overall survival (OS) was 8.1 months (95% CI, 5.1, 22.8) in the MT group and 5.6 months (95% CI, 3.1, 11.0) in the WT group (p=0.33).

Conclusions: The results of this study suggest that the DNACHK pathway may be a valuable source of biomarkers for ICI and worthy of further study.

#7625 The liquid biomarker thymidine kinase activity reflecting proliferation rate can provide guidance in drug development and address Project Optimus.

M. Bergqvist, H. Ritzen, A. Williams;
Biovica International, Uppsala, Sweden

Thymidine Kinase (TK) plays a basic role in DNA synthesis and cell proliferation. The enzyme is highly cell cycle dependent and correlates with cell growth state. Numerous studies have consistently shown elevated TK activity (TKa) in the blood of patients with solid tumors and active disease. DiviTum® TKa, a clinically and analytically validated FDA cleared assay, measures and quantifies TKa in serum or plasma in humans and animals. TKa as a biomarker offers valuable information at all stages of drug development, from drug efficacy and dose response studies in cell culture and xenograft models, to patient selection and treatment monitoring in clinical trials. The launch of FDA Project Optimus highlights the need for new biomarkers to assist in drug development to identify optimal dose. Using TKa to measure the impact on cell proliferation as a drug evaluation endpoint can confirm mechanism of action efficacy and a minimally effective dose of a new compound rather than a maximally tolerated dose. TKa can be used as a pharmacodynamic tool to improve study endpoints. TKa data in cultured cells and mouse xenografts demonstrates that a complete shutdown of tumor cell proliferation can be observed well before and at much lower drug-doses than when cell death or toxicity is used as the dose determination endpoint. Increased dosing of CDK4/6 inhibitors demonstrates immediate impact on TKa levels in cell lines and provides signals of drug effect at doses where cell viability is unaffected. After initiation of samuraciclib treatment, a CDK7 inhibitor, a significant reduction in TKa levels in blood from metastatic breast cancer (MBC) patients was observed, indicating inhibition of cell cycle progression. For patients on samuraciclib therapy and with stable disease before progression, TKa levels were significantly lower than pre-treatment ($p=0.0038$). Post-progression TKa levels increased to significantly higher levels than during therapy including the last sample measured before progression ($p=0.014$). Baseline blood TKa levels are predictive for progression free survival (PFS) allowing for the early stratification of patients with long vs short PFS. In patients with MBC, TKa levels during the first treatment cycle are strongly predictive for PFS. Suppressed TKa levels after 2 and 4 weeks of CDK4/6 inhibitor therapy predict longer PFS than high TKa levels at the same time points (HR 5.65; $p< 0.0001$). MBC patients monitored >3 months and showing low TKa levels have very low likelihood of progression within 30- to 60 days, <2% and <6%, respectively. TKa is a translational liquid biomarker that bridges results between preclinical and clinical studies, providing fundamental information for drug development decision making.

#7626 Assessment of precision melanoma diagnostics: Circulating microrna expression to monitor late-stage treatment.

T. Harris[1], P. Zaenker[2], A. C. McEvoy[2], H. Soyer[1], M. A. Khattak[2], M. Ziman[2], M. Millward[3], E. S. Gray[2], **M. S. Stark**[1];

Metastatic melanoma patients are commonly treated with targeted (e.g., BRAF/MEK inhibitors) and/or immune checkpoint therapies and treatment efficacy is then assessed with radiological scans. These scans are highly effective for the staging of the disease but in terms of follow-up, there are several limitations including the inability to detect minimal residual disease (MRD). Circulating biomarkers are a viable solution to overcome these limitations, and this study sought to investigate a panel of melanoma-specific microRNA (miRNA) biomarkers in stage IV patients undergoing therapy. This panel had previously been assessed in treatment naïve stage IV patients, with members of the MELmiR-7 panel able to detect an increase in tumor burden in 100% of cases, as well as the ability to define overall survival (OS) superior to serum lactate dehydrogenase (LDH) and S100B levels (delta log-likelihood = 11, p< 0.001). In this multi-center longitudinal study, bloods were drawn from study participants from 2013-2015, with clinical follow-up until October 2018. The expression levels of the MELmiR-7 panel were assessed in serially collected serum (≥3 timepoints; ≥2-month intervals) collected from a total of 23 melanoma patients, treated with BRAF/MEK inhibitors and/or anti-CTLA4 and/or anti-PD-1. The goal was to determine if the panel could predict treatment success/failure, as well as patient OS, if treated with the same therapy. All miRNA panel members were measured using a sensitive real-time PCR assay at each time point, but only miR-4731 gave stable expression over the course of the therapy, with other panel members fluctuating post treatment. The stability of miR-4731 expression over time indicated that this marker was not affected by treatment type, rather changes in its expression were reflective of disease progression/regression (as determined by radiological images), thus making it an ideal biomarker. Importantly, across the cohort of 23 patients, miR-4731 expression had the ability to predict treatment outcome (Complete Response/Stable Disease (n=12) vs Melanoma Death (n=11)) for patients at ≥2 months post therapy vs baseline, with a high degree of precision (Mann Whitney, 2-tailed; p=0.0004). Area under the curve analysis also found miR-4731 expression to be highly sensitive and specific (AUC=0.91; p=0.0009) at predicting overall survival (OS). Furthermore, in Kaplan-Meier survival analysis, participants with high serum expression (≥2 months post therapy vs baseline) of miR-4731, had poor OS (p=0.0045; 14-month median survival) as compared with low serum miRNA expression which was predictive of a positive prognosis. In sum, assessment of this miRNA marker during therapy would permit early on-treatment prediction of patient outcomes, independent of imaging, to either continue to treat with current regimen, or to switch treatment modalities.

#7627 First NGS-based companion diagnostic to aid in selecting non-small cell lung cancer patients with *ERBB2* (HER2) activating mutations for treatment with trastuzumab deruxtecan.

T. Ha;
Thermo Fisher Scientific, Carlsbad, CA

Introduction The *ERBB2* companion diagnostic program aims to expand the intended use of the Oncomine ™ Dx Target Test (ODxTT) to determine *ERBB2* single nucleotide variants (SNVs) in exons 8, 17, 18, 19, 20, 21 and 22 and exon 20 insertions from formalin-fixed, paraffin-embedded (FFPE) tumor samples in non-small cell lung cancer (NSCLC) patients who may benefit from targeted drug therapy.
Methods The ODxTT is a qualitative in vitro diagnostic test that uses targeted high throughput, parallel-sequencing technology to detect SNVs, deletions, insertions, and CNVs in genes from DNA and fusions from RNA isolated from FFPE tissue samples using the Ion PGM ™ Dx System. Analytical validation (AV) studies interrogated ODxTT's ability to detect *ERBB2* mutations. The clinical validation (CV) study involved a method comparison/concordance analysis of *ERBB2* mutations between the ODxTT and the TruSight Tumor 170 (TST170) assay, as well as a series of clinical trial assays (CTAs). The CV study was conducted using clinical specimens from 91 patients enrolled in Destiny-Lung01 and 121 stage-matched commercially procured samples. The aim was to evaluate positive percent agreement (PPA), negative percent agreement (NPA) and overall percent agreement (OPA) for CTAs and TST170 assay.
Results A total of 91 *ERBB2* subjects were included in the full analysis of the Destiny-Lung01 clinical trial. 49 samples had valid ODxTT results available and 42 samples were unevaluable which included 13 unknowns and 29 test not performed. The 49 patient samples that were evaluable were used to assess the clinical efficacy based on ODxTT results. In the series of 121 samples that were used to assess clinical efficacy in the CV study, 109 had evaluable ODxTT results. The PPA, NPA and OPA of ODxTT to the CTAs when excluding unknowns were 98%, 100% and 99.4%, respectively, and based off the Clopper-Pearson method for binomial distribution a 95% lower bound confidence interval (CI) were 89.6%, 96.6% and 96.5%, respectively. There was one discordant sample with a negative ODxTT and a positive CTA result (false negative). The PPA, NPA and OPA of ODxTT to TST170 assay were 100%, 99.1% and 99.3% respectively with a 95% lower bound CI of 90.8%, 95.0% and 96.3%, respectively. There was one discordant sample with a negative TST170 and a positive ODxTT result (false positive).
Conclusion AV and CV studies successfully verified and validated the ODxTT for the detection of ERBB2 mutations in NSCLC FFPE samples. The 6 AV studies met the necessary product requirements and acceptance criteria to detect clinical samples with ERBB2 mutations. Additionally, the CV study clinical accuracy and clinical efficacy results demonstrated the safety and effectiveness of the use of the ODxTT in FFPE samples as an aid to identify NSCLC patients eligible for treatment with the Daiichi Sankyo lung cancer therapeutic T-DXd.

#7628 Pharmacodynamic biomarkers for Rac and Cdc42 inhibitor efficacy.

A. Torres-Sanchez[1], A. M. Cruz-Collazo[2], M. Rivera-Robles[3], O. Katsara[4], S. Dorta-Estremera[2], V. Negron[5], V. P. Carlo[5], R. J. Schneider[4], S. Dharmawardhane[2];

[1]University of Puerto Rico - Rio Piedras, San Juan, PR, [2]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [3]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR, [4]New York University School of Medicine, New York, NY, [5]Auxilio Mutuo Hospital, San Juan, PR

Metastatic disease drastically reduces clinical prognosis, and remains the primary cause of mortality from solid cancers, such as breast and pancreatic cancer. Since targeted therapeutic options are limited, we developed small molecule compounds to block activation (GTP loading) of the Rho GTPases Rac and Cdc42. Rac and Cdc42 are ideal molecular targets due to their regulation of cell migration, proliferation, invasion, and signaling in cancer and immunosuppressive cells in the tumor microenvironment. Our lead compound MBQ-167 is a dual Rac and Cdc42 inhibitor with IC_{50} of ~100 nM for inhibition of Rac/Cdc42 activation and the phosphorylation of their common downstream effector p21-activated kinase (PAK). MBQ-167 is highly effective in mouse models of breast cancer metastasis and is currently undergoing a Phase I clinical trial in advanced breast cancer patients. The purpose of this study is to investigate potential target molecules that can be used as biomarkers predictive of Rac/Cdc42 inhibitor efficacy. We recently published that in addition to inhibiting the growth and migration of breast and pancreatic cancer cells, MBQ-167 inhibits macrophage cell migration, immunosuppressive myeloid cell activation and release of interleukin-6 (IL-6), a pro-inflammatory cytokine associated with cancer. Transcriptomic data of tumors from mice treated with vehicle or MBQ-167 identified a number of immunomodulatory pathways downregulated by MBQ-167, including IL-6 and S100A family signaling, and Chitinase 3-like (CHI3L1/CHI4L1) genes coding for the human YKL-40 protein. We tested for the activation status of PAK (phospho (p)-PAK) as a diagnostic marker for Rac/Cdc42 inhibitor efficacy using breast cancer patient tissue in *ex vivo* culture treated with vehicle or MBQ-167 and found decreased p-PAK staining following immunohistochemistry of MBQ-167-treated tissue. From flow cytometry, using Alexa-488-tagged anti p-PAK antibody, we found that p-PAK was reduced from peripheral blood mononuclear cells (PBMCs) following MBQ-167. ELISA assays for YKL-40/CHI3L1 proteins after treatment of pancreatic cancer cell lines and macrophage-like cells with Rac/Cdc42 inhibitors show that MBQ-167 and the derivative MBQ-168 reduced CHI3L1 levels from conditioned media. These results demonstrate the potential of p-PAK and YKL-40/CHI3L1 from blood as biomarkers for Rac/Cdc42 inhibitor efficacy. This study impacts pharmacodynamic biomarker design for the planned Phase 2 clinical trials for MBQ-167 in breast and pancreatic cancer.

#7629 Association between COMT expression and therapeutic efficacy of androgen receptor-axis targeted in prostate cancer.

S. Maekawa, R. Takata, E. Shiomi, D. Ikarashi, T. Matsuura, R. Kato, M. Kanehira, J. Sugimura, W. Obara;
Iwate Medical University, Iwate, Japan

Background: The enzyme of catechol-O-methyltransferase (COMT) inhibits the proliferation of prostate cancer (PCa). There has been no obvious biomarker that contributes to the selection of a therapeutic agent among new-generation androgen receptor-axis targeted (ARAT) therapy, such as abiraterone (ABI) or enzalutamide (ENZ). We aimed to assess the possibility of using COMT expression as a biomarker for PCa progression and the criteria for selecting ABI or ENZ.

Methods: We retrospectively evaluated 60 patients with PCa treated with ABI or ENZ via needle biopsy or radical prostatectomy. Immunostaining of COMT was performed using formalin-fixed, paraffin-embedded blocks obtained from the initial prostate biopsy for diagnosis or prostatectomy. Immunostaining evaluations were scored by immunostaining intensity (0-3) and staining area (0-3), and the total score ≥4 was defined as "high expression" and the total score <4 was defined as "low expression." The associations between COMT expression levels and clinical outcomes, including the duration of ENZ or ABI response, were also assessed.

Results: Of the 60 cases, nine (15%) showed low expression of COMT. Overall survival was significantly shorter in patients with lower COMT expression (hazard ratio [HR] = 0.24, 95% confidence interval [CI] 0.07-0.83, P= 0.024). When ENZ was administered as the first ARAT, progression-free survival (PFS) was significantly different between patients with COMT expression scores <4 and ≥4 (median 5.9 and 23.3 months, respectively). However, when ABI was administered as the first ARAT, there was no significant difference in the PFS of ARAT between COMT expression scores <4 and ≥4.

Conclusion: Patients with lower COMT expression have a significantly poorer prognosis for PCa. In addition, PFS after ENZ administration, as the first ARAT, correlated with COMT expression levels. To our knowledge, this is the first report of an association between COMT expression and the duration of ARAT.

#7630 Therapeutic relevance of systemic immune status to treatment effects of abemaciclib.

T. Ueno[1], S. Kitano[1], T. Kobayashi[1], M. Yamashita[1], F. Hara[1], Y. Ozaki[1], M. Nishimura[1], T. Takano[1], N. Toriguchi[2], T. Kawaguchi[2];
[1]Japanese Foundation for Cancer Research, Tokyo, Japan, [2]Eli Lilly Japan K.K. Japan, Tokyo, Japan

Background: The addition of a CDK4/6 inhibitor (CDK4/6i) on endocrine therapies (ET) has been currently a standard treatment for hormone receptor (HR)-positive HER2-negative metastatic breast cancers (MBCs). Especially abemaciclib has been implicated in multiple mechanisms of action including cell cycle arrest, senescence. In addition, immunomodulatory effects have been suggested but are not yet clear. The aim of the study was to investigate the clinical relevance of abemaciclib to systemic immune status by examining the status of peripheral immune cells in patients with MBC who received abemaciclib plus ET.
Methods: Patients with MBC who were treated with abemaciclib plus ET in our hospital were included in this study. Response was evaluated by RECIST 1.1. Peripheral blood at the initiation of abemaciclib treatment, 4 weeks, 12 weeks and 24weeks after abemaciclib treatment initiation were analyzed using mass cytometry by time of flight (CyTOF). Changes of cellular densities of each immune cell and survival by immune cell density were analyzed without calculating p values because of small sample number.
Results: Twenty patients were enrolled, among whom 14 and 6 received an aromatase inhibitor and fulvestrant, respectively, as concomitant ET. 7 premenopausal patients received an LH-RH analogue.
The analysis of serial blood collection showed an increase in CD8-positive T cell density by 12.5% and conversely a decrease in monocyte density by 52.3% at 4 weeks after treatment initiation. In responders (N = 10), an increase of the ratio between CD8-positive T cell density and Treg density (CD8/Treg) at 4 weeks after the treatment initiation were observed (65.2%), while not in non-responders (7.3%).
In the analysis of the blood samples at the treatment initiation, lower Treg density and lower NK density at treatment initiation indicated longer PFS than the counterparts (median PFS for Treg: low, not reached; high, 8.8 months; for NK: low, not reached; high, 8.8 months).
Conclusion: An increase of CD8/Treg at 4 weeks after the treatment initiation was associated with a good response in patients with HR-positive HER2-negative MBC treated with abemaciclib plus ET. Our results suggest an association between systemic immune status and clinical outcome in MBC patients who received abemaciclib plus ET treatment. A larger study is needed to validate the results.

#7631 Protein Plus BCT: A novel blood collection tube for stabilizing plasma proteins of interest in ambient whole blood storage.

J. Li, N. M. George, S. Mehta, J. LaRue, E. Seong, N. Binbuga, R. Miller, K. Bisselou;
Streck, La Vista, NE

Introduction: Many of the soluble plasma proteins (e.g., cytokines) that are crucial for cancer diagnosis, prognosis, and prediction of cancer immunotherapy outcomes are found in blood cells such as platelets and leukocytes. During blood collection and sample storage, *ex vivo* platelet activation, hemolysis, and blood cell degradation can occur, which causes the release of blood cell-secreted proteins into the plasma. The contamination of these proteins may confound true *in vivo* levels of plasma proteins of interest, resulting in inaccurate or inconsistent assay results. Protein Plus BCT is a new blood collection tube that maintains accurate plasma protein levels during ambient whole blood storage.

Methods: Blood samples from self-proclaimed healthy donors were drawn into Protein Plus BCT, EDTA, and ACD-A tubes. All the samples were stored at ambient temperature for up to 5 days. Plasma was isolated using a general double-spin protocol and frozen at -80 °C until use. Plasma levels of protein biomarkers were measured by Ella Simple Plex Assays (Bio-Techne) and Luminex xMAP® Technology Assays (Bio-Techne, samples tested by LuminexPLORE Lab) following manufacturers' dilution and processing recommendations.

Results: Over 50 key plasma proteins like cytokines, cancer, and immuno-oncology checkpoint markers in samples collected into Protein Plus BCT were analyzed by immunoassays and compared side-by-side to those collected in EDTA and ACD-A tubes. EDTA and ACD-A samples exhibited a substantial elevation in the plasma concentration of many, such as IL-8, IL-1β, HGF, VEGF, MMP-9, CCL5/RANTES and TGF-β1 post draw, indicating platelet activation and blood cell degradation during ambient temperature storage. Samples collected into Protein Plus BCT displayed limited *ex vivo* platelet activation and minimal contamination by blood cell-secreted proteins, maintaining the draw-time plasma levels of proteins of interest for up to 5 days in whole blood at ambient temperature.

Conclusions: The novel Protein Plus BCT maintains draw-time plasma protein levels during extended whole blood storage at room temperature by limiting *ex vivo* platelet activation, hemolysis, and blood cell degradation. Protein Plus BCT ensures sample integrity and minimizes preanalytical variables, providing cancer researchers and clinical assay developers greater flexibility in sample handling and improved confidence in downstream plasma protein analysis. Protein Plus BCT is for Research Use Only. Not for use in diagnostic procedures.

#7632 Final survival outcomes and post-hoc tumor gene expression pathway analyses of complete responders from a phase Ib clinical trial of HSP90 inhibitor onalespib and paclitaxel in patients with advanced triple-negative breast cancer.

D. M. Quiroga[1], H. Savardekar[1], E. Schwarz[1], N. O. Williams[1], C. Johnson[1], A. Brufsky[2], M. Chambers[3], S. Bhattacharya[4], M. Patterson[1], S. D. Sardesai[1], D. Stover[1], M. Lustberg[1], A. Noonan[1], M. Cherian[1], D. M. Bystry[1], K. Hill[1], M. Chen[1], M. A. Phelps[1], J. Stephens[1], L. Yu[1], B. Ramaswamy[1], R. Wesolowski[1], W. E. Carson III[1];

[1]The Ohio State University Comprehensive Cancer Center, Columbus, OH, [2]University of Pittsburgh Medical Center Hillman Cancer Center, PIttsburgh, PA, [3]University of Kentucky Markey Cancer Center, Lexington, KY, [4]University of Pennsylvania Abramson Cancer Center, Philadelphia, PA

Background: Heat shock protein 90 (HSP90) is a molecular chaperone required for stabilization of client proteins over-activated in triple-negative breast cancer (TNBC). Over-expression of HSP90 client proteins has been implicated in paclitaxel resistance, therefore, it was hypothesized that the potent HSP90 inhibitor onalespib could improve paclitaxel efficacy. As TNBCs are a heterogenous population of tumors, it is important to establish biomarkers of response to this treatment combination.

Methods: Patients with TNBC were treated with intravenous (IV) paclitaxel and IV onalespib at doses ranging from 120 mg/m2 to 260 mg/m2 on days 1, 8, and 15 of a 28-day cycle utilizing a standard 3+3 design. The primary objectives were to determine dose-limiting toxicities and maximum tolerated dose. Secondary objectives included determination of overall response rate (ORR), duration of response (DOR), and progression-free survival (PFS). Retrospectively, archival tumor tissue was obtained from study patients and processed for RNA expression analysis by NanoString nCounter platform with the Breast Cancer 360 panel. Post-hoc gene expression analysis was performed through Qiagen Ingenuity Pathway Analysis (IPA). Linear models were employed to detect differential expression between conditions while considering cartridge effect.

Results: 31 patients were enrolled in this study, of which 90% received prior taxane therapy. The established recommended phase II dose was 260 mg/m2 onalespib when given with 80 mg/m2 paclitaxel. ORR was 20%, median DOR was 5.6 months. Three patients achieved complete responses (CR), all of whom had received prior taxane therapy. Nanostring profiling analysis revealed that patients who had a CR to treatment expressed higher levels of several breast cancer-associated genes also known to be dependent upon HSP90 activity compared to patients with progressive disease (PD) as their best treatment response. These genes include FGFR4, JAK2, PIK3R1, TGFB3, and TGFBR2 (all $p<0.05$). Tumor genes overexpressed in patients with PD versus CR included IRF6, MMP7, and KRT17 (all $p<0.01$). Additionally, IPA showed patients with CR to have substantial upregulation of PD-1, PD-L1, CTLA-4, p53, HER2, and cyclin/cell cycle regulatory signaling pathways compared to patients with PD (all $p<0.01$).

Conclusions: Combination treatment with onalespib and paclitaxel had an acceptable toxicity profile and showed anti-tumor activity in patients with advanced TNBC. Gene expression analysis of patient tumor samples suggest that TNBCs with greater activation of immune checkpoint pathways and those with proteins dependent on HSP90 activity, including p53 and HER2, may be more susceptible to HSP90 inhibition.

ClinicalTrials.gov study identification: NCT02474173

#7633 CXCR6 positive circulating mucosal-associated invariant T cells play the anti-tumor effect in non-small cell lung caner immunotherapy.

J. Qu, B. Wu, Y. Li, Q. Shen, W. Sun, L. Chen, J. Zhou, J. Zhou;
The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: Mucosal-associated invariant T (MAIT) cells is are unconventional innate-like T lymphocytes abundant in human tissues. Recent studies have shown that MAIT cells play important roles in regulating tumor immunity. However, the immune characteristics of MAIT cells in non-small cell lung cancer (NSCLC) and its correlation with ICIs treatment efficacy remain unclear.
Method: In this study, we used single-cell RNA-sequencing (scRNA-seq), flow cytometry and multiplex immunofluorescence to assess the proportion and characteristics of CD8+MAIT cells in metastatic NSCLC patients who respond or not respond to anti-PD-1 therapy.
Results: The proportions of activated and proliferating CD8+ T cells and MAIT cells were significantly higher in responders-derived PBMC or lung tissues prior to anti-PD-1 therapy. Both peripheral and tumor-infiltrating CD8MAIT cells displayed upregulated CXCR6($P<0.05$). Besides, CXCR6+CD8MAIT cells from responders had higher expression of cytotoxicity-related genes, like CST7, GNLY, KLRG1, NKG7 and PRF1. Moreover, we found that patients with >1.7% of MAIT among peripheral CD8+ population showed a better response to immunotherapy.
Conclusion: CD8MAIT cells may be considered a predictive biomarker for patients responding to anti-PD-1 therapy in NSCLC. The correlation between CD8MAIT and immunotherapy sensitivity may ascribe to high expression of CXCR6.

#7634 HER2 extracellular domain in serum samples from HER2+ metastatic breast cancer patients as a potential biomarker of progression-free survival.

D. O'Reilly[1], M. Nolan[2], A. Teiserskiene[2], B. T. Hennessy[3], J. Crown[4], D. M. Collins[1];

[1]Dublin City University, Dublin, Ireland, [2]Cancer Trials Ireland, Royal College of Surgeons Ireland, Ireland, [3]Beaumont Hospital, Dublin, Ireland, [4]St Vincent's University Hospital, Dublin, Ireland

Introduction: The detection of serum biomarkers holds potential for non-invasive methods for early cancer detection, monitoring of disease progression, and assessment of treatment responses leading to earlier interventions that may significantly improve patient outcomes. Human epidermal growth factor receptor 2 (HER2) overexpression plays a key role in the prognosis of HER2+ breast cancer (BC). While HER2 is well-established as a cell surface marker, its soluble extracellular domain (ECD) in serum has gained attention as a potential prognostic biomarker. Elevated levels of HER2 ECD (>15ng/ml) have been associated with a poor outcome. However only a small percentage of primary BC patients have levels of HER2 ECD >15ng/ml. Research has suggested that HER2 targeted therapies can influence the rate of HER2 ECD shedding. Therefore, this study aimed to explore the association between circulating HER2 ECD levels with progression-free survival (PFS) and overall survival (OS) in patients with metastatic HER2+ BC.

Methods: Matched Pre and post treatment serum samples (n=25) from BC patients enrolled in TH V THL (ICORG (CTRIAL-IE) 11-10/NCT01526369) clinical trial were assessed. Human ErbB2 (HER2) ELISA Kit (Invitrogen) was used to detect levels of soluble HER2 ECD in the serum. Serum levels were stratified as Low (<300pg/ml n=5), Intermediate (300-700pg/ml n=10) or High (>700pg/ml n=10). Patient data correlation was used to assess PFS and OS, Kaplan-Meier survival curves were constructed based on the serum levels of HER2 ECD. Significance p values were determined using log-rank (Mantel-Cox) test.

Results: Levels of HER2 ECD detected (94-1730pg/ml) did not exceed 15ng/ml for any sample. There was no significant difference in HER2 ECD levels between treatment arms (TH vs. THL) for PFS (p=0.4685) or OS (p=0.1376). There was no change between the pre and post treatment HER2 ECD serum levels in the samples tested (p=0.344). However, when pre-treatment samples were stratified based on Low, Intermediate or High HER2 ECD levels, there was a significant increase in PFS for patients in the High cohort. Median PFS increased from 8.31 months in the Low cohort to 13.57 months in the Intermediate cohort. The median PFS increased further to 22.24 months in the High cohort (Log rank p=0.0197). The same parameters were applied for the analysis of OS, which also improved as the level of HER2 ECD increased. Median OS increased from 35.19 months (Low) to 68.7 months (Intermediate), with a Median OS not reached for the High cohort (Log rank p=0.077).

Conclusions: Patients with HER2 ECD levels above 700pg/ml display a survival advantage in this limited study. Further validation and prospective studies are warranted to fully establish the clinical utility of HER2 ECD as a biomarker in metastatic HER2+ BC.

#7635 Orion™: 14-plex clinical sample imaging of liver cancer modalities using one-step staining and imaging.

S. Larkin[1], J. Currenti[2], R. Pai[2], S. Chatterjee[3], A. Mishra[3], J. George[4], B. Gardner[1], A. Sharma[2];
[1]RareCyte, Inc., Seattle, WA, [2]Harry Perkins Institute of Medical Research, Sydney, Australia, [3]Telethon Kids Institute, Perth, Australia, [4]Westmead Institute of Medical Research, Sydney, Australia

Background To better understand the complexities of the tumor microenvironment (TME), high-resolution imaging at a sub-cellular resolution and high-plex is needed. These serve as a basis for biomarker quantification and more downstream, may provide the ability to predict patient outcome. Here, we investigate three whole slide liver sections: fetal liver, hepatocellular carcinoma (HCC), and colorectal cancer (CRC) liver metastasis.
Methods 5-micron sections were cut and mounted on Superfrost Plus slides prior to de-paraffinization and antigen retrieval using the BioGenex EZ-Retriever system. Autofluorescence was quenched using UV and white light and blocked with Image-iT™ FX Signal Enhancer. Whole slides were stained with the 14-plex antibody panel, coverslip mounted with ArgoFluor™ Mounting Medium and cured overnight. Whole slides were imaged at 20X using the Orion™ spatial biology platform. Coverslips were removed in aqueous solution prior to H&E staining and scanning.
Results Sample specific differences were observed, likely stemming from the different tissue sources. Data revealed a distinction between hepatocytes highlighted in the autofluorescence channel, sinusoids filled with proliferating progenitor cell and macrophages, and epithelial cells lining the border of the fetal liver forming the ductal plate surrounding the portal vein. Whereas in HCC, imaging revealed autofluorescent hepatocytes obliterating the sinusoids with some hepatocytes dividing, an extensive capillary network, and red bloods cells also highlighted in the auto fluorescent channel. T cells and macrophages showed clustering within the capillary networks and as expected, hepatocytes expressed high levels of Albumin. In the CRC liver metastasis sample, hepatocytes were shown to be surrounded by T cells, neoplastic glands (PanCK), and $CD163^{\pm}$ $FOLR2^{\pm}$ macrophages. Furthermore, the majority of the metastatic epithelial cancer cells were observed to be proliferating.
Conclusions We were able to observe precise differences in the tissue architecture of liver samples from three divergent sources. Specifically, the ability to identify distinct cell subtypes and their spatial co-localization may provide mechanistic insights into the spatial immune landscape and its role in disease progression and treatment outcome. This exemplifies the need for dissecting the spatial heterogeneity of the TME using a technology that offers a high-resolution subcellular snapshot in time; exhibiting the potential for Orion to bridge the gap from bench-to-bedside.

#7636 Quantitative analysis of colorectal adenocarcinoma images obtained by single-shot 17-plex staining followed by imaging with the Orion™ spatial biology platform.

E. Lo, T. George, **S. Larkin**;
RareCyte, Inc., Seattle, WA

Background To understand the tumor microenvironment (TME), high resolution imaging of multiple biomarkers with whole slide context can be used as a basis for downstream biomarker quantitation and predicting patient outcomes[1]. Here we investigate a sample of invasive colorectal adenocarcinoma using whole slide, single-step high-plex staining and imaging at single-cell resolution followed by quantitative analysis.

Methods The slide was stained in one round with a 17-plex immune-oncology panel then imaged in one round with the Orion™ spatial biology platform. Quantitative analysis was performed on the resulting TIFF file using the following pipeline:- Manually annotate regions of interest (ROI) on the tissue- Segment whole slide images into cells with UnMICST and S3segmenter - Import mask and clean data in QuPath - Generate primary feature data table with QuPath - Classify cells into populations in QuPath - Generate spatial biomarkers - Compare cell populations and their spatial interactions in the different ROIs.

Results Data revealed a distinction between normal colonic epithelium, well-differentiated adenocarcinoma with immune cell collection, and an infiltrating border of the carcinoma. Differences in immune cell content and spatial organization were measured, and the infiltrating border found to contrast with other tumor regions by showing a lower proliferative fraction (Ki-67, nuclear) and differences in E-cadherin and cytokeratin expression patterns.

Conclusions These data highlight the importance of sufficient plex, resolution and whole slide context to derive reliable spatial biomarkers of potential prognostic value. Further, hours vs. days speed for whole-section multiplexed biomarker quantitation, along with same-section conventional chromogenic analysis, makes this approach suited to multi-patient clinical studies.

CLINICAL RESEARCH: Prognostic Biomarkers 2
Poster Session

#7640 Prognostic significance of S100A16 expression in patients with resected lung adenocarcinoma.
J.-J. Hung;
National Yang Ming Chiao Tung University and Taipei Veterans General Hospital, Taipei, Taiwan

Background: Lung cancer is the leading cause of cancer death worldwide. Tumor recurrence is the most common cause of treatment failure after surgical resection. The S100 protein family is a multigenic group of cytoplasmic calcium-binding proteins. S100A16 has to be reported to be an independent prognostic indicator of poor overall survival in lung adenocarcinoma recently. However, the prognostic value of S100A16 in recurrence-free survival (RFS) in patients with resected lung adenocarcinoma has not been well demonstrated. The relationship between S100A16 expression and the histological subtypes of lung adenocarcinoma remained unknown.
Methods: A total of 79 patients with resected lung adenocarcinoma were included in the study. S100A16 expression was determined by immunohistochemistry in tumor specimens. The prognostic value of S100A16 overexpression and its relationship with clinicopathological variables, including histology subtypes, were investigated.
Results: S100A16 overexpression tended to be significantly associated with order age (P = 0.074). There was no significant association between S100A16 overexpression and predominant pattern group (lepidic/acinar/papillary vs. micropapillary/solid) (P = 0.447). Univariate analysis indicated that pathologic stage (II or III vs. I) (P = 0.001) and S100A16 overexpression (P = 0.005) were significant prognostic factors for worse recurrence-free survival (RFS). Predominant pattern group (lepidic/acinar/papillary vs. micropapillary/solid) (P = 0.064) tended to be a significant prognostic factor for worse RFS. In multivariate analysis, pathologic stage (II or III vs. I) (HR, 27.847; 95% CI, 4.173 to 185.831; P = 0.001), and S100A16 overexpression (HR, 21.740; 95% CI, 2.516 to 187.870; P = 0.005) were still significant prognostic factors for worse RFS.
Conclusions: S100A16 overexpression was a significant prognostic factor for worse RFS in patients with resected lung adenocarcinoma. This information is useful to stratify high-risk patients of recurrence after resection of lung adenocarcinoma.

#7641 Prognostic impact of functional germline mutations in muscle-invasive bladder cancer identified by neural network analysis.

G. P. Sonpavde[1], A. H. Nassar[2], A. Ravi[3], L. Sadler[4];

[1]AdventHealth Cancer Institute, Orlando, FL, [2]Yale Cancer Center, New Haven, CT, [3]Dana-Farber Cancer Institute, Boston, MA, [4]KeyBio, Boston, MA

Background: An accurate prognostic algorithm based on germline whole exome sequencing (WES) would complement tumor omics as a non-invasive source of biomarkers for guiding cancer patient therapy. In a previous study, we used WES and RNA-seq data from muscle-invasive bladder cancer (MIBC) and normal host cells to train a survival model, wherein we discovered that mutated germline genes accounted for 90% of feature importance. We have since defined a larger cohort to identify key germline biomarkers of overall survival (OS) that may be scalable for application in the clinic.

Methods: 169 patients from The Cancer Genome Atlas (TCGA) with MIBC stages T2-T4 that underwent radical cystectomy (RC) w/o neoadjuvant treatment were eligible. OS at 4 years was the primary clinical endpoint as it is associated with death due to metastatic tumor recurrence. Patients were dichotomized to *control* survivors who were alive at 4+ years, and *cases* who died within 4 years but no less than 4 months after RC. 49 qualifying survivors were propensity matched against 49 dead patients by stage, adjuvant treatment, gender, race, and age. The remaining 71 dead patients served as a holdout. Only high (e.g. frameshift) and moderate (e.g. indel) impact germline variants were included. Mutations were weighted for allele frequency (penalize common) and genotype (reward homozygous) before grouping at the gene level. A panel of the 21 most differential genes in stratified patients were selected for neural network training using AIQC. The model forced protective/ pathogenic genes to interact and produced individual survival probabilities. Gene importance was determined via permutation.

Results: OS was accurately predicted for 98.2% of patients: 1 FN, 2 FP, 37 TN, 119 TP. The top 3 permuted genes (and related pathways) were: SORL1 (Aβ), KIF27 (hedgehog), CUL7 (p53). The most differential gene was CUL7: 31% of survivors mutated vs 2% of dead.

Conclusion: Neural network analysis identified the promise of germline genetics as an accurate predictor of survival and tumor recurrence in MIBC patients. Upon validation in an external cohort, these biomarkers could be used to inform adjuvant therapy and complement molecular residual disease alongside circulating tumor (ct)-DNA.

#7642 Activated FAP+ cancer-associated fibroblasts in non-muscle invasive bladder cancer are associated with progression to muscle-invasive disease.

A. Abbas[1], S. Maskey[2], E. Cheng[2], Z. Li[3], K. Ganesh[1], S. Izadmehr[2], S. Janho dit Hreich[1], B. Demaille[1], J. Mesple[1], P. Sirven[1], C. Krucker[4], J. Fontugne[4], I. Bernard-Pierrot[4], Y. Allory[4], M. Merad[2], J. Adam[5], J. Sfakianos[6], E. Kenigsberg[2], M. Galsky[3], H. Salmon[1];

[1]Institut Curie, INSERM, U932, Equipe Leader Fondation ARC, PSL Research University, Paris, France, [2]The Precision Immunology Institute, Icahn School of Medicine at Mount Sinai, New York, NY, [3]The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, [4]Institut Curie, CNRS, UMR144, Equipe labellisee Ligue Contre le Cancer, PSL Research University, Paris, France, [5]Department of Pathology, Paris Saint-Joseph Hospital, Paris, France, [6]Icahn School of Medicine at Mount Sinai, New York, NY

The majority of patients with bladder cancer initially present with non-muscle-invasive disease (NMIBC). While NMIBC may be cured with transurethral resection +/- intravesical therapies, approximately 20% of patients develop progression to muscle-invasive bladder cancer (MIBC) which requires life-altering treatments such as cystectomy and has a high risk of lethal metastatic recurrence. Current risk stratification for NMIBC relies on clinicopathologic features that overlook the potential role of the tumor microenvironment (TME) in bladder cancer pathogenesis. We sought to delineate the stromal and immune landscape alterations within the TME upon bladder cancer progression and to identify TME-related features that could enhance current prognostic approaches. Analyzing by single-cell RNA sequencing and multiplexed imaging of 22 untreated NMIBC and MIBC specimens, coupled with publicly available datasets, we discovered significant transcriptional variability among cancer-associated fibroblasts (CAFs) and macrophages across patients. This inter-patient variability was attributable to the extensive remodeling of these cell types during cancer progression. Notably, a specific subset of CAF, characterized by ITGA8+F3+ markers, was found to be highly enriched in NMIBC lesions and transcriptionally related to sub-urothelial fibroblasts of the healthy bladder, whereas a FAP+ CAF subset enriched for core matrisome related genes was dominant in MIBC lesions. We developed a FAP+ CAF signature which was then projected onto a large public dataset of bulk-RNAseq data from patients with NMIBC demonstrating that the FAP+ CAF signature was significantly associated with progression to MIBC independently of contemporary risk stratification scores. The presence of FAP+ CAFs in a subset of NMIBC specimens was orthogonally validated using immunohistochemistry. Importantly, areas with FAP staining were observed in close contact with individual or small groups of tumor cells exhibiting an invasive phenotype and partial epithelial-mesenchymal transition, likely explaining the higher risk of progression to MIBC. Our study improves our understanding of fibroblasts remodeling during bladder cancer progression and highlights the potential of integrating CAF-derived biomarkers into NMIBC risk stratification models.

#7643 Prognostic significance and immune infiltration patterns related to Claudin heterogeneity in pancreatic ductal adenocarcinoma patients.

A. A. Bhat[1], S. Usmani[1], H. Q. Sadida[1], S. Hashem[1], T. Masoodi[1], I. Ahmed[1], R. Kumar[2], M. Singh[3], P. Dhawan[4], S. Uddin[5], M. A. Macha[6], A.-S. Akil[1]; [1]Sidra Medicine, DOHA, Qatar, [2]School of Biotechnology, Shri Mata Vaishno Devi University, Katra, Jammu and Kashmir, India, [3]All India Institute of Medical Sciences (AIIMS), New Delhi, India, [4]University of Nebraska Medical Center, Omaha, Omaha, NE, [5]Translational Research Institute, Academic Health System, Hamad Medical Corporation, DOHA, Qatar, [6]Watson-Crick Centre for Molecular Medicine, Islamic University of Science and Technology, Awantipora, Kashmir, India

Background: Pancreatic ductal adenocarcinoma (PDAC) stands out for its aggressive nature, often manifesting through invasion, metastasis, and recurrence. These characteristics are partly attributable to the Epithelial-mesenchymal transition (EMT), a critical phenomenon that follows the disintegration of epithelial barriers, including tight junctions (TJs), where Claudin (CLDN) proteins are integral components.
Objective: This study focused on elucidating the differential expression of claudins in PDAC and exploring their correlations with disease progression, invasiveness, and immune infiltration.
Methodology: Utilizing UCSC TOIL RNA-seq, TCGA-PAAD genomic, and clinical data, we investigated the genomic alterations and differential expression of claudins in PDAC. Conducted survival analysis using log-rank tests. Assessed immune infiltration patterns using the EPIC deconvolution algorithm.
Results: Of 177 PDAC samples examined, 23 (13%) exhibited at least one form of claudin gene alteration, including mutations, amplifications, or deep deletions. Remarkably, 10 claudins (CLDN1, 2, 4, 5, 7, 11, 12, 15, 18, and 23) were found to be significantly overexpressed in PDAC samples, meeting a log2FC threshold of ≥1 ($p < 0.05$). Further, we identified a direct correlation between mRNA expression and copy numbers, alongside an inverse relationship with methylation levels, particularly in CLDN1, CLDN12, CLDN15, CLDN23, and CLDN4. Intriguingly, claudin expression escalated from grades G1 to G3 but diminished in G4, with CLDN1, CLDN4, and CLDN7 showing significant variability (Kruskal-Wallis rank test p-values of 1.2E-5, 0.00064, and 0.023, respectively). Survival analysis indicated that high expression levels of CLDN1 and CLDN4 were linked to poorer patient outcomes, while higher levels of CLDN5 and CLDN15 correlated with improved survival (log-rank p-values of 0.007, 0.016, 0.0035, and 0.0012, respectively), findings consistent across both univariate and multivariate analyses. Furthermore, immune infiltration patterns, assessed via the EPIC deconvolution algorithm, varied significantly between high and low CLDN expression groups. Specifically, low CLDN1 expression was associated with increased presence of B-cells, CAF, and $CD8^{+}$ T-cells but fewer endothelial cells, a pattern reversed in high CLDN1 expression cases. A similar trend was observed for CLDN4.
Conclusion: Our study underscores the significant prognostic value of claudin proteins in PDAC, highlighting their potential as indicators of disease progression and survival and their influence on the tumor's immune environment.

#7644 Prognostication of genomic characteristics of residual breast cancer after neoadjuvant chemotherapy.

J.-Y. Kim[1], S. Park[2], S. Ahn[3], E. Seo[4], S. Kim[3], M. Gregory[5], E. Killingbeck[5], E. Cho[1], J. Lee[1], J. Ahn[1], Y. Park[1], W.-Y. Park[4], H. Kim[3], S. Lee[2], Y.-H. Im[1]; [1]Samsung Medical Center, Seoul, Korea, Republic of, [2]Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of, [3]Sungkyunkwan University, Suwon, Korea, Republic of, [4]Samsung Genome Institute, Seoul, Korea, Republic of, [5]NanoString Technologies, Seattle, WA

Residual cancer burden (RCB) based on pathologic characteristics is the most powerful prognostic factor in breast cancer (BC) which received neoadjuvant chemotherapy (NAC) followed by surgery. According to RCB classification, class III predicted short survival duration regardless of BC subtypes according to hormone receptor (HR) and human epidermal growth factor receptor-2 (HER-2) state. However, up to 20-40% of BCs with RCB class III did not experience BC recurrence and had long term survival without disease recurrence. In our study, we evaluated genomic characteristics of BC which had high RCB class. We collected 96 fresh frozen BC specimens which had undergone surgery after NAC between 2010 and 2018 from Samsung Medical Center Biobank. We performed whole genome or exome sequencing, RNA sequencing and high-plex single-cell spatial transcriptomics. Of 96 BCs, 65 BCs had experienced BC recurrence and 31 BCs have not been BC recurrence. Of 65 BCs with dismal prognosis, 12 were HR+HER2-, four in HR+HER2+, 39 in triple negative breast cancer (TNBC) and 10 in HR-HER2+ BC. Of 31 BCs without recurrence, 11 were HR+HER2-, two in HR+HER2+, 14 in TNBC and four in HR-HER2+ BC. In HR+HER2- BC, ten of 12 BCs with dismal prognosis were categorized into basal like intrinsic subtype and two were into luminal B subtype compared that six of luminal A and five of luminal B subtype categorization in good prognosis BC group. Age associated mutation signature were enriched in HR+HER2- BC with good prognosis (p=0.027). Tumor microenvironment (TME) analysis using Kassandra suggested that high monocytes were associated with BC with dismal prognosis (p=0.00031). In single-cell spatial transcriptome analysis, T-cell abundance in the tumoral niche is associated with dismal prognosis in HR+HER2- BC (p=0.039). In TNBC, almost BCs (88.7%) were categorized into basal-like intrinsic subtype regardless of their prognosis. TME analysis presented that immune cells including macrophages and lymphocytes with CD4 and CD8 T cells were significantly enriched in TNBC with good prognosis (ps <0.05, respectively). In HER2+ BC, intrinsic subtypes were heterogeneous in both groups. Focal amplification in HER2+BC patient harbored DNA segments from different chromosomes more frequently than in those with good prognosis (p=0.00091), which was prominent in oncogenic extrachromosomal DNA amplifications compared to other oncogenic amplifications. In TME analysis, there were no specific cell enrichments according to BC prognosis but sing-cell spatial transcriptome analysis revealed that higher T-cell abundance in the tumoral niche was associated with HR+HER2+ BC with good prognosis (p=0.047). In conclusion, each BC subtype had their own genomic characteristics to determine their prognosis. Our study also suggested that TME characteristics was common prognostic factor for survival outcome of BC with residual tumor after NAC.

#7645 Differentially expressed genes as prognostic markers in racial disparities of prostate cancer.

A. A. Ahmed, S. Verma, I. M. Atawia, D. L. Shen, G. T. MacLennan, P. Fu, **S. Gupta**;
Case Western Reserve University School of Medicine, Cleveland, OH

Racial disparities in prostate cancer are prevalent, with African American (AA) men experiencing 60% greater incidence and 2 to 3 times higher mortality than Caucasian American (CA) men. Consequently, there is a pressing need for improved means of interrogating race/ethnicity-based prostate cancer biology in order to identify biomarkers to help stratify men at high-risk for prostate cancer-specific progression and death and offer treatment recommendation that would mostly benefit AA men undergoing early aggressive therapies. Current predictive models rely on clinical variables but do not account for these disparities. The overall goal is to construct a race-specific prostate cancer prognostic prediction model for risk assessment. Here we performed comprehensive bioinformatics analysis using the data from 17 pairs of gene expression array from AA and CA cohorts and identified 63 differentially expressed genes (DEGs) by race. Among them, chemokine receptor 4 (CXCR4), viz. p-Akt (Ser473), fatty acid synthase (FASN), interleukin-6 (IL-6) and matrix metallopeptidase 9 (MMP-9) gene expressions were significantly altered in AA groups. Immunohistochemistry was performed on 163 prostate cancer patient specimens to validate DEG expression and immunoreactive scores (IRS) were calculated. CXCR4 exhibited significantly higher expression in AA tumors, with > 85% of AA prostate tumors showing weak to strong CXCR4 expression, compared to < 5% in CA specimens. While immunostaining for IL-6, FASN, MMP9 and p-Akt did not provide a significant distinction between CA and AA cases. IRS analysis confirmed higher expression of CXCR4 in AA cancers, compared to CA prostate cancer ($p < 0.001$). MMP9 and IL6 expression were moderately higher in AA cancer compared to CA prostate cancer ($p < 0.05$). In contrast, FASN expression was significantly higher in CA cancer, compared to AA prostate cancer ($p < 0.001$). We further investigated the impact of these genes on biochemical recurrence-free survival (BCRFS) using Kaplan-Meier analysis to examine the differences between low-risk versus high-risk groups. BCRFS analysis demonstrated that CXCR4 is a determinant factor of recurrence risk in AA prostate cancer patients. The activation of the PI3K-Akt signaling pathway, particularly in AA patients, suggests its role in prostate cancer aggressiveness. Taken together, this study demonstrates the importance of differential expression of biomarkers which constitute the bulk tumors in driving cancer. The distinct gene expression patterns, especially the upregulation of CXCR4, in AA prostate cancer highlight its potential as a prognostic biomarker and a target for personalized treatment strategies. These findings encourage further study into the role of population-specific difference in adding CXCR4 in risk model construction, especially in machine learning models.

#7646 Evaluation of tumor immune microenvironment after neoadjuvant immunotherapy in patients with esophageal squamous cell carcinoma (ESCC): Towards a prediction for recurrence risk.

Z. Liu[1], B. Yu[1], Y. Yang[1], C. Qi[1], C. Yuan[1], Y. Yang[1], J. Wei[1], S. Chen[2], Y. Wang[2], Z. Li[1];
[1]Shanghai Chest Hospital, Shanghai, China, [2]Virtue Diagnostics (Suzhou) Co., Ltd, Shanghai, China

Background: Despite the promising potential of neoadjuvant immune checkpoint blockade (ICB) in ESCC, postoperative recurrence remains a critical challenge. Besides pathological response, there remains no biomarkers for recurrence risk prediction after neoadjuvant ICB. Recent studies have highlighted a strong association between ICB efficacy and tumor immune microenvironment (TIME). Thus, we sought to investigate the TIME features in surgically resected tumors following neoadjuvant ICB from patients with ESCC to develop a potential way for recurrence risk prediction.

Methods: This is a side study of a phase 2 NICE trial (ChiCTR1900026240) of 51 patients with resectable locally advanced ESCC who received neoadjuvant ICB plus chemotherapy followed by surgery from 2019 to 2020. TIME features of surgically resected tumors after neoadjuvant therapy were assessed by multiplex immunohistochemistry (mIHC) for immune markers (CD8, PD-L1, CD45RO, PD-1, Pan-CK, CD4, FoxP3, CD68, CD163). We first analyzed TIME features in tumors evaluated as pathological complete response (pCR) and major pathological response (MPR). Then, we divided 51 patients into a training and validation set; and machine learning was applied to identify a list of TIME features that predict recurrence-free survival (RFS) and to develop a TIME-based signature (TIS) on neoadjuvant ICB prognosis.

Results: Fifty-one patients from NICE trial were used for primary analysis. A higher positive rate of $CD8^{\pm}$ cells, $CD163^{-}CD68^{\pm}$ macrophages and $CD8^{\pm}CD45RO^{\pm}$ cells was observed in patients with pCR. Similarly, MPR patients exhibited a higher positive rate of $CD8^{\pm}$ cells and $CD8^{\pm}CD45RO^{\pm}$ cells. Regarding RFS prediction, machine learning selection of TIS were identified: $CD8^{\pm}PD1^{-}$(cytotoxic T cells), $CD4^{\pm}Foxp3^{\pm}$ (Treg), $CD8^{\pm}CD45RO^{\pm}$ (memory T cells), and M1 macrophages ($CD163^{-}CD68^{\pm}$) exhibited significant predictive value. Stratifying patients into low- and high-risk groups using TIS for RFS revealed a prolonged prolonged RFS in the low-risk group ($p<0.001$; HR: 0.08, 95% CI [0.03-0.25]). Notably, when applying TIS to pCR patients, we identified a subset of high-risk pCR patients (median RFS = 8.9 months, 1- year RFS=32%) relapsed earlier than low-risk pCR patients (median RFS = not reached, 1-year RFS=100%, $p<0.001$). Multivariable Cox regression analysis demonstrated that TIS was an independent predictor for RFS as well as overall survival (both $p<0.001$). Further independent validation (ICB and non-ICB cohort) of TIS is ongoing.

Conclusion: The establishment of a risk prediction model based on TIME demonstrated the potential to enhance postoperative monitoring management for ESCC patients who underwent surgery after neoadjuvant ICB. Our study provides insights into development of optimal post-immunotherapy management strategy.

#7647 Identification of transcriptional plasticity biomarkers for patient stratification.

J. Goldstein, C. Gavazzi, M. Grushko, M. Samizadeh, Z. ElSeht, K. Arline;
SHEPHERD Therapeutics, Boston, MA

Biomarker signatures associated with disease progression are important tools for the management of patient care. However, such signatures are frequently indication-specific, which limits their utility to stratify broader populations. Transcriptional plasticity, the ability of a transcriptome to change in response to external stimuli, is of interest due to its relation to disease progression and therapeutic response. To extend and generalize the measurement of a patient's risk of disease progression to a pan-cancer, sequencing-based biomarker, Emax, the maximum cytotoxicity of a compound in a cell line, was explored as a potential universal marker of transcriptional plasticity.

To explore correlation between Emax and transcriptional plasticity, cancer cell lines were ranked by mean Emax across multiple classes of cytotoxic compounds analyzed in GDSC (Yang et. al., 2013). Cell lines with lower Emax (more surviving cells at high drug concentrations) were filtered to exclude cell lines which tended to have higher IC50 values to remove cell lines that may be generally more resistant. With GDSC1 as the train set and GDSC2 as the test set, differentially expressed genes between high-Emax and low-Emax cell lines were selected for further analysis and possible inclusion in the plasticity biomarker signature.

Test analysis in GDSC2 revealed an R2 of 0.88 suggesting transferability. For clinical validation, public repositories were queried for tumor RNA sequencing data with paired response data. To avoid batch effects between experiments, preliminary validation focused on one sufficiently large dataset with well-curated response data (n = 170; Barrett et. al., 2013, GSE91061; phs000452.v1.p1). Analysis of the expression of the genes identified in the in vitro signature revealed significant differential expression between patients who were reported as having an objective response and patients who achieved stable disease as best response. In silico pathway analysis of this signature revealed enrichment in cell-cell adhesion, signaling, and gene regulation, which relate to the hallmarks of phenotypic plasticity and epigenetic reprogramming (Hanahan, 2022).

This analysis reveals similarity between gene expression patterns associated with Emax measured in vitro and transcriptional plasticity in the clinic. Additional experimentation is underway to prospectively analyze this set of biomarkers and to retrospectively validate this signature in additional datasets with the goal of patient stratification by the risk of disease progression following an initial, incomplete response to therapy.

#7648 COL6A1 expression as a potential prognostic biomarker for risk stratification of T1HG bladder cancer: Unveiling the aggressive nature of a distinct non-muscle invasive subtype.

X.-M. Piao[1], Y. Byun[1], C.-M. Zheng[1], S.-K. Kim[2], S.-H. Park[3], K. Min[4], H. Park[4], S. Moon[5], K. Kim[5], H. Kang[5], W. Kim[5], S. Yun[5];
[1]College of Medicine, Chungbuk National University, Cheongju, Korea, Republic of, [2]Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of, [3]University of Science and Technology, Daejeon, Korea, Republic of, [4]Gwangju Institute of Science and Technology, Gwangju, Korea, Republic of, [5]Chungbuk National University Hospital, Cheongju, Korea, Republic of

Introduction and Objectives: T1 high grade (T1HG) bladder cancer (BC) is a type of non-muscle invasive BC (NMIBC) that is recognized as an aggressive subtype with a heightened propensity for progression. Current risk stratification methods for NMIBC rely on clinicopathological indicators; however, these approaches do not adequately capture the aggressive nature of T1HG BC. Thus, new, more accurate biomarkers for T1HG risk stratification are needed. Here, we enrolled three different patient cohorts and investigated expression of *COL6A1*, a key component of the extracellular matrix, at different stages and grades of BC, with a specific focus on T1HG BC. **Materials and Methods:** Samples from 298 BC patients were subjected to RNA sequencing and real-time PCR. **Results:** We found that T1HG BC and muscle invasive BC (MIBC) exhibited comparable expression of *COL6A1*, which was significantly higher than that by other NMIBC subtypes. In particular, T1HG patients who later progressed to MIBC had considerably higher expression of *COL6A1* than Ta, T1 low-grade patients, and patients that did not progress, highlighting the aggressive nature and higher risk of progression associated with T1HG BC. Moreover, Cox and Kaplan-Meier survival analyses revealed a significant association between elevated expression of *COL6A1* and poor progression-free survival of T1HG BC patients (multivariate Cox hazard ratio, 16.812; 95% confidence interval, 3.283-86.095; P=0.001 and P=0.0002 [log-rank test]). **Conclusion:** These findings suggest that *COL6A1* may be a promising biomarker for risk stratification of T1HG BC, offering valuable insight into disease prognosis and guidance of personalized treatment decisions.

#7649 Inflammatory biomarkers by sarcopenia status in diverse individuals with lung cancer.

C. A. Byrne[1], G. Fantuzzi[1], V. M. Oddo[1], S. Kim[1], T. J. Koh[1], S. L. Gomez[2];
[1]University of Illinois at Chicago, Chicago, IL, [2]Rush University, Chicago, IL

Background: Sarcopenia and inflammation are independent prognostic indicators of poor survival in lung cancer. Systemic inflammation contributes to sarcopenia or low muscle mass through increased catabolism and decreased synthesis of muscle protein. In turn, sarcopenia leads to inflammation in the muscle and exacerbation of systemic inflammation. Specific Aim: The aim of this study was to determine the association between sarcopenia and systemic biomarkers of inflammation including neutrophil to lymphocyte ratio (NLR), platelet to lymphocyte ratio (PLR), and albumin in diverse individuals with lung cancer and determine their use as prognostic indicators of sarcopenia. Methods: This retrospective cross-sectional study included 218 non-Hispanic Black (n=111) and White (n=107) individuals with lung cancer. Computed tomography scans were analyzed to calculate skeletal mass index (SMI) at the third lumbar vertebra. Sarcopenia was defined using published sex-specific criteria for SMI in healthy individuals then categorized into the binary variable of sarcopenia/no sarcopenia. NLR, PLR, and albumin were analyzed as both continuous and categorical variables, with NLR> 3, PLR >150, and albumin <3.5 defining moderate to high inflammation. T-tests, Mann Whitney U, Chi square, and adjusted Logistic Regression were used as appropriate. Results: Subjects presented with a mean age of 68.5 + 9.8 years, BMI of 26.3 + 5.9 kg/m^2, 50.9% non-Hispanic Black, and 49.5% female with significantly higher prevalence of late-stage lung cancer (61.9% versus 38.1% early-stage, p<0.001) and no differences in age and BMI by race/ethnicity. Mean NLR (6.2 + 7.2), PLR (226.9 + 157.9), and albumin (3.2 + 0.6) indicated an inflammatory state in diverse individuals with lung cancer, with significantly higher NLR (8.5 + 9.7 versus 4.7 + 4.2, p<0.001) and PLR (268.9 + 204.5 versus 198.7 + 108.9, p<0.01) and significantly lower albumin (3.1 + 0.7 versus 3.4 + 0.5, p<0.01) in those with sarcopenia compared to those without sarcopenia. The odds of sarcopenia were 2.2 higher with NLR > 3 compared to NLR <3 (95% CI: 1.1, 4.4) and 2.5 higher with albumin <3.5 compared to albumin >3.5 (95% CI: 1.2, 5.3) after controlling for race/ethnicity, stage of cancer, age, and BMI. PLR > 150 was not a significant predictor of sarcopenia. Conclusion: Diverse individuals with sarcopenia of lung cancer present with higher inflammation compared to individuals with lung cancer but without sarcopenia as indicated by NLR, PLR, and albumin levels. Moderate to high levels of inflammation as indicated by high NLR and low albumin may help predict sarcopenia status in diverse individuals with lung cancer.

#7650 An analysis of the prognostic role of sarcopenia derived with fully automated deep learning slice-based muscle estimation in patients with metastatic non-small cell lung cancer (NSCLC).

W. Safta[1], R. Santana-Davila[2], D. Paulucci[1], W. J. Geese[1], D. J. Grootendorst[1];
[1]Bristol Myers Squibb, Princeton, NJ, [2]Fred Hutchinson Cancer Center, Seattle, WA

Introduction: Sarcopenia, progressive and generalized loss of skeletal muscle mass, is difficult and labor intensive to directly measure as it requires manual segmentations by radiologists from computed tomography (CT) scans. Sarcopenia has been shown to be a prognostic factor in some metastatic cancers. We evaluated the impact of sarcopenia derived via an automated segmentation algorithm on outcomes in the Phase 3 NSCLC clinical trial, CheckMate 227 (NCT02477826)

Methods: The sarcopenia score assessment involves automated selection of the L3 vertebra level slice from abdominal or chest, abdomen, and pelvis (CAP) CT scans, followed by automated segmentation of the muscle area from that slice. Sarcopenia scores were derived from previously established definitions of sarcopenia, with values below 41 cm^2/m^2 for female patients (regardless of BMI) and below 43 cm^2/m^2 or 53 cm^2/m^2 for male (based on BMI < 25 kg/m^2 or ≥ 25 kg/m^2). Among the 967 patients with evaluable scans, sarcopenia at baseline was identified in 68.39% (n=329/481) patients receiving nivolumab (NIVO) with ipilimumab (IPI) and 70.2% (n=341/486) receiving chemotherapy (Chemo).

Results: There was a trend of worse overall survival (OS) in patients with baseline sarcopenia across both treatment arms (minimum follow up 49.4 months). In patients with baseline sarcopenia vs ITT, median OS was 16.5 mo vs. 21.8 mo (p= 0.219) within the NIVO + IPI arm and 12.9 mo vs.15.0 mo (p= 0.273) within the Chemo arm respectively. Any increase in muscle mass from baseline to week 12 was associated with better OS for patients treated with NIVO+IPI (n=98) with sarcopenia at baseline compared to those without an increase in muscle mass (median OS 45.3 mo vs.19.5 mo, p= 0.012). This was not seen in those who received Chemo (n=87). Weight and muscle mass were moderately correlated at baseline (r=0.60).

Conclusions: We found that in CheckMate 227, baseline sarcopenia is associated with numerically worse OS, regardless of treatment, leading to potential use as a negative prognostic biomarker. Patients with NSCLC receiving immunotherapy might benefit from changes in muscle mass being monitored during treatment. Validation of these findings in other studies and other tumor types is warranted.

#7651 Evaluating epigenetic markers for naive, memory and overall B cells for disease diagnosis and prognosis in patients with B-CLL.

K. Schildknecht[1], K. Bourquain[1], J. Werner[2], J. Schulze[2], S. Walter[2], E. Raschke[3], D. Phippard[3], **A. Bisconte**[3], B. Seliger[4], C. Wickenhauser[4], S. Olek[1]; [1]Precision for Medicine, Berlin, Germany, [2]Epimune GmbH, Berlin, Germany, [3]Precision for Medicine, Frederick, MD, [4]Martin Luther University Halle-Wittenberg, Halle/Saale, Germany

Chronic lymphocytic leukemia (CLL) is a hematological cancer classified as low-malignancy non-Hodgkin lymphoma that accounts for approximately a quarter of all leukemias. Since only some patients will develop aggressive cancer and require treatment, accurate disease prognosis is crucial. A wide range of parameters with prognostic value have been described, including age, clinical stage, mutational status, protein markers, and flow cytometry levels of CD19+CD38+ B cells above 20%. Here, we investigated epigenetic markers for B cell types including a marker for overall B cells, naïve B cells, memory B cells and IgM positive B cells in a cohort of more than 40 patients with B-CLL. When comparing to a cohort of more than 100 healthy donors, the epigenetic B cell marker identified all patients with 100% sensitivity and specificity. In addition, the epigenetic B cell markers for naïve and memory B cells identified with high sensitivity and excellent specificity a subgroup of B-CLL patients with CD19+CD38+ B cell levels above 20% which is associated with an unfavorable prognosis. The results suggest that the epigenetic analysis of B cells in capillary blood may be a promising tool for B-CLL diagnosis and disease prognosis.

#7652 Plasma markers of hemostasis, fibrinolysis, and angiogenesis prior to androgen deprivation therapy (ADT) in progressive prostate cancer (PC) and associations with long-term thrombotic events and survival.

Jessica S. Palmer, Charlene Thomas, Nicole Jacobs, David Nanus, Scott T. Tagawa

Weill Cornell Medicine, New York, NY

Background: PC is the third most common malignancy associated with thrombosis, procoagulants may play a role in tumorigenesis and progression, and patients (pts) with PC may have activation of the hemostatic system evident in plasma. The prognostic significance of these markers and their relationship to thrombotic events and overall survival (OS) are under-explored.
Methods: Patients >18 years were included if they had progressive PC planned to start ADT, were >6 months from surgery or RT, with no history of prior VTE, unexplained bleeding, current or planned anticoagulation, or an additional active malignancy. Plasma samples were obtained via peripheral venipuncture in tubes containing 3.2% sodium citrate and immediately placed on ice. Samples were analyzed for D-dimer, thrombin-antithrombin complex (TAT), IL-6, IL-8, VEGF, and tissue factor (TF) levels by ELISA. Patients had markers drawn at baseline (prior to initiation of ADT), 1 month, and 6 months after initiation.
Results: 40 patients were accrued with a median age of 68 years. At baseline, 29 (73%) had presence of metastases. Baseline median PSA was 15 and median PSA doubling time was 0.32. Baseline median hemoglobin was 13.85, platelets were 218, D-dimer was 322 ng/dL, IL-6 was 0 pg/mL, IL-8 was 0 pg/mL, TAT was 3 ug/L, VEGF was 21 pg/mL, and TF was 26 pg/mL. Median follow-up was 78 months. During follow up, 35 (87.5%) had metastases. 10 (25%) had thrombotic events (6 [15%] venous, 4 [10%] arterial) at median 37 months follow up. Median baseline age of pts with subsequent thrombotic events was 74, vs 67 in those without a thrombotic event. While there was no significant difference in baseline PSA between groups with and without clotting events, pretreatment PSA doubling time was significantly lower in pts with subsequent thrombosis (0.27 vs 0.35, p=0.047). Median baseline D-dimer and TF were higher in patients with subsequent thrombosis (D-dimer: 516 vs 282, p=0.10; TF: 36 vs 24, p=0.12). In univariate analysis, baseline IL-6 and VEGF were associated with OS (IL-6: HR=1.05, 95% CI [1.01,1.09], p=0.025; VEGF: HR=1.02, 95% CI [1.00,1.03], p=0.028). When controlling for presence of metastasis, baseline TAT was associated with OS (HR=1.05, 95% CI [1.00,1.11], p=0.055).
Conclusions: Plasma markers of hemostatic activation, fibrinolysis, and angiogenesis prior to initiation of ADT are associated with subsequent thrombotic events and overall survival years later. Further analysis will examine how these markers change over time with hormonal therapy.

#7653 Role of ITGB2 in patients with luminal B1 breast cancer.

C.-Y. Liu, J.-L. Chen, Y.-F. Tsai, T.-C. Chao, W.-L. Wang, P.-J. Lien, C.-Y. Hsu, J.-I. Lai, C.-C. Huang, J.-H. Chiu, L.-M. Tseng;
Taipei Veterans General Hospital, Taipei, Taiwan

Purpose: Luminal-type breast cancers are the most commonly diagnosed in women. Among them, the luminal B1 subtype exhibits higher proliferation rates and a worse prognosis compared to the luminal A subtype. Despite significant advancements in detection and therapies, recurrence still occurs after primary treatment. In this study, our aim is to identify genomic alterations in early recurrent luminal B1 breast cancer.
Experimental Design: In this VGHTPE cohort, we recruited a total of 42 patients diagnosed with stage I-III luminal B1 breast cancer, comprising 15 subjects who experienced recurrence within five years and 27 subjects who did not. Genomic DNA was extracted from formalin-fixed paraffin-embedded samples and subjected to targeted next-generation sequencing. We assessed cell aggressiveness through in vitro transwell migration, invasion, and sphere assays.
Results: Luminal B1 breast cancer patients with advanced stage and poorly differentiated tumors were associated with recurrence within five years. Driver gene mutation analysis revealed that *TP53* mutations were present in 46.7% of patients who experienced recurrence within five years, compared to 29.6% in the non-recurrence group. In the analysis of copy number variations, the most common amplifications/gains observed in luminal B1 breast cancer patients were in *MCL1*, *MYC*, and *KLF6*. Remarkably, patients who experienced recurrence within five years showed a higher occurrence of gain in *ITGB2*, the gene encoding the integrin β chain, compared to those who remained recurrence-free. Patients with *ITGB2* amplifications/gains had a shorter 5-year recurrence-free survival compared to those with a neutral status. *In vitro* studies revealed that the knockdown of ITGB2 suppressed cell migration, invasion, and sphere formation in estrogen receptor-positive HER2-negative breast cancer cells.
Conclusion: Our study has identified *ITGB2* amplifications/gains as a potential biomarker for early recurrence in luminal B1 breast cancer.

#7654 Tertiary lymphoid structure associates with poor prognosis in locally advanced esophageal squamous cell carcinoma treated with neoadjuvant chemoradiotherapy.

T.-C. Huang[1], C.-W. Liang[2], Y.-I. Li[2], J.-C. Guo[3], C.-C. Lin[1], J.-M. Lee[1], Y.-K. Chao[4], C.-H. Hsu[1];
[1]National Taiwan University Hospital, Taipei, Taiwan, [2]Fu-Jen Catholic University Hospital, New Taipei City, Taiwan, [3]National Taiwan University Cancer Center, Taipei, Taiwan, [4]Chang-Gung Memorial Hospital, LinKou, Taoyuamg, Taiwan

Introduction: Tertiary lymphoid structure (TLS) has been found to associate with good prognosis in various cancer types including esophageal squamous cell carcinoma (ESCC). A recent study involving patients receiving curative surgical resection alone for localized ESCC showed TLS as a favorable prognostic factor associated with improved progression free survival (Hayashi et al. British Journal of Cancer, 2023;128:2175-2185). Our study aimed to investigate the prognostic significance of TLS in patients with locally advanced ESCC receiving neoadjuvant chemoradiotherapy (CRT).
Patients and Methods: We retrospectively enrolled 137 patients of locally advanced ESCC patients from two referral centers of Taiwan from 2002 to 2018. All patients received paclitaxel/platinum-based CRT followed by esophagectomy. Primary esophageal tumor tissues biopsied endoscopically before treatment were collected for immunohistochemical stains for CD20 (clone L26; Zytomed, Berlin, Germany) and CD23 (clone DAK-CD23; agilent Dako, California, U.S.A.). The TLS status of each patient was defined as no TLS (no aggregation of CD20-positive cells), immature TLS (aggregation of CD20-positive cells without CD23-positive cells in it), and mature TLS (aggregation of CD20-positive cells with CD23-positive cells in it). The associations of the TLS status with pathologic complete response (pCR) and overall survival (OS) were analyzed univariately and multivariately by logistic regression and cox regression, respectively. The variables included in the analyses were age, gender, tumor location, clinical T stage, clinical N stage, the institutes, PD-L1 expression on tumor cells (PD-L1 TC) and immune cells (PD-L1 IC), and the TLS status.
Results: The median age was 54 years with 125 males and 12 females. The TLS status of no, immature, and mature TLS were seen in 64, 40, and 33 patients, respectively. Mature TLS was associated with PD-L1 IC (p=0.0007). Compared to no TLS, mature TLS associated with lower pCR rate (24% vs 47%) in both univariate (OR: 0.36, p=0.034) and multivariate (OR: 0.26, p=0.023) analysis. Compared to no TLS, mature TLS was associated with shorter OS (median OS: 27 vs 46 months) in multivariate analysis (HR: 2.96, p=0.0008), but not in univariate analysis (HR: 1.29, p=0.29). Other prognostic factors associated with OS in multivariate analysis include male gender (HR: 2.88, p=0.021), PD-L1 TC (HR: 1.62, p=0.039), and PD-L1 IC (HR: 0.30, p<0.0001).
Conclusion: Mature TLS is an independent factor for poor treatment outcomes, including pathologic response and overall survival in locally advanced ESCC patients receiving neoadjuvant CRT. Additional studies are warranted to validate this finding. (The study was supported by the grant NTUH 110-S5021, MOST 108-2314-B-002-076-MY3, and MOHW 111-TDU-B-221-114006)

#7656 Clinicogenomic anlaysis reveals a role for TP53 mutations in distant progression of high-grade glioma.

B.-H. Kang[1], S. Lee[2], J. Lee[2];

[1]Ewha Womans University School of Medicine, Seoul, Korea, Republic of, [2]Seoul National University College of Medicine, Seoul, Korea, Republic of

Purpose: High-grade glioma (HGG), the most common form of primary brain tumor, is highly lethal and treatment options remain limited. Despite advances in genomic technologies, there are few molecular biomarkers to guide precision medicine for HGG. Here, we aimed to identify the clinicogenomic features associated with HGG prognosis and recurrence patterns.

Methods: Our single-institution retrospective analysis included 220 patients initially diagnosed with adult HGG (grade 3 or 4) who underwent next-generation sequencing targeting 82 brain tumor-relevant genes. The patients were categorized according to the 2021 WHO classification and their clinical status, survival, genomic profile, and recurrence patterns were analyzed.

Results: At a median follow-up of 23 months (ranges, 2-59 months), 180 patients (82%) showed either progression or recurrence. A total of 15% of patients were reclassified under the 2021 WHO classification, revealing a clear separation of progression-free survival (PFS) and overall survival (OS) curves between grades 3 and 4 gliomas. We found that *TP53* mutations were significantly associated with the occurrence of distant progression, especially in grade 4 gliomas. Additionally, *TP53* mutations were more common in patients with higher Ki67 index and subependymal/leptomeningeal seeding, indicating an increased risk of distant progression in *TP53*-mutated grade 4 glioma patients. Following multivariate Cox regression analysis, *TP53* mutations were independent predictors of OS (hazard ratio [HR]=1.47, P=0.039) and distant PFS (HR=1.71, P=0.005).

Conclusion: Considering the elevated risk of distant progression in grade 4 gliomas with TP53 mutations, our results underscore the necessity for additional research into the most effective treatment approaches for these patients.

Keywords: high-grade glioma, *TP53*, pattern of failure, distant progression, next-generation sequencing

#7657 Detection of *KMT2A*-PTDs and *KMT2A* fusions using next generation sequencing.

J. Huang[1], H. Gu[2], J. Orton[2], M. Sedova[1], A. Marcovitz[1], J. Burke[1], S. Brozio[1], P. Williams[3], S. Myrand[3], N. Olowo[1], A. Broomer[4], B. Deal[1], C. Seeger[5], S. Sadis[3], S. Rozenzhak[4], F. Hyland[1], G. Liu[2];

[1]Thermo Fisher Scientific, South San Francisco, CA, [2]Sonora Quest Laboratories, Phoenix, AZ, [3]Thermo Fisher Scientific, Ann Arbor, MI, [4]Thermo Fisher Scientific, Carlsbad, CA, [5]Thermo Fisher Scientific, Guilford, CT

Introduction: *KMT2A (MLL)* rearrangements (fusions) is a therapeutic biomarker for Menin inhibitors. *KMT2A*-PTDs (partial tandem duplications) are considered a prognostic biomarker in myeloid malignancies. *KMT2A* fusions and PTDs are traditionally detected by RT-qPCR (quantitative real-time PCR). This study investigates *KMT2A* PTDs levels in healthy donors and myeloid malignancy samples to establish a threshold to report samples with high PTDs, using next generation sequencing (NGS) with Oncomine™ Myeloid Assay GX v2. We also report *KMT2A* fusions in myeloid malignancies.

Methods: We sequenced 8483 research samples with known myeloid malignancies at Sonora Quest Laboratories™ and at Thermo Fisher Scientific™. We acquired 20 healthy donor whole blood samples (total 127 replicates) from Stanford™ Blood Center and Discovery Life Sciences™ and sequenced them at 3 different sites of Thermo Fisher Scientific™. Samples were sequenced with the Ion Torrent™ Genexus™ 6.6 or Ion GeneStudio™ S5 System. They were profiled for 6 different *KMT2A*-PTD variants and 199 *KMT2A* fusion isoforms.

Results: The mean read length of this data set is 90 - 120 bp and the mean mapped fusion reads is 20,000 - 30,000. *KMT2A*-PTDs were detected in both healthy donors and myeloid samples. Healthy donor PTD read counts were consistently <2000 and averaged 1/3 of myeloid sample PTD read counts. About 33% of myeloid samples had higher PTD read counts than any healthy donor sample. BLAT (BLAST-Like Alignment Tool) analysis confirmed specific exon matching on the *KMT2A* gene in both cohorts. Among the 8483 myeloid samples, 162 samples contained a total of 5 unique *KMT2A* PTDs, and 105 samples contained a total of 30 unique *KMT2A* fusion isoforms with *KMT2A-MLLT1* and *KMT2A-MLLT3* being the most prevalent *KMT2A* fusion gene pairs.

Conclusions: We characterize the *KMT2A* fusions present in myeloid malignant samples. We also describe the abundance of *KMT2A* PTDs in both healthy donor and myeloid samples, with myeloid cases showing significantly higher PTD read counts. *KMT2A* PTD read count >2000 is present only in malignant samples but not in healthy donors. This intriguing finding opens opportunities for prospective studies to monitor individuals with elevated PTD levels for myeloid malignancy development and retrospective studies to explore whether healthy donors identified with this alteration years ago after blood donation were subsequently recorded in the national health system with myeloid malignancies.

#7658 Artificial intelligence-powered spatial analysis of tumor-infiltrating lymphocytes as a prognostic biomarker for pembrolizumab plus chemotherapy in recurrent or metastatic head and neck squamous cell carcinoma.

S. Park[1], J. Shin[1], C.-Y. Ock[2], C. Ahn[2], H. Jung[1], S.-H. Lee[1], M.-J. Ahn[1];

[1]Samsung Medical Center, Seoul, Korea, Republic of, [2]Lunit, Seoul, Korea, Republic of

Background: Programmed cell death ligand 1 (PD-L1) expression alone has limited predictive value for pembrolizumab plus 5-fluorouracil and platinum (PFP) therapy in recurrent or metastatic head and neck squamous cell carcinoma (HNSCC). An artificial intelligence (AI)-powered spatial tumor-infiltrating lymphocyte (TIL) analyzer may provide independent prognostic information.

Methods: This study included 63 patients with locally incurable HNSCC who received first-line PFP at Samsung Medical Center. Patients were classified into inflamed phenotype (IP) or non-inflamed phenotype (NIP) based on the 5% proportion threshold of inflamed 1 mm^2-sized grids over total grids within hematoxylin and eosin-stained whole-slide images (WSIs) analyzed using Lunit SCOPE IO. We evaluated the prognostic value of inflamed status and densities of intratumoral TILs (iTILs), stromal TILs (sTILs), and tumor microenvironment TILs (tTILs).

Results: Patients were predominantly male (78%). The median age at PFP initiation was 57 years. The most common primary tumor site was oral cavity (49.2%), followed by oropharynx (16%) and hypopharynx (10%). Of the 37 patients with available PD-L1 combined positive score (CPS), 2 (5%), 23 (62%), and 12 (32%) had CPS values of <1, 1-19, and ≥20, respectively. The overall response rate was 54%, with 67% in the CPS ≥20 subgroup and 48% in the CPS <20 subgroup. The median progression-free survival (PFS) was 7.2 months, with 10.8 months for patients with CPS ≥20 and 5.5 months for patients with CPS <20. The median overall survival (OS) was 18.6 months. Among 62 patients with available WSIs, 47 (74%) and 15 (26%) patients were categorized as having an IP and NIP, respectively. Oral cavity cancer was enriched with IP (57.4% of all IP cases vs 26.7% of all NIP cases), while all four paranasal sinus tumors had NIP. The overall response rate was 57% in the IP group and 44% in the NIP group. Patients with IP had significantly longer PFS and OS than patients with NIP, both in unadjusted (hazard ratio
[HR] for PFS, 0.4; 95% confidence interval [CI], 0.21-0.78; P = 0.007; HR for OS, 0.43; 95% CI, 0.2-0.95; P = 0.036) and PD-L1 CPS-adjusted analyses (HR for PFS, 0.41; 95% CI, 0.21-0.79; P = 0.008; HR for OS, 0.4; 95% CI, 0.18-0.89; P = 0.025). High densities (≥25th percentile) of iTILs, sTILs, and tTILs were all significantly associated with prolonged PFS after CPS adjustment (P = 0.001, 0.001, and 0.012). High density of iTILs was also significantly associated with improved OS (P = 0.001 after CPS adjustment), while there was no significant association between OS and high density of sTILs or tTILs (0.077 and 0.085, respectively, after CPS adjustment).

Conclusion: An AI-driven spatial TIL analyzer might serve as a simple and independent prognostic biomarker in HNSCC patients receiving pembrolizumab plus chemotherapy.

#7659 AI-driven hypothesis-free analysis for biomarker discovery: Introducing the Biomarkers Navigator Framework.

I. Kagiampakis[1], M. Gidwani[2], I. Korkodinov[2], G. Ponomarev[2], E. Jacob[3];
[1]AstraZeneca US, San Francisco, CA, [2]AstraZeneca US, Gaithersburg, MD, [3]AstraZeneca US, Waltham, MA

The pivotal role of biomarkers in personalizing patient treatment and guiding drug development is well-recognized, with the ultimate goal of enhancing therapeutic efficacy and patient quality of life by minimizing adverse events. Their development, however, is challenged by strict regulations and high costs, leading to sparse and varied data collected over extended periods and through diverse technologies. These variations complicate the harmonization and analysis of the data. Traditional methods struggle to navigate these complexities, further obscuring biomarker identification. For instance, PDL-1, approved as a biomarker by the FDA, has its effectiveness debated in several studies. To address these issues, we introduce Biomarkers Navigator, a flexible and automated analysis framework engineered explicitly for the robust identification of biomarkers. This framework is designed to aggregate, standardize, and store expansive biomarker information, ensuring efficient and traceable knowledge retrieval. By pre-calculating each potential biomarker, Biomarkers Navigator enables immediate and comprehensive meta-analyses, facilitating rapid decision-making tailored to the level of risk acceptance. Large Language Models (LLMs) further enhance the framework's capability to uncover signatures of response and resistance. LLM integration has accelerated the discovery of new potential biomarkers for hematological malignancies by combining prior knowledge and previously obscured associations. Our approach demonstrates the feasibility of large-scale hypothesis-free analysis and substantiates the utility of AI in unveiling hidden biological connections within clinical data. Our findings underscore the potential of AI-augmented frameworks in revolutionizing biomarker discovery and advancing personalized medicine.

#7660 L-Arginine metabolism is of prognostic relevance in women with breast cancer, but varies considerably between subtypes in vitro - A bedside-to-bench translational approach.

J. Hannemann[1], L. Oliveira Ferrer[1], A. Roglin[1], F. Kleinsang[1], V. Muller[1], I. Witzel[2], R. Boger[1];

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]University Hospital Zurich, Zurich, Switzerland

Availability of the semi-essential amino acid L-arginine (L-arg) is limiting for proliferation in highly proliferative tissues. L-Arg is also a substrate for nitric oxide synthases (NOS) and arginases (ARG) 1 and 2. Methylation of L-arg residues within proteins by protein L-arg methyltransferases (PRMTs) leads to asymmetric (ADMA) and symmetric dimethylarginine (SDMA). Protein L-arg methylation is an important post-translational mechanism to regulate gene expression and cell cycle control. We measured L-arg and its metabolites in a prospective cohort of patients with primary breast cancer (BC). We further measured these metabolites and expression of genes involved in L-arg metabolic pathways in cell lines representing intrinsic BC subtypes. Plasma L-arg-related metabolite concentrations from 243 women with primary BC were associated with total mortality and disease recurrence during a median follow-up of 88 (IQR, 82-93) months. MCF-7, BT-474, SK-BR-3, and MDA-MB-468 cells representing ER-positive, HER2-positive, and triple negative BC were cultured in standard conditions and compared to MCF-12A normal breast epithelial cells. The plasma (*in vivo*) and intracellular concentrations (*in vitro*) of L-arg, L-ornithine (L-orn), L-citrulline (L-cit), ADMA, and SDMA were measured by UPLC-MS/MS. mRNA expression was quantified by qRT-PCR and protein expression was analyzed by Western Blot. In vivo, the plasma concentrations of all L-arg metabolites differed significantly between BC patients and healthy controls. L-Arg and ADMA were significantly higher in patients with recurrent disease and in those who died during follow up. ADMA was significantly associated with total mortality and recurrent disease in Luminal A patients; low L-orn/L-arg ratio was associated with survival in HER2+ BC patients, and low L-cit was associated with survival in triple negative BC. With the exception of MCF-7 cells, DDAH1 and DDAH2 mRNA concentrations in vitro were significantly higher in BC cells than in MCF-12A cells (DDAH1: 32-44 fold, DDAH2: 1.7-4.2 fold; $p<0.05$). These differences were mirrored by DDAH1 and DDAH2 protein concentrations. By contrast, MCF-7 cells were characterized by low DDAH1 and DDAH2, but high PRMT4 and PRMT6 mRNA expression and high L-arg content. BT-474 cells showed high ARG2 expression and high L-arg and L-orn concentrations, and MDA-MB-468 cells had the highest L-cit/L-arg ratio. In conclusion, regulation of L-arg metabolic pathways shows a complex and differential pattern between intrinsic BC subtypes, which is mirrored in representative cell lines in vitro. ADMA is a prognostic biomarker in Luminal A breast cancer patients; its metabolizing enzyme, DDAH, is highly overexpressed in BC cells in vitro. Thus, fingerprinting of L-arg metabolism may offer novel personalized treatment options within intrinsic BC subtypes.

#7661 Integrating radiomic features from primary tumor and lymph node for survival prediction of HPV-associated oropharyngeal squamous cell carcinoma.

B. Song[1], A. Leroy[2], K. Yang[3], Q. Liu[4], X. Li[1], J. Lee[3], S. Stock[3], N. F. Saba[1], J. S. Lewis, Jr.[5], E. Deutsch[6], M. Bilen[7], S. A. Koyfman[3], A. Madabhushi[1]; [1]Emory University, Atlanta, GA, [2]therapanacea, Paris, France, [3]Cleveland Clinic, Cleveland, OH, [4]California State University, Los Angeles, CA, [5]Vanderbilt University Medical Center, Nashville, TN, [6]Paris-Saclay University, Paris, France, [7]Winship Cancer Institute, Atlanta, GA

Background: HPV-associated oropharyngeal squamous cell carcinoma (OPSCC) is a unique disease with improved prognosis which could benefit from treatment de-escalation. Current radiographic-based biomarkers mainly focus on primary tumor (PT) alone, neglecting the potential prognostic value from the lymph node (LN). In this work, we constructed a radiomic model integrating texture features from both PT and LN to predict overall survival (OS) in HPV-associated OPSCC patients.

Methods: Pretreatment CT scans for 647 OPSCC patients treated with definitive radiation with or without chemotherapy were acquired from The Cancer Imaging Archive (TCIA) and the Cleveland Clinic (CCF), which were divided into training set D_1 (n=294) and test set D_2 (n=353). PT and LN contours were annotated by three. 2045 texture radiomic features were extracted from both PT and LN and were concatenated as input to a LASSO Cox model to predict OS. We used the harrell's concordance index (C-index) and hazard ratio (HR) to evaluate the prognostic performance. We also performed the multivariable cox proportional hazard analysis adjusting for clinicopathological variables to validate the independent prognostic significance.

Results: Among the 647 patients, median follow-up time was 70.23 months, with 155 patients (24%) experienced death. 22.6%, 38.8%, 23.2% and 15.4% had T stage I, II, III and IV tumors, respectively. 203 patients (31.4%) were treated with radiation alone. The model integrating PT and LN (M_PTLN) yielded higher C-index compared to PT alone (M_PT) on D1 (0.74 vs 0.66) and on D2 (0.64 vs 0.61). In univariate analysis on D2, M_PTLN is prognostic of OS (HR, 2.26; 95% CI, 1.32 - 3.87; log rank p = 0.003). In multivariable analysis, M_PTLN is still statistically significant (p = 0.04) accounting for clinicopathologic factors (age, gender, smoking pack-year [PY], T stage, N stage and treatment modality).

Conclusions: We developed and validated a CT-based survival prediction model for HPV-associated OPSCC patients with significant prognostic values, accounting for both primary tumor and lymph node. If prospectively validated, the model has the potential to inform trial eligibility and treatment-related decision making.

#7662 Convolutional neural network algorithms and hematoxylin-and-eosin-stained images predict clinical outcomes in high-grade serous ovarian cancer patients with advanced age and stage.

C. Ng, K.-k. Wong, B. Lawson, S. Ferri-Borgogno, S. Mok;
UT MD Anderson Cancer Center, Houston, TX

Ovarian cancer is the deadliest among gynecologic cancers. It is partly due to the mild symptoms in early stages and relatively high diagnostic age (about 63-year-old median age). These factors contribute to the short chemotherapy response time and survival time with about 18- and 36-months median progression-free survival and overall survival duration, respectively. The advancements of convolutional neural network (CNN) machine learning algorithms provide opportunities for the development of cost- and time-effective models which is urgently needed for ovarian cancer patients, especially for those with elevated risk. A CNN model was trained with hematoxylin and eosin (H&E) stained tumor whole slide images (WSIs) from ovarian cancer patients with advanced stages. 773 WSIs of 335 patients from TCGA-OV dataset were separated randomly for training and testing cohort. The model was then applied on testing cohort with advanced stage and age patients for H&E survival score. The c-index of the predicted risk on overall survival (OS) and progression-free survival (PFS) were 0.66 and 0.63, respectively. The log-rank p-values of patients between low and high risk were 0.00137 and 0.00138, respectively. The model was then further evaluated with an external dataset. The c-index of the predicted risk were 0.64 and 0.72 for OS and PFS, respectively. And the log-rank test between patients with low and high risk achieved p-values 0.017 and 0.0047 for OS and PFS, respectively. In conclusion, a novel prognostic CNN model was developed for ovarian cancer patients with advanced age and stage for better disease management.

#7663 Identification of high-risk patients in multiple myeloma using a clonal gene signature.

J.-R. Li, C. Wang, C. Cheng;
Baylor College of Medicine, Houston, TX

Introduction: Multiple myeloma (MM) is a heterogeneous disease with a small subset of high-risk patients associated with poor prognosis. The identification of these patients is crucial for treatment management and strategic decisions.
Methods: We developed a novel computational framework that only requires gene expression profiles to define prognostic gene signatures by selecting genes with expression driven by inferred clonal copy number alterations. We applied this framework to MM and developed a clonal gene signature (CGS) consisting of only 22 genes. This prognostic signature was evaluated in 5 independent datasets with gene expression data of a total of 2,155 MM samples. For each patient, we calculated a prognostic score based on the expression of the signature genes. Multivariate Cox regression analyses were performed to investigate the association of these signature scores with patient prognosis after adjusting established clinical factors. The performances of CGS and the only commercialized MM gene signatures, GEP70 and SKY92, in identifying high-risk patients were carefully compared by multiple different approaches.
Results: Our results indicated that CGS provided significant prognostic values after adjusting for well-established prognostic factors including cytogenetic abnormalities, International Staging System (ISS), and Revised ISS (R-ISS). In addition, it showed significant prognostic associations in patient subsets stratified by these conventional prognostic factors. Importantly, CGS demonstrated a better performance in identifying high-risk patients compared to the GEP70 and SKY92 signatures, which have been recommended for prognostic stratification in MM. Moreover, CGS can further stratify patients into subgroups with significantly differential prognoses when applied to the high-risk and low-risk groups already identified by GEP70 and SKY92. The higher CGS score of patients is significantly associated with poor response to dexamethasone, a commonly used drug for MM treatment.
Conclusions: In summary, we proposed a computational framework that only requires gene expression data to identify clonal gene signatures for prognosis prediction. The CGS provides a useful biomarker for improving prognostic stratification in MM, especially for the identification of patients with the highest risk. The computational framework used for defining this signature provides a useful tool, which can be readily applied to many other cancer types.

#7664 Early detection of racial disparity and treatment resistance in triple negative breast cancer.

A. H. Tang[1], R. A. Hoefer[2], M. L. Guye[3], B. Samli[4], J. S. Winston[4], J. Koblinski[5], V. Robila[5], M. O. Idowu[5], R. J. Jansen[6], H. D. Bear[5];
[1]Eastern Virginia Medical School, Norfolk, VA, [2]Sentara Cancer Network, Norfolk, VA, [3]Sentara Surgery Specialists, Newport News, VA, [4]Sentara Norfolk General Hospital, Norfolk, VA, [5]Virginia Commonwealth University, Richmond, VA, [6]University of Minnesota, Minneapolis, MN

Introduction: Triple-negative breast cancer (TNBC) is an aggressive breast cancer subtype that disproportionately affects BRCA1 mutation carriers and young Black/African American (AA) women. Black/AA patients have the highest mortality and the shortest survival of any racial/ethnic group in the US. With the approval of pembrolizumab, the addition of immune checkpoint blockade (ICB) to neoadjuvant chemotherapy (NACT) has become the standard of care (SOC) for high-risk early-stage TNBC. The pathologic complete response (pCR) is a reliable prognostic marker that correlates with tumor remission and good outcome, whereas pathologic incomplete response (pIR) with high residual cancer burden (RCB) is often associated with early relapse, treatment resistance, and poor survival. Many similarly-treated patients with identical TNM and RCB classifications still experience racial disparity, different relapse rates, and disparate survival. Current methods fall short in predicting tumor recurrence/chemo-resistance/patient survival with high accuracy in the clinic.
Methods: We detected a major racial disparity in our large regional cohorts of TNBC patients (> 1,000 patients), of which 48% patients are Black/AA and 48% patients are white patients, at the Sentara Cancer Network and VCU Massey Comprehensive Cancer Center, that have historically provided excellent healthcare and quality cancer care to the social-economically-disadvantaged, medically underserved, and underinsured racial/ethnic minorities in low income communities in Virginia. Despite Sentara/VCU's best efforts, Black/AA breast cancer patients still suffer 70-100% higher MBC mortality, and the worst survival compared to their white counterparts, based on our clinical studies and the SEER/CDC databases.
Result: We showed that persistent EGFR/RAS/SIAH pathway activation is a major driving force of TNBC malignancy. The most downstream and evolutionarily conserved signaling gatekeeper, SIAH, is an RING domain E3 ligase that is a high-resolution prognostic biomarker for patient risk stratification and racial disparity prediction in TNBC. High SIAH expression in residual tumors reflects ineffective NACT/IO therapy and persistent EGFR/K-RAS/SIAH pathway activation (ON) that drives tumor relapse, resistance, and reduced survival. Low SIAH expression in residual tumors reflects effective NACT/IO therapy and EGFR/K-RAS/SIAH pathway inactivation (OFF) that predicts tumor remission, good outcome, and prolonged survival. We found that SIAH expression is 2.0-fold higher in Black/AA patients' residual tumors than in the white patients' residual tumors, mirroring a 1.8-2.0-fold higher death rates in the Black/AA patients than the white patients.
Conclusion: In this study, we demonstrate the prognostic power of SIAH for patient risk stratification, therapy quantification, and relationship to cancer racial disparity in TNBC.

#7665 Detection of γ-OHPdG as a hepatocellular carcinoma recurrence biomarker by CTCs and LC-MS/MS.

M. Kuo[1], M. Aktop[1], E. Ghabi[2], M. A. Ouf[1], M. Carder[3], V. Muralidaran[1], J. Ascue[1], M. Hlouskova[3], P. Wu[2], G. Cheng[4], S. S. Hecht[4], H.-B. Fang[1], N. Hanna[3], J. He[2], A. H. Kroemer[1], M. Aggarwal[1], A. R. He[1], **F.-L. Chung**[1];

[1]Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC, [2]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD, [3]University of Maryland Medical Center, Baltimore, MD, [4]Masonic Cancer Center, University of Minnesota, Minneapolis, MN

Background: Hepatocellular carcinoma (HCC) is the third leading cause of cancer death globally. Recurrence risks following curative resection remain high, ~50% after three years and 75-100% over five years. A biomarker for HCC recurrence is urgently needed to help lead treatment strategies. We previously showed that hepatic γ-hydroxy-1, N^2-propano-2′-deoxyguanosine (γ-OHPdG), a DNA adduct derived from lipid peroxidation, increased during hepatocarcinogenesis. Furthermore, in a retrospective study, higher γ-OHPdG levels in post-surgical liver tumor tissues were associated with poorer survival ($p<0.0001$) and shorter recurrence-free survival ($p=0.007$), suggesting that it may be a prognostic biomarker for HCC (Hepatology 2018). In this study, we aimed to test γ-OHPdG detected in livers after curative resection as a recurrence biomarker in a prospective study and, in addition, we developed a new non-invasive method for γ-OHPdG in circulating tumor cells (CTCs). This multicenter study seeks to validate γ-OHPdG as a biomarker for HCC recurrence.

Methods: A total of 28 HCC patients undergoing hepatectomy at MedStar/Georgetown University Hospital, Johns Hopkins University Hospital, and the University of Maryland Medical Center were enrolled. γ-OHPdG was detected in DNA isolated from hepatic tumors and non-tumors by a previous liquid chromatograph-tandem mass spectrometry (LC-MS/MS) method and in HCC CTCs isolated from blood samples. CTCs were isolated using hepatocyte-specific rabbit anti-asialoglycoprotein-1 (ASGPR-1), followed by staining with mouse anti-γ-OHPdG antibodies. Clinical outcomes were correlated with γ-OHPdG in liver tissues and CTCs.

Results: In our current cohort of 28 patients (mean age: 64.7 years; 82% male), five patients experienced HCC recurrence, with an estimated progression-free survival (PFS) rate of 85% over 8 months. γ-OHPdG levels (adducts/10^9 nucleotides) detected by LC-MS/MS varied widely in tumor tissues (5-56, mean: 11.8) and non-tumor tissue (7-71, mean: 20.6). Preliminary analysis showed shorter PFS associated with γ-OHPdG in non-tumors (cutoff: 16, $p=0.0271$). γ-OHPdG (arbitrary units x10^7) in CTCs also varied widely in the nucleus (0.95-18.84, mean: 2.85) and in the whole cell (0.16- 52.18, mean: 9.72). Total CTC γ-OHPdG intensity in both the nucleus ($p=0.006$) and in the whole cell ($p=0.005$) was associated with its levels in non-tumor tissue. Furthermore, a shorter PFS was associated with CTC count (cutoff: 270 cells, $p=0.01$), and total CTC whole cell γ-OHPdG intensity (cutoff: 21.17x10^7 arbitrary units, $p=0.002$).

Conclusion: Preliminary results suggest that γ-OHPdG, measured in tissues by LC-MS/MS and in blood by CTC, predicts HCC recurrence. Once evaluated in all enrolled subjects, multiple variant analyses will be carried out to include stage, AFP, grade of differentiation, vascular invasion on surgical samples, and status of viral hepatitis infection.

#7666 Type XVII collagen as potential biomarker of epithelial damage in patients with atopic dermatitis and patients with metastatic colorectal cancer.

M. Crespo-Bravo[1], N. N. Nissen[1], R. S. Pedersen[1], M. K. Boisen[2], M. Liljefors[3], A. Z. Johansen[2], J. S. Johansen[2], M. A. Karsdal[1], N. Willumsen[1];
[1]Nordic Bioscience, Herlev, Denmark, [2]Copenhagen University Hospital - Herlev and Gentofte, Herlev, Denmark, [3]Intervention and Technology, Karolinska University Hospital Huddinge, Stockholm, Sweden

Background Type XVII collagen is a membrane-associated collagen with interrupted triple-helices (MACIT) facilitating adhesion between the basement membrane (BS) and epithelial cells. Mutations in *COL17A1* lead to junctional epidermolysis bullosa (JEB), while autoimmunity against type collagen XVII ectodomain can cause bullous pemphigoid (BP). In multiple epithelial cancers, both type XVII collagen and its shed ectodomain are associated with cancer development and invasiveness. This study aims to assess the potential of type XVII collagen as an epithelial damage biomarker in patients with metastatic colorectal cancer (mCRC) and in patients with skin diseases like atopic dermatitis (AD) and psoriasis. Methodology Type XVII collagen ectodomain levels were measured in serum using a competitive ELISA (nordicPRO-C17). The study included two cohorts: cohort 1 comprised 212 patients with mCRC and 28 healthy controls and cohort 2 included patients with AD (n=8) or psoriasis (n=3). PRO-C17 levels in mCRC patients were compared to 28 healthy controls using a t-test. The association between PRO-C17 levels and overall survival (OS) was evaluated by categorizing patients into low PRO-C17 levels (tertiles 1+2) and high PRO-C17 levels (tertile 3). Kaplan-Meier curves and the log-rank test were used to assess differences in survival between the two groups. The independent predictive value of PRO-C17 was evaluated using multivariate Cox analysis. PRO-C17 levels in AD and psoriasis patients were compared to 15 healthy controls using one-way ANOVA, followed by multiple comparisons with Dunn's test. Results PRO-C17 levels were elevated ($p<0.05$) in mCRC patients treated with bevacizumab compared to healthy controls. Patients with high PRO-C17 levels had a shorter overall survival (390 days) compared to those with low levels (539 days) ($p=0.007$). High levels of the biomarker were associated with an increased risk of mortality and PRO-C17 levels were independent of other risk factors, such as the number of drugs in the treatment regimen, tumor location, synchronous metastatic disease, primary tumor resection, performance status, and the number of metastatic sites (HR=1.43, 95% CI 1.01-2.01, $p=0.044$). Further, patients with AD had increased PRO-C17 levels ($p=0.0057$), while patients with psoriasis showed no significant differences in biomarker levels compared to healthy controls ($p=0.58$). Conclusions This study demonstrated that high PRO-C17 levels were independently associated with shorter OS and an increased risk of mortality in patients with mCRC. Additionally, elevated levels of PRO-C17 were observed in patients with AD. These findings suggest that type XVII collagen may serve as a reflection of epithelial damage in the invasive front during tumor metastasis. The role of this biomarker in other cancer types and skin diseases warrants further exploration.

#7667 Neutrophil to lymphocyte ratio (NLR) as an indicator of tumor immune status in non-small cell lung cancer.

R. Yoshichika[1], K. Iwata[1], K. Suzawa[2], Y. Thu[1], D. Mizuno[1], T. Higashihara[1], N. Hayashi[1], A. Matsuoka[1], M. Yoshikawa[1], F. Mukohara[1], K. Shien[2], H. Yamamoto[2], S. Toyooka[1];

[1]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, [2]Okayama University Hospital, Okayama, Japan

Background: Neutrophil to lymphocyte ratio (NLR) has been reported as a prognostic biomarker in non-small cell lung cancer (NSCLC), while its biological rationale has yet to be clarified. In cancer patients, inflammation and immune status plays crucial roles in tumor growth and the prognosis. While several studies have explored the relationship between NLR and inflammation, there are few reports on the relationship between NLR and immune status in the tumor microenvironment of cancer patient so far. The purpose of this study is to explore the potential utility of NLR as a surrogate biomarker for assessing the immune response to tumors.

Methods: The medical records of NSCLC patients who underwent surgery at our institution in 2012 were retrospectively reviewed. The patients' clinical information including age, sex, performance status, smoking history, histology, clinical stage (7th), and NLR, was obtained. NLR was calculated based on blood tests conducted within a month before surgery. Tumor immune status was evaluated by Immunohistochemical staining for CD3, CD8, and FOXP3 in their surgical specimens. The relationship between NLR, clinicopathology, and tumor immune status was examined. The survival curves were estimated using the Kaplan-Meier method and compared using the log-rank test. Blood cell counts and ratios between different groups were compared using nonpaired t test or Mann-Whitney U test, with a significance threshold set at $p = 0.05$.

Results: A total of 120 patients were included. The 5-year overall survival rate (OS) in all 120 patients was 63.4%. The 5-year OS of the patients with lower NLR was significantly better than those with high NLR (low < 2.2 vs high ≥ 2.2; 70.1% vs 56.8%, $p = 0.042$). The 5-year OS of the patients with high density of CD3+ TILs was significantly better than that in patients with low density of CD3+ TILs (high ≥ 242 vs low < 242; 70% vs 56.8%, $p = 0.019$). The 5-year OS of the patients with high density of CD8+ TILs was significantly better than that in patients with low density of CD8+ TILs (high ≥ 112 vs low < 112; 72.4% vs 54.1%, $p = 0.011$). Conversely, the 5-year OS of the patients with low density of FOXP3+ TILs was significantly better than that in patients with high density of FOXP3+ TILs (high ≥ 7.5 vs low < 7.5; 46.2.% vs 79.6%, $p = 0.0006$). The number of CD3+ TILs had negative correlation with NLR ($p = 0.005$), while the number of CD8+ TILs and FOXP3+ TILs didn't exhibit an association with NLR.

Conclusion: Our results suggest that NLR might potentially reflect immune status in the tumor microenvironment, explaining its impact on the prognosis of NSCLC patients. While further research is needed, these findings may offer valuable insights for guiding treatment options.

#7668 Novel pretreatment nomograms based on pan-Immune-inflammation value for predicting clinical outcome in patients with head and neck squamous cell carcinoma.

Q. Chen, X. Li, Y. Bai, Y. Chen;
The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: The prognostic value of an effective biomarker, Pan-Immune-Inflammation Value (PIV), for head and neck squamous cell carcinoma (HNSCC) patients after radical surgery or chemoradiotherapy has not been well explored. This study aimed to construct and validate nomograms based on PIV to predict survival outcomes of HNSCC patients.
Methods: 161 HNSCC patients underwent radical surgery and 50 patients received chemoradiotherapy were enrolled retrospectively for development and external validation cohort, respectively. The cut-off of PIV was determined using the maximally selected rank statistics method. Multivariable Cox regression and least absolute shrinkage and selection operator (LASSO) regression analyses were performed to develop two nomograms (Model A and Model B) that predict disease-free survival (DFS).
Results: Patients with higher PIV (≥123.3) experienced a worse DFS (HR: 5.01, 95% CI: 3.25-7.72, p<0.0001) and overall survival (OS) (HR: 5.23, 95% CI: 3.34-8.18, p<0.0001) compared to patients with lower PIV (<123.3), which was also consistent in the external cohort. Predictors of Model A included age, TNM stage, neutrophil-to-lymphocyte ratio (NLR) and PIV, and that of Model B included TNM stage, lymphocyte-to-monocyte ratio (LMR) and PIV. In comparison with TNM stage alone, the concordance index (C-index), receiver operating characteristic (ROC) curves and calibration curves of the nomograms demonstrated good calibration and discrimination, and the decision curve analysis (DCA) also showed satisfactory clinical utility in both internal and external validation.
Conclusions: The nomograms based on PIV, a simple but forceful indicator, can provide intuitive and precise prognosis prediction of individual HNSCC patients after radical surgery or chemoradiotherapy.

#7669 Use of computational pathology to predict biochemical recurrence in prostate cancer (Pca) (Rp) patients following radical prostatectomy: Evaluation in low decipher risk category.

K. Hammouda[1], T. Pathak[1], T. Mirtti[2], P. Lal[3], S. Gupta[4], A. Madabhushi[1];
[1]Emory University, Atlanta, GA, [2]University of Helsinki, Helsinki, Finland, [3]Hospital of the University of Pennsylvania, Philadelphia, PA, [4]The Cleveland Clinic Taussig Cancer Institute, Cleveland, OH

Background: Current tools for predicting prostate cancer biochemical recurrence (BCR) after RP often depend on parameters determined by pathologists, such as tumor grade, which is known to vary between reviewers. Genomic risk classifiers provide useful information but require substantial tissue, are costly, and are not commonly accessible in many medical centers. The study presents an artificial intelligence (AI) model for automated risk assessment of biochemical recurrence (BCR) by analyzing nuclear morphologic patterns from Pca archival H&E slides. Nuclear morphometric features are essential for disease diagnosis and gaining insights into cellular functions. Specifically, we sought to evaluate whether the computational pathology approach could provide additional granular risk stratification within the low-risk group identified by Decipher.
Methods: The study employed two cohorts from the University of Pennsylvania D_1 and D_2. D_1 comprised 180 patients, while D_2 comprised 175 patients, including 63 individuals from the Decipher low-risk group. None of the patients in either cohort had received any pre-operative treatments. Within the Decipher cohort, a tumor segmentation model was created using the U-net deep learning network. The HoVer-Net model was used to both segment and classify nuclei. The feature extracted included a combination of nuclear texture and quantitative measurements of the spatial arrangement of nuclei. The eleven most significant features, selected via the least absolute shrinkage and selection operator (LASSO), were utilized to build a Cox regression model for predicting the risk of BCR in D_1. In D_2, patients were classified as either low-risk or high-risk for BCR based on the median risk score derived from D_1.
Results: Patients from D_1 identified as high risk by the AI model experienced shorter survival, with a median BCR time of 27 months, in contrast to 55 months for those classified as low risk. The AI model demonstrated significant prognostic value for BCR in both D_1 (HR = 6.82, 95% confidence interval [CI]: 3.54-13.12, $p < 0.0019$), and D_2 (HR = 2.72, 95% CI: 1.53-4.82, $p < 0.0032$). Furthermore, the model effectively stratified the Decipher low-risk group in D_2 into distinct low and high-risk categories (HR = 4.52, 95% confidence interval [CI]: 1.70-12.05, $p < 0.0085$). The most prognostic features identified included five related to nuclei shape diversity (Minor Axis Length, Eccentricity, Equivalent Diameter, Solidity, and Circularity) in conjunction with nine nuclear texture features.
Conclusions: The AI model's findings suggest that a digital image-based prognostic classifier for prostate cancer could serve as an alternative or complementary method to molecular-based companion risk tests. Additional, independent multi-site and prospective validation of these findings are warranted.
