Methods: Urine was stabilized using a urine collection/stabilization solution under development at PreAnalytiX (QIAGEN/BD Company) or STRECK as preservative. Blood was collected in PAXgene Blood ccfDNA Tubes (PreAnalytiX). Matched blood and urine cfDNA samples from 122 metastatic prostate cancer patients were isolated using the QIAsymphony platform. Tumor fraction and presence of somatic copy number alterations (SCNA) were assessed from shallow whole genome sequencing data using the ichorCNA algorithm.
Results: In 22/122 (18%) of patients SCNAs could be detected in both, urine and blood. Although the copy number profile was highly concordant in those patients, tumor fractions varied between plasma and urines on an individual patient level. In addition, in 52/122 (43%) and 48/122 (39%) patients, tumor-derived DNA was detected only in plasma or urine. Considering the entire cohort, neither the absolute cfDNA concentration nor tumor fraction did significantly differ between urine and plasma samples.
Conclusion: Our data demonstrate that ucfDNA can provide complementary information to blood about prostate tumors, which would be missed by the sole analysis of plasma cfDNA. Taking this into account and adding that urine represents a non-invasive specimen type that can be collected at great ease, ucfDNA holds promise in the clinical management of prostate cancer.

#2424 Detection of prostate cancer in urine by fragment-level DNA methylation analysis.

T. Bedekovics, W. R. Taylor, Z. Sun, S. Baheti, X. Cao, K. N. Burger, K. A. Doering, P. H. Foote, B. Gochanour, D. W. Mahoney, M. T. Gettman, J. B. Kisiel; Mayo Clinic, Rochester, MN

Introduction: Screening for prostate cancer (PCa) with molecular markers is hindered by low tumor allele fraction (TAF) in liquid biopsy samples such as blood or urine. Others have suggested that tumor allele enrichment can be achieved by evaluating fragment-level methylation patterns generated by next generation sequencing (NGS). Here, we test this concept using target capture NGS on cfDNA from prediagnostic collected urine samples to discriminate PCa from otherwise healthy men.

Methods: Buffered urines were collected from 23 patients with biopsy confirmed PCa (Gleason score 6-9) and 24 otherwise healthy age matched cancer-free controls. cfDNA was isolated and enzymatic methyl-seq libraries were prepared and enriched by hybrid capture using probes mapping to 197 differentially methylated regions (DMRs) from a previous PCa/normal tissue marker discovery study in our lab. These DMRs were subsequently vetted independently using a methylome-wide dataset from a cohort of 36 clean and disease control urines to ensure low non-cancer background signal (<1%). Indexed libraries were sequenced at 560X deduplicated coverage and fragment-level CpG methylation information was extracted from individual sample .bam files. Mapped sequencing reads exhibiting concordant methylation were used to derive a quantitative α-score. Reads had to contain at minimum 5 CpGs and have an α-value (% 5mC per read) > 60%. Positivity for the 197 markers required an α-score greater than 6 sigma (σ) above the mean of the control arm. Values were variance-adjusted to ensure equal weighting. Beta (β) analysis (mean % 5mC across all reads) of the data was also performed for comparison.

Results: Of the 197 markers, 187 were positive for one or more PCa patients. Tumor-derived fragments were detected in 22 of 23 cases, which included 8 G-6, 9 G-7, 2 G-8, and 3 G-9 patients. 1 G-7 was missed, however the sequencing coverage for this sample was significantly lower than the others due to poor library enrichment. 2 of the 24 healthy controls were positive, one with extremely high fragment counts. Upon re-review of the full control cohort, this patient had been diagnosed with bladder cancer 2 years after urine collection. The 2nd patient had was diagnosed with lung cancer in a similar timeframe. The other 22 confirmed cancer-free controls had α-scores below the 6σ threshold. Using a co-captured reference gene (*B3GALT6*) to mimic genomic equivalents, the TAFs ranged from 0.015% to 8%. β analysis of the data detected only 13 PCa patients (>6σ) and marker positivity was lower than the fragment-level approach.

Conclusion: Target capture NGS coupled with fragment-level analysis is a rational approach for sensitive and specific detection of low tumor-derived DNA in liquid biopsy samples. For PCa assay in urine, we were able to uncover positivity in cancer patients approaching 1 in 10,000 ctDNA dilution levels. These results warrant further validation studies with this and other cancers.

#2425 Pairwise analysis of plasma cell-free DNA before and after paclitaxel plus ramucirumab treatment in patients with metastatic gastric cancer.

J.-W. Kim[1], D. Kyung[2], W. Ko[2], H.-P. Kim[2], S.-H. Hwang[1], K.-J. Kim[1], J. Lee[3], J. Seo[1], M. Kang[1], E. Jung[1], K. Suh[1], S. Kim[1], J. Kim[1], Y. Kim[1], J. Kim[1], K.-W. Lee[1];

[1]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, [2]IMBdx, Inc., Seoul, Korea, Republic of, [3]Hankuk University of Foreign Studies, Yongin, Korea, Republic of

Background: Plasma cell-free DNA (cfDNA) analysis has emerged as an appealing alternative to detect somatic mutations. This study compared cfDNA at baseline (baseline-cfDNA) and progressive disease (PD-cfDNA) and tumor tissue DNA (ttDNA) in patients with metastatic gastric cancer who underwent palliative second-line paclitaxel+ramucirumab treatment.

Methods: We conducted targeted sequencing of 106 cancer-related genes using germline DNA, baseline-cfDNA, and PD-cfDNA samples. The results were then compared with conventional cancer panel results using ttDNA.

Results: Of 76 consecutively enrolled patients who received paclitaxel+ramucirumab treatment, 46 patients (27 males; median age 57.5 [range, 32-73] years) with access to all three samples were analyzed along with their ttDNA data. A total of 138, 145, and 80 mutations were detected in baseline-cfDNA, PD-cfDNA, and ttDNA respectively. Combined analysis of baseline-cfDNA and ttDNA revealed that *TP53* (56.5%) was the most frequently mutated gene, followed by *CDH1* (26.1%), *KRAS* (21.7%), and *APC* (13.5%). For the top four genes, the sensitivity and positive predictive value of baseline-cfDNA compared with ttDNA were 71.8% and 51.9%, respectively. Compared with ttDNA alone, 32 patients (70.0%) benefited from baseline-cfDNA in detecting novel mutations. When combined with baseline-cfDNA and PD-cfDNA, novel mutations were discovered in 34 patients (73.9%). Of note, PD-cfDNA analysis detected 9 novel pathogenic mutations in *TP53*, *APC*, *PIK3CA*, *CDH1*, *RNF43*, *CTNNB1*, and *BRCA2* genes in 8 patients (17.4%) after treatment. In baseline-cfDNA, patients with a circulating ttDNA fraction concentration at 110-160 bp of >4.3777 ng/μL had significantly shorter progression-free survival (PFS) (median 3.5 vs. 5.3 months, P=0.016). In addition, maximal variant allele frequency (VAF) values of >0.1045 (median 3.4 vs. 5.2 months, P=0.022) and the sum of VAF values of >0.2071 (median 3.4 vs. 5.2 months, P=0.028) were significantly associated with shorter PFS. In patients with *TP53* mutations, those with *TP53* VAF values of >0.1014 significantly had worse PFS (median 4.6 vs. 6.4 months, P=0.022).

Conclusions: Although cfDNA could not entirely take over the role of ttDNA, cfDNA analysis identified additional somatic mutations that were otherwise missed by ttDNA alone. Moreover, PD-cfDNA analysis detected novel pathogenic mutations that developed during treatment, implicating the clonal evolution of cancer. In addition, baseline cfDNA predicted PFS of patients receiving paclitaxel+ramucirumab therapy.

#2426 Liquid biopsy for a predictive biomarker of resistance to immunotherapy.

A. Sinkoe, J. L. Gulley;
National Cancer Institute, Bethesda, MD

Immunotherapy has become a mainstay for cancer treatment. However, immune editing is a well-known resistance paradigm that limits the efficacy of immunotherapy in many patients. One type of immune editing that occurs in 1/6 of all cancer patients, with prevalence over 40% in some cancer types, is human leukocyte antigen loss of heterozygosity (HLA LOH). Liquid biopsies provide a non-invasive and inexpensive way of guiding treatment decision-making. We have developed a liquid biopsy assay for detecting HLA LOH in cancer patients, with the goal of utilizing the assay for deciding whether immunotherapy is the right course of treatment for a given patient.

The assay was tested utilizing sample sets from cancer patients, where each sample set from a patient included a solid tumor biopsy, a liquid biopsy plasma sample, and PBMC sample for control. Tumor HLA LOH results were used for ground truth, and HLA LOH results from the liquid biopsy sample were compared to those from the tumor sample from the same patient. Whole exome sequencing (WES) was performed on tumor DNA, cell-free DNA (cfDNA) from plasma, and germline DNA from PBMCs, and we ran our novel liquid biopsy HLA LOH detection algorithm on the plasma WES data. Standard copy number variant (CNV) calling tools were utilized for calling HLA LOH from the tumor sequencing data. In both cases - tumor and plasma - germline PBMC DNA was used as control. We tested the liquid biopsy HLA LOH detection method on sample sets from 2 HPV-negative primary head and neck cancer patients, 14 castration-resistant prostate cancer patients, and 27 metastatic breast cancer patients. The samples from the head and neck cancer patients were obtained from patients on clinical trials at NCI, while WES data from prostate cancer patient samples and breast cancer patient samples were downloaded from NCBI Database of Genotypes and Phenotypes (dbGaP) after applying for access to dataset phs001417.v1.p1 (Adalsteinsson, et al., Nature Communications, 2017). The method for liquid biopsy HLA LOH detection utilizes a novel mathematical framework that takes into account biological and experimental variables to generate allele-specific HLA LOH information from sequencing data.

In the first two cohorts tested - the head and neck cancer cohort and the prostate cancer cohort - the method was 100% consistent when comparing liquid biopsy HLA LOH results from our method to CNV calling results from matched tumors (4 true positives and 36 true negatives; 0 false negatives and 0 false positives). In the breast cancer cohort, some false negatives and false positives were observed (6 true positives and 48 true negatives; 5 false negatives and 8 false positives). Experiments are ongoing in a CLIA lab to establish sensitivity, specificity, and limit of detection (LoD) for the assay. Upon improvements and validation of the assay, the goal is to utilize the liquid biopsy HLA LOH detection method in the clinic for treatment selection in the context of immunotherapy.

#2427 The development of a tissue-agnostic genome-wide methylome enrichment MRD assay for applications across the cancer care continuum for head and neck malignancies.

G. Liu[1], J. Min[2], Y. Wang[2], J. Burgener[3], B. Brown[2], K. Budhraja[2], J. Zhang[3], O. Hall[2], S. Shen[3], M. Pienkowski[1], S. Huang[1], L. Ailles[1], K. Rey-McIntyre[1], J. B. Provance[2], E. Sosa[2], C. Frye[2], S. Bratman[2], B. Allen[2], J. T. Jones[2], A. Licon[2], J. Zhang[2], A.-R. Hartman[2], D. D. De Carvalho[3];
[1]University Health Network, Toronto, ON, Canada, [2]Adela, Inc., Foster City, CA, [3]Adela, Inc., Toronto, ON, Canada

Background: Plasma-based tests to quantify circulating cell-free DNA cancer signal have emerged as viable applications across the cancer continuum, from early detection to optimal disease management. Here we demonstrate the feasibility of a tissue-agnostic, genome-wide methylome enrichment platform based on cell-free methylated DNA immunoprecipitation and high throughput sequencing (cfMEDIP-seq) for cancer detection, cancer signal quantification, and prognostication in head and neck cancer (HNC).
Methods: Pre-treatment plasma samples from individuals with newly diagnosed stage I-IV HPV+ or HPV- HNC were analyzed with a bisulfite-free, non-degradative, genome-wide methylome enrichment platform using 5-10 ng of cell-free DNA. For cancer detection, a machine learning classifier used differentially methylated regions to distinguish cancers from non-cancer controls. The area under the receiver operating characteristic curve (AUC) and 95% confidence intervals were calculated. Cancer signals were quantified from average normalized counts across informative methylated regions and a 95% specificity threshold. For prognostication, events were defined as recurrence, progression, or death due to HNC, whichever occurred earliest. Time to event was compared for samples with cancer signal quantities above versus below the threshold. Post-treatment and longitudinal plasma samples from individuals with Stage I-IVB HNC (HPV+ and HPV- included) will be analyzed for recurrence prediction and detection of relapse. More than 100 patients and 300 samples will be analyzed.
Results: For cancer detection, 92 pre-treatment plasma samples from HNC cases were distinguished from 674 controls with an AUC of 0.96 (0.94, 0.98). The AUC was 0.93 (0.86, 1.0) for Stage I, 0.93 (0.83, 1.0) for Stage II, 0.96 (0.94, 0.99) for Stage III, and 0.97 (0.96, 0.99) for Stage IV. For prognostication, 91 pre-treatment samples were included (7 stage I, 16 stage II, 23 stage III, 45 stage IV). Median follow-up time was 50.6 months with 27 events. Likelihood of recurrence or progression was significantly higher in samples with cancer signal above the threshold [hazard ratio 5.4 (95% CI 2.25, 12.95), log-rank P<0.001]. In the upcoming analysis, data will be reported on the ability to predict recurrence and relapse in post-treatment samples.
Conclusions: The cfMeDIP-seq approach demonstrated robust detection of HNC, across all stages and subtypes, and the ability to predict recurrence and progression from pre-treatment samples. We will report training data with cross validation to predict recurrence and relapse using post-treatment and longitudinal sampling. Collectively, data from these studies indicate that genome wide methylome enrichment has multiple use cases across the care continuum for patients with HNC.

#2428 Novel ctDNA technology for early cancer detection by immunoprecipitation of tumor associated ctDNA fragments and analysis by qPCR.

J. Micallef, D. Pamart, J.-V. V. Turatsinze, T. Bygott, B. Berman, B. Cuvelier, M. Herzog;
Volition Ltd, Henderson, NV

Introduction: Current ctDNA methods involve extraction of all plasma cfDNA, next generation sequencing (NGS) and complex bioinformatic analysis. We have developed a novel ctDNA analysis in which classes of tumor derived ctDNA are isolated, with removal of all non-tumor cfDNA of the same sequences, for analysis by qPCR. We now report the results of this analysis on cohorts of patients diagnosed with common solid cancers.
Methods: We developed a chromatin immunoprecipitation (ChIP)/qPCR method for the isolation of cell free plasma CTCF-DNA (cfCTCF-DNA) nucleoproteins that include binding sites selectively occupied in cancer. CfDNA fragments of non-cancer origin that comprise the same CTCF binding site sequences are nucleosome covered and washed away. We performed plasma CTCF ChIP-Seq discovery experiments to identify CTCF gain of occupancy cancer biomarker sequences by analysis of plasma samples taken from cancer patients as well as patients with inflammatory conditions and healthy volunteers. Suitable pan-cancer, or cancer tissue specific, biomarkers were selected as characterized CTCF binding site sequences that were present in the ChIP isolates of cancer patients but absent in isolates from patients without cancer. We then developed qPCR assays for selected CTCF gain of occupancy biomarker sequences. We initially investigated whether CTCF gain of occupancy biomarkers would identify patients with cancer in a small cohort of subjects with acute myeloid leukemia (AML) (n=31), breast (n=10), prostate (n=10), liver (n=10) or colorectal cancer (CRC) (n=13) and 50 control subjects including 15 subjects with an inflammatory condition.
Results: In our small initial experiments, a simple cutoff where a qPCR result exceeding the cutoff was positive, a single qPCR assay detected 19 of 31 AML cases (61%) with 1 false positive result among 50 control samples (98% specificity). Addition of a second qPCR assay to make a 2-member qPCR panel, where a result exceeding cutoff in either or both assays was classified as positive, resulted in the detection of 23 of 31 AML cases (74%) with 2 false positive results (96% specificity). On the same basis a 2-member qPCR panel also detected 58% of solid cancers including 44% of stage I cases. Another 2-member qPCR panel detected 77% of CRC cases at 92% specificity. We now report the results of investigations of larger cohorts of patients with common solid cancers by cancer type, stage and tissue specificity.
Conclusion: Combining the isolation of plasma cfCTCF-DNA nucleoproteins with PCR analysis of cancer associated CTCF gain of occupancy binding site sequences is a novel ctDNA analysis technology that may provide the basis of useful, rapid, low cost, automated liquid biopsy methods. Further clinical studies to ascertain the clinical accuracy of the method are required.

#2429 Longitudinal ctDNA monitoring using a high sensitivity tumor-informed assay in patients with metastatic HR^{+}/HER2^{-} breast cancer receiving endocrine therapy and CDK4/6 inhibitors.

J. Fuentes-Antras[1], M. J. Elliott[1], P. Echelard[1], A. Dou[1], Z. Veitch[1], P. L. Bedard[1], E. Amir[1], M. B. Nadler[1], N. Meti[2], N. Gregorio[1], E. Shah[1], E. Van de Laar[1], C. Yu[1], L. Gates[3], C. Murray[4], C. G. Smith[4], A. Chevalier[3], L. L. Siu[1], H. K. Berman[1], D. W. Cescon[1];

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]St. Mary's Hospital Center, Montreal, QC, Canada, [3]NeoGenomics, North Carolina, NC, [4]NeoGenomics, Cambridge, United Kingdom

BACKGROUND: ctDNA burden is prognostic and its dynamics during therapy may permit innovative strategies in metastatic breast cancer (mBC). Previous analyses have focused on driver genes, with limited sensitivity to quantify depth of response or detect early molecular progression. To enable sensitive, quantitative ctDNA monitoring, we analyzed samples from a cohort of HR^{+}/HER2^{-} mBC pts treated with endocrine therapy (ET) and CDK4/6 inhibitors (CDKi) using RaDaR, a patient-specific assay that tracks tumor-informed truncal variants independent of driver status with a limit of detection of 0.001%.

METHODS: HR^{+}/HER2^{-} mBC pts receiving standard ET + CDKi were enrolled in a prospective observational cohort from 2018. Plasma samples were collected at baseline (BL), within 30 days (d), and ~q3 months (mo) with radiological scans. RaDaR was performed on all samples for pts with tissue available for WES (as per assay). Clinico-pathological variables were collected. Endpoints were time to treatment failure (TTF) and overall survival (OS).

RESULTS: 51 pts were available for analysis. Median age was 60 years (range 38-88), 63% had visceral disease, and most pts were treated as first (75%) or second (20%) line. RaDaR was successful on 43 pts, with the rest dropping out due to failed WES (1) or panel failure (7). Archival tissue WES was used to design bespoke assays targeting a median 48 (23-52) variants in 248 samples, with a median of 5 samples/pt (2-14) collected over a median follow up of 27.8 (0.9-64.3) mo. ctDNA was detected in 91% (39/43) of BL and 70% (174/248) of all samples, with a median estimated variant allele fraction (eVAF) of 0.05%. Higher BL eVAFs were associated with liver disease (p=0.02) and with shorter TTF (p<0.01 adjusted by age and visceral disease) and OS (p<0.01). 36/39 pts had ≥1 sample with ctDNA decrease from BL, occurring within the first mo of therapy in 77% (24/31) of pts with available early samples. In 13 pts ctDNA became undetectable ('suppressed') at a median time (T) of 157 d (14-343). Among 25 pts with treatment failure (TF), the median T from the last negative/decreasing eVAF to TF was 163 d (0-943). Only 3 pts with TF had prior negative ctDNA, occurring with a median lead T of 198 d (119-595). Among ongoing pts, the median T from the last ctDNA decrease to last follow up was 317 d (163-1508), and from the last negative ctDNA sample was 352 d (163-993).

CONCLUSION: RaDaR enabled sensitive ctDNA monitoring in 91% HR^{+}/HER2^{-} mBC pts on ET + CDK4/6i. ctDNA levels were prognostic and fell rapidly with therapy, but suppression occurred in less than one-third of pts, taking a median of 5.2 mo. Pts with negative/decreasing ctDNA may require less frequent clinical/radiographic tumor evaluations. Highly sensitive ctDNA tracking may inform prognostic assessments, follow up strategies, and innovative interventional trial designs.

#2430 Enhancing urine-based cfDNA detection for prostate cancer diagnosis through increased urine input volume.

Nafiseh Jafari[1], Annika Dorn[2], Jason Saenz[1], Lauren Lee[1], Carlos Hernandez[1], Andrew Dunnigan[1], Mayer Saidian[1]

[1]nRichDX, Irvine, CA,[2]Agilent Technologies, Deutschland GmbH, Germany

Introduction: Cell-free DNA (cfDNA) extracted from urine has created new opportunities in non-invasive cancer diagnostics, particularly for prostate cancer. Detecting cfDNA in urine can be challenging due to its inherently low concentration. Increasing the input volume of urine addresses this limitation, enhancing the sensitivity of cfDNA detection. This study explores the benefit of collecting larger volumes of urine spiked with a TP53 mutation and the corresponding increase in assay sensitivity for early prostate cancer diagnosis and monitoring.

Methods: Pooled urine from healthy donors was collected, preserved, processed, and extracted from 10 mL, 20 mL, 30 mL, 40 mL, and 50 mL inputs (with four replicates each) using the Revolution Max 20 cfDNA Extraction kit. Replicate samples were also extracted using a MagMAX cfDNA Isolation kit from Thermo Fisher Scientific. All samples were spiked with a cfDNA standard containing TP53 R58L mutation. The quantity and quality of extracted cfDNA were determined using the Agilent TapeStation system with the Cell-free DNA ScreenTape assay and qPCR mutation detection assay.

Results: The Revolution Max 20 cfDNA kit consistently delivered a higher yield of cfDNA, demonstrating excellent extraction efficiency and quality, as shown by the Agilent Cell-free DNA ScreenTape assay. Notably, the Revolution Max 20 cfDNA kit exhibited a linear increase in yield as the sample volume grew from 10 mL to 50 mL. The MagMax kit did not provide this yield linearity. Furthermore, both methods successfully maintained the integrity of cfDNA fragmentation, which was confirmed through the Agilent Cell-free DNA ScreenTape assay.

Conclusion: Compared to the MagMax kit, the Revolution Max 20 cfDNA kit outperforms in extracting cfDNA with high efficiency, as shown by the Agilent Cell-free DNA ScreenTape and the qPCR assay. The Revolution Max 20 cfDNA kit offers the unique advantage of accommodating up to 50 mL of urine in a single extraction. As input volume increases, it consistently produces high cfDNA yields while maintaining quality. In contrast, the MagMax kit is limited to an input volume of only 10 mL, necessitating the cumbersome process of dividing a 50 mL urine sample into five separate extractions and pooling the eluates. This scheme resulted in lower yields. The Agilent Cell-free DNA ScreenTape assay is a valuable tool for quickly and accurately assessing the %cfDNA quality metric. Its minimal sample volume requirement makes it an efficient quality control method for determining cfDNA samples before performing downstream testings. The enhanced capability of the Revolution Max 20 kit to yield more significant quantities of high-quality cfDNA from urine samples can profoundly impact liquid biopsy test sensitivity and the early detection of prostate cancer, potentially revolutionizing the diagnostics process.

#2431 Identification of highly expressed exosomal RNAs derived from pancreatic cancer cell lines and exploration of their potential as biomarkers.

Yuhan Rong, Naoki Okubo, Noritoshi Kobayashi, Eriko Katsuta, Yasushi Ichikawa

Yokohama City Univ. Graduate School of Med., Yokohama, Japan

Background: Not all exosomes in the blood of cancer patients originate from cancer cells. This study evaluated the relationships between mRNAs and miRNAs in pancreatic cancer (PC) cell lines and those in exosomes secreted into the supernatant. We aimed to identify candidates for PC biomarkers from cancer-specific exosomal mRNAs and miRNAs.
Materials and Methods: Three PC cell lines were utilized. Exosomes were isolated from the supernatant, and cellular and exosomal mRNAs and miRNAs were extracted. Subsequently, RNA sequencing (RNA-seq) was performed, and the data were analyzed using R software.
Results: In the MIAPaCa-2 cell line, the expression of cellular mRNAs and corresponding exosomal mRNAs showed a strong correlation. In the other two cell lines, a moderate correlation was observed. Across all three cell lines, cellular miRNAs and corresponding exosomal miRNAs exhibited moderate correlation. We focused on RNAs that were lowly expressed in cells but highly expressed in exosomes and conducted differential expression analysis using R. Compared with healthy volunteers in the GEO database, some RNAs showed high expression in the supernatant and low expression in the plasma of healthy volunteers.
Conclusion: We identified three mRNAs and three miRNAs that may serve as promising biomarker candidates for PC.

#2432 Improved liquid biopsy assay performance using sequencing by binding (SBB).

D. Nasko, P. Pham, S. Joshi, K. Kim, N. Pezeshkian, Y. Kim, **A. Sockell**, J. Korlach;
PacBio, Menlo Park, CA

Liquid biopsy is revolutionizing the field of early cancer detection research through non-invasive detection of tumor DNA in the blood. However, existing liquid biopsy assays are limited in their sensitivity for ctDNA detection at low variant allele frequencies (VAFs), with most relying on extreme sequencing depth and computational error correction to separate the true ctDNA signal from background errors. This limitation is particularly problematic in the area of early cancer detection, in which expected ctDNA allele frequencies are extremely low. Novel strategies are therefore needed to help improve liquid biopsy assay sensitivity and reduce per-sample sequencing requirements. Here we describe PacBio's application of the Onso short-read sequencing system to enable detection of ctDNA at low VAFs using the SeraCare Complete ctDNA Mutation Mix reference standard. The Onso system makes use of a novel sequencing by binding (SBB) method to achieve up to 15x greater quality scores, with ≥90% of reads at Q40 or above. We performed targeted capture and sequencing of libraries prepared from the SeraCare reference mix diluted into WT human DNA at the following VAFs: 0.00% (WT), 0.05%, 0.10%, 0.25%, and 0.50%, and compared the sensitivity at each VAF for SBB compared to a competitor method using sequencing by synthesis (SBS) at varying sequencing depths. We observed superior sensitivity for ctDNA detection at low VAFs (0.05%, 0.1%) using SBB at half the sequencing depth compared to SBS, in part due to reduced false positive calling in the WT sample for SBB. Furthermore, SBB was able to achieve comparable sensitivity results to SBS using four-fold less sequencing, and without the use of computational error correction. Finally, combining SBB with computational error-correction methods boosted sensitivity even further, suggesting an additive value for these technologies. Taken together, our results demonstrate the potential of SBB to improve upon existing methods of liquid biopsy and better enable research on early cancer detection.

CLINICAL RESEARCH: Early Detection Biomarkers 2
Poster Session

#2436 In-depth analysis of microRNA signature in breast cancer derived extracellular vesicles: A potential biomarker repository for breast cancer diagnosis.

Jee Ye Kim, Min Woo Kim Kim, Young Kim, Sol Moon, Suji Lee, Hyojung Lee, Joon Ye Kim, Seung Il Kim

Yonsei University College of Medicine, Seoul, Korea, Republic of

Breast cancer remains one of the leading causes of cancer-related mortality among women worldwide. With the rising incidence of breast cancer, early and accurate diagnosis is pivotal in improving survival rates and patient outcomes. Our study addresses to identify vesicles associated with breast cancer in scope of miRNA signature. We focused on isolating breast cancer-derived extracellular vesicles (BEVs) from the bloodstream with immune affinity capture techniques. Then, we analyzed the miRNA profiles of BEVs in plasma samples from 120 breast cancer patients, 46 individuals with benign tumors, and 45 healthy controls. In this study, we analyzed to discover miRNA candidates for diagnosis of breast cancer with The Gene Expression Omnibus (GEO) database and found 379 down-regulated and 584 up-regulated differentially expressed miRNAs (DEMs) in tissue samples across 5 GEO datasets, and 28 down-regulated and 80 up-regulated DEMS in blood samples. Subsequently, we measured the expression levels of these 10 candidate miRNAs in BEVs from breast cancer cells and compared them with EVs from human mammary cells (MCF10a), using our BEV isolation method. The expression profiles of these miRNAs in BEVs were significantly elevated, supporting their potential as surrogate markers for breast cancer diagnosis. When comparing the AUC values of 10 candidate miRNAs through ROC analysis, 5 EV miRNAs (miR-21, miR-106b, miR-181a, miR-484, and miR-1260b) showed a high AUC values above 0.8. Subsequently, we verified a distinct signature of 5 EV miRNAs that effectively differentiate breast cancer patients from normal controls with 57.14% of sensitivity and 95% of specificity. Overall, our study not only complements existing diagnostic methods with high accuracy but also provides a deeper understanding of the molecular aspects of breast cancer, heralding a significant advancement in precision medicine and personalized cancer care.

#2437 Distinct DNA methylation patterns in male urogenital cancers.

G. Yu[1], J. Wang[1], L. Li[1], W. Xie[2], Y. Liu[1], Q. Yang[1], B. Xu[1];

[1]Shanghai Ninth People's Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, [2]Burning Rock Biotech, Guangzhou, China

Background: Male urogenital cancers including prostate cancer (PCa), bladder cancer (BLCA) and kidney renal cancer (KIRC), account for 38% of the total number of new male cancers. Previous studies have shown that changes in DNA methylation patterns are associated with the occurrence and progression of these cancers. Here, we performed whole-genome bisulfite methylation sequencing (WGBS) on tissue samples from these cancers to comprehensively characterize the methylation patterns to provide insights into the potential biological functions of methylation and to identify possible early detection biomarkers.
Methods: Tissue samples were collected from patients with PCa, BLCA and KIRC who had not received any treatment prior to surgery from Shanghai Ninth People's Hospital, Shanghai Jiaotong University School of Medicine. Samples with the cancer cells content ≥30% in cancer tissues and no cancer cells in the adjacent tissues was deemed qualified. A total of 43 samples were sequenced by whole-genome bisulfite methylation sequencing (WGBS) with a depth of 30X, including PCa, BLCA, KIRC cancer tissues, and their adjacent cancer tissues.
Results: Distinct methylation patterns were observed in the 3 cancers. By comparing cancer and adjacent tissues, the numbers of differentially methylated sites (DMSs) were 21,195 (31% hyperDMSs and 69% hypoDMSs), 587,010 (23% hyperDMSs and 77% hypoDMSs) and 7,855,162 (5% hyperDMSs and 95% hypoDMSs) in PCa, BLCA and KIRC, respectively. The distribution of hyperDMSs and hypoDMSs across various chromosomes was relatively consistent in KIRC and BLCA. However, in PCa, the hypoDMSs were mainly located on chromosome 8 (5265/14666, 36%). Among the three cancers, only 2-3% of hypoDMSs were located in gene promoter regions, while the proportions of hyperDMSs in gene promoter regions were higher with 4%, 8% and 17% for PCa, BLCA and KIRC, respectively. Among the above DMSs, 1901 DMSs-related genes were shared by PCa, BLCA and KIRC and 251, 4252, 2475 DMSs-related genes were unique in PCa, BLCA and KIRC, respectively. Gene Ontology analysis revealed that the shared DMSs-related genes were enriched in Wnt signaling pathway and positive regulation of MAPK cascade.
Conclusions: Our present study demonstrated the differential methylation patterns in male urogenital cancers, which may provide insights into the potential biological functions of methylation and to identify possible early detection biomarkers.

#2438 A retrospective pilot study to validate the utility of proteomic biomarkers in the blood for diagnosis of breast cancer.

S.-Y. Jung[1], E.-G. Lee[1], J. Han[1], S. Lee[1], S. Shin[1], J. Lee[1], S.-S. Kim[2], Y. Kim[3], D.-Y. Noh[3];

[1]National Cancer Center - Korea, Goyang-si, Korea, Republic of, [2]Manufacturing and Technology Division, Bertis Inc, Yongin-si, Korea, Republic of, [3]CHA Gangnam Medical Center, CHA University School of Medicine, Seoul, Korea, Republic of

Background: Previously, three-protein signature (Mastocheck®, Bertis Inc.) from plasma has been launched to overcome the limitation of low accuracy of mammography. In addition, nine-protein signature from serum was newly developed to improve the accuracy of three-protein signature as a blood-based diagnostic tool. This study aimed to validate the diagnostic utility for breast cancer of nine-protein signature with comparison with three-protein signature.
Methods: A blood-based test using multiple reaction monitoring (MRM) by mass spectrometry to quantify nine proteins (APOC1, CHL1, FN1, VWF, PPBP, CLU, PRDX6, PRG4, and MMP9) in serum and three proteins (APOC1, CHL1, CA1; Mastocheck®) in plasma was investigated using blood of 30 health women and 30 breast cancer patients. Using the cut-off values confirmed by AI-based deep learning model, we evaluated the sensitivity, specificity, and accuracy of nine- and three-protein signature for detecting breast cancer.
Results: Among 60 cases, the sensitivity and specificity of nine-protein signature was 87.9% and 80.7% for diagnosis of breast cancer. These values were 20% and 10% higher than those of three-protein signature, respectively (66.7% of sensitivity and 70.0% of specificity). The accuracy of nine-and three-protein signature was 83.3% and 68.3%.
Conclusion: This study demonstrated that nine-protein signature could be a more accurate and effective tool for detecting breast cancer compare to three-protein signature). For a confirmatory study, we need to perform a large scaled validation study in future. Grants: This research was supported by Bertis, Republic of Korea (grant number: NCC 2341770-1)

#2439 Potential target genes for early stage detection in Hispanic colorectal cancer.

E. V. Caraballo, **C. Zenon-Melendez**, J. Perez-Santiago, M. Cruz-Correa;
University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Background: Colorectal Cancer (CRC) has become the second leading cause of death related to cancer worldwide and the third most common malignancy. CRC tumors are classified into stages to describe the cancer; early (stages I and II) and advanced (stages III and IV). Despite the available screening methods and the scientific efforts in the development of a universal biomarker panel for CRC early detection, there still exists a gap in a reliable non-invasive screening method for the Hispanic community. *We aimed to elucidate the most important pathways along with the differential gene expression in early and advanced CRC stages in a Hispanic population.*

Methods: We examined restrospectively 7 tissue samples from a Puerto Rican Hispanic population recruited throughout the Puerto Rico Familial Colorectal Cancer Registry (PURIFICAR) IRB #A2210207. We evaluated transcriptomic changes in advance tumors (n=4) vs. early tumors (n=3) with their respective normal mucosal tissue as negative control. Extracted RNA was sequenced using the Illumina NextSeq (2 X 75bp). The higher-quality reads were aligned, annotated, and quantified to the human genome (hg38) using STAR and RSEM softwares. Gene expression analysis was performed in R statistical software (packages tximport and DESeq2). We compared significantly expressed genes (adjusted p-value <0.05) between study groups (Tumor Advance [TA] vs. Mucosal Advance [MA] and Tumor Early [TE] vs. Mucosal Early [ME]) using Venny, and we performed enrichment analyses and protein-protein interaction networks using Metascape and STRING database, respectively.

Results: There were 2284 differentially expressed genes (TA vs. MA) and 984 (TE vs. ME), in which 1736 were unique to advance stages, 436 were unique to early stages and 548 were shared in both tumor stages. Significantly impacted biological processes and pathways include: granulocyte chemotaxis, regulation of inflammatory response, positive regulation of apoptotic process, tissue morphogenesis, G alpha signaling events, interleukin-10 signaling, signaling by interleukins. Additionally, physical and functional interaction networks showed 11 major clusters (≥ 5 genes), which contained several gene hubs including LYN (proto-oncogene), IL-1β, IL-1α, TNF, CCL3, CCL4, CXCR1 and CXCR2 (cytokines/ chemokines) among others genes previously reported as CRC biomarkers (DKK1, AQP8, AQP9, CTNNB1, and GNAQ).

Discussion/Conclusions: Differential analysis of early CRC tumor samples shows a deregulation of genes related to the inflammatory response which plays an important role in CRC. Modulation of these genes suggests significant potential targets for early detection of CRC in a Hispanic population. Future studies will be focus on the evaluation of selected target genes as a non-invasive early CRC screening method.

#2440 Cancer driver mutations as quantitative biomarkers of cancer risk interspecies analyses using CarcSeq.

K. L. Harris, B. Gong, B. Parsons, J. Faske, J. Xu;
FDA-NCTR (National Center for Toxicological Research), Jefferson, AR

Unmet needs in cancer risk assessment include the ability to predict rodent life-time tumor responses from short-term exposures and a scientific basis for rodent to human extrapolation. As an approach to address these needs, the use of hotspot cancer driver mutations (CDMs) as biomarkers of cancer risk was integrated with an error-corrected, next generation sequencing (NGS) approach. We have developed and investigated the sensitivity of a high-throughput NGS method capable of detecting a panel of the most prevalent point mutations observed in human oncogenes and tumor suppressor genes. This method, CarcSeq, involves performing multiple, high-fidelity PCR reactions to amplify the most prevalent mutations reported to occur in human tumors, tagging the amplicons with 9 bp unique identifier sequences at each end, constructing libraries using Illumina ChIP Seq kits, sequencing the libraries on an Illumina NextSeq500 platform and generating single-strand consensus sequences (SSCS), bioinformatically, as a means of error-correction. We validated CarcSeq mutant fraction measurements through observations related to known cancer driver tissue-specificities and mutation spectra for normal human breast and lung, ductal carcinoma, and lung adenocarcinoma samples. Performance of a reconstruction experiment established CarcSeq has a sensitivity of 10^{4}. The approach has now been adapted to analyze analogous conserved codons in rat and mouse. For each of the three species, the developed panel includes 13-15 amplicons encompassing known cancer driver genes (e.g., *KRAS*, *PIK3CA*, and *TP53*) encompasses the equivalent of 30 known human hotspot codons and has a combined target sequence length of ~1 kb. Amplicons were generated from DNA isolated from 16-week-old, untreated rodent tissue samples with known differences in spontaneous tumor incidence: female Wistar, Sprague Dawley, and F344 rat mammary samples and male and female $B6C3F_{1}$ and CD-1 mouse lung samples. The rodent panel was optimized to generate ~100,000 SSCS/amplicon. CDMs were observed at conserved codons in young, untreated rodents, and results are consistent with what was expected based on strain differences in spontaneous tumorigenesis.

#2441 Higher levels of LPS in blood plasma as potential novel biomarker for cancer risk in Puerto Rican people living with HIV.

J. Torres Reyes[1], T. L. Shull[2], G. Borges-Velez[1], V. S. Sanchez Gonzalez[1], J. L. Salgado Montilla[1], J. Perez Santiago[1];
[1]UPR - Comprehensive Cancer Center, San Juan, Puerto Rico, [2]Medical Center, Chicago, IL

Background: People living with HIV (PWH) have a significantly higher risk of developing cancers than people without HIV (PWOH), even with suppressive antiretroviral therapy. Puerto Rico (PR) is considered a high-risk group disproportionately affected by HIV and a priority group for cancer prevention strategies. Dysbiosis of the human microbiota can contribute to persistent inflammation by upregulating TGF-β (microbial-induced oncogenesis biomarker), which can promote the translocation of microbial products into the bloodstream, increasing cancer risk at local and distant sites. However, the relationship between TGF-β, and microbial products such as lipopolysaccharide (LPS) and short-chain fatty acids (SCFA) in relation to HIV infection is poorly understood, therefore we aimed to quantify the levels of LPS and SCFA in the blood plasma of PWH vs. PWOH and investigated their relationship with cancer risk measured by TGF-β.
Methods: Blood samples, sociodemographic, and clinical data from 80 adults (50 PWH and 30 PWOH) were collected. PWH were virally suppressed (<50 copies/mL) with a median CD4 count of 699.8 cells/μL. We measured TGF-β, LPS, and soluble CD14 (sCD14, marker of innate immune activation and microbial translocation) using immunoassays. SCFA (acetate, butyrate, and propionate) were measured using gas chromatography followed by mass spectrometry. Differences in the median levels of TGF-β, LPS, and SCFAs were evaluated using a Mann-Whitney test. We assessed the effects of LPS, SCFAs, and HIV infections in relationship with levels of TGF-β using multivariate fixed-effects regression analysis in R-statistical software.
Results: PWH had significantly higher levels of TGF-β (4397 pg/mL vs. 1121 pg/mL, p=0.017), higher levels of LPS (38.97 pg/mL vs. 19.26 pg/mL, p<0.001), higher levels of sCD14 (1326 pg/mL vs. 1137 pg/mL, p=0.007), and significantly lower levels of butyrate (84.5 ng/mL vs. 62.0 ng/mL, p<0.001). Higher levels of TGF-b were associated with higher levels of LPS (rho=0.38, p=0.017) and higher levels of sCD14 (rho=0.27, p=0.016) these relationships remain significant after adjusting for HIV status (p<0.001).
Conclusion: Our findings suggest that microbial products in blood plasma can contribute to higher cancer risk in Puerto Rican PWH and may represent potential novel biomarkers for cancer prevention.

#2442 Blood based novel mRNA genomic test, for screening, early detection, prognosis and monitoring of prostate cancer using a multi-center study.

Y. Hashimoto[1], S. Verma[2], G. Deng[3], D. P. Chauhan[3], S. Nair[4], D. Chakravarty[4], H. Yoshino[5], J. Arima[5], S. Tatarano[5], Y. Liu[6], K. Hatano[6], Y. Shivakumar[7], M. Ghosh[7], K. Raghunath[7], C. Chandran[8], N. Ragavan[8], H. Enokida[5], N. Nonomura[6], K. Balaji[9], S. Rawal[10], A. Tewari[4], R. Dahiya[1], **S. Gupta**[2];
[1]UCSF School of Medicine, San Francisco, CA, [2]Case Western Reserve University and University Hospitals Cleveland Medical Center, Cleveland, OH, [3]Geneverify Inc, Hayward, CA, [4]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, [5]Kagoshima University Hospital, Kagoshima, Japan, [6]Osaka University Medical School, Osaka, Japan, [7]HCG Cancer Center Hospital, Bengaluru, India, [8]Apollo Cancer Center Hospital, Chennai, India, [9]University of Florida College of Medicine, Jacksonville, FL, [10]Rajiv Gandhi Cancer Institute & Research Centre, New Delhi, India

Background: Current screening tools, including prostate-specific antigen (PSA) and clinico-pathologic parameters, have limitations in the diagnosis and prognosis of prostate cancer. This study examined whether genomic biomarkers can improve screening and monitoring of prostate cancer.
Methods: We identified a panel of 25 prostate cancer-related genes through rigorous bioinformatics, computational analyses and genetic testing. These tests, developed by Geneverify Inc. (Hayward, CA; U.S. patent # 10801072 and 10822661) were utilized and optimized by qRT-PCR to determine the diagnostic and prognostic ability of prostate cancer using blood and tissues. The log2-fold increase in gene expression was used to assign the risk score to individual patients. ROC (receiver operator characteristic), AUC (area under ROC curve), and calibration curves were generated to display the overall performance and discrimination ability to separate cancer and non-cancer specimens.
Results: A total of 445 prostate cancer patients (135 blood and 310 tissue samples) and 130 normal samples were analyzed in this study. The eligibility criteria were to collect blood and surgical specimens from patients with prostate cancer. The study endpoints were to analyze mRNA genomic profiling and correlate with clinico-pathologic parameters of the patients. In the blood, a 25-panel gene-set separated prostate cancer patients (n=135) from non-cancer (n=30), AUC = 0.906 [sensitivity = 90% and specificity = 91%]. Assessment of tissue specimens from benign (n=100) and cancer patients (n=310) demonstrated similar results with AUC=0.9514 [sensitivity=95% and specificity=94%]. Interestingly, patients with Gleason grades more than 7 showed higher expression of these genes compared to Gleason Grades less than 7, suggesting the prognostic ability of the gene-set. When we compared the gene expression in blood verses tissues, there were similar patterns, suggesting that blood can be used for screening, diagnosis and risk assessment of prostate cancer.
Conclusions: To our knowledge, this is the first study to investigate the role of mRNA-based genomic signatures for screening, early diagnosis and prognosis of prostate cancer using blood samples. Our results suggest that blood mRNA-genomic profiling developed by Geneverify has the ability to diagnose prostate cancer and stratify patients into distinct prognostic groups, which in turn help in making better treatment strategies.

#2443 Improved detection of low frequency mutations in ovarian and endometrial cancers by utilizing a highly accurate sequencing platform.

T. Revil[1], N. Pezeshkian[2], L. Gilbert[1], **A. Sockell**[2], J. Ragoussis[1];
[1]McGill University, Quebec, QC, Canada, [2]PacBio, Menlo Park, CA

Ovarian and endometrial cancers come within the top-4 for incident cancers as well as deaths in North American women. Cure rates have not improved in 30 years as high-grade subtypes continue to be diagnosed in Stage III/IV. Attempts at early diagnosis have failed because high-grade cancer cells exfoliate and metastasize while the primary cancer is small and undetectable by existing tests based on imaging and blood-based tumor markers. DOvEEgene (Detecting Ovarian and Endometrial cancers Early using genomics) is a genomic uterine pap test developed by a McGill team to screen and detect these cancers while they are confined to the gynecologic organs and curable by surgery. The test identifies pathogenic somatic mutations in uterine brush samples. Here we tested the Onso system, a highly accurate sequencing technology from PacBio in order to potentially increase sensitivity while driving down sequencing costs by reducing required sequencing depth vs the current NGS standard. A highly sensitive, error-correcting capture technology (DOvEEgene-SureSelectHS) utilizing duplex error correction sequencing interrogated the exons of 23 genes involved in the development of sporadic and hereditary ovarian and endometrial cancers. We applied a combination of germline gene panel testing on saliva samples with deep duplex sequencing to detect somatic mutations at <0.1% VAF, interrogation of microsatellite loci for instability, and low coverage WGS for copy number analysis of uterine brush samples. We sequenced 20 duplex Illumina sequencing libraries produced using the DovEE assay at PE 100bp mode and compared Onso data in non- duplex sequencing mode as well as duplex sequencing mode to the original Illumina duplex sequencing method. Here, we present this comparison and highlight the benefits of high accuracy sequencing for the detection of very low frequency (<0.1%) somatic mutations. We observed improved mismatch rates for Onso data compared to Illumina, even after duplex error correction was applied. In addition, we found that more individuals are called as displaying microsatellite instablity from the Onso data, which may be due to improved sequencing performance in repetitive regions for Onso. Finally, we observed fewer potential false positive variant calls in the Onso data, highlighting the value of improved sequencing accuracy for rare variant detection.

#2444 Plasma levels of matrix metalloproteinases 8 are significantly increased in patients with colorectal cancer (CRC) and mRNA levels are increased in 71% of tumors vs normal tissue.

Chandana S. K. Herath Mudiyanselage, Anuj R. Sharma, Neil Mitra, Aashutosh Sah, Xiaohong Yan, Pablo Palacios, Vesna Cekic, Richard L. Whelan

Department of Surgery, Lenox Hill Hospital, New York, NY

Introduction: Matrix metalloproteinases 8 (MMP-8) is a member of the MMP protease family mainly involved in degrading extracellular matrix. A variety of cells express MMP-8 and during pathological inflammation neutrophils release IL-1, IL-8, TNF-α, and GM-CSF which triggers MMP-8 secretion. MMP-8 aids tumors in evading immune detection during the development of CRC and also regulates the role of endothelial cell in angiogenesis. Increased MMP-8 tumor expression and serum levels has been noted in hepatocellular cancer and melanoma patients and are associated with adverse outcomes. There is limited data regarding blood levels of MMP-8 in CRC patients. This study compared preoperative (PreOp) plasma MMP-8 levels in patients with CRC and benign colonic pathology (BCP) undergoing bowel resection.

Method: Patients with CRC or BCP who had elective colorectal resection who were enrolled in an IRB approved tissue and data bank for whom preop plasma samples were available were eligible. Data analyzed included demographic, clinical, operative, and final pathology reports. Blood specimens were quickly processed and plasma stored at -80°C. MMP-8 levels in Preop plasma samples were measured via ELISA, in duplicate, and reported as median +95% CI (ng/ml). MMP8 expression was examined in paired CRC and normal mucosal tissue samples from a subset of the CRC patients (n=20) via QRT-PCR. Immunohistochemistry (IHC) was conducted on formalin-preserved tissue sections (tumor/normal pairs) following standard protocols. The concept of MMP8 as CRC diagnostic marker was evaluated by assessing the receiver operating characteristic (ROC) curve and the area under the ROC curve (AUC). The analysis was done with the Mann-Whitney test (significance, $p<0.05$).

Results: 96 CRC patients (74% colon and 26% rectal cancer) and 96 BCP patients (32% adenoma, 64% diverticulitis, 4% other) met entry criteria. The CRC stage distribution was: Stage 1, 26%; Stage 2, 26% Stage 3, 40%; and stage 4, 8%. Median plasma MMP-8 levels were higher in CRC (8.21, CI: 6.92, 10.81) compared to BCP patients (5.59, CI: 4.68, 7.30; $p<0.001$). A non-significant increase in median MMP-8 levels were noted in STG IV vs STG I and STG II and STG III was found (38-89%). IHC validated the expression of MMP-8 in CRC tumors relative to normal colon. Increased expression of MMP-8 was seen in 71% of the tested CRC samples (12/17). The AUC value for the ROC curve was 0.653 (sensitivity 35%, specificity 0.95%).

Conclusion: The median MMP-8 level in CRC patients was found to be 47% higher compared to BCP patients and 89% higher in stage IV vs stage II patients ($p=0.06$). The tumor is the most likely the cause of elevated plasma levels. Increased tumor expression of MMP-8 mRNA was noted in 71% of tumors. The low sensitivity of the ROC curve suggests MMP8 alone has no value as diagnostic factor. Larger studies are justified.

#2445 Peripheral blood immune phenotypes in pancreatic ductal adenocarcinoma.

K. D. Pavelko, J. C. Villasboas, W. R. Taylor, K. A. Doering, J. B. Kisiel, S. Majumder;
Mayo Clinic, Rochester, MN

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a major cancer killer with a low 5-year survival rate of 12%. Diagnosing PDAC at an early stage is one of the strongest predictors of long-term survival. Therefore, novel methods for early detection of PDAC must be explored. In this pilot study we aimed to compare the peripheral blood immune cell phenotypes in PDAC cases and cancer-free controls.
Method: CyTOF (cytometry by time-of-flight) was used to evaluate peripheral blood mononuclear cells (PBMC) from newly diagnosed treatment naïve patients with PDAC and sex and age matched cancer-free controls using a 29-marker immune phenotyping panel. Multiple analysis approaches including dimensionality reduction using tSNE and clustering using Phenograph were used to evaluate the results. Immune subsets having differential abundance differences were verified by manual gating.
Results: Twenty patients were included in this pilot study (15 PDAC cases; 5 Cancer-free controls). Among the 15 PDAC cases, 5 were early stage (Stage 1-2). Thirty-two unique immune cell clusters were identified using the Phenograph algorithm: 10 unique clusters with properties consistent with monocytes/macrophages, 9 CD4 T cell clusters, 6 CD8 T cell clusters and 4 NK cells clusters. When comparing the case and control groups we noted lower percentages of CD8+CD27+ T-cells in cases. This was further verified by manual gating that confirmed the distribution of CD8+CD27+ T-cells relative to all T-cells were decreased in PDAC patients. In addition, a 57% increase in naïve CD4 T cells was found in case samples compared to controls. A principal component analysis of the clustering results identified two unique clusters of immune profiles that emerged providing a potential peripheral blood immune cell signature that could stratify and differentiate PDAC cases from controls. A $CD14^{+}CD16^{+}CD4^{Lo}CD38^{+}CD45RO^{+}$ population of monocytes was the primary cell population driving this difference.
Conclusion: This study provides early evidence to indicate that a distinct PBMC immune phenotype may differentiate PDAC patients from control subjects. Further analysis in larger sample sets is warranted for in-depth characterization and identification of unique immune based biomarkers for PDAC detection.

#2446 Genomic landscape of longitudinally collected preinvasive airway lesions.

A. Alhendi, L. Kalinke, A. Pennycuick, K. Davies, P. Durrenberger, K. Gowers, K. Grigoriadis, N. McGranahan, S. Janes;
University College London (UCL), London, United Kingdom

Lung carcinoma in situ (CIS) lesions, as precursors to squamous cell carcinoma, exhibit microscopic uniformity while displaying diverse clinical trajectories. Half of these lesions progress to invasive cancer, while the remaining half either regress or remain indolent. Previous genomic profiling efforts have elucidated progression-specific genomic changes against a backdrop of inherent heterogeneity and notable chromosomal instability signatures. Here, we present a novel approach by analyzing longitudinally collected samples of preinvasive airway lesions, encompassing both progressive and indolent trajectories.
Our findings reveal that genomic integrity and cell cycle dynamics constitute key distinctions between progressive and indolent lesions. Notably, a decrease in clonal diversity and an inverse correlation between TCRA-Tcell fraction and genomic instability are observed as lesions approach invasion. Somatic mutations in cancer driver genes *BRAC2*, *CSMD3*, and *MUC16* are found significantly associated with lesion progression. Furthermore, progressive lesions exhibit a higher frequency of copy number changes compared to indolent lesions. Copy number loss in 1p, 3p, 9p, and 17p are found to be significantly associated with lesion progression. Phylogenetic analysis further confirms positive selection for copy number loss in these specific genomic regions, providing insights into the evolutionary trajectory of alterations in progressive lesions. The comprehensive understanding derived from these genomic analyses is anticipated to advance early detection strategies, mitigate overtreatment, and facilitate the development of preventative therapies targeting early clonal events in lung cancer.

#2447 Identification of tumor marker gangliosides for early cancer detection: A mass spectrometry approach.

Rachel Culp-Hill, Collin Hill, Adele Blackler, William Ricketts

AOA Dx, Inc., Boulder, CO

Tumor-marker gangliosides (TMGs) have enormous potential for early-stage cancer detection as diagnostic biomarkers despite being relatively understudied in this context. AOA Dx is focused on the development of a mass spectrometry platform for the quantitation of TMGs in human serum, particularly disialogangliosides GD2 and GD3. The development of a mass spectrometry platform for TMG quantitation may allow for the identification of diagnostic signatures for early-stage cancer detection. Briefly, we monitored fragment moieties characteristic of gangliosides in an untargeted fashion by mass spectrometry. We then identified those differentially altered in cancerous groups compared to normal, and subsequently performed targeted MRM analysis. Through these investigations, we have identified multiple TMGs, specifically multiple types of GD2 and GD3 species characterized by unique lipid tails across different cancer types in human serum from confirmed cancer diagnoses. Other ganglioside classes including GMs and relatively understudied GTs were also identified in this study. Notably, the serum of melanoma and ovarian cancer patients exhibited significantly increased levels of several ganglioside species compared to age-matched healthy serum, highlighting the potential of TMGs as a promising avenue for cancer diagnosis. Further experiments will focus on refining this mass spectrometry method and expand demographic representation to confirm our initial findings and identify additional TMGs of interest. In addition, we intend to apply immune-based platforms such as thin-layer chromatography and ELISA, which have already shown promising results in the detection and quantitation of these compounds. Taken together, AOA Dx is advancing the development of a high-throughput mass spectrometry platform designed for the detection of TMGs, with a primary focus on GD2 and GD3. Our objective is the identification of a diagnostic disease signature for early-stage cancer detection. The validation of this type of diagnostic panel would allow for expedited diagnosis and treatment of cancers currently diagnosed at late stages, ultimately reducing healthcare costs and increasing survival rates. Future research will aim to validate these biomarkers in independent prospective studies.

#2448 Field cancerization proteomic analysis provides a novel class of functional risk biomarkers for non small cell lung cancer.

R. I. Alhammad[1], N. B. Vuong[1], W. Zhou[1], D. Johann Jr[2], B. Birkaya[1], L. Liotta[1], A. Luchini[1];
[1]George Mason University, Manassas, VA, [2]UAMS Medical Center, Little Rock, AR

Lung cancer carcinogenesis is the outcome of a field of premalignant changes that occur in the bronchial tree leading to the overt emergence of the malignant lung cancer (field cancerization). A tissue or blood proteomic signature of these premalignant changes represent a novel concept of risk biomarkers that can predict the probability of future emergence of Lung Cancer. In this study, we analyzed two independent cohorts of non-small cell lung cancer (NSCLC) patients. One cohort consisted of 18 patients who donated blood before and after tumor resection surgery and matched tissue samples (UAMS Medical Center). The second set derived from a longitudinal case-control study of plasma sample collected during the physician health study that were donated at different times prior to the diagnosis of Non-Small Cell Lung Cancer (N=272). We used affinity-enriched mass spectrometry analysis and statistical learning techniques to identify a set of common markers that discriminated plasma cases and controls and were conserved in different bronchial tissue compartments including tumor and adjacent tissue. The tumor microenvironment adjacent to and surrounding cancer cells undergoes to progressive stages of carcinogenesis during field cancerization. We identified 22 proteins involved in cell adhesion, protein folding, immune response, angiogenesis, and cancer proliferation. This is a novel class of functional risk biomarkers to determine the probability of NSCLC onset. In conclusion, our findings shed light on a new class of functional biomarkers that underly tumor pathogenesis mechanisms and can provide hints for new strategies of tumor prevention therapy or lifestyle modification.

#2449 Case report: DETECT-A participants with pre-malignant conditions.

O. A. Choudhry[1], A. Kharge[1], **S. P. Rego**[1], P. Z. Elias[1], A. H. Buchanan[2], A. Lennon[3], N. Papadopoulos[3], F. Diehl[1], T. M. Beer[1];
[1]Exact Sciences Corp., Madison, WI, [2]Geisinger, Danville, PA, [3]Johns Hopkins University, Baltimore, MD

Background: Blood based tests for multi-cancer early detection (MCED) are being developed to facilitate the earlier detection of various cancer types. The Detecting cancers Earlier Through Elective mutation-based blood Collection and Testing (DETECT-A) study evaluated the CancerSEEK MCED test, an early version of the Exact Sciences MCED test in development, in 9,911 women, age 65-75, without previous history of cancer (Lennon et al., Science 2020). The degree to which MCED testing will facilitate detection of precancerous conditions or incidental findings is unclear. Here we focus on DETECT-A participants who had pre-cancerous conditions diagnosed during a diagnostic work-up for a positive CancerSEEK MCED test.
Methods: In a post-hoc analysis, we report on the detection of precancerous conditions consequent to CancerSEEK MCED testing and follow-up. Electronic health records were reviewed for diagnostic procedures performed, details of premalignant and cancer diagnoses, and vital status.
Results: In three individuals, mutations in *PIK3CA*, *TP53*, or *KRAS* genes led to a positive CancerSEEK MCED test result. The prescribed imaging protocol using 2-deoxy-2[fluorine-18] fluoro-D-glucose positron emission tomography-computed tomography (18-FDG PET-CT), revealed a 10.3x9.8x7.8(cm) ovarian mucinous cystadenoma, a 0.8 cm appendiceal mucinous neoplasm, and 3 colonic polyps displaying high-grade dysplasia. All three participants were diagnosed with clinically significant pre-cancerous lesions, subsequently underwent surgical treatment, and remain alive and cancer-free as of February 2023 (Table 1).
Conclusion: The diagnostic evaluation of a positive MCED test may occasionally reveal clinically significant pre-cancerous conditions amenable to interventions. The frequency of such findings and their clinical impact warrants further study.

#2451 Investigation of SIRT6 usefulness as a novel biomarker for oral cancer.

H. Yoshii, A. Shimoda, K. Mitsudo, M. Kioi;
Yokohama City Univ. - Fukuura Campus, Yokohama, Japan

Introduction: SIRT6 is one of the seven human sirtuin genes and is known to function as an onco-suppressor gene in colorectal and ovarian cancers, although it is up-regulated in other cancers. Thus, SIRT6 is considered performing both tumor-suppressing and promoting roles. However, the association of SIRT6 with oral squamous cell carcinoma (OSCC) and its role in OSCC pathogenesis are currently unclear. Currently, SCC or CYFRA are used as a tumor marker to assist in the diagnosis of OSCC in a clinical setting whereas its sensitivity is low. Therefor the development of a novel biomarker for early diagnosis and identification of new therapeutic targets is critical to resolve the pressing clinical issues related to the management of OSCC. This study aimed to investigate the expression and the relevance of SIRT6 in patients with OSCC and its potential as a biomarker for early detection and prognosis prediction.
Materials and Methods: This study enrolled 78 patients with OSCC and 9 patients with carcinoma in situ (CIS) . The OSCC patients had undergone surgery or chemoradiotherapy (51 surgery and 27 chemoradiotherapy). The CIS patients had undergone surgery. Samples were also obtained from 10 patients with oral potentially malignant disorders (OPMDs). Biopsied or surgical resected samples were used for the study. We obtained 21 noncancerous tissues as normal tissues from the adjacent noncancerous tissues after tumor resection. Immunohistochemistry, quantitative real-time RT-PCR, and microarray analyses were performed to determine SIRT6 expression and its association with clinicopathological features in OSCC, CIS, and OPMDs using clinical paraffin embedded specimens.
Results: SIRT6 mRNA levels were higher in OSCC tissues than those in noncancerous tissues ($p<0.05$). And SIRT6 protein expression levels were higher in OSCC, CIS and OPMDs tissues than those in noncancerous tissues ($p<0.05$). SIRT6 expression was predominant in patients aged ≥65 years and significantly correlated with shorten overall survival. In the microarray analysis, some SIRT6-associated genes, such as ANXA2 was significantly up-regulated, and PIGC and RGPD4 were down-regulated in OSCC.
Conclusion: SIRT6 plays a role in tumor homeostasis, leading to a poor prognosis in OSCC. SIRT6 may represent a novel target not only for the treatment, but also as a prognostic marker in OSCC.

#2452 Clinical importance of nicotinamide nucleotide transhydrogenase in obesity-associated colorectal cancer.

S. Jeong[1], S. Park[1], J. An[2], m. Kang[1], S. Nam[1], J. Kim[1];

[1]Gachon University Gil Medical Center, Incheon, Korea, Republic of, [2]Korea University Anam Hospital, Seoul, Korea, Republic of

Background: Obesity is increasing worldwide, and many associated diseases are emerging as global health problems. There is a relationship between body mass and the risk of developing colorectal cancer (CRC). However, predictive biomarkers of survival with body mass remain elusive. Therefore, we aimed to identify novel clinically relevant biomarkers for obesity-associated CRC.

Methods: We searched for biomarker candidates in The Cancer Genome Atlas CRC cohort. We divided the TCGA CRC cohort (n=268) data into 3 groups (healthy weight CRC group [HT], adjacent normal tissue from the HT group [AN]), and obesity CRC group [OT]). Candidates were validated by survival analysis after immunohistochemistry in an independent cohort of 420 patients.

Results: The gene expression levels of NNT, PANK3, PPARGC1B, RTL6, FAM220A, and TMEM9 were associated with survival in overweight and obese patients with CRC from TCGA cohort. These findings were validated using protein expression data from our independent cohort. In our patient cohort, the hazard ratio (HR) of the subgroup of low NNT versus that of high NNT in terms of 5-year event-free survival (EFS) was 2.20 (adjusted for age and sex, 95% CI: 1.01-4.80, $p < 0.05$) among patients of obesity-associated CRC. When both TNM staging and NNT expression were considered, patients of obesity-associated CRC with low NNT expression and advanced stage III-IV cancer had a HR of 21.20 (adjusted for age and sex, 95% CI: 2.88-156.08, $p < 0.01$) compared to those with high NNT expression and early stage I-II cancer. However, when patients of obesity-associated CRC with high NNT expression and advanced stage III-IV cancer were compared to those with high NNT expression and early stage I-II cancer, the former subgroup had a HR of 8.39 (adjusted for age and sex, 95% CI: 1.03-68.39, $p < 0.05$) in terms of the 5-year EFS. Finally, when the 5-year disease-specific survival analysis was performed, the patients of obesity-associated CRC with low NNT expression and advanced stage III-IV cancer were found to have a HR of 14.05 (adjusted for age and sex, 95% CI: 1.89-104.38, P = 0.01) compared to those with high NNT expression and early stage I-II cancer. Furthermore, low NNT expression results in the inactivation of several metabolic pathways, including ROS-related pathways.

Conclusions: NNT is a novel and promising CRC prognostic biomarker for overweight and obese patients. It can provide clinicians with early indicators of patient prognosis and aid in appropriate treatment selection.

#2453 Soluble B7H3 has a potential of novel serum biomaker for colorectal cancer.

A. Koizumi[1], T. Ito[1], K. Kato[2], T. Iwasawa[1], T. Kushida[1], K. Sato[1], C. Okamoto[1];
[1]Juntendo Shizuoka Hospital, Izunokuni City, Japan, [2]Toyo University, Kawagoe, Japan

B7H3 (also known as CD276, an immune checkpoint molecule) is aberrantly over expressed in many types of cancer. Recently, several reports indicate a crucial role for B7H3 in promoting carcinogenesis and metastasis. We investigated whether concentration of the soluble B7H3 could be used as a new prognostic predictor of colorectal cancer by measuring serum level of B7H3. Recently we established a new mAb to B7H3 and developed sandwich ELISA-system detecting human serum B7H3 with high sensitivity and specificity. Measuring the levels of B7H3 in the serum specimens of colorectal cancer donors, we examined the usefulness of B7H3 as a novel biomarker for colorectal cancers. We tested the blood from the 82 donors of colorectal cancers and 9 healthy donors who agreed in writing to this research, just before the operation. The mean value + 2SD in 9 healthy donors was set as the cutoff value. We classified cancer patients into 2 groups with high value of B7H3 and low value of B7H3. We also analyzed the relationships between serum B7H3 levels and disease-free survival (DFS) and overall survival (OS). Serum B7H3 levels were also compared with diagnostic biomarkers such as CEA and CA19-9. B7H3 immunostaining was also performed on tissue samples. The serum levels of B7H3 in patients with colorectal cancer were significantly higher than those of healthy donors. However, there were no correlation between B7H3 and other diagnostic markers CEA and CA19-9. Regarding DFS, the higher value group of serum B7H3 showed a tendency for DFS to decrease in Stage II and III. Regarding OS, there was no significant difference of serum levels of B7H3 in Stage I and IV cases, however, in Stage II and III, OS decreased significantly in the high B7H3 group. In B7H3 immunostaining, the tissue was not sufficiently stained. These data indicate that serum B7-H3 should be useful for novel biomarker for a rationale of disease monitoring and prognosis of colorectal cancer.

CLINICAL RESEARCH: Immunomodulatory Interventions and Mechanisms
Poster Session

#2457 Brain derived endothelial cells as a mediator of cGAS-STING driven anti-tumor efficacy in glioblastoma.
A. Schmidt, S. Remson, P. Vaughn-Beaucaire, J. L. Jimenez-Macias, P. Srinivasan, M. Pinho-Schwermann, S. Lawler;
Legorreta Cancer Center at Brown University, Providence, RI

The median survival time for newly diagnosed patients with glioblastoma (GBM) is 15 months, highlighting the need for improved therapies. Current treatment for newly diagnosed and recurrent GBM consists of tumor resection and chemoradiation therapy. The immunosuppressive tumor microenvironment (TME) is a central obstacle in the treatment of GBM. Lack of NK cell and CD8+ T cell infiltration prevents efficacy with immunotherapies like immune checkpoint blockade (ICB).One approach our lab is pursuing to enhance tumor infiltrating lymphocytes is through harnessing the anti-viral cGAS-STING pathway. Upon cGAS activation by cytosolic double stranded DNA, the TBK1 kinase is phosphorylated, initiating a subsequent type I interferon (IFN) response and the recruitment of immune cells. This pathway is commonly altered in many cancer types to evade immune activation. Our lab has demonstrated survival benefits with STING agonist treatment in immunocompetent GBM mouse models. We have also shown strong STING localization in the vasculature, implicating endothelial cells as a potential treatment target for anti-tumor efficacy. Here we investigated the potential role of tumor vasculature in mediating the effects of STING agonists in GBM therapy.We have shown robust cGAS-STING activation in brain endothelial cell lines through enhanced secretion of CXCL10, IFN-β, and RANTES upon STING agonist treatment *in vitro*. Western blotting also shows pathway activation in response to treatment through increased phospho-TBK1 levels. Activation was further potentiated by manganese.To investigate the effects of STING activation in brain endothelial cells in detail, we performed RNA sequencing. This showed 262 differentially expressed genes in response to pharmacologic cGAS-STING activation, with 183 of these being upregulated. The top gene ontology terms enriched include type I interferon signaling pathway, defense response to virus, and antigen processing and presentation of exogenous peptide antigen via MHC class I, TAP-independent. In addition, gene expression of tight junction protein Claudin 5 was also enhanced. We have also shown increased resistance in response to activation, through transendothelial electrical resistance (TEER) assays. Taken together, these results suggest that cGAS-STING activation in endothelial cells leads to tight junction remodeling in addition to immunomodulatory changes, implicating roles for endothelial cells in barrier function and immune cell interactions respectively. Current research in our lab focuses on elucidating the mechanisms behind these changes. Our goal is to identify beneficial endothelial cell changes which promote anti-tumor immunity in order to inform future treatment strategies. We are currently performing studies aimed at demonstrating that cGAS-STING activation in endothelial cells is critical for the efficacy of STING agonist treatment.

#2458 Targeting the CXCR3 axis in HER2+ breast cancer to enhance anti-tumor immunity.

A. Bhagat, J. Joseph, J. D. Ginzel, C. Rabiola, A. C. Hobeika, J. C. Snyder, H. K. Lyerly, E. J. Crosby;
Duke University, Durham, NC

Breast cancer (BC) is the most frequently diagnosed cancer in women worldwide with more than 2 million new cases in 2020. The efficacy of immunotherapies for BC is limited, with response rates of <10% for anti-PD-1/PDL1 monotherapy in pre-treated triple-negative breast cancer (TNBC) patients and even lower in subtypes that express human epidermal growth factor receptor 2 (HER2+) and/or hormone receptors. Hence, there is an urgent need to improve immune based strategies for BC. One possible approach to enhance response is the application of intratumoral (IT) immunotherapy utilizing IL-12; a potent pro-inflammatory cytokine that is critical in producing an anti-tumor response. However, systemic delivery of IL-12 has substantial toxicity and localized delivery of protein has insufficient residence time. To circumvent these issues, we have previously reported the efficacy of intratumorally injected plasmid IL-12 (pIL-12-EP) followed by electroporation in a TNBC mouse model and in clinical trials. Following pIL-12-EP, treated tumor expressed genes that were associated with increased CD8+ T cell infiltration, activation, trafficking, antigen presentation, and exhaustion. Single-cell RNA sequencing (scRNAseq) of tumor infiltrating immune cells from treated tumors revealed a striking enrichment of the CXCL9/10/11/CXCR3 family. This CXCR3 axis is upregulated in response to IFNγ production and has been studied extensively in melanoma and NSCLC patients as a potential predictive biomarker for responses to immune checkpoint inhibitors but has not been well characterized in BC. We hypothesized that this axis may be the critical component downstream of pIL-12-EP treatment that is responsible for anti-tumor responses and that targeting it will be effective in other molecular subtypes of BC beyond TNBC. We first evaluated the expression of CXCR3 by tumor infiltrating lymphocytes (TILs) in biopsies of human HER2+ BC. Using a single cell resolution spatial transcriptomic Xenium instrument we find not only expression of CXCR3 by TILs, but can also track the distance and gradients of the chemokine ligands CXCL9 and CXCL10 in this tumor microenvironment. Having confirmed the activity of this axis in human HER2+ BC, we used our well-established spontaneous HER2-driven mouse model to compare treatment of HER2+ tumors with pIL-12-EP or pCXCL9-EP intratumorally. We observed tumor growth inhibition in both treatment groups as compared to control treated tumors. Interestingly, the abscopal effect previously seen with pIL-12-EP was not evident for distant tumors in mice treated with pCXCL9-EP. These data suggest that IT CXCL9 therapies may benefit from combination with a systemic immune activator like a vaccine or immunogenic chemotherapy. Ongoing studies will continue to evaluate ways to better target this axis therapeutically and define clinically active combination therapies.

#2459 ADT-030 is a novel dual-acting RAS/β-catenin inhibitor that potentiates antitumor immunity.

M. Y. Gazi[1], O. Okoko[1], X. Wang[1], C. Brandle[1], X. Chen[2], K. Fadlalla[2], A. Keeton[2], Y. Maxuitenko[2], C. Hedrick[1], H. Shi[1], G. Piazza[2], **G. Zhou**[1];
[1]Augusta University Medical Center, Augusta, GA, [2]Auburn University, Auburn, AL

ADT-030 is a novel indene identified from a screening campaign and chemically optimized for drug-like properties that acts as a dual inhibitor of RAS and β-catenin signaling. Here we demonstrate that ADT-030 binds RAS with high affinity and inhibits MAPK/AKT signaling with high potency and selectivity in KRAS mutant cells to inhibit proliferation and induce apoptosis. ADT-030 also inhibits phosphodiesterase 10A (PDE10) that is overexpressed in cancer cells to selectively activate cyclic guanosine monophosphate (cGMP)/protein kinase G (PKG) signaling, which induces phosphorylation and degradation of the oncogenic pool of β-catenin. ADT-030 exhibited cytotoxicity to a variety of murine cancer cell lines *in vitro*, and inhibited tumor growth in syngeneic immunocompetent mice when orally administered. The antitumor activity of ADT-030 was diminished in mice that were immunodeficient or depleted of CD8+ T cells, indicating a critical role of the host immune system. In a metastatic breast tumor mouse model (4T1), ADT-030 not only delayed the growth of the primary tumor but also reduced tumor colonization in the lungs, leading to increased survival. CyTOF and scRNAseq analyses provided a plethora of information revealing the impact of ADT-030 on the immune milieu in the tumor microenvironment. Notably, ADT-030 selectively induced apoptosis of myeloid-derived suppressor cells (MDSCs) while CD8+ T cells were not affected. Consequently, ADT-030 treatment resulted in a marked reduction of MDSCs, which was accompanied by increased tumor infiltration of effector CD8+ T cells. ADT-030 treatment of cancer cells led to immunogenic cell death and enhanced dendritic cell activation. Furthermore, the ability of ADT-030 to augment the antitumor activity of immune checkpoint blockade therapy underlines its potential as a desirable immune-potentiating agent to improve the outcome of cancer immunotherapy. ADT-030 represents a development candidate ready for IND-enabling safety assessment.

#2460 Receptor antibody conjugated engager (RACE): A novel bispecific 4-1BB engager platform for enhanced immuno-oncology therapy.

DaeHee Lee[1], Jihye Yoon[1], Jonggwan Jeong[1], Jeonghyeon Bak[1], KkaBi Son[1], Heechan Kim[1], Seil Jang[1], **Minseok S. Kim**[2]

[1]CTCELLS Inc., Seoul, Korea, Republic of,[2]Daegu Gyeongbuk Institute of Science and Technology (DGIST), Daegu, Korea, Republic of

Background: Traditional immuno-oncology strategies, such as checkpoint blockade therapy, are evolving to immune cell engagers as a smarter strategy. The early successes of Blincyto, a CD3 engager, demonstrated its capacity to activate host pan-T cells irrespective of their TCR-pMHC restriction status. However, this broad activation has been linked to off-target immunotoxicities, thus limiting its therapeutic applicability. In response, targeting immune co-stimulatory receptors like CD28 or 4-1BB has gained attention by their expression being induced on activated immune effector cells, presenting a more targeted approach to cancer therapy.

Methods: We developed RACE, a novel bispecific 4-1BB engager. This platform fuses a 4-1BB ligand (4-1BBL) trimer with antibody F(ab')2 fragments, excluding Fc domains. A Key and lock design on the 4-1BBL trimer interface facilitates asymmetric assembly of 4-1BBL dimer and monomer in the endoplasmic reticulum, achieving over 95% assembly efficiency in mammalian systems.

Results: RACE differs from conventional 4-1BB agonistic antibodies in its ability to form natural hexagonal hyper-clusters of 4-1BB receptors, enhancing NF-κB signal transduction. Unlike first-generation 4-1BB antibodies, which incurred off-tumor hepatotoxicity, RACE selectively activates 4-1BB receptors only in the presence of tumor antigens. Enhanced cytotoxicity requires successful TCR signaling complex formation between T cells and cancer cells. In CT26 and MC38 tumor models, RACE not only induced strong anti-tumor effects without hepatic or systemic toxicities but showed synergistic efficacy with anti-PD-1 antibodies as well.

Conclusion: The novel RACE platform represents a potent as well as safe immuno-oncology strategy, demonstrating significant potential for clinical application.

#2461 Discovery of an orally available and liver-targeted ALPK1 agonist for cancer immunotherapy.

Yupeng Wang[1], Nana Du[1], Xiaona Dong[1], Xuebing Sun[1], Yuan Hong[1], Xiaolong Yang[1], Zhijiang Ji[1], Qianyu Wang[1], Yun Lv[1], Zhichen Shi[1], Yajuan Gao[1], Xiaofu Hou[1], Yaxin Zhang[1], Juan Wang[1], Rui Mao[1], Yinxin Liu[1], Liang Li[1], Jingjin Ding[2], Hexiang Wang[1], Nan Hu[1], Counde O'Yang[1], Zhihong Li[1], Keith Bley[3], Feng Shao[4]

[1]Pyrotech (Beijing) Biotechnology Co., Ltd., Beijing, China,[2]National Laboratory of Biomacromolecules, CAS Center for Excellence in Biomacromolecules, Institute of Biophysics, Chinese Academy of Sciences, Beijing, China,[3]Pyrotech Therapeutics, Inc., Reno, NV,[4]National Institute of Biological Sciences, Beijing, China

Boosting anti-tumor immune responses can be achieved by activating the innate immune system. Despite the ongoing development of numerous STING and TLR agonists for this purpose, none of them have progressed to late-stage clinical evaluation. Alpha protein kinase-1 (ALPK1) is an intracellular innate immune receptor newly identified for its ability to detect ADP-heptose, a metabolite released during the biosynthesis and degradation of lipopolysaccharides (LPS). Since heptose is not naturally present in mammalian cells, the recognition of heptose metabolites by ALPK1 serves as a reliable mechanism to identify bacterial infections. When ADP-heptose binds to ALPK1, it initiates the phosphorylation of TIFA, thereby triggering a cascade of immune responses. Systemic administration with ADP-heptose induces robust ALPK1-dependent cytokine responses in mice. While high doses of ADP-heptose demonstrate anti-tumor effects, its instability and low *in vivo* potency hinder its clinical development. Through a SBDD medicinal chemistry effort, a novel, stable, and potent ADP-heptose analog, designated PTT-936, has been discovered and is progressing into clinical evaluation in cancer patients. PTT-936 exhibits remarkable nanomolar potencies for ALPK1 activation in various cellular assays. Notably, in human PBMCs, PTT-936 induces both concentration-dependent release of cytokines and activation of NK and T cells. Consistent with *in vitro* studies, oral administration of PTT-936 triggered significant cytokine responses in mice at microgram dose levels. However, overt toxicities were observed only at milligram dose levels, indicating a wide therapeutic window for this compound. In syngeneic tumor models, oral administration of PTT-936 induced dose-dependent tumor growth inhibition, which correlated with elevations in several cytokine biomarkers. Mechanistic studies show that PTT-936, working exclusively through the ALPK1 pathway, elicited strong innate and adaptive immune responses, as evidenced by robust cytokine induction and immune cell activation and recruitment. In syngeneic mouse models, the anti-tumor effects of PTT-936 were significantly hindered by either $CD8^+$ T cell depletion or neutralization of select cytokines. Besides monotherapy studies, compelling evidence demonstrates strong synergistic anti-tumor effects when combining PTT-936 with immune checkpoint inhibitors. Intriguingly, PTT-936 exhibits favorable tolerability and a wider therapeutic index compared to certain clinical-stage STING and TLR agonists. Furthermore, PTT-936 does not enhance cytokine elevations induced by checkpoint inhibitors, which have been linked to adverse events (including CRS) observed in clinical combination studies. The dosing frequency of PTT-936 in the upcoming first-in-human clinical trial is carefully designed to prioritize both tolerability and patient compliance.

#2462 Live attenuated Salmonella ZH9 as novel microbial immunotherapy for the treatment of bladder cancer.

N. Glanville[1], O. Oke[1], C. Prevosto[1], A. Sevko[1], A. Scott[1], S. Domingos-Pereira[2], L. Polak[2], D. Nardelli-Haefliger[2], L. Deban[1];
[1]PROKARIUM, London, United Kingdom, [2]Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland

Microbial immunotherapy with Bacillus Calmette-Guérin (BCG) has been the standard-of-care for non-muscle invasive bladder cancer (NMIBC) for over 30 years. Today, global demand for BCG exceeds supply, leaving many patients untreated. BCG is associated with high disease recurrence and presents high treatment burden for patients. There remains therefore significant unmet need for novel therapeutic approaches for NMIBC and we sought to establish the utility of the live-attenuated *Salmonella enterica* Typhi ZH9 as a more effective microbial immunotherapy. Efficacy of ZH9 was established in orthotopic, syngeneic, mouse MB49 tumor models in which animals were treated in the bladder via catheterization, with or without prior subcutaneous immune priming. Immune responses were measured by flow cytometry and Nanostring transcriptomic analyses of bladder tissues. An intravesical dose of ZH9 after orthotopic MB49 tumour inoculation demonstrated significant survival benefit compared to both vehicle control and equivalent colony forming unit (CFU) BCG treatments. Repeat, weekly dosing studies showed a single administration of ZH9 was sufficient for maximum efficacy. To explore the durability of protection, surviving intravesical ZH9 treated animals were rechallenged, demonstrating protection from both bladder and subcutaneous MB49 tumors suggestive of lasting local and systemic anti-tumor immunity. Flow cytometry analysis of bladders showed that intravesical ZH9 treatment resulted in cellular immune response characterised by recruitment of NK cells, CD4+ and CD8+ T cells, and dendritic cells with an activated, cross-presenting phenotype, in all cases of greater magnitude than after treatment with an equivalent dose of BCG. Based on observations that pre-existing immunity to BCG has been associated with improved outcomes to intravesical BCG therapy in NMIBC, we explored whether systemic priming with ZH9 benefits local bladder therapy. Systemic prime with ZH9 followed by a single intravesical dose of ZH9 showed a trend for improved survival and will be explored in the clinical setting. This systemic immune priming effect was associated with enhanced local bladder immune cell infiltrates and the upregulation of more than 150 immune response genes in the bladder compared to intravesical therapy alone. These data form the basis of preclinical package accepted by the FDA for a Phase 1/1b study evaluating the safety, pharmacology, and clinical effect of ZH9 treatment in patients with NMIBC, currently recruiting patients. The investigation includes thorough translational and biomarker studies to delve into the mechanism of action of ZH9 and explore patient stratification approaches. By easing the treatment burden on patients, lowering healthcare costs, and featuring a scalable manufacturing process, ZH9 has the potential to revolutionize the treatment paradigm in NMIBC and reshape the patient journey.

#2463 Targeting CXCR4 impaired T regulatory function through PTEN in renal cancer patients.

Giuseppina Rea[1], Sara Santagata[1], Anna Maria Bello[1], Anna Capiluongo[1], Maria Napolitano[1], Sonia Desicato[1], Alessandra Fragale[2], Crescenzo D'Alterio[1], Anna Maria Trotta[1], Caterina Ierano[1], Luigi Portella[1], Marilena Di Napoli[1], Salvatore Di Maro[3], Florinda Feroce[1], Rosa Azzaro[1], Lucia Gabriele[4], Nicola Longo[5], Sandro Pignata[1], Sisto Perdona[1], Stefania Scala[1]

[1]IRCCS National Cancer Inst. G. Pascale Foundation, Naples NA, Italy,[2]Oncology and Molecular Medicine, Istituto Superiore di Sanit, Roma, Italy,[3]Biological and Pharmaceutical Science and Technology, University of Campania "Luigi Vanvitelli, Naples NA, Italy,[4]Oncology and Molecular Medicine, Istituto Superiore di Sanit, Naples NA, Italy,[5]Reproductive Sciences and Odontostomatology, Urology Unit, University of Naples "Federico II", Naples NA, Italy

Purpose: In Renal Cell Carcinoma (RCC) a crucial role is played by tumor microenvironment (TME). The high presence of T regulatory cells (Tregs) in TME cause a suppressive environment that promotes the tumor growth and its treatments failure. Tregs trafficking is controlled by CXCR4. In RCC, the new CXCR4 antagonist R54 was explored in peripheral blood Tregs isolated from primary RCC patients.

Experimental Design: To investigate the mechanism by which the new CXCR4 antagonist R54 impairs Tregs activity, peripheral blood (PB) Tregs were explored on primary RCC patients. PB-Tregs were isolated from 77 RCC patients and 38 healthy donors-(HD) and CFSE-Tregs suppression assay, IL-35 secretion and Nrp-1+Tregs frequency was conducted. PB-Tregs were analyzed for PTEN, CD25, TGF-β1, FOXP3, DNMT1 expression. PTEN-pAKT signaling was evaluated in the presence of R54 and/or triciribine (TCB), Akt inhibitor. TSDR (Treg-specific Demethylated Region) methylation analysis was conducted.

Result: Ex vivo R54 impaired PB-RCC-Tregs function, reduced IL-35 release and Nrp-1+Tregs. As PTEN and CD25 expression significantly decreased in R54-PB-RCC-Tregs, PTEN signaling was evaluated. While CXCL12 recruited PTEN+CD25+Tregs cells, R54 significantly reduced it in PB-RCC-Tregs. Tregs activation through IL-2/PMA impaired pAKT+Tregs while R54 increased it. The Akt inhibitor, triciribine, prevented the pAKT+Tregs R54 induction. As active Tregs present demethylated Treg-specific region (TSDR), a significant decrease in demethylation rate (DMR) of Foxp3-TSDR was observed in R54 treated PB-RCC-Tregs. As consequence of TSDR modulation, the expression of Tregs regulating genes was evaluated with significant reduction in DNMT1 and FOXP3 expression. Taken together, our findings demonstrated that R54 causes an impairment of peripheral Tregs functionality in primary RCC patients through regulation of PTEN/PI3K/AKT pathway, resulting in impaired Tregs activity.

Conclusion: The CXCR4 antagonist R54 affects Tregs function in primary RCC patients through regulation of PTEN/PI3K/AKT pathway, reduction in TSDR demethylation and Foxp3 and DNMT1 expression. CXCR4 targeting is thus a strategy to inhibit Tregs activity contributing to the CXCR4 function in RCC tumor microenvironment.

#2464 Defective NMD promotes aberrant intron retention in clear cell renal cell carcinoma.

M. Zhou, G. Giri, W. Y. Kim, D. Dominguez;
UNC Chapel Hill, Chapel Hill, NC

Clear cell renal cell carcinoma (ccRCC) is the 8th most common cancer in the United States, constituting 75% of all kidney cancer cases. Clear cell RCC (ccRCC) along with melanoma has traditionally been viewed as an immunotherapy responsive disease with a storied history of immunotherapy treatments including high dose interleukin 2 (IL2), interferon, and allogeneic stem cell transplant. Indeed, RCC was one of the first tumor types to garner FDA approval for PD1 immune checkpoint inhibition (ICI). However, unlike melanoma, most RCC tumors do not have a high tumor mutational burden (TMB) to potentially explain their immunotherapy responsiveness. We and others have sought to explain this unanswered question and have demonstrated that *non-canonical tumor associated antigens* like endogenous retroviruses (ERVs) may in part explain ICI response in RCC. We have noted that ccRCC tumors have the highest level of retained introns (RI) across all TCGA tumors, that RI levels are secondary to suppressed non-sense mediated decay (NMD) activity, and that one can subset ccRCC into RI-high and normal-like tumors. Moreover, we have found that mTOR signaling plays a key role in regulating NMD and intron retention and that mTOR inhibition can promote intron retention. We hypothesized that these aberrantly retained introns could serve as a rich source of highly foreign, tumor associated neoantigens and that of retained intron neoantigens, the ones not observed in normal tissue would be the most immunogenic. We derived a so called “Neo-RI-antigen burden” that represents the burden of retained intron neoantigens not found in normal tissues and demonstrate that the Neo-RI-antigen burden of complete responders is numerically higher than those with partial response or progressive disease in a dataset of immunotherapy treated melanoma patients. Our work suggests the possibility of using NMD-targeting drugs as a potential therapeutic in combination with ICI to enhance the overall treatment response.

#2465 A novel agonist of CD137 as a single agent shows cancer immunoprevention efficacy against various tumor types that is not dependent on the trained immunity.

F. N. Arguc, M. Tarique, V. Ulker, E. S. Yolcu, H. Shirwan;
University of Missouri - Columbia, Columbia, MO

Introduction: We recently demonstrated that pretreatment of mice with SA-4-1BBL, a novel oligomeric form of CD137 agonist, as a single agent prevents the development of various tumor types in mice. The tumor immunoprevention efficacy is long-lasting (>14 weeks) and contingent upon $CD4^{\pm}$ immune cells, NK cells, and IFN-γ, but not CD8+ T and B cells. Trained immunity mediated by previously activated myeloid cells has been shown to have efficacy against cancer. The objective of this study was twofold: i) assess the role of trained immunity and ii) elucidate the mechanistic underlying of cancer immunoprevention.
Study Design: Wild-type C57BL/6 mice and various transgenic ($CD4^{\pm}$ OT-II.$Rag^{+/+}$, $CD4^{\pm}$ OT-II.$Rag^{-/-}$, $CD8^{\pm}$ OT-I/$Rag2^{-/-}$ KO, and $Rag1^{-/-}$) mice on C57BL/6 background were pretreated subcutaneously with SA-4-1BBL or an agonistic Ab that does not have immunoprevention efficacy (3H3) twice two weeks apart. Mice were challenged two weeks later with a cervical cancer cell line (TC-1) and monitored for tumor development. A group of mice was also treated with monophosphoryl lipid A (MPLA), an agonist of TLR4 involved in trained immunity, using the above scheme. Mice treated with saline served as the control throughout all studies. Deep immunophenotyping was conducted to assess immune correlates of cancer immunoprevention.
Results: Pretreatment with SA-4-1BBL prevented tumor growth in wild-type mice (> 60%), whereas all MPLA treated mice developed tumor. SA-4-1BBL did not show tumor immunoprevention efficacy in mice lacking adaptive immune cells ($Rag1^{-/-}$ KO), OT-II cells on $Rag^{-/-}$ or $Rag^{+/+}$ background, and OT-I on $Rag2^{-/-}$ background. Deep immunophenotyping revealed a significant increase in the absolute number of $CD4^{\pm}$ T central memory and $CD4^{\pm}$ T stem cell-like memory cells, NK cells, NKT cells, and various myeloid cells in mice treated with SA-4-1BBL as compared with those treated with the 3H3 Ab or saline treated controls.
Conclusions: These results demonstrate that cancer immunoprevention efficacy of SA-4-1BBL requires a diverse T cell receptor repertoire as OT-II mice on $Rag^{+/+}$ background, restricted to a TCRβ chain, but have all other myeloid and NK cells, do not show efficacy. Furthermore, treatment with MPLA involved in trained immunity has no efficacy. Altogether, these observations do not implicate trained immunity as a mechanism of cancer immunoprevention. Elucidation of the mechanistic basis of SA-4-1BBL immunoprevention may have significant clinical implications.

#2466 tRNA-derived fragments as immunotherapy response targets in head and neck squamous cell carcinoma.

R. Yalamarty[1], D. John[1], A. Do[1], T. Chen[1], M. Ngo[1], P. Gande[1], M. Uzelac[1], W. Li[2], W. M. Ongkeko[1];
[1]University of California San Diego - UCSD, San Diego, CA, [2]University of California San Francisco School of Medicine - UCSF, San Francisco, CA

Background: Despite significant advances in immunotherapy-based treatment options for Head and Neck Squamous Cell Carcinoma (HNSCC), patient prognosis and survival remains poor. To enhance response to immune-based therapies, specific targeting of immunomodulatory pathways has been investigated through co-stimulatory gene targets, the microbiome, and more. An emerging biomolecule is Transfer RNAs (tRNAs), which are a class of RNAs that transport amino acids from the cytoplasm to ribosomes, and synthesize new proteins encoded by mRNA transcripts. tRNA-derived fragments (tRFs) are a category of cleaved, mature tRNA that participate in post-transcriptional regulation and have been implicated in the modulation of cancer and other immune-associated diseases. While tRFs are primarily implicated in diagnostic signatures for various cancers, few studies have investigated their role in modulating the immunotherapy-based response in HNSCC. In this study, we characterized the role of tRFs in modulating immunotherapy gene targets pertinent to HNSCC.
Methods: We extracted tRF read counts from MINTbase 2.0 for 455 primary HNSCC tumor samples and 44 adjacent normals. Differential expression analysis was first performed to identify tRFs implicated in HNSCC tumors, with respect to adjacent normal tissue. Next, these tRFs were associated with immunotherapy target genes and response markers with Spearman's correlation. Further characterization of these tRFs was performed by correlating their abundance to infiltrating immune cells, pathway enrichment of immunotherapy targets, and clinical variables.
Results: Significant differential expression of tRFs were found between HNSCC primary tumor samples and adjacent normal tissue, including 7 tRFs (FDR < 0.05, |log fold change| > 0.5). All were enriched in normal samples. AlaCGC5tRF appeared to be an important regulator of immunotherapy target genes through increased co-expression of PTPN11, STAT3, and PTEN (p-value < 0.05, R > 0) and decreased co-expression of CD58 and TNFRSF14 (p-value < 0.05, R < 0). Immune Checkpoint Inhibitor (ICI) genes were significantly correlated with several tRFs. Among several pertinent tRF markers, AlaCGC5tRF was strongly associated with negatively correlated with infiltrating activated NK cells naïve CD4 T cells (p-value < 0.05, R < 0).
Conclusion: Our study is the most comprehensive to date to characterize the role of tRF elements in modulating HNSCC immunotherapy targets. We found several potential tRF biomarkers that may be indicative of enhanced immunotherapy treatment susceptibility, including AlaCGC5tRF and ArgTCT3tRf. Further studies are needed to investigate how these tRFs may be targeted alongside immunotherapies to enhance response to treatment.

#2467 Enhanced CD8+T-cell infiltration, PD-L1 expression, and T-cell repertoire expansion in patients with metastatic uveal melanoma responding to treatment with RP2 alone or in combination with nivolumab.

P. K. Bommareddy[1], A. Kalbasi[1], K. J. Harrington[2], A. Olsson-Brown[3], T. Y. Chan[3], P. Nenclares[2], I. Leslie[2], M. R. Middleton[4], D. M. Cohan[1], K. Xynos[1], R. Coffin[1], J. J. Sacco[3];

[1]Replimune, Inc., Woburn, MA, [2]The Institute of Cancer Research, London, United Kingdom, [3]The Clatterbridge Cancer Centre and University of Liverpool, Liverpool, United Kingdom, [4]Churchill Hospital and University of Oxford, Oxford, United Kingdom

Background: Metastatic uveal melanoma (MUM), typically an immune-excluded tumor, has few effective treatments and shows limited clinical response to immunotherapy. RP2 is an enhanced-potency oncolytic HSV-1 that expresses GM-CSF, an anti-CTLA-4 antibody-like molecule, and the fusogenic gibbon ape leukemia virus membrane R− glycoprotein (GALV-GP-R−). Here, we present the biomarker data of RP2 monotherapy and RP2 + nivolumab (nivo; anti-PD-1) in patients (pts) with MUM from an ongoing clinical trial (NCT04336241).

Methods: Tumor biopsies and peripheral blood mononuclear cells (PBMCs) were collected pre-treatment and at Day 43 (D43). The tumor microenvironment (TME) was analyzed by immunohistochemistry (IHC). Systemic peripheral anti-tumor immunity was assessed by sequencing the CDR3β region of the T-cell receptor (TCR) using immunoSEQ Assay. HLA typing was obtained from patient history when available. Correlations between baseline tumor PD-L1 and CD8 expression, HLA type, prior treatment with ipilimumab (ipi)/nivo, and HLA status—vs clinical response status—were assessed.

Results: As of August 2022, 17 pts with MUM were enrolled (RP2 monotherapy, n = 3; RP2 + nivo, n = 14). The majority of pts had previously received both anti-PD-1 and anti-CTLA-4 therapy (12/17, 70.6%), and 17.6% had received ≥3 prior lines of therapy. ORR for the 17 pts was 29.4% (5/17; all PRs; RP2 monotherapy, 1/3; RP2 + nivo, 4/14). Eight pts (2 PR, 3 SD, and 3 PD) had evaluable baseline and post-treatment biopsies for IHC, and 13 pts (4 PR, 4 SD, and 5 PD) had evaluable baseline and post-treatment PBMCs for TCR sequencing analyses. Of the 10 patients that achieved clinical benefit (PR/SD), IHC analysis of all available (n = 5, 2 PR, 3SD) paired biopsies demonstrated an increase in intra-tumoral PD-L1 expression, and 4 patients (2 PR, 2 SD) exhibited an increase in CD8+ T-cell infiltration into tumors at D43. No increase in either CD8+ T-cell infiltration or PD-L1 expression was observed at D43 in patients with PD. There was no correlation between HLA-A2*02:01 status or prior treatment with ipi/nivo and response. In addition, TCR sequencing revealed expansion of pre-existing TCRs (including a tumor antigen-specific clone targeting MART-1 in a responding patient) and generation of new T- cell clones, following RP2 + nivo.

Conclusions: Preliminary RP2 + nivo data demonstrated meaningful antitumor activity in pts with MUM. Biomarker data indicated a conversion of the TME from an immune-excluded to an immune-infiltrated phenotype in responding patients following treatment with RP2 + nivo. Furthermore, systemic peripheral T-cell clonal expansion was noted. These results support further clinical development of RP2 + nivo in pts with MUM.

#2468 Phase II study of cryoablation and post-progression immune checkpoint inhibition in metastatic melanoma.

M. J. Mooradian, F. J. Fintelmann, T. J. LaSalle, J. Simon, A. Graur, A. Muzikansky, M. Mino-Kenudson, S. Shalhout, H. L. Kaufman, R. W. Jenkins, D. Lawrence, A. Lawless, T. Sharova, R. N. Uppot, J. Fang, E. M. Blaum, A. L. K. Gonye, I. Gushterova, G. M. Boland, N. Hacohen, M. Sade-Feldman, R. J. Sullivan;

Massachusetts General Hospital, Boston, MA

Introduction: Efforts to overcome resistance to immune checkpoint inhibition (ICI) are paramount, and novel combination strategies are in development. Image-guided percutaneous cryoablation is an established minimally invasive oncologic treatment that has demonstrated immune modulatory effects. We hypothesized that cryoablation may prime the tumor microenvironment (TME) through direct modulation of the tumor, thereby generating an anti-tumor response in ICI refractory tumors.

Methods: In this non-randomized phase II single-center study, subjects with unresectable melanoma progressing on ICI underwent cryoablation of an enlarging metastasis, and ICI was continued for a minimum of two additional cycles. The primary endpoint was safety and feasibility, with objective response rate (ORR) and disease control rate (DCR) in non-ablated lesions a key secondary endpoint. To better understand the inflammatory state of TME as well as factors determining response to cryoablation, we performed immunohistochemistry (PD-L1, CD8+ TIL) as well as single-cell RNA-sequencing (ScRNAseq) on evaluable pre- and post-cryoablation biopsies obtained from metastatic sites of 15 patients.

Results: From May 2018 through July 2020, 17 patients were treated. This regimen was feasible with all patients ongoing cryoablation with no unexpected safety signal. The ORR and DCR was 23.5% (95% CI 6.81-49.9) and 41.2% (95% CI 18.44-67.08), respectively, with four patients experiencing PR and three patients SD. Durable control, defined as tumor control ≥6 months, was achieved in 35%. Median progression-free survival (PFS) was 59 days (95% CI 42, 179) with a 6-month PFS rate of 23.5% (95% CI 7.3%, 44.9%). Median overall survival (OS) was 387 days (95% CI 106, 608) with a 1-year OS rate of 53% (95% CI (27.6%, 73%). Correlative analysis demonstrated pre-ablation tumors were uniformly associated with a “cold” TME, as all samples were PD-L1 negative and the majority had low levels of CD8+ TIL, defined as <5% of tumor cells associated with CD8+ TILs. ScRNAseq revealed no clear trends of cell type composition to predict best response to cryoablation, however an increase in B/plasma cells was seen in patients with disease control, suggesting these cells may play a role in mounting a durable anti-tumor response after cryoablation.

Conclusion: The anti-tumor efficacy of combining cryoablation and post-progression ICI was superior to what would be expected with the use of post-progression ICI alone with an acceptable safety profile. Our data support further study of this novel, synergistic therapeutic approach.

#2469 PROTAC mediated NR4A1 degradation as a novel strategy for cancer immunotherapy.

L. Wang[1], Y. Xiao[1], Y. Luo[2], R. Master[3], J. Mo[4], M.-C. Kim[5], Y. Liu[1], C. Maharjan[1], U. Patel[1], X. Li[6], D. Shaffer[6], G. Kevin[6], H. Zhuang[1], E. Moser[1], K. Smalley[7], D. Zhou[8], G. Zheng[1], W. Zhang[1];

[1]University of Florida, Gainesville, FL, [2]University of Copenhagen, Copenhagen, Denmark, [3]Florida State University, Tallahassee,, FL, [4]Thermo Fisher Scientific, Alachua, FL, [5]Veterinary Diagnostic Laboratory Medicine, Jeju-si, Jeju-do, Korea, Republic of, [6]Sanofi, Cambridge, MA, [7]Moffitt Cancer Center & Research Institute, Tampa, FL, [8]University of Texas Health Science Center at San Antonio, San Antonio, TX

An effective cancer therapy requires both killing cancer cells and targeting tumor-promoting pathways or cell populations within the tumor microenvironment (TME). We purposely search for molecules that are critical for multiple cell types in the TME and identified nuclear receptor subfamily 4 group A member 1 (NR4A1) as one such molecule. NR4A1 has been shown to promote the aggressiveness of cancer cells and maintain the immune suppressive TME. Using genetic and pharmacological approaches, we establish NR4A1 as a valid therapeutic target for cancer therapy. Importantly, we have developed the first-of-its kind proteolysis-targeting chimera (PROTAC, named NR-V04) against NR4A1. NR-V04 effectively degrades NR4A1 within hours of treatment in vitro and sustains for at least 4 days in vivo, exhibiting long-lasting NR4A1-degradation in tumors and an excellent safety profile. NR-V04 leads to robust tumor inhibition and sometimes eradication of established melanoma tumors. At the mechanistic level, we have identified an unexpected novel mechanism via significant induction of tumor-infiltrating (TI) B cells as well as an inhibition of monocytic myeloid derived suppressor cells (m-MDSC), two clinically relevant immune cell populations in human melanomas. Overall, NR-V04-mediated NR4A1 degradation holds promise for enhancing anti-cancer immune responses and offers a new avenue for treating various types of cancer such as melanoma.

#2470 Harnessing cytomegalovirus immunity against pancreatic tumors for immunotherapy.

R. Marrocco[1], J. Patel[2], S. Sun[2], R. Medari[2], K. Gulay[2], E. Lucero-Meza[1], E. Mose[2], A. Lowy[2], C. Benedict[1], **T. Hurtado de Mendoza**[2];
[1]La Jolla Institute for Immunology, La Jolla, CA, [2]UCSD Moores Cancer Center, La Jolla, CA

Immunotherapy has had very limited success in pancreatic cancer, due to its low mutational burden and immunosuppressive microenvironment. Our approach consists in redirecting pre-existing antiviral immunity against pancreatic tumors by delivering viral antigens using the tumor penetrating peptide iRGD .This peptide, targets the tumor vasculature through αv integrins and neuropilin-1, delivering conjugated or co-administered cargo to tumors. Here we used mouse cytomegalovirus (CMV) as an infection model. CMV is a β-herpesvirus that induces a strong T-cell response in mice and humans, comprising >10% of all circulating CD4 and CD8 T cells mostly with effector-memory phenotype. Importantly, human CMV infects over 60% of the world's population rendering it a suitable candidate for translation. Mice latently infected with CMV were orthotopically implanted with KPC pancreatic tumor cells and treated with systemic injections of vehicle or iRGD plus CMV class I and II binding peptides. Another cohort of age matched uninfected mice was used as a control. Tumor growth and mouse weight were monitored twice a week and CMV specific immune responses were measured in spleen and tumor by flow cytometry, using tetramer staining and CMV specific peptide recall. CMV infected mice receiving iRGD + CMV peptides responded to treatment as evidenced by delayed tumor growth associated with increased tumor necrosis and T cell infiltration. In addition, flow cytometry analysis of tumor and spleen showed a significant increase in CMV specific T cells that produced significant amounts of IFN-γ and TNF-α upon CMV peptide recall. Furthermore, tumor regulatory T cells (Treg) were significantly reduced and the CD8/T reg ratio was greatly increased. Survival studies showed a 68% increase in median survival in the treated and infected group. Combining this strategy with anti-PD1 and or anti-IL10R did not significantly improve the benefits of iRGD + CMV therapy alone. Other combinations with chemotherapy and TME remodeling agents are being tested.Taken together, this data shows we can deliver antigens to pancreatic tumors via iRGD and elicit an anti-tumor immune response that results in delayed tumor growth and has a survival benefit. This is a mutation agnostic approach with high translational value, since more than 60% of the population has previous CMV immunity and iRGD in combination with chemotherapy is already in phase II clinical trials for advanced pancreatic cancer.

#2471 State-of-the-art Specific T cell Activating Modulator on ePENDY platform (STAM.eP) activates specific CD8+ T cell by stimulating TCR signal.

K.-g. Hyun[1], S. Kang[1], Y. Kang[1], J. Koo[1], S. Park[1], S. Byun[1], S. Yoon[1], J. Lee[1], H. Lee[1], H. Lee[2], E. Cho[1], C. Lee[1], K.-C. Choi[2], G. Ha[1];
[1]IMBiologics, Suwon-si, Korea, Republic of, [2]Chungbuk National University, Cheongju-si, Korea, Republic of

After decades of research, therapeutic cancer vaccine approach now sheds light on developing efficient cancer therapy treating patients who have resistance to other cancer immunotherapy. However, cancer vaccine approach using conventional modalities such as protein, peptide, and mRNA is considered a powerful cancer treatment only when the patients have healthy immune systems. In addition, dendritic cell (DC) cancer vaccine can be a great alternative therapy, but manufacture of DC vaccines in vitro is a labor-intensive, time- and money-consuming procedure. Here, we developed Specific T cell Activating Modulator (STAM) on our engineered IgM backbone, ePENDY (engineered PENtamer boDY), with high avidity based on multivalent binding sites to overcome the disadvantages of other therapeutic cancer vaccines. STAM on ePENDY (STAM.eP) consists of ten peptide-loaded-HLAs linked to ePENDY to simulate priming signal of CD8+ T cell by TCR cluster and a costimulatory signal molecule is linked to J chain of ePENDY to prevent CD8+ T cell from becoming anergic status. With these features, STAM.eP mimics cognately licensed DC that can present tumor peptide-loaded MHC class I molecule to CD8+ T cell and promote its priming. Thus, one of the greatest advantages of STAM.eP is to be a potential treatment for immunosuppressive cancer patients with DCs that do not respond appropriately. Another advantage is that any tumor specific antigen (TSA), including from intracellular proteins, can be applied to STAM.eP concept to activate specific CD8+ T cells for targeting cancer cells. In this study, we used Human Papillomavirus (HPV) E7-derived peptide which is an oncoprotein associated with cervical and head/neck cancers. We observed that HPV E7-derived peptide loaded STAM.eP, named IMB-401, increases antigen-specific CD8+ T cell population and shows cytotoxicity activity against cancer cells expressing HPV E7 protein in vitro test model. In vivo test model, it was also observed that population of specific CD8+ T cells and memory T cells were increased in the blood and spleens of transgenic mice treated with IMB-401. Furthermore, we confirmed that IMB-401 shows anti-tumor efficacy due to an increase of antigen-specific CD8+ T cell in vivo humanized mouse model. These results suggest that IMB-401 can be a new therapeutic cancer vaccine technology that replaces DC function and is expected to have robust anti-tumor activity in combination with immune checkpoint inhibitors.

#2472 Inhibition of ENPP1 catalyzed ATP and cGAMP hydrolysis and *in vivo* antitumor efficacy of RBS2418 in the Hepa1-6 and GL261-luc syngeneic liver and glioblastoma mouse models.

N. Huang, J. Cheng, R. Hawley, K. Klumpp;
Riboscience LLC, Sunnyvale, CA

Background: ENPP1, a nucleotide pyrophosphatase and phosphodiesterase, has emerged as an important modulator of anti-tumor immune activation, as it regulates the concentrations of cGAMP and ATP in the TME. ENPP1 expression in tumors is common and correlates with a cold tumor phenotype. Its loss has been reported to suppress metastasis, restore immune cell infiltration into the tumor and potentiate the response to immune checkpoint blockade, while, conversely, the overexpression of ENPP1 promoted metastasis and rendered tumors resistant to checkpoint blockade. RBS2418 was designed as a potent and selective inhibitor of ENPP1 and is in clinical development.
Methods: ENPP1 enzyme inhibition was measured in vitro using cGAMP and ATP substrates. Effects of pH and serum and selectivity against related enzymes were evaluated. In vivo efficacy was assessed in Hepa1-6, and GL261-luc syngeneic liver and glioblastoma mouse models. Compound exposures were determined in tumor and blood samples. Cures were confirmed by re-challenge of cured animals with the same cancer cells.
Results: RBS2418 inhibited hydrolysis of cGAMP and ATP in vitro with similar potency (Ki =0.14 and 0.13 nM). Inhibition was also similar in human serum, consistent with low binding affinity to human serum albumin. In humans, oral dosing at doses of 100 mg could inhibit ENPP1 enzyme activity during the full dosing interval. Dosing of RBS2418 was performed in mice to achieve trough concentrations of RBS2418 in tumors and plasma exceeding ENPP1 EC90 levels for the complete dosing interval. In the Hepa1-6 model treatment with RBS2418 for either 2 or 10 days resulted in significant reduction of tumor growth and prolongation of survival as compared to vehicle control. There was no significant difference between the RBS2418 groups. Complete tumor regression was observed in 44% of treated mice across the two treatment groups. These mice were resistant to rechallenge with Hepa1-6 tumor cells. In the GL261-luc model treatment with RBS2418 showed significant reduction of tumor burden and prolongation of survival as compared to vehicle control. The mice that achieved complete tumor regression were resistant to rechallenge with GL261-luc tumor cells.
Conclusions: RBS2418 inhibited ATP and cGAMP hydrolysis by ENPP1 with similar high potency. The pharmacology profile was optimized to achieve low serum protein binding and oral bioavailability in humans. RBS2418 treatment was well tolerated in mice under conditions where tumor and plasma levels exceeding ENPP1 serum EC90 levels were achieved. In the syngeneic mouse models Hepa1-6 and GL261-luc significant tumor growth reductions, complete tumor regression and cures were observed. Resistance to cancer cell rechallenge was consistent with treatment-induced anti-tumor immunity.

#2473 A novel anti-PD-1 and proIL-2 bifunctional fusion protein delivers potent anti-tumor activity via PD-1 checkpoint inhibition and tumor selective IL-2R agonism preferentially on antigen specific T cells.

Z. Li, F. Zhang, Z. Zhang, **H. Zhou**;
Proviva Therapeutics, Inc, Bedford, MA

High-dose IL-2 (HD IL-2) induces complete and durable responses in RCC and melanoma but the treatment is associated with severe toxicities. PD-(L)1 blockade represents a recent breakthrough in immunotherapy with solid tumors, but only 20-30% of patients can benefit from the therapy and most responders eventually develop resistance. In more recent clinical studies with small number of subjects, HD IL-2 has shown promising responses in patients who progressed on anti-PD-1 therapy and combination therapy of HD-IL-2 and PD-1 blockade has resulted in high rate of objective response. In an attempt to maximize the clinical benefit of these immunotherapies to a broader patient population with deeper response and in the meantime to minimize the severe toxicity of HD IL-2, we have generated a novel bifunctional PD-1-proIL-2v fusion protein harnessing the mechanisms of PD-1 blockade and PD-1-cis directed tumor conditional IL-2R activation. PD-1-proIL-2v shows dose dependent inhibition of PD-1 immune checkpoint pathway measured by GM-CSF and IFNγ production in an MLR assay. Protease activated PD-1-proIL-2v, but not the intact drug, stimulates the phosphorylation of STAT5 of NK and T cells, the proliferation of CD8 T cells as well as the cytokine production in human whole blood. The potency of pSTAT5 by protease activated product is enhanced by 10-20 folds on PD-1^{+} T cells than T cells without PD-1. When tested in mouse tumor models resistant to PD-1 blockade, PD1-proIL-2v demonstrated high potency of tumor inhibition at as low as 0.1 mg/kg dose. In contrast, non-targeted proIL-2v at molar equivalent or higher dose showed minimal antitumor effect in either monotherapy or combination with anti-PD-1. Analysis of PD-1-proIL-2v treated mice showed dramatically increased tumor infiltrating CD4^{+} and CD8^{+} T cells, including PD-1^{+}Tcf-1^{+} and PD-1^{+} IL-18Ra^{+}TIM3^{-} CD8^{+} T cells, referred to “stem-like” progenitor effector cells and “fresh” effector cells, respectively. Activation of the IL-2 procytokine in PD-1-proIL-2v was observed in mouse tumor tissues but not in the plasma. In monkey GLP-compliant 4-week repeat-dose toxicity study, PD-1-proIL-2v demonstrated excellent safety profiles without overt irAEs that are characteristic of IL-2. In conclusion, our preclinical data demonstrated that PD-1-proIL-2v effectively stimulated the expansion and reinvigoration of antigen specific T cells in the tumor tissue resulting in strong anti-tumor efficacy while it did not cause significant peripheral toxicity. Phase 1 clinical trial of PD-1-proIL-2v is planned to start in early 2024 to evaluate the safety, pharmacokinetics and anti-tumor activity in advanced solid tumors.

#2474 Antitumoral efficacy of ASKG812, a Smartkine® based bifunctional PD-1-eIL-2 molecule, through enhancing T effector cis agonism.

C. Yu, K. Shanebeck, S. Yu, J. Ruiz, S. Li, S. D. Shi, H. Ma, Y. Lu;
AskGene Pharma Inc., Camarillo, CA

Cytokines are potent molecules, yet their broad application as therapeutics has been significantly hampered due to short PK, severe systemic toxicity, and narrow therapeutic window. To improve the developability of cytokines, AskGene has invented a proprietary cytokine platform (Smartkine®) to achieve its overarching objective of modulating immune reactions at a disease site in a selective and controlled manner. Several antibody-cytokine fusion molecules using the SmartKine® platform have been moving into preclinical and clinical development. ASKG812 is a unique fusion molecule composed of anti-PD-1 antibody and engineered IL-2 (eIL-2). The eIL-2 moiety also comprises a specific mask such that the eIL-2 molecule binding biases towards PD-1$^{\pm}$ T effector cells in a *cis* agonism manner for improved efficacy and therapeutic window. In *ex vivo* human PBMC assays, we demonstrated that ASKG812 significantly reduced activity in PD-1^{-} T and NK cells, and enhanced activity in PD-1$^{\pm}$ T cells judged by levels of pSTAT5, Ki67 and Granzyme B. In a cytotoxicity assay, ASKG812 can efficiently induce PBMC-mediated killing of MDA-MB-231 tumor cells in a dose-dependent manner. Moreover, in both anti-PD-1 therapy responsive and non-responsive syngeneic mouse tumor models, ASKG812 showed robust efficacy; without noticeable toxicity compared to a reference anti-PD-1-IL-2v fusion molecule. In conclusion, these findings provide the basis for the development of this new generation of PD-1 cis-targeted IL-2R agonists with enhanced therapeutic potential for the clinical treatment of cancer.

#2475 MB5029: A novel anti-PD-1 x IL-2v with improved safety profile and enhanced anti-tumor efficacy by selectively targeting activated T cells.

B. Park, H. Bang, S. Kim, S. Kim, S. Cho, S. Kim, M. Kim, Y. Park, J.-E. Park;
Research Institute of MustBio, Seoul, Korea, Republic of

Interleukin-2 (IL-2) offers therapeutic potential for cancer treatment, however, its clinical application is limited due to systemic adverse effects, such as vascular leakage syndrome (VLS). Notably, the high affinity of IL-2 for the IL-2 receptor α (IL-2Rα) activates immune-suppressive Treg cells and endothelial cells, leading to undesired outcomes. To address this challenge, a number of clinical studies are under development including non-α IL-2 variant (IL-2v) drugs and further the anti-PD-1 x IL-2v for targeted delivery of its IL-2v to PD-1 enriched T cells. Nevertheless, concerns about peripheral toxicity have not yet been solved. Thus, here we present MB5029, a novel anti-PD-1 x IL-2v bispecific fusion protein with modulated IL-2R binding affinity to mitigate the peripheral toxicity maintaining the anti-tumor efficacy. MB5029 has unique characteristics with no binding affinity to IL-2Rα and reduced binding affinity to IL-2Rγ, which is widely and highly expressed in various immune cells. MB5029 exhibited strong STAT5 phosphorylation activity under activated conditions but weak activity in the resting conditions, while the anti-PD-1 x IL-2v (non-α) showed strong STAT5 phosphorylation in both resting and activated conditions. In addition, MB5029 strongly induced the expansion of $CD8^{+}$ T cells in the activated conditions but less expansion of $CD8^{+}$ T cells in the resting conditions, in contrast to anti-PD-1 x IL-2v (non-α). The murine surrogate of MB5029 showed remarkable anti-tumor efficacy without body weight loss at the dose range of 1 to 10 mg/kg, whereas anti-muPD-1 x IL-2v (non-α) showed significant body weight loss in several tumor-bearing mice models. Moreover, MB5029 showed 100% complete regression (6/6) at the dose of 5 mg/kg or higher in the MC38 tumor model. The mice with complete response showed no signs of relapse upon tumor re-challenge until day 56, indicating a durable memory response. MB5029 exhibited a comparatively superior safety profile in normal mice. While anti-muPD-1 x IL-2v (non-α) led to significant body weight loss at the dose of 5 mg/kg in normal mice, the murine surrogate of MB5029 was shown to be well-tolerated up to a dose of 30 mg/kg without body weight loss. MB5029 exhibited dose-proportional PK properties and induced expansion of $CD8^{+}$ T cells in a dose-dependent manner in cynomolgus monkeys. MB5029 is shown to be well-tolerated up to 9 mg/kg without severe clinical signs and no significant increase in eosinophil and cytokines in the blood. Overall, MB5029 represents a promising potential as an immunotherapeutic approach, as it has demonstrated both strong efficacy and good tolerability, along with improved safety margins.

#2476 Electroporation-mediated novel albumin-fused Flt3L DNA delivery promotes cDC1-associated anticancer immunity.

M.-H. Hu[1], T.-C. Wu[2], C.-F. Hung[2];

[1]Wan Fang Hospital, Taipei, Taiwan, [2]Johns Hopkins University, Baltimore, MD

Introduction: Dendritic cells (DCs) constitute a distinct type of immune cell found within tumors, serving a central role in mediating tumor antigen-specific immunity against cancer cells. Frequently, DC functions are dysregulated by the immunosuppressive signals present within the tumor microenvironment (TME). Consequently, DC manipulation holds great potential to enhance the cytotoxic T cell response against cancer diseases. The Fms-like tyrosine kinase receptor 3 ligand (Flt3L) is a pluripotent growth factor that regulates the maturation and differentiation of DCs in hematopoiesis. The *in vivo* administration of Flt3L itself is limited by its short serum half-life. To overcome this major drawback, our group developed a novel fusion protein albumin-Flt3L (alb-Flt3L), which is the conjugation of albumin to Flt3L. Our hypothesis is that the Flt3L, which has extended bioavailability, is a feasible therapeutic strategy to overcome these treatment limitations.

Method: A novel alb-Flt3L DNA, a plasmid encoding the alb-Flt3L protein, was administrated for its anti-tumor effect on TC-1 tumor-bearing C57BL/6 mice. For the generation of pcDNA3-albFlt3L, mouse Flt3 ligand was amplified by PCR using cDNA template of pcDNA3-Flt3L[1] and a set of primers, 5′-TTTGAATTCGGGACACCTGACTGTTACTTC-3′ and 5′- AAACTTAAGCTACTGCCTGGGCCGAGGCTCTGG -3′. alb-Flt3L DNA (10ug), Flt3L DNA (10ug) or vehicle control was injected intratumorally followed by electroporation for a total of three times in 5-day intervals. Peripheral blood mononuclear cells and tumor-infiltrated immune cells were isolated after treatment. Flow cytometry was performed for immune cell analysis.

Results: In this current study, the electroporation-mediated delivery of alb-Flt3L DNA demonstrated the ability to induce an anti-tumor immune response. This albumin fusion construct possesses more persistent bioactivity in targeted organs. Furthermore, mice receiving alb-Flt3L DNA treatment presented better tumor control and superior survival. Cellular analysis revealed that alb-Flt3L DNA administration displayed greater systemic DC population. In addition, robust cDC1 expansion, which is associated with superior antigen cross-presentation and cellular immunity against tumors, developed extensively in the tumor, lymph node, and blood. In addition, increased levels of IFN-γ-secreting $CD8^+$ lymphocytes and tumor-infiltrated immune cells were found in correlation to greater cDC1 population.

Conclusion: Our data showcases a novel DC-based immunotherapy using electroporation to administer alb-Flt3L DNA. The treatment effect is revealed by a controlled tumor response, characterized by enhanced DC mobilization and accumulation in both the lymph nodes and TME, coupled with an increase in the expansion of cDC1 subsets and a heightened level of $CD8^+$ T cell activation.

#2477 Selective IL-21 and IFN-alpha immunocytokines engineered using the AlphaSeq platform.

C. Lin, C. Shikany, L. Homad, J. Fint, R. Bansal, D. Goodnight, J. Adamo, D. Van Citters, **R. Swanson**, R. Lopez;
A-Alpha Bio, Seattle, WA

Although cytokine therapies have demonstrated curative effects in some cancer patients, clinical use remains limited due to undesired toxicity profiles accompanying systemic administration. Next generation cytokine approaches include conditional signaling focused on sites of interest, such as the tumor microenvironment or specific immune cell populations. Here, we share a novel approach for generating detuned cytokine therapeutic candidates using the AlphaSeq platform, which involves the re-engineering of yeast agglutination and mating to quantitatively measure protein-protein interactions at a library-on-library scale. Engineering interferon-alpha (IFNα) and interleukin-21 (IL-21), we show how AlphaSeq measures cytokine-receptor interactions and identifies cytokine variants with a broad range of affinities. A saturated mutational library was created for IFNα and IL-21and subsequently screened against a second library consisting of human IFNAR2 or human IL-21R, species orthologs and off-target receptors. AlphaSeq enabled identification of hundreds of detuned IFNα and IL-21 variants against both human and mouse receptors in parallel assays. Cytokine variants with lower affinity than parental IFNα or IL-21 were recombinantly expressed as Fc fusion proteins to orthogonally measure affinity with biolayer interferometry and characterize potency with an in vitro human PBMC phosflow assay, which showed strong correlation with AlphaSeq affinity measurements. Finally, detuned cytokine candidates were fused to anti-CD8 and other localizing antibodies to demonstrate cell population-specific signaling. Candidate molecules showed 1000-fold or greater potency in the targeted cell population than non-targeted populations. Our results show the AlphaSeq platform can accurately quantitate thousands of cytokine variant affinities simultaneously against multiple relevant receptors, enabling the selection of candidate immunocytokine antibody fusion proteins with targeted cell biased signaling. AlphaSeq's rapid, comprehensive affinity determination is being used to develop clinically relevant IFNα and IL-21 therapeutic immunocytokines with accompanying preclinical data.

#2478 Inhibition of CD39 by AB598 increases extracellular ATP resulting in activation of myeloid cells and T cells to enhance anti-tumor immunity.

K. Jin, J. Clor, K. Parashar, R. Fuchs, L. Stetson, S. Cho, M. J. Walters, E. Fernandez-Salas, C. E. Bowman;
Arcus Biosciences Inc., Hayward, CA

Extracellular ATP (eATP) is a potent immunostimulatory signal in the tumor microenvironment (TME), but it is rapidly degraded into AMP and immunosuppressive adenosine. Therefore, ATP metabolism is an attractive anti-tumor target. Several enzymes are involved in the immunosuppressive process used by the TME to convert ATP to AMP and adenosine. Among them, CD39 (gene: *ENTPD1*), an extracellular ATPase, is a promising target. Analyzing mRNA expression from the TCGA, we show that CD39 is consistently expressed at high levels in comparison to the other extracellular ATP-converting enzymes, ENPP1 and TNAP. We further demonstrate that CD39 has greater enzymatic activity at the slightly acidic physiological pH (pH = 6.8) of the TME than either ENPP1 or TNAP. Flow cytometry profiling of dissociated primary human gastric tumors showed that CD39 was highly expressed on both myeloid and lymphoid cells, including several populations of T cells present in the tumors. This is distinct from findings in healthy primary human PBMCs that show high expression of CD39 on myeloid subsets and relatively few subsets of T cells with high CD39 expression. AB598 is a novel, humanized, Fc-silent anti-CD39 therapeutic antibody that potently binds to CD39 and inhibits its enzymatic activity with sub-nanomolar potency. Treatment of dissociated primary human gastric tumor cells with AB598 resulted in a decrease in the rate of ATP degradation, indicating both the effectiveness of AB598 and the relevance of CD39 as a main contributor to the ATPase activity of the TME. Although eATP is low in healthy tissues, high levels of ATP can be released when cancer cells are treated with immunogenic cell death (ICD)-inducing agents, increasing the eATP in the TME, providing a rationale for the combination of ICD-inducing chemotherapy and AB598. Thus, cancer cells were co-cultured with monocyte-derived dendritic cells (moDCs) and treated with chemotherapy and AB598 to preserve the eATP released by dying cancer cells. The increased expression of CD83 and CD86 on moDCs demonstrated that the combination treatment enhanced the maturation of moDCs, compared to single or no treatment. To further elucidate the anti-tumor effects of the combination treatment, autogenous T cells were introduced into this system. AB598 significantly enhanced T cell activation in the presence of chemotherapy. These data demonstrate that using AB598 results in elevated eATP, which boosts immune cell activation to promote anti-tumor immunity.

#2479 Discovery of agonist CD28-specific single domain antibodies from alpaca.

Y. Chen, Y. Ding, X. Liu, Q. Zhu, W. Xin, **H. Liu**, T. Yang, Y. Qiu;
ChemPartner Biologics Co., Ltd., Shanghai, China

Upon immune activation, in addition to the first signal driven by the TCR-peptide/MHC interactions, the costimulatory signals are indispensable to optimal T-cell activation, the absence of which will trigger naive T cells to an anergic state. The CD28-CD80/CD86 pathway is widely known as the most classical and critical costimulatory signal for the initial activation of T cells. Bispecific T-cell engagers targeting CD3e can activate cytotoxic T-cells and have shown remarkable tumor regressions in clinical trials. However, the absence of a costimulatory signal through CD28 results in insufficient T-cell activation and early exhaustion. Combination of both CD3e and CD28 targeting antibodies offers attractive approach to optimally boost T-cell activity. Development of superagonistic CD28-targeting antibody has been paused after TeGenero's TGN1412 Phase 1 trial in 2006 due to life-threatening cytokine release syndrome. Unlike superagonist TGN1412, which activates T cells and induce cytokine storm, tumor targeting antigen and cross-linking dependent CD28 bispecific antibody is supposed to display little or no toxicity. In the present study, we explored Alpaca immunized phage library approach to generate cross-linking dependent agonist CD28 single domain antibody for bispecific antibody development. Alpacas were immunized subsequently with recombinant human CD28 extracellular domain and 293F cells stably expressing human CD28. Serum samples after immunizations showed decent immune response against CD28. At the end of Boost 2 and 3, peripheral blood was collected and phage display libraries were constructed using VHH specific primers. Phage display libraries were panned against recombinant CD28 ECD protein and CHOK1 cells overexpressing CD28. After one round of panning, both protein and cell panning tracks showed robust enrichment in output titer and repeating sequences. Next, 600 clones were randomly picked for screening by the binding to U266B1 cells endogenously expressing CD28. Of the 326 clones showed positive binding to U266B1, 79 unique sequences were identified. Secondary screening by ELISA and FACS using periplasmic extract confirmed 69 unique sequences that bound to both CD28 protein and cells expressing CD28. Seventeen unique sequences were selected for VHH-Fc production. All purified VHH-Fc showed sub-nanomolar affinity by ELISA and bind to primary T cells by flow cytometry. Three VHH-Fc induced IL-2 production in a primary T cells activation assay only when cross-linked and in the presence of CD3 co-stimulation and are suitable for further bispecific T cell engager development.

#2480 Treatment of steroid-refractory immune checkpoint inhibitor-associated myocarditis: A case series of 18 patients.

R. Jayakrishnan, S. Brongiel, D. Luon, S. Halene, J. M. Kwan;
Yale New Haven Hospital, New Haven, CT

Background: Immune checkpoint inhibitors (ICI) have improved survival in various malignancies but are associated with significant immune-related adverse events (irAE). Up to 2% of patients on ICI develop ICI-myocarditis, which is associated with significant mortality. Treatment guidelines for ICI-myocarditis are limited. The initial treatment starts with high dose glucocorticoids, but the subsequent lines of treatment remain ill-defined.
Methods: We retrospectively identified patients at our institution from 2021 onwards who were treated for ICI-myocarditis and who had an inadequate response to steroid treatment (thus steroid refractory). Baseline characteristics, laboratory and imaging data, and outcomes were reviewed.
Results: Of the 34 patients diagnosed with ICI-myocarditis, 18 (53%) were steroid refractory. Amongst the 18, 11 were female and 7 were male, with a mean age of 73. Cancer types included head and neck, thoracic, urologic, gynecologic, and gastrointestinal. Patients had received a median of 2 ICI doses prior to myocarditis presentation. Thirteen (72%) patients had prior or concurrent irAE, most commonly neurologic or neuromuscular such as myasthenia gravis/myositis (44%) or hepatitis (33%). For initial treatment, 14 (41%) patients received a max dose of methylprednisolone 1g/day, while 4 (12%) received smaller doses (less than 500mg/day). Following steroids, the most common next treatment was mycophenolate mofetil (MMF) for 9 (50%), IVIG for 6 (33%), and Abatacept for 3 patients (17%). MMF was most often added and uptitrated to wean steroids, with 8 (44%) patients being able to be tapered off after a median duration of 112 days. IVIG was more commonly used for patients with concomitant neurologic symptoms while Abatacept was more commonly used for patients presenting with grade IV toxicities. The most encountered side effects following steroids were hyperglycemia, weight gain, adrenal insufficiency, and myopathy and following MMF were cytopenias and hypertension. The median survival since myocarditis diagnosis was 412 days. The patient with the longest documented survival of 645 days received IVIG and then MMF following steroids. Two patients with severely immunosuppression-resistant myocarditis responded well to tofacitinib, with one patient living 521 days after diagnosis (after methylprednisolone, IVIG, MMF, Abatacept, Tofacitinib) and one still alive more than 400 days after diagnosis (after methylprednisolone, MMF, Abatacept, IVIG, Infliximab, Tofacitinib).
Conclusion: Steroid-refractory ICI-associated myocarditis can be responsive to other immunosuppression agents. Our case series, one of the largest studies of this population, highlights their effectiveness and the populations they can cater to. Adjunctive treatments for ICI-myocarditis require further study to identify right doses and order of treatment.

CLINICAL RESEARCH: Predictive Biomarkers 1
Poster Session

#2484 Association of artificial intelligence (AI)-based HER2 scoring with clinical outcomes to first-line trastuzumab plus chemotherapy in HER2-positive metastatic gastric cancer (mGC).

M. Kang[1], **Y. Lim**[2], H. Oh[1], J. Lee[1], J. Kim[1], J.-W. Kim[1], S. Song[2], H. Song[2], K.-W. Lee[1];
[1]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, [2]Lunit, Seoul, Korea, Republic of

Background: Although trastuzumab plus chemotherapy is the treatment of choice for HER2-positive mGC, not all patients respond to the therapy. To date, there is no reliable and efficient biomarker that can predict the response to trastuzumab-based treatment.
Methods: Clinical data and pathology slides from HER2-positive mGC patients treated with first-line trastuzumab and capecitabine/5-fluorouracil plus cisplatin were retrospectively collected. HER2 positivity was confirmed using standard methods with immunohistochemistry (IHC) and/or in situ hybridization. An AI-based model was applied to a single HER2 IHC-stained whole slide image (WSI) of each patient to identify and quantify the tumor cells with HER2 IHC staining intensity categories of 0, 1+, 2+, or 3+ on the slide. The proportion of tumor cells with 3+ staining intensity among total tumor cells (h3 percentage) in each slide was calculated and analyzed in relation to clinical outcomes.
Results: A total of 160 cases were included in this analysis. Overall, the median progression-free survival (PFS) was 9.2 mo, and the overall survival (OS) was 18.9 mo. By standard IHC HER2 grading, 107 (66.9%) 3+ and 53 (33.1%) 2+ cases were included. The median AI-estimated h3 percentage in these patients was 14.8% (range 0 - 99.5%). The patients with their best tumor response of complete (CR) or partial response (PR) (44.4%) exhibited significantly higher h3 percentages (mean h3 percentage 46.6% in CR/PR vs. 29.4% in stable or progressive disease, p = 0.018). The h3 percentage exhibited strong associations as a continuous variable with longer PFS (hazard ratio [HR] 0.94 [95% confidence interval (CI) 0.90 - 0.99] for 10% change of h3 percentages, p = 0.015) or OS (HR 0.93 [95% CI 0.89 - 0.98] for 10% change of h3 percentages, p = 0.004). Notably, patients having a proportion of 3+ tumor cells at ≥ 90% (27/160, 16.9%) showed particularly longer PFS (median PFS 21.4 mo in ≥ 90% vs. 8.5mo in < 90%, p = 0.006) and OS (median OS 40.3 mo in ≥ 90% vs. 16.6 mo in < 90%, p = 0.004).
Conclusion: AI-based models interpreting WSI can provide additive predictive information to HER2-positive mGC patients treated with trastuzumab plus chemotherapy.

#2485 A combined mregDC and Treg signature associates with antitumor efficacy of CCR4 antagonist tivumecirnon FLX475.

Adam Grant[1], Juraj Adamik[1], Jingtao Qiu[1], Jacob Wert[1], Molly Grandcolas[1], Scott Jacobson[1], Rakesh K. Goyal[1], William Ho[1], Shoji Ikeda[1], Marvin Au[1], Damian Trujillo[1], Michael Chisamore[2], Denise de Almeida Nagata[1], Mohsen S. Ghomi[1], Dirk G. Brockstedt[1], Paul D. Kassner[1], **George Katibah**[1]

[1]RAPT Therapeutics, Inc., South San Francisco, CA,[2]Merck & Co., Inc, Rahway, NJ

Cancers evade immune surveillance through multiple mechanisms including the recruitment of immunosuppressive regulatory T cells (Treg). Tivumecirnon (formerly known as FLX475), a small molecule oral CCR4 antagonist under clinical evaluation, blocks the binding of CCR4 to its ligands CCL17 and CCL22 and thereby reduces Treg infiltration into the tumor microenvironment (TME). This relieves Treg-mediated immune suppression resulting in increased antitumor immunity. Our clinical study (NCT03674567) demonstrated that tivumecirnon can block the local accumulation of Treg in the TME and has clinical activity as monotherapy as well as in combination with pembrolizumab. In both mouse and human tumors, we identified a subset of tumor infiltrating dendritic cells (DC) producing high levels of CCL22, previously identified as mregDC, suggesting a potential role in the CCR4-dependent recruitment of Treg.

To study the role of mregDC in the recruitment of Treg, non-clinical studies were performed. CD45+ immune cells from the TME of MB49 tumor bearing mice treated with tivumecirnon or vehicle and were analyzed by flow cytometry, scRNA-seq and CITE-seq. We confirmed that mregDC cells are the primary producer of CCL22 in the TME and that tivumecirnon treatment reduced the number of Treg cells in the TME and increased the percentage of IFN gamma and granzyme B expressing CD4+ T cells.

Based on these findings we interrogated tumor biopsies from patients from our clinical study prior to (n = 33), and after approximately 6 weeks of treatment (n = 22, pre/post-treatment paired samples) with tivumecirnon +/- pembrolizumab. We performed RNAseq and compared to published biopsy data from anti-PD-1 treated patients. We found that higher mregDC + Treg signature levels at baseline significantly ($p < 0.001$) associated with response to tivumecirnon and pembrolizumab therapy. Importantly, analysis of published datasets revealed that higher baseline mregDC and Treg levels are not associated with response to anti-PD-1 monotherapy. Analysis of TCGA gene expression data demonstrated a positive correlation with mregDC and Treg cells across human tumor types, indicating a previously unknown relationship between these cell types. Further application of this mregDC and Treg signature to the TCGA dataset identified a subset of cancer types resistant to prior treatments that could potentially benefit from combinatorial treatment with tivumecirnon. Overall, this study demonstrated that inhibition of the CCR4 pathway using tivumecirnon can disrupt the immunosuppressive mregDC – Treg axis leading to enhanced antitumor activity. Furthermore, the levels of mregDC and Treg may be used as a biomarker for selection of patients more likely to respond to tivumecirnon in combination with anti-PD-1. Additional studies are required to confirm these results

#2486 Dissecting tumor-immune interaction in response and resistance to immune checkpoint blockade in metastatic melanoma.

G. Tarantino[1], Y. He[1], P. Solanky[1], A. Thorner[1], T. Aprati[1], R. Sullivan[2], E. Robitschek[1], T. Blosser[3], X. Zhuang[3], X. Zhuang[3], E. Boblitt[4], A. Frangieh[1], M. Holovatska[1], A. Lawless[2], M. Manos[1], K. Pfaff[1], K. Helvie[1], T. Sharova[2], D. Frederick[4], J. Fahey[2], D. Villamarin[2], S. Farhi[4], S. Rodig[1], B. Johnson[1], A. K. Shalek[4], E. Van Allen[1], S. [1]Dana-Farber Cancer Institute, Boston, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Harvard University, Cambridge, MA, [4]Broad Institute of MIT and Harvard, Cambridge, MA

Background: Immune checkpoint blockade (ICB) has revolutionized the treatment and prognosis of various cancers, including melanoma. Nevertheless, intrinsic or acquired resistance is common, and the interactions between tumor-intrinsic features and the microenvironment underlying these resistances remain unclear for most patients.

Methods: In this study, we developed a framework to analyze response and resistance, both intrinsic and acquired, via tumor-intrinsic programs, immune features, and tumor-stromal-immune interactions in a standardized, uniformly processed, and deeply clinically annotated cohort of metastatic melanoma patients (n=61) treated with ICB as part of the NCI funded human tumor atlas network (HTAN) initiative. From the same tumor samples (pre-treatment (n=33) and post-progression (n=28)), we conducted bulk whole-exome sequencing (WES), single-nucleus RNA sequencing, and for a subset of the samples high-resolution spatial imaging (including protein mIHC, CODEX, and transcriptomics MERFISH). Standardized processing and data pipelines allowed for integration of genomic, transcriptomic, and spatial features to elucidate shared tumor and microenvironmental states and their relationships with resistance.

Results: Our preliminary analysis on a subset of 28 samples identified an enrichment of B cells, plasma cells, and T follicular helper-like cells in the tumor microenvironment (TME) of patients sensitive to treatment. The TME of non-responders was predominantly characterized by macrophage/monocyte cell populations. Post-treatment responder samples showed an enrichment of CD4+ T cells. Genomic heterogeneity, assessed through WES, was confirmed as a feature of intrinsic resistance across different ICB treatment settings, while ploidy was associated with treatment response in pre-treatment, ipilimumab-naïve patients treated with PD-1 inhibitors. Comparing the immune compartments of samples with high and low heterogeneity revealed NK cell enrichment in samples with a high proportion of subclonal mutations.

Conclusions and Future Directions: Overall, our work provides a high-resolution understanding of the tumor-stromal-immune interaction in metastatic melanoma, shedding light on the factors contributing to therapy response and resistance, and contributing a repository of data from deeply clinically annotated, multimodally characterized and uniformly processed patient samples. Ongoing spatial analysis will further enhance our understanding of these compartments at a spatial level. The results of our study have the potential to guide more personalized and effective treatment strategies for metastatic melanoma in the future.

#2487 KRAS and TP53 co-mutation predicts benefit of immune checkpoint blockade in lung adenocarcinoma.

Jan Budczies[1], Eva Romanovsky[1], Martina Kirchner[1], Olaf Neumann[1], Miriam Blasi[2], Johannes Schnorbach[2], Rajiv Shah[2], Farastuk Bozorgmehr[2], Rajkumar Savai[3], Thorsten Stiewe[4], Solange Peters[5], Peter Schirmacher[1], Thomas Michael[2], Daniel Kazdal[1], Petros Christopoulos[2], Albrecht Stenzinger[1]

[1]Heidelberg University Hospital (UKHD), Heidelberg, Germany,[2]Thoraxklinik, Heidelberg University Hospital and National Center for Tumor Diseases, Heidelberg, Germany,[3]Institute for Lung Health (ILH), Justus Liebig University, Giessen, Germany,[4]Institute of Molecular Oncology, Member of the German Center for Lung Research (DZL), Philipps-University, Marburg, Germany,[5]Department of Oncology, Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne University, Lausanne, Switzerland

PD-L1 protein expression is the most important predictive biomarker for immune checkpoint inhibition (ICI) in advanced non-small cell lung cancer (NSCLC), but has limited sensitivity and specificity. We analyzed the potential of activating KRAS and pathogenic TP53 mutations to provide additional predictive information. The study cohort included 713 consecutive immunotherapy patients with advanced lung adenocarcinomas of the Thoraxklinik Heidelberg who were negative for actionable EGFR and ALK/RET/ROS1 alterations. Two external cohorts of patients treated with immunotherapy (SU2C-ICI: n=247, MSK-ICI: n=135) and two external cohorts of surgical early stage patients were additionally analyzed (TCGA-LUAD: n=417, MSK-LUAD: n=394). Therapy benefit was assessed stratified by KRAS and TP53 mutations. RNA-Seq data of TCGA were analyzed to reveal the molecular characteristics of KRASmut/TP53mut tumors. Analyzing overall survival, an interaction between KRAS and TP53 mutations was observed in univariate and multivariate analyses (HR=0.56, p=0.0044 and HR=0.53, p=0.0021). KRASmut/TP53muts tumors performed better than tumors not harboring the dual mutation configuration (HR=0.71, CI 0.55-0.92). This observation could be confirmed in the external cohorts of immunotherapy patients (SU2C-ICI: HR=0.54, CI 0.28-1.03 and MSK-ICI: HR=0.35, CI 0.14-0.88), whereas KRASmut/TP53mut was not associated with prolonged survival in the surgical cohorts. Tumor mutational burden, proliferation (measured by TOP2A mRNA expression), and PD-L1 mRNA were significantly higher in TP53mut compared with TP53wt tumors, regardless of KRAS status. Genome-wide mRNA expression analysis revealed 64 genes including the chemokine CX3CL1 (fractalkine) as specific transcriptomic characteristic of KRASmut/TP53mut tumors. In summary, KRAS/TP53 co-mutation predicts ICI benefit in univariate and multivariate survival analyses and is associated with unique molecular tumor features. Further validation studies are warranted. Mutation testing of the two genes can be easily implemented using small gene panels or even single gene analyses.

#2488 The penile cancer tumor microenvironment and immunotherapy response: Results from the PERICLES trial.

T. S. Rafael[1], A. Gil-Jimenez[1], H. M. de Vries[1], I. M. Seignette[1], E. Bekers[1], M. Lopez-Yurda[1], D. Peters[1], E. Hooijberg[1], A. Broeks[1], O. R. Brouwer[1], E. Schaake[1], D. J. Vis[1], T. D. de Gruijl[2], L. F. Wessels[1], M. S. van der Heijden[1];
[1]Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Amsterdam University Medical Center, Amsterdam, Netherlands

Introduction: The phase II PERICLES trial investigated the efficacy of atezolizumab (anti-PD-L1) for advanced penile cancer, with or without radiotherapy. As previously published, durable responses (progression-free at 12 months) were observed in 4 out of 32 enrolled patients. Here, we present the final overall survival (OS) results and an analysis of potential biomarkers for immunotherapy response.

Methods: Preplanned analysis projected that at 27/32 events, the study would have 80% power (2-sided α=0.05) to assess whether the OS for the entire cohort significantly differed from the hypothesized historical median for stage IV patients. Baseline tumor tissue samples were subjected to bulk-RNA sequencing (n=31), fluorescent (n=28) and chromogenic (n=30) multiplex immunohistochemistry. We quantified the densities of $CD3^{+}CD8^{+}$ cytotoxic T-cells, $CD3^{+}CD8^{-}FoxP3^{-}$ T-helper cells, $CD3^{+}CD8^{-}FoxP3^{+}$ regulatory T-cells, $CD68^{+}$ macrophages and $CD20^{+}$ B-cells in both the tumor and stromal compartments and assessed spatial relationships. We also quantified $CD8^{+}PD1^{+}$ (potentially enriched for tumor reactivity) and $CD8^{+}PD1^{-}$ T-cells. Differential expression and gene set enrichment analysis (GSEA) were performed using the hallmarks gene sets.

Results: The median OS for the entire study cohort was 11.3 months (95% CI, 5.5-16.7), which is an improvement compared to the hypothesized historical median of 7.8 months for stage IV patients (one sample log-rank p=0.033). Biomarker analyses showed an increased density of stromal macrophages (p<0.001) and intratumoral cytotoxic T-cells (p=0.035) in durable responders compared to non-responders. Additionally, we observed an increased density of intratumoral $CD8^{+}PD1^{+}$ in durable responders (p<0.001). In contrast, intratumoral $CD8^{+}PD1^{-}$ densities were comparable between durable and non-responders (p=0.057). Patients with a high density of intratumoral $CD8^{+}PD1^{+}$ also had an improved progression-free survival (PFS) (log-rank, p<0.001) and OS (log-rank, p=0.002). Analysis of the spatial relationships in the tumor microenvironment (TME) showed that durable responders had larger distances between cytotoxic T-cells and T-helper cells (p=0.034). GSEA revealed significant (FDR≤5%) up-regulation of IFN-α/γ responses in durable responders. In contrast, non-responders showed up-regulation of epithelial-mesenchymal transition, KRAS signaling and angiogenesis, suggesting potential barriers to an anti-tumor response.

Conclusion: In the final clinical analysis, OS was improved with atezolizumab compared to the historical population of stage IV patients. $CD8^{+}PD1^{+}$ T-cells, a common proxy for tumor-reactive T-cells, and spatial relationships in the TME might serve as biomarkers of durable response to immunotherapy in advanced penile cancer.

#2489 A cell-free DNA methylation biomarker outperforms irRECIST in predicting treatment outcome.

P. Xie[1], M. Innoue[1], P. Siejka-Zielińska[1], R. Amess[1], J. Chang[1], S. Wilding[2], G. Griffiths[2], M. R. Middleton[1], R. P. Owen[1], C. Song[1], X. Lu[1], **B. Schuster-Boeckler[1];**

[1]University of Oxford, Oxford, United Kingdom, [2]Southampton General Hospital, Southampton, United Kingdom

Immune checkpoint inhibitors (ICI) are established as first-line treatment for inoperable esophageal adenocarcinomas (EAC), in combination with chemotherapy (CTX). Unfortunately, response to immunochemotherapy is highly variable, despite most EAC cases featuring a high mutation burden. EAC response to ICI is assessed using radiological criteria such as irRECIST, but its ability to predict long-term survival is poor. Consequently, early recognition of a failing therapy is challenging. More accurate early biomarkers of response to ICI are therefore of critical importance.

Here, we show that a classifier based on epigenetic features in cfDNA taken 4 weeks after treatment initiation accurately predicts treatment benefit after one year. Strikingly, this blood-based biomarker predicts OS better than radiological criteria.

We collected cell free DNA (cfDNA) from patients enrolled in the LUD2015-005 trial, in which ICI was administered for four weeks before adding standard-of-care chemotherapy (ICI+CTX). For each patient, we collected cfDNA, tumor and adjacent normal tissue at diagnosis, before ICI+CTX, during and at the end of treatment, in addition to radiological clinical imaging.

Tissue and cfDNA samples were sequenced using TET-Assisted Pyridine-borane Sequencing (TAPS), a method recently developed in Oxford which provides high-depth, base-resolution DNA methylation information from low-input samples.

Based on tissue data, we identified a genome-wide hypomethylation signature specific to tumor cells. By accounting for sample-to-sample variability in stromal composition, we show that this signature is present in most EACs, allowing us to model the admixture of tumor and normal methylation patterns to quantify the amount of tumor methylation detected (TMD) in cfDNA.

16 patients had increased TMD (TMD-up) after 4 weeks of ICI monotherapy compared to pre-treatment levels, while 15 patients had decreased TMD (TMD-dn). Median OS for the two groups were 37 and 112 weeks, respectively ($p < 0.0001$). We evaluated the radiological response according to irRECIST at similar timepoints. 17 of 32 patients (53.1%) had no definitive evidence of progression nor response and were deemed to have radiologically stable disease. 8 of these patients went on to develop progressive disease within 1 year - all 8 patients belonged to the TMD-up group. Contrastingly, 8 out of 9 patients who had PFI greater than 1 year belonged to TMD-dn. In all 32 patients, TMD predicted radiological disease progression within 1 year with 83.3% sensitivity and 92.3% specificity.

Taken together, we report the discovery of a circulatory biomarker that measures molecular response to ICI in EAC and identifies poor prognosis patients that appear stable from radiological imaging. Furthermore, patients with favorable molecular response were found to have a median OS almost 3 times that of patients with unfavorable molecular response.

#2490 Quantification of tumor fraction and outcomes association in a real-world non-small cell lung cancer (NSCLC) cohort using a tissue agnostic epigenomic circulating tumor DNA (ctDNA) assay.

S. Wienke[1], S. Gordon[1], S. Liang[2], J. Wang[1], R. Barnett[1], K. Chang[1], S. Zhang[1], C. R. Espenschied[1], K. Quinn[1], K. Banks[1];
[1]Guardant Health, Palo Alto, CA, [2]Parker Institute for Cancer Immunotherapy, San Francisco, CA

Background: The validity of ctDNA assays for evaluating molecular response to therapy by measuring changes in variant allele fraction (VAF) while on treatment is well established, but they are prone to limitations such as low ctDNA levels and interference from copy number variation and clonal hematopoeisis (CH), which may be overcome by methylation-based quantification. ctDNA levels may be monitored throughout a patient's (pts) journey to indicate when relapse or progression is present, often sooner than current methods (RECIST). Here we describe the performance of a methylation-based ctDNA assay to quantify ctDNA levels and correlate changes with outcomes in a real-world NSCLC cohort.

Methods: RADIOHEAD is a pan-tumor observational study of 1200 patients on standard of care ICI treatment regimens with plasma samples collected prospectively for retrospective analysis. We randomly selected 241 NSCLC pts that have a combined total of 761 samples (236 baseline, 191 C3D1, and 128 at 6 months post first dose). Samples were analyzed using a commercial NGS assay, which quantifies circulating tumor fraction (cTF) via interrogating thousands of methylation sites from ctDNA, validated with LoB, LoD, LoQ, and linearity studies. Cox proportional hazards (CPH) were used for comparison of real-world progression free survival (rwPFS). Gender, age, disease stage, and blood-assessed tumor mutational burden (bTMB) were included as covariates. Median rwPFS was calculated using Kaplan Meier analysis. rwPFS ordinal groups were defined as PFS event within 3mo, 3-6mo, 6-12mo, and greater than 12mo, and association with early ctDNA changes was assessed with a chi-squared test.

Results: In this cohort, 4, 11, 83 and 142 pts were stage I to IV, respectively (1 unknown). Methylation based detection of ctDNA at baseline or C3D1 was associated with shorter rwPFS (baseline: mPFS 12.7 mo [9.3-19.5] vs NR [16.4-NR]; HR=2.2 [1.3-3.7] p<0.005, C3D1: mPFS 12.4 mo [9.3-16.1] vs NR [19.5-NR] HR= 2.2 [1.3-3.5], p<0.005) independent of stage, gender, or age. Longer rwPFS was associated with >95% reduction in cTF from baseline to C3D1 or low ctDNA at both timepoints (rwPFS <3mo = 12.5%, 3-6 mo = 30.8%, 6-12 = 37.1%, ≥12 mo = 55.3%; N=153, p=0.015). For pts with ctDNA not detected at C3D1, ctDNA detection at 6 months post first dose was strongly associated with shorter rwPFS (mPFS 13.5 mo [9.5-NR] vs. NR [19.5-NR]; HR= 6.2 [1.9-20.1], p<0.005).

Conclusions: These data demonstrate a significant association of ctDNA detection via methylation-based cTF and on-treatment changes in cTF with rwPFS. Furthermore, subsequent cTF detection 6-months on-treatment, without cTF detected early on-treatment was associated with worse outcomes, suggesting the value of serial monitoring to improve identification of patients likely to progress.

#2491 The Oxford Classic can identify HGSOC patients who may benefit from EMT-targeting therapies.

Introduction: Despite development of novel targeted therapies such as PARP inhibitors and anti-angiogenic drugs, there is a clear lack of treatment options for High Grade Serous Ovarian Cancer (HGSOC) patients who are Homologous Recombination Repair proficient (50% of cases) and those with intrinsic resistance to these drugs. In this study we demonstrate the ability of the Oxford Classic (OxC)[1,2], a non-genetic classifier, to identify HGSOC patients who may benefit from EMT targeting drugs.

Methods: 139 HGSOC diagnostic tumor tissue (Brescia cohort) underwent RNA sequencing. Scottish cohort[3] was used for external validation and TCGA, AOCS & OVCAD datasets were used for meta-analysis. Deconvolution of tumor RNAseq data, survival analyses, differential gene expression (DGE) analysis, gene pathway analyses in R and tumor immune profiling using CIBERSORT were performed.

Results: Risk stratification of HGSOC using the Oxford Classic Patients with a higher OxC-EMT score had 3.6 times increased risk of death (95%CI: 1.6-8.0; p=2e-03) compared to patients with a lower OxC-EMT score by a multivariable cox regression analysis of Brescia cohort. By Kaplan-Meier survival analyses, a significant difference in overall survival in Brescia cohort (p=9e-06), Scottish cohort (p=2e-03) and a combined set of 1023 cases (p=1e-04), was observed between EMT-low risk patients (OxC-EMT score-0) and EMT-high risk patients (OxC-EMT score>0). Notably, 5-year median survival of EMT-low risk and EMT-high risk group was 50% and 13%, resp. (95%CI: 36.1%-69.3% vs 7.1%-23.5%) in Brescia cohort. Therapeutic options for OxC-EMT-high risk group DGE analysis of EMT-low patients and EMT-very high patients (OxC-EMT score>0.5) identified 404 differentially expressed genes common to the datasets. These included genes related to extracellular matrix organisation (*VCAN, TGFβI*), epithelial cell proliferation (*RUNX2, FABP4, SERPINF1*), cell chemotaxis (*CCL19, DUSP1*), angiogenic factors (*VEGFC, CXCL12*) and transmembrane kinase signalling pathways (*TGFβ1/3, PDGFRα/β, IGFBP4/5/6, Wnt11*). Of note, key EMT transcription factors, *TWIST1/2, SNAI1/2, ZEB1/2,* and stemness marker, *ALDH1A3,* were 2-7 times overexpressed in EMT-very high group. Furthermore, immune modulators, *IL6 and IL10* were significantly upregulated and M2 macrophages were significantly more abundant in EMT-very high patients. Multiplex IHC is currently underway to confirm the abundance of TAMs and CD8-positive TRM in the two risk groups.

Conclusions: 1) The Oxford Classic-based EMT is a robust prognostic biomarker of overall survival in HGSOC, that faithfully represents the complex circuitry of pathways which are a hallmark of Epithelial to Mesenchymal Transition. 2) OxC-EMT risk stratification can identify HGSOC patients who may benefit from EMT-targeting therapies.

#2492 Enhanced patient selection for anti-PD-L1 treatment in metastatic NSCLC with quantitative continuous scoring of PD-L1.

J. Lesniak[1], M. Schick[1], T. Kunzke[1], F. Pollastri[1], J. Vigueras-Guillen[1], H. Hessel[1], S. Haneder[1], P. Sontakke[1], K. DaCosta[1], R. Alleze[1], H. Sade[1], J. Barrett[2], G. Schmidt[1], R. Stewart[3];

[1]AstraZeneca, Munich, Germany, [2]AstraZeneca, Gaithersburg, MD, [3]AstraZeneca, Cambridge, United Kingdom

Background: Anti-PD-L1 therapy has demonstrated clinical activity in patients with metastatic non-small cell lung cancer (mNSCLC). However, only subgroups of patients respond and their identification via PD-L1 as a biomarker remains imperfect. PD-L1 expression is commonly assessed by pathologist tumor cell (TC) scoring of immunohistochemically (IHC) stained tissue. We developed a system for digitally scoring PD-L1 in IHC (PD-L1 QCS), which demonstrated robust scoring across studies [1]. Here, we present a comparison of PD-L1 QCS against manual scoring of PD-L1 (SP263 assay, Ventana) in the MYSTIC clinical trial.

Methods: PD-L1 QCS on digitized whole slide images (WSI) comprises two deep learning models, enabling segmentation of single TCs followed by PD-L1 expression quantification via their optical density (OD). Positive cells are classified based on an OD threshold, allowing robust digital calculation of the TC percentage [1]. The analysis included 502 WSI from the MYSTIC trial (NCT02453282), representing 256 patients treated with anti-PD-L1 therapy and 246 treated with chemotherapy as standard-of-care (SoC) [2]. First, an optimal cut-point was determined by optimization against outcome, classifying patients with ≥0.575% TC as biomarker positive (BM+). Next, the approach was compared against manual TC scoring at 1%, 25% and 50% cut-off.

Results: In durvalumab treated patients, median overall survival (mOS) in the PD-L1 QCS BM+ subgroup (prevalence 54.3%) was 12.1 months longer than in the BM- subgroup (19.9m vs. 7.8m, HR=0.45, CI [0.33, 0.60]). Analogous comparison of subgroups based on manually scored TC proportion at 1% (prev. 75.0%), 25% (prev. 42.6%) or 50% (prev. 29.7%) cut-points yielded a mOS difference of 7.8m (HR=0.52, CI [0.38, 0.72]), 8.3m (HR=0.61, CI [0.45, 0.82]) and 11.0m (HR=0.55, CI [0.40, 0.77]) respectively. Comparing durvalumab treatment against SoC within the PD-L1 QCS BM+ subgroup yielded a HR of 0.62 (CI [0.46, 0.82], log rank p=0.0008, 7.4m mOS delta). In comparison, a HR of 0.69 (CI [0.46,1.02], p=0.0642, 8.4m mOS delta) was obtained for manual TC scoring at 50%.

Conclusion: We compared a computational pathology approach for continuous PD-L1 scoring for the selection of mNSCLC patients for anti-PD-L1 treatment against established manual scoring. Our results suggest that PD-L1 QCS has the potential to identify a larger patient subgroup that retains benefit from anti-PD-L1 treatment and more precisely identifies non-responders.

#2493 Prospective evaluation of predictive biomarkers for Palbociclib (P) and endocrine therapy (ET) benefit in hormone receptor (HR)-positive [+]/human epidermal growth factor receptor 2 (HER2)-negative [-] advanced breast cancer (ABC) patients (pts) from PARSIFAL clinical trial: The transFAL sub-study.

Joan Albanell[1], Angelo Gamez Pozo[2], Carlos L. Arteaga[3], Meritxell Bellet[4], Federico Rojo[1], Abel Gonzalez[1], Beatriz Bellosillo[1], Violeta Serra[4], Petra Gener[5], Jose Antonio Guerrero[5], Laura Lopez-Montero[5], **Mario Mancino**[5], Jose Rodriguez-Morato[5], Leonardo Mina[5], Jose Manuel Perez-Garcia[5], Javier Cortes[5], Antonio Llombart-Cussac[5]

[1]Hospital del Mar Medical Research Institute, Barcelona, Spain,[2]Molecular Pathology Lab, La Paz Hospital Center, IDIPAZ, Madrid, Spain,[3]Harold C. Simmons Comprehensive Cancer Center, UT Southwestern, Dallas, TX,[4]Vall d'Hebron Institute of Oncology, Barcelona, Spain,[5]Medica Scientia Innovation Research (MEDSIR), Barcelona, Spain

BACKGROUND Combining cyclin-dependent kinases 4 and 6 inhibitors (CDK4/6i) with first-line ET is the standard of care for pts with HR[+]/HER2[-] ABC. PARSIFAL was a randomized, open-label, phase II trial that evaluated the efficacy and safety of first line P plus fulvestrant (F) or letrozole (L) in this pts population. Both treatments had comparable efficacy and safety results (JAMAOncol. 2021;7(12):1791-1799). Although multiple CDK4/6i clinical outcomes biomarkers have been reported, the only validated predictive factor for response is HR positivity. TransFAL, a translational study of PARSIFAL, assessed a comprehensive set of biomarkers of sensitivity/resistance to P plus ET.

MATERIALS AND METHODS TransFAL employed a sample biorepository from PARSIFAL comprising formalin-fixed paraffin-embedded (FFPE) tissue and blood samples obtained from pts included in either study arm. Tumor samples (N=33) derived from the primary tumor at initial diagnosis or from primary tumor or metastatic lesions at study entry. Blood samples were obtained at baseline (N=73) and disease progression (N=22). Pts were categorized as sensitive or resistant based on progression-free survival (PFS). CDK4/6 pathway activation was assessed by immunohistochemistry for CDK4, CDK6, Rb, pRb, ER, PgR, and Ki67. Proteins extracted from FFPE slides were analyzed using hierarchical clustering, significance analysis of microarrays, and probabilistic graphical models. RNA expression and circulating tumor DNA (ctDNA) analysis were assessed by next-generation sequencing (NGS) and analysis of panel of 56 genes/gene regions, respectively.

RESULTS A worse median PFS was found in pts with CDK6 positive (≥ 1% positive cells; $p < 0.001$) and high Ki67 (≥ 10% positive cells; $p = 0.013$)at baseline. ctDNA density at baseline was significantly higher for resistant (PFS < 9 months; 17.1 ng/mL) pts compared to sensitive (PFS > 31 months; 11.3 ng/mL) pts ($p < 0.001$). Most pts (83%) presented a genomic alteration detected in ctDNA, TP53 (28%) and PIK3CA (28%) being the most frequently mutated genes. Pts (9%) who harbored ARID1A mutation had lower PFS ($p = 0.052$). ESR1 mutations at progression were numerically higher in the L arm (37.5%) compared to F arm (14.3%); (p=0.31), but numbers were low. Proteomic and RNA analyses did not yield confirmable distinctive expression pattern between resistant/sensitive pts...

CONCLUSIONS High Ki67 levels and CDK6 expression in the tumor and high ctDNA density, but not proteomic or RNA sequencing data, were associated to poor outcome in this analysis of pts treated with CDK4/6i and ET. This data adds to the growing evidence of poor prognosis biomarkers in this setting, highlighting the need of novel strategies for these pts.

#2494 RAS-Bio a unique pan-cancer biobank for RAS-driven tumors.

M. Carter[1], K. D. Brown[1], H. Adderley[1], G. Morrissey[1], L. Woodhouse[1], J. Weaver[1], K. Simpson[2], J. Roebuck[2], J. Rogan[3], J. Mercer[3], A. Chaturvedi[3], D. Wedge[4], C. Jorgensen[2], A. Malliri[2], C. Dive[2], C. R. Lindsay[4];

[1]The Christie NHS Foundation Trust and University of Manchester, Manchester, United Kingdom, [2]Cancer Research UK, Manchester Institute, University of Manchester, Manchester, United Kingdom, [3]The Christie NHS Foundation Trust, Manchester, United Kingdom, [4]University of Manchester, Manchester, United Kingdom

Background: RAS-driven cancers represent a significant unmet clinical need, while breakthroughs in treatments targeting *KRAS*^{G12C} driven-NSCLC have invigorated drug-development for other RAS mutant cancers. Most RAS mutant cancers are not driven by *KRAS*^{G12C}, leaving an enormous amount of work needed to establish the contextual treatment vulnerabilities of cancers driven by different RAS mutant subtypes. RAS-Bio was pioneered within The Cancer Research UK Lung Cancer Centre of Excellence in Manchester. RAS-Bio is a uniquely curated resource of unparalleled clinical, genomic, translational and biological detail. RAS-Bio was established with the aim of generating novel model systems along with clinical observation to facilitate RAS precision medicine breakthroughs.

Method: RAS-Bio recruits patients affected by epithelial cancers with RAS pathway mutations, aiming to i) optimize sample collection & processing protocols (FFPE/fresh/frozen) for multi-omic profiling, ii) validate preclinical hypothesis-generating findings in a clinical cohort, iii) generate novel RAS-mutant organoid, PDX and other models for analyses and drugging experiments, iv) foster academic/industry collaboration using a unique dataset including demographics, pathology/imaging details, treatment types and survival outcomes.

Results: In two years, we have recruited 190 cancer patients with cancers harboring *KRAS*^{G12C} (*n*=71), *KRAS*^{G12D}(17), *KRAS*^{G12V}(23), *KRAS*^{G12A}(8), *KRAS*^{G12S}(2), *KRAS*^{G12F} (3), *KRAS*^{G12R} (1) and *KRAS*^{G12E} (1). A further 20 harboring KRAS codon 13 mutations and 12 *KRAS*^{Q61} cancers and an additional 32 patients with mutations in other key signaling nodes of the MAPK pathway have been recruited. Seventeen PDX models have been attempted; lung cancer (14) and colorectal cancer (3). Four lung cancer cases are currently growing (*KRAS*^{G12C} treatment naïve, *KRAS*^{G12C} inhibitor resistance, *KRAS*^{G12C} inhibitor refractory, *KRAS*^{G13C} treatment naïve) and two colorectal cancer cases (KRAS^{G12C} and KRAS^{G12V}). We will present two deep-dive lung patient cases i) *KRAS*^{G12C} 'OFF' state inhibitor (sotorasib) resistance where multiple tissue samples, CTCs and a successful PDX were derived, and ii) sotorasib resistance where paired biopsies and PDXs were derived pre- and post-treatment. Both cases demonstrate the clinical utility of longitudinal sampling in understanding clinically relevant resistance mechanisms to targeted treatment.

Conclusion: RAS-Bio represents a comprehensive biobank of clinical, pathological, and genomic detail in RAS-mutant lung cancers. Optimizing collaborative potential with academia/industry to facilitate prospective sampling of patients at different timepoints and integrating colorectal and pancreas cancers in our protocol.

#2495 CCL3 predicts an exceptional response to TGFβ inhibition in pancreatic ductal adenocarcinoma by sustaining a basal-like ecotype enriched in LIF-producing macrophages.

S. Pietrobono, M. Bertolini, V. De Vita, E. Scarlato, F. Fazzini, F. Sabbadini, D. Mangiameli, A. Quinzii, S. Casalino, **D. Melisi**;
University of Verona, Verona, Italy

The TGFβ receptor inhibitor galunisertib (GAL) exhibited promising efficacy in patients with pancreatic ductal adenocarcinoma (PDAC) in the randomized phase 2 H9H-MC-JBAJ study. However, the identification of predictive biomarkers remains of unique importance. We used a 279 multi-analyte panel and confirmed CCL3 as the most significant plasma protein for chemoresistance in patients receiving gemcitabine (GEM) [overall survival (mOS) (95%CI), high vs low, 3.6 (2.5-4.0) vs 10.1 (7.2-17.0) months, HR (95%CI)= 3.92 (2.14-7.20); p<0.001]. GAL dramatically reverted this resistance and CCL3 was the most significant predictive marker for the combination of this agent plus GEM [mOS (95%CI), GAL + GEM vs. placebo + GEM, 9.0 (5.5-12.1) vs 3.6 (2.5-4.0) months, HR (95%CI)= 0.39 (0.23-0.68); p<0.001]. We delved into the mechanisms behind this exceptional response in PDAC with this prognostically negative ecotype sustained by CCL3 in 6 different murine PDAC models. Mice bearing high-Ccl3 tumors had a significantly shorter mOS, a higher infiltration of M2-macrophages (TAMs), and a more mesenchymal/basal-like phenotype than did models with undetectable Ccl3.Ccl3 was stably expressed in DT4313 and PAN610, and silenced in RC416 cells. In co-culture models, $DT4313^{Ccl3}$ and $PAN610^{Ccl3}$ had a more mesenchymal phenotype and induced a M2 polarization of RAW264.7 murine TAMs than did controls. Mice bearing $DT4313^{Ccl3}$ or $PAN610^{Ccl3}$ tumors had a significantly shorter mOS, an higher infiltration of M2-polarized TAMs and a more mesenchymal/basal-like phenotype than controls. The expression of Tgfβ1 ligand and the phosphorylation of Smad2 were triggered only in TAMs if co-cultured with Ccl3-high $RC416^{scr}$, $DT4313^{Ccl3}$ or $PAN610^{Ccl3}$ cells. This activation of Tgfβ pathway was blocked by maraviroc, a selective inhibitor of Ccl3-receptor Ccr5. In co-culture, GAL reverted the mesenchymal phenotype of PDAC cells and the M2 polarization of TAMs. By using an 111 different cytokine immunoassay, Leukemia Inhibitory Factor (Lif) was the most significantly factor overexpressed by TAMs if stimulated by Ccl3. GAL suppressed this Lif expression. In mice bearing $DT4313^{Ccl3}$ tumors GEM was ineffective, whereas it prolonged mOS in those with $DT4313^{NTC}$ tumors. Conversely, GAL plus GEM doubled mOS duration vs. GEM, modulated M2- TAMs infiltration, the mesenchymal/basal-like phenotype and plasma Lif only in mice bearing $DT4313^{Ccl3}$ tumors, but not in those with $DT4313^{NTC}$ controls. In summary, we demonstrated that tumor-derived Ccl3 activates an autocrine Tgfβ signaling in TAMs, triggering their M2-phenotype and secretion of Lif. This Tgfβ-Lif axis sustains paracrinally a mesenchymal/basal-like PDAC ecotype resistant to GEM. Inhibition of Tgfβ signaling modulates this poor prognosis ecotype, and explains the exceptional response to GAL in patients with high-CCL3 PDAC.

#2496 Molecular characterization of stage III colon cancer patients with recurrence after adjuvant chemotherapy.

I. Franken[1], S. Ketelaars[2], C. Rubio-Alarcon[2], S. van Nassau[1], S. Schraa[1], G. Meijer[2], M. Sausen[3], M. Koopman[1], G. Vink[4], S. Abeln[5], R. Fijneman[2], J. Roodhart[1], on behalf of the PLCRC-MEDOCC group;

[1]UMC Utrecht, Utrecht, Netherlands, [2]Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Personal Genome Diagnostics (LabCorp), Baltimore, MD, [4]Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands, [5]Utrecht University, Utrecht, Netherlands

Introduction: Patients with stage III colon cancer are routinely treated with resection followed by adjuvant chemotherapy (ACT) with a fluoropyrimidine and oxaliplatin. This one-size-fits-all approach does not account for heterogeneity in tumor biology and fails to cure ~30% of patients, highlighting the urgency for biomarkers to better understand and predict resistance to ACT or to offer alternative targeted treatment.

Aim: To identify molecular characteristics predictive of resistance to standard ACT in stage III colon cancer.

Methods: Patients with resected stage III colon cancer who received ACT (93% CAPOX, 7% CAP) were selected from the Prospective Dutch Colorectal Cancer cohort (PLCRC). RNA exome capture sequencing was performed on resected FFPE tumor tissue to compare differential gene expression, hallmark pathway enrichment, immune cell deconvolution and consensus molecular subtypes (CMS) between patients with versus without recurrence after surgery and ACT. Postsurgery circulating tumor DNA (ctDNA) detected in PLCRC-PROVENC3 (separate abstract) was used to select a subgroup with minimal residual disease (MRD) postsurgery, as sensitivity analysis of patients with recurrence despite ACT (chemoresistant) versus curation by ACT (chemosensitive).

Results: For 264 out of 278 patients (95%), tumor-derived RNA sequencing libraries were of sufficient quality. 67 patients (25%) with recurrence (median after 13 months [IQR 7-23]) were compared to 178 patients with at least 2 year recurrence-free follow-up (median 42 months [IQR 30-53]). A total of 320 genes were differentially expressed between patients with versus without recurrence. Genesets defining epithelial-mesenchymal transition ($p = 0.002$) and angiogenesis ($p < 0.001$) were enriched in the primary tumor of patients with recurrence, in part explained by the estimated larger fraction of stroma (Wilcoxon effect size r 0.18, $p < 0.001$) and cancer-associated fibroblasts (CAFs) (r 0.19, $p = 0.003$). In contrast, the fraction of CD4+ T cells was lower (r 0.14, $p = 0.001$). Consistently, CMS4 was found more frequently in tumors from patients with versus without recurrence (57% versus 34%, $p < 0.001$).

Of the subgroup with ctDNA-based MRD postsurgery (26 out of 171 assessed patients), 19 patients (73%) with recurrence (median after 12 months [IQR 7-17]) were compared to 7 patients without recurrence (minimum follow-up 32 months). This sensitivity analysis showed similar trends in pathways, immune cells and CMS as the main analysis, with a more pronounced effect size for CAFs (r 0.27).

Conclusion: Stage III colon tumors of patients who experience recurrence after resection and ACT are enriched for stroma and CAFs, while displaying less CD4+ T cells. The observed trends are sustained in the patients with MRD postsurgery. These findings may help to better predict resistance to standard ACT and elucidate targets for alternative personalized treatment.

#2497 Extracellular vesicle based ALPPL2 and THBS2 as biomarkers for disease monitoring in patients with pancreatic ductal adenocarcinoma.

K. Halder[1], G. Jameson[2], E. Borazanci[2], W. Lin[1], D. Cridebring[1], D. Von Hoff[1], H. Han[1];
[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [2]HonorHealth Research Institute, Scottsdale, AZ

Pancreatic ductal adenocarcinoma (PDAC) remains a formidable challenge in the realm of oncology, characterized by its aggressive nature and resistance to treatment. Several therapeutic regimens have been shown to extend patient survival, but the majority of the patients become refractory to the treatments in a short period of time. Hence, it is critical to monitor a patient's response to treatment in a timely manner so that different treatment regimens can be considered promptly. Currently, CA19-9 is the most common blood-based marker being used to monitor disease burden in patients with PDAC. However, 15-20% of patients with PDAC do not have elevated blood CA19-9 levels. In this study, we sought to determine the utility of two circulating extracellular vesicle (EV) based protein biomarkers, ALPPL2 (Alkaline phosphatase, placental-like 2) and THBS2 (Thrombospondin 2), for disease monitoring in patients with PDAC. We first established and optimized EV assays using the ExoView^{TM} platform for detecting and quantifying the number of ALPPL2^{+} or THBS2^{+} EVs in serum samples. We then determined the concentrations of ALPPL2^{+} or THBS2^{+} EVs in samples from healthy individuals and longitudinal samples from patients with Stage IV PDAC undergone treatment. The longitudinal samples were from 26 patients of which 16 were CA19-9 secretors (defined as >35 U/ml) and 10 were CA19-9 non-secretors (defined as <35 U/ml) that were treated with various regimens for 4-24 months with monthly blood sample collection and CT scans (a total of 305 samples). We found that the concentrations of ALPPL2^{+} and THBS2^{+} EVs are on average 1,737 and 1,113 times higher in PDAC patients than in the healthy controls, respectively. Correlation analysis using the mixed linear model showed that the concentrations of both ALPPL2^{+} and THBS2^{+} EVs significantly correlate with changes in tumor size (based on RECIST measurements) in the longitudinal samples of CA19-9 non-secretors or secretors. In CA19-9 non-secretors the correlation p values are 0.003 and 0.006 for ALPPL2^{+} and THBS2^{+} EVs, respectively, whereas in CA19-9 secretors, the p values are 0.014 and 0.016 for ALPPL2^{+} and THBS2^{+} EVs, respectively. Our data indicates that EV based ALPPL2 and THBS2 could potentially serve as biomarkers for disease monitoring in patients with PDAC. (This work was supported in part by the Dorrance Family Fund and the Flinn Foundation)

#2498 Assessing the clinical value of ctDNA sequencing for initial tumor profiling in metastatic colorectal cancer patients with sufficient tumor tissue.

Y. Cha, B. Kim, D. Lee, H. Yeo, C. Hong, K. Han, B. Kim, H. Chang;
National Cancer Center - Korea, Goyang, Korea, Republic of

Introduction Tumor profiling including RAS, BRAF, HER2, and MSI/MMR status, is required to determine the treatment for patients with metastatic colorectal cancer (mCRC) at the time of diagnosis. While comprehensive tumor profiling using tissue-based next-generation sequencing (NGS) is increasingly adopted for initial profiling in mCRC, the role of circulating tumor DNA (ctDNA) NGS as initial testing in patients with sufficient tumor tissue is not clearly understood. We assessed the clinical value of ctDNA sequencing compared to tumor NGS in patients with newly diagnosed mCRC who have sufficient tumor specimens.
Methods We prospectively enrolled consecutive patients with newly diagnosed mCRC at the National Cancer Center Korea. As per the institutional protocol for mCRC, initial tumor profiling was performed on primary tumor tissue using an in-house NGS panel (NCC PCP ver.3), which included 525 genes. For ctDNA sequencing, patients were evaluated using the AlphaLiquid®100 comprehensive cancer panel (IMBdx, Inc.), which included 118 genes, before the initiation of chemotherapy. Additionally, immunohistochemical (IHC) testing for HER2 and polymerase chain reaction (PCR)/IHC testing for MSI and/or MMR were performed to assess the accuracy of HER2 and MSI/MMR status.
Results A total of 188 patients were enrolled. In 139 eligible patients, 275 potentially actionable mutations were found in 12 selected CRC-related genes (APC, TP53, KRAS, NRAS, BRAF, FBXW7, PIK3CA, ERBB2, SMAD4, NF1, EGFR, MET). Of these, 32% were found both in ctDNA and tissue; 54% were found in ctDNA only; 12% in tissue only, and 2% were discordant. For RAS/BRAF mutations, which are required for anti-EGFR treatment decisions, the concordance rate between ctDNA and tissue NGS was 83.1%, and the concordance was higher in patients with higher ctDNA concentrations. For 9 patients with potentially actionable copy number variations (CNV) in EGFR, HER2, MET, and FGFR1, 3 cases were found by both assays; 4 were found by ctDNA only, and 2 were found by tissue only. ctDNA NGS correctly predicted MSI/MMR status in 2 out of 4 patients with MSI-H/dMMR; in the 2 other patients, the MSI and MMR statuses were different, suggesting potential false positivity. In addition, the fold changes in ctDNA dynamics during treatment significantly correlated with changes in tumor size and CEA levels, as well as with droplet digital PCR copy number fold changes. In a patient with MET amplification, ctDNA NGS identified MET Y1230H as a potential acquired resistance mutation after crizotinib treatment, which responded to cabozantinib but not to capmatinib.
Conclusions Initial tumor profiling using ctDNA NGS yielded outcomes comparable to those of tumor tissue NGS in guiding treatment for patients with newly diagnosed mCRC, thereby suggesting its utility as an initial profiling method in mCRC.

#2499 Window-of-opportunity trial of metastatic pancreatic cancer reveals potential mechanisms of response to targeting RAS signaling.

M. Tsuda, C. Daniel, X. Wang, C. Pelz, H. Zimny, A. Smith, J. Muschler, X. Li, T. Yildiran Ozmen, F. Ozmen, D. Keith, C. Corless, K. Chin, J. Brody, C. Lopez, G. Mills, R. Sears;
OHSU, Portland, OR

KRAS is mutated in ~85% of pancreatic ductal adenocarcinoma (PDAC) patient's tumors, suggesting that it is a key node of PDAC targeted therapy. RAF/MEK/ERK signaling is downstream of KRAS signaling. Preclinical studies targeting MEK showed promises but clinical trials failed to show the benefit compared to Standard-of-Care treatment chemotherapy. To elucidate the mechanism of action and resistance to several targeted therapies including MEK inhibition in human PDAC, we conducted a Window-Of-Opportunity trial for Metastatic pancreatic cancer (WOOM trial). In this trial, metastatic PDAC patients received 10 days of Cobimetinib, a FDA approved MEK inhibitor, therapy and specimens of pre- and post- treatment were obtained by biopsy to evaluate the response to targeted treatment using deep multi-omic analytics including DNA-seq, RNA-seq, multiplex IHC, cyclic IF and Digital Spatial Profiling (DSP). The clinical grade KI67 staining positivity was used as a readout of tumor response. We found three of 15 patient's tumors had significantly decreased KI67 staining positivity after Cobimetinib treatment and defined them as Responsive tumors. Genomic sequence showed that KRAS allelic imbalance and $Kras^{G12R}$ mutations were seen significantly higher frequency in Responsive tumors compared to Non-responsive tumors. RNA-seq analysis showed that these Responsive tumors were more likely to be classical-like subtype compared to Non-responsive tumors. DSP analysis confirmed the downregulation of ERK phosphorylation after treatment in all examined cases consistent with effective target inhibition. Interestingly, MEK phosphorylation was upregulated after treatment paradoxically. This suggests that paradoxical upstream pathway activation including RAF activation could be potential resistance mechanism. MYC protein expression change was significantly correlated with KI67 protein expression change, which suggests MYC downregulation could contribute to action of Cobimetinib. We also found that Cobimetinib treatment increased the immunosuppressive TREM2+ Macrophage population from single cell RNA-seq data. Furthermore, PDX from biopsy recapitulated patient's response to therapy and could be a great tool for testing new therapeutic strategies. Here, we summarize the multi-omics data and discuss potential mechanisms of response and resistance to targeting RAS signaling and related microenvironmental changes.

#2500 Technical feasibility of CRISPR-based functional profiling for solid tumor precision medicine.

K. Hodel[1], A. Varkaris[2], N. Chevalier[2], M. Meyers[1], A. Kehlmann[2], S. Corbel[1], A. Stavridi[3], P. Kilfeather[1], L. Hagmann[1], K. Tran[1], Y. Li[1], C. Schmedt[1], I. Sanidas[2], S. Sampath[1], S. Sampath[1], D. Juric[2];

[1]Function Oncology, Inc., San Diego, CA, [2]Termeer Center for Targeted Therapies, Massachusetts General Hospital, Boston, MA, [3]Beth Israel Deaconess Mexicali Center, Boston, MA

Introduction: Next generation sequencing (NGS) has revolutionized precision oncology by enabling identification of cancer patients harboring actionable mutations who may benefit from corresponding targeted therapies. However, sequencing-based biomarkers are not detected for most patients and imperfectly predict response to therapy even when present. To address this unmet need, we have developed a CRISPR-based diagnostics platform for 'personalized functional genomics', allowing identification of patient-specific therapeutic vulnerabilities irrespective of mutation status. We have previously applied this approach to primary hematologic malignancies, and here report application to solid tumor-derived samples.

Methods: Patient-derived solid tumor samples from several tumor types including breast, ovarian, colon and lung were obtained from 3 sources: fresh tissue (obtained from patients via core biopsy, surgical resection, or malignant fluid sampling), primary Patient-Derived Cell Lines (PDCLs, generated from surgical material and adapted for *ex vivo* culture), and commercially obtained viably frozen dissociated tumor cells (DTCs). Samples were dissociated to single cell suspensions and transduced with a lentivirus encoding Cas9 and an sgRNA library covering a custom targeted oncology gene panel. The panel consists of genes encoding targets of FDA-approved oncology drugs, as well as reference genes. After a short culture period, transduced cells were harvested and relative sgRNA distribution was measured by amplicon NGS. Changes in sgRNA abundance were collapsed into gene-level log2-fold changes, and significantly depleted genes scored as functional dependencies. For select PDCLs, cells were treated with cognate small molecule inhibitors over the course of 4 days. Cell viability was read out using CTG assay and a calculated IC50 lower than 500nM inferred as inhibitor sensitive.

Results: In a double-blind study using primary PDCLs, functional dependencies identified by CRISPR perfectly discriminated alpelisib sensitive (2/2) from resistant samples (6/6). Using fresh primary samples from varying cancer types and specimen sources, we achieve a technical success rate >70%. Among gene dependencies identified, targets of FDA-approved oncology drugs and those under late-stage clinical investigation were both observed including BRAF, CDK4/6, VEGFR1/2 and PARP1/2.

Conclusion: We demonstrate technical proof of concept of the FX platform for CRISPR-based personalized functional genomics. This approach is feasible when applied to primary patient samples from a variety of tumor types and tissue sources, and results are validated by comparison with orthogonal methods. CRISPR-based functional profiling represents a powerful adjunct to traditional genomic profiling, for the first time allowing drug target dependency mapping in a patient-specific and mutation-agnostic manner.

#2501 High mutation burden and ultraviolet light signature in conjunctival squamous cell carcinoma.

B. Esmaeli[1], F. O. Gleber-Netto[1], O. Sagiv[1], C. R. Pickering[2], N. Gross[1], J. Ning[1], M. M. Yeshi[3], J. Mitku[3], M. T. Tetzlaff[4], P. Nagarajan[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Yale University, New Haven, RI, [3]Mekelle University, Mekelle, Ethiopia, [4]UCSF, San Francisco, CA

Purpose: Conjunctival squamous cell carcinoma (conjSCC) is endemic in sub-Saharan Africa and is a major cause of ocular morbidity and mortality. This study aims to evaluate Tumor Mutation Burden (TMB), genomic signature, and histologic characteristics of conjunctival squamous cell carcinoma (conjSCC) in two cohorts of patients; one from the USA and one from Ethiopia.
Methods: Whole exome sequencing data, PD-L1 expression, histologic features, and human papillomavirus (HPV) status were analyzed in conj SCC tumors of 25 patients treated at an Ethiopian (ETH) cancer center and 29 patients treated at a US cancer center. Genomic alterations in conjSCC were compared with SCCs from other anatomic sites using data from The Cancer Genome Atlas (TCGA).
Results: TMB was found to be relatively high in conjunctival SCC (3.01/Mb, log10), was comparable to TMB values associated with cutaneous SCC, and was higher than most other SCC types available in the TCGA database. ETH samples had higher tumor mutational burden compared to the US cohort (3.34 vs 2.73). Solar elastosis was seen in a higher percentage of tumors from Ethiopia compared with the US cohort (78% vs. 10%). HPV status was similar between the cohorts (ETH: 21%, MDA: 28%). PD-L1 positivity defined as > 1% of tumor cells was seen in 33 of 53 tumors (62%). Mutations associated with ultraviolet light (UV) signature were the most frequently encountered signatures in both cohorts (SBS7b: 74% and SBS7a: 72%). UV signatures were more prevalent in the ETH cohort compared with the US cohort.
Conclusions: Conjunctival SCC is associated with a high TMB providing the opportunity for immune checkpoint inhibitor therapy for patients with locally advanced and/or metastatic conjunctival SCC. Clinical trials are needed to assess the efficacy of immune checkpoint inhibitors in patients with conjunctival SCC, particularly in sub-Saharan Africa where this cancer is more frequently seen, and is associated with significant morbidity and mortality.

#2502 Identification of poor responders to trastuzumab-deruxtecan with a multi-modal HER2-status predictor.

K. Nadhamuni, T. Ahmed, M. Carty, B. Terdich, W. L. Hensing, T. Taxter, C. Chao, **R. Pelossof**;
Tempus Labs, Chicago, IL

Trastuzumab deruxtecan (TDXD) is approved for HER2 low or positive metastatic breast cancer. HER2-status is assessed through HER IHC and ERBB2 FISH assays. HER2-status has been shown to be correlated to RNA expression. This study aimed to assess if the addition of DNA to an RNA-based model can improve HER2-status prediction performance. Furthermore, to investigate the relationship between model score and outcomes for TDXD patients according to their overall survival (OS).

Training and test sets of breast cancer samples were collected for HER2 status prediction (n = 1275, n = 397 respectively). HER2 status was reported positive: 11%, 12%, low: 61%, 60%, negative: 28%, 29% for each set respectively. HER2 testing and NGS were performed on samples with the same collection date. A TDXD discovery cohort of 284 patients included patients who received TDXD after RNA/DNA collection and had at least a 30-day follow-up. Metastatic disease was reported for 98% of the TDXD cohort. Receptor status was HR+/HER2- 39%, HR-/HER2- 17%, HR+/HER2+ 16%, HR-/HER2+ 9%, unknown 19%, and HER2-status was negative 11%, low 42%, and positive 27%, unknown 20%. OS was measured from medication start date.

We trained a 12-gene linear model based on RNA expression and DNA copy number to predict HER2-positivity. The genes were selected by stepwise-selection on RNA and DNA features when predicting HER2-positivity using a random forest model. A baseline model consisting only of ERBB2 RNA expression was compared. Setting a HER2-positivity score threshold and allowing for an indeterminate group of 15% of the validation cohort, the RNA-DNA model achieved 91% PPA and 91% PPV in validation, whereas the RNA-only model achieved 83% PPA and 85% PPA. This indicates that the addition of DNA data improved the RNA-only HER2 predictor.

The Concordance index of the RNA-DNA model score and OS for TDXD was 0.64. Characterizing this relationship, we partitioned the TDXD cohort to three equal sized sub-cohorts (33 1/3%) ordered by model score: low, intermediate, and high. Median OS in months for groups was: low 13.6, intermediate 18.5, and high 20.4. High-group patients had significantly better OS on TDXD compared to the low-group (HR = 0.39, log-rank p-value < 0.002). For patients with reported status, HER2-positivity rate in each group respectively was 6%, 16%, 85% (n=78), and HR-positivity in each group was 70%, 68%, 67% (n=156).

Together, these findings indicate that HER2 status prediction improved by adding DNA to an RNA base predictor, and the predicted score was positively correlated with OS for TDXD.

#2503 The role of APOBEC in early stage-*EGFR* mutant non-small cell lung cancer.

H. Jung, J. Lim, Y.-L. Choi, S. Park, J.-M. Sun, M.-J. Ahn, S.-H. Lee;
Samsung Medical Center, seoul, Korea, Republic of

Background: The APOBEC family of zinc-coordinating enzymes converts cytosines to uracils in single-strand DNA. APOBEC plays a crucial role in the mutation process of non-small cell lung cancer (NSCLC) and is essential for both adaptive and innate immune responses. This study aims to evaluate the role of the APOBEC mutation signature in early-stage non-small cell lung cancer (NSCLC).
Methods: We conducted whole-exome sequencing and whole-transcriptome sequencing using fresh tissue or formalin-fixed paraffin-embedded samples from 100 patients diagnosed with pathologic stage II-IIIA non-squamous NSCLC, all of whom underwent complete resection between January 2014 and December 2020 at Samsung Medical Center. This study aimed to assess the impact of APOBEC enrichment on disease-free survival (DFS), progression-free survival (PFS) of EGFR-TKI, and overall survival following recurrence.
Results: Median follow-up duration was 58.2 months (range, 11.3-141.1). Of the patients, 74% were never-smokers, and 52% had stage III disease. Among the 100 patients, 18 (18%) exhibited APOBEC enrichment (≥ 2). The median RFS was 25.2 months (95% CI, 17.3-33.2). Notably, APOBEC enrichment did not show a significant association with DFS (P=0.14). Among the 76 patients who experienced radiological recurrence, 69 received EGFR-TKI as first-line treatment. The median PFS for EGFR-TKI was 22.9 months (95% CI, 13.0-32.8). However, within this group, patients with APOBEC enrichment showed a shorter PFS compared to those without APOBEC enrichment (8.1 months vs. 24.6 months, P=0.014). In multivariate analysis, poor PFS of EGFR-TKI was associated with the type of EGFR mutation (L858R vs. exon 19 deletion, HR=1.9, P=0.04), TP53 mutation (mutation vs. wild type, HR=2.1, P=0.03), and APOBEC enrichment (≥ 2 vs. <2, HR=2.2, P=0.02). Overall survival from the starting EGFR-TKI was 61.1 months and 21.7 months for patients with APOBEC enrichment or patients without APOBEC enrichment, respectively (P=0.027).
Conclusions: APOBEC mutation signature may be presented at initial diagnosis of early-stage *EGFR* mutant NSCLC and it was associated with poor PFS of EGFR-TKI and overall survival.

#2504 Determining tumour homologous recombination repair status in PDX and clinical samples using automated RAD51 scoring.

J. Robertson[1], J. Ashton[1], G. N. Jones[1], G. Mills[2], T. Y. Ozmen[2], M. J. Rames[2], S. Park[2], P. Waring[1], N. Lukashchuk[1], E. Harrington[1];
[1]AstraZeneca, Cambridge, United Kingdom, [2]Oregon Health & Science University, Portland, OR

PARP inhibitors (PARPi) as monotherapy are approved in a wide variety of cancers that show genetic alterations that result in homologous recombination repair (HRR) deficiency. Current genomic scar tests for HRR deficiency (HRD) are predictive of response to PARPi on a population scale but they may fail to provide a real-time functional status of HRR in an individual. RAD51 is a critical DNA repair factor that functions in HRR to safeguard the integrity of the genome and could be a useful patient selection biomarker for PARPi response.During HRR, RAD51 forms filamentous structures to facilitate repair, which can be visualised by direct immunofluorescence (IF) as nuclear foci. Quantification of these RAD51 foci has been shown to be a functional readout of HRR status, however current manual counting of foci is challenging and can result in high inter-observer variability. In order to standardise RAD51 quantification, we aimed to develop an image analysis solution.Tumour samples from patient derived xenograft (PDX) studies and human tissues from commercial sources and clinical trials were co-stained with IF for RAD51 and geminin, as a marker of cells in S/G2 phase of the cell cycle. Manual scoring was performed as reported previously. Visiopharm was used to create and image analysis pipeline in allowing delineate tumour epithelial areas, detection of the geminin positive nuclei and RAD51 foci within these and the quantification of the foci.We have successfully developed an image analysis solution to select geminin positive proliferating tumour cells from PDX and clinical material, then quantify the RAD51 foci within these cells. There is a good correlation with manual scores with a similar accuracy to the manual inter-observer variability (PDX: R^2 = 0.76, F1 = 0.95 [n=34]; breast cancer samples: R^2 = 0.72, F1 = 0.92 [n=33]). Developing and image analysis solution has challenges due to several factors such as pan-nuclear staining of non-focus forming RAD51 being variable across samples, manual scoring using a wider Z-plane, susceptibility of RAD51 to pre-analytical factors and the fact that a duplex IF stain with geminin is required to mark actively replicating cells.The frequent inactivation of HRR is known to sensitise cancer cells to PARP inhibitors, we demonstrate a quantitative functional readout of HRR competency using RAD51 foci staining and an image analysis algorithm. This solution may enable the use of RAD51 foci as a patient selection biomarker for PARP inhibitors by providing an objective, robust and reproducible algorithm for scoring.

#2505 Immune dynamics and response predictors to regorafenib, ipilimumab, and nivolumab (RIN) treatment in chemotherapy resistant microsatellite stable (MSS) metastatic colorectal cancer (mCRC).

Jian Ye[1], Chongkai Wang[2], Colt Egelston[1], Weihua Guo[1], Peter Lee[1], Marwan Fakih[2]

[1]Department of Immuno-Oncology, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Department of Medical Oncology and Therapeutics Research, City of Hope National Medical Center, Duarte, CA

Background: In our previous study, RIN therapy in MSS mCRC patients, excluding those with liver metastases, yielded a notable 36.4% objective response rate. RIN treatment was observed to remodel the local tumor microenvironment by enhancing immune infiltration, especially in responders. Systemic immunity, as assessed through peripheral blood analysis, showed that responders had lower baseline immune activity, which increased markedly post-treatment. Patients with liver metastases demonstrated a reduced CD4/CD8 T cell ratio, indicative of immunosenescence.
Methods: Building on our prior research, we analyzed blood samples from 29 chemotherapy-resistant MSS mCRC patients undergoing RIN therapy, collected at baseline and after two consecutive treatment cycles. Two 28-marker spectral flow cytometry panels were used to assess immune senescence and cytokine production in lymphocytes. Additionally, T cell receptor repertoires and transcriptional profiles were analyzed using RNA sequencing from sorted non-naïve T cells. Results: The study unveiled distinct immunological profiles in MSS mCRC patient responders vs non-responders to RIN treatment. Responders demonstrated increased numbers of newly expanding CD8 T cell clones on-treatment, indicative of an active immune responses. In contrast, non-responders displayed evidence of increased DNA damage in circulating lymphocytes (T, B, and NK cells), as marked by elevated γ-H2AX levels. We also identified divergent cytokine production profiles patterns at baseline: T cells in non-responders demonstrated increased capacity for production of IL-2, IL-10, IL-4/-13, and IL-22, while production of IFN-γ in both T cells and NK cells correlated with improved outcomes. Notably, patients with liver metastases exhibited greater frequencies of senescent T cells, characterized by increased expression of senescence markers (SA-βGal, CD57, Granzyme B/K) and a reduction in CD27 and CD28 in CD4 T cells, along with an accumulation of terminally differentiated CD8 T cells both pre- and post-treatment. Additionally, RNA sequencing revealed an upregulation of FOXO1 related genes in non-naive T cells of responder patients, which is consistent with its important role for this pathway in attenuating senescence and maintenance of stem-like properties in T cells.
Conclusions: The effectiveness of RIN therapy is associated with baseline functional potential of circulating T cells and an on-treatment expansion of T cell clonotypes. Pre-existing and persistent features of senescence and DNA damage in circulating lymphocytes may be a major barrier to RIN treatment efficacy in MSS colorectal cancer and should be validated further in future studies.

#2506 Novel biomarkers that predict response to neoadjuvant chemoradiotherapy in locally advanced rectal cancer.

A. Hasan[1], E. V. Demidova[1], P. Czyzewicz III[1], K. Devarajan[1], M. B. Einarson[1], D. Baldwin[1], E. A. Golemis[2], J. E. Meyer[1], S. Arora[1];
[1]Fox Chase Cancer Center, Philadelphia, PA, [2]Lewis Katz School of Medicine, Temple University, Philadelphia, PA

Background: Neoadjuvant chemoradiotherapy (nCRT) followed by surgery is standard of care for locally advanced rectal cancer (LARC). About 20% patients receiving nCRT alone experience a pathologic complete response (pCR), while up to 25% patients exhibit a poor response. Currently, there is no biomarker to predict response to nCRT. We hypothesized that inherited ability to recognize and repair DNA damage, especially lethal double-strand breaks (DSBs), manifest in lymphocytes, would yield a reproducible test predicting therapeutic response to nCRT.
Methods: Expression of DNA damage response (DDR) proteins was studied using peripheral blood lymphocytes (PBLs) from LARC patients and healthy controls. PBLs from LARC patients collected either before nCRT or after a standard course of ~5.5 weeks of nCRT were assessed by immunofluorescence (IF) for phospho-γH2AX^{Ser139} and by Luminex multi-analyte platform (xMAP) approaches. The xMAP assay was modified from a qualitative to a semi-quantitative assay that measures the following DDR-associated proteins- total ATR, phospho-γH2AX^{Ser139}, total MDM2, phospho-Chk1^{S345}, phospho-Chk2^{T68}, phospho-p53^{S15}, total p21. The analytical performance of the assay was assessed with vendor-provided reference controls and banked PBLs from healthy controls (n=50). LARC patients were segregated by neoadjuvant rectal (NAR) score to determine if tested biomarkers correlated with nCRT response. We used two independent sets of LARC biospecimens for xMAP analysis (set 1, n=48; set 2, n=44).
Results: IF-based assessment: Using PBLs from LARC patients, we found that poor responders (PoR; NAR score>14; n=21) had significantly lower γH2AX foci than complete responders (CR; NAR score<1; n=21) (P<0.0001, logistic regression). No significant difference was observed in positive γH2AX foci from PBLs drawn pre-nCRT versus post-nCRT from the same patient (p=0.4961, n=11, Wilcoxon test). xMAP assay performance: The performance assessment showed linear sample curves, precision with acceptable inter- and intra-assay coefficients of variability, and high reproducibility with ~1% outliers identified in replicates. Clinical associations using xMAP assay: levels of six proteins (ATR, p-γH2AX^{Ser139}, MDM2, p-Chk1^{S345}, p-Chk2^{T68}, p-p53^{S15}) significantly differentiated CRs from PoRs (p-values and False Discovery Rate <= 1e-5). The strongest associations with nCRT response were observed for: ATR, MDM2 and γH2AX.
Conclusion: 1) we standardized an xMAP assay to assess DDRs in human PBLs, and 2) found novel biomarkers that predict response to nCRT in LARC patients using minimally invasive PBL biospecimen. In ongoing work, we are using a larger biospecimen set to establish clinical validity parameters.

#2507 Drivers of immunotherapy response within the CPI3000+ cohort.

K. Thakkar[1], A. Castro[1], D. Qian[1], C. Swanton[2], K. Litchfield[1];

[1]University College London (UCL) Cancer Institute, London, United Kingdom, [2]The Francis Crick Institute, London, United Kingdom

Introduction: Multiple genomic and transcriptomic biomarkers have been associated with response to immune checkpoint (CPI) therapy. These markers include tumor mutational burden (TMB), immune infiltration and HLA loss of heterozygosity. Our previously published meta-analysis of biomarkers included over 1000 patients (CPI1000) across multiple cancer types and demonstrated that clonal TMB and CXCL9 expression were the strongest predictors of response pan-cancer. Biomarkers were combined into a multivariable predictor of response which out-performed TMB in three validation cohorts. However, even with an extensive systematic review, the literature and exploratory biomarkers only accounted for ~60% of the variance explained in CPI response. Approach and Results: Extending the cohort to over 3000 patients from 20 studies, across 11 tumor solid tumor types, we have utilized available genomic and transcriptomic data to further validate the multi-variable predictor of response as well as conduct additional exploratory analysis to uncover the remaining variance explained. The raw data is processed through a robust bioinformatics pipeline and is harmonized across studies. The pipeline developed to process the CPI3000+ cohort will be open-access and available to promote federated learning and collaborations. Firstly, we have expanded the systematic review to include recent biomarkers from literature. The literature review included over 1000 papers, and we identified greater than 200 unique biomarkers which can be quantified and assessed in the CPI3000+ cohort. Data presented on this extensive set of genomic and transcriptomic biomarkers across the cohorts will improve understanding of biomarkers of response to CPI therapy. Second, we will explore novel biomarkers of response including non-classical sources of antigen such as retained introns as well as pathways such as the unfolded protein response. We will also survey the effects of tumor-associated antigens such as those involved in CAR-T cell and vaccine trials in CPI response which was limited in the CPI1000 cohort. We will also be presenting data on emerging checkpoints in late-stage trials across cancer types. Finally, we will be combining the biomarkers into a novel multivariable predictor of response.
Conclusions: Results from this work will highlight the varying determinants of immunotherapy response across solid tumor types, offering insight into tumor intrinsic and extrinsic drivers of immunogenicity. We have shown that sources of tumour antigen are a major group of biomarkers for CPI response, here we expand on this further in a larger cohort as well as identifying novel biomarkers to create an improved multivariable predictor of clinical value.

#2508 EMP2 is a targetable biomarker in GBM tumors resistant to anti-angiogenic therapies.

B. Aguirre, M. Mekonnen, R. Mehta, M. Suresh, A. Chandla, K. Han, I. Yang, M. Wadehra;
UCLA David Geffen School of Medicine, Los Angeles, CA

Background: Glioblastoma (GBM) is characterized as the most aggressive and lethal primary brain tumor. One of the hallmarks of GBM tumor growth and progression lies within the proangiogenic tumor microenvironment. Current anti-angiogenic drugs such as the anti-VEGF antibody take effect by inducing tumor cell starvation, leading to a functional normalization of the tumor vasculature. However, the survival benefits of anti-angiogenic drugs have been very limited. To this end, we hypothesized that the tetraspan Epithelial Membrane Protein-2 (EMP2) may help mediate resistance.
Objective: We hypothesize that Epithelial Membrane Protein-2 may serve as a targetable biomarker for anti-VEGF resistance. We further explored the effectiveness of combination therapy in SB28 and GL261 GBM mouse models using anti-VEGF drug, Aflibercept, with a novel anti-EMP2 monoclonal antibody (mAb).
Results: Tumor tissue was collected prospectively from patients undergoing surgery for suspected glioblastoma and stained for EMP2 and HIF2a using standard immunohistochemistry. Patients had banked tumor tissue both prior to and after bevacizumab treatment with 3 months of clinical and radiologic follow-up available. Bevacizumab treatment increased EMP2 protein expression. This increase in EMP2 correlated with reduced mean survival time post-bevacizumab therapy. Similarly, HIF-2a showed increased expression post-bevacizumab treatment and showed expression in both tumor and stromal cells. Limited animal models exist for anti-VEGF therapy for GBM. To establish syngeneic models, 10 week-old mice were subcutaneously implanted with murine SB28 or GL261 GBM cells. Treatment with either polyclonal sera to VEGF or Aflibercept failed to reduce tumor load or provide a therapeutic benefit. To next investigate if this model could recapitulate the response obtained patients tumors, formalin fixed paraffin embedded tissue was analyzed for both EMP2 and HIF-2a expression. Both markers were significantly upregulated in Aflibercept treated samples compared to the control.To next investigate if combination treatment could produce a significant reduction in tumor load, animals were treated with a combination treatment with Aflibercept and anti-EMP2 mAb. The combination therapy significantly reduced tumor volume and weight in comparison to control-treated tumors. Combination treatment in SB28 tumors resulted in a two fold reduction in tumor load and 50% reduction in tumor weight. Moreover, tumors showed reduced Ki67 expression. Similarly, treated GL261 tumors produced a 2.3 fold reduction in tumor size and ~2.7 fold reduction in tumor weight. Our results suggest that EMP2 can be a promising new target therapeutic target that can be combined with anti-VEGF treatment to potentially increase overall survival in GBM patients.

#2509 Abundant glucocorticoid receptor (GR) expression in human tumors: A tissue microarray study on more more than 18,000 tumors.

C. Tsourlakis, F. Wegener, K. Moller, M. Kluth, C. Hube-Magg, C. Bernreuther, G. Sauter, A. H. Marx, R. Simon, T. Krech, C. Fraune, N. Gorbokon, **M. Lennartz**, S. Minner, F. Viehweger;
University Medical Center Hamburg-Eppendorf, Hamburg, Germany

The glucocorticoid receptor (GR, or GCR) is a nuclear receptor protein for cortisol and other glucocorticoids and regulates the transcription of thousands of genes involved in metabolism, development, stress, and inflammatory response. In cancer, both an oncogenic and a tumor suppressive function of GR has been proposed. To comprehensively evaluate GR expression in normal and tumorous tissues, a tissue microarray containing 18,570 samples from 147 different tumor types and subtypes and 608 samples of 76 different normal tissue types was analyzed by immunohistochemistry (IHC). GR positivity was found in 76.3% of 14,349 interpretable cancers, including 18.5% with weak, 19.6% with moderate, and 38.3% with strong positivity. GR positivity of at least a fraction of tumors was found in all 147 analyzed tumor types and at least one strongly GR positive tumor was found in 136 tumor types. 77 of our 147 tumor entities showed GR positivity of variable intensity in all analyzed cases. 43 further tumor entities showed GR positivity in 80-99.9% of cases. 21 tumor entities had a GR positivity rate between 50 and 80%, including urothelial carcinoma as well as gastric and esophageal adenocarcinoma. Only 6 tumor types had less than 50% GR positive. These included adenomas (21.7-32.5%), adenocarcinomas (17%) and neuroendocrine carcinomas (45.5%) of the colorectum. Reduced GR staining was significantly associated with adverse histopathological and clinical features in several tumor types. Low GR expression was linked to grade progression in pTa ($p<0.0001$) and to nodal metastasis in pT2-4 urothelial carcinoma of the urinary bladder ($p=0.0051$), advanced pT stage ($p=0.0006$) and estrogen receptor positivity ($p=0.0126$) in breast carcinomas of no special type (NST), as well as to high grade ($p\leq0.0076$), advanced pT stage ($p<0.0001$), distant metastasis ($p=0.0081$), and poor overall survival ($p=0.002$) in clear cell renal cell carcinoma. GR expression was unrelated to clinic-pathological parameters in gastric, pancreatic, and colorectal adenocarcinoma as well as in serous high-grade carcinoma of the ovary. In summary, our data demonstrate frequent GR expression across all cancer types. Significant associations between reduced GR expression and unfavorable tumor features in some but not all tumor types suggest that the functional importance of GR regulated genes for cancer progression depends on the cell of tumor origin.

CLINICAL RESEARCH: Predictive Biomarkers 2
Poster Session

#2513 MAGE-A3, MAGE-A4, and PD-L1 protein show co-expression in colon, lung and bladder cancer.
R. Gonzalez, Y. Guo, J. Yom, B. Gilmore, E. Zewdu, X.-A. Han, D. Kong, T. Qu, Q. Ren, X. Hu, R. Zhang, Z. Wu, A. Strom, X. Liu, W. Fu;
OriGene Technologies, Inc., Rockville, MD

PD-L1 programmed death ligand 1/CD274 has been shown to be an excellent immune therapy target for many tumors. Currently, studies have shown PD-L1in combination with other immune therapy targets can improve patient outcomes generating the need for new targets. One candidate is the cancer testis antigen Melanoma Antigen Gene Family (MAGE-A) because these genes have limited expression in normal tissues and high expression in cancer. Clinical trials have already begun targeting MAGE-A3 and MAGE-A4 proteins in multiple tumor types. Protein assessment of individual MAGE-A family members has been challenging due to sequence homology as high as ninety-five percent between members. Previously, with the use of CytoSections two highly specific antibodies for immunohistochemistry to MAGE-A3 (clone OTI1H1) and MAGE-A4 (clone OTI2C1) were found. In this study, the MAGE-A3 and MAGE-A4 antibodies were screened with PD-L1 on colon, lung, and bladder cancers. Results show detection of both MAGE-A3 and MAGE-A4 in 25% of colon; 30% of lung; and 20% of bladder cancers. More than 70% of the lung and bladder cancers were positive for MAGE-A4 but only six of twenty-four colon cancers were positive for MAGE-A4. The results show 60 percent of the positive for MAGEA3 or MAGEA4 in colon, lung, and bladder cancers were also positive for PD-L1. This study suggests that MAGE-A3 and MAGE-A4 have tumor specific expression patterns and a potential to be a co-immunotherapy target with PD-L1.

#2514 Adjuvant chemotherapy drug response-related gene detection using JASPAC01 pancreatic cancer resection cohort.

Y. Okamura[1], T. Otsu[2], M. Hayashi[2], R. Ashida[3], K. Uesaka[3];

[1]Nihon University School of Medicine, Itabashi-ku, Tokyo, Japan, [2]Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]Shizuoka Cancer Center, Sunto-Nagaizumi, Shizuoka, Japan

Background of Purpose: Although various multidisciplinary treatments have been attempted for pancreatic cancer, sufficient improvement in prognosis has not been achieved. It is necessary to establish biomarkers that can predict the malignant potential for each patient and the therapeutic effect of chemotherapy in order to select the optimal treatment for each individual case.This study was designed as a companion study to the phase III comparative study (JASPAC 01 of gemcitabine (GEM) and S-1 therapy as adjuvant chemotherapy after pancreatectomy. Among the 22 candidate biomarker genes that have been reported to be involved in pancreatic cancer treatment prognosis, we focused on E2F transcription factor 7 (E2F7), which is associated with a significantly poor overall survival rate when highly expressed. E2F7 is one of the target proteins of p53 and has been reported to be involved in cell cycle regulation. We examined the possibility of E2F7 expression in pancreatic cancer surgery and the effect of adjuvant chemotherapy.

Patients and Methods: After optimizing the E2F7 imunostaining protocol, we scored E2F7 protein expression using the slides from excised tissues from JASPAC 01 registered cases. We investigated the relationship between malignancy and treatment efficacy using the case cohort treatment allocation information, clinicopathological information, and prognosis data.

Results: Immunostaining was performed on approximately 330 resected pancreatic cancer specimens from 24 facilities nationwide. Of the 311 patients for whom E2F7 protein expression could be scored, 202 patients who completed the assigned treatment were included in the analysis. In 88 cases with high E2F7 expression, no significant difference in clinicopathological factors was observed between the S-1 treatment group and the GEM treatment group, but the S-1 treatment group showed better recurrence-free survival (RFS, P=0.066) and overall survival (OS, P=0.015) were observed. On the other hand, in the 114 patients with low E2F7 expression, there was no significant difference in clinicopathological factors between the two groups (RFS, P=0.168, OS: P=0.276). High E2F7 expression in pancreatic cancer tissues may affect S-1 sensitivity, GEM resistance, or both.

Conclusions: It is considered that high expression E2F7 in pancreatic cancer may affect the therapeutic efficacy of GEM and S-1, which are frequently used in adjuvant chemotherapy for pancreatic cancer.

#2515 Cation transport gene signature predicts overall and progression free survival in bacillus-calmette-guerrin-treated non-muscle invasive bladder cancer in The Cancer Genome Atlas.

L. K. Tran, S. P. Lerner;
Baylor College of Medicine, Houston, TX

Introduction: Bacillus Calmette-Guerrin (BCG) is a commonly used immunotherapy for non-muscle invasive bladder cancer (NMIBC), and there is limited understanding of its *in vivo* mechanisms. *In vitro* studies on patient-derived tumor cells suggest the role of calcium signaling as an effector of immune response. We aimed to elucidate further understanding of important signaling pathways implicated in BCG response using gene expression data. The goal is to identify a gene signature for predicting BCG response and survival post-BCG therapy.

Methods: Gene expression data for the BCG treated NMIBC cohort was downloaded from TCGA. Individual gene expression data analyzed with univariate cox proportional hazard models versus overall survival (OS) and progression-free survival (PFS) independently. The survival outputs were then fed into String DB network analysis. Overlapping genes in the 2 networks were combined into a Z- sum composite score for survival prediction. Correlation analysis was performed for the overlapping genes.

Results: Based on the selection criteria, 35 patients were available for the study. In OS analysis a total of 622 genes were filtered based on HR>2 or <0.5 with adjusted-p <0.05. Network analysis of those significant genes demonstrated significant calcium ion transmembrane transport upregulation in patients with better OS, showing a subnetwork of 16 genes. In the PFS analysis, 500 genes with HR>2 or <0.5 with adjusted-p<0.05 were subjected to network analysis. The main cluster was enriched in cation transmembrane transport upregulated in patients with better PFS, and consisted of a subnetwork of 39 genes. There were 295 shared genes between the genes associated with improved OS and PFS gene sets. A composite score constructed from these 295 genes revealed an optimized cutoff of the lower 70th percentile of expression versus the upper 30th percentile of normalized summed gene expression (HR = 0.192, p = 0.00048 for OS; and HR = 0.171, p < 0.0001 for PFS). Internal correlation reveals 3 sub-clusters of gene expression within our data set.

Conclusion: Similar to *in vitro* studies we report increased cation transport expression *in vivo*, that was significantly associated with improved OS after BCG immunotherapy. Our composite gene signature score was able to identify a poor survival subgroup—about 1/3 of patients—with 5-fold worse PFS and OS following BCG therapy. Increasing calcium signaling may potentiate BCG response in currently poor BCG-responders.

#2516 Influence of pre-treatment nutrition and inflammation on immunotherapy response in non-small cell lung cancer.

L. A. Robinson, Y. Kim, A. Buro, S. R. Hogue, A. Bailey, G. M. DeNicola, C. Pierce, M. Umbarger, D. A. Byrd;
Moffitt Cancer Center, Tampa, FL

Purpose: Immune checkpoint inhibitor therapy (ICI) is effective in non-small-cell lung cancer (NSCLC) but only a minority respond, likely due in part to the gut microbiome. Given the coupling of host nutritional status and gut microbiota composition, we investigated the pre-treatment associations of nutritional status and biomarkers with ICI treatment response and survivals.

Methods: We recruited stage III-IV NSCLC patients. Pre-ICI treatment clinical information and blood samples were obtained. Clinician assessed ICI response and survival data were recorded. The nutritional/inflammatory indicators were compared based on treatment response and survivals. ICI Clinical Benefit was defined as 12-month progression free survival. Pearson Chi-square or Fisher's Exact test was used to compare categorical metrics; non-parametric analysis compared continuous metrics by treatment response. Overall survivals were assessed using multivariable Cox proportional hazards models to estimate associations.

Results: Of the 76 patients recruited, all were ECOG performance status 0 (14.5%) or 1 (85.5%). 36 (47%) had Clinical Benefit with median survival 21.3 mo. vs. 6.6 mo. among the No Clinical Benefit patients ($p<0.01$). Non-responders had significantly more often weight loss, lower serum albumin, elevated red cell distribution index (RDW) and worse scores for Frailty Index, Geriatric Nutritional Risk Index and Mini-Nutritional Assessment (MNA). Non-responders had significantly more inflammation with a higher Systemic Immune Response Index (SIRI) and RDW. Overall survival was negatively correlated with: 1. weight loss; 2. low serum albumin; 3. low serum sodium; 4. high RDW; 5. elevated total neutrophils, total white blood cells, total monocytes, neutrophil to lymphocyte ratio, and monocyte to lymphocyte ratio; 6. adverse MNA and Geriatric Nutritional Risk Index; 7. elevated SIRI and Systemic Immune Inflammation Index (SII). ICI response prediction accuracy using a solely MNA-based model was significantly high in terms of AUROC of 0.85 [95% CI= (0.76, 0.93); $p<0.05$]. In multivariable analysis, the predictor of immunotherapy response and survival was the 6-measure MNA which strongly correlates with weight loss, low serum albumin and depressed Frailty Index.

Conclusions: An adverse nutritional status with accompanying chronic inflammation is strong predictor of non-response to ICI. Since lung cancer patients with depressed pre-treatment nutrition have a low likelihood of an ICI response, they should be promptly referred for dietician consultation for intensive nutritional therapy which may improve their clinical outlook. Considering the negative association of malnutrition/inflammation with response to ICI treatment in NSCLC patients who still qualify as ECOG performance status 0-1 patients, prospective clinical trials should also stratify their results by nutritional status.

#2517 The amplification of TPX2 is a potential biomarker of oxaliplatin-sensitivity of colorectal cancers (CRCs) with CIN phenotype.

Shohei Ueno[1], Taichi Isobe[2], Ryosuke Taguchi[1], Kenji Tsuchihashi[3], Koichi Akashi[1], Eishi Baba[2]

[1]Department of Medicine and Biosystemic Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan,[2]Department of Oncology and Social Medicine, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan,[3]Department of Hematology, Oncology and Cardiovascular Medicine, Kyushu University, Fukuoka, Japan

The amplification of Chr20q11.21 harboring TPX2 gene is the most frequent copy number alteration among the cases of colorectal cancers (CRCs), especially left-sided ones. We retrospectively examined 2828 cases of CRC patients who took cancer-genome panel tests in Japan between June 2019 and November 2022. The time to first-line treatment failure was longer with regimen with oxaliplatin than with those with irinotecan in CRC patients with Chr20q11.21 amplification (12.2 versus 9.2 months, p=0.0481). Oxaliplatin induces double-strand breaks (DSBs) and then cellular apoptosis. A key event of the DNA damage response to DSBs for cellular survival is the extensive phosphorylation of Ser139 of Histone H2AX adjacent to the chromosomal break. TPX2 whose gene resides in Chr20q11.21 has been reported to repress the phosphorylation of H2AX upon ionizing radiation. The purpose of this study is to identify the relationship between the amplification of TPX2 and oxaliplatin sensitivity in human CRCs. The knockdown of TPX2 decreased the oxaliplatin-susceptibility of COLO320 and Caco-2, CIN phenotype CRC cell lines which highly expressed TPX2. However, TPX2 knockdown did not reduce the oxaliplatin sensitivity of HCT-116, an MSI phenotype CRC cell line with low-level of TPX2 expression. The knockdown of TPX2 in CIN phenotype CRC cells, not in the MSI phenotype CRC cells, enhanced the phosphorylation of H2AX upon the DNA-damage induced by oxaliplatin. These findings suggest that amplification of TPX2 contributes to the oxaliplatin-susceptibility of CRCs with CIN phenotype through DNA repair machinery.

#2519 Alteration of tumor immune microenvironment after recurrence and its impact on the efficacy of anti-PD-1 antibody in resected non-small cell lung cancer patients.

Y. Matsumoto, T. Watanabe, M. Mizutani, A. Sugimoto, H. Nagamine, Y. Tani, K. Sawa, T. Tsukioka, H. Kaneda, S. Mitsuoka, N. Nishiyama, T. Kawaguchi; Osaka Metropolitan University, Osaka, Japan

Background: Tumor immune microenvironment (TIME), including programmed death-1 ligand-1 (PD-L1) and CD8-positive tumor-infiltrating lymphocytes (TIL), has been suggested as a potential biomarker to predict the efficacy of anti-PD-1 antibody. Postoperative recurrence in patients with non-small cell lung cancer (NSCLC) is treated with therapeutic strategies similar to those for metastatic disease. However, in postoperative recurrence cases, PD-L1 evaluation is generally based on archival resection specimens, because there is little opportunity for a new biopsy of the recurrent site. Therefore, it remains unclear whether TIME of recurrent lesion is similar to TIME of primary lesion at surgery, and the efficacy of anti-PD-1 antibody for postoperative recurrent NSCLC patients based on TIME status at surgery is unknown.

Materials and Methods: Cohort A included 59 patients with advanced and 25 patients with postoperative recurrence NSCLC who treated with first-line pembrolizumab monotherapy. PD-L1 expression and CD8-TIL were evaluated immunohistochemically in tumor specimens obtained at diagnosis in the advanced cases and at surgery in the postoperative recurrence cases. Tumor proportion score for PD-L1 and the extent of CD8-TIL were evaluated and classified as high or low. TIME was categorized into 4 subclasses, according to the respective PD-L1 and CD8-TIL, as follows: (class I) high/high; (class II) low/low; (class III) high/low; and (class IV) low/high. Progression-free survival (PFS) of pembrolizumab was compared based on TIME. Cohort B consisted of 50 NSCLC patients who underwent radical resection, and whose tumor specimens were obtained from recurrent site. As in cohort A, TIME was assessed for paired resection and recurrent tumor samples.

Results: In cohort A, the median PFS of pembrolizumab for the advanced cases were 25.7 months in class I (n=25), 2.3 months in class II (n=8), 8.0 months in class III (n=20), and 6.5 months in class IV (n=6) (p<0.001), respectively; while those for the postoperative recurrence cases were 9.0 months (n=7), 4.3 months (n=7), 7.6 months (n=6), and 2.5 months (n=5) (p=0.55), respectively. In cohort B, TIME for resected primary lesion were observed in 9 with class I, 20 with class II, 3 with class III and 18 patients with class IV, respectively. The concordance of PD-L1 category (high vs low) between resected primary lesion and recurrent lesion was 88.0%, while that of TIME classification was 54.0%.

Conclusion: TIME classification using tumor specimens just before administration of anti-PD-1 antibody was useful predictive biomarker. However, TIME alterations between resection and postoperative recurrence were observed in many cases, suggesting that TIME based on tumor specimens at surgery may not be useful for predicting the efficacy of anti-PD-1 antibody for postoperative recurrent NSCLC.

#2520 CD133 expression is associated with less DNA repair, better response to chemotherapy, and survival in ER-positive/ER-negative breast cancer.

T. Sato[1], M. Oshi[2], J. Lee[2], A. M. Roy[2], K. Chida[2], I. Endo[3], M. Obayashi[4], K. Takabe[2];
[1]The University of Tokyo Hospital, Tokyo, Japan, [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [3]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [4]National Hospital Organization Disaster Medical Center, Tokyo, Japan

Introduction: Cancer stem cells (CSC) constitute only 0.1-1% of all the cells in a bulk tumor, yet they play a crucial role in treatment resistance and relapses. Its role in breast cancer (BC) has been studied but a consensus remains elusive. We focused on gene expression of a CSC marker CD133 and studied its clinical significance in ER-positive/HER2-negative (ER+/HER2-) BC, the most prevalent subtype. We utilized multiple independent large patient cohorts of gene expression and clinical variables for transcriptome analysis.
Methods: A total of 2969 patients from The Cancer Genome Atlas (TCGA, n=1065) and the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC, n=1904) BC cohorts, as well as BC patients who underwent neoadjuvant chemotherapy (NAC; GSE25066, GSE20194, GSE32646 cohorts) were analyzed.
Results: By analyzing SCP1039 and SCP1106 single-cell sequencing cohorts, we found that epithelial cells were the predominant source of CD133 gene expression in the tumor microenvironment. High expression of CD133 in ER+/HER2- BC correlated with elevated gene expressions of the other CSC markers; CD24, NOTCH1, DLL1, and ALDH1A1 (all $p<0.001$), and significantly enriched WNT/β-Catenin, Hedgehog, and Notch signaling (all FDR<0.25), which are all known pathways related with CSC in TCGA and validated in METABRIC cohort. Consistent with CSC phenotype, CD133-high BC was negatively enriched with Hallmark cell proliferation-related gene sets, such as E2F Targets, G2M Checkpoint, MYC Targets V1, Ki67 gene expression and proliferation score (FDR<0.25 and $p<0.001$, respectively) in both cohorts. CD133-high BC was negatively associated with DNA repair genes, such as BRCA1, E2F7 in both cohorts (all $p<0.001$). In agreement, CD133-high BC was associated with less homologous recombination deficiency, lower silent and non-silent mutation rates. Surprisingly, CD133-high BC exhibited a proinflammatory microenvironment, as represented by higher cytolytic activity in the METABRIC and higher lymphocyte infiltrations, TGF-beta response, and TCR richness in TCGA (both $p<0.001$), but less Th1 cells, M1 macrophages and dendritic cell infiltrations consistently in both cohorts. It also enriched signaling pathways related to inflammation and immune responses such as inflammatory response, allograft rejection, TNF-alpha, IL-6, TGF-beta signaling, and complement signaling (all FDR<0.25). CD133-high tumors had better pathological complete response after NAC in GSE25066 cohort and improved Disease-Free Survival and Overall Survival in both TCGA and METABRIC cohorts (all $p<0.05$).
Conclusion: CD133-high ER+/HER2- BC is associated with CSC phenotype, reduced cell proliferation, and impaired DNA repair, but enhanced inflammation, potentially explaining the better response to NAC and favorable patient prognosis.

#2521 New predictive markers for dasatinib responsiveness in triple-negative breast cancer: A biomarker discovery study.

D. Ortega-Alvarez[1], D. Tebar[1], M. Casado[1], E. Castillo[1], C. Guardia[1], D. Olivares-Osuna[1], E. Musulen[1], E. Mereu[1], G. Luengo[2], E. M. Galan-Moya[3], **V. Rodilla**[1];

[1]Josep Carreras Leukaemia Research Institute, Badalona, Spain, [2]Instituto Murciano de Investigacion Biosanitaria (IMIB), Murcia, Spain, [3]Centro Regional de Investigaciones Biomedicas (CRIB), Albacete, Spain

Triple negative breast cancer is the most heterogeneous and aggressive type of breast tumor type and is characterized by the lack of expression of clinical biomarkers (ER, PR, and HER2) and targeted therapies. In this regard, different clinical trials have failed, unable to stratify these patients to find an effective response to specific therapy. This study aimed to identify biomarkers exclusively expressed in the basal mammary compartment that can help us to subclassify the triple-negative breast cancer subtype. Based on computational analysis from single-cell RNA sequencing data, we have identified a list of basal identity-associated genes (BC-markers). Subsequent histological validation confirmed the expression pattern of these markers in a cohort of 50 samples, which has allowed us to stratify triple-negative breast cancer patients into BC-TNBC and luminal-like subtypes. Importantly, the expression of these markers correlated with poorer prognosis in TNBC patients. Functional analysis revealed that *TAGLN* played a significant role in cell proliferation and migration, potentially impacting tumor aggressiveness. Moreover, the expression of these BC-markers is associated with a mesenchymal phenotype which corresponds to the previously described Lehmannn's mesenchymal-like signature. In this study, *TAGLN* appeared to influence dasatinib sensitivity, suggesting its potential as a predictive biomarker for dasatinib response in TNBC patients.

#2522 Predictive value of tumor mutational burden (TMB) in patients with metastatic microsatellite-stable (MSS) colorectal cancer (CRC) given first-line oxaliplatin-based chemotherapy and immune checkpoint blockade (ICB).

A. H. Ree[1], P. A. Bousquet[1], H. L. Nilsen[1], T. Luders[1], S. Wang[1], T. Visnovska[1], D. L. Bordin[1], E. Hoye[2], H. M. Hamre[1], C. Kersten[3], E. Hofsli[4], M. G. Guren[2], H. Sorbye[5], K. Flatmark[2], S. Meltzer[1];

[1]Akershus Univ. Hospital, Lorenskog, Norway, [2]Oslo Univ. Hospital, Oslo, Norway, [3]Sorlandet Hospital, Kristiansand, Norway, [4]St. Olav's Univ. Hospital, Trondheim, Norway, [5]Haukeland Univ. Hospital, Bergen, Norway

Purpose: Most CRC patients harbor primarily non-immunogenic MSS tumor. The randomized METIMMOX trial (NCT03388190) examined if patients with previously untreated, unresectable abdominal metastases from MSS-CRC may achieve therapeutic efficacy from short-course oxaliplatin-based chemotherapy (FLOX) and sequential ICB (nivolumab) repeatedly. Half of study patients assigned to this experimental treatment had significantly extended progression-free survival (PFS) while the other half had shortened PFS, compared to the control-group patients given standard FLOX chemotherapy with median PFS 9.3 months. Here we explored if somatic mutations (mut) unveiled by next-generation sequencing might provide insights into responsiveness to the METIMMOX regimen.

Procedures: Patients had MSS-CRC with infradiaphragmatic metastases deemed unresectable and were eligible for first-line oxaliplatin-based therapy. They were randomly assigned to the control group of FLOX (oxaliplatin, 5-fluorouracil, folinic acid) Q2W or the experimental group of alternating 2 cycles each of FLOX Q2W and nivolumab Q2W, with prespecified break periods. Radiologic response assessment was done every 8 weeks with PFS as the primary endpoint. Diagnostic tumor biopsies and baseline metastasis biopsies were sequenced with the TruSight Oncology 500 assay. TMB was calculated using only coding, non-synonymous single-nucleotide variants and insertions/deletions with variant allele frequency ≥5% and sequencing depth ≥50×, applying the effective panel size as the megabases (Mb) denominator.

Results: Sequencing data were acquired from 20 experimental-group patients with median PFS 7.9 months (minimum 2.0, maximum 41.6). Median TMB was 5.1 mut/Mb (minimum 0.8, maximum 11.8), concordant in patient-paired primary tumor and metastasis specimens. The TMB was associated with treatment outcome; the higher TMB, the better PFS with hazard ratio 0.83 (95% confidence interval (CI) 0.70-0.98; $p = 0.026$, Cox regression) for a PFS event with increasing TMB. TMB cut-off as low as 5.0 mut/Mb distinguished between patient groups ($p = 0.007$, log-rank test) with median PFS 34.9 months (95% CI 10.6-59.2; TMB>5, $n = 10$) and median PFS 4.6 months (95% CI 2.7-6.5; TMB≤5, $n = 10$). In the TMB>5 group, 8/10 were *KRAS*- or *BRAF*-mutant cases. In the TMB≤5 group, 9/10 metastasis specimens were *RAS*/*BRAF*-wildtype cases.

Conclusions: TMB >5 mut/Mb was associated with tumor *KRAS* or *BRAF* driver mutation and remarkably long PFS in first-line treatment of patients with abdominal metastases from MSS-CRC with alternating short-course oxaliplatin-based chemotherapy and ICB.

#2523 Predictive biomarkers for neoadjuvant FLOT4 chemotherapy response in gastroesophageal cancer: Results of multi-omics approach.

A. Al-Fahdi, S. Al Zadjali, I. Al Haddabi, A. Pullanhi, M. Al Jabri, A. Al Yayahee, N. Al Shuaili, N. Al Mahrouqi, M. Al Moundhri;
Sultan Qaboos Comprehensive Cancer Care & Research Centre, Muscat, Oman

Background: The FLOT4 chemotherapy regimen is a standard preoperative treatment for gastroesophageal junction (GEJ) and gastric cancer (GC), yet the response to this treatment is variable. Identification of predictive biomarkers is crucial for optimizing therapeutic strategies. This study aims to identify predictive biomarkers for FLOT4 treatment efficacy using a multi-omics approach.
Methods: We conducted a preliminary differential gene expression analysis in diagnostic tissue pre-treatment and surgical resection post-treatment in six patients (two GEJ and four GC) who all exhibited a partial pathological response (G2) to neoadjuvant FLOT4 chemotherapy. Utilizing DESeq2 for differential gene expression and David pathway analysis for functional insights, we have begun to unravel the complex molecular response to treatment. Upcoming assays include blood gDNA and tumor tissue whole exome sequencing (WES), comprehensive methylation profiling, miRNA characterization, and proteomics via LC-MSMS.
Results: Our preliminary data suggest alterations in gene expression associated with cell adhesion, extracellular matrix interaction, and immune response pathways. Three common genes (*CXCL2*, *CXCL3*, *CXCL1*) were identified among upregulated pathways in GEJ patients, while one common gene (*IL1A*) was observed in GC patients. These findings suggest a complex network of biological processes influenced by FLOT4. In-depth results, including whole-exome sequencing, methylation patterns, and miRNA profiles, will be completed and presented at the conference.
Conclusion: These initial findings propose that changes in gene expression related to cellular architecture and immune response are indicative of a partial response to FLOT4 in both GEJ and GC patients. The identified genes and pathways may serve as potential biomarkers for predicting treatment outcomes.
Future Directions: By the time of the conference, we anticipate including a more extensive patient cohort with complete response or no response to FLOT4, and comparative analyses with a FOLFOX treatment group. The integration of forthcoming WES, methylation, miRNA, and proteomics data will provide a more comprehensive molecular predictive model.
Keywords: FLOT4 chemotherapy, gastroesophageal junction cancer, gastric cancer, predictive biomarkers, differential gene expression.

#2524 Molecular and clinicopathologic landscape of HER2 positive breast cancer: A single institution study.

G. Ardor, Z. M. Coty-Fattal, L. Z. Blanco, Jr., K. Siziopikou;
Northwestern Memorial Hospital, Chicago, IL

Background: Human epidermal growth factor receptor 2 (HER2) is a transmembrane tyrosine kinase that is encoded by the *ERBB2* gene, located on chromosome 17. Expression levels of HER2 are a key pathogenic and treatment-associated factor in breast carcinomas, with HER2 expression reported as per the ASCO/CAP scoring guidelines. Outside the intense focus on the HER2 overexpression few studies currently exist that look at the comprehensive molecular profile of these aggressive tumors .

Design: Our institutional pathology database was searched for patients with breast carcinoma diagnosed between 2009 and 2013 and with HER2 scored as 3+ based on immunohistochemistry, or HER2 2+ with confirmatory positive FISH results. Comprehensive next-generation sequencing (NGS) was performed using the Illumina TruSight Oncology 523 gene panel, and clinicopathologic data were gathered from the institutional electronic health record system. A CoMutation plot was made using the CoMut python library.

Results: The mean age of the patients at time of diagnosis was 56.1±12.7 years. The tumors were overwhelmingly high-grade, with 26/30 being grade 3 and the remaining 4/30 being grade 2 and a mean size of 2.6 cm. All were histologically invasive ductal carcinoma, and 26/30 were scored as HER2 3+ on IHC while 4/30 were HER2 2+ with positive FISH. ER was positive in 30% of cases (9/30), PR was positive in 23.3% (7/30), p53 was positive by IHC in 53.3% (16/30), and the mean Ki-67 proliferative index was 47.1%. 20 of the 30 (66%) cases meeting the inclusion criteria had pathogenic mutations detected by NGS testing. Several distinct molecular subgroups were seen on the CoMutation plot (figure 1). The mean tumor mutational burden (TMB) was 14.1 mutations per megabase. A significant subset of the tumors 70% (14/20) showed *TP53* mutations, and 30% (6/20) show PIK3CA mutations. Of interest, only 1/14 tumors showed a co-occurring homologous recombination repair gene mutation and one tumor (1/20) showed mutations in 2 homologous recombination pathway genes (*FANCA* and *BRCA1*) as well as numerous additional mutations (tumor mutational burden of 65.3 mutations per megabase).

Conclusion: Overall the mean TMB was 14.1 mutations/megabase in this HER2-positive breast cancer study set. Over 2/3 of our HER2-positive breast cancer cases also had *TP53* mutations. In addition, 1/3 had PIK3CA mutations, suggesting that a subset of HER2-positive carcinomas also harbor other potentially actionable mutations which may increase the effectiveness of our existing interventions. Additional studies are needed to further subclassify genetically distinct subsets of HER2-positive breast cancers and to further understand clinical, pathologic and treatment-related differences in this aggressive breast cancer subset.

#2525 A novel splicing factor, SPF45/RBM17, might influence 5-FU resistance of gastric carcinoma.

K. Maruo, M. Yashiro, T. Sakuma, G. Tsujio, y. Fukui, H. Kasashima, K. Maeda;
Koji Maruo (Individual), Osaka, Japan

Background: SPF45/RBM17 was identified as a factor required for splicing of short introns in mRNA precursors transcribed from DNA. SPF45 is also thought to be related to anti-cancer drug resistance, suggesting that the SPF45 molecule has a different resistance mechanism from the conventional mechanism of anticancer drug resistance. In this study, we investigated the relationship between SPF45 expression and anticancer drug sensitivity in gastric cancer.
Materials and Methods: A total of 654 gastric cancer cases were used in this study. SPF45 expression was examined using immunohistochemistry. The correlation between SPF45 expression and clinicopathological factors was evaluated.
Results: Of the 654 gastric cancer cases, 240 were positive for SPF45 expression and 414 were negative for expression. There was no significant difference in age and gender between the two groups, but SPF45-positive cases were significantly more frequent in patients with undifferentiation ($p = 0.004$), lymphatic invasion ($p = 0.013$) and venous invasion ($p < 0.001$). As for anticancer drug therapy, 215 of the 654 patients with gastric cancer who underwent radical surgery were treated with adjuvant chemotherapy and 94 patients with advanced recurrent gastric cancer were treated with chemotherapy. 75 SPF45-positive-patients who received 5FU-based adjuvant chemotherapy (S-1, UFT, 5-DFUR) after surgery had significantly worse recurrence-free survival (RFS) than 140 SPF45-negative-patients ($p=0.027$). 102 SPF45-positive-patients who didn't receive adjuvant chemotherapy was no significantly different in RFS from 203 SPF45-negative-patients. In the 215 patients who received adjuvant chemotherapy, 81 DPD-positive patients had significantly worse RFS than DPD-negative patients ($p=0.043$). In the 305 patients who didn't receive adjuvant chemotherapy, there was no significant difference in RFS between DPD-positive patients and DPD-negative patients ($p=0.880$). SPF45-positive cases were significantly more frequent in patients with DPD expression ($p < 0.001$).In 94 patients with advanced recurrent gastric cancer treated with chemotherapy, there were 42 recurrent patients and 52 stage IV patients. 50 of SPF45-positive patients had significantly worse progression-free survival than 44 of SPF45-negative patients ($p < 0.001$). Regarding overall response, SPF45-positive-patients had worse response rate than SPF45-negative-patients ($p=0.016$). In SPF45 positive group, 20.0% responded (CR in 0% and PR in 20%) and 80.0% did not respond (SD in 52% and PD in 28%). In SPF45 negative group, 42.6% responded (CR in 0% and PR in 42.6%) and 57.4% did not respond (SD in 46.8% and PD in 10.6%)
Conclusion: Our results suggest that the splicing factor SPF45 influences anticancer drugs such as 5-FU resistance in gastric cancer.
Acknowledgments: We thank Kazuhiro Fukumura and Akila Mayeda, Fujita Health University.

#2526 Exploratory study of predicting systemic therapy response by IGRA in advanced stage NSCLC patients.

H. Huang[1], C.-L. Chiang[1], Y.-H. Luo[1], Y.-M. Chen[1], C.-H. Chiu[2];

[1]Taipei Veterans General Hospital, Taipei, Taiwan, [2]Taipei Medical University Hospital, Taipei, Taiwan

Purpose: In this study, we aim to prospectively evaluate how patients' pretreatment PSIG correlated with chemotherapy, immune checkpoint inhibitors (ICI) and epidermal growth factor receptor (EGFR) Tyrosine Kinasae Inhibior (TKI) . Also, to assess the change of PSIG during anti-cancer treatment and the relation with clinical condition.

Materials and Methods: Newly diagnosed advanced stage non-small cell lung cancer patients were enrolled. The inclusion criteria included pathology or cytology-proved stage IV and non-operable stage III non-small cell lung cancer, treatment-naïve, and planned to receive chemotherapy, EGFR-TKI therapy. Or, planned to receive any line of singe agent immunotherapy. We planned to enroll 30 patients in each treatment group (chemotherapy, immunotherapy, EGFR TKI therapy) with and additional control group of stage I NSCLC.Blood sample from each enrolled patient was obtained for INF-γ release assay (IGRA) within 3 days before the initiation of systemic therapy and 8-12 weeks after treatment. The IGRA was performed with QuantiFERON-TB In-Tube (QFT-GIT; Qiagen, Germany) according to the manufacture's instruction. The amount of INF-γ produced in response to PHA is determined by the INF-γ level in the PHA-coated tube minus saline-coated tube, and is termed PHA-stimulated INF-γ (PSIG) level. Patients with PSIG level above 7.06IU were defined had high PSIG level according to our previous study. we also performed our in house INF-γ level by ELISA. Tumor response was assessed mainly by chest CT and brain MRI (if available) according to Response Evaluation Criteria in Solid Tumors (RECST) .

Results: Total 116 patients were enrolled. Demographic distribution was summarized in Table 1. Thirty-five of 116 (30.2%) patients had latent TB infection, while 12 patients (10.3%) had indeterminate OFT test, all due to low mitogen-stimulated INF-γ level. 84 patients had been obtained post-treatment blood test, and the box-plot of in-house INF-γ level were shown in Figure1. For stage I control group, INF-γ level seemed higher after surgery; for chemotherapy and immunotherapy, the INF-γ level also seemed increase among responders (who achieved disease control after treatment). There were no statistically difference of disease control rate between patients with high PSIG level and low PSIG level. Overall survival also showed no statistically difference between 2 PSIV level patient group among advanced stage NSCLC patients.

Conclusions: There were no statistically different of disease control rate in PSIG high and low group. The increased trend of INF-γ level after surgery, immunotherapy and chemotherapy may suggested improving immune function after treatment even in the very early disease stage.

#2527 PD-L1 regulation by Dual Oxygenase 2 (DUOX2), a reactive oxygen species (ROS) producing enzyme in gastric cancers.

F. Carrier, **M. B. Martins**;
Univ. of Maryland Marlene & Stewart Greenebaum Cancer Ctr., Baltimore, MD

Immune checkpoint inhibitors have shown outstanding activities in some cancers, but their efficacy is rather variable with limited long-term response in most patients while others do not respond well or even develop resistances. The oxidative state of the tumor and its microenvironment plays a critical role in this response and highlights the importance of better understanding the role of redox enzymes in response to immunotherapy. In fact, Reactive Oxygen Species (ROS) effectors can either up or down regulate PD-L1 expression depending on their targets and mechanisms of action. Our data indicate that DUOX2, an NADPH enzyme involved in the production of H_2O_2, is expressed in about forty percent of human gastric cancers and is significantly increased in esophageal cancers. Moreover, DUOX2 expression in human gastric and esophageal cancer cells corresponds to down regulation of the immune checkpoint PD-L1. Conversely, down regulation of DUOX2 increases PD-L1, HIF-1α and c-Myc expression in these cells. To better understand the role of DUOX2 in the production of ROS and how it interferes with the expressions of HIF-1α and PD-L1, we also evaluated its effects on the ROS scavenger glutathione (GSH) and the ROS generating Ceramide in cells expressing or not DUOX2. The down regulation of DUOX2 reduced by more than half Ceramide levels and significantly increased GSH levels. This is consistent with the known effect of H_2O_2 on Ceramide generation through sphingomyelin hydrolysis and H_2O_2 inhibitory effect on HIF-1α binding and accumulation of HIF-1α protein. Because HIF-1α is a known regulator of PD-L1, DUOX2 expression on some tumors could thus interfere with PD-L1 expression through generation of H_2O_2. Moreover, because HIF-1α and PD-L1 expression contribute to radio-resistance, DUOX2 expression could sensitize cancer cells to radiation therapy. On the other hand, tumors lacking DUOX2 expression would be expected to be more sensitive to immunotherapy targeting PD-1 and/or PD-L1. DUOX2 expression thus appears to hold significant potential as a valuable biomarker to guide therapeutic decisions regarding radiation or immuno-therapy.

#2528 Genomic and immune microenvironment features influencing chemoimmunotherapy response in gastric cancer with peritoneal metastasis: A retrospective cohort study.

Pengfei Yu[1], Guangyu Ding[1], Xingmao Huang[1], Chenxuan Wang[2], Jingquan Fang[1], Ling Huang[1], Zeyao Ye[1], Qi Xu[3], Xiaoying Wu[2], Junrong Yan[2], Qiuxiang Ou[2], **Haimeng Tang**[2], Yian Du[1], Xiangdong Cheng[1]

[1]Department of Gastric Surgery, Zhejiang Cancer Hospital, Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, Hangzhou, China,[2]Nanjing Geneseeq Technology Inc, Nanjing, China,[3]Department of Medical Oncology, Zhejiang Cancer Hospital, Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, Hangzhou, China

Background: Patients with peritoneal metastasis (PM) from gastric cancer (GC) exhibit poor prognosis. Chemoimmunotherapy offers promising clinical benefits; however, its efficacy and predictive biomarkers in a conversion therapy setting remain unclear. We aimed to retrospectively evaluate chemoimmunotherapy efficacy in a conversion therapy setting for GC patients with PM and establish a prediction model for assessing clinical benefits.

Methods: A retrospective evaluation of clinical outcomes encompassed 55 GC patients with PM who underwent chemoimmunotherapy in a conversion therapy setting. Baseline PM specimens were collected for genomic and transcriptomic profiling. Clinicopathological factors, gene signatures, and tumor immune microenvironment were evaluated to identify predictive markers and develop a prediction model.

Results: Chemoimmunotherapy achieved a 41.8% objective response rate and 72.4% R0 resection rate in GC patients with PM. Patients with conversion surgery showed better overall survival (OS) than those without the surgery (median OS: not reached vs 7.82m, P<0.0001). Responders to chemoimmunotherapy showed higher *ERBB2* and *ERBB3* mutation frequencies, *CTLA4* and *HLA-DQB1* expression, and CD8+ T cell infiltration, but lower *CDH1* mutation and naïve CD4+ T cell infiltration, compared to non-responders. A prediction model was established integrating CDH1 and ERBB3 mutations, HLA-DQB1 expression, and naïve CD4+ T cell infiltration (AUC=0.918, 95%CI: 0.846-0.991), which were validated using an independent external cohort (AUC=0.785, 95%CI: 0.637-0.933).

Conclusion: Our study comprehensively evaluated clinicopathological, genomic, and immune features and developed a novel prediction model, providing a rational basis for the selection of GC patients with PM for chemoimmunotherapy-involved conversion therapy.

#2529 Comparison of small cell lung cancer transcriptional factor expression by immunohistochemistry, multiplex immunofluorescence, and a targeted RNA expression panel.

H. Ozakinci, A. Alontaga, J. Nguyen, C. Moran Segura, D. Saeed-Vafa, J. Gray, E. Haura, A. Chiappori, T. Boyle;
Moffitt Cancer Center, Tampa, FL

Recent studies have identified distinct molecular subtypes of small cell lung cancer (SCLC) (SCLC-A, SCLC-N, SCLC-P, and SCLC-Y) based on ASCL1, NEUROD1, POU2F3, and YAP1 expression. In this study, we investigated the correlation between immunohistochemistry (IHC), multiplex immunofluorescence (mIF), and RNA Salah Targeted Expression Panel (RNA STEP) for ASCL1, NEUROD1, POU2F3, and YAP1 in formalin-fixed-paraffin-embedded (FFPE) samples from 14 SCLC samples collected under an IRB-approved protocol (MCC19163). For the mIF evaluation, FFPE samples were immunostained using the AKOYA Biosciences OPAL TM 7-Color Automation IHC kit on the BOND RX autostainer. For RNA STEP, nanoString nCounter TagSet chemistry was used to measure gene expression levels of test FFPE samples relative to a reference pooled human normal mRNA control. All three methods demonstrated significant correlation for ASCL1 levels (Table 1). IHC and RNA STEP NEUROD1 results exhibited significant correlation. However, mIF NEUROD1 results did not correlate with the results of other methods likely due to non-specific positivity of the NEUROD1 mIF antibody. No strong correlation was observed between any of the methods for POU2F3 and YAP1. Only 2 of the 14 samples displayed positive POU2F3 protein expression by IHC; one of these also had elevated POU2F3 expression by RNA STEP. Importantly, the sample with the highest POU2F3 protein expression by IHC also had the highest values by mIF and RNA STEP. All samples were negative for YAP1 by IHC and RNA STEP. Notably, ASCL1 staining was primarily observed in CD56+ POU2F3- cells by mIF. These findings highlight the reliability and utility of IHC and RNA STEP in assessing transcriptional factors in SCLC. Also, mIF presents an innovative method for the simultaneous analysis of multiple markers using a single tissue section, enabling the concurrent detection of multiple markers within individual cells.

Table 1. Statistical Significance (p-values) and Correlation Analysis (Spearman's Coefficients)

	IHC vs RNA STEP		***IHC vs mIF***		***RNA STEP vs mIF***	
	p	**r**	**p**	**r**	**p**	**r**
ASCL1	0.021	0.62	<0.0001	0.91	0.010	0.67
NEUROD1	0.002	0.78	0.517	-0.14	0.671	0.12
POU2F3	0.201	0.36	0.422	0.18	0.045	0.55
YAP1	0.299	0.30	0.364	0.20	0.295	0.30

#2530 Advancing ICK assay: Real-time, label-free imaging of lymphocyte subsets.

S. Oh[1], J. Do[1], H.-S. Min[1], D. Ryu[1], W. Park[2];

[1]Tomocube, Inc., Daejeon, Korea, Republic of, [2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

Background: Immune Cell Killing (ICK) Assay is pivotal in immunology and clinical research, uncovering the intricate connections between the immune system and diseases. Traditional ICK assays utilizing antibody staining for endpoint data generation pose challenges in capturing dynamic interactions. Moreover, antibody labeling for data quantification may compromise sensitivity, especially with low-affinity antibodies or a limited number of cells. The anticipation of label-free lymphocyte subset classification and real-time effector/target cell interaction analysis in one field of view is expected to provide more valuable insights than traditional ICK assays. Previous studies achieved 70-80% accuracy in image-based lymphocyte subset classification using digital holographic microscopy, light scattering, etc. but the cells' condition during the cell sorting or sample preparation process may affect the lymphocyte subset status, resulting in real morphological discrepancies. Our approach focuses on directly sorting human PBMCs to enable label-free, dynamic interaction analysis of natural immune system responses in one field of view.

Method: In this study, PBMC samples from 6 individuals were separated using standard-density gradient centrifugation and labeled with antibodies. Data were acquired using the Holotomographic Microscope HT-X1 (Tomocube Inc.). We employed Densenet 121 as the deep learning model architecture, considering the trade-off between memory consumption and performance. The cross-entropy loss function was utilized, and the AdamW optimizer was chosen for model parameter optimization. Input data consisted of 3D refractive index (RI) data for individual cells, each of sized (20, 54, 54). Individual cell labeling was performed using staining information.

Results: An overall accuracy of 93.75% in Human PBMC subtype cell classification was achieved. In stage 1, an accuracy of 97.56% was demonstrated in classifying [CD14, CD15, Others]. Among the cells classified as "Others" in stage 2, [CD3, CD19, CD16&CD56] displayed an accuracy of 93.5%. In stage 3, classifying [CD4, CD8] within the CD3 subtype achieved an accuracy of 90.2%. This classification is presumably based on pattern recognition of the chromosomal landscape in holotomography images.

Conclusion: Our research has successfully demonstrated the feasibility of real-time label-free lymphocyte subset classification. This approach enabled the classification of effector cells as live cells in ICK assay and the analysis of effector-target cell dynamic interactions. Further training in the classification of more detailed subtype cells and various cell death types will provide additional insights. The advancement of this technology is expected to play a pivotal role in disease prevention, treatment, vaccine development, medical research, and academic studies.

#2531 rs822336 as a predictive biomarker for anti-PD-1/PD-L1 immunotherapy in advanced NSCLC: Unraveling molecular mechanisms.

G. Polcaro[1], L. Liguori[2], V. Manzo[3], A. Chianese[4], G. Donadio[1], A. Caputo[1], G. Scognamiglio[5], F. Dell'Annunziata[4], M. Langella[3], G. Corbi[6], A. Ottaiano[5], M. Cascella[5], F. Perri[5], M. De Marco[1], J. Dal Col[1], V. Pagliara[1], P. Zeppa[1], A. Filippelli[1], G. Franci[1], F. Dal Piaz[1], V. Conti[1], S. Pepe[1], **F. Sabbatino**[1]; [1]University of Salerno, Baronissi, Italy, [2]University of Naples "Federico II", Napoli, Italy, [3]University Hospital "San Giovanni di Dio e Ruggi d'Aragona", Salerno, Italy, [4]University of Campania "Luigi Vanvitelli", Naples, Italy, [5]Istituto Nazionale Tumori di Napoli, IRCCS "G. Pascale", Naples, Italy, [6]University of Naples "Federico II", Naples, Italy

Efficient predictive biomarkers are needed for immune checkpoint inhibitor (ICI)-based immunotherapy in non-small-cell lung cancer (NSCLC). So far, testing the predictive value of single nucleotide polymorphisms (SNPs) in programmed cell death 1 (PD-1) or its ligand 1 (PD-L1) has shown contrasting results. Here, we aimed to validate the predictive value of PD-L1 SNPs in advanced NSCLC patients treated with ICIs as well as to define the molecular mechanisms underlying the role of identified SNP candidate. rs822336 SNP efficiently predicted response to anti-PD-1/PD-L1-based immunotherapy in advanced NSCLC patients as compared to rs2282055 and rs4143815 SNPs. rs822336 SNP mapped on promoter/enhancer region of PD-L1, differentially affecting the induction of PD-L1 expression in human NSCLC cell lines. The induction of PD-L1 expression by rs822336 SNP was predicted by allele-specificity binding of two identified transcription factors: C/EBPβ and NFIC. As a result, silencing of C/EBPβ and NFIC differentially modulated the induction of PD-L1 expression in human NSCLC cell lines carrying different rs822336 genotypes. In addition, binding microarray validated the allele- specificity binding of C/EBPβ and NFIC to PD-L1 promoter/enhancer region based on rs822336 genotype in human NSCLC cell lines. Lastly, the induction of PD-L1 expression by rs822336 genotype differentially affected the susceptibility to anti-PD-1 monoclonal antibody nivolumab of human NSCLC cell lines co-cultured with HLA class I antigen matched PBMC. These results have clinical relevance since identified rs822336 SNP and the induction of PD-L1 expression as novel biomarkers for predicting ICI-based immunotherapy in NSCLC patients.

#2532 Deciphering multiple protein complexes in BCL2 family to measure apoptotic dependencies in acute myeloid leukemia.

Hongwon Lee[1], Changju Chun[2], Byungsan Choi[1], Saem Hong[1], Yunseo Lee[1], Youngil Koh[3], Tae-Young Yoon[2]

[1]PROTEINA Co., Ltd, Seoul, Korea, Republic of,[2]School of Biological Sciences and Institute for Molecular Biology and Genetics, Seoul National University, Seoul, Korea, Republic of,[3]Department of Internal Medicine, Seoul National University College of Medicine, Seoul National University Hospital, Seoul, Korea, Republic of

The BCL2 protein family controls apoptosis by shifting the dynamic equilibrium state of complex formation. BH3 mimetics disrupt this balance by disturbing the interaction of a specific anti-apoptotic protein, leading to the initiation of apoptosis. However, relying solely on molecular data for the specific anti-apoptotic protein can be challenging due to the functional redundancy within the BCL2 protein family and their complex interaction network. Therefore, comprehensive profiling information considering protein complexes is essential to determine apoptotic dependencies, particularly in a clinical context. In this study, we adapted a Single-molecule Protein Interaction Detection (SPID) platform that can assess levels of protein complexes in a quantitative manner. Out of the 47 metrics included in our Apoptosis Signaling 47 panel, we utilized 22 assays to measure apoptosis dependencies in acute myeloid leukemia (AML) cells obtained from 32 patients. By combining these metrics, we developed a predictive model for the ex vivo response to ABT-199 treatment, focusing on three key biomarkers: BCL2-BAX complex, BCL2-BIM binding potential, and BCLxl-BAK level. From a receiver operating curve (ROC) analysis, the model exhibited high accuracy with a value of 0.94 area under the curve (AUC). We further validated our model by comparing the predicted response to the therapeutic outcomes in 10 AML patients according to the 2017 ELN guidelines, and achieved 100% sensitivity (4 out of 4 identified correctly) and 83.3% specificity (5 out of 6 identified correctly). Overall, our platform provides an effective method to explore apoptosis dependencies in clinical samples based on the information regarding protein complexes within the BCL2 protein family. Three key molecular biomarkers can be translated into a gauge for predicting therapeutic outcomes of BH3 mimetics, suggesting an improvement of precision medicine in AML treatment.

#2533 In-depth multi-omic profiling of immune cells in cancer patients developing immune-related adverse events.

D. Shek[1], B. Gao[2], J. Lai[3], B. Gloss[3], A. Nagrial[4], I. Pires da Silva[5], M. S. Carlino[2], S. A. Read[3], G. Ahlenstiel[1];

[1]Western Sydney University, Sydney, Australia, [2]Blacktown Hospital, Sydney, Australia, [3]Westmead Institute for Medical Research, Sydney, Australia, [4]Westmead Hospital, Sydney, Australia, [5]Melanoma Institute Australia, Sydney, Australia

Background: The clinical efficacy of immune-checkpoint inhibitors is complicated by the risk for immune-related adverse events (irAEs) that can involve any organ systems. To date, (1) we cannot predict irAE risk reliably at patient level and (2) irAEs remain a diagnosis of exclusion as there are no specific clinical or biological markers. The goal of this study was to elucidate intricate transcriptomic and proteomic signatures of immune cells in patients evolving irAEs.

Methods: This pilot trial was conducted as part of a prospective multicenter cohort study (NCT04631731). The study cohort consisted of n=71 patients who were treated with ICIs across Blacktown and Westmead Hospitals, NSW, Australia. Peripheral blood mononuclear cells (PBMCs) were collected from both pre-treatment and after 6-8 weeks post-ICI commencement. Samples were further utilized for RNA sequencing, flow cytometry and Chromium 3' gene expression analysis (10x Genomics).

Results: The median age was 67 years old with the 78% (n=56) of Caucasian origin. The predominant number of patients were treated with dual ICIs. N=21 patients experienced irAEs. Firstly, a differential analysis established a set of genes which were significantly (FDR<0.01) dysregulated between patients with (group A) and without irAEs (group B) and were mostly related to cell cycle and regulation. Notably, phospholipase D signaling pathway was exclusively upregulated in group A and is known to be linked to B cell expansion. Secondly, a cell enrichment analysis within the group A revealed a significant increase of CD4+ and CD8+ T central memory (Tcm) cells upon the toxicity onset as compared to baseline stage. Thirdly, the flow cytometry data established that group A had (1) higher expression of CD27 on CD4+ T cells, a member of Traf-linked tumor necrosis factor receptor family essential for T cells' maturation and (2) lower expression of inhibitory receptor LAG3 (CD223) which is crucial for maintaining homeostasis of immune system through suppression of T cell proliferation. Finally, we sequenced CD45+ cells from n=4 patients from group A and n=4 from group B at both pre- and post-treatment stages. The unsupervised clustering established 17 different clusters in our single cell dataset with cluster 11 was unique only to patients from group A. The differential analysis established that a set of n=62 genes was significantly upregulated ($p<0.05$) in cluster 11. Functional annotation established that B cell activation and proliferation pathways were enriched by those genes further stressing B cells' role in irAEs development.

Conclusions: Our real-world cohort study established significant molecular and cellular differences between patients with and without irAEs. Further research in larger cohorts is imperative to validate the established findings and to elucidate the precise mechanisms contributing to the development of irAEs.

#2534 Single-cell dissection of heterogeneity and dynamics of tumor ecosystem upon immune-checkpoint blockade in hepatocellular carcinoma.

A. S. Cheng[1], Z. Xiong[1], H. Wu[1], J. Cao[1], Z. Liang[1], J. Zhou[1], J.-Y. Sung[2], K. Yip[3], S. Chan[1];

[1]Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong, [2]Nanyang Technological University, Singapore, Singapore, [3]Burnham Prebys Medical Discovery Institute, La Jolla, CA

Background: Therapy-induced alteration of tumor ecosystem poses a major barrier for cancer regression. As the majority of patients with hepatocellular carcinoma (HCC) develops resistance to immune checkpoint blockade (ICB) therapy, we aimed to characterize heterogeneity and dynamics of multicellular tumor ecosystem following anti-PD-1 treatment using scRNA-seq.

Methods: In a phase II clinical trial of pembrolizumab on advanced hepatitis B virus-related HCC patients (NCT03419481), we performed a comprehensive single-cell transcriptomic profiling of biopsy samples from 26 patients before and during treatment. The composition and distribution of immune aggregates in responsive tumors was characterized by scRNA-seq and spatial transcriptome analyses. The anti-tumor efficacy of combined therapy with anti-PD-1 and inhibition of immunosuppressive macrophage were further determined in RIL-175-derived PD-1-resistant mouse model.

Results: After initial data processing and quality control, we obtained 353,329 high-quality cells that included tumor cells, myeloid cells, lymphoid cells, endothelial cells and fibroblasts. Our analysis revealed that baseline tumor-reactive $CD8^{+}$T cells exhibited a strong association with improved prognosis. Notably, treatment-induced expansion and differentiation of tumor-reactive $CD8^{+}$T cells with memory-like phenotype highly correlated with durable ICB response. Moreover, we observed a co-occurrence pattern of key anti-tumor immune subsets in the tumor microenvironment (TME), which associated with ligand-receptor pair interactions. Spatial transcriptome analysis further validated the presence of immune aggregates in responsive tumors. Importantly, we derived an responsive signature from immune aggregates, which showed a strong association with improved prognosis in pan-cancer ICB datasets. Paired comparisons of pre- and on-treatment macrophage percentages in non-responders revealed a specific expansion of an immunosuppressive macrophage subset. Inhibition of this macrophage subset could overcome ICB resistance by enhancing T cell function in our PD-1 resistant model. We further observed that a tumorous epithelial-mesenchymal transition (EMT) program might contribute to therapeutic resistance via TME remodeling.

Conclusions: Our study suggests that tumor-reactive $CD8^{+}$T cells and immune aggregates may be associated with durable ICB response, while ICB-induced upregulation of immunosuppressive macrophages and EMT^{hi} tumor cells contributed to therapeutic evasion. These findings provide valuable insights for identification of predictive biomarkers and therapeutic strategies for ICB therapy of HCC. This project is supported by the General Research Fund (14119023, 14120621 and 14115820), the Li Ka Shing Foundation, and the CUHK Strategic Seed Funding for Collaborative Research Scheme.

#2535 Development of Claudin 18.2 IHC 14G11 pharmDx as a clinical trial assay for the clinical development of anti-claudin 18.2 monoclonal antibody osemitamab (TST001) in gastric and gastroesophageal junction adenocarcinoma.

H. Alderson[1], K. Lefley[1], L. Fregoso[1], A. Bharadwaj[1], D. Castellanos-McKenney[1], S. Tabuena-Frolli[1], D. Kell[1], X. Yao[2], X. Qian[2], L. Xu[3], C. Germa[3], E. Oroudjev[1];

[1]Agilent Technologies, Inc., Santa Clara, CA, [2]Suzhou Transcenta Therapeutics Co., Limited, Suzhou, China, [3]Transcenta Therapeutics Inc., Princeton, NJ

Clone 14G11 is a mouse anti-Claudin 18.2 monoclonal antibody developed by Transcenta. The antibody was generated against a linear epitope located on the extracellular domain of loop1 and has a binding site that overlaps with the binding site of therapeutic antibody Osemitamab. It was selected to further develop for the detection of Claudin 18.2 expression in human cancer. Agilent Technologies, Inc. is developing Claudin 18.2 IHC 14G11 pharmDx as an immunohistochemical (IHC) assay for the detection of Claudin 18.2 protein in gastric and gastroesophageal junction (GEJ) adenocarcinoma in support of clinical studies conducted by Transcenta Therapeutics. Analytical verification for Claudin 18.2 IHC 14G11 pharmDx included sensitivity, specificity, and precision assessment. Testing was performed on human formalin-fixed, paraffin-embedded (FFPE) gastric and GEJ tissues using Autostainer Link 48 with EnVision FLEX visualization system. Biomarker expression was evaluated using Tumor Proportion Score (TPS). TPS is defined as the percentage of viable invasive tumor cells that exhibit convincing partial or complete membrane staining at any intensity. Sensitivity testing of 102 commercially procured FFPE gastric/GEJ specimens demonstrated a broad dynamic range of Claudin 18.2 positivity that covered TPS from 0% to 100%. Specificity tests confirmed specific targeting of the Claudin 18.2 protein in a variety of normal and abnormal tissues. For laboratory precision testing, which evaluated the assay variability in relation to run, instrument, operator, and reagent lot, ≥ 95% of TPS values were within expected variability limits for each parameter. For observer precision testing, two-sided 95% confidence intervals were ≥ 85% for negative, positive, and overall agreements when assessing two clinical cutoffs. These results demonstrated the Claudin 18.2 IHC 14G11 pharmDx assay can provide reliable and reproducible results in day-to-day testing. Analytical verification testing indicates Claudin 18.2 IHC 14G11 pharmDx is a sensitive, specific, and precise assay for detecting Claudin 18.2 in gastric and GEJ adenocarcinoma. Claudin 18.2 IHC 14G11 pharmDx for Investigational Use Only/for Performance Evaluation Only will be used for patient selection in the upcoming phase III trial of gastric/GEJ adenocarcinoma where applicable ethics committee and regulatory approvals have been granted.

#2536 Multimodal stratification of predictive biomarkers in head and neck cancers: A focus on cytokine-based immunotherapy.

C. Ramos, R. Ruez, S. Delebecq, V. Senechal;
Aliri, Lille, France

Background Immunotherapy, particularly cytokine-based therapy, has been gaining traction in the treatment of head and neck cancers. Cytokines are small proteins that play a crucial role in the immune response to cancer. However, not all patients respond to cytokine-based immunotherapies, and some may experience severe side effects. The ability to predict which patients are most likely to benefit from these therapies could greatly improve the efficacy and tolerability of treatment. In this context, the study of predictive biomarkers, such as the expression of immune checkpoint molecules like PD-L1 and TIGIT, and the profiling of cytokines within the tumor microenvironment, has become crucial. These biomarkers could provide valuable information about the patient's immune response to the tumor and their likelihood of responding to cytokine-based immunotherapies.
Method A multimodal approach to stratify predictive biomarkers in head and neck cancers was used. The methodology was founded on combining metabolic, transcriptomic, and proteomic data to offer a comprehensive understanding of potential biomarkers. The data from different modalities were integrated using bioinformatics and machine learning algorithms. This comprehensive dataset was analyzed to identify multimodal biomarker signatures that could predict patient responses to cytokine-based therapies.
Result Preliminary finding showed significant heterogeneity in the expression of PD-L1, TIGIT, and various cytokines across the tumor microenvironment. This underscored the complexity of head and neck cancers. Certain multimodal biomarker signatures, which included specific patterns of immune checkpoint molecule expression, cytokine profiles, and immune cell infiltration, correlated robustly with patient responses to cytokine-based therapies.
Conclusion Our study demonstrates the considerable potential of a multimodal stratification approach in deciphering the complexity of head and neck cancers and predicting responses to cytokine-based immunotherapies. By integrating metabolomic, transcriptomic, and proteomic data, we identified unique biomarker signatures that strongly correlated with therapy responses. This work underscores the invaluable role of integrated predictive biomarker profiles in enhancing the precision of immunotherapy.

CLINICAL RESEARCH: Real-World Biomarkers
Poster Session

#2541 The landscape of circular extrachromosomal amplification in pediatric cancers.

S. Sridhar[1], **O. S. Chapman**[2], S. Wang[3], A. Dutta[3], J. P. Mesirov[3], L. Chavez[2];
[1]Rady Childrens Hospital San Diego, San Diego, CA, [2]Sanford Burnham Prebys Medical Discovery Institute, San Diego, CA, [3]University of California San Diego, San Diego, CA

Circular extrachromosomal DNA (ecDNA, also known as double minutes, dm) has emerged as a driver of oncogenic copy number amplification, intratumoral heterogeneity, tumor evolution and therapy resistance. We recently screened the whole genomes of 481 medulloblatomas for ecDNA and concluded that medulloblastoma tumors harboring ecDNA are more than twice as likely to progress within 5 years of diagnosis. To evaluate the frequency and clincical impact of ecDNA across the spectrum of childhood cancers, we performed a retrospective analysis of 1671 tumors from 1482 patients across 47 pediatric tumor types from two large cloud pediatric cancer genomics resources, the Children's Brain Tumor Network and St. Jude Cloud. ecDNA was detected in 15 pediatric tumor types, including ETMR (100%, n=4), osteosarcoma (47%, n=57), rhabdomyosarcoma (40%, n=35), neuroblastoma (30%, n=106), high-grade glioma (20%, n=157), and retinoblastoma (19%, n=32). Patients with tumors containing ecDNA had significantly poorer 5-year overall survival. In sequential samples from the same tumor at diagnosis and relapse, we observe evidence of ecDNA evolution including sequence instability and generation of new high-copy ecDNA amplification not detected at initial diagnosis. These results comprise the most detailed survey to date of the landscape of extrachromosomal amplifications across childhood cancers.

#2542 Real-world validation of the PurIST classifier demonstrates enhanced therapy selection for pancreatic ductal adenocarcinoma (PDAC) patients.

S. Wenric[1], J. M. Davison[2], J. Guittar[1], G. M. Mayhew[2], K. Beebe[2], A. Zander[1], S. Hyun[1], K. Beauchamp[1], M. V. Milburn[2], V. Chung[3], T. S. Bekaii-Saab[4], C. M. Perou[5];

[1]Tempus Labs, Chicago, IL, [2]GeneCentric Therapeutics, Durham, NC, [3]City of Hope, Duarte, CA, [4]Mayo Clinic, Phoenix, AZ, [5]University of North Carolina, Chapel Hill, NC

Background: PDAC is a particularly fatal condition lacking established biomarkers for the choice of first-line treatment (1L). The PurIST algorithm is a gene signature (Rashid et al. Clin. Cancer Res., 2020) that categorizes PDAC tumors into basal or classical molecular subtypes and has been previously validated in a patient cohort of advanced PDAC (N=258). In this post-hoc analysis study, we examine whether the PurIST subtypes can distinguish patients likely to respond to FOLFIRINOX (FFX) versus Gemcitabine + nab-paclitaxel (GnP).

Methods: A cohort of de-identified PDAC patients was selected from the Tempus Oncology Database following an IRB-approved protocol. Inclusion criteria required no prior systemic treatment, a surgically unresectable/metastatic status, available RNA-sequencing data from primary or metastatic tissue, and the use of FFX or GnP as 1L systemic therapy with documented outcomes. RNA-sequencing was generated by the CAP/CLIA validated Tempus xR assay. The PurIST gene signature was applied to normalized gene expression values to classify samples into basal or classical subtypes. Univariate and multivariate Cox PH analyzes comparing overall survival (OS) with adjustment for delayed entry, between two common 1L treatment regimens, FFX and GnP, were performed for classical patients with an ECOG performance status of 0 or 1.

Results: Application of the PurIST model to the PDAC cohort (N=258) resulted in 67% (N=173) labeled as classical, 23% (N=59) as basal, and the remainder as no-call. Amongst classical patients, 35% (N=61) had a known ECOG score of 0 or 1 and were retained for subsequent analysis. Within this subset, 37 were treated with FFX and 24 with GnP as 1L, with an overall median OS of 11.4 months (95% CI: 9.5-16.5) and a 12-month survival rate of 47.2%. A univariate Cox PH analysis showed that classical patients treated with FFX had a significantly longer OS time (HR (95% CI) = 2.32 (1.29-4.17)). This result remained significant in a multivariate Cox PH, adjusting for age and ECOG, (HR=2.5 (1.15-5.44)).

Conclusion: In this real-world cohort of advanced PDAC patients, we showed that classical patients with low ECOG scores had superior OS with 1L FFX treatment compared to 1L GnP. These findings demonstrate the potential for PurIST to aid in optimal treatment selection for patients with advanced PDAC.

#2543 Evaluating biomarkers of immunotherapy response in a real-world metastatic NSCLC cohort.

K. C. Chua, A. Saadatpour, A. Chen, A. Hasan, B. Huang, S. Bates;
Interventional Oncology at Johnson & Johnson, New Brunswick, NJ

Background: Non-small cell lung cancer (NSCLC) is the leading cause of global cancer deaths, since a large proportion of cases are initially diagnosed at advanced stages. Therapeutic developments have shifted first-line (1L) therapy in the metastatic setting to immunotherapy (IO)-based regimens, albeit with heterogeneity in response. Patients harboring KEAP1 and STK11 mutations have been reported to exhibit both poorer outcomes and IO treatment resistance. Recent work suggests gene expression signatures which characterize mutant phenotypes may better identify those with compromised IO response. Leveraging a molecular real-world dataset of metastatic NSCLC patients treated with 1L IO, we aimed to evaluate gene expression signatures representing KEAP1 and STK11-mutated phenotypes and their impact on real-world outcomes.
Methods: Metastatic NSCLC patients who received 1L anti-PD(L)1 as a monotherapy or in combination were identified from the multimodal real-world database of Tempus Labs, Inc. All patients in the analytical cohort had tissue biopsies sequenced on Tempus targeted DNA and whole transcriptome RNA assays within 90 days prior to the start of the 1L IO regimen. Patients were negative for actionable mutations with record duration of at least 30 days from 1L initiation. KEAP1 and STK11 mutants were identified with likely pathogenic and/or pathogenic mutations as annotated by Tempus bioinformatic pipelines. Gene expression signatures related to these mutations were obtained from recently published literature. Evaluation of mutations or signatures as genomic markers for IO non-response were conducted using real-world progression-free survival (rwPFS) and overall survival (rwOS).
Results: A total of 332 patients were included in the study (45% IO monotherapy, 55% IO combination therapy). Previously validated biomarkers, including tumor mutation burden, T-cell inflamed GEP signature, and PD(L)1 expression, were associated with prolonged rwPFS. KEAP1 mutations were observed in 9% of analytical cohort with a higher proportion in non-squamous (11%) compared with squamous (4%) samples. For STK11, 10% were identified as mutants with a similar histology distribution (12% vs. 3%). Neither KEAP1 mutations nor related gene signatures evaluated in this study were significantly associated with real-world survival outcomes. Patients harboring STK11 mutations trended towards poor outcomes; furthermore, those with higher STK11 inactivation signature score were associated with shorter rwPFS and rwOS.
Conclusions: STK11 inactivation phenotype described by a gene expression signature was able to distinguish patients with significantly poorer survival outcomes. This finding would need validation in independent cohorts. This real-world cohort study adds supporting evidence for the utility of gene expression signatures encompassing mutant phenotypes for patient stratification.

#2545 *KRAS* co-mutational landscape dictates treatment outcomes in pancreatic cancer (PC) patients.

P. Ghosh, R. George, N. Singh, S. Agrawal;
ConcertAI, Bengaluru, India

Background: *KRAS* is commonly mutated in PC patients, with a prevalence of ~80%. A holistic understanding of the landscape of *KRAS* mutations, co-occurring mutations (co-mutations) in other driver genes, and their impact on patient outcomes treated with current standard-of-care (SoC) therapies may inform better treatment decisions.

Methods: In this study, we use a real-world clinico-genomics PC database (ConcertAI's Genome360™ PC dataset; N=1302) to:1.Examine the distribution of *KRAS* mutations.2.Identify the genes most frequently co-mutated with *KRAS*, both positively and negatively, based on their odds ratios.3.Evaluate patient outcomes (overall survival (OS) and progression-free survival (PFS)) for the two most common first-line SoC therapies (FOLFIRINOX: folinic acid, fluorouracil, irinotecan hydrochloride, oxaliplatin, and GEMPAC: gemcitabine, paclitaxel) stratified by the mutational status of *KRAS* and *TP53*.

Results: The top 5 most observed *KRAS* mutations and the top 3 positively (OR>1) and negatively (OR<1) *KRAS* co-mutated genes are shown in Table 1. 80%, 71%, and 65% of PC patients had pathogenic mutations in *KRAS*, *TP53*, and both genes, respectively. In the entire cohort, FOLFIRINOX (n=327, OS/PFS=1.26/0.58 years) was more effective (p-value<0.05) than GEMPAC (n=305, OS/PFS=0.79/0.44 years). However, the underlying genetic makeup (mutational status of *KRAS* and *TP53*) significantly affects these outcomes (Table 1). The $KRAS^{+}/TP53^{-}$ (pathogenic mutations in *KRAS*, but not in *TP53*) cohort has the worst prognosis, and the advantage of FOLFIRINOX as the treatment of choice is not observed in this cohort.

Conclusions: This study provides insights into the genetic makeup of patients with *KRAS* mutations and how co-mutation with *TP53* affects outcomes of SoC treatments. It highlights the need for comprehensive genetic profiling to make better therapy decisions.

Table 1: Evaluation of *KRAS* mutational landscape in PC and its impact on treatment outcomes.

Top 5 *KRAS* mutations	***KRAS* mutations**	**G12D**	**G12V**	**G12R**	**Q61H**	**Q61R**
	% PC patients tested positive	42.51	32.52	14.33	4.62	1.79

#2546 Identifying co-mutational signatures in *STK11* mutated advanced non-small cell lung cancer (aNSCLC) patients that help overcome poor response to immune checkpoint inhibitors (ICI's).

N. Singh, S. Agrawal;
ConcertAI, Bengaluru, India

Background: ICIs, either alone or in combination with chemotherapy, have become the primary treatment options for aNSCLC patients without any targetable mutations. However, not all patients benefit similarly from these therapies even after selection based on the currently approved biomarker PD-L1 expression. Previous studies have shown that mutations in certain genes like *STK11* and *KEAP1* may predict non-response to these therapies. Mutations in *STK11* occur in 25-30% of aNSCLC patients. We have used a real-world clinico-genomics dataset to investigate how this *STK11*+ aNSCLC patient population responds to ICIs in the context of other underlying co-mutations and whether some beneficial co-mutations may help patients overcome resistance due to their *STK11* status.

Methods: The ConcertAI Genome360™ NSCLC dataset (N=14193) was used in this retrospective study. aNSCLC patients who tested positive for *STK11* mutations and received ICIs were considered (N=377). Based on their response to ICIs, the patients were divided into responder (N= 192) and non-responder (N=185) cohorts. Other genes with pathogenic mutations, fusions, and copy number changes were identified in both cohorts, and enrichment analysis was performed to identify co-mutations significantly enriched in one cohort vs the other. Once significant co-mutations were identified, pathway analysis was performed, taking into account the immune signaling network to help rationalise and validate the results.

Results: One potential mechanism by which STK11 mutations influence the response to ICIs is through downregulation of the cGas-Sting pathway, which has been shown to play an important role in ICI response. Our co-mutational analysis also strongly supported this theory. We found that additional mutations that can nullify the effect of *STK11* mutations on the cGas-Sting pathway led to a positive response (p=0.002) within the *STK11*+ cohort. Two such co-mutational signatures in responder patients identified were co-mutations in *STK11*/*SMARCA4*/*TP53* (no *KEAP1*) (p-value = 0.003) and *SKT11*/*KRAS*/*RBM10* (p-value = 0.04). Additionally, co-mutations in the DNA damage pathway genes (*ATM*, *BRCA1*, *BRIP1*, *PALB2*, *STAG2*) (p-value = 0.001) were also predictive of response to ICIs in the *STK11*+ cohort.

Conclusion: By leveraging a real-world clinico-genomics dataset linking the tumor genomic profiles with patient response to ICIs, we have been able to perform a comprehensive co-mutational analysis of *STK11*+ aNSCLC patients to tease out the interplay of various biomarkers and signaling pathways that determine response to ICIs. Even though 25-30% aNSCLC patients are *STK11*+, we find that ~23% of these patients could still benefit from ICI treatment due to the presence of other co-mutations.

#2547 *KRAS* Q61 mutations in patients with gastrointestinal malignancies and association with real-world clinical outcomes.

M. Yousef, A. Yousef, S. Chowdhury, M. Fanaeian, M. Knafl, P. M. Roy, A. Pillai, M. Zeineddine, F. Zeineddine, J. Peterson, B. G. Smaglo, R. A. Wolff, S. Pant, M. S. Lee, J. A. Willis, M. Overman, E. B. Ludmir, M. W. Hurd, J. Shen, D. Zhao;
The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Gene-wide *KRAS* mutation has been associated with worse outcomes in multiple malignancies with newer data suggesting differential impact based on specific allele. Mutation at codon Q61 is relatively infrequent with clinical significance not well understood. Here we aim to investigate the clinical significance of $KRAS^{Q61}$ mutation in gastrointestinal (GI) malignancies.
Methods: The Foundry software platform was used to retrospectively query electronic health records to identify patients diagnosed with colorectal (CRC), pancreatic (PDAC), appendiceal (AA), cholangiocarcinoma (CC) and gastroesophageal carcinoma who underwent clinical testing for *KRAS* mutations in our institution between 2002-2023; clinical, molecular, and overall survival (OS) data were collected.
Results: *KRAS* mutation was tested in 9,088 patients with CRC, PDAC, CC, AA, and gastroesophageal carcinoma. Incidence of *KRAS* mutation was 47% (n= 3,181) for patient with CRC, 82% for PDAC (n= 579), 16% for CC (n= 76), 51% for AA (n= 236), and 7% for gastroesophageal carcinoma (n= 43). $KRAS^{Q61}$ mutation was in 5% (n=218) of patients with *KRAS* mutation (n= 4,115). Overall frequency of $KRAS^{Q61}$ was 2% (n= 156) for CRC, 5% (n= 36) for PDAC, 3% (n= 12) for CC, 2% (n= 10) for AA and 1% (n= 4) for gastroesophageal carcinoma. $KRAS^{Q61}$ fraction of *KRAS* mutations was 5% for CRC, 6% for PDAC, 16% for CC, 4% for AA, 9% for gastroesophageal carcinoma. $KRAS^{Q61H}$ was the most frequent $KRAS^{Q61}$ mutation among all tumor types, 57%, 61%, 60%, 50% out of $KRAS^{Q61}$ for CRC, PDAC, AA, and gastroesophageal carcinoma respectively; followed by $KRAS^{Q61L}$ (20%) for CRC, but $KRAS^{Q61R}$ for PDAC (25%), AA (20%), and gastroesophageal (25%); Patients with CC showed exclusively $KRAS^{Q61H}$ mutations. Compared to patients with *KRAS* wildtype, patients with $KRAS^{Q61}$ mutations had worse OS in PDAC (median OS=20 vs 37 months, HR=1.9, 95%CI=1.2-3, p=0.006), while (55 vs 63 months, HR=1.2, 95%CI=0.98-1.5, p=0.076) for CRC, (29 vs 25 months, HR=1.3, 95%CI=0.64-2.6, p=0.47) for CC, and (33 vs 52 months, HR=1.1, 95%CI=0.5-2.6, p=0.75) for AA. Compared to other *KRAS* mutations, $KRAS^{Q61}$ median OS was (55 vs 53 months, HR=1, 95%CI=0.81-1.3, p=0.96) for patients with CRC, (20 vs 26 months, HR=1.4, 95%CI=0.91-2.1, p=0.1) for PDAC, (25 vs 28 months, HR=1.1, 95%CI=0.54-2.5, p=0.72) for CC, (33 vs 78 months, HR=1.6, 95%CI=0.72-3.7, p=0.24) for AA.
Conclusion: $KRAS^{Q61}$ mutations frequency varied from 1% to 5% across different GI malignancies, with highest frequency in PDAC and CC. $KRAS^{Q61}$ mutations had worse OS in patients with PDAC which may suggest different co-mutations rather than specific $KRAS^{Q61}$ activity difference. Further allele specific analysis of $KRAS^{Q61}$ and co-mutations landscape is underway.

#2548 Retrospective prediction of clinical response to standard-of-care therapies in acute myeloid leukemia by an *ex vivo* drug sensitivity assay using cryopreserved primary samples.

L. Patil[1], C. J. Gu[1], W. Anderson[1], N. Long[2], K. Johnson[2], C. Tognon[2], M. D. Lacher[1];
[1]Notable Labs, Foster City, CA, [2]Oregon Health & Science University, Portland, OR

Background: Assessing drug efficacy in primary acute myeloid leukemia (AML) patient cells is crucial for pinpointing drug targets and rationally selecting therapies for patients. We have previously shown that our flow cytometry-based predictive precision medicine platform (PPMP) predicts patient outcomes for standard-of-care (SOC) AML treatments using fresh blood or bone marrow samples with high precision. Here, we wanted to test the feasibility and efficacy of the PPMP on cryopreserved patient-derived leukemic samples. However, cryopreserved leukemic samples are known for exhibiting low viability and cell recovery, rendering their practical utilization often challenging. In this study, we adapt an existing methodology for cryopreservation for patient-derived leukemic cells to investigate the potential of cryopreserved samples as an alternative to fresh samples for ex vivo prediction of treatment outcomes on our PPMP.
Methods: We screened freshly isolated white blood cells from AML patients on the PPMP to assess their response to multiple SOC single agents and combinations. The assay was also run without drug treatments immediately after receiving the fresh sample (≤ 2 days from draw) to establish a phenotype baseline. The cryopreserved samples were processed using a similar protocol, with post-thaw culture times of either 24 or 48 hours in two types of cytokine-containing media. A comparative analysis between untreated fresh and cryopreserved samples determined the optimal post-thaw culture time for cryopreserved samples. Once culture time was optimized, we screened cryopreserved samples on the PPMP with identical SOC drug conditions as the fresh samples and compared the response of leukemic blasts to drug treatment as well as impacts on other phenotypic markers.
Results: Based on our preliminary data, we found that culturing cryopreserved cells for 24 hours post-thaw was sufficient to maintain a minimum cell viability of 80% while closely maintaining a phenotype that recapitulated that of the corresponding fresh samples. In response to drug treatments within the ex vivo assays, preliminary data support a correlation (Decitabine single agent, R^2=0.81) between the response profiles of cryopreserved and fresh patient samples as gauged from AUC calculations.
Conclusion: While the preferred method for screening is to use fresh patient samples, many practical constraints make it challenging or unfeasible. The ability of Notable Lab's high-throughput platform to use cryopreserved samples opens the doors to enhanced retrospective studies leveraging clinically annotated data from biobanks or clinical trials. These retrospective studies provide a substantial reduction in the time needed to conclude such investigations.

#2549 Activity-regulated cytoskeleton-associated protein (ARC) gene expression is associated with high infiltration of stromal cells and immune cells, but with less cancer cell proliferation and better overall survival in ER-positive/HER2-negative breast cancers.

G. Yee[1], R. Wu[1], T. Ishikawa[2], K. Takabe[1];

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Tokyo Medical University, Tokyo, Japan

Introduction: Recently peritumoral lidocaine infiltration prior to removal was reported to be associated with better survival in early-stage breast cancer (BC). This led us to hypothesize that innervation to the tumor affects its biology and patient survival. Activity-regulated cytoskeleton-associated protein (ARC) gene expression is known to be regulated by neuronal activity. Therefore, we studied the clinical relevance of ARC gene expression as a surrogate of neuronal activity in BC. **Methods:** Sweden Cancerome Analysis Network-Breast (SCAN-B (GSE96058), n=3273) cohort was analyzed, and the results were validated using The Cancer Genome Atlas (TCGA, n=1069). **Results:** ER+/HER2- and Luminal A type cancers expressed significantly higher ARC compared to the other subtypes in both cohorts ($p<0.005$). In the tumor microenvironment, the stromal cells (fibroblasts, endothelial cells and adipocytes) were all found to be significantly infiltrated in high ARC BC ($p<0.01$). Multiple immune cells were significantly infiltrated in high ARC BC, including CD8, CD4 memory cells, helper type II T cells, regulatory T cells, M1 and M2 macrophages, dendritic cells and B cells (all $p<0.03$ in both cohorts). In terms of cancer characteristics, there was no difference in silent or nonsilent mutations, single nucleotide variant or indel neoantigens between tumors with low or high ARC expression. However, high ARC BC was significantly associated with less homologous recombination deficiency, intratumor heterogeneity and fraction altered mutation rate compared to low ARC BC in TCGA ($p<0.001$). High ARC expression was significantly associated with smaller tumor size ($p<0.001$) and without lymph node metastasis in the SCAN-B cohort ($p<0.02$), and less Stage IV disease in the TCGA cohort ($p<0.02$); however, these results were not validated by the other. High ARC BC was significantly associated with lower Nottingham histologic grade and lower MKi67 expression in both cohorts ($p<0.001$). Cell proliferation-related gene sets in the Hallmark collection (E2F targets, G2M checkpoint, and MTORC1 signaling) were significantly less enriched to high ARC BC consistently in both cohorts. Overall survival (OS) was significantly better in high ARC BC in the ER+/HER2- subtype consistently in both cohorts ($p<0.01$) and when including all subtypes in the SCAN-B cohort ($p<0.001$); however this was not validated in TCGA. No significant difference in OS was found between low and high ARC gene expression in triple negative BC in either cohort. **Conclusion:** ARC gene expression as a surrogate of neuronal activity in BC was associated with high infiltration of stromal cells and immune cells but with less cancer cell proliferation and better overall survival, particularly in the ER+/HER2- subtype.

#2550 Investigating glutathione peroxidases as potential prognostic factors in uterine corpus endometrial cancer.

A. Dukesherer, **C. A. Davison-Versagli**;
Saint Mary's College, Notre Dame, IN

Introduction: Uterine corpus endometrial cancer (UCEC) is one of the deadliest women's reproductive cancers in the United States, and mortality rates have not improved in the last 30 years due to poor prognostic methodologies. Altered expression patterns of Glutathione Peroxidases (GPX1-8) have been connected to the outcome of many cancers. Still, GPX expression patterns and their use as prognostic biomarkers in UCEC have yet to be explored. This project aimed to evaluate the potential utility of GPX1-8 as prognostic biomarkers for UCEC.

Methods: To identify GPX1-8 expression alterations in UCEC tumors, the UCEC tissue samples (n=543) from the Cancer Genome Atlas Database (TCGA) dataset were analyzed using the University of Alabama at Birmingham Cancer Data Analysis portal (UALCAN) software to statistically compare mRNA levels between UCEC tumor samples and non-tumorigenic uterine tissue. To determine the impacts of GPX1-8 expression on overall survival (OS) and relapse-free survival (RFS), the UCEC TCGA dataset was analyzed using the pan-cancer RNA seq platform using Kaplan-Meier Plotter (KM plotter). The patient cohort was split into groups according to high GPX expression status and low GPX expression status using the trichotomization function in KM plotter. Hazard ratio (HR), 95% confidence interval (95% CI), and log-rank P value were calculated using the KM plotter platform.

Results: GPX1, GPX2, GPX4, GPX7, and GPX8 were differentially expressed in UCEC tumor tissue compared to non-cancerous uterine tissue. However, unfavorable OS in patients associated with low GPX4 expression in UCEC tumor samples (P=0.0043, HR=0.39, 95% CI=0.2-0.76) only. Unfavorable RFS in UCEC patients only correlated with low GPX1 expression (P=0.019, HR=0.43, 95% CI=0.21-0.89) or high GPX6 expression (P=0.0032, HR=2.37, 95% CI=1.31-4.27) in UCEC tumor samples.

Conclusion: Low GPX1 and GPX4 expression and high GPX6 expression may be novel unfavorable UCEC prognostic markers.

#2551 Harness the power of real-world-data for oncology target and biomarker research: A case study by applying clinic-genomics data for 2,659 lung cancer patients and beyond.

S. Wu, W. Zhao, C. Choi, M. Cai, P. Ansell, A. Liede, R. Chen, X. Zhao, J. Samayoa;
Abbvie, South San Francisco, CA

Randomized controlled trials (RCTs) are the gold standard for evaluating drug safety and efficacy in controlled settings, but they have limited generalizability due to their focus on selective and homogeneous populations. Real-world-data (RWD), collected from larger and more varied patient populations, can address inherent limitations of RCTs and aid in clinical trial design and drug approval. However, with the challenges of RWD, unlocking its full potential for tumor target and biomarker identification and validation demands innovative analytical approaches. Here we present RWD analyses of ConcertAI® electronic health records (EHR) linked with Caris Lab data for 2,659 lung cancer patients. Comprehensive genomics analyses incorporate WES and RNA-seq data, coupled with rich clinical EHR data. By integrating clinical and genomics data, we showcase the potential of harnessing RWD as follows: (1) we investigated genomic alterations across five histology groups (adenocarcinoma, squamous, large cell, small cell lung cancer [SCLC], neuroendocrine [NE] lung cancer). Notably, TP53 and LRP1B mutations were prevalent across all groups. LRP1B mutations correlated with higher tumor mutation burden, indicative of a favorable response to immunotherapy. Biallelic TP53 and RB1 inactivation was predominant in SCLC and NE lung tumors. The five histological groups exhibit distinct expression profiles, reflecting tumor intrinsic characteristics. Most immune gene signature scores were significantly lower in SCLC and NE tumors, aligned with that they are cold tumors with immune resistance, except CD56-centered NK and neuroendocrine gene signatures; (2) we analyzed patient treatment patterns and persistence by line of therapy. Among the 206 NSCLC patients with clinically actionable EGFR mutations, 143 received targeted therapy during their treatment courses (69.4%). Time to treatment discontinuation (TTD) was used as a surrogate clinical outcome endpoint. TTD was significantly longer when TKI was the first line treatment compared to later lines ($p = 0.01$), while the trend is opposite for ICI where TTD is significantly shorter in the 1st line setting ($p = 0.025$); (3) we highlight the unique potential of leveraging H&E imaging modality in such RWD. In summary, we successfully identified unique molecular signatures among various lung cancer histological groups, pinpointed distinct subpopulations within lung adenocarcinoma and squamous tumors linked to their immune phenotypes, and investigated the different patient treatment patterns and outcomes, facilitating personalized medicine. In the broader context of our work, we have developed a framework for harnessing various data modalities (clinical, multi-omics, imaging) within AbbVie's oncology RWD realm, enhancing the discovery and validation of new oncology targets and biomarkers.

#2552 Real-world analysis of biomarker testing and use of targeted therapies in metastatic non-small cell lung cancer (mNSCLC) in the United States (US).

M. J. Dennis[1], D. Abrahami[2], M. Vieira[2], D. Benjumea[3], M. Boyd[3], A. Shao[3], K. Duncan[2], J. Kelton[2], **S. P. Patel**[4];
[1]Dana-Farber Cancer Institute, Boston, MA, [2]Pfizer, Inc., New York, NY, [3]Genesis Research Group, Hoboken, NJ, [4]University of California - San Diego, San Diego, CA

Background: Between 1998 and 2022, over 40% of new oncology drugs approved by the US FDA were precision therapies. In nonsquamous mNSCLC, detecting biomarkers where targeted therapies exist (EGFR, ALK, ROS1, BRAF V600E variant, MET exon 14 skipping variant, RET and PD-L1) has become essential for adequate clinical care. This study investigated real-world use of these biomarker tests, their characteristics, and associated use of targeted therapies in mNSCLC patients in the US.
Methods: Adults ≥18 years old with stage IV mNSCLC from the nationwide Flatiron Health electronic health record-derived de identified database (01/2011 - 04/2023). The proportion of patients receiving biomarker tests, timing, characteristics, test type (single, multiple or next-generation sequencing), and proportion of patients receiving guideline recommended associated targeted therapies (i.e. actionable treatment) was assessed. Actionable treatment was defined in study years where at least one actionable therapy was FDA approved (biomarker, therapy, date: ALK, crizotinib, Aug 2011; BRAF V600E, dabrafenib+trametinib, Jul 2015; EGFR, afatinib, Jul 2013; MET exon 14 skipping, capmatinib, May 2020; PD-L1, pembrolizumab, Oct 2015; RET, pralsetinib, Sep 2020; ROS-1, crizotinib, Mar 2016).
Results: In 42,037 patients with mNSCLC, the proportion of patients receiving each test were: ALK: 71.6%, BRAF: 48.8%, EGFR: 74.9%, MET: 41.4%, PD-L1: 49.3%, RET: 42.3%, and ROS1: 54.2%. Median (Q1, Q3) time from mNSCLC diagnosis to first biomarker result was 21 (12, 37) days. Tissue was the most common sample type for biomarker testing, although sampling by blood has increased in recent years. Multiple testing methods were more common in ALK and PD-L1 (48.1% and 50.3%, respectively) and next generation sequencing was more common in the other biomarkers (BRAF: 77.7%, EGFR: 57.1%, MET: 74.1%, RET: 70.7%, ROS1: 54.0%). Testing rates increased from 2011 through 2023 for each biomarker, with the highest rates in 2023: ALK (87.7%), BRAF (85.2%), EGFR (88.7%), MET (85.7%), PDL1 (78.7%), RET (84.8%), and ROS1 (86.9%). Testing rates were similar when timing was restricted to a 1-year window from mNSCLC diagnosis. Receipt of actionable treatment varied by biomarker, in order of increasing frequency: RET+ (23.0%), MET+ (34.0%), BRAF+ (42.7%), PDL1+ (56.3%), ROS1+ (59.8%), EGFR+ (70.6%), and ALK+ (89.0%). Generally, across all biomarkers, receipt of actionable therapy increased in more recent years.
Conclusion: Current real-world biomarker testing rates and use of actionable treatments may reflect increased adoption of clinical guideline recommendations. Despite increased testing, use of actionable therapy remains low for certain biomarkers. Further improvements in the implementation of robust biomarker testing to use appropriate therapies are needed, which can lead to better patient outcomes.

#2553 Functional precision medicine as a valid tool in glioblastoma clinical practice.

N.-G. Her[1], A. Woehrer[2], G. Lee[1], S. Hyun[1], J. Ahn[1], J. Kang[1], R. Hwang[1], A. El-Heliebi[2], B. Prietl[2], S. Stanzer[2], T. R. Pieber[2], **D.-H. Nam**[1];
[1]Aimed Bio Inc., Seoul, Korea, Republic of, [2]Center for Biomarker Research in Medicine (CBmed), Graz, Austria

Background: Glioblastoma remains a formidable therapeutic challenge, necessitating innovative strategies such as functional precision medicine (FPM). FPM offers personalized treatment by utilizing high-throughput screening of 10-100 compounds on patient-derived tumor cells (PDCs), assessing both efficacy and relative sensitivity, with results reported to the molecular tumor board within 2 weeks. The focus of this study is the cross-laboratory validity of this approach in glioblastoma, an essential step towards confirming FPM's consistency and potential as a game-changing tool in personalized cancer treatment.
Methods: Patient-derived tumor cells from glioblastoma cases were cultured for 3-7 days followed by automated high-throughput screening. The drug library contained ~80 compounds, including specific numbers of cytotoxic and targeted drugs. Drug response curves informed the calculation of sensitivity scores, which were compared to the AimedBio reference library to identify potentially effective drug candidates for a given patient. Additionally, corresponding tumor tissues were analyzed through panel sequencing of 50 glioma-related genes.
Results: A total of >50 patients with glioblastoma were included, with subgroups from CBmed, Austria, and AimedBio, South Korea. PDC cultures were successful in over 90% of cases, and informative high-throughput drug screening results were obtained. Integration of drug response with genetic tumor profiles yielded testable treatment candidates. Additionally, transcontinental shipping and re-screening of PDCs yielded comparable results, affirming the robustness of the method.
Conclusion: This study establishes and validates high-throughput drug screening platforms specifically tailored for functional precision medicine, utilizing glioblastoma as a model. The findings reveal a high degree of validity in the drug screening results, reinforced by the excellent performance of both technical and biological replicates. Such success not only lays a solid foundation for further academic and pharmaceutical collaborations but also opens the path for regulatory approval, bringing the platforms one step closer to clinical implementation. Funding: K1 COMET Competence Centre CBmed, funded by the Federal Ministry of Transport, Innovation and Technology; the Federal Ministry of Science, Research and Economy, Land Steiermark (Dep. 12, Business and Innovation), the Styrian Business Promotion Agency (SFG), and the Vienna Business Agency. COMET is executed by the Austrian Research Promotion Agency (FFG).

#2554 Development/validation of a molecular and clinical evidence-based algorithm for selecting optimal precision therapeutic strategy for cancer patients - continuous study.

Y. Sun, T. Meissner, R. Elsey, C. Hattum, C. Williams;
Avera Cancer Institute, Sioux Falls, SD

Background: The integration of genotyping and genomics in clinical practice has brought about significant advancements in precision oncology. However, a persistent challenge for treating oncologists lies in selecting the most effective patient-specific therapeutic strategy due to the molecular rationale, disease relevance, and patient-specific issues. To address this challenge, we have developed an algorithm that incorporates both molecular and clinical evidence-based criteria to rank therapeutic strategies in order to deliver optimal care and improve outcomes in patients with malignancy. The purpose of this part of our studies was to evaluate the effectiveness and accuracy of our novel algorithm.

Methods: History of present illness and comprehensive genomic profiling results of 306 patients with malignant tumors were reviewed by Avera Molecular Tumor Board (MTB) from June 2021 to February 2023. Therapeutic recommendations were provided with the Matching Score that we used in the I-PREDICT study based on molecular matching only as well as with the Ranking Score calculated by our novel algorithm with the criteria not only focusing on molecular matching, but also including disease relevance, patient-specific clinical considerations and treatment availability as weighting factors (Cohort 2). The other 50 patients with previously treated solid tumors reviewed by MTB (before 2018) and treatment recommendations provided with Matching Score only, were used as a control group (Cohort 1). The matching rates from recommendations and treatment outcomes of the patients were then assessed.

Results: In Cohort 1, of the 50 patients, 33 patients (66%) received matched therapeutic plans recommended by our MTB. The other 17 patients were not on a matched plan from the MTB. At 12 weeks, 12 patients (36.4% of 33 patients) remained progression free, including 8 patients (24.2%) who were progression free at 6 months. The other 21 patients (63.6% of 33 patients) could not be assessed due to treatment termination per drug toxicity or death before the follow-up time point. The median PFS/overall survival (OS) for patients with a Matching Score > 50% (N = 17) were 7.5/10.5 months, whereas with Matching Score ≤ 50% (N = 16) were 3/7.35 months. In Cohort2, of the 306 patients, 130 (42.5 %) patients have initiated matched therapeutic plans and follow-up is ongoing. Updated results will be presented at the meeting.

Conclusion: Our novel molecular and clinical evidence-based algorithm may be used to support oncologists' decision-making to utilize the most clinically appropriate and effective therapeutic options to benefit patients. Further validation studies and development of a user-friendly computational ranking platform based on the algorithm are planned in order.

#2555 Real-world data analysis of comprehensive genomic profiling using plasma samples from non-small cell lung cancer patients.

M. Morishita, K. Fujii, M. Ueki, H. Ikushima, H. Isago, K. Watanabe, K. Oda, H. Kage;
The University of Tokyo Hospital, Tokyo, Japan

Introduction: Comprehensive genomic profiling (CGP) tests which use plasma samples can detect driver mutations and are recommended when tissue samples are unavailable. Multiple studies have shown that plasma CGP tests can result in genomically matched treatment for cancer patients, especially in gastrointestinal cancer. However, data for non-small cell lung cancer (NSCLC) remain limited.
Methods: We searched the database of the Center for Cancer Genomics and Advanced Therapeutics (C-CAT), which comprised 99.7% of the CGP data under insurance coverage in Japan. NSCLC patients analyzed with FoundationOne Liquid CDx (F1LCDx) between August 1 2021 to July 31 2023 were included, all of whom were previously treated.
Result: 694 patients with NSCLC underwent liquid biopsy. Among them, 572 cases were adenocarcinoma, and 71 were squamous cell carcinoma. The median age was 68 years (range: 24-93), and 423 patients were male. Pathogenic or likely pathogenic *EGFR* mutations, *ALK* rearrangements, *ROS1* rearrangements, *MET* exon 14 skipping mutations, *BRAF* V600E, *RET* fusions, *ERBB2* mutations, and *KRAS* G12C were detected in 174 cases (25.1%), 18 cases (2.6%), 2 cases (0.3%), 9 cases (1.3%), 3 cases (0.4%), 7 cases (1.0%), 26 cases (3.7%) and 17 cases (2.4%), respectively. Among the 499 patients without known driver mutations, driver mutations were detected by F1LCDx in 60 patients (12.0%). The detection rate of each driver oncogene is shown in Table 1. Conversely, among the 174, 20, 9 and 3 patients with known *EGFR*, *ALK*, *ROS1*, or BRAF V600E alterations, F1LCDx showed false negative results in 48 (27.6%), 10(50.0%), 8 (88.9%), and 3 cases (100%) (*EGFR/BRAF* vs. *ALK/ROS1*, p = 0.001), respectively.
Conclusion: In patients without known driver oncogenes, mutations associated with approved therapeutic implications were detected in 12.0%. The detection of gene rearrangements using liquid biopsy may be limited compared with genetic mutations.

Genomic profiling detected by FoundationOne Liquid CDx

Cases (%)	EGFR, known	EGFR, unknown	ALK, known	ALK, unknown	ROS1, known	ROS1, unknown	BRAF V600E, known	BRAF V600E, unknown
Detected by F1LCDx	126 (72.4)	48 (9.2)	10 (50.0)	8 (1.2)	1 (11.1)	1 (0.15)	0	3 (0.43)
Undetected by F1LCDx	48 (27.6)	472 (90.8)	10 (50.0)	666 (98.8)	8 (88.9)	684 (99.9)	3 (100)	688 (99.6)
Total	174	520	20	674	9	685	3	691

#2556 Longitudinal analyses of clinical sequencing data provide novel insights into the evolutionary dynamics of lung adenocarcinoma.

B. Mastrogiacomo, E. G. Dunne, C. N. Fick, J. Nguyen, J. Hathwar, M. Lankadasari, Y. Liu, S.-R. Yang, J. Chang, W. K. Chatila, N. Schultz, D. R. Jones, F. Sanchez-Vega;
Memorial Sloan Kettering Cancer Center, New York, NY

Background: Tumor heterogeneity plays a crucial role in disease progression, metastasis and treatment response in lung adenocarcinoma (LUAD). Limited availability of multiple molecularly profiled samples from the same patients poses a challenge to validate models of tumor evolution using real-world data. We investigated genomic changes in a large cohort of patients with clinically directed DNA sequencing of multiple LUAD samples.
Methods: We analyzed longitudinal genomic data from 524 patients with at least two LUAD samples sequenced with MSK-IMPACT- a targeted panel that identifies somatic mutations, copy number alterations and gene fusions in 341-505 genes. Our analysis of 1084 tumors (634 primaries [P] and 450 metastases [M]) included 189 matched P-P pairs, 99 M-M pairs and 271 P-M pairs. Pairs were required to share an identical somatic mutation to confirm relatedness. Additional criteria included: excision of primary tumor prior to excision of the metastasis in P-M pairs collected over 90 days apart and collection of M-M pairs from the same anatomic site. Intra-pulmonary metastases were removed from P-P pairs.
Results: Tumor mutational burden was correlated in paired specimens from the same patient, irrespectively of P-P (R= 0.75, p<0.001; Spearman correlation), P-M (R=0.72, p<0.001) or M-M (R=0.6, p<0.001) status. Chromosomal instability, measured as the fraction of genome altered by copy number changes (FGA), was also correlated in P-P (R=0.69, p<0.001) and M-M (R=0.57, p<0.001) pairs, but tended to increase in metastases with respect to matched primaries (median 0.58 vs. 0.72, p<0.001; Wilcoxon test). In M-M pairs, changes in FGA differed by anatomic site. Liver pairs had the strongest correlation (n=17 pairs, R=0.86, p <0.01), whereas brain pairs had the weakest (n=35 pairs, R=0.085, p=0.71). Most somatic mutations were shared between paired samples (P-P: 639/1055, 60%, P-M: 1563/2877, 54%, M-M: 550/958, 57%), including those in LUAD drivers- *TP53*, *KRAS*, and *EGFR*. Conversely, most oncogenic copy number alterations - including *CDKN2A* deletions and *MET* amplifications - were private to one specimen (P-P: 183/276, 66%, P-M: 880/1148, 76%, M-M: 430/601, 71%), most often in the later sample (P-P: 113/183, 61%, P-M: 636/880, 72%, M-M: 212/430, 49%). Clinically targetable alterations (OncoKB Level 1) tended to be shared by tumor pairs from the same patient (93% shared vs. 6% private in P-P, p<0.01; 85% vs. 14% in P-M, p<0.01; 78% vs. 21% in M-M, p <0.01).
Conclusions: In LUAD, metastatic specimens exhibit increased chromosomal instability in relation to their matched primaries. This translates into unique copy number alterations detected only in the metastasis. By contrast, driver mutations - which account for most of the clinically targetable alterations with currently approved FDA drugs - are more often shared between paired samples from the same patient.

#2558 Molecularly matched targeted therapies benefit high risk pediatric cancer patients.

A. Tao, J. Pavisic, J. A. Oberg;
Vagelos College of Physicians and Surgeons, Columbia University, New York, NY

Introduction: Genomic technologies have the potential to transform the paradigm for diagnosing and treating children with cancer. Although druggable alterations are identified in a large fraction of pediatric cancer patients, the extent to which point-of-care genomic testing directly impacts therapeutic outcomes of individual patients in real-world settings is less well-known. A review of patients sequenced through the Precision in Pediatric Sequencing (PIPseq) program at Columbia University Irving Medical Center (CUIMC) was conducted to describe outcomes of patients treated with a molecularly matched targeted therapy (MTT).
Methods: Matched tumor-normal whole exome and tumor transcriptome sequencing was conducted in a CLIA-certified laboratory at CUIMC between January 2013 and March 2023 on samples from 373 high risk pediatric cancer patients including those with <50% survival, rare cancers lacking standard therapies, and relapsed/refractory disease. All cases were reviewed at a multi-disciplinary molecular tumor board and reports were transmitted to the electronic health record (EHR). EHR data were reviewed to identify patients who received a MTT. Tumor-specific response and progression-free survival (PFS) among the MTT cohort were investigated. Clinical benefit was further assessed using the Growth Modulation Index (GMI) whereby patients served as their own control. GMI is the ratio of PFS on the MTT therapy to the PFS on the most recent prior therapy. A ratio of >/=1.3 indicates meaningful clinical activity.
Results: Thirty pediatric patients (solid tumors, n=5; CNS tumors, n=15; hematologic malignancies, n=10) received a MTT. Median age at sequencing was 11 years, range 10 months-23 years. Median time to MTT from sequencing was 4.5 months, range 7 days to 19.2 months. Best overall response included 7 complete responses (23%), 6 partial responses (20%), 5 with stable disease (17%), 10 with progressive disease (33%), and 2 indeterminate due to early death or lack of follow-up during therapy (7%). GMI was calculated for 19/30 patients (63%); median GMI=1.1. 11 patients were excluded due to lack of prior therapy, early death, insufficient follow-up, or lack of progression between prior and targeted therapies. GMI ratios indicated clinical benefit from MTT for 12/19 patients (63%), median GMI=1.5.
Conclusions: Clinical comprehensive molecular profiling for pediatric patients with high risk cancers identified patients who are candidates for MTT. Overall, MTT led to stable disease, partial or complete response, for 60% of patients. Utilizing GMI ratios as an indicator of clinical benefit for select patients provided additional information beyond traditional endpoints. Twelve patients with GMI >/=1.3 experienced improved PFS compared to their most recent prior therapy. These results demonstrate real-world clinical benefit from MTT, supporting molecular profiling of pediatric high risk tumors.

#2559 Genotype-phenotype associations in von hippel-lindau syndrome: Implications for screening.

N. Murray, C. Leavitt, N. Shepard, Z. Gonzales, J. Li, B. O'Neil, C. Dechet, B. Schmidt, B. L. Maughan, K. Pauley, A. Naumer, W. Kohlmann, **A. Sanchez**; University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Introduction and Objectives: Von Hippel-Lindau (VHL) is an autosomal dominant genetic disease. The type of *VHL* alteration has been shown to impact downstream VHL expression and clinical phenotype. However, current screening practices do not differ based on VHL genetic subtype. We aim to define the genotype-phenotype association among an institutional cohort of VHL patients.

Methods: We conducted a retrospective cohort study of 69 patients (27 families) with von Hippel-Lindau at the Huntsman Cancer Institute from 1998-2023. 55% (38/69) patients have documented VHL variants for review. We evaluated the association of VHL type with risk of pheochromocytoma (Pheo), renal cancer (RCC), and hemangioblastoma (HB). *t* test and Fisher's exact test were used to assess differences in clinicopathologic characteristics by VHL Type. P-value < 0.05 was considered significant.

Results: We identified 24 unique *VHL* alterations among 38 patients. 66% (25/38) of patients had missense mutations, 10% (4/38) nonsense mutations, 21% (8/38) splice mutations, and 3% (1/38) deletion/duplication (Table 1). The median age at VHL diagnosis was 31 years old (range 4-76). VHL Type 2 was more common, 87% (33/38). All VHL Type 1 patients (5/5) developed RCC and HB. No patients with VHL Type 1 developed PheoPara. Of the VHL Type 2 patients, 39% (13/33) have not developed any VHL-associated clinical manifestations. Of the 33 patients diagnosed with VHL Type 2, 18% (6/33) were diagnosed with PheoPara, 30% (10/33) with RCC, and 48% (16/33) with HB.

Conclusion: VHL type 2 comprised the majority of VHL diagnoses in our cohort with a notable absence of PheoPara phenotype. VHL Type 1 had higher penetrance and a higher prevalence for RCC and hemangioblastoma. With validation in larger cohorts, this cohort supports utilizing VHL genetic subtypes to personalize surveillance. Additional VHL testing for the remainder of the cohort is ongoing.

Clinicopathologic characteristics of von Hippel-Lindau Syndrome cohort with known genetic mutations

	All (n=38)	Type 1 (n=5)	Type 2 (n=33)	p-value
AgeMean (Median)	33.1 (31)	42 (28)	31.7 (31)	0.38
White, n (%)	92% (n=35)	5 (100%)	30 (91%)	1
Hispanic, n (%)	8% (n=3)	-	3 (9%)	1
VHL alteration, n (%)				-
Missense	25 (66%)	-	25 (76%)	
Nonsense	4 (10%)	4 (80%)	-	
Splice site	8 (21%)	-	8 (24%)	
Deletion/Duplication	1 (3%)	1 (20%)	-	
Penetrance, n (%)	25 (66%)	5 (100%)	20 (61%)	0.14
Phenotype, n (%)				
PheoPara	6 (16%)	-	6 (18%)	0.57
RCC	15 (39%)	5 (100%)	10 (30%)	0.006
Hemangioblastoma	21 (55%)	5 (100%)	16 (48%)	0.26

#2560 Genomic biomarkers of survival in patients (pts) with metastatic castrate-sensitive prostate cancer (mCSPC) undergoing androgen deprivation therapy (ADT) intensification (ADTi).

A. Narang, G. Gebrael, C. Hage Chehade, N. Sayegh, Y. Jo, B. Chigarira, N. Tripathi, A. Srivastava, C. Tandar, B. L. Maughan, U. Swami, N. Agarwal; Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Background: ADTi with androgen receptor pathway inhibitors (ARPI) with or without docetaxel improves survival outcomes in pts with mCSPC. Even with ADTi, 20% of these pts progress within a year and experience poor overall survival (OS). Identifying baseline genomic biomarkers predicting poor survival outcomes in pts receiving ADTi remains an unmet need.

Methods: In this IRB-approved retrospective study, pts with a new diagnosis of mCSPC who underwent comprehensive genomic profiling of primary prostate tissue or metastatic site or cell-free DNA and treated with ADTi (ADT with ARPI or docetaxel) were included. Genomic alterations with an incidence > 5% were included in the analysis. Study endpoints: progression-free survival (PFS) was defined from the start of therapy for mCSPC to progression (per PCWG-2) or death from any cause. OS was defined from the start of therapy for mCSPC to the date of death from any cause or censored at the last follow-up. A multivariable analysis using the Cox proportional hazards model was used, adjusting for age at mCSPC diagnosis, disease volume (high vs. low), Gleason score (≥ 8 vs. < 8), Log_2PSA at baseline, and initial timing of metastasis (de novo vs. non de novo). A subgroup analysis by intensification treatment received (ARPI vs. docetaxel) was also performed. Missing baseline characteristics such as volume of disease, Gleason score, and Log_2PSA were multiply imputed on 50 chained equations using “mice” package in R. All the analyses were done using R version 4.3.1.

Results: A total of 289 pts were included in the study. The baseline characteristics of the cohort will be presented in the meeting. The alterations included in the analysis were *TP53* (31.8%), *TMPRSS2* (30.4%), *PTEN* (17%), *APC* (10.4%), *SPOP* (9%), *RB1* (6.2%), *BRCA2* (5.2%), and *CDK12* (5.2%). In the multivariable analysis, *TP53* (HR 1.87, 95% CI 1.29-2.72, p = 0.001), *RB1* (HR 2.56, 95% CI 1.45-4.53, p = 0.001), *PTEN* (HR 1.77, 95% CI 1.15-2.72, p = 0.009), and *BRCA2* (HR 2.68, 95% CI 1.47-4.89, p = 0.002) were associated with significantly shorter PFS while *TP53* (HR 1.78, 95% CI 1.1-2.88, p = 0.019), *RB1* (HR 4.78, 95% CI 2.53-9.02, p < 0.001), and *PTEN* (HR 2.37, 95% CI 1.37-4.1, p = 0.003) were associated with significantly worse OS. Results of the subgroup analysis by intensification treatment (ARPI vs. docetaxel) will also be presented in the meeting.

Conclusions: In this real-world study, we identified genomic biomarkers that could be associated with shorter PFS and OS in pts with mCSPC treated with ADTi. Upon external validation, these results may aid in developing a clinical-genomic risk stratification model, patient counseling, and treatment selection.

#2563 Understanding the new subgroup- Her 2 low breast cancer.

R. Kulkarni, M. A. Shahid, O. Hinojosa Castro, K. Patel, C.-H. Lin, C. Rose, V. Dabak;
Henry Ford Health System, Detroit, MI

Introduction: Outcomes have greatly improved for patients with HER2+ breast cancer. Recently, tumors with IHC 1+ or 2+/negative FISH have been classified as 'HER2-low'. The development of novel HER2 agents has shown clinical benefit in this subset of patients. Information on the clinical characteristics of these patients which could be prognostic, and which could impact therapeutic options is limited.
Methods: This was an IRB-approved study. Relevant patient demographics, disease characteristics, and treatment details of patients with metastatic breast cancer seen at our center from 2018 to 2021 were collected by chart review. All data analyses were performed using R version 4.3.1, and a p-value ≤ 0.05 was considered statistically significant.
Results: A total of 102 patients with metastatic breast cancer were included. Patients were divided as HER2+, HER-, HER2 low ER+ and HER2 low ER -. 66.6% of patients had HER2 low disease. Patients with HER2 low ER- disease were more likely to have tumors that were of higher grade (grade 3, 71.4%, p=0.003), higher mean Ki67 (60%, p<0.001), and of ductal histology (100%, p=0.006). There was a statistically significant difference in PFS among the four groups (p=0.001). Median survival was longer in patients with HER2 low ER+ compared to the HER2- group. (1.42 vs 0.58, p<0.001, Table 1). Amongst HER2 low ER+ patients, there was a significant PFS difference in those treated with CDK4/6 inhibitors compared to chemotherapy (2.83 vs. 0.67, p=0.009). We found no difference in PFS between patients who were HER2 1+ ER+ and HER2 2+ ER+. In multivariate analysis, there was no significant association of race, grade, menopausal status, Ki67, histologic subtype, and metastatic sites with PFS.
Conclusion: In this small single-center retrospective study, patients with metastatic HER2 low ER- breast cancer had higher-grade tumors. HER2 low ER+ patients had a better PFS compared to HER2- patients. This seems to suggest that the HER2 low group may have some inherent biologic differences. Larger studies are needed.

Table 1: PFS Summary

Group	Total number	Progression/Death	Median Survival
HER2-	13	13	0.58
HER2 low ER-	14	11	0.88
HER2 low ER+	54	32	2.42
HER2+	20	12	1.08

#2564 Circulating monocytes decrease significantly following disease-directed therapy and may reflect disease expansion in Langerhans cell histiocytosis.

H. Ali, S. Reynolds, S. Wilcox, N. Chipalkatti, A. Ahmed;
University of Michigan, Ann Arbor, MI

Introduction: Langerhans Cell Histiocytosis (LCH) is a rare disorder characterized by clonal hematopoietic cell expansion forming eosinophilic granulomas. Treatment approaches vary based on disease severity. Despite established therapies, assessing treatment response, particularly regarding peripheral blood monocytes, lacks comprehensive markers.

Methods: We studied 76 LCH patients, collecting data on demographics, diagnostic methods, and treatment responses. Peripheral blood absolute monocyte counts were analyzed at key time points, including disease onset, progression, and post-therapy reinstatement, using statistical tests for comparison.

Results: Analyzing data from 76 patients (average age: 38), we found diverse disease presentations, with common imaging modalities being CT (37), PET (29), and MRI (22). Complete responses were observed in 17 of 49 patients, with 11 undergoing local therapy. Conversely, 5 patients with pulmonary LCH and chronic tobacco use showed persistent progression. Notably, peripheral blood monocyte counts did not differ between initial and latest assessments, but on disease progression, the mean count (0.94 K/μL) significantly exceeded that following therapy reinstatement (0.31, p=0.000794).

Results: Analyzing data from 76 patients (average age: 38), we found diverse disease presentations, with common imaging modalities being CT (37), PET (29), and MRI (22). Complete responses were observed in 17 of 49 patients, with 11 undergoing local therapy. Conversely, 5 patients with pulmonary LCH and chronic tobacco use showed persistent progression. Notably, peripheral blood monocyte counts did not differ between initial and latest assessments, but on disease progression, the mean count (0.94 K/μL) significantly exceeded that following therapy reinstatement (0.31, p=0.000794).

Discussion: LCH is proposed to result from dysregulated hematopoiesis, leading to sequential somatic mutations during monocyte differentiation leading to clonal expansion of CD1A and CD207+ histiocytes. Our finding of increased monocyte count during disease progression may suggest elevated circulating LCH or heightened monocyte production for subsequent differentiation, potentially contributing to MHC Class 1 upregulation. This phenomena mirrors published findings from our own group in patients with Rosai Dorfman and Erdheim Chester Disease. To further elucidate the molecular underpinnings of LCH and explore the etiology of this monocyte trend, genetic sequencing analysis is in progress. Ultimately, monitoring peripheral blood monocyte dynamics could offer valuable insights into LCH progression and treatment response.

#2565 Vitamin D deficiency and outcomes in prostate cancer patients: A real-world database.

L. L. Hart[1], J. Reeves[2], S. Garofalo[2], W. Amick[3];

[1]Atrium Health-Wake Forest Baptist Comprehensive Cancer Ctr., Fort Myers, FL, [2]Florida Cancer Specialists, Fort Myers, FL, [3]Immunonutrition, Inc, Miami, FL

Introduction: Vitamin D is essential for many bodily functions, including bone health and the prevention of osteoporosis and rickets. In recent years, the importance of vitamin D metabolism in immune system regulation and cancer prevention has been studied with increased focus. With the advent of cancer immunotherapies this has become more important. Multiple recent publications document that vitamin D deficiency is prevalent in cancer patients. This has also been observed specifically in prostate cancer patients, with a high percentage of these deficient patients being of African- American ancestry. It has been theorized that high levels of vitamin D deficiency among African American prostate cancer patients could contribute to worse cancer outcomes and increased health disparities. However, routine vitamin D testing has not been commonly performed in the oncologic community. We hypothesized that deficient levels of vitamin D could lead to inferior prostate cancer outcomes in men with a wide range of ethnic and socio-economic backgrounds. In this project we recorded vitamin D levels in prostate cancer patients at a large community oncology group and evaluated them by stage, pathologic data, survival, race/ethnicity, and other clinical features.

Methods: This study is a retrospective, observational study of the data from the electronic medical records of patients with prostate cancer who received vitamin D level testing at Florida Cancer Specialists & Research Institute from 2008- 2023, throughout the state of Florida. All data used in this study will constitute secondary data, it will have been collected originally for clinical use in the general oncology practice setting. No date parameters or patient limits will be applied to this study, and all eligible patients are included.

Results: 451 patients with prostate cancer had determination of vitamin D levels, out of a total of 27,772 prostate cancer patients in the database. 38% of the prostate cancer patients analyzed had low 25-OH vitamin D levels (<32 ng/ml). Patients with low vitamin D levels had an average Gleason score of 7.46. Patients with low vitamin D levels who died had an average survival of 144 months. Patients with low vitamin D levels who presented with localized disease had a 35% chance of eventually developing castrate-resistant disease. 45% of the low vitamin D group developed metastatic disease during their course of treatment. Further comparisons of vitamin D levels with pathologic data, survival/longevity, race/ethnicity, and clinical course will be evaluated and presented.

#2566 Molecular characteristic profile in early colorectal cancer with V600E and non-V600E BRAF mutations.

Z. Quan An;
Xiangtan Central Hospital, Xiangtan, China

Background: The BRAF V600E mutation in colorectal cancer (CRC) is a significant indicator of poor prognosis, especially in tumors exhibiting microsatellite instability (MSI). It is more common on the right side of the colon but can occur anywhere within the colon. Although other BRAF mutations existed, current research primarily focused on BRAF V600E. Most clinical data sets were centered on advanced colorectal cancer. There was limited understanding of the molecular characteristics of early-stage colorectal cancer patients with BRAF mutations, which impacted postoperative prognosis management, including refining adjuvant therapy regimens. Therefore, we analyzed the molecular characteristics of early-stage CRC surgical patients.
Methods: Tumor tissue from 767 early-stage CRC patients diagnosed between 2021 to 2022 in China were analyzed using NGS (panel on 733 gene) to validate the mutation characteristics. Tumor specimens were tested for the BRAF mutation and MSI status.
Result: Among 767 early CRC cases tested, BRAF mutations accounted for 6.52% (50/767), with 62% (31/50) being BRAF V600E, followed by 14% (7/50) for BRAF D594G. Notably, there were two cases of fusion variations, TRIM24-BRAF, and one case of BRAF copy gain. Among the BRAF mutation population, 11 cases were MSI-H, with 8 of them being BRAF V600E/MSI-H. Only one MSH-H patient had a germline mutation in the MLH1 gene, with a concurrent mutation in BRAF K601T.Interestingly, when comparing the mutation profiles of the BRAF V600E population with those of the non-V600E BRAF mutation population, we found distinct co-mutated genes despite both being BRAF mutations. In the BRAF V600E group, the top three frequently mutated genes were TP53 (52%), RNF43 (32%), and SMAD4 (32%). Additionally, the BRAF V600E/MSI-H subgroup presented a distinct
mutation profile, with minimal occurrences of TP53 and SMAD4 mutations. In the non-V600E BRAF mutation group, the top three frequently mutated genes were TP53 (84%), APC (63%), and KRAS (32%).
Conclusions: In examining the mutation profile characteristics of early colorectal cancer with BRAF mutations, the proportion of BRAF V600E/MSI-H appeared to have been lower than that reported in advanced cases. Furthermore, in terms of the frequency of co-mutated genes, it seemed that BRAF V600E had exhibited a higher malignant driving mutation effect as a single gene, while non-V600E mutations had required more cooperative tumor suppressor genes or oncogenes. Analyzing the molecular characteristics of early colorectal cancer patients with V600E and non-V600E BRAF mutations could help improve postoperative management and further our understanding of tumor progression.

#2567 An analysis of proviral insertion site of Moloney murine leukemia virus, PIM1, kinase expression and clinical outcomes in renal cell carcinoma.

S. L. Holder[1], G. Lagos[1], B. A. Carneiro[1], A. Mega[1], A. De Souza[1], R. R. McKay[2], A. Elliott[3], C. Nabhan[3], S. L. Graff[1];
[1]Legorreta Cancer Center and Warren Alpert Medical School at Brown University, Providence, RI, [2]Moores Cancer Center - UC San Diego Health, La Jolla, CA, [3]Caris Life Sciences, Irving, TX

Background: Wild-type Proviral Insertion Site of Moloney Murine Leukemia Virus 1 Kinase (PIM1) is a constitutively active serine/threonine kinase that inhibits apoptosis and promotes cell cycle progression, proliferation, angiogenesis, invasion, and migration. Due to constitutive activation, PIM1 is regulated at transcription and degradation. We have previously shown PIM1 protein levels are elevated in clear cell renal cell carcinoma (ccRCC) compared to normal kidney and that PIM1 inhibition induces tumor regression in pre-clinical models. Current approved therapies for ccRCC do not inhibit PIM1. We hypothesized that high PIM1 expression will adversely affect clinical outcomes in ccRCC.
Methods: Whole transcriptome sequencing (WTS) data in the Caris Life Sciences database were examined for PIM1expression and overall survival (OS; defined as time from diagnosis to last contact or death). We assessed PIM1 in primary and metastatic ccRCC, and the impact on survival in ccRCC and papillary RCC. Differentially expressed genes (DEGs) associated with high PIM1 were also determined.
Results: PIM1, in the highest quintile, was associated with a shorter OS (869 vs 1738 days; HR 2.629; CI 1.495 - 4.611; p<0.001; N=147) in ccRCC. PIM1 is enriched in metastatic (median 7.62 transcripts per million (TPM), CI 6.35 - 9.26) vs primary (median 5.07 TPM; CI 4.28 - 6.45; p=0.0025) RCC. Upregulated DEGs associated with high PIM1 are involved in the extracellular matrix. IL-6 expression, known to correlate with worse outcomes, was 6.5-fold higher in PIM1 high vs PIM1 low (13.2 vs 2.1 TPM, p<0.0001) RCC. High PIM1 was associated with poor survival following checkpoint inhibition (HR 3.714, 95% CI 1.339 - 10.303, p=0.007) and a trend towards poorer survival following mTOR inhibition and VEGF inhibition. PIM1 did not affect survival in papillary RCC.
Conclusions: Real-word data show that high PIM1 correlates with poorer survival in ccRCC but not in papillary RCC. This effect likely persists independent of treatment received. PIM1 enrichment in metastatic ccRCC, and associated DEGs, suggest that PIM1 influences the extracellular matrix to promote metastases. The correlation between IL-6expression and PIM1 supports our prior data that an IL-6/JAK/STAT/PIM1 pathway is involved in ccRCC.

#2568 High infiltration of neurons was associated with lower cell proliferation and less immune response but not with response to treatments or survival in estrogen receptor-positive breast cancer.

K. Chida[1], M. Oshi[2], A. M. Roy[1], J. Arima[1], P. Sharma[1], I. Endo[2], K. Hakamada[3], K. Takabe[1];

Introduction: Psychological stress aggravates cancer cell biology which leads to cancer progression and metastasis through its influence on the sympathetic nervous system. Recently, infiltration of a local anesthetic lidocaine around a tumor prior to its removal was reported to lead to better survival in early-stage breast cancer (BC). Therefore, we hypothesized that neuron infiltration within the bulk tumor of BC could be associated with cancer aggressiveness and worse survival.
Methods: A total of 5755 BC patients from five independent cohorts, including METABRIC (*n*=1903), SCAN-B (*n*=3273), GSE25066 (*n*=508), and ISPY2 (GSE173839; *n*=105), which have both clinical and transcriptomic data, were included in the study. The fraction of neuron infiltration was calculated using the xCell algorithm.
Results: High neuron infiltration in BC was not associated with survival in either the METABRIC or SCAN-B cohorts. BC with high neuron infiltration had high expressions of neurotransmitter receptors: adrenergic receptor α1B and 2A, dopamine receptor D2, muscarinic acetylcholine receptor M3 and M4, and TAC1, which encodes TACR1, the receptor for substance P, but had lower expression of adrenergic receptor β2 and cholinergic acetylcholine receptor 1 and 10. Further, levels of neuron infiltration were highest in estrogen receptor-positive/HER2-negative (ER+/HER2-) among the subtypes and lower in tumors with lymph node metastasis, but was not associated with tumor size. Neuron infiltration was associated with higher AJCC staging in METABRIC, which was not validated in SCAN-B cohort. High neuron infiltration in BC was associated with reduced homologous recombination defects, mutation rate, and SNV neoantigen, and with less cell proliferation, evidenced by lower Nottingham histological grade and Ki67 gene expression, as well as less enrichment of Hallmark cell proliferation-related gene sets: E2F targets, G2M checkpoint, and Mitotic spindle. Despite its association with less cell proliferation, BC with high neuron infiltration was not associated with pathological complete response (pCR) in the GSE25066 cohort. High neuron infiltration in BC was associated with higher infiltration of lymph endovascular cells as well as less immune cell infiltration; CD8, CD4 memory, T-helper 1 and 2, dendritic cells, M1 and M2 macrophages, regulatory T cells, and B cells, lower cytolytic activity, and immune response; interferon-alpha and interferon-gamma and IL2 stat signaling. Despite this association, BC with high neuron infiltration was not associated with pCR after immunotherapy in the ISPY2 clinical trial cohort.
Conclusion: BC with high infiltration of neurons was associated with lower cell proliferation and less immune response but not with response to systemic therapies or patient survival in ER+/HER2- subtype.

#2569 VEGFA gene expression is associated with cell proliferation, less immune cell infiltration, and worse survival, but better response to chemotherapy and immunotherapy.

P. Sharma[1], K. Chida[1], K. Hakamada[2], K. Takabe[1];

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Hirosaki University Graduate School of Medicine, Hirosaki, Japan

Introduction: Vascular endothelial growth factor-A (VEGFA) is a well-known factor that induces angiogenesis, one of the hallmarks of cancer, which generates new blood vessels in the tumor microenvironment (TME) and provides conduit for cancer to metastasize. Interestingly, an anti-VEGFA drug (Avastin) failed to show benefit in clinical trials for breast cancer (BC). In this study we investigated the clinical relevance of VEGFA gene expression in BC. **Methods:** A total of 7336 BC patients from eight independent cohorts, TCGA (n= 1073), METABRIC (n= 1903), SCAN-B (GSE96058, n= 3069), GSE20194 (n=278), GSE34138 (n=178), GSE163882 (n=222), GSE25066 (n=508), and ISPY2 (GSE173839, n= 105) were analyzed. These cohorts were divided into high and low VEGFA gene expression groups using the median. **Results:** High VEGFA expression in BC was associated with worse overall survival in SCAN-B cohort which was validated in METABRIC cohort with overall, disease-specific, and disease-free survival (all $p<0.02$). VEGFA expression was higher in Triple Negative BC (TNBC) but was lower in BC with lymph node metastasis. High VEGFA BC was associated with significantly high intratumoral heterogeneity, homologous recombination defect, silent and non-silent mutations, and SNV neoantigens in TCGA, and was also associated with higher cell proliferation, evidenced by higher Nottingham histological grade, higher Ki67 gene expression, and enrichment of all the Hallmark cell proliferation-related gene sets: Mitotic spindle, G2M Checkpoint, E2F Targets, MYC Targets v1 and v2, and mTorC1 signaling, consistently, in SCAN-B, METABRIC, and TCGA cohorts. Reflecting its enhanced growth, high VEGFA expression was associated with less infiltration of fibroblasts and adipocytes (all $p<0.05$). Surprisingly, VEGFA expression did not enrich angiogenesis gene set in any of the cohorts, nor was related with infiltrations of blood or lymphatic vascular endothelial cells, besides pericytes. But high VEGFA BC was associated with significantly less infiltrations of anti-cancer immune cells; CD8, CD4, and dendritic cells were all significantly less, and T helper type 1 cells and regulatory T cells were significantly higher consistently in SCAN-B, METABRIC, and TCGA cohorts. VEGFA expression was significantly higher in BC that achieved pathological complete response after Anthracycline and Taxane based neoadjuvant therapy in both ER+/HER2- and TNBC subtypes in the GSE25066 cohort, and after immunotherapy in ER+/HER2- subtype, but not TNBC, in the ISPY2 clinical trial cohort. This was not validated in GSE20194, GSE34138, GSE163882 cohorts. **Conclusion:** Our research indicates that high VEGFA BC is associated with high cell proliferation, less immune cell infiltration, and worse survival, but better response to Anthracycline and Taxane based chemotherapy, and immunotherapy.

#2570 Gastric cancer with high neuron infiltration was associated with enhanced epithelial-to-mesenchymal transition, angiogenesis and poor clinical outcomes.

K. Chida[1], M. Oshi[2], A. M. Roy[1], J. Arima[1], P. Sharma[1], G. K. Mann[1], I. Endo[2], K. Hakamada[3], K. Takabe[1];
[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [3]Hirosaki University Graduate School of Medicine, Hirosaki, Japan

Introduction: Neurons within the tumor microenvironment of gastric cancer (GC), as identified through immunohistochemistry, have been reported to be associated with worse overall survival (OS) of GC patients. However, histology-based analyses have limitations in quantifying nerve cells and investigating the underlying biology. Thus, we aim to study the clinical significance of intratumoral nerve cells in GC using computational deconvolution of transcriptomes from bulk tumors.
Methods: Total of 807 GC patients from two independent cohorts (TCGA; n = 375, GSE84437; n = 432) were included, encompassing both clinical and transcriptomic profiles. The neuron infiltration fraction was determined using the xCell algorithm.
Results: GC with high neuron infiltration was associated with high expressions of neurotransmitter receptors; beta-adrenaline, dopamine, muscarinic acetylcholine, and neurokinin receptors in TCGA cohort (all $p < 0.02$). It was associated with reduced mutation rate and increased intratumoral heterogeneity (all $p \leq 0.002$), as well as less immune response; interferon-alpha and interferon-gamma, and with low infiltration of immune cells; CD4 memory, T-helper 1, M1 and M2 macrophages, and NK cells (all $p \leq 0.02$). Further, neuron highly infiltrated GC enriched Epithelial-to-Mesenchymal Transition and Angiogenesis gene sets and had higher lymphatic and microvessel endothelial cells and pericyte infiltrations (all $p \leq 0.001$). Conversely, GC with high neuron infiltration showed an inverse relationship with cell proliferation-related gene sets; E2F Targets, G2M Checkpoint, and MYC Targets v1 and v2, and had lower Ki67 gene expression (FDR < 0.25 and $p < 0.001$, respectively). High neuron infiltration in GC was associated with worse patient OS in TCGA cohort, which was validated in GSE84437 cohort (both $p < 0.05$). It was an independent prognostic factor of OS in both univariate and multivariate Cox-regression analysis in the TCGA cohort (hazard ratio [HR]: 1.46; 95% confidence interval [CI]: 1.01 to 2.12; $p = 0.045$ and [HR]:1.54; 95% CI: 1.05 to 2.26; $p = 0.026$).
Conclusion: Our research indicates that high infiltration of neurons in GC correlates with high expressions of neurotransmitter receptors, high intratumoral heterogeneity, less immune response and immune cell infiltrations, and less cell proliferation. It enriched EMT and angiogenesis which may explain its association with worse patient survival.

#2574 The effect of epidermal growth factor expression in detecting oropharyngeal tumors during fluorescence-guided robotic surgery.
L. Stone, S. M. Rao, M. L. Gonzalez, D. Lin, H. Jeyarajan, C. M. Thomas, J. Warram;
University of Alabama at Birmingham, Birmingham, AL

Intro: Oropharyngeal squamous cell carcinoma (OPSCC) has been shown to overexpress epidermal growth factor receptor (EGFR), making it a targetable biomarker for fluorescently labeled monoclonal antibodies such as panitumumab-IRDye800, which can be used during fluorescence-guided trans oral robotic surgery (TORS). Although antibody-based fluorescence-guided surgery is being evaluated in several late-stage trials, the use of intraoperative fluorescence imaging for TORS has not been thoroughly explored. We observed that the bi-polar cautery tool[AHM(1] of the TORS robot was auto-florescent and would appear dimmer in the presence of fluorescence from surgically exposed tumor. We aim to characterize the florescence contrast of the tool and tumor to create a rapid qualitative assessment on tumor presence.
Methods: During a phase 2 clinical trial evaluating panitmumab-IRDye800 fluorescence-guided TORS of OPSCC, consenting patients (n=12) with biopsy-confirmed OPSCC received 50mg panitumumab-IRDye800 48 hours prior to surgery. Intraoperative fluorescence images were acquired using the onboard fluorescence camera of the Da Vinci Xi robot and post-operation fluorescence exams were conducted by the Pearl and Odyssey Systems (Li-Cor)[BK2] . For each patient, 3 intraoperative views (pre, mid and late resection) showing pathology-confirmed tumor, normal mucosa, and the tool were taken, and several frames from each view were analyzed via ImageJ to calculate mean fluorescence intensity (MFI) in regions of interest. The MFI of tumor and normal muscoa was normalized with MFI of the tool to obtain a standard fluorescence ratio (SFR) per patient[BK3] . A paired t-test was used to compare differences in MFI between the tumor and tool or normal mucosa.
Results: The MFI for each time point was graphed for the tool, tumor and normal mucosa. Significant differences were found between tumor and mucosa and tumor and tool for every time point. Tumor/tool SFRs per patient ranged from 2.1 to 60.9, while normal/tool SFRs ranged from 0.4 to 3.1. Receiver operator characteristics curve analyses of tissue-to-tool SFR data showed a sensitivity of 90.9% and a specificity of 96% to identify the presence of tumor.
Conclusion: The auto-fluorescent properties of the bipolar cautery tool of the Da Vinci Xi robot can be used for qualitative assessments of tumor presence during fluorescence-guided TORS. Bright fluorescence from the tool relative to surrounding tissue suggests the lack of carcinoma presence, which could confirm the surgeon's complete resection of OPSCC.

#2575 GD2 targeted dual-labeled intraoperative molecular imaging probe for neuroblastoma.

R. E. Sever[1], L. T. Rosenblum[2], **K. C. Stanley**[2], D. M. Menendez[3], W. B. Edwards[3], M. M. Malek[2], G. Kohanbash[1];
[1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Missouri, Columbia, MO

Neuroblastoma (NB) is the most common pediatric extracranial solid tumor, with a 5-year survival rate under 50% for those with high-risk disease. Complete surgical resection is essential for these patients and is associated with improved outcomes. However, NB resection presents significant technical challenges due to encasement of vital structures that must be preserved, as well as remote deposits of disease. The current approach to find and safely resect tumor depends on the surgeon's eyes and hands alone. Fluorescence tracers allow enhanced tumor visualization, but most are not molecularly targeted which leads to poor tumor to background signal. Further, fluorescent signal does not penetrate more than a few millimeters, a limitation that can be overcome by inclusion of a radiotracer. We, therefore, generated and evaluated a dual radio and fluorescent antibody-based probe targeting the GD2 tumor antigen to improve the identification of NB with widely available intraoperative handheld instruments. We generated an intraoperative probe (^{111}In-αGD2-IRDye800CW) with retained affinity and stability. *In vivo*- Nu/j mice were injected with SK-N-BE(2) NB cells. After tumors grew for five weeks, mice were given tail vein injections of the probe. Gamma and optical biodistribution studies were performed to determine the specificity of binding and tumor to background signal four- and six-days post probe injection. Probe uptake was compared to an isotype. Gross dissections and surgeries aimed at improving completeness of resection were performed using a handheld fluorescent camera (SPY-PHI) and a gamma probe (Neoprobe). The handheld gamma probe detected xenografts with great sensitivity (average *in vivo* 818 cps of In^{111} in tumor region versus 34.8 cps in the tail). The fluorescent imaging showed high specific binding to the tumor region. Gamma biodistribution results indicated high accumulation within tumor (13.5 %ID/g) with lower accumulation in blood (3.49 %ID/g) and muscle (0.45 %ID/g). Uptake of the probe greatly exceeded isotype control antibody on days 4 and 6 post-agent injection, for both gamma and optical biodistributions. Initial tumor resection using ^{111}In-DTPA-aGD2-IRDye800CW in an NB bearing mouse identified residual disease left behind when resection was performed using white light alone; the residual disease was then removed, guided by fluorescence imaging. Our dual-labeled probe demonstrated antigen specificity and allowed for the sensitive detection and visualization of NB *in vivo* with widely available intraoperative tools. This targeted probe could provide a means to improve surgical NB resection, by enabling localization of the all regions of tumor using radio-guidance, followed by clear definition of tumor margins with fluorescent signal, to maximize preservation of vital tissues. Ultimately, we believe this approach can improve safety, extent of NB resection, and patient outcomes.

#2576 Radiomic features of intrathoracic lesions can predict the mixed response in non-small cell lung cancer treated with immunotherapy.

M. Yadav[1], J. Lee[2], **P. Kim**[3], M. J. A. Chuchuca[1], T. Um[1], L.-Y. Chung[1], Y. S. Velichko[1], Y. Chae[1];

[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, [2]School of Medicine, Kyungpook National University, Daegu, Korea, Republic of, [3]The University of Texas at Austin, Austin, TX

Background: Although immunotherapy has emerged as a promising treatment for lung cancer, the decision to continue immunotherapy becomes challenging when mixed response (MR) occurs. This study is aimed to evaluate whether radiomic features from pre-treatment intrathoracic images can predict MR.
Methods: 127 consecutive patients with NSCLC who received first line systemic treatment containing immunotherapy were included in this study. Chest CT scans were obtained at baseline and 1-3 times from 11 different CT scanners and harmonization method was applied to minimize scanner-related bias. The durable response of intrathoracic lesions (n=266) at least 24 weeks was evaluated based on RECIST 1.1 and irRECIST. MR was defined as the simultaneous presence of at least one lesion that increased and decreased in a single patient during immunotherapy and two different criteria of MR for the change of tumor lesions were applied: Definition-A (MR-A), Δ [baseline - first follow-up] ≥ 5 mm; Definition-B (MR-B), any change of Δ [baseline - first follow-up]. All intrathoracic lesions were identified and segmented by four different physicians. Radiomic features, including morphological, intensity, GLCM, GLRLM, GLSZM, and NGTDM, were extracted using LIFEX software (IMIV/CEA, Orsay, France). Confusion matrix was used to assess tumor responses, and area under the curve (AUC) for intrathoracic lesions was calculated.
Results: Tumor responses based on irRECIST were CR (n=1, 0.8%), PR (n=33, 26.0%), SD (n=55, 43.3%), and PD (n=39, 30.7%). There were 10 cases (7.9%) of MR-A and 25 cases (19.7%) of MR-B. While the median progression-free survival (PFS) and overall survival (OS) in MR-A group were 22.9 (range, 0.5-50.6) and 23.5 (range, 1.1-42.2) months, those in MR-B group were 2.0 (range, 0.5-50.6) and 3.3 (range, 0.7-49.0) months respectively. While the overall sensitivity (SN) and specificity (SP) for MR-A in intrathoracic lesions were 0.55 and 0.87, those for MR-B were 0.52 and 0.71, respectively. The AUC for MR-A and MR-B were 0.71 and 0.62 respectively, and the AUC for durable response was 0.56. In the SD group, median PFS and OS were 3.3 (1.4-18.9) and 6.1 (4.8-26.2) in the MR-A group and 9.7 (0.7-18.9) and 23.9 (0.7-26.2) respectively in the MR-B group. Median PFS and OS were 18.2 (0.5-65.2) and 23.9 (0.9-55.3) respectively in the non-MR-A group and 18.2 (0.5-65.2) and 23.9 (0.9-55.3) respectively in the non-MR-B group. In the PD group, median PFS and OS were 23.5 (0.5-41.3) and 24.7 (1.1-42.2) respectively in the MR-A group and 5.1 (0.5-41.3) and 11.5 (1.1-49.0) respectively in the MR-B group. Median PFS and OS were 20.3 (0.7-71.4) and 37.1 (1.0-72.9) respectively in the non-MR-A group and 20.3 (0.7-71.4) and 37.1 (1.0-72.9) respectively in the non-MR-B group.
Conclusion: The radiomic features in NSCLC patients who received immunotherapy may help predict MR in NSCLC patients treated with immunotherapy.

#2577 Analyzing specific and nonspecific tissue uptake of antibodies by SPECT imaging and non-linear compartmental modeling.

N. Cho, P. Spinosa, D. Mandikian, G. Del Rosario, S.-F. Yu, J. Ho, G. Ferl, C. A. Boswell;
Genentech, South San Francisco, CA

Understanding the mechanisms driving specific target engagement versus off-target nonspecific cellular uptake of antibodies can help inform design and/or delivery strategies that maximize therapeutic indices. Receptor binding kinetics, rates of receptor-mediated internalization and nonspecific pinocytosis are often measured through *in vitro* cell culture models, but there have been fewer efforts to collectively measure these cellular parameters *in vivo*. Single photon emission computed tomography (SPECT) imaging is a powerful method of estimating these parameters by quantifying both free/bound (intact) and internalized/catabolized antibody using non-residualizing halogen labels and residualizing radiometal-chelates, respectively. Modeling longitudinal *in vivo* imaging data of non-residualizing antibody can inform receptor occupancy (RO), while residualizing tracer kinetics can provide additional insights into catabolism due to pinocytosis and receptor-mediated internalization in the intracellular spaces. Here, we describe SPECT imaging of tumor-targeting trastuzumab (anti-HER2) and non-targeting anti-glycoprotein D (anti-gD) antibody, each labeled with non-residualizing ([^{125}I]SIB) and residualizing radiometal-chelate (^{111}In-DOTA) radionuclides in HER2^{+} xenograft-bearing mice. A non-linear compartmental model was fitted to SPECT imaging data to characterize RO of 10 mg/kg of anti-HER2 out to 7 days post dosing as well as to estimate rate constants of pinocytosis and receptor-mediated internalization of anti-HER2 in tumor. Longitudinal SPECT imaging demonstrated statistically significant differences in tumor drug exposure between ^{125}I- and ^{111}In-labeled anti-HER2 relative to anti-gD ($p < 0.01$). Tracer kinetics of anti-HER2 and associated RO simulations in tumor showed rapid extravasation from blood to tumor with peak RO of 25% at 13 hours post administration followed by a reduction in RO, reaching ~10% by day 7. Simulations for free, bound and catabolized tracer kinetics from our fitted model showed that anti-HER2 in the tumor interstitium was primarily receptor-bound with minimal pinocytosis of unbound anti-HER2 as well as gradual receptor-mediated catabolism, reaching a peak concentration of 113 µg/mL 7 days post dosing. Rate constants of nonspecific pinocytosis and HER2-mediated receptor internalization were estimated to be 0.0145 and 0.036 hours^{-1}, respectively. Our model allowed us to successfully capture anti-HER2 antibody receptor binding and specific and nonspecific internalization over time *in vivo*. These data and analyses demonstrate the power of SPECT imaging using both non-residualizing and residualizing radiolabels combined with compartmental modeling to better characterize the different biological states (free, bound, and catabolized) of antibody within interstitial and intracellular compartments.

#2579 A nectin-4 PET radiotracer for pharmacodynamic evaluation of enfortumab vedotin (EV) therapy in urothelial carcinoma.

A. Mishra, A. K. Sharma, K. Gupta, B. A. Johnson III, D. J. McConkey, J. Hoffman-Censits, S. Nimmagadda;
Johns Hopkins University, Baltimore, MD

Introduction: Enfortumab vedotin (EV), an antibody-drug conjugate targeting nectin-4, offers hope for urothelial carcinoma patients (UC) but prolonged use leads to treatment-related toxicities often necessitating dose adjustments. How EV engages nectin-4 at the tumor and its relevance to efficacy is unknown. To understand the pharmacodynamics (target engagement) of EV at the tumor across FDA approved dosing levels, we developed a nectin-4 specific peptide-based radiotracer, [^{68}Ga]AJ647, for positron emission tomography (PET) imaging.

Methods: Six UC cell lines of luminal (HT-1376, UC-14, RT-112) and basal (UC-9, SCaBER, T24) morphological type were selected for in vitro and in vivo testing of [^{68}Ga]AJ647 and nectin-4 target engagement by EV. Cell uptake and competitive binding assays were conducted to test [^{68}Ga]AJ647 specificity for nectin-4 in the presence or absence of EV. Flow cytometry derived receptor density was used to correlate [^{68}Ga]AJ647 uptake in cells with nectin-4 expression. Pharmacokinetics, biodistribution and specificity of [^{68}Ga]AJ647 for nectin-4 expression was evaluated in six xenograft models by PET imaging and biodistribution studies. Target engagement by EV was quantified by measuring unoccupied nectin-4 levels by [^{68}Ga]AJ647-PET in HT-1376 xenografts at different doses (15, 9, and 6 mg/kg) and time (1, 3, and 6 days).

Results: [^{68}Ga]AJ647 was generated in 20-30% radiochemical yield with >95% purity. In vitro assays showed distinctive uptake in cell lines (HT-1376 > UC-14 > RT-112; UC-9 > SCaBER > T24) that correlated with nectin-4 density (R^2=0.85). PET and biodistribution studies showed tractable pharmacokinetics of [^{68}Ga]AJ647 enabling high contrast images in 60 min and exhibiting nectin-4 dependent uptake in all the six xenografts. Uptake of [^{68}Ga]AJ647 in UC cells reduced in a dose dependent manner in the presence of EV, indicating that [^{68}Ga]AJ647 measures unoccupied nectin-4, and paving the way for EV target engagement evaluation. For target engagement evaluation, [^{68}Ga]AJ647 accumulation in HT-1376 tumors in saline treated mice was assumed as 100% unoccupied nectin-4 levels. In mice treated with EV for 24 hrs (n=3-5), unoccupied nectin-4 levels were 21.1±11.6, 23.2±14.5, and 24.3±18.8 for 15, 9, and 6 mg/kg doses, respectively. Whereas on day 6, unoccupied nectin-4 levels showed significant differences at 29.5±15.8, 64.2±21.0, and 89.5±18.9 for 15, 9, and 6 mg/kg dose, respectively. These data indicate that FDA approved doses of EV show higher target engagement at 24 h but a dramatic reduction at lower doses over time.

Conclusion: [^{68}Ga]AJ647-PET quantifies variable nectin-4 expression in tumors. Furthermore, [^{68}Ga]AJ647-PET quantifies EV therapy induced pharmacodynamics at the tumor. Such real-time ADC target engagement assessment could inform patient selection and dosing strategies to enhance efficacy and minimize toxicities.

#2580 Targeting chromatin in ovarian cancer stem cells.

Y. Wang[1], J. Frederick[2], Y. Zhang[1], E. T. Bartom[1], G. Bauer[2], E. Tanner[1], V. Backman[2], D. Matei[1];
[1]Northwestern University - Chicago, Chicago, IL, [2]Northwestern University - Chicago, Evanston, IL

The dynamic organization of chromatin, governed by epigenetic modifiers, critically regulates cell plasticity and determines cell fate in both normal and malignant stem cells. We hypothesized that chromatin architecture plays a role in regulating transcriptional heterogeneity in ovarian cancer stem cells (OCSCs) to maintain stemness and chemoresistance. PWS microscopy showed that ALDH+ OCSCs derived displayed higher nuclear fractal dimension D signals ($P<0.05$) than ALDH- non-OCSCs, indicating that chromatin in OCSCs possesses higher packing compared to non-OCSCs. Cut & TAG Sequencing showed that of the 3606-histone repressive H3K27m3 enriched regions ($P<0.05$, fold change >2), 3208 were detected in OCSCs while 398 peaks were present in non-OCSCs, consistent with findings supporting high D features in OCSCs. The active mark H3K4me3 was enriched at the promoter of stemness-associated genes, including SOX2, ALDH1A3, and FZD7 in OCSCs; and the repressive histone mark H3K27me3 was enriched at the promoter of the epithelial cell marker CDH1 in OCSCs. These results support that the chromatin of OCSCs contains open genomic regions, corresponding to stemness-associated genes and repressed regions associated with genes related to differentiation. RNA sequencing indicated that the coefficient of variance (COV) reflecting transcriptional heterogeneity in OCSCs was higher than in non-OCSCs at baseline. In response to platinum, genes with low baseline expression in OCSCs were most upregulated, supporting increased transcriptional heterogeneity in response to chemotherapy. Inhibitors of epigenetic modifiers (DNMTi, EZH2i, and Dot1Li) induced chromatin re-organization in OCSCs and promoted OCSCs transition toward differentiation, supporting that stemness-associated chromatin structure is targetable. We demonstrated that a Dot1L inhibitor (Dot1Li) targeted OCSCs by decreasing chromatin packing D, resulting in decreased transcriptional heterogeneity. In conclusion, OCSCs harbor highly packed chromatin, contributing to chemoresistance and cell plasticity. Epigenetic modifiers (such as Dot1Li) inhibit stemness by regulating chromatin organization and transcriptional malleability.

#2581 Measuring interstitial fluid flow to predict and optimize spatial CAR-T dynamics in the clinic.

R. T. Woodall[1], C. Esparza[2], C. C. Brown[1], J. M. Munson[2], R. C. Rockne[1];
[1]Beckman Research Institute of The City of Hope, Duarte, CA, [2]Fralin Biomedical Research Institute, Roanoke, VA

Interstitial fluid flow dynamics in brain tumors are known to be an important indicator for tumor invasion into healthy tissue, as cancerous cells follow the interstitial flow towards tumor-stimulating chemokines. These flow gradients not only carry tumor-stimulating chemokines, but also carry cytokines secreted by immune response. CAR-T cells are known to also depend highly on the cytokines present in the CSF and serum. For these reasons, we have developed a novel method, Localized Convolutional Function Regression (LCFR) for measuring interstitial fluid flow, perfusion, and diffusion using dynamic contrast-enhanced MRI. LCFR works by applying the known physics of contrast agent transport, and fitting the observed contrast agent dynamics to the known physics. From LCFR, we can recover standard Tofts-Kety perfusion dynamics, including Ktrans and Vp, and also recover the underlying flow field and diffusivity. These new measurements allow for the prediction of where tumors invade, and allow for us to model how CAR-T cells move within a tumor. In a case study, we model the spatial distribution of CAR-T cells and glioblastoma cells over time, assuming that the fluid velocity field drives CAR-T spread throughout the tumor. Using multiple delivery locations, we identify the optimal catheter placement to optimally distribute CAR-T cells through the tumor, improving the 50% kill rate of simulated tumor cells by over 25% from a naive delivery strategy. Further, we collect longitudinal cytokine levels from patients undergoing CAR-T therapy, allowing us to understand how interstitial flow, CAR-T dynamics, and tumor dynamics interact with each other. We report a case study wherein a patient is longitudinally followed through their treatment with CAR-Ts. Perfusion imaging reveals that the patient experienced a steady increase in perfusion and decrease in fluid leakage into surrounding tissue. VEGF and IL12 levels are observed to increase as tumor volume increases. To better understand this patient's dynamics, we use the fluid velocity field measured by LCFR to simulate the development of CAR-T cells within the tumor, using the cytokine profile as a surrogate measurement of CAR-T population. These results demonstrate the importance of fluid flow and cytokines in understanding how brain tumors develop and respond to treatment.

#2582 Intra- and peri-tumoral radiomic features are predictive of pathologic response to multiple neoadjuvant therapy regimen in rectal cancers via pre-treatment MRI.

Leo Bao[1], **Thomas DeSilvio**[1], Benjamin N. Parker[1], Mohsen Hariri[1], Prathyush Chirra[1], Murad Labbad[1], Stephen Tang[1], Gregory M. O'Connor[2], Emily Steinhagen[2], Jennifer L. Miller-Ocuin[2], Amit Gupta[2], Eric L. Marderstein[3], Aaron Carroll[4], Marka Crittenden[4], Michael J. Gough[4], Smitha Krishnamurthi[5], Kristina H. Young[4], Satish E. Viswanath[1]

[1]Case Western Reserve University, Cleveland, OH,[2]University Hospitals Cleveland Medical Center, Cleveland, OH,[3]Louis Stokes Cleveland Veterans Affairs Medical Center, Cleveland, OH,[4]Providence Cancer Institute, Portland, OR,[5]Cleveland Clinic Foundation, Cleveland, OH

Introduction: Rectal cancers undergo neoadjuvant chemoradiation prior to resection, with increasing evidence that neoadjuvant chemotherapy or immunotherapy can boost clinical or pathologic response rates. However, baseline clinical tumor staging and carcinoembryonic antigen levels are limited for identifying which patients will most benefit from a multimodal neoadjuvant regimen, and which will not. We evaluated whether radiomics (computational features from radiographic images) from pretreatment MRI could identify which rectal cancer patients will achieve clinical or pathologic response to different neoadjuvant treatment regimens.

Methods: MRI scans were retrospectively obtained from 3 different institutions for rectal cancer patients who had either undergone neoadjuvant chemoradiation or an experimental immunotherapy + chemoradiation. After pre-processing all MRI scans, tumor was manually delineated with an automated annotation of a 10 mm peritumor region. 916 radiomic features were extracted from two planes of acquisition (axial, coronal) and two ROIs (tumor, peritumor). 5 top-ranked radiomic features were identified from each region and plane via multi-stage mutual information feature selection to train a linear discriminant machine classifier to assign a predicted likelihood of achieving complete response to each patient. Model performance was validated via ROC analysis against response groups defined via (i) tumor regression grade indicating no tumor present on surgical pathology, and (ii) 1-year clinical complete response for patients who underwent non-operative management. Clinical variables (CEA, clinical stage) were statistically compared between response groups.

Results: Training cohort comprised 64 patients who underwent chemoradiation alone (2 institutions, median age 61 yrs, M:F:MtF = 36:27:1). Validation cohort included 37 patients who underwent experimental TGFß inhibitor therapy prior to chemotherapy + chemoradiation (1 institution, median age 51 yrs, M:F = 25:12). Area under the ROC curve for multi-plane tumor+peritumor radiomic features (0.765 ± 0.054) was significantly higher for distinguishing complete response vs non/partial response compared to tumor (AUC = 0.635 ± 0.057, $p < 0.0001$) or peritumor (AUC = 0.612 ± 0.064, $p < 0.0001$). In holdout validation, performance was maintained with AUCs of 0.742 (tumor) 0.596 (peritumor), and 0.700 (all), respectively. Baseline CEA levels (p=0.3385) and cT stage (p=0.3386) were found to lack statistical significance as a predictor of response.

Conclusion: Radiomic features from tumor and peritumor regions on pre-treatment MRI scans in rectal cancer patients may enable robust and accurate identification of pathologic or near-complete response after multiple neoadjuvant treatment regimen, while outperforming baseline clinical variables.

#2583 [^{68}Ga]Ga-RYZ-GPC3: A glypican-3 targeted diagnostic radiopharmaceutical for hepatocellular carcinoma molecular imaging.

A. J. Braat[1], A. J. Poot[1], C. Lapa[2], M. G. Lam[1], W. A. Weber[3], A. Karmann[4], Y. Yuan[4], J. Rearden[4], K. Song[4], R. A. Bundschuh[2];
[1]UMC Utrecht, Utrecht, Netherlands, [2]University Augsburg, Augsburg, Germany, [3]Technische Universitat Munchen, Munchen, Germany, [4]Rayzebio, San Diego, CA

Introduction & Purpose: Hepatocellular carcinoma (HCC) is the most common type of liver cancer. To date, the imaging of HCC is difficult, insufficient for disease staging and barely improved over the past decades. Glypican-3 (GPC3) is a cell-surface receptor highly expressed by HCC and of diagnostic and prognostic value. GPC3 has been reported as potential target for diagnosis and treatment of HCC for nuclear theranostics. RYZ-GPC3 is a DOTA modified macrocyclic peptide with high affinity for GPC3, which may allow PET imaging or nuclear therapy. Here we report the first clinical results of [^{68}Ga]Ga-RYZ-GPC3 PET-imaging in patients with known or suspected HCC.

Methods: [^{68}Ga]Ga-RYZ-GPC3 was obtained upon labeling the peptide precursor with ^{68}Ga from a ^{68}Ge/^{68}Ga-generator and heating till 90^{0}C for 10 min followed by sterile filtration. After administration of 2 MBq/kg [^{68}Ga]Ga-RYZ-GPC3, a 60 min dynamic PET scan was acquired or multiple static PET/CT were acquired at 20 min, 1, 2 and 4 hours. Besides qualitative interpretation, standardized uptake values (SUV_{max}, SUV_{mean}) were measured in various compartments; HCC lesions, healthy liver (HL), kidneys, blood pool activity in the left ventricle (BP) and gastric fundus. Additionally, tumor-to-healthy liver ratios (TLR) were calculated: $SUV_{mean,HCC}$ divided by $SUV_{mean,HL}$.

Results: Radiolabeling to obtain [^{68}Ga]Ga-RYZ-GPC3 was near quantitative, making the production highly reliable. Eleven patients (4 patients dynamic; 7 patients static protocol) were scanned. One patient did not have an HCC. Another patient had a concurrent metastatic prostate adenocarcinoma, which did not show uptake, both qualitatively and quantitatively. All HCC lesions showed uptake in qualitative assessment, even in immunohistochemistry confirmed GPC3-negative HCC lesions (3 lesions). In 23 HCC lesions, including the aforementioned GPC3-negative lesions, mean SUV_{max} was 17.9 (range 2.7-95.3) and mean SUV_{mean} was 10.2 (range 1.0-49.2) at 60 minutes. Uptake in HL and BP decrease over time and become negligible 45 minutes after administration (SUV_{mean} ≤1.5). The opposite occurs for HCC and TLR, which continuously increase up to 4 hours after administration (TLR 4.4 to 19.2, at 18 minutes and 4 hours respectively). In individual lesion analysis, TLR was the highest at 60 or 120 minutes post-injection scans. Uptake in the gastric fundus, gradually increases in the first hour, and decreases gradually afterwards (SUV_{mean} from 4.0 to 12.7, back to 10.1).

Conclusions: [^{68}Ga]Ga-RYZ-GPC3 is the first peptide based PET tracer that allows the high quality molecular imaging of HCC. Thereby [^{68}Ga]Ga-RYZ-GPC3 is suitable for the selective diagnosis of HCC. In addition, based on the biodistribution and in vivo dynamics on these diagnostic images, RYZ-GPC3 is very likely to hold therapeutic potential upon labeling with a therapeutic isotope (e.g ^{177}Lu or ^{225}Ac).

#2584 Decoding colon cancer recurrence: Unveiling accurate predictions with attention-guided deep neural networks on histopathological whole slide images.

Mohammad K. Alexanderani, Mohamed Omar, Matthew Greenblatt, Luigi Marchionni

Weill Cornell Medicine, New York, NY

Background: Up to 40% of colon cancer patients are at high risk of cancer recurrence, yet accurate and timely prediction tools are lacking. Leveraging whole slide images (WSIs) and deep learning models, we aimed to develop precise algorithm for prediction of colon cancer recurrence. Thus, enables risk stratification for optimized therapeutic interventions and improved health outcomes.

Design: We designed an attention-based deep learning model for predicting colon cancer recurrence on paraffin-embedded, hematoxylin and eosin-stained colon tissue biopsies of digital slides. The WSIs were downloaded from the TCGA dataset, and preprocessed for color normalization, tissue segmentation, tilling, and histopathological features extraction. The entire dataset was then labeled based on cancer recurrence status, and divided into training (70%), validation (15%), and testing sets (15%). The model's performance was then evaluated by standard evaluation metrics, including receiver operating characteristic Area Under the Curve (AUC) and accuracy, on the training, validation, and testing datasets, where interpretability attention heatmaps were applied to gain insights into specific histological features and patterns involved in the model's decision-making process. The study is supported by the NIH-NCI-T32 for Next Generation Pathologists Program at our institution.

Results: A total of 350 WSIs were included and labeled into two classes: post-therapeutic colon cancer recurrence and no recurrence. The tissue segmentation process involved converting RGB images to HSV color space, applying a median blur filter (kernel size: 7), and performing thresholding using Otsu's method. The extracted features were utilized to train and construct a Clustering-constrained Attention Multiple Instance Learning (CLAM) model. The model demonstrated consistent performance across the validation and testing datasets, achieving an AUC of 0.85 with an accuracy of 0.83 on the validation set, and an identical AUC of 0.85 with an accuracy of 0.83 on the testing set, indicating the model's robust ability to identify patients at risk of cancer recurrence.

Conclusion: The study demonstrates the strong performance of our deep learning model in accurately identifying patients at risk for colon cancer recurrence based on H&E WSIs. This capability paves the way for optimizing therapeutic interventions and implementing effective surveillance strategies. Consequently, highlighting the crucial role of pathologists in collaborating with the oncologist for optimizing the management of colon cancer care in the era of personalized medicine.

#2585 First in human study with a novel peptide binder to glypican-3, demonstrates high specificity as a PET imaging agent in patients with hepatocellular carcinoma.

C. Bal[1], S. Ballal[1], K. Kallur[2], A. Karmann[3], Y. Yuan[3], J. Rearden[3], K. Shah[3], C. Lorenz[3], S. Moran[3], K. Song[3], I. Sen[4];
[1]All India Institute of Medical Sciences, New Dehli, India, [2]HCG, Bangalore, India, [3]RayzeBio, San Diego, CA, [4]Fortis, New Dehli, India

Introduction: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy. The American Association for the Study of Liver Disease recommends surveillance for high-risk individuals with abdominal ultrasound, triple phase contrast CT or MRI. However, these imaging techniques have limited sensitivity in classifying lesions smaller than 2 centimeters. The use of [^{18}F]FDG Positron Emission Tomography (PET) is constrained due to insufficient uptake by HCC lesions over background liver uptake. Hence, there is an urgent need for more precise radiotracers for HCC. This study introduces the development of a novel radiotracer that binds to glypican-3 (GPC3), a cell membrane-anchored oncofetal protein overexpressed in HCC with minimal normal tissue expression.

Methods: [^{68}Ga]Ga-RYZ-GPC3 is composed of a small macrocyclic peptide binder with high affinity to GPC3 linked with a tetraxetan moiety capable of chelating a variety of radioisotopes including positron-emitting ^{68}Ga and other radiometals. The unlabeled binder to GPC3 was synthesized by the sponsor and provided to three imaging centers in India as part of investigator-initiated trials reviewed and approved by each site's institutional review board and ethics committee. Labeling with ^{68}Ga and quality checks of the product was performed locally at each center. Patients with high clinical suspicion or with confirmed HCC who gave informed consent received injections of 1.5-5.5 mCi of [^{68}Ga]Ga-RYZ-GPC3 and underwent PET-CT scanning at predetermined intervals. Some patients underwent companion [^{18}F]FDG PET-CT scans in accordance with local guidelines.

Results: A total of 64 patients underwent [^{68}Ga]Ga-RYZ-GPC3 PET-CT scans. The median age within the cohort was 61 (41-83), 22% were female. Liver cirrhosis was present in 72% of patients, attributed to hepatitis B, hepatitis C or NASH in 17%, 13% and 20% of cases. Notably, 92% of patients exhibited at least one positive lesion on [^{68}Ga]Ga-RYZ-GPC3 scans. The median SUVmax of GPC3-avid liver lesions was 15.5 (range 1.1 to 137.0) while the median liver SUVmean was 1.6 (0.3-7.9). Physiologic uptake was predominantly observed in the kidneys, the primary route of clearance, with a median SUVmean of 10.9 (2.2-20.7). Additionally, 20 patients underwent [^{18}F]FDG PET-CT scan for comparison. The median SUVmax of lesions on ^{68}Ga-RYZ-GPC3 vs [^{18}F]FDG PET was 11.0 (1.1-137.0) vs 3.8 (1.2-12.2).

Conclusion: Early human imaging results in patients with HCC indicate that [^{68}Ga]Ga-RYZ-GPC3 has high tumor lesion specificity compared to normal liverand demonstrates the potential of [^{68}Ga]Ga-RYZ-GPC3 to improve detection of HCC over conventional [^{18}F]FDG PET-CT. In addition, the binder could be complexed with a therapeutic radioisotope as a novel targeted therapeutic option for HCC. Further investigation of this first-in-class binder to HCC is warranted.

#2586 Heterogeneous enhancement pattern of Gd-EOB-DTPA-enhanced MRI predicts vessels encapsulating tumor clusters (VETC)-positive hepatocellular carcinoma.

K. Matsuda[1], A. Ueno[2], J. Tsuzaki[1], Y. Kurebayashi[1], K. Yamazaki[1], M. Tamura[1], M. Jinzaki[1], Y. Abe[1], Y. Hasegawa[1], M. Kitago[1], M. Sakamoto[1];
[1]Keio University School of Medicine, Tokyo, Japan, [2]Keio University Hospital, Tokyo, Japan

Background: Vessels encapsulating tumor clusters (VETC) pattern is known as a distinct hepatocellular carcinoma (HCC) vascularization that correlates with angiogenic status, lower lymphocytic infiltration, and higher recurrence rates. Despite the molecular and clinical significance of VETC$^{\pm}$ HCC, its characteristics on radiological imaging have not been clearly elucidated. We aimed to characterize VETC$^{\pm}$ HCC on gadolinium-ethoxybenzyl-diethylene-triamine-pentaacetic acid-enhanced MR imaging (EOB-MRI) and provide pathological evidence.

Method: We studied 204 surgically resected HCCs with preoperative EOB-MRI. VETC$^{\pm}$ HCC was defined as ≥1% VETC occupied area evaluated by CD34 immunostaining. The visual pattern classification of the arterial and hepatobiliary phase images is shown in Table 1. To investigate the relationships between imaging patterns and VETC$^{\pm}$ HCC, we evaluated immunohistochemical expression of h-caldesmon$^{\pm}$ arterial vessel density (AVD) and OATP1B3.

Result: In the arterial phase, VETC$^{\pm}$ HCCs showed heterogeneous hypervascular pattern and homogeneous hypovascular pattern. Accordingly, VETC$^{\pm}$ HCCs had lower AVD than VETC^{-} HCCs, as well, VETC regions had lower AVD than other regions within the same tumor. In the hepatobiliary phase, VETC$^{\pm}$ HCCs were observed more frequently in heterogeneous hyperintense pattern (36%) compared to homogeneous hyperintense pattern (5%). Hyperintensity in the hepatobiliary phase was correlated with high expression of OATP1B3. Among tumors with high OATP1B3 expression, VETC regions showed decreased expression of OATP1B3.

Conclusion: VETC$^{\pm}$ HCC showed reduced vascularity and heterogeneous hyperintensity in the hepatobiliary phase of EOB-MRI. These findings were explained by locally reduced AVD and downregulated OATP1B3 expression in the VETC regions. The potency to predict VETC$^{\pm}$ HCCs by radiological findings could improve HCC treatment strategy.

Relationship between enhancement patterns and VETC+ HCC in arterial and hepatobiliary phase

Arterial phase					
	Hypervascular/Homogeneous	Hypervascular/Heterogeneous	Hypovascular/Homogeneous	Hypovascular/Heterogeneous	Rim-like
Number of tumors	68	103	8	15	11
VETC^{+} HCC (%)	6 (9%)	32 (31%)	3 (37%)	3 (20%)	1 (9%)
Hepatobiliary phase					
	Hyperintense/Homogeneous	Hyperintense/Heterogeneous	Hypointense/Homogeneous	Hypointense/Heterogeneous	
Number of tumors	21	39	115	31	
VETC^{+} HCC (%)	1 (5%)	14 (36%)	23 (20%)	8 (26%)	

#2587 Evaluating the potential of radiomics features to predict outcome to an antibody-drug conjugate therapy in non-small cell lung cancer patients.

A. W. Chen[1], **L. K. Brady**[2], E. A. Cohen[1], W. C. Mankowski[1], L. Roshkovan[1], M. Qutaish[2], S. Katz[1], P. G. Castro[3], N. Pencheva[3], M. Jure-Kunkel[3], B. W. Higgs[2], D. Kontos[1];

[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]Genmab, Princeton, NJ, [3]Genmab B.V., Utrecht, Netherlands

This study evaluated radiomics, a non-invasive biomarker, for assessment of tumor heterogeneity in non-small cell lung cancer (NSCLC) patients treated with an AXL-targeting antibody-drug conjugate (ADC), enapotamab vedotin (EnaV), through analyzing baseline and post-treatment radiomic features from CT images for predicting outcome.

Clinical development of EnaV was discontinued in 2020 due to low response rates unimproved by dose optimization and/or predictive biomarkers. Study data included CT images, target expression and clinical data from 77 advanced NSCLC patients treated at 1.0 mg/kg (3Q4W), 1.8 mg/kg (Q3W), or 2.2 mg/kg EnaV (1Q3W) in the first in human phase I/II study assessing safety and preliminary efficacy of EnaV (NCT02988817). Radiologist-segmented tumors were examined using the cancer imaging phenomics tooklit CaPTk[1], deriving 225 radiomic features from 77 baseline and 50 Cycle 2 post-treatment CT images. Batch effects were balanced using nested ComBat[2], and radiomic feature dimensionality was reduced in two stages: clustering features with ≥80% similarity followed by principal component analysis (PCA). Radiomic PC1 was utilized in statistical models to assess overall and progression-free survival (OS, PFS), overall response rate (ORR), and disease control rate (DCR). Both baseline and delta radiomic PC1 were evaluated for correlation with biomarker and clinical activity, independently and with soluble or tumoral AXL expression.

Baseline radiomic PC1 significantly predicted DCR: confirmed (p=0.03), and unconfirmed (p=0.03). Baseline tumor membrane AXL predicted ORR for this NSCLC subset: confirmed (p=0.03) or unconfirmed (p=0.02). Delta analysis showed delta PC1 predicted unconfirmed (p=0.03) and confirmed (p=0.03) DCR and remained predictive for DCR with soluble AXL (p=0.04). No association was found between baseline and delta radiomics with OS or PFS.

Baseline and delta radiomic signatures showed potential in predicting NSCLC response. Preliminary findings suggest that radiomics combined with target expression predicted DCR, an early clinical activity indicator, although they did not predict OS or PFS. These outcomes pertain to a NSCLC subset and might not apply to other tumor types. Tumoral AXL expression did not linearly correlate with EnaV activity in a patient-derived soft tissue sarcoma model[3], possibly due to AXL expression in both tumor cells and myeloid-derived suppressor cells, or the presence of tumor-intrinsic MMAE resistance[4], implying the AXL expression and EnaV activity relationship is contingent on the tumor microenvironment[5]. Further validation in larger cohorts is planned.

#2588 Bioengineering of site-specific antibody labeling from basic research to spatial omics platforms.

K. Tao[1], M. J. Rames[1], M. Dai[1], G. Sener[1], S. Olson[1], S. Ranganathan[1], S. Ozdemir[1], A. Oken[2], M. Brasino[1], R. Armstrong[1], Y.-J. Chiu[1], E. Eksi[1], B. Branchaud[1], S. Esener[1];

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]Oregon Health & Science University, Portland, OR

Over the last few years, spatial multi-omics platforms have emerged as a powerful tool for characterizing cancer biology in multiple dimensions. Notably, these systems typically rely on multiplex immunolabeling. Conventionally, multiplexing is accomplished through carefully selecting primary antibodies from different animal species, and in combination with their corresponding polyclonal secondary antibodies. However, given the practical complication related to the species availability of primary antibodies, the multiplexing labeling is still under constraint due to the necessity for matched secondary species labels and the availability. For decades, non-specific labeling of primary antibodies through amine- or thiol-reactive chemistries was widely performed. Evolving research and commercial products have sought to overcome this antibody-based multiplexing limitations by developing enzymatic reaction-directed chemical reaction or antibody targeting proteins that could contain affinity to the Fc or Fab regions of antibodies. However, these methods mentioned above have substantive limitations and side-effects on affinity, conjugation number, buffer incompatibilities, storage incompatibilities, insufficient conjugation, and uncontrolled stoichiometric labeling. Herein, we introduce an efficient, sustainable, reproducible site-specific antibody covalent labeling strategy through engineering anti-IgG secondary nanobodies. These infer the stability, high-affinity of species specific and easy-to-produce IgG binders with the permanence of controlled activation for proximity-driven intermolecular covalent conjugation, with a promise for efficient multiplexity. This labeling technology addresses antibody labeling challenges through currently available approaches, and would substantially enhance multiplexity in a wide variety of research and clinical settings.

#2589 Novel workflow to generate natural killer cell sensitivity prediction model based on the epithelial mesenchymal transition related reprogramming at a single cell resolution.

Y. Zou, H. Ball, C. Harris, N. Ramnath, V. Keshamouni, S. Nagrath;
University of Michigan, Ann Arbor, MI

Single cell technology allows us to examine cell heterogeneity and identify rare cell populations; however, the high cost of single cell RNAseq limits its adoption into clinical and research environments. As an inexpensive alternative, immunofluorescent assays analyzing cell morphologies have been used in high content screening to examine cell phenotype and response to external stresses. Natural Killer cells (NK) are the bodies first line of defense and gained traction as a potential target in treating cancer. A study showed that cancer cells undergoing the process epithelial mesenchymal transition (EMT) increase their vulnerability to NK mediated cytotoxicity. We hypothesize that the EM morphology change can be correlated with NK sensitivity. Our goal is to develop an image-based, cost-effective, and efficient workflow capable of extracting cancer cell morphological features to predict its NK sensitivity at the single-cell level. To optimize this workflow, we use A549 cell line cells treated with transforming growth factor- β (TGF-β) as a representative models of cells with various EM phenotypes as NK sensitivities. We utilized a Cell Painting inspired novel image based live cell cytotoxicity assay. To capture cell morphological features, we optimized an organelle specific and live cell compatible staining panel that targets the nucleus, nucleic acid, cell membrane, F-actin, and mitochondria. The cell viability is assessed by Propidium Iodide, which stains dead cell nuclei. Our image analysis pipeline can extract the morphological features and track the cells of interest during the experiment and assess their viability. Subsequently, the morphology and viability data will be processed by a classification algorithm that could discern morphological features of cancer cells that indicate high NK vulnerability. We started with treating A549 cells with 5ng/mL TGF-β for 0, 24, 48, and 72 hours, and successfully applied the organelle staining panel. We observed distinct cell morphologies at each timepoint of TGF-β treatment, with cells shifting from a cobblestone (no TGF-β) to a spindle-like (72 hours TGF-β) morphology. Notably, the F-actin signal was significantly overexpressed in the 72 hours TGF-β treated A549 cells. A CellProfiler based preliminary image analysis pipeline was established for cell segmentation, cell features extraction, and cell viability tracking with quality control filters. Further optimization for cell segmentation, viability tracking, and classification algorithms will be needed to enhance the robustness of the workflow. Our established workflow demonstrates the feasibility of live cell functional assay with organelle staining. This workflow could be adopted to correlate and predict single tumor cell susceptibility to cytotoxic immune cells, with the goal of developing a therapeutic index.

#2590 Automating 6-plex chromogenic multiplexing with BOND RX.

D. Talia, S. Lindsay, S. Ketting, R. Williamson, D. Cockfield;
Leica Biosystems, Deer Park, IL

Multiplex staining using a sequential approach provides a means of visualizing multiple targets in a single biopsy section, further evaluation paired with digital imaging provides a deeper analysis into the spatial relationship at a cellular level. Leica Biosystems enables researchers to complete proof of concept for sequential multiplex staining methods, on board the BOND RX system. Thus, paired with a compatible reagent workflow and a digital slide imaging offering (Aperio GT 450/Aperio AT2) enhances the possibilities for analysis. As with any assay there is a requirement for user optimization, in particular, marker/chromogen layer selection and the pertinent use of an elution step. Such elution step is specifically important within a sequential stain utilizing the same detection reagents on subsequent layers. The results from the multiple staining rounds show a successful 6-plex fully automated stain, possible without the removal and reapplication of the slide onto the BOND system between staining layers. The marker combinations chosen demonstrate compatibility of different host species (Rabbit & Mouse), cellular compartments and isotypes which are provided by Leica Biosystems as BOND Ready to Use reagents. Overall, chromogenic multiplexing provides a stained image which enables color separation, due to the assignment of each chromogen to a marker with an individual cell type and cellular compartment. Finally, the process outlined avoids the risk of signal quenching commonly associated with fluorescent offerings and negates the requirement for specialized equipment due to the enablement of brightfield primary analysis.

#2591 Nonclinical ocular toxicity of a maytansinoid payload-antibody drug conjugate: Ocular tissue distribution, lesion pathogenesis, and mitigation.

A. Warbington[1], O. Ab[1], S. Lakshmikanthan[1], S. Dalton[2], P. Miller[3], E. Stevens[2], P. Zweidler-McKay[1], G. Lytle[1];
[1]ImmunoGen Inc., Waltham, MA, [2]Labcorp Early Development Laboratories, Madison, WI, [3]Ocular Services On Demand, Madison, WI

Background: Antibody-drug conjugates (ADCs) have emerged as a compelling therapeutic modality in oncology with several recent regulatory approvals. However, on and off-target toxicities require further evaluation. Corneal microcyst-like epithelial changes (MECs) are a well-known off-target class effect of ADCs with microtubulin-acting payloads, with varying degrees of severity. Manifestation of MECs is generally unrelated to antibody target and occurs in the absence of corneal target expression.
Methods: An ocular toxicology model in Dutch belted rabbits was established using a humanized monoclonal antibody not cross-reactive in rabbits conjugated through an SPDB linker to the maytansinoid drug, DM4. Radiolabeled ADC was administered once and tissues were collected for radioanalysis at multiple time points to evaluate the contribution of ADC exposure and ocular tissue distribution to corneal toxicity. Non-radiolabeled ADC was administered once or twice to evaluate onset and characterization of MECs using slit lamp microscopy and histopathology. Furthermore, potential prophylactic methods for reducing MECs were evaluated.
Results: The drug radioactivity was measured over 14 days and was widely distributed with elimination from most ocular tissues (except cornea) similar to blood/plasma elimination ($T_{1/2}$ of 4.5-7.5 days). In contrast, the corneal layers had an apparent absorption phase followed by a relatively stable concentration plateau through 14 days. Furthermore, preferential distribution to the corneal epithelium was evident by high tissue-to-plasma ratio (1.6 vs <0.5 for other ocular tissues, including other corneal layers). Generally, MECs increased in frequency (number of eyes affected) and decreased in time to onset with increasing dose. Ophthalmic observations of MECs began in the perilimbal cornea with axial migration over time and were reflected by the histopathologic findings in the corneal epithelium of single cell necrosis, increased mitosis, mononuclear cell infiltration, and/or atrophy. A topical ophthalmic vasoconstrictor (brimonidine tartrate 0.2%) delayed the onset of MECs compared to controls (8% vs. 67% of eyes at 7 days; 33% vs. 100% at 10 days) and mitigated severity of some histopathological findings (reduced or absent corneal epithelial atrophy, punctate erosion, pigment, and/or mononuclear cell infiltration). In contrast, corticosteroid administration (prednisolone acetate 1%) did not reduce MECs clinically but did reduce the histologic incidence and severity of corneal pigment and mononuclear cellular infiltration.
Conclusion: Collectively, this rabbit model reproduces the MECs associated with maytansinoid ADCs, demonstrates selective long-term corneal epithelium exposure, and provides data to support clinical testing of vasoconstrictor drops as ocular prophylaxis.

#2592 New technologies and capabilities supporting the development of novel molecular radiotherapy agents.

S. Belderbos[1], C. Mothes[1], C. Bernhard[2], F. Denat[2], P. Adumeau[1], M. Chevalier[3], J. Llop[3], A. Kownacka[1], C. Tihansky[4], M. Ruch[2], M. Claron[2], M. Moreau[2], **C. Berthet**[1], E. Koumarianou[1];

[1]Oncodesign Services, Dijon, France, [2]ICMUB Institut de Chimie Moleculaire de l'Universite de Bourgogne, Dijon, France, [3]CIC Biomagune, Donostia, Spain, [4]ImaginAb, Bracknell, United Kingdom

At Oncodesign-Services we aim to provide cutting-edge technologies and products to support the development of radiopharmaceuticals for theranostics.
Starting from the optimization of lead compounds, the site-specific bioconjugation chemistry of a bifunctional chelator to large biological compounds, such as antibodies, can preserve the biological profile and the reliable batch production. Thanks to new technologies we can conjugate a variety of payloads (cytotoxins, radioactive chelates, fluorescent dyes) on antibodies at targeted lysine residues of the Fc region, independent of Fc glycosylation.
Moreover, we aim to use relevant models for valuable translational results. In line with this, we established tumor spheroids to finely monitor the diffusion and subcellular distribution of novel fluorescent and radioactive probes in a 3D environment.
Furthermore, we are currently generating two animal tumor models for optimal target expression levels and recapitulation of the human tumor microenvironment. Our first model is a PSMA+ expressing tumour model, in a non radiosensitive rodent strain allowing improved assessment of novel radiopharmaceuticals. Our second tumor model is under development to assess novel FAPI tracers.
Finally, we present in partnership with *ImaginAb* ^{89}Zr Crefmirlimab Berdoxam, a minibody (human and murine analog) with high affinity to the CD8α glycoprotein, a valuable PET imaging tool for preclinical tracking and assessment of CD8 cells. This PET imaging can be used to evaluate immunoresponse following treatment, autoimmune, inflammatory and/or infectious diseases models.
To conclude, our continuous efforts aim at expanding our service portfolio to fulfil the needs of our various projects, as presented herein. Our experience and expertise allow us to suggest alternatives based on the latest technological progresses to facilitate and expedite the drug discovery progress from bench to bedside.

#2593 Spatial multi-omics profiling of tumor cell phenotypes in primary cutaneous melanoma at single-cell resolution.

T. Vallius[1], E. Novikov[1], A. Nirmal Johnson[2], S. Yingxiao[3], R. Pelletier[1], S. Pant[1], Z. Maliga[1], A. Chen[1], C. Yapp[1], S. Chan[3], C. Lian[2], G. F. Murphy[2], S. Santagata[1], P. Sorger[1];

[1]Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Dana-Farber Cancer Institute, Boston, MA

Primary cutaneous melanomas develop in stages from melanoma precursor cells that may progress to melanoma *in situ* (MIS) and eventually to invasive disease. Molecular changes, such as tumor cell state switches from melanocytic to undifferentiated and neural-crest-like phenotypes, have been associated with the development of melanoma metastases and therapeutic resistance. However, it is unknown whether cell states or gene expression changes enriched in advanced tumors exist at the premalignant stage and if they can elicit tumor-infiltrating lymphocytes (TILs). To address this gap, we analyzed a cohort of clinical samples from 43 patients with primary cutaneous melanoma using whole-slide cyclic multiplex immunofluorescence imaging (CyCIF), morphology-guided micro-regional RNA sequencing, and high-resolution 3D imaging. Each specimen contained multiple histologically-distinct regions representing a progression axis from normal to precursor to melanoma *in situ* to invasion. Subsequently, we examined the molecular profiles of both atypical melanocytes and tumor cells, and the gene expression and tumor microenvironmental (TME) changes that occurred during these progression stages. We identified major intra- and inter-specimen heterogeneity in the tumor intrinsic and extrinsic features across progression stages. Multiple tumor samples contained regions where publicly available gene signatures linked to both melanocytic and undifferentiated cell phenotypes were enriched. CyCIF analysis confirmed that various tumor cell phenotypes can coexist in close proximity to each other in early-stage untreated melanomas, and that the majority of undifferentiated tumor cells were located within regions of dermal invasion. Moreover, the cellular neighborhoods around undifferentiated tumor cells had a higher proportion of CD8+ T cells and cells of myeloid lineage compared to the neighborhoods around melanocytic tumor cell phenotypes. When assessing the localization and abundance of various tumor cell phenotypes, the levels of spatial and regional heterogeneity increased proportionally along normal to premalignant to malignant progression. Furthermore, the regional entropy of tumor cell phenotypes decreased along tumor depth in the majority (63%) of the samples, and even the melanoma *in situ* regions showed varying levels of spatial heterogeneity. Our in-depth multimodal molecular analyses highlight the presence of spatial heterogeneity among tumor cell phenotypes as well as the organization of early-stage primary melanomas, and are suggestive of tumor cell adaptation to the local environment.

#2594 AI-powered radiomics model predicts immune checkpoint inhibitor-related pneumonitis (CIP) in advanced NSCLC patients.

S. Lee[1], A. Hiremath[2], J. Lee[1], P. Kim[3], K. Zhang[2], S. Lee[4], M. Yadav[5], M. J. A. Chuchuca[5], T. Um[5], M. Nam[6], L.-Y. Chung[5], H. Kim[5], J. Yu[7], T. Djunadi[8], L. Kim[9], Y. Oh[10], S. Yoon[5], Z. Shah[11], Y. Kim[5], I. Hong[12], G. Kang[12], J. Jang[12], A. Cho[12], S. Lee[13], C. Nam[12], T. Hong[12], Y. Velichko[5], V. Velcheti[14], A. Madabhushi[2], N. Braman[2], Y. Chae[5],

[1]Kyungpook National Univeristy, Daegu, Korea, Republic of, [2]Picture Health, Cleveland, OH, [3]The University of Texas at Austin, Austin, TX, [4]School Of Medicine at UCI, Irvine, CA, [5]Feinberg School Of Medicine, Northwestern University, Chicago, IL, [6]Lincoln Medical Center, Bronx, NY, [7]Dignity Health - St. Rose Dominican Hospital, Henderson, NV, [8]Richmond University Medical Center, Staten Island, NY, [9]Ascension Saint Francis, Evanston, IL, [10]John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, [11]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [12]Northwestern University, Evanston, IL, [13]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [14]Laura and Isaac Perlmutter Cancer Center, New York University Langone Health, New York, NY

Background: With the escalating integration of immunotherapy in the management of advanced non-small cell lung cancer (NSCLC), the emergence of adverse events, particularly immune checkpoint inhibitor-related pneumonitis (CIP), poses important challenges. CIP is not uncommon and can be life-threatening. It often necessitates the discontinuation of immunotherapy, even in patients with an otherwise favorable response. Prevention, early detection and early management of CIP can enhance patient outcomes, yet no such predictive models have been established. This study investigates the use of Artificial Intelligence (AI) algorithms in analyzing radiomic features for the prediction of CIP in NSCLC patients receiving immunotherapy.

Methods: A cohort of 105 stage III-IV NSCLC patients receiving immunotherapy was examined. Half of the patients were randomly split to a training set, while the remaining half were reserved for algorithm testing. The manual segmentation was performed by three physicians annotating in consensus using LIFEx software v7.3.0 (IMIV/CEA, Orsay, France). The Picture Health Px platform was utilized to perform an AI-powered deep phenotyping of the tumor and its surrounding habitat. A number of interpretable feature measures were extracted from baseline CT scans, which were in turn used to train a deep learning classifier for the detection of pneumonitis. Weighting techniques were applied to compensate for the imbalance of pneumonitis cases.

Results: Among the 105 patients, 63 (60.0%) received immunotherapy-only regimen and 42 (40.0%) received combination immunochemotherapy. 18 (17.1%) patients had pneumonitis events. Within this subset, 10 (55.6%) had CIP. Among the CIP group, six patients (60.0%) had grade 1 pneumonitis, three patients (30.0%) had grade 2 pneumonitis, and one patient (10.0%) had grade 3 pneumonitis, and none had grade 4 or grade 5 pneumonitis. Within the training set (n=51), the cross-validated area under the ROC curve (AUC) was 0.71 (95% CI: 0.68-0.74). When applied to the test set, the model predicted pneumonitis with AUC=0.63. Across the two datasets, the model correctly identified 4/6 (66.7%) grade 1 pneumonitis events and 2/3 (66.7%) grade 2 pneumonitis events, but misclassified the only available grade 3 event.

Conclusion: The utilization of CT-based radiomic features demonstrates promise in predicting CIP in NSCLC patients undergoing immunotherapy. This approach holds potential for enhancing the identification and management of CIP, among NSCLC patients treated with immunotherapy.

#2595 Accelerated and precise tumor segmentation in NSCLC: A comparative analysis of automated ClickSeg and manual annotation for radiomics.

Seyoung Lee[1], Kai Zhang[2], Jeeyeon Lee[1], Peter Haseok Kim[3], Amogh Hiremath[2], Salie Lee[4], Monica Yadav[5], Maria J. A. Chuchuca[5], Taegyu Um[5], Myungwoo Nam[6], Liam Il-Young Chung[5], Hye Sung Kim[5], Jisang Yu[7], Trie Arni Djunadi[8], Leeseul Kim[9], Youjin Oh[10], Sungmi Yoon[5], Zunairah Shah[11], Yuchan Kim[5], Ilene Hong[12], Grace Kang[12], Jessica Jang[12], Amy Cho[12], Soowon Lee[13], Cecilia Nam[14], Timothy Hong[12], Yuri S. Velichko[5], Anant Madabhushi[2], Nathaniel Braman[2], Young Kwang Chae[5]

[1]Kyungpook National Univeristy, Daegu, Korea, Republic of,[2]Picture Health, Cleveland, OH,[3]The University of Texas at Austin, Austin, TX,[4]School Of Medicine at UCI, Irvine, CA,[5]Feinberg School Of Medicine, Northwestern University, Chicago, IL,[6]Lincoln Medical Center, Bronx, NY,[7]Dignity Health - St. Rose Dominican Hospital, Henderson, NV,[8]Richmond University Medical Center, Staten Island, NY,[9]Ascension Saint Francis, Evanston, IL,[10]John H. Stroger, Jr. Hospital of Cook County, Chicago, IL,[11]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[12]Northwestern University, Evanston, IL,[13]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[14]Northwestern University, Chicago, IL

Background: Radiomics models utilizing artificial intelligence are being explored as a potential biomarker in the field of oncology. Radiomics analysis requires segmentations of radiographic imaging. However, manual segmentation is a labor-intensive process that is time consuming, and acts as a major rate-limiting step. Thus the development of automated segmentation tools presents an opportunity for innovation in regards to efficiency and precision. Our study aims to explore the feasibility of autosegmentation in comparison with manual segmentation.
Methods: A cohort of 105 stage III-IV non-small cell lung cancer patients receiving immunotherapy was examined, with a total of 168 lesions. We conducted a comprehensive comparative analysis of manual versus automated segmentation in time efficiency and segmentation quality, utilizing CT scans from the patients. Manual segmentation was performed by three physicians annotating in consensus using LIFEx software v7.3.0 (IMIV/CEA, Orsay, France). For a subset of randomly selected patients, annotation time was recorded as a reference point for the automated segmentation. In addition, automated segmentation was performed on all 168 lesions using ClickSeg from PictureHealth, a click-based interactive segmentation algorithm optimized for NSCLC lesions. Segmentation quality was evaluated using the Dice similarity coefficient to measure the concordance between ClickSeg outputs and consensus expert annotations.
Results: Average manual annotation time of the tumor region was 15min 34sec, and ranged from 1min 2sec to 53min 12sec. . Average prediction time for the automated segmentation model was 1.94 seconds, and ranged from 0.71 seconds to 4.39 seconds. The median Dice coefficient, reflecting segmentation accuracy, was 0.72, highlighting the robust performance of the automated method.
Conclusion: Our study demonstrates the efficient and accurate nature of automated segmentation supporting its potential integration into routine radiomic analysis procedures, streamlining the assessment of treatment response and ultimately improving patient care.

: Advocates Poster Session 2
Poster Session

#ADV021 Angelmira's Center for Women with Advanced Cancer.

Maricarmen Delia Planas-Silva

Angelmira's Center for Women with Advanced Cancer, Houston, TX

The poster will cover the following items: 1. We will present the background about AC4WAC. 2. We will explain the four programs AC4WAC and how they relate to cancer or cancer research. 3. We will share some of our data on those we serve. 4. We will comment on future goals. 5. We will provide contact information.

#ADV022 Disparities in Breast Cancer or Social Determinants of Health.

Marshelle Harris

Patient Advocate, Gardendale, AL

This poster will provide information on establishing a Health and Wellness Program for your individual needs that help you advocate for your own health and wellness with confidence so that you can navigate through the healthcare system with confidence.

#ADV023 THE CANCER HEALTH FUND - Giving Hope to the Nigerian Cancer Patient.

Mary-Gloria A. Orji

Patient Advocate, Abuja, Nigeria

The poster reflects on a true life story of a middle aged cancer patient named Alice [Pseudonym] who shared her cancer treatment journey with me and how the Cancer Health Fund {CHF}, a fund set aside for indigent cancer patients to enable them access care without having to pay for treatment, enabled her to continue with her treatments. Her story is typical of what a Nigerian Cancer patient faces. The stigma is very apparent especially from close relatives.. This leads to most patients not wanting to go to the hospital for care due to lack of funds and due to stigma associated with being diagnosed with cancer in my country. This, in effect, leads to late presentation, hence the very high morbidity recorded in the country. The fund was part of a 2 years advocacy by the Health Federation of Nigeria {HFN} and myself, as a cancer patient advocate, to the legislators to have it appropriated in the national budget and this, when it came to fruition was a great relief for many cancer patients who could access treatments even when they cannot afford it. Currently there are plans underway by the Nigerian government to have the funds expanded to other chronic diseases.

#ADV024 Patients First: Leveraging Investor Influence for Patient-Centric Pharmaceutical Research and Clinical Trials.

Mike Herman

Patient Advocate, Toronto, ON, Canada

The pharmaceutical industry often grapples with the tension between profit motives and patient-centricity. This abstract delves into the potential of the influence of investors in reshaping this dynamic to prioritize patients' needs and viewpoints. By leveraging investor power, all stakeholders can drive a transformative shift towards patient-focused practices, thereby enhancing study design, speed of approval, and ensuring patient-centric outcomes. This presentation explores strategies to align investor interests with patient welfare, while maximizing return on investment (ROI). While seeking successful instances of investor-driven improvements in pharmaceutical research and clinical trials, our analysis revealed a gap. This prompts reflection on whether we are asking the right questions. This discussion aims to inspire collaborative efforts among investors, pharmaceutical industry leaders, and patient advocates to ensure patients remain central to medical innovation.

#ADV025 Uncovered: The breast cancer journey of a Black woman from advocacy to awareness to action.

Michelle Audoin

Patient Advocate, Toronto, ON, Canada

This poster will provide a summary description of Uncovered: A Breast Recognition Project, which I created in 2020, in collaboration with Rethink Breast Cancer. It will focus on the Wish List action items of the 2021 edition of Uncovered, which have served as my guide and catalyst for growth as a patient advocate and partner. It will describe my journey from advocating for my own personal needs to be met to how education has empowered my growth as a patient advocate, by moving beyond awareness campaigns, to becoming an informed and engaged patient partner who is taking action to drive systemic change in breast cancer from early detection to survivorship, with a focus on equity, diversity, and inclusion. The purpose of the poster will not only be to describe my journey, but it will also serve as an inspiration for Black women and other underserved groups to engage more in cancer research and trials as partners.

#ADV026 AACR Cancer Disparities Progress Report shows us the gap of Health Equity for Racial and Ethnic Minorities and Other Underserved Populations.

Naomi Sakurai

CSR Project, NPO, Tokyo, Japan

Medical treatment including hormonal therapy and chemotherapy is critical to cure breast cancer. However, many breast cancer patients are also suffering from the side effects and financial burden.In order to highlight the current situation regarding side effects, employment conditions and financial burden, we conducted a web survey with 150 breast cancer patients (100 patients : early stage breast cancer, 50 patients : metastatic breast cancer).Our survey found that metastatic breast cancer patients, compared to early-stage breast cancer patients, are more affected by side effects such as fatigue, hair loss, symptoms and changes in skin color, pain and depression. In addition, we found that 54% of metastatic breast cancer patients are not able to return to work and 96% of breast cancer patients had financial toxicity on 'COST scores'. Return to Work is very critical both to continue medical treatment and keep patients' quality of life (QOL).Medical professionals should be more concerned about the side effects of treatment and how they affect the patients' daily lives. They should also be aware that social environmental factors play a very important role in maintaining health and treatment adherence, and look for ways to improve them.

#ADV027 What advocacy looks like in Rural and Frontier Communities: Cancer Advocacy in Indian Country.

Nathan Begaye

Huntsmans Cancer Institute, Salt Lake City, UT

It is the work of Huntsman Cancer Institute to understand cancer from its beginnings. To use that knowledge in the creation and improvement of cancer treatments to relieve the suffering of cancer patients. To also provide education about cancer risk, prevention, and care. The American Indian (AI) Program (AIP) in the Office of Community Outreach and Engagement at Huntsman Cancer Institute at the University of Utah seeks to reduce the impact of cancer in tribal communities through; (1) culturally tailored educational cancer outreach, (2) advocate for equitable access to clinical care for rural, frontier and AI patients from prevention to palliation, including access to clinical trials and cancer research, (3) to provide in-reach for clinicians and principal investigators about best practices in working with rural, frontier and AI persons and communities. The AIP centers it's advocacy in the rural and frontier Rocky Mountain West, knowing that it takes commitment, communication and consistency to build trust. Which involves engaging with community members and leaders where they gather and on their terms. To develop bidirectional relationships that facilitate connection and communication about their needs, resources and experience in accessing cancer related services. It is AIP's approach in working with rural, frontier and AI patients, survivors and their caregivers to be culturally informed. Understanding as best we can their lived reality, and considering the barriers they face in accessing treatment and care.

#ADV028 Ways to reduce breast cancer risk.

Nicole Stromer

Breast Cancer Options, New York, NY

Patient advocates serve a critical role in educating the public about various factors that can influence and reduce breast cancer risk. This poster will describe this role and the impact patient advocates can have.

#ADV029 Increasing Early Onset Colorectal Cancer Awareness and Screening in Young Adults in African American Communities.

Paulette Duggins

Patient Advocate, Winston Salem, NC

This poster will present the following: 1. The Mission of the Angelic Warrior Foundation (To increase Colorectal Cancer Awareness and provide support to patients, caregivers, and families). 2. Identify the cancer focus and the significance of the problem—The cancer focus is Colorectal Cancer Awareness with emphasis on Early Onset Colorectal Cancer (CRC). According to the American Cancer Society, “In 2023 an estimated 153,020 people will be diagnosed with CRC, 52,550 of them will die from CRC and 3,750 of them will be younger than age 50.”. 3. An overview of AWF’s Early Onset CRC Awareness Initiative—This initiative will address the need for increased CRC awareness and screening, especially among younger, Black and African American individuals, by building partnerships with Universities and Churches to plan and implement an evidence-based intervention focused on increasing CRC awareness.

#ADV030 Advancing Pediatric Oncology Research Through Collaboration: A Survivor/Clinician/Scientist Tri-Lens Perspective.

Rachel Hamilton

Patient Advocate, Markham, ON, Canada

Introduction: Cancer is the leading cause of death in children globally, with over 400,000 cases diagnosed annually. Although the overall outlook on pediatric cancer has drastically improved over the last half-century, survival rates remain poor for some cancer types, indicating the need for new treatment advances and continued research to improve treatment efficacy. Discussion: Advancing pediatric oncology research requires collaboration with multiple stakeholders to urgently drive new trials with the goal of creating new therapies to cure more patients. My unique tri-lens as a childhood cancer survivor, pediatric oncology registered nurse, and a pediatric cancer researcher allows me to apply the viewpoints from each facet of my identity, and understand where gaps may arise if partnership is not engaged. Supporting collaboration by involving all invested parties in pediatric cancer research, including patients, clinical staff, researchers, parents/caregivers, advocates and policy-makers, will encourage the implementation, and overall success of the science.Reflections: Each invested group involved in pediatric oncology research brings a wealth of knowledge and value, thus it is imperative to learn from each other to improve our practices. It is of utmost importance to include the patient and family, as equals, in all phases of research, in order to ensure research is done with, and not to participants. Together, with devoted parties pushing the science forward collaboratively, there is hope for progress.

#ADV031 Striving to Hold Accountability in Research Equity.

Rachel Hirschey

Patient Advocate, Durham, NC

This poster will present the following about Striving to Hold Accountability in Research Equity (SHARE): 1. Mission (To reduce cancer disparities in African American and Black communities by informing research and program development. SHARE identifies community needs, promotes evidence-based interventions and information, raises awareness about health disparities in communities, and educates researchers.), 2. Core Values (dignity, humility, openness, representation, transparency, honesty, service and accountability), member profiles, community partners and 2023 impact report.

#ADV032 Making the cancer journey easier and safer for patients and caregivers..

Robert Blomquist

CAREBOX PROGRAM, TX

The poster will describe the CareBOX process and how this model can be replicated in other cities and communities. Patients Apply: We have removed barriers and made a simple process for patients to apply. Visit the Get a CareBOX page to see just how easy it is. Customized CareBOXes: We have curated a list of 40 care supplies patients can choose from to meet their needs. They can replenish their CareBOXes every three months. Packaged with Love: Once wishlists are submitted our team of staff and volunteers get busy packing.

#ADV033 Empowered Choices: Transforming Breast Cancer Care through Patient-Friendly Online Clinical Trial Matching.

Sabrina Mayhew

Patient Advocate, Markham, MI

Breast cancer patients often find it challenging to navigate the landscape of clinical trials. For patients seeking information and participation in trials, BCT (breastcancertrials.org) and MTS (metastatic trial search) are important resources to assist patients with the complexity of trial matching. Recognizing the need for personalized support, this investigation aims to address the complexities in trial eligibility, and the need for breast cancer navigator assistance to optimize the trial search process.

#ADV034 Helping Older Breast Cancer Patients Navigate Cancer Care.

Sophia Turner

Patient Advocate, London, United Kingdom

Patients over the age of 70 are less likely to be offered the same treatment opportunities as younger patients (real world data supports). This poster will discuss guidelines for older patients that I have developed and mechanisms that I have used to distribute to this group (materials embedded). Issues that arise when accessing this population (timely, paper-based, confidence). Survey results of patient response to guidelines (graphs of patient response). Further enabling patients of 70 and over to receive the best care for their breast cancer, regardless of age.

#ADV035 Co-creation of a patient engagement strategy in cancer research funding.

Suzanne Bays

Patient Advocate, Piedmont, QC, Canada

As research teams, networks, and institutes, and health, medical, and scientific communities begin to build consensus on the benefits of patient engagement in cancer research, research funders are increasingly looking to meaningfully incorporate patient partnership within funding processes and research requirements. The Canadian Cancer Society (CCS), the largest non-profit cancer research funder in Canada, set out to co-create a patient engagement in cancer research strategy with patients, survivors, caregivers and researchers. The goal of this strategy was to meaningfully and systematically engage with patients in research funding and research activities.

#ADV036 “Ask Me!”: Transforming Patient Communication to Improve Enrollment and Adherence in Clinical Trials and Cancer Care.

Tambre Leighn

Patient Advocate, Rincon, Puerto Rico

This poster presentation delves into the pivotal role of effective communication in healthcare, specifically in the context of cancer research and cancer care. Challenging the traditional view that considers communication skills to be soft skills, this presentation highlights the pivotal role of mastering effective communication and positions these skills as the new hard skills essential for revolutionizing patient communication.

• Only at 6.3% of all oncology patients participate in cancer treatment clinical trials • Less than one quarter of patients have had their doctor or nurse suggest a clinical trial • Poor communication can result negative outcomes, such as decreased adherence to treatment, patient dissatisfaction, and inefficient use of resources • There is a 19% higher risk of nonadherence among patients whose physician communicates poorly

The poster includes real life examples of poor communication received by patients along with tips and strategies for how to better address these scenarios. The poster also discusses barriers and perceptions that impede communication, negatively impacting clinical trial enrollment and adherence. Too many patients continue to share experiences online and during speaking engagements about harmful and, sometimes, life threatening communication breakdowns. Stories about being ignored only to be later diagnosed with advanced stage cancers, side effects being deemed ‘normal’ or ‘tolerable’ with no interventions being provided, and patients not being asked to participate in clinical trials are still too common, particularly for diverse populations.

Drawing on her professional training in communication and coaching, this poster session by patient advocate, Tambre Leighn, promises to be interactive with tangible tips and takeaways that can be put into practice with relative ease.

This poster encourages researchers and clinicians to ask patients more often while highlighting the transformative power of advanced communication skills in cancer research and care. The “Ask Me!” approach paves the way for a more empathetic, effective, efficient, and patient-centered approach to communication in cancer research and cancer care.

#ADV037 Growth of Collaborative Partnerships: An Advocate's Aspiration for Improved. Global Approaches to Cancer Research.

Vivian Simbul Sim

Patient Advocate, Toronto, ON, Canada

I was diagnosed with breast cancer in 2011 and had a lumpectomy followed by radiation in 2012 at Sunnybrook Health Sciences Centre in Toronto. Like other people who have had a cancer diagnosis, I continue to ask:• How did I get cancer in the first place?• Is it still there?• Will it recur? And if so, will it spread?• How will my loved ones be affected?

#ADV039 KARMANOS CANCER INSTITUTE, OFFICE of CANCER HEALTH EQUITY & COMMUNITY ENGAGEMENT.

William Winkler

Patient Advocate, Canton, MI

Our poster will describe, through the 15 Karmanos sites, our statewide effort to educate and facilitate the formation of local Cancer Action Councils in an attempt to gain input from cancer survivors. Our purpose is to educate, especially populations of color that have been marginalized, thus increasing enhanced involvement in their treatment and possibly more engagement with clinical trials.

#ADV039 Designing a Culturally Tailored Educational Tool to Improve Engagement of African Americans in Clinical Trials.

Yvonne McLean Florence

Patient Advocate, Yeadon, PA

This poster highlights the perceptions of African Americansurvivors and caregivers about participation in clinical trials.

SURVIVORSHIP: Advocates Poster Session 1
Poster Session

#ADV001 Portraits of Resilience: Exploring the Lung Cancer Diagnosis Journey among BIPOC Young Women through Narrative Inquiry.

Aurora Lucas

Patient Advocate, Romeoville, IL

This qualitative study delves into the lived experiences of BIPOC (Black, Indigenous, and People of Color) young women who have been diagnosed with lung cancer. Utilizing a methodological approach grounded in portraiture and narrative inquiry, the research seeks to illuminate the multifaceted dimensions of their journey from diagnosis onwards. Through in-depth interviews, the study captures the nuanced narratives, perspectives, and coping mechanisms of these resilient individuals. By employing portraiture, the research aims to create rich, contextualized portrayals of their experiences, highlighting their agency, challenges, and triumphs in navigating the complexities of lung cancer diagnosis as BIPOC young women. This exploration not only contributes to a deeper understanding of the psychosocial aspects of lung cancer within this demographic but also underscores the importance of amplifying their voices within healthcare discourse and policy-making.

#ADV002 Patient Cancer Identification Begins with Primary Care.

Cathy Nobil-Dutton

Patient Advocate, Glenside, PA

Primary care physicians (PCP) are on the front line of identifying possible genetic links that may indicate a predisposition for a hereditary cancer. A PCP's relationship with their patient is an ongoing one and it is at this entry point that possible risk factors can be noted and testing recommended. Educating PCPs about the possible genetic factors and how to take a thorough family history could result in lifesaving early interventions for their patients.

#ADV003 AYA Can: Canadian Cancer Advocacy - A Pan-Canadian Patient Led Organization for Adolescents and Young Adults.

Chantale Thurston

AYA CAN - Canadian Cancer Advocacy, Winnipeg, MB, Canada

This poster outlines the establishment of a peer-led advocacy charity, AYA Can, in Canada dedicated to adolescents and young adults (AYAs) affected by cancer. The charity's vision is to advocate for an equitable and integrative system of care, incorporating patient perspectives into policy, research and care practices. It aims to amplify AYA research, particularly in integrative oncology and precision medicine, improving care quality. Through fostering interdisciplinary collaboration, the organization seeks to advance the field of AYA oncology and ultimately enhance the quality of life and survivorship outcomes for young cancer patients across Canada.

#ADV004 Patient Advocate Perspective: Conversation in Cancer Care.

Christina Sisti

Patient Advocate, Bradenton, FL

The poster will highlight how conversations can begin between researchers and patient advocates. The poster will have tips about including patient advocates in research. And ways to decrease inaccessibility to patient advocacy opportunities and care.

#ADV005 More Than a Token: A BIPOC's Experience with Patient Engagement.

Clare Cruickshank

Patient Advocate, Hamilton, ON, Canada

This poster focuses on the author's experiences providing a patient perspective in research, and provides suggestions for improving engagement along IAP2's spectrum of participation.

#ADV006 Expanding Outreach to Uterine Cancer Survivors.

Davida Pantuso

Kent State University, Barberton, OH

Uterine cancer is the most common gynecologic cancer, and the fourth most common cancer among women in the United States. Unlike most cancers, incidence and mortality rates are increasing. Despite these concerns, a silence about uterine cancer exists and resources remain limited. This poster will highlight how SHARE Cancer Support is committed to expanding awareness and resources to uterine cancer patients and survivors, especially for Black Women - a population that is particularly impacted.

#ADV007 The Amy Krouse Rosenthal Foundation: Spearheading Innovative Research for the Early Detection of Ovarian Cancer.

Deborah Binder

Patient Advocate, Barberton, OH

Ovarian cancer is the 5th leading cause of cancer-related deaths in women. Research shows that, if ovarian cancer is found before the cancer has spread outside the ovary, the 5-year relative survival rate is 92%. However, only 15% of all ovarian cancers are found at this early stage. Because we know that early detection exponentially increases a woman's survival rate, the Amy Krouse Rosenthal (AKR) Foundation focuses on early detection research, education and awareness. Among the Foundation’s programs and efforts, we are proud to provide grant funding for groundbreaking ovarian cancer early detection research.

#ADV008 Advocacy: A Cancer Survivor's Holistic Approach to Community Wellness.

Deirdre F. Lea

Patient Advocate, Burlington, NC

This poster will provide an overview of the establishment and growth of the Cancer Support Ministry and Health Fair at Jeffries Cross Baptist Church (JCBC). It will detail the community-driven initiatives that focus on delivering cancer prevention and awareness services. Additionally, the poster will highlight the community-initiated partnerships with health services and academic entities to support the health fair which provides a holistic approach to wellness. Healthcare professionals attend to offer blood pressure screenings, flu and COVID-19- vaccines, as well as educate attendees about cancer, mindfulness, diet, physical activity, insurance benefits, mental health, substance abuse, and oral health. We also offer a farmer's market with fresh produce from local farmers and a food truck offering healthy food options such as fresh salads, fruits and veggies, and hibiscus power drinks. We believe these offerings bring the wellness approach full circle; from educating attendees on how to live a healthy life to providing foods, mindfulness activities, and preventive measures to help our church members and community live longer, healthier lives.

#ADV009 Advocacy: A Cancer Survivor’s Holistic Approach to Community Wellness.

Don Desserud

Patient Advocate, Cornwall, PE, Canada

Proper communication with patients is recognized as an important skill for health-care providers. However, good communication with patients is more than simply speaking slowly or simply: communication with patients is teaching. Whenever a health-care provider tells patients something they do not know, they are teaching. What, however, is the appropriate teaching technique for dealing with patients who are frightened and who have just had their world turned upside down? We need to develop a unique teaching methodology for patients with life-threatening diseases, which I am calling kamnagogy, or teaching the sick. I am looking for research partners to help me design this method.

#ADV010 Caregivers have experience too!.

Don Wood

Patient Advocate, Calgary, AB, Canada

This poster describes becoming a caregiver when you never wanted to be one (due to a cancer diagnosis) and how I turned that into a career in patient engagement in cancer research. How I used my lived experience to gain experience so that I was able to work in the cancer research space and add value as a caregiver with lived experience. This poster is also an opportunity to coach and mentor other patient advocates and researchers as to how to engage caregivers in their projects and work.

#ADV011 Struggle with Diagnosis and Pandemic Across State Lines: A Case For Point of Care.

Donna Short

Patient Advocate, Brookfield, CT

Two weeks into the shutdown due to Covid, I was diagnosed with breast cancer. I struggled to receive treatment but ultimately navigated those waters and was able to access care. Then, I struggled as a cancer patient to receive expedited access to Covid shots because I lived in one state but was being treated in another. It is time for State Guidelines for care to be dissolved and replaced with guidelines due to point of care. We are a mobile society and live and work beyond state borders and our care should reflect this.

#ADV012 The State of Mental Health Supports for the Cancer Community.

Ethan Schilling

Patient Advocate, Waynesville, NC

This poster will present an overview of best practices in the mental health support of cancer patients and survivors. The most effective evidence-based treatments will be presented as well as current barriers that exist to treatment. Finally, implications and future directions for mental health research in the cancer space will be discussed.

#ADV013 Surgery for Invasive Lobular Carcinoma: A Patient Experience Survey from the Lobular Breast Cancer Alliance.

Gitte Joergensen

Patient Advocate, Coventry, CT

The Lobular Breast Cancer Alliance (LBCA) is a nonprofit, patient advocacy organization committed to raising awareness and promoting research into invasive lobular carcinoma (ILC). While ILC accounts for 15% of breast cancers, knowledge about ILC remains limited. ILC's hallmark is a lack of E-cadherin, which results in non-cohesive formation and impacts the accuracy of imaging tests and staging. Consequently, patients with ILC have higher rates of positive surgical margins, mastectomies, and axillary lymph node (LN) dissections. To understand the surgery experience of individuals with ILC, LBCA conducted an anonymous online survey from 6/21-7/2/23, distributed via the LBCA newsletter, social media, and partner organizations. Questions addressed pre-operative imaging, type of surgery, surgical margins, LN status, decision-making about, and patient experience with surgery. Analyses were limited to those respondents who had surgery. Study limitations include potential recall and selection bias. Results 1,482 individuals with a diagnosis of ILC completed the survey and 1,426 had undergone surgery. 76% were from North America, 11% from England, and 4% from Australia. The average age at diagnosis was 56 (range 31-86). At diagnosis, 38% were clinically stage 1; 37% stage 2; 17% stage 3; and 4% de novo metastatic. 75% had a mammogram that indicated dense breasts. Of 1,426 surgery respondents (SR), 95% reported that ILC was identified in only one breast at diagnosis. 80% had a pre-surgical MRI. MRI revealed larger tumors than seen on other imaging for 43% and revealed previously unseen contralateral ILC for 3%. 375 (26%) of SRs were diagnosed with ipsilateral disease and had a pre-surgical MRI that did not reveal new information about their ILC. Of these, post-surgical pathology reports indicated 16% had additional ipsilateral foci, 2% had contralateral disease, and 40% had larger tumors than seen on pre-surgical imaging. 614 (43%) of SRs had one or more lumpectomy (L), 560 (39%) of SRs had a double mastectomy (DM), and 451 (32%) of SRs had a single mastectomy (SM). 123 (20%) of SRs who had one or more Ls, had a subsequent SM or DM. For those undergoing L (614), reasons for this choice included: a recommendation from their care team (83%), wanting to keep their breast (25%), thinking it was better for their overall survival (OS) (14%), and 13% indicated they wanted breasts but did not want reconstruction. Of the 560 women who had a DM, 60% indicated that they thought a DM would improve their OS, 50% were concerned about the risk of local recurrence, 47% doubted that imaging would detect future ILC tumors and 45% noted concern that ILC is more likely to be bilateral. Of note, only 9% had ILC or ILC and another invasive breast cancer in both breasts at initial diagnosis and 31% who had a pre-surgical MRI changed their initial surgical treatment plan. Post-surgery, pathology for the DM group revealed larger tumors than seen on imaging (57%), and 6% had tumors found in a second breast that were not seen on imaging. For those 451 who had an SM, reasons for this choice included: 75% said it was what their care team recommended, 35% thought it would improve OS, 20% feared risk for local recurrence, and 15% doubted imaging would detect future ILC. Of 614 respondents who had L, 33% had positive margins at first surgery. Of those, 17% reported multiple Ls and M; and 24% reported clear margins were never achieved. Of the 1011 SM or DMs reported, 10% did not achieve clear margins after these surgeries. Conclusion The survey demonstrates the experience of a large cohort of women with ILC, reporting high rates of uncertainty about the accuracy of imaging, high rates of repeat surgery, bilateral mastectomies, and positive margins. Patients are factoring concerns about the potential extent of disease and future recurrence in their surgical decision-making. These results support the need for improved pre-operative staging and imaging modalities specific to ILC.

#ADV014 The NC Minority Prostate Cancer Awareness Action Team.

John L. Milner

Patient Advocate, Garner, NC

This poster will provide an overview of the NC Minority Prostate Cancer Awareness Action Team. It will detail our mission: “Promoting education, awareness, advocacy, best practices treatment, and support services to the residents of North Carolina with an emphasis on African-American, Hispanic/Latino, and Native American residents.” and vision: “Carrying the Sword Against Prostate Cancer for the Next Generation.” It will include an overview of our leadership, membership, partnerships, programs, events, and large-scale screenings for men.

#ADV015 iCCaRE Engagement with Black Faith-Based Organization Leveraging Their Use of Communication Technology to Remedy Disparities in Cancer Literacy, Screening, and Clinical and Biospecimen Studies Participation.

John McCall

D'Veal Family and Youth Services, Pasadena, CA

Faith-based organizations have a longstanding role as essential pillars of community health in predominately Black communities, filling in gaps for inequitable public health infrastructure. The COVID-19 pandemic highlighted the significance of faith-based organizations (e.g., churches) as trusted members in reaching the Black community for COVID-19 testing and vaccination. Additionally, in response to the COVID-19 social distancing guidelines, faith-based organizations including Black churches mastered the importance of communication technology platforms to maintain their congregation. The COVID-19 pandemic also had a significant impact on cancer prevention and control -- leading to 9.4 million undone cancer screenings specifically for breast, colorectal and prostate cancer. Specifically, Black men experience the highest incidence of prostate cancer among ethnic men, and studies repeatedly show that Black men are less likely to be screened for early detection. Therefore, recognizing Black faith-based organizations' status, credibility and effectiveness in engaging the Black community, as well as our proficiency in using communication technology, we are leveraging our status and communication capacity for disseminating health information focusing on cancer literacy and screening guidelines towards enhancing the health and well-being of Black communities.

#ADV016 Colontown - A Paltown Community A Wildly Supportive Colorectal Cancer Community.

Keith Hollingsworth

Patient Advocate, Lafayette, IN

COLONTOWN under the 503c umbrella of PALTOWN, empowers proactive colorectal cancer patients and caregivers with educational tools and relevant peer-to-peer support.

•Colorectal cancer is now the #1 killer of men and #2 killer of women under 50, with an expected 152,810 new cases in the US in 2024.•COLONTOWN is currently home to 10,000+ patients and caregivers. A large makeup of our “population” consists of those under the age of 60 (85%) as well as many considered late stage III or IV (81%).•Every program available in COLONTOWN has been created in response to a specific need expressed by patients or caregivers.

This poster highlights several of our key programs. These resources are all available to our members at no charge, and aim to empower, educate, and ultimately put the patient and caregiver in the driver’s seat with their medical team.

#ADV017 Cancer Doesn’t Know Age.

Kirsten Efremov

Patient Advocate, Brampton, ON, Canada

In pediatric oncology the most common cancers are leukemia, lymphoma and central nervous system (CNS) cancers. In those 60 years and older it is common to see breast, lung and colon cancers. The adolescent and young adult (AYA) population has a mix of both, but that population often hears, “you're too young to get cancer”, so their diagnosis is delayed. AYA’s are being diagnosed with cancer and it is not often in a timely manner. Anecdotally, diagnosis is delayed due to dismissal of symptoms and for the patient to lose weight, seek mental health help or blame it on their sexual orientation. However, the data shows that AYA’s are being diagnosed with a mix of both common pediatric and older adult cancers and the incidence of cancer in this population is increasing. Cancer doesn’t know age. There are cases of children with breast, colon and lung cancers and older adults with leukemia, lymphoma and CNS cancers. Person-centered health care is now, and the concept of “you are too young for cancer” and defining cancer by age is gone by the wayside. Cancer doesn’t know age, nor does it care.

#ADV018 My Walk With Cancer - And Why Faith, Spirituality And Its Leaders Should Be In A Clinician's Toolbox.

Linda Kitts

Patient Advocate, Burlington, NJ

This poster will describe my experience with cancer and how my journey was impacted by the following:• A positive, faith-filled attitude goes far in beating cancer.• I gave a talk to "Women of Faith", speaking of grace and blessings God has given to me through cancer. o Because of my new, faith-filled attitude, positive experiences far outweigh the negatives.• I am passionate about spreading positive, encouraging messages, and speaking freely to others about how, despite dreadful illness, good can come from it.• The quality of life is greatly enhanced with a positive attitude.

#ADV019 Multilevel Educational Strategies and Support for the Cholangiocarcinoma Patient Population.

Lourdes Rocha-Nussbaum

Patient Advocate, Golden, CO

Cholangiocarcinoma is a cancer that starts in the bile ducts. It can be diagnosed as cancerous cells located in the bile ducts that branch inside the liver (intrahepatic), or outside of the liver (distal), or where the right and left bile ducts join and leave the liver (perihilar). The Cholangiocarcinoma Foundation (CCF) has partnered with Komodo Health to gather data on the number of newly diagnosed patients in the United States to help CCF identify potential needs and gaps for support that can be addressed. Since cholangiocarcinoma is a rare cancer, it is important for patients to find information that can help them navigate their diagnosis, as well as have resources that support them through their cancer journey. Incorporating different strategies to provide education and support has been an important effort led by CCF.

#ADV020 Vaping and Gastric Cancer Risk - Is There a Link?.

Mahathi Vojjala

Patient Advocate, Marina del Rey, CA

This poster will present findings from my dissertation titled "The Relationship between Electronic Cigarettes and Risk Factors for Gastric Cancer in US Adults: Secondary Data Analysis using the PATH Study, Wave 1 and 5." The dissertation aims to: 1) Explore the association between e-cigarette, cigarette, dual user, and nonuser groups and gastric ulcers, cancer diagnoses, gastrointestinal bleeding, and other GI cancer-related issues using PATH Wave 5 data. 2) Characterize biomarkers of harm/outcome in PATH Wave 1, evaluating trends across tobacco-user groups and demographic correlates (race and sex) using cross-sectional data from Wave 1 of the PATH Restricted Use Files. 3) Determine the overall effect of e-cigarette and oral tobacco use specificity on H. pylori or gastric cancer risk in adults through a meta-analysis. I will also discuss my advocacy work with Hope for Stomach Cancer, highlighting my learning experiences and contributions to their campaigns and patient support initiatives.

IMMUNOLOGY: Antibody-Drug Conjugates
Poster Session

#2599 Trastuzumab deruxtecan reprograms immune response by stimulating cGAS-STING pathway in gastric cancer cells.
K.-S. Oh, A.-R. Nam, J.-H. Bang, Y. Jeong, S. Choo, H. Kim, S. Lee, J.-M. Kim, J. Yoon, T.-Y. Kim, D.-Y. Oh;
SNU Medicine, Seoul, Korea, Republic of

Background: The combination approach of antibody-drug conjugates and immune checkpoint inhibitors (ICIs) is being tested to enhance efficacy and overcome resistance in solid tumors. Although trastuzumab deruxtecan (T-DXd) is approved in HER2-positive gastric cancer (GC), its impact on the GC immune microenvironment remains elusive. This study explores how T-DXd modulates the immune response, providing essential insights on the development of T-DXd and immunotherapy combinations.
Methods: Comet assays and immunofluorescence assessed DNA damage. RNA-seq delineated the impact of T-DXd on GC cells (NCI-N87 and SNU-484). In vivo complex of enzyme assays and immunostaining of topoisomerase 1-DNA covalent cleavage complex (TOP1cc) were used to determine the action mechanism of T-DXd. RT-qPCR, and ELISA measured cGAS-STING cytosolic dsDNA sensing pathway activation. Further validation included cGAS knockdown and 2'3'-cGAMP addition to confirm the role of cGAS in T-DXd-induced promotion of inflammatory response. In coculture experiments, we utilized THP-1-derived dendritic cells (TDDCs) and PBMCs from healthy donors to prove the effect of T-DXd on immune cells. FACS analyses probed the activation markers of TDDCs and $CD8^+$ T cells.
Results: T-DXd-induced DNA damage upregulated PD-L1 expression in GC cells in an IRF1-dependent manner. RNA-seq revealed gene signatures associated with increased antitumor immune response, including proinflammatory response and type-I IFN, following T-DXd treatment. Mechanistically, T-DXd co-localized TOP1cc with γ-H2AX-positive micronuclei, activating the cGAS-STING pathway and triggering a robust IFN-I response. Knockdown of cGAS in cancer cells abolished the T-DXd-induced IFN-I response. T-DXd enhanced HLA-DR and CD86 expression in TDDCs, particularly when cocultured with GC cells. The physical interaction between cancer cells and TDDCs, along with the presence of cGAS in cancer cells, was found to be essential for the upregulation of dendritic cell (DC) activation marker by T-DXd. Furthermore, T-DXd elevated CD69, Granzyme B, and IFNG expression in $CD8^+$ T cells exclusively under coculture setting with NCI-N87.
Conclusion: T-DXd exerts immunostimulatory effects in GC cells through the activation of the cGAS-STING pathway, leading to a reprogramming of DC and $CD8^+$ T cell phenotypes. This provides a molecular rationale for combining T-DXd with ICIs for the treatment of patients with HER2-positive tumors.

#2600 Novel dual TOP1i ADC inducing superior tumour growth inhibition at low-drug load vs. trastuzumab deruxtecan.

P. Spycher, R. Fay, R. Bertrand, P. Probst, R. Stark, R. Santimaria, P. Maurhofer, L. Kallenberger, E. Renard, B. Schlereth, D. Grabulovski, I. Attinger-Toller; Araris Biotech AG, Au ZH, Switzerland

The Araris' site-specific and one-step conjugation technology aims at generating stable, safe and highly potent ADCs without the need for antibody engineering prior to payload conjugation. Here, we generated an anti-HER2 ADC using two different Topoisomerase-1 inhibitors (TOP1i) as payloads that shows superior anti-tumor efficacy compared to trastuzumab deruxtecan (T-DXd) in head-to-head in vivo studies.

For proof-of concept and comparison to T-DXd, trastuzumab was used as the targeting antibody. The Araris ADC was designed to combine two features in one ADC to maximize tumor-specific activity by using two different exatecan-based payloads: one that is able to exert bystander activity to address tumor heterogeneity and low-target expression and one that accumulates in cancer cells (no bystander activity) to achieve greater potency.

We found that the ADC was well-defined with a drug to antibody ratio (DAR) of 4 (2+2), as expected and no signs of aggregation under stressed conditions (40°C) during a period of 14 days. In in-vitro assays on target positive cell-lines, the ADC demonstrated taget-specific cell-cytotoxicity in the low nM-range similarly to T-DXd. Importantly, the non-bystander exatecan showed an increased intracellular concentration (up to 4x) and the bystander capable exatecan demonstrated high bystander activity in co-cultured, target-negative cell lines. In mouse pharmacokinetic studies, the ADC showed excellent stability in circulation with no signs of payload loss or linker-cleavage with a PK profile comparable to the unconjugated trastuzumab antibody which is key for a maximal and tumor-specific payload delivery.

Finally, a head-to-head study vs T-DXd was done in a challenging, medium HER2-expressing breast cancer model (JIMT-1), known to be resistant against the FDA-approved ADC T-DM1 (trastuzumab emtansine) and for T-DXd only showing limited activity (Ogitani et al., 2016). Impressively, it was found that the dual-TOP1i DAR4 Araris ADC showed superior anti-tumor efficacy compared to the payload-dose-adjusted T-DXd (DAR8). Using published doses for T-DXd, the Araris ADC was administered at ADC doses of 2x10mg/kg on days 1 and 8, resulting in superior anti-tumor activity and tumor eradication compared to T-DXd lasting for more than 47 days. T-DXd dosed at 2x5mg/kg (same payload dose) on days 1 and 8, only showed a very limited tumor growth inhibition with tumor regrowth occurring in all animals already at around 21 days.

We here show first encouraging results on a novel concept of combining TOP1i payloads that have two different features in one ADC to maximize efficacy. We believe that this concept in combination with a stable payload attachment at low DAR and an excellent exposure may help to develop ADCs with an improved therapeutic index for various solid tumor indications.

#2601 Potent antitumor activity of anti-HER2 antibody-topoisomerase I inhibitor conjugate based on self-immolative dendritic dimeric-linker.

Y. Liubomirski[1], G. Tiram[1], A. Scomparin[1], S. Gnaim[1], S. Das[1], S. Gholap[1], L. Ge[1], E. Yeini[1], O. Shelef[1], A. Zauberman[2], N. Berger[2], D. Kalimi[2], M. Toister-Achituv[2], C. Schroter[3], S. Dickgiesser[3], J. Tonillo[3], M. Shan[3], C. Deutsch[3], S. Sweeney-Lasch[3], D. Shabat[1], **R. Satchi-Fainaro[1]**;
[1]Tel Aviv University, Tel Aviv, Israel, [2]Merck KGaA, Yavne, Israel, [3]Merck KGaA, Darmstadt, Germany

Antibody-drug conjugates (ADCs) are a rapidly expanding class of anticancer therapeutics, with 14 ADCs already approved worldwide. We developed unique linker technologies for the bioconjugation of drug molecules with controlled-release applications. We synthesized cathepsin-cleavable ADCs using a dimeric prodrug system based on a self-immolative dendritic scaffold, resulting in a high drug-antibody ratio (DAR) with the potential to reach 16 payloads due to its dendritic structure, increased stability in the circulation and efficient release profile of a highly cytotoxic payload at the targeted site. Using our novel cleavable linker technologies, we conjugated the anti-human epidermal growth factor receptor 2 (anti-HER2) antibody, trastuzumab, with topoisomerase I inhibitors, exatecan or belotecan. The newly synthesized ADCs were tested in vitro on mammary carcinoma cells overexpressing human HER2, demonstrating a substantial inhibitory effect on the proliferation of HER2-positive cells. Importantly, a single dose of our trastuzumab-based ADCs administered in vivo to mice bearing HER2-positive tumors, showed a dose-dependent inhibition of tumor growth and survival benefit, with the most potent antitumor effects observed at 10 mg/kg, which resulted in complete tumor regression and survival of 100% of the mice. Overall, our novel dendritic technologies using the protease-cleavable Val-Cit linker present an opportunity for the development of highly selective and potent controlled-released therapeutic payloads. This strategy could potentially lead to the development of novel and effective ADC technologies for patients diagnosed with HER2-positive cancers. Moreover, our proposed ADC linker technology can be implemented in additional medical conditions such as other malignancies as well as autoimmune diseases that overexpress targets, other than HER2.

#2602 Near-infrared light-triggered pyroptosis boosts anti-tumor immunity via a novel antibody-drug conjugate.

F. Chen[1], X.-F. Tian[2], Y. Lu[1], P. Guo[1], W.-H. Tan[1];

[1]Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, Hangzhou, China, [2]Institute of Molecular Medicine, Hangzhou Institute for Advanced Study (UCAS), Hangzhou, China

Background: Cancer remains a significant health challenge, driving advancements in therapies. Despite progress in chemotherapy and radiotherapy, the quest for more precise, immunostimulatory interventions continues. Photodynamic therapy (PDT)/photothermal therapy (PTT) has utilized various photosensitizers to induce programmed cell death in tumors. The mechanism of action (MoA) solely relies on apoptosis. Among these, indocyanine green (ICG), a clinically approved photosensitizer, has shown efficacy in PDT/PTT. Meanwhile, pyroptosis, a newly discovered programmed cell death, holds promise in boosting anti-tumor immunity by generating pro-inflammatory factors. However, there remains a lack of therapeutic agents for facilitating precise and controllable pyroptosis of cancer cells.

Methods: In this study, ICAM1-ICG was developed as a novel near-infrared (NIR) pyroptosis agent for anaplastic thyroid carcinoma (ATC). The *in vitro* cytotoxicity on ATC cells under NIR light was determined by flow cytometry. Morphological changes were confirmed under both light microscopy and transmission electron microscopy (TEM). Western blot evaluated the impact of ICAM1-ICG under NIR light on pyroptosis-related proteins. Considering that the NIR radiation product of ICG is mainly reactive oxygen species (ROS), we next investigated the role of ROS in ICAM1-ICG-mediated pyroptosis using the ROS scavenger n-acetyl-l-cysteine (NAC). Anti-tumor activity and biosafety were determined using animal models with different immune backgrounds. In addition, we assessed its impact on the anti-tumor immune response through RNA-seq and evaluated the synergistic effect of NIR-pyroptosis and PD-1 combination therapy.

Results: ICAM1-ICG exhibits a NIR light dose-dependent cytotoxicity on ATC cells under a serial dose of NIR light irradiation, along with pyroptosis-like morphological changes that are directly visualized under both microscopy and TEM. Western blot further revealed that ICAM1-ICG can induce tumor-specific pyroptosis under NIR light, evidenced by NLRP1 activation, Caspase1 tetramer formation, and GSDMD cleavage, indicating that ICAM1-ICG induces tumor-specific pyroptosis under NIR light through a ROS/NLRP1/Caspase1/GSDMD signaling cascade by using NAC. Animal models' dates validated the anti-tumor efficacy of NIR-pyroptosis and enhanced anti-tumor immune responses. Additionally, NIR-pyroptosis synergizes with PD-1 immunotherapy to boost anti-tumor immunity in naïve and immune-rechallenged tumor models.

Conclusions: Overall, we discovered that antibody-conjugated ICG can work as a novel tumor-specific NIR-pyroptosis agent and explored its potential in boosting anti-tumor immunity, providing a viable approach for the clinical translation of pyroptosis-based therapy.

#2603 Targeting chemo-resistant ovarian cancer with a first-in-class, first-in-human immune-oncology agents containing granzyme B.

A. Alvarez-Cienfuegos, L. H. Cheung, K. A. Mohamedali, M. G. Rosenblum;
UT MD Anderson Cancer Center, Houston, TX

Ovarian cancer (OC) is the fifth leading cause of cancer-related mortality in women. The current standard of care consists of debulking surgery with platinum-taxane maintenance chemotherapy. However, OC will recur in most patients, resulting in a five-year survival rate of 45%. In the past decades, there have been several developments in front-line maintenance therapy including bevacizumab or PARP inhibitors. While these therapies have shown effectiveness in prolonging progression free survival, this has not translated into improvements in overall survival. It is, therefore, essential to develop more effective maintenance therapies and most of the current efforts are focused on targeted approaches and immune therapeutics. Though immunotherapeutic strategies have induced durable responses in patients with melanoma, lung cancer, and other malignancies, the OC response to immunotherapy is limited as there is a significant subset of patients who do not respond. Our laboratory has developed several fully human granzyme B (GrB) based fusion proteins against key OC targets including folate receptor 1 (GrB-Fc-mov018) and fibroblast growth factor-inducible 14 (GrB-Fc-IT4) which retain high specificity of the targeting agent, combined with the GrB specific activity, a pro-apoptotic mechanism of action, and a robust in vivo efficacy. We assessed the *in vitro* cytotoxicity of GrB-based constructs against a panel of OC cell lines sensitive (OVCAR8, SKOV3, A2780, HeyA8) or resistant (SKOV3-TX, A2780/Cl-16, HeyA8-MDR) to common chemotherapeutic agents. SKOV3-TX cells were >10 fold more resistant to Paclitaxel than the parental SKOV3 cells while A2780/Cl-16 were 11-fold more resistant to Cisplatin than the parental A2780 cells. In contrast, none of the chemo-resistant cell lines showed resistance to the GrB-based constructs and the IC_{50} values observed were similar to those of the parental cell lines in the low nanomolar range (≤50 nM). Moreover, target expression analysis did not show significant differences between parental and chemo-resistant cell lines. A pilot *in vivo* efficacy study of GrB-Fc-IT4 and GrB-Fc-mov018 against a subcutaneous, established ovarian tumor (OVCAR8) xenograft showed promising growth inhibition of established tumors compared to vehicle controls. *In vivo* studies evaluating the response to different treatments of mice bearing chemo-resistant ovarian tumors are ongoing. Our results suggest that the mechanism of resistance developed to conventionally used chemotherapeutic agents such as Paclitaxel, Doxorubicin, Cisplatin or Mitomycin do not confer resistance to GrB-based constructs. Hence, we speculate that GrB-based constructs could be an effective therapy in OC patients with immune-excluded tumors that have developed resistance to conventional treatment. Research conducted, in part, by the Clayton Foundation for Research.

#2605 STX-1, a potent first-in-class ADC directed against DPP4 (CD26) as a biomarker of senescent tumor cells.

E. Angevin[1], V. Lelarge[2], R. Capelle[2], J. Choeur[2], T. Mathieu[2], B. Le Calve[2];
[1]Gustave Roussy, Villejuif, France, [2]Starkage Therapeutics, Lille, France

Dipeptidyl Peptidase 4 (DPP4/CD26) is a membrane glycoprotein involved in particular chemotactic and inflammatory responses, via its N-terminal protein cleavage enzymatic activities. DPP4 expression is found in various cell types, in certain subsets of lymphocytes and frequently overexpressed in primary tumors and metastases where its role remains still poorly understood. Recently, DPP4 was identified as a novel biomarker of senescent cells. In cancers, the harmful effect of senescent tumor cells is well recognized and mediated by the local production of pro-inflammatory cytokines, soluble immunosuppressive factors and metalloproteinases, called 'SASP' phenotype which could be induced by many chemotherapy and radiation regimens. This deleterious microenvironment promotes tumor growth, invasion and neoangiogenesis which can lead to treatment resistance, relapses and poor prognosis in many cancers, especially at advanced stages. STX-1 is a leading first-in-class ADC platform based on a proprietary anti-DPP4 mAb generated after a screen between normal and senescence-induced cells identifying DPP4 as a candidate for cancer targeting. Other biomarkers of interest were also identified as being selectively expressed for further preclinical evaluation. This IgG1/k mAb has potent *in vitro* activities on DPP4+ cells : i) in a bleomycin-induced senescent fibroblasts model; ii) on DPP4-expressing and chemotherapy- or radiotherapy-induced senescent human tumor cell lines with overexpression of DPP4; iii) binding of the mAb to its target results in its internalization into the endolysosomal compartment of cells. The first formulations of STX-1 are undergoing preclinical evaluation *in vitro* and *in vivo* and consist of a classical maleimide-based conjugation, an enzymatically cleavable cathepsin-dipeptide linker comprising a self-immolative spacer and either inhibitor of tubulin (MMAE/DAR4) or topoisomerase I inhibitor (exatecan/DAR8) payloads. Plasma stability and affinity, dose-response potency and permeability bystander activity on human tumor cell lines were evaluated *in vitro*. Preliminary efficacy is demonstrated *in vivo* on tumor xenograft models with various DPP4 expressions (constitutive or chemo/radio-induced to senescence) based on a 21-28 days weekly infusion schedule (3 or 5 µg/kg). The indications selected for further therapeutic development are prostate, liver and colorectal carcinoma models. Data on antitumor efficacy, tolerability and pharmacokinetics will be presented. Further studies will include optimization of the best STX-1 formulation, NHP studies and GMP scale-up with planned IND submission expected in Q3-2024. Exploiting the targeting of senescent cells in cancer based on selected biomarkers such as DPP4 constitutes a new therapeutic avenue to counteract tumor dormancy, recurrences and resistance to conventional chemo/radiotherapies.

#2606 Targeting mesothelin on tumor cells with a novel, completely human fusion construct delivering the serine protease granzyme B.

K. A. Mohamedali[1], L. H. Cheung[1], M. G. Iurascu[1], L. R. DePalatis[2], C. Thuning-Roberson[2], M. G. Rosenblum[1];
[1]UT M.D. Anderson Cancer Center, Houston, TX, [2]H2Biologics, Bolton, MA

Mesothelin is a cell-surface antigen identified as an excellent cancer-associated target upregulated on numerous tumors, including pancreatic and ovarian cancers, as well as mesotheliomas and lung cancers. Granzyme B is a highly cytotoxic serine protease nominally delivered by immune effector cells to target cells, resulting in induction of cell death pathways that are both caspase-dependent and -independent. We developed a fusion protein (GrB-Fc-SD1) composed of GrB and containing SD1, a novel human single-domain antibody that uniquely targets Region III of the mesothelin glycoprotein. The SD1 and GrB domains are tethered by a human IgG heavy chain fragment which enables dimerization. The fusion protein was transiently expressed in HEK-293E cells in serum-free conditions with a final yield of 5 mg/L. Western blot analysis confirmed the expression of this construct as a homodimer. The GrB enzymatic activity in GrB-Fc-SD1 was similar to that of commercially available human granzyme B. ELISA studies confirmed the specific recognition of the SD1 antibody to mesothelin extra-cellular domain. Biacore analysis confirmed binding of GrB-Fc-SD1 with a dissociation constant between 10^{-7} and 10^{-8} M. *In vitro* cytotoxicity against a limited panel of lung, pancreatic and ovarian cancer cell lines expressing surface mesothelin indicate cytotoxicity in the nanomolar range, while cytotoxicity against mesothelin-negative cells was at micromolar levels. *Ex vivo* serum stability studies showed excellent stability of GrB-Fc-SD1 at both 4°C and -20°C over ninety days and a half-life of approximately three days at elevated temperatures (37°C). *In vivo* efficacy studies against Capan-2 xenografts in nude mice using both weekly x 5 and QOD x 5 doses of GrB-Fc-SD1 (130 mg/mg total dose, delivered IP) indicated highly significant efficacy in both dose regimens, with $p < 0.001$ compared to vehicle-treated mice. Mouse body weights were not impacted at the efficacy doses used in this study, indicating that this dose was non-toxic. Histopathology studies revealed a significant decrease in the percentage of Ki-67+ nuclei in treated tumors compared to controls. These data warrant continued investigation of the protein as a therapeutic candidate. Research supported by H2Biologics. Research conducted, in part, by the Clayton Foundation for Research.

#2607 Dual payload immunochemotherapy to treat CD276 positive cancers.

Zhuoxin "Zora" Zhou[1], Jiashuai Zhang[2], Lufang Zhou[3], **Xiaoguang "Margaret" Liu**[4]

[1]Chemical and Biomolecular Engineering, The Ohio State University, Columbus, OH,[2]Biomedical Engineering, The Ohio State University, Columbus, OH,[3]Surgery and Biomedical Engineering, The Ohio State University, Columbus, OH,[4]The Ohio State University, Columbus, OH

The Cancer Genome Atlas (TCGA) dataset showed higher level of CD276 (B7-H3) transcript in multiple cancers, including triple-negative breast cancers (TNBCs), non-small cell lung cancers (NSCLCs) and other cancers, than normal tissues. Our immunohistochemistry staining of hundreds of patient tissue microarrays confirmed the high expression of CD276 surface receptor in >60% of TNBC and >70% of NSCLC while minimal or low expression in 33 normal organs or tissues. This study aims to develop and evaluate a novel treatment strategy, i.e. anti-CD276 mAb-dual payloads conjugate (DualADC), as immune-chemotherapy to treat CD276-positive TNBCs and NSCLCs. First, a new CD276-targeting monoclonal antibody (mAb) capable of delivering payloads and upregulating tumoral immunity was developed and engineered. Then, a new platform to concurrently conjugate both traditional cytotoxic payload and immunoregulating regent with one CD276 mAb (DualADC) was established. Our evaluations showed that this targeted therapy effectively killed multiple subtypes of TNBC and NSCLC, significantly upregulated immune functions in tumor microenvironment, and reduced tumor burden by up to 90-100% in seven animal models (including patient-derived xenograft). The post-treatment analysis using single-cell RNA sequencing, Luminex multiplex cytokine assay, whole blood, histology and histopathology analysis demonstrated an integrated anti-cancer mechanisms and minimal systematic toxicity. Altogether, our study suggested that the 276-DualADC could provide a promising targeted chemo-immunotherapy for CD276-postive cancer patients. In future, translational investigations will be performed to determine the toxicology, optimal dose, and treatment strategy, and the combination with other therapy will also be evaluated.

#2608 Hu2G10 antibody-drug conjugates selectively target cleaved-activated Trop-2 in cancer cells and show therapeutic efficacy against multiple human cancers.

S. Alberti[1], M. Trerotola[2], A. Moschella[1], R. Giavazzi[3], E. Guerra[2];
[1]University of Messina, Messina, Italy, [2]University of Chieti-Pescara, Chieti, Italy, [3]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milano, Italy

Trop-2 is a transmembrane calcium signal transducer which activates growth-signaling networks that converge on Akt, ERK, Cyclin D1, NFkB (1). Trop-2 cleavage by ADAM10 was shown to be an activator switch for induction of cancer growth and metastatic diffusion (2). We devised a strategy to obtain monoclonal antibodies (mAb) capable of recognizing ADAM10-exposed sites in cancer cells. We succeeded at obtaining mAb that efficiently bound Trop-2 expressing cancer cells and were able to inhibit cell growth *in vitro*. We humanized the 2G10 mAb as the IgG1/k Hu2G10 antibody. Hu2G10 binds cancer-specific, cleaved/activated Trop-2 with K_d 10^{-12} M. On the other hand, it binds uncleaved/wtTrop-2 in normal cells with K_d $3.16x10^{-8}$ M, thus promising an unprecedented therapeutic index in patients. Antibody-drug conjugates (ADC) of Hu2G10 were obtained using stable linkers, multiple conjugation chemistries and different payloads, among them topoisomerase I inhibitors, bleomycin, RNA polymerase inhibitor, MMAE and calicheamicin. Hu2G10-ADC selectively killed Trop-2-expressing cells *in vitro.* Dose-response curves were obtained for the BxPC-3 pancreatic cancer, DU-145 prostate cancer, HT29 colon cancer cell lines and KM12SM/Trop2 colon cancer transfectants, reaching EC_{50} values as low as $5.05\ x10^{-10}$ M. Hu2G10-ADC drove high anticancer effectiveness on cell- and patient-derived xenografts from colon, pancreas, prostate and ovarian cancer. Effectiveness followed a gradient of payload potency, with correspondingly high therapeutic indexes. Consistently, neither detectable toxic effects nor weight loss were observed in any subgroup of treated xenotransplant-bearing mice. Taken together these findings candidate anti-Trop-2 Hu2G10-ADC for best-in-class anticancer therapy. (1) E. Guerra et al., The Trop-2 signaling network in cancer growth. Oncogene 32, 1594-1600 (2013).(2) M. Trerotola *et al.*, Trop-2 cleavage by ADAM10 is an activator switch for cancer growth and metastasis. *Neoplasia* 23, 415-428 (2021).

#2609 Vesicular LGALS3BP is a neuroblastoma biomarker and a therapeutic target for combination therapy with antibody-drug conjugate and checkpoint inhibitors.

G. Sala[1], E. Capone[1], I. Cela[1], G. Lovato[1], A. Lamolinara[1], M. Iezzi[1], C. Rossi[1], V. De Laurenzi[1], R. Ippoliti[2], S. Iacobelli[3],
[1]University of Chieti-Pescara, Chieti, Italy, [2]University of l'Aquila, University of L'Aquila, Italy, [3]Mediapharma srl, Chieti, Italy

We have recently shown that targeting circulating LGALS3BP with a maytansinoid-based non-internalizing antibody-drug conjugate (ADC) resulted in tumor eradication of high-risk NMYC-amplified neuroblastoma patient-derived xenografts. LGALS3BP is a high molecular weight, hyperglycosylated and secreted protein which is enriched at the surface of cancer-derived extracellular vesicles (EVs). Here, using a neuroblastoma pseudometastatic preclinical model, we extended our previous work demonstrating that EVs-associated LGALS3BP strictly correlates with disease progression and dissemination. Moreover, to investigate whether LGALS3BP ADC, named 1959sss/DM4, possesses immune-modulating properties, we analyzed DM4 ability to induce immunogenic cell death (ICD). Interestingly, using NXS2 murine neuroblastoma cells, we found that DM4 induced a time-dependent surface expression of three different ICD marker, i.e. calreticulin, HSP70 and HSP90. As it was recently demonstrated that to limit immune surveillance NXS2 cells increase PD-L1 expression in response to IFNγ production in the tumor immune infiltrate, we evaluated potential synergism between LGALS3BP targeting ADC and an anti-PD1 immune check-point inhibitor. To this aim, we genetically manipulated NXS2 cells which resulted nearly negative for murine LGALS3BP expression. Therefore, using a lentivirus-based gene transduction system, we obtained NXS2 cells producing large amounts of vesicular human LGALS3BP. Of note, the vesicular LGALS3BP could be quantified by ELISA and imaged by confocal microscopy using 1959 antibody. Strikingly, while single agent treatment showed a limited antitumor activity in NXS2-LGALS3BP syngeneic model, the LGALS3BP ADC/anti-PD1 combination resulted in a marked inhibition of tumor growth, which was followed by a prolonged survival. In conclusion, our findings establish that vesicular LGALS3BP is a potential biomarker for liquid biopsy and reveals this protein as a suitable target for therapeutic strategy that combines 1959sss/DM4 ADC with immune checkpoint blockade for the treatment of LGALS3BP expressing neuroblastoma.

#2610 Discovery of AM E3: A novel α-TLSPR monoclonal antibody for the ADC treatment of CRLF2-rearranged Ph-like B-ALL.

C. Dall'Armi, V. Di Biasio, C. Paolini, D. Natale, F. Scalabri, A. Missineo, N. Alaimo, M. Nuzzo, A. Demartis, P. Di Pasquale, R. Benoni, F. Caretti, E. Beghetto, F. Colaceci, R. Sasso, V. Pucci, A. Carugo, L. Tomei, C. Toniatti;
IRBM S.p.A., Pomezia, Italy

Background: Patients affected by Ph-like B-cell acute lymphoblastic leukemia (B-ALL) have a high mortality rate and elevated levels of disease relapse upon chemotherapy treatment. More than 60% of Ph-like B-ALL is characterized by genomic rearrangements resulting in high expression level of the CRLF2/TLSPR receptor on the cell surface. While significant advances have been made in developing targeted agents for B-ALL treatment, the CRLF2-rearranged subpopulation is in complete absence of selective and effective therapies. Here, we report the identification of α-TLSPR monoclonal antibodies with therapeutic potential and the preclinical validation of AM E3 as an Antibody-Drug Conjugate (ADC) for the treatment of CRLF2-rearranged Ph-like B-ALL.
Material and Methods: Leveraging a high-complex phage display platform we have first identified several fully human α-TLSPR monoclonal antibodies with single-digit nanomolar affinity for the target. Among them, AM E3 emerged as suitable for ADC development due to its rapid internalization by CRLF2-expressing cells. As a proof of concept, upon conjugation with the cytotoxic payload tesirine (SG3249) AM E3 was validated for anti-tumor response in both CRLF2-rearranged *in vitro* cell lines and *in vivo* xenograft models. Further, since human/mouse CRLF2 homology is low (<35%), we have also developed an ADC surrogate against murine TLSPR to establish a therapeutic window for the ADC therapy in CRLF2-rearranged preclinical models.
Results: ADC AM E3 demonstrated strong cytotoxicity (EC_{50}=40pM) on cell lines derived from hCRLF2-rearranged B-ALL patients. In xenograft models a single injection of ADC AM E3 (0.7mg/Kg) showed antitumoral activity proportional to hCRLF2/TSLPR receptor density at the cell surface. Moreover, ADC AM E3 treatment reduces tumor growth and disease burden of hCRLF2-rearranged B-ALL orthotopic xenografts and extends survival over standard induction therapy. ADC surrogate mB4 AM23, which retains similar properties as the human ADC AM E3, reduces tumor growth and is well tolerated in xenograft models engineered to express mCRLF2/TSLPR.
Conclusions: AM E3 is a novel α-TLSPR mAb with ideal features for the development of a first-in-class ADC therapy. α-TLSPR ADC demonstrated *in vitro* and *in vivo* efficacy as a monotherapy for the treatment of CRLF2/TLSPR rearranged Ph-like B-ALLs and proven to be well-tolerated in surrogate animal studies.

#2611 Non-specific elimination of tumor-associated neutrophils by antibody-drug conjugates boosts anti-tumor immunity for PD-1 immunotherapy.

S. Yao[1], L. Sun[2], X. Zhu[2], H. Xie[3], T. Yang[4], P. Guo[4], H. Tang[2], T. Zhu[2];

[1]School of Materials Science and Engineering, Tianjin University, Tianjin, China, [2]Zhejiang Cancer Hospital, Hangzhou, China, [3]Postgraduate Training Base Alliance of Wenzhou Medical University (Zhejiang Cancer Hospital), Wenzhou, China, [4]Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, Hangzhou, China

Background: Antibody-drug conjugates (ADCs) play a key role in targeted therapy of solid tumors. However, few studies have examined the impact of ADCs on the tumor microenvironment (TME), particularly on innate immune cells. To elucidate this, this study focuses on investigating the comprehensive impacts of ICAM1-DXd on the tumor microenvironment, especially on tumor-associated neutrophils (TAN) and its synergistic effect with PD-1 immunotherapy.
Methods: Firstly, the efficacy and prognosis of ICAM1-DXd, a potent ADC for cervical cancer, were determined in pre-clinical tumor models, providing crucial transcriptomic and biological function information by using RNA-seq. Then, pathological studies were performed to evaluate the abundance and location of TAN (Ly6G+/MPO+) in TME post-ADC treatment. The interaction between TAN and ICAM1-DXd and subsequent impacts on adaptive immune cells (e.g., CD8+ cells) was examined by flow cytometry (FACS), confocal fluorescent imaging, and western blot techniques (WB). Eventually, the synergistic effect of ICAM1-DXd and PD-1 monoclonal antibody were investigated in an immunocompetent animal model.
Results: ICAM1-DXd potently inhibits cervical tumor growth in preclinical models, and RNA-seq analysis revealed that ICAM1-DXd treatment induces a strong down-regulation of neutrophil activation, especially for Ly6G+/MPO+ TANs, a subtype with pro-tumor function. IHC and FACS results confirmed that pro-tumor TANs were efficiently eliminated in TME by ICAM1-DXd treatment via non-specific phagocytosis in comparison with peripheral blood neutrophils. ICAM1-DXd-phagocytised TANs also elicit a strong bystander killing effect by cleaving the quadra peptide linker of ICAM1-DXD by cathepsin B. This ADC-mediated TAN elimination effectively ameliorates immunosuppressive TME and works in synergy with PD-1 immunotherapy in preclinical models.
Conclusion: In preclinical models of cervical cancer, ICAM1-DXd not only directly ablates cancer cells via antigen recognition but also non-specifically kills tumor-promoting TANs, resulting in an improved tumor immune microenvironment, providing a shred of mechanistic evidence supporting ADC and PD-1 combination therapy.

#2613 Treatment of solid tumors with antibody drug conjugates targeting aberrant O-glycoproteins.

A. C. W. Groen[1], N. Shrestha[1], B. Klebanov[1], B. Yu[2], B. Lee[2], C.-W. Chung[2], C. Park[2], M. K. M. Aasted[3], S. Dabelsteen[3], H. H. Wandall[3];
[1]GO Therapeutics, Natick, MA, [2]LegoChem Biosciences, Daejeon, Korea, Democratic People's Republic of, [3]University of Copenhagen, Kobenhavn, Denmark

The lack of antibodies with sufficient cancer selectivity is currently limiting the treatment of solid tumors by immunotherapies. Many solid tumors display aberrant glycosylation that results in the expression of tumor-associated carbohydrate antigens (TACAs) distinct from healthy tissues. Targeting aberrantly glycosylated glycopeptide epitopes provides the cancer selectivity needed for immunotherapy of solid tumors. However, only a few such glycopeptide epitopes have been targeted to date. We have developed a strategy to predict, design, and produce cancer-specific antibodies targeting novel O-glycoprotein epitopes with exquisite cancer specificity. Our mAbs avoid on-target off-tumor toxicity due to the specificity of aberrant glycosylation, and cover a broad range of cancer indications, including breast, lung, colon, pancreatic, and ovarian cancer. Additionally, our antibodies can be used as an IHC companion diagnostic and can be functionalized across a number of modalities, including next-generation CAR-T, T-cell bispecifics, and antibody-drug-conjugates (ADCs).Here, we present two novel antibodies, GO-08 and GO-013, selectively targeting cancer-specific Tn-glycosylated proteins in a site-specific manner with low nanomolar affinities. GO-008 and GO-013 were collectively shown to be highly cancer-selective by immunohistochemistry of sections from a large array of different squamous and adenocarcinomas, including triple-negative breast cancer, lung cancer, gastric cancer, ovarian cancer, pancreatic, and colorectal cancer. The two antibodies were functionalized utilizing ConjuAll™ technology, conjugating the microtubule disrupting payload MMAE via a site-specific beta-glucuronidase cleavable linker. ConjuAll™ functions as a plasma stable, tumor labile linkage, and due to the minimal expression pattern of beta-glucuronidase in healthy tissues, reduces both off- and on-target toxicity due to the minimization of release of free payload in non-tumor tissues. The ADCs based on GO-08 and GO-013 (LCB45A and LCB22A) demonstrated target-specific cytotoxicity invitro and in vivo with tumor elimination in breast and lung PDX models. GO-013 conjugated to MMAE (LCB22A) was well tolerated in cynomolgus monkey toxicity studies. Moreover, the ADCs selectively kill target cells in a human mixed organotypic cancer model without affecting healthy cells, indicating tolerability and safety. The combination of specificity of TACA targeting to differentiate ADC binding from healthy tissue and ConjuAll's tumor selective payload release promises to enable an excellent anti-cancer therapy.

#2614 GlycoConnect™ ADC toolbox expansion with high DAR technology.

L. Lelieveldt, E. Post, M. Nassiet, V. Hendriks, M. Verhagen, R. van Geel, S. van Berkel, F. van Delft;
Synaffix - A Lonza company, Oss, Netherlands

Recently topoisomerase 1 inhibitors have gained significant traction as a cytotoxic payload for ADCs based on the clinical success of camptothecin-based ADCs Enhertu® (DXd) and Trodelvy® (SN-38). In contrast to the majority of other approved ADCs, both Enhertu® and Trodelvy® are feature an average of 7-8 payloads per antibody. Obviously, such a high drug-to-antibody ratio (DAR) effectively delivers more drug to the tumor per internalization event, which is key in driving the clinical success.

Previously, we have shown that the native glycan of monoclonal antibodies is a privileged site for attachment of cytotoxic payloads[1], for the generation of site-specific and stable ADCs with DARs varying from 1-6, while the therapeutic index is further elevated by a highly polar spacer technology (HydraSpace™)[2]. The success of GlycoConnect™/HydraSpace™ ADCs is further driven by the use of exatecan as a potent and highly cell-permeable payload (SYNtecan E™).

Here we show that GlycoConnect™ technology can be readily extended to generate efficacious and safe DAR8 ADCs. We have developed a modular, non-genetic method, involving three simple process steps from any antibody: (a) enzymatic glycan remodeling, (b) strain-promoted azide-alkyne cycloaddition of a bifunctional, branched spacer comprising one strained alkyne and two orthogonal click tags (e.g. tetrazines), and (c) inverse electron-demand Diels-Alder cycloaddition with a branched linker-drug construct based on BCN and a two cytotoxic payloads. The resulting conjugates, with DAR 6 or 8, are rapidly generated with high homogeneity and with good stability. In addition, HIC profiles of the resulting ADCs indicate small relative retention time as an indication of good PK profile. Excellent in vivo tolerability is demonstrated, while efficacy studies in mice xenograft models show that the DAR8 technology clearly out-performs currently marketed ADCs (including Enhertu®).

#2615 Preclinical development of a next generation antibody drug conjugate (ADC) targeting cMET for treatment of solid tumors.

L. Xiao[1], W. Lian[1], S. Song[1], Q. Liu[1], Q. Zong[1], S. Stann[2], J. Cai[1], T. Xue[1];
[1]MediLink Therapeutics (Suzhou) Co., Ltd., Suzhou, China, [2]MediLink Therapeutics USA, INC., Boston, MA

cMET (mesenchymal-epithelial transition factor), which belongs to the MET family, is a type of receptor tyrosine kinase that is expressed on the surfaces of various epithelial cells. The elevation of cMET can promote the development and progression of multiple cancers. cMET- ADCs have shown promising clinical activity with highest cMET levels, indicating tumor cMET levels may be limited for efficacy. YL211, a novel cMET-ADC was developed by leveraging on MediLink's tumor microenvironment activable linker-payload platform (TMALIN platform), which could release the payload both in the tumor cell and in the tumor microenvironment. YL211 is comprised of an anti-cMET humanized monoclonal antibody conjugated to a novel topoisomerase 1 inhibitor *via* a protease-cleavable linker. The novel linker-payload and site-specific conjugation of YL211 results in a homogeneous product with a DAR (Drug-to-Antibody Ratio) of 8. Furthermore, the advancement in linker-payload design has facilitated the development of more hydrophilic ADCs, which exhibit minimal impact on the antibody's characteristics while being less prone to aggregation and showcasing lower systematic clearance. Along with release of the payload in the tumor microenvironment extracellularly, upon binding to cMET on tumor cell surfaces, the antigen-ADC complexes are internalized to lysosomal vesicles and subsequently release the toxic payload. The cytotoxic features drive cell cycle arrest, apoptosis, elevation of PARP/caspase 7 expression, as well as cell death and bystander effect. These findings translated in vivo where YL211 showed superior efficacy in causing tumor regressions and good tolerability in both cell lines and patient-derived xenograft (CDX and PDX) mouse models with both low to high cMET expression levels (H358, CR5088, *ect.*). The *in vivo* pharmacokinetics in monkeys showed that YL211 is highly stable with less than 0.1% (molar ratio) payload released in circulation. GLP safety evaluations demonstrated good safety profiles and no off-target toxicity in monkeys. These non-clinical data suggest the stability of the linker in circulation as well as efficient release of the payload in tumors with improved therapeutic window. Taken together, preclinical data suggest that YL211 could be a promising treatment strategy for cMET positive cancer patients.

#2616 BCG033, a novel bispecific antibody-drug conjugate targeting PTK7 and TROP2, demonstrates preclinical efficacy against triple-negative breast cancer and other solid tumor xenografts.

S. Yao, C. Shang, G. An, **C. Guo**, W. An, Y. Yang;
Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

Metastatic triple-negative breast cancer (TNBC) patients have poor overall survival, highlighting the need for novel treatments. Although the TROP2-targeting ADC sacituzumab govitecan recently received accelerated approval from the FDA for the treatment of patients with metastatic TNBC, the on-target toxicity of this single-target agent has limited clinical efficacy. We sought to improve the specificity and efficacy of future TNBC-targeted therapies by generating a bispecific antibody-drug conjugate (bsADC) targeting TROP2 and PTK7, another tumor-associated antigen (TAA) that is highly expressed in TNBC and correlates with poor prognosis and metastatic disease.

We previously generated fully human antibodies targeting PTK7 and TROP2 from Biocytogen's fully human, common light chain antibody transgenic RenLite® mice, which were selected such that their monovalent antibodies exhibited reduced internalization profiles for improved tumor selectivity. These antibodies were then constructed into a bispecific antibody targeting PTK7×TROP2, which demonstrated reactivity to human and cynomolgus monkey antigens and binding to multiple cancer cell lines, including TNBC, with high affinity. PTK7×TROP2 bsAb also showed enhanced internalization *in vitro* compared with parental monovalent antibodies. Next, the PTK7 x TROP2 bsAb was conjugated to vcMMAE with a drug-to-antibody ratio (DAR) of 4 to generate a bsADC (BCG033). BCG033-vcMMAE demonstrated superior activity to benchmark and parental ADCs in a cell line-derived xenograft (CDX) TNBC model with low PTK7 expression. Here, we demonstrate that BCG033-vcMMAE ADCs also exhibited superior efficacy to benchmark ADCs in PDX models, including TNBC xenografts and NSCLC xenografts. We next tested the efficacy of the PTK7 x TROP2 bsAb conjugated to BLD1102, Biocytogen's novel, proprietary linker/payload composed of a DNA Topo I inhibitor payload and a highly hydrophilic protease-cleavable linker, with a DAR of 8. BCG033-BLD1102 showed potent activity in a colorectal cancer PDX model in which benchmark ADCs were inactive, even at high doses.

In summary, BCG033 conjugates demonstrate promising preclinical efficacy *in vivo*, which ultimately could provide a new treatment option for TNBC and other solid tumors expressing PTK7 and TROP2.

#2617 BCG022, a novel HER3×MET bispecific antibody-drug conjugate (bsADC), demonstrates promising anti-tumor efficacy.

Z. Li, C. Shang, Z. Han, G. An, **C. Guo**, W. An, Y. Yang;
Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

HER3 and MET expression act as bypass resistance mechanisms, conferring resistance to multiple therapeutic agents, such as EGFR TKI treatment. HER3 and MET are also co-expressed at high prevalence in multiple tumor types, including gastric, colorectal, breast, and non-small-cell lung cancer (NSCLC). In addition, HER3 and MET are frequently overexpressed in liver metastases from patients with colorectal cancer, indicating that targeting both targets may provide clinical benefit.

We previously reported generation of a fully human bispecific antibody (bsAb) targeting HER3 and MET using RenLite® mice, which contain the full human heavy chain variable domain with a common human kappa light chain to facilitate bispecific antibody assembly. This bsAb demonstrated reactivity to human and cynomolgus monkey antigens and binding to multiple cancer cell lines, including NSCLC, gastric, colorectal, and hepatocellular cancer cell lines. The bsAb also showed enhanced internalization activity compared to parental monovalent antibodies in the NUGC-4 cell line expressing HER3 and MET.

Here, we evaluated the efficacy of the bsAb when conjugated to two distinct payloads: vcMMAE and BLD1102, Biocytogen's novel, proprietary linker/payload system composed of a DNA Topo I inhibitor payload (BCPT02) and a highly hydrophilic protease-cleavable linker. The *in vivo* efficacy of BCG022-vcMMAE and BCG022-BLD1102 was evaluated in cell-derived NSCLC and gastric cancer xenografts, and in patient-derived gastric and pancreatic xenograft models. Both demonstrated strong anti-tumor activity, with efficacy greater than or comparable to benchmark ADCs. Taken together, these promising preclinical results suggest that the BCG022 bsADC could be a novel treatment for HER3 and MET co-expressing tumors.

#2618 BCG017, a bispecific ADC targeting PTK7 and EGFR exhibits anti-tumor efficacy in PDX models.

S. Yao, C. Shang, Z. Li, G. An, **C. Guo**, W. An, Y. Yang;
Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

EGFR is a favored target in various cancer therapies. However, EGFR-based treatments have been challenged by drug resistance and cytotoxicity. Targeting EGFR with an antibody-drug conjugate (ADC) is a promising new therapeutic strategy to address the drug resistance, due to the potent killing effects of the payload. Furthermore, we hypothesized that development of a bispecific ADC (bsADC) targeting EGFR and another tumor-associated antigen (TAA) might improve the tumor selectivity, thereby limiting the on-target off-tumor toxicity. One such TAA candidate is PTK7, which belongs to the same receptor tyrosine kinase family as EGFR, and is co-expressed with EGFR in multiple types of solid tumors, including lung, esophageal, head and neck, and colon cancers. Herein, we developed a fully human anti-human PTK7 EGFR bsAb using our proprietary common light chain RenLite® mouse platform and knobs-into-holes technology. The anti-PTK7 EGFR bsAb demonstrates good purity by SEC-HPLC, and can cross-react with human and cynomolgus monkey antigens with favorable affinity. The PTK7 x EGFR bsAb demonstrated higher binding to various types of cancer cell lines, as well as enhanced internalization *in vitro* compared with PTK7 parental antibody. Next, the bsAb was conjugated with monomethyl auristatin E (MMAE) to generate an anti-PTK7 x EGFR bsADC, BCG017, with a drug-to-antibody ratio of approximately 4. BCG017 demonstrated superior anti-tumor activity compared to benchmarks and its PTK7 parental ADC in cell-derived non-small-cell lung cancer (NSCLC) xenografts, and showed enhanced anti-tumoractivity when compared to benchmark ADCs and parental ADCs in patient-derived breast and pancreatic ductal adenocarcinoma xenograft models. These results suggest that BCG017 have the potential to be a novel therapeutic alternative for PTK7 and EGFR co-expressing tumors.

#2619 A novel EGFR×HER3-targeting bispecific antibody drug-conjugate, BCG019, demonstrates robust anti-tumor efficacy in preclinical evaluation.

Z. Li, C. Shang, G. An, **C. Guo**, W. An, Y. Yang;
Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

EGFR and HER3 are receptor tyrosine kinases that are highly expressed in multiple epithelial tumors. EGFR point mutations and small insertions within the kinase domain are common in lung cancer. HER3 is overexpressed in patients who are resistant to EGFR-TKI therapy, and is one of the common resistance mechanisms of EGFR and HER2-targeted therapy. We hypothesize that simultaneous targeting of EGFR and HER3 with a bispecific ADC will have the potential to overcome the resistance caused by HER3 after EGFR-targeted therapy and obtain better efficacy than the combination of EGFR monotherapy and HER3 monotherapy.

We first generated fully human bispecific antibodies (bsAbs) targeting EGFR and HER3 using RenLite® mice, which contain the full human heavy chain variable domain with a common human kappa light chain to facilitate bispecific antibody assembly. The anti-EGFR×HER3 bsAb demonstrated reactivity to human and cynomolgus monkey antigens and binding to multiple cancer cell lines, including NSCLC, gastric, pancreatic, colorectal, and breast cancer cell lines. The anti-EGFR×HER3 bsAb also showed high internalization activity in cell lines expressing EGFR and HER3.

The anti-EGFR×HER3 bsAb was then conjugated with vc-MMAE (valine-citrulline-monomethyl auristatin E) for proof-of-concept studies, as well as BLD1102, Biocytogen's novel, proprietary linker/payload system composed of a DNA Topo I inhibitor payload (BCPT02) and highly hydrophilic protease-cleavable linker, to generate EGFR- and HER3-targeting bispecific ADC candidates BCG019. *In vivo* efficacy of the bsADC candidates were evaluated in cell-derived NSCLC and gastric cancer xenografts and in patient-derived gastric and colorectal xenograft models. Both bsADCs showed superior anti-tumor activity when compared to benchmark ADCs. Collectively, these results suggest that our novel anti-EGFR×HER3 bsADC has therapeutic potential for EGFR and HER3 co-expressing tumors.

#2620 BCG016, a first-in-class bispecific antibody-drug conjugate targeting 5T4 and MUC1, demonstrates potent preclinical anti-tumor activity.

Z. Han, C. Shang, Y. Zhang, G. An, **C. Guo**, W. An, Y. Yang;
Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

5T4 is a highly expressed tumor-associated antigen associated with adverse clinical outcomes in solid tumors, and is an attractive therapeutic target due to low expression on normal adult tissues. While several therapeutic agents targeting 5T4 antigen are currently being evaluated in human clinical trials, none have yet entered the market. Another target, MUC1, is currently under clinical investigation, with most drugs in clinical trials showing limited efficacy due to shedding of the target antigen MUC1-N. 5T4 and MUC1 are commonly co-expressed in various solid tumors, including lung, breast, colorectal and pancreatic cancers, suggesting that targeting both antigens with a single drug could be a promising therapeutic strategy.

We previously identified and evaluated antibodies targeting human 5T4 and MUC1-C (cleaved MUC1) using RenLite® fully human common light chain mice. Here, selected antibodies were constructed into 5T4×MUC1 bispecific antibodies (bsAb). The 5T4-MUC1 bsAb demonstrated high avidity in multiple human tumor cell lines by flow cytometry. Notably, the parental 5T4 antibody also binds strongly to many tumor cell lines. Internalization assays demonstrate that the internalization of 5T4-MUC1 bsAb in breast cancer cells was enhanced compared to the parental anti-5T4 and anti-MUC1 monoclonal antibodies, as measured by Incucyte® live cell imaging. Subsequently, the 5T4-MUC1 bsAb was then conjugated with monomethyl auristatin E (MMAE) to generate 5T4 x MUC1 bsADC (BCG016). Cytotoxicity assays indicate that BCG016 improved tumor cell killing *in vitro* compared to benchmark ADCs, and *in vivo* efficacy studies showed superior anti-tumor efficacy of BCG016 in patient-derived NSCLC xenografts compared to benchmark ADCs and parental ADC combination therapy.
In summary, we have generated a novel bispecific ADC targeting 5T4 and the cleaved MUC1-C protein, which remains membrane-bound on tumor cells. The 5T4-MUC1 bsADC showed superior anti-tumor efficacy in PDX models and has the potential to be a novel therapeutic for 5T4 and MUC1 co-expressing tumors.

#2621 Preclinical Efficacy of DM002, a bispecific HER3×MUC1 antibody-drug conjugate with a novel DNA topoisomerase I inhibitor, in solid tumor models.

Y. Zhang[1], C. Shang[1], N. Wang[2], G. An[1], **C. Guo**[1], W. An[1], Y. Yang[1];
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China, [2]Doma Biopharmaceutical (Suzhou) Co., Ltd., Suzhou, China

MUC1 is a known tumor-associated antigen (TAA), but previous anti-MUC1 agents have shown limited clinical efficacy due to neutralization by the soluble N-terminal autoproteolytic product of MUC1. More recently, HER3-targeted ADCs, such as Patritumab deruxtecan, have shown encouraging early clinical activity in a variety of tumors. However, the majority of patients did not exhibit response to paritumab deruxtecan treatment. Therefore, improved therapies targeting these TAAs are needed.

As HER3 and MUC1 are co-expressed in a wide range of cancer types, we hypothesized that simultaneous targeting of HER3 and MUC1 with a bispecific antibody-drug conjugate (bsADC) could potentially lead to increased efficacy, reduced resistance and improved safety in the clinical setting. We generated an anti-HER3×MUC1 bispecific antibody using the fully human common light chain antibody transgenic mice (RenLite®).

The HER3×MUC1 bsAb showed improved cell binding and internalization *in vitro* compared to the parental mAb, suggesting synergy between the two arms. We then conjugated the HER3xMUC1 bsAb with vcMMAE for proof-of-concept studies, or with our novel DNA topoisomerase I inhibitor linker/payload conjugates (BLD1102) to make DM002-BLD1102 bsADC. Both bsADCs potently inhibited the growth of HER3+MUC1+ PDX tumors. DM002-vcMMAE also showed greater *in vivo* efficacy than its parental mAb ADCs, consistent with their *in vitro* internalization activity. DM002-BLD1102 also showed strong anti-tumor activity in DM002-vcMMAE resistant PDX models, suggesting the superiority of this new DNA topoisomerase I inhibitor linker/payload over the classical vcMMAE linker/payload. In conclusion, the HER3×MUC1 bsAb is a promising agent for the treatment of HER3 and MUC1 positive tumors.

#2622 TUB-040, a novel Napi2b-targeting ADC built with ethynylphosphonamidate conjugation chemistry, demonstrates high and long-lasting anti-tumor efficacy via Topoisomerase-I inhibition and excellent tolerability predictive of a wide therapeutic window in humans.

S. Schmitt, I. Mai, P. Machui, S. Herterich, D. Hauswald, P. Ochtrop, P. Cyprys, I. Kozlowska, A. Kitowski, M. Gerlach, O. Marcq, P. A. Trail, D. Schumacher, M.-A. Kasper, G. Fingerle-Rowson, B. Hock, **J. Helma-Smets**, A. M. Vogl;
Tubulis GmbH, Planegg, Germany

TUB-040 is a novel Antibody-Drug Conjugate (ADC) targeting Napi2b, a highly overexpressed target in ovarian cancer and lung adenocarcinoma. Napi2b is a member of the solute-carrier transporter family with eight transmembrane domains and an antibody-accessible extracellular loop, that regulates sodium-dependent phosphate homeostasis. Ethynylphosphonamidate conjugation chemistry was used to build TUB-040 with a homogenous DAR (drug-antibody-ratio) of 8 and the Topoisomerase I inhibitor Exatecan as payload, which is connected to a humanized, Fc-silenced IgG1 antibody targeting Napi2b using a cleavable linker system. *In vitro*, TUB-040 is characterized by sub-nanomolar affinity and specific binding to Napi2b, efficient target-mediated internalization and high cytotoxicity towards Napi2b-expressing ovarian and lung cancer cell lines as well as bystander activity against co-cultured target-negative cells. TUB-040 induces DNA damage and apoptosis in a dose-dependent fashion as well as markers of immunogenic cell death. In addition, no unspecific uptake and cytotoxicity in healthy, target-negative human cells could be detected, reducing the risk of target-independent toxicities. Pharmacokinetic analysis showed that - in contrast to maleimide-conjugated ADCs - TUB-040 is highly stable - and does not lose or transfer its linker-payload to serum proteins during blood circulation, thus enabling most efficient and continued delivery of Exatecan to the tumor. Across a variety of cell line derived xenograft (CDX) and patient derived xenograft (PDX) models of ovarian and non-small cell lung cancer, including models with low target expression, single dose administration of TUB-040 results in long-lasting tumor growth inhibition with high complete remission rates *in vivo*. The minimally effective dose (MED) leading to complete remission is 1 mg/kg. Preliminary repeat-dose toxicological assessment of TUB-040 in the pharmacologically relevant species cynomolgus monkey demonstrated that TUB-040 is well tolerated with no signs of lung toxicity and thrombocytopenia. Allometric scaling and PK/PD modelling predicts a human serum half-life greater 10 days and a therapeutic index in humans up to 55. Based on these results, TUB-040, designed with differentiating technology for optimal efficacy and tolerability, is ready for testing in clinical trials.

#2623 Enabling 5T4 for targeted cancer therapy: TUB-030, a novel ADC built with ethynylphosphonamidate conjugation chemistry, shows long-lasting anti-tumor activity via Topoisomerase-I inhibition with an optimized therapeutic index.

S. Schmitt, I. Mai, P. Machui, S. Herterich, D. Hauswald, P. Ochtrop, P. Cyprys, I. Kozlowska, A. Kitowski, M. Gerlach, O. Marcq, P. A. Trail, D. Schumacher, M.-A. Kasper, G. Fingerle-Rowson, B. Hock, **J. Helma-Smets**, A. M. Vogl;
Tubulis GmbH, Planegg, Germany

TUB-030 is a novel Antibody-Drug Conjugate (ADC) targeting the oncofetal 5T4 antigen, a glycoprotein, that is functionally involved in regulation of the Wnt signalling pathway and promoting cellular motility and adhesion. Immunohistochemical analysis identified 5T4 overexpressed in many types of cancers, including bladder, lung, breast, stomach, esophagus, head and neck, colon, and ovarian. Analysis in fresh frozen healthy human tissue with the therapeutic mAb candidate of TUB-030 revealed limited cross reactivity. Ethynylphosphonamidate conjugation chemistry was used to build TUB-030 with a homogenous DAR (drug-antibody-ratio) of 8 and the Topoisomerase I inhibitor Exatecan as payload, which is connected to a humanized, Fc-silenced IgG1 antibody targeting 5T4 using a cleavable linker system. Overall, TUB-030 contrasts previous ADC designs targeting 5T4, implementing several layers of differentiation in terms of antibody, payload and conjugation technology. In vitro, TUB-030 is characterized by sub-nanomolar affinity to 5T4, efficient target-mediated internalization and strong cytotoxicity towards cancer cells from different tumor indications with a broad range of 5T4 expression levels. Differently to previous 5T4-targeting ADCs, TUB-030 has efficient bystander activity against co-cultured target-negative cells, which facilitates targeting of tumors with heterogenous 5T4 expression. Pharmacokinetic analysis showed that TUB-030 is highly stable - and does not lose or transfer its linker-payload to serum proteins during blood circulation and antibody-like clearance profile contrasting maleimide-conjugated ADCs and enabling most efficient and continued delivery of Exatecan to the tumor site. Single-dose treatment with TUB-030 results in long-lasting tumor regression with high complete remission rates across a variety of both cell-line derived xenograft (CDX) and patient-derived xenograft (PDX) cancer models of multiple tumor indications in vivo, including models with low target expression. Preliminary repeat-dose toxicological assessment of TUB-030 in a pharmacologically relevant non-human primate species demonstrated that TUB-030 is well tolerated. The preclinical results underline that TUB-030 with novel ADC technology has the potential to enable 5T4 as a therapeutic target and provide treatment options in numerous solid cancer indications with high unmet medical need supporting further development towards the clinic.

IMMUNOLOGY: Epigenetic Regulation of Tumor Immunity
Poster Session

#2627 PanCancer epigenetic regulators of lymphocyte activation states.
A. Karpova, N. V. Terekhanova, S. Chen, R. G. Jayasinghe, A. Houston, W. Caravan, R. C. Fields, L. Ding;
Washington University in St Louis, St. Louis, MO

Several immune cell types have been successfully targeted for immunomodulatory therapy; however, the efficacies of such therapies are hindered by incompatible immune cell activation states. CD8+ T-cell exhaustion is one of the most studied T-cell states in the context of cancer and was shown to limit checkpoint blockade efficacy. Although CD8+ T-cell exhaustion studies in mice showed this state is tightly regulated by chromatin accessibility of cis-regulatory elements (CREs) and transcription factor activation, the exploration of these mechanisms, their prevalence, and their specificity in human cancers remains limited. In addition, chromatin accessibility signatures of other lymphocyte (CD4+ and NK) states frequently found in solid tumors have not been carefully characterized in a pan-cancer setting. Here we introduce the first single-nuclei atlas of pan-cancer and disease-specific cis- and trans-regulatory elements in tumor infiltrating lymphocytes. We profiled ~140K T-cell and NK cell nuclei with snATAC-seq and snRNA-seq from 227 tumor and normal samples from eleven cancer types. We distinguished two major subpopulations among exhausted CD8+ T-cells: GZMK expressing (CD8+ GZMK+ Tex) and ITGAE+ tissue-resident (CD8+ Trm ex). CD8+ GZMK+ Tex was enriched in clear cell renal cell carcinoma, while CD8+ Trm ex was found in all other cancers. Both exhausted groups featured high motif accessibility and expression of NR4A1, NFATC2, and NFKB2 transcription factors (previously reported to regulate exhaustion), but differed in EOMES motif accessibility and gene expression. We have identified other lymphocyte subpopulations showing exhaustion signatures, including CD4+ follicular helpers (CD4+ Tfh), CD4+ regulatory cells (CD4+ Tregs), and weakly cytotoxic tissue-resident NK cells (trNK weak). All these subpopulations showed increased expression and motif accessibility of the NR4A1 transcription factor, highlighting its role in regulating dysfunctional states not only in CD8+ T-cells, but also in CD4+ and NK cells. Additionally, CD4+ Tfh and Tregs showed enhanced activity of NFKB1, NFKB2, and POU2F2, and trNK weak cells had increased activity of NR4A2 and NR2F2. To put our results into clinical perspective, we have collected cohorts of renal cancer, melanoma and triple-negative breast tumors treated with immunotherapy in clinical trial settings, and showed elevated GZMK expression in exhausted T-cells in responders compared to non-responders.

#2628 Generation of multi-antigen specific T cells for ovarian cancer using Prussian Blue nanoparticles and photothermal therapy.

E. E. Grundy[1], A. Lee[1], S. Chin[1], M. Hadley[1], D. Schmidt[1], L. Wang[1], O. Cox[1], K. Omar[1], C. M. Bollard[2], R. Fernandes[1], K. B. Chiappinelli[1];
[1]The George Washington University, Washington, DC, [2]Children's National Hospital, Washington, DC

The immunosuppressive nature of ovarian cancer (OC) allows these tumors to evade the immune system, contributing to late-stage diagnoses and poor clinical outcomes for patients. However, a higher number of tumor-infiltrating lymphocytes is associated with improved clinical outcomes in OC. One type of lymphocyte, the T cell, can traffic to the tumor and kill tumor cells. We have shown that treating tumor cells with Prussian Blue nanoparticles and photothermal therapy (PBNP-PTT) results in immunogenic cell death, a form of cell death that is visible to the immune system, including T cells. PBNP-PTT-treated tumor cells were then used to expand tumor-specific T cells from partially genetically matched healthy donors against breast and brain cancer cell lines. These expanded T cells were better able to recognize and kill the target tumor cell lines than bulk unexpanded T cells from the same donors. Hence, we hypothesized that using PBNP-PTT-treated OC cells would allow us to expand a polyclonal tumor-specific T cell product that is cytolytic against OC cells *in vitro* and *in vivo*.We first evaluated whether multi-antigen OC-specific T cells could be expanded from partially genetically matched healthy donors and confirmed that PBNP-PTT elicited immunogenic cell death in the HLA-A*02:01 human OC cell lines Hey and TykNu. Using our established *in vitro* T cell expansion protocol, we then successfully expanded T cells from multiple HLA-A*02:01 healthy donors (n=3) against these cell lines. Functional analyses—including interferon-gamma ELISPOT, multi-color flow cytometry, and cytotoxicity assays—demonstrated that the expanded T cells had enhanced anti-tumor responses against OC cell lines compared to bulk unexpanded T cells derived from the same donors. Current work is expanding this approach to a syngeneic murine setting in C57BL/6J mice. Moreover, we will evaluate HLA-matched T cells and tumor cells from patients with OC *ex vivo*. Collectively, these efforts serve as a novel approach towards a curative immunotherapy for OC.

#2629 N6AMT1-mediated DNA 6mA modification in DNA repetitive elements LINE-1 dynamically regulates the IFN signal pathway in colorectal cancer.

Z. Yuan, X. Liu, X. Wang, Y. Luo, **H. Yu**;
The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: DNA N^6-methyldeoxyadenosine (6mA) modification is the most prevalent DNA modification in prokaryotes, like bacteria, which participates in the host defense system. However, the presence and function of DNA 6mA in eukaryotes remains elusive. Many studies have reported that DNA 6mA modification is distributed across the genome and regulates transcription and the activity of transposable elements, in which the DNA 6mA methyltransferases and demethylases are involved, including the methyltransferase N6AMT1. LINE-1 is a genome-wide DNA repetitive element that acts as a diagnostic and prognostic biomarker for colorectal cancer. Therefore, we aimed to map the DNA 6mA in LINE-1 and investigate its role in the colorectal cancer (CRC) development.
Methods: The restriction-enzyme-digestion assay followed by quantitative PCR (6mA-RE-qPCR) was used to evaluate the LINE-1 DNA 6mA levels in the tumor and normal tissues. The DNA Nanopore sequencing was utilized to determine DNA 6mA and 5mC modifications. After the knockdown of N6AMT1, the dynamic changes of LINE-1 DNA 6mA methylation and RNA transcription under various stresses were determined by 6mA-RE-qPCR and qPCR, and the subsequent RNA-seq was performed to explore the downstream regulated pathways.
Results: The DNA 6mA methylation in LINE-1 is highly variant in the tumor and normal tissues, and it was significantly less prevalent in tumor tissues. The genomic distribution of LINE-1 DNA 6mA is significantly different from that of LINE-1 5mC. The LINE-1 DNA 6mA methylation and RNA transcription levels were dynamically changed in response to various stimuli, including 5-FU and H_2O_2. Knockdown of N6AMT1 downregulated LINE-1 DNA 6mA methylation and RNA transcription, promoted the proliferation, migration and invasion of CRC cells in vitro, and suppressed the IFN-gamma pathway. The co-culture assay showed N6AMT1 facilitated chemotaxis of macrophages and cytotoxicity of T cells via the IFN-gamma signal pathway.
Conclusions: The heterogeneity of DNA 6mA methylation in LINE-1 and its dynamic change in response to stimuli indicate a biological role of LINE-1 6mA methylation in the primary and adaptive tumor heterogeneities, which provides a novel insight into cancer development. The N6AMT1-mediated DNA 6mA modification in LINE-1 regulates CRC development through the IFN-gamma pathway.
Keywords: N6AMT1, LINE-1, DNA 6mA methylation, colorectal cancer

#2630 Identifying most promising combination therapies for immune suppressive breast cancer using a combined in vitro/ in vivo approach.

H. Silberzahn, M. Bleisch, A. Lohr, V. Knauff, K. Lashuk, **J. B. Schueler**;
Charles River Laboratories, Inc., Freiburg, Germany

Combining epigenetic therapy with immunotherapy is a promising strategy to address the complexities of cancer biology. However, it's important to note that the field is still evolving, and more research is needed to understand the optimal combinations, timing, and patient populations that will benefit the most from these approaches. We evaluated a combination of two different checkpoint inhibitor therapies (anti-CTLA4 and anti-PD1) with two different hypomethylating agents (5-azacytidine, AZA and Decitabine, DEC) in vitro and in vivo using a mouse breast cancer cell line 4T1 known to be resistant towards checkpoint inhibition (CPi). Beside tumor cell killing and tumor volume measurement, cytokine expression and immune cell phenotyping was determined. In a co-culture assay with autologous T cells and 4T1 cells, antitumor efficacy weas increased in all combination arms using AZA but not in combination with DEC. The combination of AZA with anti-CTLA4 was significantly better than the respective monotherapies (oneway ANOVA, $p< 0.001$). This effect was observed as well in the combination with anti-PD1 and AZA, however it was less pronounced (oneway ANOVA, $p< 0.01$). Of note, AZA restored the CTLA4 expression on CD8+ T cells in vitro, which was reduced by co-culture with tumor cells alone. In the follow-up in vivo experiment we focus on the combination of both CPi with AZA on different treatment schedules in the combination arms. The combination of anti-CTLA4 and AZA in a staggered treatment schedule displayed significant efficacy compared to control (oneway ANOVA, $p< 0.05$). The implantation of 4T1 reduced the number of T cells in bone marrow (BM), peripheral blood (PB) and spleen of the mice, confirming the immune-suppressive nature of the breast cancer line. This effect was restored under treatment with AZA in monotherapy and combination with CPi. Interestingly AZA reduced the number of immunosuppressive MDSC in BM, spleen and in tumor tissue. Vice versa NK cells were increased in BM, spleen and tumor tissue under treatment with AZA. AZA reduced the number of circulation tumor cells in PB and increased as already shown in vitro the percentage of CD8/CTLA4++ in PB. The PCA analysis of 36 mouse cytokines in vivo displayed two main clusters separated mainly by the presence of absence of AZA in the treatment arms. The combination arms which displayed the highest efficacy showed an increase in CXCL1, G-CSF, IL-6, LIF, M-CSF, MCP-1 (CCL2) and MCP-3 (CCL7) and a decrease of IFN-gamma, CXCL2. This is in line with the more inflammatory pattern of the tumor infiltrating lymphocytes in those groups. In summary, we have strong evidence that AZA influences the immune landscape of breast cancer towards a more inflammatory subtype. The combination with CPi was superior to the monotherapy. In addition, our data indicate that the treatment schedule of the combination might have a crucial influence on efficacy.

#2631 HMGA1 chromatin regulators drive immune evasion in myeloproliferative neoplasms by repressing gene networks involved in antigen presentation.

A.-A. Supreme, L. M. Resar, J. Kim, B. West, M. Antopia, H. Woo, K. Reddy, J.-H. Kim, L. Cope, J. Spivak, A. Moliterno;
Johns Hopkins University School of Medicine, Baltimore, MD

Myeloproliferative neoplasms (MPN) are clonal hematopoietic stem cell disorders caused by hyperactive JAK/STAT signaling and increased risk of transformation to acute myeloid leukemia (AML). However, targetable mechanisms driving progression remain elusive and therapies are ineffective after leukemia develops. We discovered that HMGA1 chromatin regulators are required for leukemogenesis in *JAK2*^{V617F} models of MPN AML by dysregulating transcriptional networks involved in proliferation and cell fate (Li et al, *Blood* 2022). Multi-omics analyses also showed that HMGA1 represses gene networks involved in interferon γ signaling in *JAK2*^{V617F} AML cells, a pathway that drives immune escape in solid tumors. We therefore sought to test whether HMGA1 drives immune evasion during leukemic transformation in MPN. Integrating RNA/ChIP/ATACseq in *JAK2*^{V617F} AML cells revealed that HMGA1 represses transcriptional networks involved in antigen presentation, including genes encoding major histocompatibility complex (MHC) class I and II proteins. Silencing *HMGA1* via CRISPR or shRNA results in up-regulation of MHC genes, with greatest induction of MHC class II (MHC II) genes (*HLA-DRA, DRB1, DPA1, DPB1*). Further, HMGA1 depletion increases protein levels of MHC II. To determine how HMGA1 represses MHCII genes, we examined genome architecture at the MHC II loci. We found that HMGA1 recruits repressive histone marks to regulatory regions for MHC II genes which preclude binding by CTCF, a chromatin regulator involved in genome organization, and CIITA, a transcription factor that activates MHC II genes. HMGA1 depletion enhances chromatin accessibility at critical enhancers (super enhancers) involved in MHC II expression, which allows CIITA and CTCF to activate MHC II genes. Because the histone acetylase inhibitor, entinostat, induces MHC II genes in solid tumors, we assessed MHC II with entinostat and HMGA1 depletion. *HMGA1* silencing enhances up-regulation of MHC II by entinostat. To test the functional significance of HMGA1 in immune evasion, we performed co-culture experiments with T cells and *JAK2*^{V617F} AML cells which showed that *HMGA1* silencing in AML cells activates T cells, resulting in cytotoxic T cell killing of *JAK2*^{V617F} AML cells. To examine the relevance of this pathway in patients, we interrogated RNAseq from peripheral blood mononuclear cells and found that *HMGA1* overexpression is associated with repression in MHC II genes in about 30% of MPN patients after progression to AML. Together, these data define a new mechanism of gene repression by HMGA1 through chromatin compaction and repressive histone marks that preclude CIITA and CTCF binding to the MHC II loci. Both HMGA1 depletion and entinostat up-regulate MHCII genes, thus illuminating HMGA1 as a potential therapeutic target to stimulate an immune attack and prevent MPN progression.

#2632 A new paradigm for brain tumors treatment: Guadecitabine as a fundamental player to improve tumor immune response.

M. Lofiego[1], F. Piazzini[1], F. Caruso[2], F. Marzani[1], L. Solmonese[1], E. Bello[1], F. Celesti[1], M. Costa[2], T. Noviello[3], R. Mortarini[4], A. Anichini[4], M. Ceccarelli[3], S. Coral[1], A. Di Giacomo[1], M. Maio[1], A. Covre[1];

[1]University of Siena, Siena, Italy, [2]BIOGEM Institute of Molecular Biology and Genetics, Ariano Irpino, Italy, [3]University of Miami, Miami, FL, [4]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Glioblastoma multiforme (GBM) is a highly aggressive primary brain tumor refractory to standard treatments and to immunotherapy with immune-checkpoint inhibitors (ICI) (PMID: 35626018). Interestingly, melanoma brain metastases (MM-BM), sharing the same niche as GBM, often respond to current ICI immunotherapies (PMID: 36521332). The role of epigenetic modifications in regulating GBM cellular proliferation, invasion, and prognosis, as well as their impact on the cross-talk between GBM and immune cells in the tumor milieu, has become evident (PMID: 34361090). Consequently, manipulating the epigenome has emerged as a therapeutic opportunity in GBM.

Methods: Microarray transcriptional and methylation profiles, followed by gene set enrichment and IPA analyses, were conducted to study the differences in constitutive expression profiles between GBM and MM-BM cells compared to extracranial MM cells. Additionally, the modulatory effects of the DNA hypomethylating agent (DHA) guadecitabine on different tumor cells were investigated. The prognostic relevance of DHA-modulated genes was assessed through Cox analysis in a TCGA GBM patients' cohort.

Results: The most notable differences between constitutive GBM and MM-BM cells lie in the enrichment of biological processes associated with tumor growth, invasion, and extravasation, as well as the inhibition of MHC class II antigen processing/presentation in GBM cells. Guadecitabine treatment appeared to shrink these differences, shifting the phenotype of GBM cells towards the more immunogenic MM-BM profile. This was achieved through promoter hypomethylation and subsequent up-regulation of genes mainly associated with the activation, proliferation, and migration of T and B cells, along with MHC class II antigen processing/presentation. Among DHA-modulated genes in GBM, 7.6% exhibited significant prognostic relevance. Moreover, a substantial set of immune-related upstream regulators (URs) were commonly modulated by DHA in GBM, MM-BM, and/or MM cells: DHA-activated URs enriched biological processes mainly involved in the regulation of cytokines and chemokines production, inflammatory response, and Type I/II/III IFN-mediated signaling. DHA-inhibited URs were associated with metabolic and proliferative pathways.

Conclusions: Epigenetic remodeling of GBM by DHA represents a promising strategy to enhance the efficacy of cancer immunotherapy, supporting the rationale for developing new combinatorial approaches for the treatment of brain malignancies.

#2634 CRISPR *in vivo* screen utilizing removable Cas9 system to identify epigenetic immune response modulators in antigen-sensitive mouse syngeneic models.

Y. He, Y. Liu, X. Wang, X. Li, W. Dong, T. Hao, C. Zhu, W. Zhou, Z. Peng;
Oncology & Immunology Unit, WuXi Biology, WuXi AppTec, Shanghai, China

The application of CRISPR-Cas9 screen in tumor immunology research has promoted the discovery of potential therapeutic targets and provided a deeper understanding of the mechanisms of immunotherapy resistance. Mouse syngeneic tumor model based CRISPR *in vivo* screen revealed significant features of immunotherapy by better approaching the tumor immune interaction. However, the immunogenicity of CRISPR-Cas9 has been widely observed in a variety of syngeneic models, which greatly limited for the application of CRISPR *in vivo* screen. Herein, we used two strategies for cancer cell gene editing, Cas9 protein electroporation and loxP-flanked Cas9 with Cre recombinase, to reduce the immunogenicity of CRISPR-Cas9 in CT26 subcutaneous and Renca orthotropic syngeneic models. Encouragingly, we found out that compared with constitutive Cas9-expressing All-In-One based cell pool models, both CT26 subcutaneous model and Renca orthotropic model showed a parental cell tumor comparable growth kinetics and immune checkpoint blockade ICB response by PD-1 antibody treatment. Further immuno-profiling of tumor immune microenvironment indicated limited changes from the parental cell model, which helped the data interpretation of *in vivo* screen outcome. We then performed a CRISPR *in vivo* screen by using a focused library against mouse epigenetic regulators in these two models and will discuss the hits from the screen in future.

#2635 An epigenetic regulation targeting inhibitory receptors and attenuates CD8 T cell exhaustion in breast cancer.

Y.-Z. Lin[1], W.-R. Wu[1], F.-C. Chung[1], Y.-C. Shen[2], C.-C. Lee[2], H.-W. Li[1], G.-J. Lin[1], W.-C. Cheng[1], S.-C. Wang[1];
[1]China Medical University, Taichung City, Taiwan, [2]China Medical University Hospital, Taichung City, Taiwan

T cell exhaustion is a state of dysfunctional T cell response characterized by prolonged antigen exposure and diminished effector functions, a significant cause of tumor tolerance, and poor response to immune checkpoint blockade (ICB) therapy. T cell exhaustion is a highly dynamic process involved with a network of genetic and epigenetic regulation that program the T cell functions. Epigenetic regulation by microRNAs targets multiple genes involved in T cell function and is expected to be a major contributor to the functional programming of tumor-associated T cells. However, the underlying causal mechanisms remain to be determined. Here, we show that the microRNA miR-379-5p is a critical epigenetic regulator for promoting T cell function and suppressing exhaustion induced by chronic stimulation. The microRNA is identified by integrating bioinformatic interrogation of the miRNA databases cross-referencing with the TCGA database for genes involved in T cell functioning and their correlation with clinical outcomes, coupled with molecular profiling of miRNAs in experimental T exhaustion. Notably, the expression levels of miR-379-5p in tumor tissues, which encompass cancer cells and the surrounding stromal components, including immune cells, are closely associated with favorable prognosis of various cancer types. Further molecular and cellular characterization of miR-379-5p entailing cell culture, animal models, and patient-derived tumor organoids shows that it exerts suppressive effects by targeting specific sequences in the 3' untranslated region (UTR) of critical immune checkpoint genes in T cells, thereby enhances the effector functions of cytotoxic T cells for tumor clearance. Ectopic expression of miR-379-5p shifts the evolution of primary T cells toward memory-like effector cells while silencing miR-379-5p induces exhaustion and abrogates the cytotoxic activity of primary T cells. We further demonstrate that transcriptional downregulation of miR-379-5p in T cells by a nuclear receptor transcription factor which is responsible for initiating the exhausting process impairs the tumor suppression function of T cells. Our studies indicate that miR-379-5p can function as a tumor suppressor by protecting T cells from exhaustion and bears the potential for developing novel strategies to improve the response to ICB therapy in breast cancer.

#2636 Epigenetic landscape of CD8+ T cell exhaustion and tissue residency in HPV-negative head and neck squamous cell carcinoma.

M. K. Luff, M. Craviero, M. Dar, K. McKinnon, A. Kaskas, C. T. Allen, V. Saloura;
National Institutes of Health, Bethesda, MD

Background Head and neck cancer is the 8th most common cancer worldwide. Human Papilloma Virus (HPV)-negative head and neck squamous cell carcinoma (HNSCC) overall survival rates remain low (25-40%) despite advances in treatments. CD8+ T cell differentiation into activated/cytotoxic (CTL), exhausted (T_{EX}) and tissue-resident memory (T_{RM}) phenotypes is a major determinant of successful cancer immunotherapy, which relies on the ability of CD8+ T cells to detect and eliminate cancer cells. Recent evidence suggests the importance of epigenetic regulation in the development of CD8+ T cell exhaustion and tissue residency; yet the epigenetic mechanisms that govern the transition between CTL, T_{EX}, and T_{RM} CD8+ T cell states remain unclear. This study investigates the epigenetic modifications associated with CTL, T_{EX}, and T_{RM} states using CD8+ T cells from healthy donors and HPV-negative HNSCC tumors.
Methods An *in vitro* human CD8+ T cell stimulation assay using healthy donor cells was utilized to generate CTL, T_{EX} and T_{RM} phenotypes. Naïve T cells underwent CD3/28, TCR-independent stimulation for 9 days to promote CTL (3 days) and T_{EX} (9 days) phenotypes, and TGF-β exposure (days 3-9) occurred to induce a T_{RM} phenotype. Flow cytometry to confirm expression of cell-surface and intracellular markers for each phenotype is ongoing. Genome-wide mapping for activating (H3K4me1, H3K4me3) and repressive (H3K9me3, H3K27me3, H4K20me3) histone marks with CUT&Tag assays will be pursued for each of the *in vitro* CTL, T_{EX} and T_{RM} states, along with RNA-seq. CUT&Tag and RNA-seq will also characterize the epigenetic profiles of CD8+ T cells from single-cell suspensions generated from HPV-negative HNSCC tumors (n=5). Findings will be correlated with results from our *in vitro* T cell states.
Results Preliminary flow cytometry confirmed increased expression of CD25, PD-1, Tim3 after 9 days of *in vitro* stimulation, supporting the induction of a CD8+ T_{EX} phenotype. CD103 was also highly expressed in CD8+ T cells exposed to TGF-β, supporting the induction of the CD8+ T_{RM} phenotype. Validation of the CTL state is ongoing. Phenotypic validation of cell states with flow cytometry (18 cell surface and intracellular markers) is ongoing. Feasibility of genome-wide mapping for activating and repressive histone marks with CUT&Tag on naïve CD8+ T cells has been confirmed.
Conclusion This study investigates epigenetic changes that characterize the transition between CTL, T_{EX}, and T_{RM} states of CD8+ T cells using healthy donor cells through an *in vitro* assay and CD8+ T cells isolated from HPV-negative HNSCC tumors. Understanding the epigenetic profile of T cell states can help determine the major epigenetic regulators that lead to exhaustion and tissue residency, paving the way for improved T cell-based immunotherapies. Future experiments aim to validate our findings using TCR-specific *in vitro* and *in vivo* models.

#2637 Super-enhancer-related m6A modification promotes immune escape in hepatocellular carcinoma associated with metabolic dysfunction-associated fatty liver disease via CCL4 signaling pathway inhibition.

L. Xu;
Peking University Shenzhen Hospital, Shenzhen, China

The incidence and mortality rates of hepatocellular carcinoma caused by metabolic dysfunction-associated fatty liver disease (MAFLD) have been increasing in recent decades, emphasizing the urgent need for new therapeutic approaches. Emerging evidence suggests that approximately 80% of super-enhancer RNAs (seRNAs) undergo selective m6A modifications. seRNA and m6A modifications have been implicated in the progression of various cancers, making them potential targets for therapeutic intervention. Based on our previous research, we hypothesize that the lack of m6A modification on the super-enhancer of CCL4 may contribute to the reduced expression of the CCL4 gene in HCC.To validate our hypothesis, we employ nano-chromatin immunoprecipitation combined with high-throughput sequencing (nano-ChIP-seq), m6A-seq (m6A-seq), single-cell RNA sequencing (scRNA-seq) on multiple models including clinical samples, cell lines, and mouse models. Interestingly, we have made a significant discovery that overexpression of CCL4 in tumor cells enhances the infiltration of CD8+ T cells, which are crucial for anti-tumor immune responses. In contrast, normal tissue cells undergo m6A modification on the CCL4 seRNAs, while this modification is notably absent in cancerous tissue. Consequently, the reduced expression of CCL4 could impair the tumor-killing capabilities of CD8+ T cells and facilitate immune evasion by the tumor.Furthermore, our results shed light on the underlying molecular mechanisms involving super-enhancers and m6A modifications in the regulation of immune escape in MAFLD HCC. We identify the specific super-enhancer and downstream regulatory genes influenced by m6A modification in MAFLD-associated HCC, providing valuable insights and novel targets for the treatment of this condition.

#2638 Sensitizing immunotherapy-refractory prostate cancer to immune checkpoint blockade therapy with optimized ketogenic diet regimens.

S. Murphy, S. Rahmy, D. Gan, J. Li, **X. Lu**, X. Lu;
University of Notre Dame, South Bend, IN

The purpose of this study is to investigate strategies for enhancing immune checkpoint blockade (ICB) therapy in prostate cancer (PCa).
To achieve this, we established a series of ICB-resistant PCa cell lines derived from a previously sensitive cell line, which originated from a murine model of metastatic PCa. Notably, we observed a reduction in major histocompatibility complex (MHC) class I protein levels in the resistant sublines.
Our study demonstrated synergistic efficacy through the combination of anti-PD1 and anti-CTLA4 antibodies with histone deacetylase inhibitor (HDACi) vorinostat, a cyclic ketogenic diet (CKD), or β-hydroxybutyrate (BHB) supplementation. Importantly, these interventions significantly delayed PCa tumor progression. Furthermore, our analysis revealed that the effects of these interventions were contingent on both BHB and adaptive immunity. In-depth single-cell transcriptomic and proteomic profiling unveiled mechanisms involving cancer-cell-intrinsic changes (upregulated MHC class I molecules) and extrinsic factors, including CD8+ T cell chemoattraction, M1/M2 macrophage rebalancing, monocyte differentiation toward antigen-presenting cells, and reduced neutrophil presence.
In conclusion, our findings provide valuable insights into the potential clinical utility of combining HDACi and optimized ketogenic diet regimens to enhance ICB therapy for PCa.

#2639 Combined therapy targeting AR and EZH2 restrains the growth of castration resistant prostate cancer by enhancing antitumor T cell response.

I. Fischetti[1], B. Laura[1], R. Sulsenti[1], V. Cancila[2], C. Enriquez[1], R. Ferri[1], M. Bregni[3], F. Crivelli[3], C. Tripodo[2], M. P. Colombo[1], **E. Jachetti**[1];
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [2]University of Palermo, Palermo, Italy, [3]ASST Valle Olona, Busto Arsizio, Italy

Castration resistant prostate cancer (CRPC) is a fatal disease. Androgen receptor pathway inhibitors, like enzalutamide, are initially effective but resistance eventually occurs, often associated to the emergence of aggressive neuroendocrine variants (NEPC). Even immunotherapy induced limited results in prostate cancer, governed by an immunosuppressive microenvironment. Therefore, effective therapies are needed. We here investigate in preclinical models a new approach aimed to revert castration resistance and simultaneously turn the immune milieu from “cold” to “hot”, through the combination between enzalutamide and the drug GSK-126, which inhibits the epigenetic modulator EZH2. We show that enzalutamide and GSK-126 can synergize to restrain the growth of CRPC *in vitro* and *in vivo.* Moreover, this therapeutic combination efficiently reduced NEPC differentiation, in both subcutaneous and autochthonous *in vivo* models, increasing the rate of cured mice with regressed lesions. The antitumor efficacy observed in immunocompetent mice bearing subcutaneous syngeneic CRPC tumors was lost in immunodeficient mice, indicating a contribution of immune cells. Additional experiments in the TRAMP spontaneous mouse model revealed that the combination of enzalutamide and GSK-126 significantly induced cytotoxic activity and IFNγ production by tumor-specific $CD8^+$ T cells, otherwise tolerant, and increased IL-17 production by $CD4^+$ T cells. The two drugs did not directly modulate T cell activity *in vitro*, suggesting the importance of microenvironment accomplices in triggering these effects. These results promote the combined use of enzalutamide and GSK-126 to restrain CRPC growth and NEPC differentiation, and, simultaneously, to awake antitumor T cell response, opening new possibilities for immunotherapy in prostate cancer.

#2640 HBI-2375, a first-in-class IND ready selective MLL1-WDR5 inhibitor, retains desirable preclinical characteristics in solid tumors and in leukemias to be pursued in clinical studies.

F. Shojaei, C. Fang, J. M. Ricono, M. Gillings;
HUYA Bioscience International, San Diego, CA

MLL1 (mixed lineage leukemia1) interaction with WDR5 (WD repeat domain 5) is critical for its histone methyl transferase (HMT) activity leading to transcriptional regulation of gene expression. MLL1 dysregulation such as its translocation at chromosome 11q23 results in generation of MLL1 fusion genes and leukemia development. Additionally, recent studies indicated a role for MLL1-WDR5 interaction in solid tumors progression via directly affecting cancer cells or by suppression of tumor immunity. Therefore, MLL1-WDR5 interaction is an important target in the discovery of anti-cancer drugs for both leukemia and solid tumors. We recently identified HBI-2375 as a selective inhibitor of MLL1-WDR5 interaction. HBI-2375 showed potent inhibition of WDR5 (IC50: 4.48nM) in biochemical assay and inhibited MV4-11 cellular proliferation (average IC50: 3.17μM) in CTG assays. In addition, HBI-2375 was stable in liver S9 and whole blood, with moderate to high plasma protein binding rates in multiple species, and acceptable hERG (IC50: 17μM). Furthermore, HBI-2375 displayed reasonable oral PK properties (C_{max}, $T_{1/2}$, AUC, and F%) in mouse, rat and dog and showed good safety profile in GLP tox studies. In pharmacology studies HBI-2375 showed significant dose dependent anti-tumor activity in MV4-11 AML model along with reduction in methylation of H3K4 in the tumors harvested from the treated animals demonstrating the targeted disruption of HMT activity in cancer cells by HBI-2375. Furthermore HBI-2375 in combination with PD-1 mAb significantly inhibited tumor growth in MC38, colorectal tumor model, and in 3LL lung carcinoma syngeneic tumor models. Flow cytometry and IHC showed significant increase in the infiltration of CD8+ CTLs in the combination group further providing immune-driven mechanisms for greater efficacy of combination therapy. Gene expression analysis also identified genes that are involved in promoting immune system activity in the combination group. Tissue distribution studies also showed greater accumulation of HBI-2375 in brain tissue indicative of a potential to target glioma and glioblastoma in clinical studies. Therefore, HBI-2375 represents a first-in-class MLL1-WDR5 inhibitor with promising characteristics for future testing in the clinic.

#2641 Transcriptional reprogramming of Ewing tumors: gains and losses noted when utilizing immunocompetent in vivo models.

J. D. Daley[1], E. Mukherjee[1], A. C. Tufino[1], R. Bao[2], K. M. Bailey[1];
[1]UPMC Children's Hospital of Pittsburgh/University of Pittsburgh, Pittsburgh, PA, [2]UPMC Hillman Cancer Center, Pittsburgh, PA

Objective: Ewing sarcoma is an aggressive cancer most frequently diagnosed in adolescents and young adults. Currently, there is a limited understanding of the immunobiology of Ewing sarcoma, including limited pre-clinical studies of immunotherapeutic interventions. This, in part, is due to the historical lack of an immuno-competent murine model. Here, we utilize an immunocompetent, humanized mouse model to investigate the Ewing tumor immune microenvironment. Specifically, we sought to determine the transcriptional differences that occur when comparing human Ewing tumors established in a humanized backdrop versus those developed in an NSG (immuno-deficient) model.
Methods: Human Ewing cell lines (A673, TC32, TC71) and PDX (PSaRC219) were injected orthotopically into humanized or NSG mice. After ~3 weeks, bulk RNA sequencing was performed on tumors utilizing an Illumina Next Generation Sequencer. Tumor single-cell suspensions underwent immunophenotyping by flow cytometry (CyTek Aurora) for the following human markers: CD45, CD3, CD4, CD8, CD56, CD14, CD16, etc.. Peripheral blood was collected, PBMCs isolated, and immunophenotyping was again performed to determine peripheral blood immune cell populations.
Results: Ewing tumors established in humanized mice demonstrate infiltration of human CD45+ cells as well as immune cell sub-populations (CD3+, CD14+, CD56+ cells). Bulk RNA sequencing analysis utilizing unsupervised hierarchal clustering revealed that the transcriptional profile of Ewing tumors generated in humanized vs NSG mice cluster distinctly. Pathway analysis of differentially expressed genes ($p < 0.05$) in Ewing tumors developed in humanized versus NSG mice demonstrates upregulation of pathways including extracellular matrix remodeling, collagen biosynthesis, and Wnt signaling. Notably, transcripts known to be specific to TGFBeta-dependent signaling in Ewing tumors are upregulated in the immune competent model, including *TGFB1*, *FBLN5*, and *COLEC12*.
Conclusion: This work demonstrates the Ewing tumor transcriptional remodeling that occurs when tumors are developed in an immunocompetent *in vivo* backdrop. Upregulation of several pro-metastatic pathways were noted. Ongoing work focuses on testing drug response differences between Ewing tumors developed in humanized versus NSG backdrops and pursuing immunocompetent Ewing models as a component of preclinical agent testing.

#2642 *KEAP1* mutation in lung cancer cells leads to increased immunosuppressive capability.

C. J. Occhiuto[1], K. T. Liby[2];
[1]Michigan State University, East Lansing, MI, [2]Indiana University, Indianapolis, IN

Considerable advances have been made in lung cancer therapies, but there is still an unmet clinical need to improve survival for lung cancer patients. Immunotherapies have improved survival, although only 20-30% of patients respond to these treatments. Interestingly, cancers with mutations in *KEAP1*, the negative regulator of the NRF2 cytoprotective pathway, are resistant to immune checkpoint inhibition and correlate with decreased immune cell infiltration. NRF2 is known for promoting an anti-inflammatory phenotype when activated in immune cells, but the study of NRF2 activation in cancer cells has not been adequately assessed. The overall objective of this study is to determine how lung cancer cells with constitutive NRF2 activity interact with the immune microenvironment to promote cancer progression and metastasis. To assess this, we generated CRISPR-edited mouse lung cancer cell lines (Lewis Lung Carcinoma/LL2) with knockouts (KO) of the *KEAP1* and *NFE2L2* genes. The transcriptomic profiles of 3 *KEAP1* KO and 1 *NRF2* KO cell lines were compared to the parental wildtype (WT) line using RNA-sequencing. On unsupervised hierarchical clustering of differentially expressed genes, the 3 *KEAP1* KO cell lines clustered together and the *NRF2* KO clustered with WT cells. Importantly, canonical NRF2 pathway-related genes were significantly increased in *KEAP1* KO clones, but the same genes were either decreased or similar to WT in the *NRF2* KO clone. We then used flow cytometry to evaluate immunosuppressive surface markers known to suppress T cell function when expressed on cancer cells. Importantly, PD-L1, CD155, CD80, and CD86 were increased in the *KEAP1* KO lines compared to WT, but not in the *NRF2* KO clone. In addition, the cytokine release profile was differentially regulated in the *KEAP1* KO clones in a manner that could alter T cell recruitment and function. These results were also consistent with gene expression in the sequencing dataset. Finally, using an orthotopic allograft model, we completed a preliminary immunophenotyping study of lung tumors for WT, *KEAP1* KO, and *NRF2* KO cell lines. The activation status of $CD8^+$ T cells and the ratio of $CD8^+/CD4^+CD25^+$ T cells (a prognostic marker) were decreased in *KEAP1* KO tumors. Taken together, these data suggest cancers with *KEAP1* mutations may increase tumor growth through suppression of T cells.

IMMUNOLOGY: Immune Checkpoints and Inhibitory Molecules 2
Poster Session

#2647 Topical corticosteroids stimulate T cell-dependent melanoma growth control.

C. H. Earnshaw[1], S.-C. Chiang[1], A. Moeini[1], M. Koufaki[1], E. Bonavita[1], L. Nebot-Bral[1], M. Russo[1], C. Bell[1], T. Bigirumurame[2], J. Nsengimana[2], J. Newton-Bishop[3], C. E. M. Griffiths[4], S. Zelenay[1];
[1]Cancer Research UK Manchester Institute, Manchester, United Kingdom, [2]Population Health Sciences Institute, Newcastle University, Newcastle, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]University of Manchester, Manchester, United Kingdom

Melanoma is the deadliest form of skin cancer. Treatment with immune checkpoint blockade (ICB) has transformed outcomes. However, half of melanoma patients do not derive long-term benefit. Side-effects of ICB are frequent, and typically managed by systemic or topical treatment with corticosteroids, widely known for their immunosuppressive effects. However, clinical data is contradictory as to the effect on prognosis of patients receiving ICB that also receive corticosteroids, with some studies suggesting a negative effect of steroid use, and others suggesting no effect or even positive outcomes with steroid use. Additionally, our lab recently showed that combining corticosteroids with ICB improves treatment responses in certain preclinical cancer models. Thus, understanding the role of corticosteroids in cancer progression, and their effect on the tumor immune microenvironment, is critical.
In an intradermal murine melanoma model unresponsive to ICB, we found that topical corticosteroid treatment significantly impairs tumor growth. After just two doses, glucocorticoid-treated tumors shrank, whereas control-treated tumors doubled in volume. Intriguingly, this effect was lost in *Rag1*$^{-/-}$ mice (deficient in B and T cells) or in mice depleted of CD8^{+} T cells, uncovering a key role for T cells in corticosteroid-induced tumor growth control. Genetic ablation of the glucocorticoid receptor in tumor cells abrogated this effect, suggesting corticosteroids act directly on tumor cells to stimulate anti-tumor immunity. Analysis of TCGA RNA sequencing data showed melanoma patients with high glucocorticoid receptor expression have better overall survival than those with low expression, a finding repeated in a large, independent cohort of primary melanoma specimens of the Leeds Melanoma Cohort (n=703). Through cellular and molecular profiling using multiparametric flow cytometry and whole exome RNA sequencing, we have identified promising candidate pathways that might underlie the immune-dependent tumor control induced by steroids.
Steroids induce tumor control in other, but not all, melanoma and non-melanoma tumor models studied, suggesting this may be a conserved immune-evasive pathway in a subset of tumors. Ongoing work aims to characterize the molecular and cellular effects of topical corticosteroid treatment, and to investigate their relevance in human melanoma. Given the widespread use of corticosteroids in patients receiving ICB, these unexpected findings may have significant clinical impact.

#2648 CD155 regulates cell growth and immune evasion in diffuse midline glioma.

T. Tzaridis[1], T. Eisemann[1], A. F. Andrade[2], J. L. Hope[3], O. Becher[4], N. Jabado[2], L. M. Bradley[1], P. Adams[1], R. Wechsler-Reya[5];
[1]Sanford Burnham Prebys Med. Discovery Inst., La Jolla / San Diego, CA, [2]Department of Human Genetics, Department of Paediatrics of the McGill University and Research Institute of the McGill University Health Center, Montreal, QC, Canada, [3]Department of Microbiology & Immunology, Drexler University College of Medicine, Philadelphia, PA, [4]Jack Martin Division of Pediatric Hematology-Oncology, Mount Sinai Kravis Children's Hospital, Icahn School of Medicine at Mount Sinai, New York, NY, [5]Department of Neurology and Herbert Irving Comprehensive Cancer Center, Columbia University Medical Center, New York, NY

There is an unmet need for effective treatment strategies for diffuse midline glioma (DMG), a devastating brain tumour arising in children and young adults. While immunotherapy is emerging as a powerful approach for treatment of other cancers, clinical trials with immune checkpoint inhibitors have failed to show a survival benefit for DMG patients. In this study, we analysed the expression of known immune checkpoint molecules on the surface of human and murine DMG cells by flow cytometry and identified CD155 and B7-H3 as the most highly expressed checkpoint molecules, with minimal expression of others, including PD-L1 and PD-L2. These findings were confirmed in primary patient samples from pediatric brain tumours (gliomas, medulloblastomas and ependymomas). To test whether CD155 regulates susceptibility to CD8+ T cell killing, we cultured murine DMG cells expressing ovalbumin (OVA) with CD8+ T cells from OT-I mice, which express T cell receptors specific for OVA. shRNA mediated silencing of CD155 led to a strong increase in T cell-mediated killing. *In vivo*, adoptive transfer of OT-I T cells into OVA-positive DMG-bearing immuno-compromised mice resulted in delayed tumour growth, and this effect was enhanced when tumours lacked CD155. Strikingly, CD155-deficient DMG cells failed to grow at all in immuno-competent mice, and depletion of CD8 T cells allowed these tumours to grow, highlighting a role for CD8 T cells in rejection of CD155-deficient cells. In addition to its effects on susceptibility to T cells, CD155 also exerted cell-autonomous effects on tumour cells: silencing of CD155 led to induction of apoptosis of DMG cells *in vitro* and to delayed tumour *growth in vivo*, even in immune-compromised mice. These studies demonstrate that CD155 functions as an immune checkpoint and as a regulator of tumour cell survival in DMG, and suggest that targeting CD155 could be a valuable double-pronged therapeutic strategy for this devastating disease.

#2649 A new role for the aryl hydrocarbon receptor (AhR) as a proximal mediator of immune checkpoints (PD-L1/2 and IDO1) in non-small cell lung cancer: Insights into an interferon-induced, LncRNA-and JAK/STAT-mediated signaling pathway.

B. Lara[1], M. Snyder[2], Z. Wang[1], J. Fimbres[1], E. Yang[3], D. H. Sherr[1];

[1]Boston University School of Public Health, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University, Boston, MA

Non-small cell lung cancer (NSCLC) is the second most common cancer and accounts for ~127,000 deaths/year in the U.S. Its current ~30% five-year survival rate is an improvement from a decade ago thanks in part to the introduction of immune checkpoint inhibitors including PD1- and PD-L1-specific monoclonal antibodies. While PD-1/PD-L1-targeted immunotherapy is effective in many cases, not all patients respond and complete remissions still only occur in a minority of patients. Therefore, a greater understanding of immune checkpoint regulation in human NSCLC is needed. Here, we investigated a novel role for the aryl hydrocarbon receptor (AhR), an environmental carcinogen receptor previously associated with smoking-induced lung cancers, in the regulation of immune checkpoints PD-L1, PD-L2, and IDO1. Computational analyses of existing databases for protein-protein interactions linked to the AhR signaling pathway suggested crosstalk between the AhR, type I and type II Interferon (IFN), and JAK/STAT signaling pathways. AhR deletion from human lung A549 adenocarcinoma cells significantly reduced expression of *JAK2*, *STAT1*, *STAT2*, and the JAK/STAT signaling targets *IRF1* and *IRF9*. Type II IFNγ significantly increased expression of those genes as well as the immune checkpoints IDO1, PD-L1, and PD-L2 in an AhR-dependent fashion. Interestingly, AhR deletion also eliminated IFNγ-mediated induction of a recently described long non-coding RNA, *INCR1*, which is encoded across the *CD274*/*CD273* locus, and which facilitates *JAK2*, *CD274*/*PD-L1*, and *IDO1* translation. Concomitantly, AhR knockout increased baseline expression of an RNA-binding protein, HNRNPH1, known to sequester *JAK2* and *CD274* mRNA thereby reducing IDO, PD-L1 and PD-L2 expression. Similarly, the AhR was shown to regulate Type I IFNα-mediated induction of *STAT1*, *STAT2*, *CD274*/*PD-L1*, and *CD273*/*PD-L2*. The data indicate that IFN induction of key immune checkpoints in lung adenocarcinoma cells is dependent on the AhR through its control of a conventional JAK/STAT pathway and an unconventional lncRNA (*INCR1*) and RNA-binding protein (HNRNPH1) pathway.

#2650 IGFBP2 assists EGFRvIII-positive glioblastoma to evade immune elimination.

Jikang Fan[1], Xisen Wang[1], Tao Li[1], Xuejun Yang[2], Wei Zhang[3]

[1]Tianjin Medical University General Hospital, Tianjin, China,[2]Department of Neurosurgery, Beijing Tsinghua Changgung Hospital, Beijing, China,[3]Departments of Cancer Biology, Wake Forest School of Medicine, Winston-Salem, NC

In recent years, immunotherapy has achieved significant success in the treatment of a variety of cancer types, including melanoma, non-small cell lung cancer, and colorectal cancer. However, in stark contrast, patients with glioblastoma (GBM) show remarkably poor responses to immunotherapy, failing to derive any therapeutic benefit. Thus, an understanding of the immunosuppressive microenvironment of GBM, which is considered an immunotherapy-cold tumor, is of paramount importance. One common and distinctive genetic mutation found in gliomas is that of EGFRvIII, which is linked with enhanced cell proliferation, invasion, migration, and angiogenesis in GBM. Intriguingly, we found that this mutation induced a significantly more severe immunosuppressive microenvironment compared with wild-type EGFR. To unravel the mechanisms underlying EGFRvIII mutation-induced immunosuppression in GBM, we posited that the mutant variant secretes an array of immunosuppression-related proteins into the glioma microenvironment. To investigate this, we conducted proteomic analysis of conditioned media from EGFRvIII mutant cell lines and discovered significant changes in the expression of insulin-like growth factor-binding protein-2 (IGFBP2), a well-documented oncogenic protein. Although IGFBP2 is known to be upregulated in various tumor types and is associated with malignant behaviors such as proliferation and invasion in gliomas, its role in glioma immunology remains largely unexplored. In line with our earlier bioinformatic analyses, our study revealed significant enrichment of IGFBP2 in pathways related to immunosuppression in GBM. Thus, in the present investigation, we analyzed the mechanisms by which IGFBP2 induces an immunosuppressive microenvironment. Using co-culture models, we found that IGFBP2-overexpressing glioma cells as well as glioma cells treated with exogenous IGFBP2 recruited immune cells through binding to integrin αvβ5. Furthermore, we demonstrated that IGFBP2 promoted the secretion of the classical macrophage polarization factor IL-10 by phosphorylation of STAT3. These findings indicate the significant influence of IGFBP2 in steering glioma-associated macrophages toward a pro-tumor M2-like phenotype. We also observed that IGFBP2 upregulated the expression of PD-L1 on tumor cell surfaces. These results were verified in animal experiments. Intriguingly, our preliminary data indicated that exogenous IGFBP2 translocated to the cell nucleus within hours, and immunoprecipitation assays confirmed its interaction with STAT3 *in vitro*. These findings collectively underscore the pivotal role of IGFBP2 in the creation of the immunosuppressive microenvironment induced by EGFRvIII mutation. Consequently, targeting IGFBP2 holds great promise for advancing immunotherapeutic approaches in EGFRvIII-mutant glioblastomas, offering an exciting avenue for potential treatments of GBM.

#2651 A selective HPK1 inhibitor FB849 reprograms intratumoral immune cells and elicits strong anti-cancer immunity.

H. Kim[1], S. Lim[1], A. Park[1], J. Lee[1], J. Kim[1], S. Jeon[2], Y. Lee[2], E.-C. Shin[2], S. Kim[1];

[1]1STBiotherapeutics, Yongin-si, Gyeongido, Korea, Republic of, [2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

Hematopoietic progenitor kinase 1 (HPK1) is a negative regulator of immune cells and suppresses the immune function of a wide range of cells, including T cells, B cells, and dendritic cells (DCs). Recent studies have shown that HPK1 is correlated with increased T cell exhaustion, one of hallmark phenomena for acquired resistance to immune checkpoint inhibitors (ICIs), that is a major obstacle in the current immunotherapy regimen with an increasing need of novel agent to overcome it. We have discovered FB849, a highly potent, highly selective, and orally available HPK1 inhibitor especially with an excellent selectivity over key immune-related off target kinases. FB849 confers the activation of various human primary immune cells such as T cells, B cells, and DCs *in vitro.* FB849 elicited robust anti-cancer efficacy in syngeneic mouse models including MC38 and CT26 both as a monotherapy and in combination with a PD-1 antagonist. A dramatic synergistic efficacy with FB849 and PD-1 combination was observed in EMT6. Durable effects possibly through immunological memory were also confirmed in CT26. Under a CD8+ T cell depletion condition *in vivo*, FB849 still maintained monotherapy efficacy, demonstrating its anti-cancer immunity through CD8+ T cell-independent pathway possibly via efficacy through myeloid lineage. FB849 significantly reduced the LAG3+ and PD-1+ exhausted T cells and CD25+ FoxP3+ regulatory T cells, simultaneously depleted tumor associated macrophages (TAMs), and modulated dendritic cell population in the syngeneic tumors. To better understand how FB849's effects on human cancer, FB849 was evaluated in isolated TILs (tumor-infiltrating lymphocytes) from patients with renal cell carcinoma and other cancer types. CD8+ T cells from a RCC patient was highly activated evidenced by the increased cell proliferation and the enhanced cytokine secretion by *ex vivo* treatment of FB849 alone or by the combination with PD-1 antagonist. Similar phenomena were observed in gastric cancer, hepatocellular carcinoma, colorectal cancer, and head and neck cancer. FB849 treatment resulted in the activation of not only stem-like T cells but also in the partial reinvigoration of terminally differentiated T cells from a RCC patient. These data from patient TIL's together with mouse TIL's pinpoint unprecedented anti-tumor mechanism by FB849 through modulation of exhausted T cells as well as myeloid cells. Altogether, this study supports the planned clinical development of FB849 as a promising immuno-oncology agent as a monotherapy in the selected cancer types and as post-ICI combination with a PD-1 antagonist.

#2652 NDI-101150 is a potent and highly selective HPK1 inhibitor that both synergizes with and differentiates from anti-PD1 immune checkpoint blockade.

D. Ciccone, F.-S. Kuo, S. Daigle, N. Kaila, G. Yau, M. Carlson, D. Levasseur, B. Srivastava, F. G. Basile, C. Loh;
Nimbus Therapeutics, Boston, MA

Introduction HPK1 is a member of the MAP4K family of protein serine/threonine kinases that negatively regulates activation signals in multiple immune cells and is an attractive therapeutic target for many cancers. Using structure-based drug design, we developed a highly selective HPK1 inhibitor, NDI-101150, with nanomolar potency and physiochemical properties suitable for once daily oral administration.

Methods & Results HPK1 inhibition with NDI-101150 has a differentiated pharmacology profile when compared directly to PD1 blockade. NDI-101150 was able to overcome the immunosuppressive effects of prostaglandin E2, adenosine, and TGF-β on human T cell activation. HPK1 inhibition also directly limited the suppressive capacity of T regulatory cells. In contrast, anti-PD1 treatment was not able to overcome the immunosuppressive activity associated with any of these mechanisms. In vivo, HPK1 inhibition significantly enhanced the production of antigen-specific antibodies in response to immunization with both T-dependent and T-independent antigens, while anti-PD1 treatment had minimal to no effects on antibody production. In the EMT-6 syngeneic model, 7/10 mice receiving NDI-101150 exhibited complete tumor regressions, compared to only 1/10 from an anti-PD1 cohort. Furthermore, NDI-101150 established a robust and durable immune memory response as 100% of treated mice showed complete rejection of tumor growth upon subsequent re-challenge. HPK1 inhibition with NDI-101150 also shows robust synergy with PD1 blockade in vitro and in vivo. Both NDI-101150 and anti-PD1 were able to reinvigorate exhausted human T cells, restoring cytokine production and proliferative effects in mixed lymphocyte reactions. Further, in combination HPK1 inhibition and PD1 blockade synergized to enhance the activity of exhausted human T cells to an extent exceeding that observed with naïve human T cells in similar experiments. In vivo, while NDI-101150 or anti-PD1 treatments alone induced tumor growth inhibition in the murine CT-26 syngeneic tumor model, NDI-101150 and anti-PD1 in combination mediated complete tumor regressions in several mice. Furthermore, NDI-101150 seemed to induce a durable immune memory response as evidenced by the combination-treated animals showing complete rejection of tumor growth upon subsequent re-challenge, without any further dosing of NDI-101150.

Conclusions Pharmacological inhibition of HPK1 with NDI-101150 represents a powerful system-wide immunomodulatory approach with the potential to enhance anti-tumor immunity in patients failing to respond to currently approved immune checkpoint therapies or in combination with immune checkpoint blockade therapies. NDI-101150 is currently being tested in a Phase 1/2 trial (NCT05128487) in patients with advanced solid tumors.

#2653 Integrative analysis of proteomic alterations in human PBMC's treated by HPK1 inhibitor FB849 reveals enriched pathways from various immune cells leading to potential novel biomarker discovery.

S. Lim, S. Jin, A. Park, H. Kim, S. Kim, J. Kim, J. Lee;
1ST Biotherapeutics, Inc., Gyeonggi-do, Korea, Republic of

HPK1, also known as MAP4K1, is a critical signaling kinase molecule as a negative feedback loop in various immune cells. Despite the advancement of multiple clinical programs for therapeutic inhibition of HPK1, there is an urgent need to understand HPK1 biology in genome-wide signaling networks not only from lymphocytes but also from monocytes. FB849 is designed as a potent and highly selective inhibitor of HPK1 and is currently in phase I clinical trial with advanced cancer patients (NCT05761223). We aim to generate proteomic and phosphoproteomic profiles to reveal modes of action of FB849 in the broad spectrum of cancer immunity. Human PBMCs were treated with FB849 under conditions with or without CD3/CD28 stimulation. Utilizing an antibody array comprising 1,930 antibodies, the expression of 1,438 distinct proteins was assessed. The antibody arrays in human PBMCs identified a total of 85 and 33 phospho-proteins showing differential expression in response to FB849 treatment compared to the control in the presence or absence of CD3/CD28 stimulations, respectively (fold change > 2, adj. p-value < 0.01). KEGG pathway enrichment analysis demonstrated that the differentially expressed proteins by FB849 in the presence of CD3/CD28 stimulation were significantly enriched in immune-related biological processes, including 'pathways in cancer', 'PI3K-Akt signaling pathway', 'Focal adhesion', 'cytokine-cytokine receptor interaction', 'MAPK signaling pathway', 'JAK-STAT signaling pathway', and 'Th1 and Th2 cell differentiation'. Reactome biology pathway analysis also showed significant enrichment in 'immune system', 'homeostasis', and 'cytokine signaling in immune cells'. In addition, we performed LC-MS/MS-based phosphoproteomics in PBMC samples pooled from CT26 mouse syngeneic models treated with 25mg/kg and 50mg/kg of FB849 and its derivative. The proteomics identified 1239 unique phosphorylated proteins and 915 distinct phosphorylation proteins, while 68 and 39 phosphorylated proteins were identified as differentially expressed proteins in FB849 or its derivative treated groups compared with control groups, respectively. The several phosphoproteins exhibited consistent decreases or increases in both FB849 and its derivative. Together, this work reveals genome-wide alterations in the proteomic and phosphoproteomic landscape by FB849 in both mouse PBMC's and human PBMC's with clear pathway enrichment potentially from various immune cell lineages. Further exploration of the differential expression of each protein and/or phosphoproteins especially in T cell-, B cell-, and monocyte-enriched biomarkers which link to HPK1-relevant signal transduction is needed to find out their clinical implication and to highlight new understanding of HPK1 signaling network in cancer immunity.

#2654 HPK1 inhibits CD8+ T cell effector gene expression following T cell activation.

R. Y. Ames, R. Zhao, P. Mace, A. Grant, G. Xie, H. Milestone, M. Grandcolas, E. Fang, N. Kiosea, S. Wong, M. Brovarney, S. Jacobson, D. Nebalasca, J. Arguello, B. Gomez, H. Kandala, M. Y. M. Ko, L. Nguyen, O. Robles, G. Shibuya, A. A. Shakhmin, P. Tivitmahaisoon, V.-A. Vu, A. Younai, M. Zibinsky, B. Subramanyam, D. Poon, M. Sabouri Ghomi, D. J. Wustrow, P. D. Kassner, G. E. Katibah, D. G. Brockstedt;
RAPT Therapeutics, Inc., South San Francisco, CA

Hematopoietic progenitor kinase 1 (HPK1) has been shown to act as a negative regulator of T cell receptor signaling and of subsequent effector T cell function. Inhibiting HPK1 to enhance T cell activity has emerged as a promising strategy for cancer immunotherapy. Upon T cell receptor engagement, the kinase domain of HPK1 is activated and targets components of the T cell receptor (TCR) signaling pathway for degradation, including SLP76. However, the molecular events connecting HPK1 kinase activity to observed T cell functions downstream of proximal TCR signaling are not well understood. Through transcriptional profiling of HPK1-kinase-dead (HPK1-KD) versus wild-type CD8+ T cells following an acute, attenuated Listeria monocytogenes infection, we observed increased expression of many genes associated with T cell activation and effector function, including changes in expression of several key transcription factors and their targets. Upon activation, HPK1-KD T cells, as well as T cells treated with our small-molecule HPK1 inhibitor, produce higher levels of a wide range of effector cytokines in vitro and in vivo. Treatment of mice with the HPK1 inhibitor also inhibited tumor growth in several syngeneic tumor models. These data expand our understanding of the role of HPK1 in inhibiting CD8+ T cell effector programs, and, importantly, the impact of HPK1 inhibitors on T cell function.

#2655 Unexpected role of the NuRD component, Chd4, in Foxp3+ Treg cells and its relevance to tumor immunotherapy.

W. W. Hancock[1], L. Wang[2], M. Minisini[3], E. di Giorgio[3], I. Babic[4], E. Nurmemmedov[4];
[1]University of Pennsylvania, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Udine, Udine, Italy, [4]Nerd Bio, LLC, San Diego, CA

We are investigating basic questions like why do Foxp3+ T-regulatory (Treg) cells have at least 3 nuclear complexes involving Hdac1 and Hdac2 (CoREST, Sin3, NuRD), and how can the inhibitory effects of Foxp3+ Tregs on host anti-tumor immune responses be targeted therapeutically? Here, we report on the immune functions of chromodomain-helicase-DNA-binding protein 4 (Chd4), a key enzyme of the nucleosome remodeling and deacetylase complex (NuRD) complex. TCGA analysis showed increased Chd4 expression and Foxp3+ Tregs within lung tumors, leading us to assess the effects of conditional gene deletion within Foxp3+ murine Tregs. Chd4 knockout led to systemic autoimmunity and death of mice within 3 weeks of life and RNAseq studies showed Chd4 loss led to derepression of ~1400 genes and repression of >700 further genes resulting in a Treg signature markedly different from conditional deletion of Hdac1, Hdac2 or Mbd2 in Treg cells. Chd4 is an intrinsically disordered therapeutic target without a defined structure outside its physiological cell environment. To date, no specific inhibitors targeting Chd4 have been developed. We have identified Ch41, a novel and potent inhibitor of Chd4, using a novel cellular target engagement platform. Transcriptomic and mass-spec investigations showed that Ch41 impaired thymic Treg function and iTreg development, led to decreased CNS2 demethylation within the Foxp3 locus, and significantly impaired growth of lung tumors and hepatocellular carcinomas in immunocompetent but not in immunodeficient C57BL/6 mice ($p<0.01$). Following Chd4 inhibitor therapy, intratumoral conventional T cells had increased activation and cytokine production (IL-2, IFN-g) compared to intratumoral T cells in control tumor-bearing mice but, perhaps unexpectedly, treated mice did not show histologic or biochemical evidence of autoimmunity. We conclude that while tumor associated Tregs have unique properties that include their increased suppressive activity compared to non-tumor associated Treg cells, they are also more susceptible than the latter and conventional T cells to newly developed therapeutic interventions, including targeting of the Chd4 chromodomain of the NuRD complex.

#2656 The selective IKZF2 molecular glue degrader, PVTX-405, counters Treg immune suppression,shows significant tumor growth delay as single agent and synergistic response with immune checkpoint therapies (ICTs).

H. D. Dhruv[1], D. McEachern[2], L. Bai[2], X. Zhang[1], Z. Chen[2], R. Nagilla[1], E. Behshad[1], B. Han[1], P. Orth[1], R. Rej[2], P. Kirchhoff[2], N. Shin[1], L. Jolivette[1], C. Strickland[1], Z. Sui[1], S. Priestley[1], S. Wang[2], H. Mohammad[1];

[1]SK Life Science Labs, King of Prussia, PA, [2]University of Michigan, Ann Arbor, MI

Immunosuppressive regulatory T-cells (Tregs) are key modulators of tumor immune evasion and resistance to immune checkpoint therapies (ICTs). IKZF2 (Helios) is a transcription factor that is selectively expressed by Treg and has been shown to be essential for maintaining function and stability of Tregs in the face of inflammatory conditions that include autoimmune disease as well as cancer. Here we describe the discovery of PVTX-405, a potent and selective IKZF2 molecular glue degrader (DC_{50}=6.3 nM). Our molecular glue degrader promotes a productive ternary complex with the E3 ubiquitin ligase substrate receptor cereblon (CRBN) to selectively degrade IKZF2 while sparing other CRBN neosubstrates (IKZF1/3, GSPT1, CK1a). PVTX-405 demonstrates rapid and selective degradation of IKZF2 in Jurkat cells *in vitro,* human PBMC derived Tregs *ex vivo,* and in cynomolgus monkeys *in vivo*. Degradation of IKZF2 in Jurkat cells leads to dose dependent increase in production of inflammatory cytokine IL-2. In *ex vivo* co-cultures of Tregs and effector T-cells, PVTX-405 reduces the suppressive activity of Tregs. To determine whether the relief of Treg suppressive activity observed *in vitro* and *ex vivo* can translate to anti-tumor activity *in vivo* we utilized $CRBN^{I391V}$(humanized CRBN) mice. We developed a novel MC38 syngeneic tumor model to test both monotherapy and combination efficacy in an immune-competent setting. Once daily oral administration of PVTX-405 as single agent significantly delays the growth of MC38 tumors. Further, *in vivo* treatment of PVTX-405 in combination with ICTs, anti-PD1 or anti-LAG3, significantly increased animal survival and led to durable tumor regressions compared to ICTs alone. Together, these results demonstrate a strong synergy between ICTs and Treg destabilization through pharmacological degradation of IKZF2 and represent a promising combination strategy for treatment of cancer.

#2657 Immune checkpoint therapy as a treatment option for non-muscle invasive bladder cancer.

S. Benmerzoug, K. Louche, T. Angles, N. Serhan, F. Dol-Gleizes, P. Lejeune, S. Chabot;
Evotec France SAS, Toulouse, France

Bladder cancer (BCa) is one of the most common malignancies with more than 500,000 new cases diagnosed each year. Intravesical instillations of Bacillus Calmette-Guérin (BCG) is the gold-standard treatment for non-muscle invasive BCa (NMIBC) patients despite significant side effects and high rates of refractory disease and/or recurrence. Indeed, treatment failure occurs in ~40% of cases emphasizing the urgent need to evaluate alternative and/or complementary new therapies including immunotherapies. Recently, the use of immune checkpoint inhibitor (ICI) anti-PD-1 therapy has been approved for the treatment of BCG-unresponsive NMIBC patients. Here, we investigated whether targeting PD-1 or CTLA-4 can boost anti-tumor immunity in the orthotopic murine MB49 BCa model. To this purpose, $2.5x10^5$ luciferase-expressing MB49 cells (MB49-Luc) have been instilled into the preconditioned bladder of female C57Bl/6 mice by intra-urethral catheterization. *In vivo* tumor growth has been monitored three times a week using the IVIS spectrum *in vivo* imaging system. All the inoculated mice showed a luciferase signal at day 3 post-bladder tumor inoculation, demonstrating 100% of tumor uptake. Based on the *in vivo* bioluminescence, a randomization has been performed before ICI treatment consisting of anti-CTLA-4 (10 µg/mouse; q3dx4, intraperitoneal) or anti-PD-1 (100 µg/mouse, q3dx4, intraperitoneal). Our data indicate that ICI treatments significantly decreased the *in vivo* bioluminescence, indicating reduced tumor growth. Furthermore, anti-CTLA-4 and anti-PD-1 administration resulted in a significant long term anti-tumor activity, with ~90% and ~70% overall survival of anti-CTLA-4 and anti-PD-1 treated mice, respectively, while isotype control mice displayed ~10% survival by day 74 post-MB49-Luc cells inoculation. To investigate the potential development of systemic adaptive anti-tumor immunity elicited by ICI treatment, remaining ICI-treated mice and newly onboarded non-treated control mice have been (re)-challenged with MB49 tumor cells subcutaneously (s.c.). While all the control mice showed tumor outgrowth and needed to be sacrificed due to humane endpoint by the day 32 post-s.c. challenge, rechallenged ICI-treated mice showed potent abscopal effect and displayed no tumor engraftment with 100% overall survival. Altogether, these findings demonstrate that systemic ICI immunotherapies such as PD-1 and CTLA-4 elicit potent anti-tumor activity and induce protective anti-tumor immune memory. ICI might present an alternative or a complementary treatment to BCG therapy for NMIBC patients.

#2658 The circadian clock modulates cancer immune checkpoint therapy through immune cell trafficking.

J. N. Lichterman, T. Srinivasan, W. Li, P. Sabaeifard, L. A. Coughlin, N. Poulides, L. V. Hooper, A. Y. Koh;
UT Southwestern Medical Center, Dallas, TX

Immune checkpoint inhibitor therapy (ICT) can provide durable remissions for cancer patients with previously incurable malignancies. However, ICT is ineffective for many cancer types, and even those who initially respond may develop ICT resistance and succumb to their cancer. Tumor cell extrinsic factors, termed host factors, have recently emerged as key mediators and biomarkers of ICT response. One intriguing host factor that may influence ICT response is the circadian clock, an evolutionarily conserved transcriptional-translational feedback loop that allows mammalian organisms to adapt to environmental exposures (e.g. light). However, whether “the clock” modulates the ICT anti-tumor immune response is unknown.

Utilizing preclinical mouse models of cancer immunotherapy, we found that ICT efficacy is time-of-day dependent. ICT was most efficacious if ICT was administered at two hours after first light exposure (Zeitgeber time 2, ZT2) and least efficacious at ZT18. Utilizing flow cytometry, bulk cytokine analysis, and single cell RNA sequencing, we characterized the anti-tumor immune response after administering ICT at ZT2 and ZT18. There was an increase in effector granzyme B- and interferon-*γ* producing CD8+ T-cells in the tumor at ZT2 versus ZT18. This was accompanied by an increase in CD11c+ dendritic cells (DCs) and intratumoral chemokines (e.g. CXCL10) that promote DC/T-cell migration into the tumor microenvironment, and leads to enhanced DC-T-cell priming and anti-tumor immunity. Interestingly, these time-of-day dependent differences in tumor immune cell infiltration were present prior to the administration of ICT. To interrogate the role of the clock in mediating these time-of-day dependent differences, we characterized the response to ICT in mice that lack the core clock gene, BMAL1. Loss of BMAL1 in DCs (BMAL1fl/fl crossed with CD11c-cre) attenuated ICT efficacy, abrogated time-of-day dependent differences in ICT efficacy and dampened anti-tumor immunity. These findings highlight a role for a novel host factor, the circadian clock, in mediating the efficacy of cancer immune checkpoint therapy.

#2659 Therapeutic administration of an engineered sphingosine-1-phosphate lyase improves T cell trafficking to tumors and enhances antitumor response.

A. Araujo, M. Rodnick-Smith, R. Al-Khaledy, G. Georgiou, **M. Badeaux**, E. Stone;
The University of Texas At Austin, Austin, TX

Introduction: Immunotherapy has revolutionized the landscape of cancer treatment; however, to date, only limited aspects of the tumor-immune interaction have been exploited successfully, e.g., relief of immune checkpoints, increase of tumor-associated antigen presentation. Although it is well-known that trafficking and entry of T cells from the circulation into tumors is often impaired, leading to an immune “cold”, checkpoint inhibitor-refractory state, there are no available therapies that address this important aspect of antitumor immunity.

Sphingosine-1-phosphate (S1P) is a pleiotropic, bioactive lipid that has been shown to regulate lymphocyte egress from lymph nodes through its interaction with one of its several receptors, S1P1. Clinically, tumor expression levels of the sphingosine-1-phosphate-producing enzyme sphingosine kinase 1 (SPHK1) strongly and negatively correlates with survival of melanoma patients after immune checkpoint inhibitor (ICI) therapy, and pre-clinically correlates with reduced tumor infiltrating lymphocytes (TILs). We therefore hypothesize that aberrant S1P signaling in tumors and in their draining lymph nodes (TDLN) causes immune exclusion by impeding lymphocyte egress from the TDLN, ultimately restricting immune cell infiltration of tumors.

Methods: We tested the therapeutic efficacy of an engineered S1P-degrading enzyme, S1P lyase (S1PL), on established (~100mm^3) syngeneic B16, CT26, and MC38 murine tumors. Using flow cytometry, we performed immune profiling of systemic, TDLN, and intratumoral T cell populations, assessing both activation status and expression of the S1P1 receptor.

Results: Treatment of tumor-bearing animals with S1PL depleted systemic S1P, and dramatically increased both trafficking of lymphocytes out of TDLNs and T cell infiltration of tumors relative to control-treated animals. Mice treated with S1PL evinced a higher proportion of S1P1+ circulating and intratumoral T cells relative to control-treated mice, suggesting that the increase in liberation of T cells from the TDLN was effected through the S1P/S1P1 axis. This increased lymphocyte trafficking correlated with strong inhibition of tumor growth when S1PL was administered as a single agent.

Conclusions: Therapeutic administration of S1PL may represent an attractive strategy for modulating lymphocyte trafficking to improve the efficacy of therapies that rely on the adaptive immune system to exert antitumor activity. This approach may be particularly potent in settings wherein tumor-mediated immune exclusion is a dominant method of immune escape.

#2660 CXCL9/10 is critical for immunotherapeutic efficacy by recruiting and activating T lymphocytes in tumor microenvironment.

C.-C. Cheng[1], J. Chang[2], Z.-L. Sie[1], A.-S. Ho[3], C.-L. Peng[4], C.-C. Chang[5];

[1]Chang Gung University, Taoyuan City, Taiwan, [2]Taipei Medical University, Taipei City, Taiwan, [3]Cheng Hsin General Hospital, Taipei City, Taiwan, [4]National Atomic Research Institute, Taoyuan City, Taiwan, [5]Taipei Medical University Hospital, Taipei City, Taiwan

Background: Tumor immunotherapies targeting PD-(L)1 exhibit anti-tumor efficacy in only about 20% of patients with a variety of cancers. Literature has demonstrated that “hot tumor” which contains high T lymphocytes in tumor microenvironment exhibits a better response to immunotherapies than “cold tumor”. Therefore, we hypothesize that T lymphocyte-recruited factors play the roles determining the immunotherapeutic efficacy, including CXCL9, 10, and 11, which are located in human chromosome 4 with consistent co-expression and protein structure.

Aims: The aim of this study is to investigate whether CXCL9/10 is critical in determining the anti-PD-(L)1 immunotherapeutic efficacy.

Methods: GEPIA, cBioPortal, and Kaplan-Meier Plotter were used to investigate the gene expression, co-expression, and immunotherapeutic association for CD274 (PD-L1), ICAM1, and CXCL9/10 in lung, colon, and liver cancers. qPCR and flow cytometry were used to detect the gene expression in tumor cells and T lymphocytes, particularly comparing the differences between LL/2 and CT26 cells whereas LL/2 is immunotherapy-resistant and CT26 is immunotherapy-sensitive. CD8+ T cell transwell assay and qPCR were used to measure the function of CXCL10 on CD8+ T cell migration and activation, whereas IFNγ and IL-2 as the activation markers.

Results: We found that CXCL9/10 overexpressed in a variety of tumors, including lung, colon, and liver tumors with a correlation with PD-L1. However, PD-L1 was not overexpressed in most tumors. High PD-L1 and CXCL10 are basically associated with better survival rates in tumor patients receiving immunotherapies. Correlation analysis revealed that IRF-1 and STAT1 were correlated with PD-L1 and CXCL10 expression in lung cancer. Since literature has indicated that LL/2-derived syngeneic tumor exhibits immunotherapy-resistant and CT26 exhibits immunotherapy-sensitive, we further compared the gene expression between them. We found that IFNA, IFNG, CXCL10, and PD-L1 all expressed higher levels in CT26 cells than LL/2. Moreover, we found that T lymphocytes specifically expressed high CXCR3, a receptor of CXCL9/10, including CD4+ T and CD8+ T cells by flow cytometry. As expected, CD8+ T cells can be recruited in a transwell assay by IFNα and CXCL9. In addition, we found that IFNα induced CXCL10 expression in monocytes and CXCL10 increased activation markers IFNγ and IL-2 in CD4+ T and CD8+ T cells.

Conclusions: This study revealed that CXCL9/10 expression is correlated with PD-L1 in tumors, resulting in better immunotherapeutic efficacy. The evidence demonstrated that CT26 intrinsically exhibited higher IFNs and CXCL9/10 compared to LL/2. Therefore, CXCL9/10 potentially recruits and activates CD8+ T cells to tumor microenvironment, transferring “cold tumor” to “hot tumor”. This study indicates that CXCL9/10 is critical for immunotherapeutic efficacy.

#2662 Deciphering the cellular and molecular determinants of immunotherapy resistance in NASH-associated hepatocellular carcinoma by single-cell analysis.

L. Zhang, Y. Zhang, W. Tang, Z. Xiong, X. Liu, Z. Liang, Y. Tsang, W. Yang, X. Long, A. S. Cheng;
The Chinese University of Hong Kong, Shatin, Hong Kong

Introduction: Non-alcoholic steatohepatitis (NASH) has emerged as a prominent risk and the most rapidly increasing aetiology of hepatocellular carcinoma (HCC). Despite the effectiveness of immune checkpoint blockade (ICB), like anti-programmed cell death-ligand 1 (anti-PD-L1) antibodies, in a subset of HCC patients, NASH has been shown to impair the anti-tumor immunity in ICB-treated HCC. We aim to elucidate the mechanisms responsible for ICB resistance in NASH-HCC at single-cell resolution.
Methods: Orthotopic NASH-HCC mouse models were generated by orthotopically injecting liver cancer cell line into NASH liver induced by methionine-and choline-deficient diet (MCD) or choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD). Multi-color flow cytometry and single-cell RNA-sequencing (scRNA-seq) were utilized to dissect the liver and tumor immune microenvironment upon anti-PD-L1 treatment.
Results: Anti-PD-L1 treatment failed to alleviate tumor burden in NASH mice, indicating that orthotopic NASH-HCC mouse models were resistant to ICB therapy. Compared to the control liver, multi-color flow cytometry demonstrated that $CD11b^{+}F4/80^{+}CD206^{+}$M2 macrophages accumulated in NASH liver and further increased in liver and tumor upon anti-PD-L1 treatment. Tumor-infiltrating M2 macrophages exhibited the most significant and robust correlation with tumor weight among all immune cell types. Moreover, PD-1 expression on tumor-infiltrating $CD8^{+}$ T cells positively correlated with tumor weight and intratumoral M2 macrophages. Furthermore, scRNA-seq analysis identified a NASH-specific tumor-infiltrating monocyte subcluster, which may differentiate into an ‘M2-like’ macrophage subtype upon anti-PD-L1 treatment as demonstrated by cell trajectory analysis.
Conclusion: Our study provides insights into the significance of monocyte/macrophage reprogramming in ICB resistance in NASH-HCC. Further investigation is conducted to identify the molecular mechanisms during monocyte-macrophage differentiation and explore potential targeted strategies to overcome ICB resistance in NASH-HCC.

Keywords: hepatocellular carcinoma, single-cell RNA-sequencing, anti-PD-L1, macrophages.

#2663 Determining the role of tumor mutational burden in a pre-clinical model of glioblastoma.

K. Breen, T. Haynes, M. Watanabe, M. Gilbert;
NIH-NCI, Bethesda, MD

Despite advances in care in many cancer types, patients with glioblastoma (GBM) have a grim prognosis of 15 to 21 months and unchanged standard therapy since 2005. These tumors have a profoundly immunosuppressive tumor immune microenvironment. Immunotherapy, including the checkpoint inhibitors (ICIs) targeting PD-1 and CTLA-4, has transformed the treatment of many cancers but has failed in trials of both newly diagnosed and recurrent GBM. Tumor mutational burden (TMB) has been proposed as a predictor of response to ICI treatment, presumably through an increase in neoantigens that can be recognized by cytotoxic CD8+ T cells leading to tumor rejection. GBM typically has a low TMB, a feature speculated as a contributor to poor response to ICI treatment. However, cases with an extremely high TMB (i.e., patients with the biallelic mismatch repair deficiency syndrome) do show response to immunotherapy. To begin to investigate the impact of mutational burden on immune response in GBM, we created a murine syngeneic tumor model using CRISPR-Cas9 to knockout (KO) the mismatch repair protein Msh2, the lynchpin to mismatch recognition, in the SB28 GBM model that has a low TMB (108 mutations) at baseline. Msh2 KO increased the TMB from 2 to 12-fold depending on single cell sorted clone, resulting in between 150 and 200 predicted strong MHC-I binding neoantigens estimated by the NetMHC algorithm. Preliminary studies have demonstrated that in vitro proliferation is similar amongst low TMB and high TMB SB28 clones. Flank implantation of high TMB SB28 clones revealed slower growth compared to the low TMB SB28 tumors. Furthermore, treatment with ICIs did provide a survival advantage in this flank model. However, no survival advantage was noted when the high TMB clones were implanted intracranially either with or without ICI treatment. These results suggested that either there is poor immune cell trafficking to the intracranial tumors, or a robust immune response was causing increased intracranial pressure that is prematurely causing death. Use of dexamethasone starting at day 11 to control cerebral edema has shown some survival improvement with ICI treatment, supporting that an inflammatory response is at least partially responsible for the lack of improved survival in early studies. We are currently evaluating CD4+ and CD8+ T cell clonality, earlier timepoints to evaluate the immune infiltrate and anti-tumor immune response, and alterations in chemokines/cytokines in the tumor microenvironment. By creating high mutation burden clones from a GBM with a low mutational burden, we will be able to interrogate potential mechanisms of heightened immunogenicity that has been reported in other cancers.

#2664 Targeting PD-L1/CMTM6 in myeloid cells results in elevated release of CCL2 to improve CD8 T cell-mediated antitumor response.

M. A. Hsu[1], X. Liu[1], Y. Li[1], W. Barham[2], K. Pavelko[1], J. Hirdler[1], F. Lucien[1], H. Dong[1];
[1]Mayo Clinic, Rochester, MN, [2]Vanderbilt University, Nashville, TN

Background: Although targeting myeloid cells has become one of the next generation targets for cancer immunotherapy, there is a lack of therapeutic tools to specifically target these cells. Our group has developed a novel humanized PD-L1-targeting antibody, H1A, that induces PD-L1 degradation via blockade of PD-L1 and CMTM6, therefore limiting PD-L1 intrinsic signaling while also preventing interactions with PD-1. In the immune cell compartment, CMTM6 expression is restricted to myeloid cells, making these cells the primary target of H1A. Recently, we unexpectedly found that targeting intrinsic PD-L1 in myeloid cells via H1A resulted in increased release of CCL2 from myeloid cells. In this study, we examined the role of CCL2/CCR2 signaling in CD8 T cell function using human peripheral blood-derived immune cells and evaluated the therapeutic potential of H1A antibody using our humanized PD-L1/PD-1 mouse model.
Methods: Human PBMCs derived from healthy donors were treated with H1A or Atezolizumab, a blocking PD-L1 antibody, followed by mass cytometry and flow cytometry to evaluate immune cell phenotype and functional states. PD-L1 expressing myeloid cells isolated from human PBMCs were treated with H1A or Atezolizumab and assessed for CCL2 secretion using multiplex immunoassays. CCL2 production and transcription were confirmed by flow cytometry and single-cell RNA-sequencing. CCR2 blockade was used on human PBMCs to evaluate the effects of CCL2/CCR2 signaling on T cell function alongside H1A treatment. Finally, in vivo antitumor activity of H1A and Atezolizumab were compared in two humanized PD-L1 tumor models.
Results: H1A reduced the frequency of regulatory T cells and increased effector T cells, in whole PBMCs upon global T cell activation with anti-CD3/CD28. H1A enhanced the secretion and production of CCL2 from myeloid cells, which was confirmed at a transcript level. CCR2 blockade diminished CD8 T cells' ability to differentiate into effector cells in H1A treated PBMCs. H1A demonstrated comparable therapeutic effects with Atezolizumab in treatment of immunogenic and ICI-responsive mouse tumor MC38, which is CD8 T cell-dependent, but showed superior therapeutic effects in treatment of ICI-insensitive mouse tumor E0771 compared to Atezolizumab. Both treatments elicited durable memory specific immune responses upon E0771 tumor rechallenge.
Conclusion: H1A demonstrated a superior antitumor activity compared to Atezolizumab in our preclinical models via a new mechanism by which H1A caused degradation of intrinsic PD-L1 in myeloid cells. This causes more release of CCL2 to improve T cell function via CCR2 upon T cell activation. Thus, H1A is emerging as a new immunotherapy tool to target PD-L1/CMTM6 in myeloid cells for treatment of cancers that are refractory to current immune checkpoint inhibitor therapy.

#2665 Fc silencing of commonly used surrogate anti-PD-1 RMP1.14 increases its therapeutic profile in MC38 syngeneic model.

E. Morgado, L. Pouyet, O. Deas, F. Romagne;
Janvier Group, Le Genest Saint Isle, France

Introduction: Anti-PD1 treatment has become a backbone treatment in several cancers such as melanoma and lung carcinoma. Adding new drugs to PD-1 requires careful evaluation of combination treatments in preclinical models to evaluate efficacy and tolerability. Syngeneic tumor model remains one of the best way of preclinical evaluation of combinations, as such evaluation requires fully immune competent animals to correctly assess both the PD-1 contribution and the added value or synergistic effect of new drugs in the combination. Anti mouse PD-1 such as RMP1.14, a rat IgG2a, is widely used in these models as anti-PD-1 mAb surrogate for such studies. Although RMP1.14 demonstrated efficacy in several models such as MC38, and CT26, it may not fully recapitulate the use of blocking mAb in the human as it may be immunogenic in mice and may retain some agonist activity due to its rat isotype. Here, we demonstrate that engineering this antibody with a mice Fc silent backbone increases its activity in MC38 model.
Methods: VH/VL from RMP1.14 rat IgG2a (mPD1) were sequenced and engineered with a mouse Fc silent IgG1 backbone (N297Q) and produced in CHO. Both antibodies (mPD-1: rat IgG2a ; and MOS2-mPD-1: Fc silent mouse IgG1) were purified on protein A using standard procedures. MC38 (1million cells) were injected subcutaneously in C57BL/6 mice, and randomized when tumor volume reached 100mm^3. Dose effect of mPD-1 and MOS2-mPD-1 and their corresponding isotype controls were tested in this MC38 model at doses of 0.5 ; 1.25 ; 2.5 and 12.5 mg/kg at day 0, day 3, and day 7 post randomization (8 mice per group). Treatment route effect was tested in the same model by comparing intraperitoneal and intravenous injections in an additional experiment using both antibodies at 1.25 mg/kg and 12.5 mg/kg doses.
Results: Both mPD-1 and MOS2-mPD-1 demonstrated efficacy in survival in MC38 model at all tested doses ($p<0,05$ Mantel-Cox test) compared to their isotype controls. MOS2-mPD-1 demonstrated increased efficacy in terms of complete responses in the above escalated doses (CR of 12.5, 12.5, 12.5 and 37.5 % and 0, 75, 50 and 62.5 % for mPD-1 and MOS2-mPD-1 respectively). Tumor volumes and survival were also always lower in the MOS2-mPD-1 groups compared to dose corresponding mPD-1 groups and were statistically different in two independent experiments at medium doses ($P<0,05$ Dunn's test performed at 1.25mg/kg at day 27, and Mantel-Cox test). IP and IV routes were equivalent in efficacy at the tested doses.
Conclusion: Mouse Fc engineered surrogate have significantly different behavior in mice models compared to the commonly used surrogates usually from rat origin. These new formatted antibodies should better mimick the efficacy and tolerability of antibodies used in human, and should be preferred when new combinations of treatments are tested.

#2666 Genetic ablation of B2M leads to resistance to PD-1/PD-L1 blockade *in vivo*.

Y. Zhang, H. Ma, B. Han, Y. Li, P. Yang, Z. Li, D. Feng, L. Ci, R. Sun, **D. X. He**;
Shanghai Model Organisms Center, Inc., Shanghai, China

Immune checkpoint inhibitors (ICIs) has revolutionized the treatment landscape of various cancers by reinvigorating the exhausted T cells in patients. However, the therapeutic efficacy is largely confined due to the primary or acquired resistance to anti-PD-1 (L1) therapy in many patients. Recently, the mechanisms of resistance to ICIs has been extensively elucidated from different aspects and emerging sequencing data from clinical samples has pointed to IFN-γ signaling defects and antigen presentation loss in patients who are resistant to PD-1(L1) blockade. The loss-of-function mutations in JAK1 and JAK2 results in lack of response to IFN-γ signaling and incapacity to upregulate PD-L1 and MHC-I, which subsequently leads to noninflammatory TMEs and resistance to anti-PD-1/PD-L1. The loss-of-function of B2M is likely a common resistance mechanism that the intratumoral cytotoxic CD8+ T cells are failed to be boosted owing to antigen presentation loss. In order to obtain higher clinical benefits in various cancers, it's appealing and urgent to develop mechanism-based strategies to overcome resistance to ICI-based immunotherapy. To this end, we developed a genetically acquired resistant tumor model with B2M mutations in syngenic MC38 tumor cells using CRISPR/Cas9 technology, which is 'hot' tumor to PD-1/PD-L1 blockade. The expression of B2M was detected by western blotting and flow cytometry. Mouse *B2M*-knockout MC38 tumors became resistant to PD-1/PD-L1 blockade in vivo. Notably, we found a remarkable increase of CD8+ T cell infiltration in B2m-KO MC38 tumors in comparison to parental MC38 tumors upon anti-PD-1 treatment, which further explains that antigen presentation loss results in inactivation of cytotoxic CD8+ T cells within the tumor microenvironments (TMEs), subsequently leading to resistance and poor survival to ICI therapy.In summary, our data consistently indicated the importance of MHC-I expression in T cell activation in the TMEs and the possibility to dig out the pathway involved in MHC-I expression independent of IFN-γ signaling by CRISPR-based screening to overcome MHC-I deficiency-induced resistance in the future. In addition, it's possible to leverage the cytotoxic NK cells and CD4+ T cells in antitumor immunity against MHC-II+ tumors even with the loss of MHC-I molecules. For example, high dose of IL-2RB-biased IL-2 agonist preferentially binding to the dimeric IL-2R can stimulate Teff and NK cells independent of immune checkpoint expression. Likewise, cytokine modified anti-PD-1 fusion formulation like anti-PD-1-IL-2 mutein and anti-PD-1-IL-15 mutein are promising to overcome the resistance. Furthermore, it has been suggested that the resistance due to genetic mutations of MHC-I could be overcome by combining NF-B targeted therapies.

#2667 Mucin 5AC inhibition via intratracheal RNAi delivery as an effective alternative strategy for prevention and treatment of Kras mutant lung cancer.

M. Zarghooni[1], M. T. Grimaldo[2], A. Krishna[2], M. J. Clowers[2], L. Phan[1], Y. H. Rezai[1], A. Gaitonde[1], C. Rodriguez Reyna[1], W. Velasco Torrez[1], E. Bush[3], S. Javad Moghaddam[1];

[1]Department of Pulmonary Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, [2]The University of Texas MD Anderson Cancer Center UTHealth Houston Graduate School of Biomedical Sciences, Houston, TX, [3]Arrowhead Pharmaceuticals, Pasadena, CA

Lung cancer, including lung adenocarcinoma (LUAD), is the leading cause of cancer-related deaths in the United States. *KRAS* mutations are the most prevalent oncogenic driver alteration in human LUAD. We have previously shown that high expression of Mucin 5 AC (MUC5AC), a main airway secretory mucin, is significantly associated with poor prognosis. Mucins are essential for mucociliary clearance and the maintenance of airway homeostasis, however, their overproduction could negatively affect the lung immune microenvironment and has been shown to promote airway diseases such as chronic obstructive pulmonary disease (COPD) and lung cancer. Previously, we have shown that genetic deletion of MUC5AC in a murine model of K-ras mutant lung adenocarcinoma (KM-LUAD) impedes tumor development and reduces pro-tumor inflammatory and immune phenotypes. These findings indicate that MUC5AC is a potential druggable target against KM-LUAD. In this study, we sought a translational approach and inhibited MUC5AC in our K-ras^{G12D} mutant mouse model of LUAD via RNA interference (RNAi). Six-week-old mice were given RNAi (5mg/kg) or vehicle (saline) via biweekly intratracheal administration for 8 weeks. This approach led to a significant decrease in tumor burden (40%) and a trending increase in total white blood cell counts, predominantly macrophages in the lung tumor microenvironment which was associated with phenotypic changes in macrophages characterized by reduced expression of *Fizz1*, and M2 pro-tumor macrophage marker. Additionally, RNAi-treated mice had reduced expression of *Siglec-E*, a mucin receptor and known inhibitor of the TLR4 endocytosis and promoter of NF-κB signaling, as well as a significant decrease in *IL-6*, a product of the NF-κB pathway and promoter of STAT3 signaling which we have previously shown to have an essential role in promotion of KM-LUAD. In summary, these findings elucidate a potential mechanism by which MUC5AC protects tumor cells from apoptosis and immune-mediated cytotoxic activity but also highlights how MUC5AC RNAi is an effective indirect preventive and therapeutic strategy in high-risk individuals (smokers with COPD) and patients with early stage KM-LUAD, respectively.

#2668 CBO421: A novel drug Fc-conjugate to prevent tumor immune evasion via the CD73/adenosine pathway.

A. Almaguer, D. Zuill, S. Dohrmann, J. Levin, N. Dedeic, E. Abelovski, J. Fortier, Q. Zhao, M. Hernandez, K. Amundson, M. Moniz, H. Chen, D. Panickar, T. Lam, T. Brady, A. Borchardt, G. Hough, J. B. Locke, J. N. Cole, L. W. Tari;
Cidara Therapeutics, San Diego, CA

Background

CD73 (5'-nucleotidase or NT5E) is a cell surface enzyme responsible for the rate limiting step in adenosine production; the conversion of adenosine monophosphate (AMP) into adenosine. Adenosine contributes to immune evasion by solid tumors by concentrating immunosuppressive adenosine in the tumor microenvironment. CBO421, a Drug Fc-Conjugate (DFC), comprises a novel small molecule CD73 inhibitor stably conjugated to an immune-silent human IgG1 Fc, combining the strengths of small molecule inhibitors and CD73-targeting monoclonal antibodies (mAbs) for potential best-in-class efficacy.

Methods

CBO421's binding affinity to human CD73 and Fc receptors was assessed by surface plasmon resonance. Antibody-dependent cellular cytotoxicity (ADCC) was evaluated using a commercial kit. Immunophenotyping and binding to cancer cells was measured by flow cytometry. Inhibition of soluble and membrane-bound CD73 on human PBMCs and mouse cancer cells was determined by measuring free phosphate levels. Functional activity was measured using PBMC rescue assays. *In vivo* efficacy of CBO421 monotherapy was evaluated in a syngeneic mouse model.

Results

CBO421 exhibited a binding affinity to human CD73 (K_D = 0.8 nM) that was comparable to or greater to the affinity observed with small molecule inhibitors (AB680, OP-5244) and CD73-targeting mAbs (oleclumab, mupadolimab biosimilars). As expected, human FcRn binding of CBO421 was comparable to the unconjugated Fc and the full-length wild-type IgG1 control mAb. CBO421 binding to human Fc gamma receptors and ADCC activity was significantly reduced or abolished compared to the control mAb, such that it poses a minimal risk for undesired autoimmune activity. CBO421 potently inhibited soluble CD73 and CD73 expressed on human MDA-MB-231 and mouse EMT6 cancer cells. Immunophenotyping revealed that CD73 expression was primarily observed on $CD8^{\pm}$ T and B cells from human PBMCs. In functional PBMC rescue assays, CBO421 demonstrated potent reactivation of AMP- or ATP-suppressed $CD4^{\pm}$ or $CD8^{\pm}$ T cells at levels comparable to small molecule inhibitors and greater than anti-CD73 mAb comparators. CBO421 monotherapy demonstrated a dose-dependent reduction in tumor volume in a syngeneic mouse model using MC38, a colorectal cancer cell line.

Conclusions

CBO421 exhibited strong binding and potent inhibition of both soluble and membrane-bound CD73, differentiating it from mAb CD73 inhibitors. The proprietary immune-silent Fc of CBO421 did not affect FcRn binding but substantially reduced Fc gamma receptor binding, leading to the elimination of ADCC activity to prevent undesired immune cell depletion in host tissues. CBO421 demonstrated high potency in functional cell-based assays and robust antitumor efficacy in a syngeneic mouse model. Currently, CBO421 is being advanced as a clinical development candidate for the treatment of solid cancers.

#2670 Development of novel anti-SIRPα/β dual antibody with single-agent phagocytosis activity.

Subhra Prakash Chakrabarty, Sandeep Sadashiv Patil, Sunaina Singh Rajput, Amrita Mukerji, Sandhya Aurumugam, Pooja Balu Gade, Sidhesha S, Anup Kumar Patra, Shivaranjini C, Vaishnavi Shivaji Khamkar, Lavanya P, Lakshmeesha K N, Ujjwal Kapoor, Jagadeesh R, Jwala Nagaraj, Vijaya Shankar Nataraj, Kavitha Nellore, Thomas Antony, Susanta Samajdar, Murali Ramachandra

Aurigene Oncology Limited, Bengaluru, India

Signal-regulatory protein alpha (SIRPα) is an inhibitory receptor expressed on macrophages that interacts with CD47, resulting a "don't eat me" signal on cancer cells. This interaction suppresses macrophage dependent phagocytosis and contributes to the evasion of host immune system. Consequently, the SIRPα-CD47 axis has become a well sought after and established therapeutic angle to treat cancer. While CD47-targeting agents have shown promise in clinical trials, the ubiquitous expression of CD47 raises the concerns about hematologic toxicity, including anaemia and thrombocytopenia, hindering the development of CD47-targeting therapies. This has prompted exploration of another end of the axis i.e., targeting SIRPα. Moreover, targeting SIRPβ protein, expressed on myleoid cells, via agonistic approach would generate ITAM-mediated activating signal through DAP12 protein contributing to cancer cell death. Considering the limited expression of SIRPα and β, a dual antibody capable of blocking the CD47-SIRPα pathway and activating SIRPβ downstream signaling may result in a desirable efficacy and safety profile. In this study, we present novel anti-SIRP α/β dual antibody clones discovered from a proprietary human antibody discovery platform consisting of a large human antibody library, along with *in vitro* and *in silico* screening technologies. The platform was explored against native SIRPα/β antigens to identify novel human antibody clones based on affinity-based epitope coverage. Subsequently, antibody clones were produced and evaluated for preclinical functional relevance. Novel full-length SIRPα/β dual antibody clones demonstrated high affinity binding to soluble human SIRPα and SIRPβ proteins as well as these receptors expressed on CHO-K1 cells and macrophages. The antibody clones effectively disrupted CD47-SIRPα interaction in biochemical assays and significantly enhanced activation of macrophages as observed by increased cytokine release. Most importantly, the dual antibody clones demonstrated potent *in vitro* single-agent phagocytosis activity against tumor cells. In summary, the novel SIRPα/β dual antibodies activating macrophage mediated phagocytosis of tumor cells without the need for tumor opsonizing antibodies or agents capable of inducing “eat-me-signals” highlight their potential as a single-agent therapy. These findings prompt us to continue the development of the anti-SIRP α/β dual antibody for use in cancer therapy.

#2671 Sustained inhibition of CSF1R signaling effectively augments antitumor immune responses through inhibiting tumor-associated macrophages.

T. Sato[1], D. Sugiyama[1], Y. Kojima[2], S. Hattori[1], K. Sone[1], T. Ishikawa[1], Y. Ishikawa[1], T. Kato[1], H. Kiyoi[1], H. Nishikawa[1];
[1]Nagoya Univ. Graduate School of Medicine, Nagoya, Japan, [2]National Cancer Center, Tokyo, Japan

Tumor-associated macrophages (TAMs) are one of the key immunosuppressive components in the tumor microenvironment (TME) and contribute to tumor development, progression, and resistance to cancer immunotherapy. Several reagents targeting TAMs have been tested in preclinical and clinical studies, but they have had limited success. Here, we show that a novel reagent, FF-10101, exhibits a sustained inhibitory effect against colony stimulating factor 1 receptor by forming a covalent bond and reduces immunosuppressive TAMs in the TME, which leads to strong antitumor immunity. In preclinical animal models, FF-10101 treatment significantly reduced immunosuppressive TAMs and increased antitumor TAMs in the TME. In addition, tumor antigen-specific $CD8^+$ T cells were increased; consequently, tumor growth was significantly inhibited. Moreover, combination treatment with an anti-PD-1 antibody and FF-10101 exhibited a far stronger antitumor effect than either treatment alone. In human cancer specimens, FF-10101 treatment reduced PD-L1 expression on TAMs, as observed in animal models. Thus, FF-10101 acts as an immunomodulatory agent that can reduce immunosuppressive TAMs and augment tumor antigen-specific T cell responses, thereby generating an immunostimulatory TME. We propose that FF-10101 is a potential candidate for successful combination cancer immunotherapy with immune checkpoint inhibitors, such as PD-1/PD-L1 blockade.

#2672 GD3 synthase (ST8SIA1) is a key immunomodulator in GD2^{+} breast cancer cells.

B. Oderinde, V. Anand, M. Siddiqui, A. Tyagi, B. Jenny, V. Battula;
UT MD Anderson Cancer Center, Houston, TX

Background: Gangliosides are acidic glycosphingolipids involved in cell adhesion, proliferation, and modulation of signal transduction pathways. It has been reported that tumor-shed gangliosides influence the activity of immune cells, including macrophages, NK cells, and T cells. GD3 synthase (GD3S) is the key enzyme that regulates the biosynthesis of the b and c-series gangliosides, particularly GD3 and GD2, and studies have shown that GD3S is upregulated in most tumors and plays a role in tumor progression. Similarly, we have found GD3S to be significantly upregulated in GD2^{+} breast cancer stem cells (BCSC) compared to GD2^{-} cells, and the knockdown of this gene prevented tumor formation in mice. Here, we hypothesize that GD3 synthase has an immunomodulatory function in breast cancer (BC) cells through the upregulation of GD2.

Methods: We stably overexpressed GD3S in BT549 and MCF-7 breast cancer cell lines by lentiviral transfection and performed CRISPR-Cas9 knockout of GD3S in BT549 and SUM 159 cell lines. We examined the effect of GD3 synthase on macrophage-mediated phagocytosis, NK cell-mediated killing, and T-cell cytotoxicity of BC cells using the live cell imaging system, IncuCyte®. Naxitamab is a US FDA-approved fully humanized anti-GD2 monoclonal antibody for the treatment of neuroblastoma. We evaluated the effects of naxitamab in GD2^{+} BC cell lines (HCC1395, Hs578T) using the Incucyte, and also examined its effect on in vivo tumor growth using TNBC PDX models.

Results: We observed a highly significant decrease in macrophage-mediated phagocytosis ($p<0.005$; $p<0.0001$) and NK-mediated killing ($p<0.0001$; $p<0.0001$) in BT549 and MCF-7 cell overexpressing GD3S compared to the control cells. Interestingly, we observed a significant increase in phagocytosis in GD3S knockout BT549 and SUM 159 cells ($p<0.05$; $p<0.005$) compared to their wild-type counterparts. Moreover, the knockout of GD3S enhanced NK cell-mediated apoptosis in BT549 cells ($p<0.001$) and T cell killing in BT549 and SUM 159 cells ($p<0.0001$; $p<0.0001$). Finally, we found that naxitamab dose-dependently enhances macrophage-mediated phagocytosis and NK cell-mediated apoptosis in HCC1395 and Hs578T BC cells, with 20µg/ml being the most effective concentration in comparison to IgG control ($p<0.0001$; $p<0.0001$). In addition, we observed a reduction in tumor volume in naxitamab-treated mice compared to IgG control ($p<0.05$)

Conclusion: GD3 synthase regulates macrophage-mediated phagocytosis, NK cell-induced apoptosis, and T-cell cytotoxicity in BC cells. Naxitamab enhances immune cell killing of breast cancer cells with high GD2 expression. Furthermore, naxitamab inhibited tumor growth in GD2^{+} TNBC PDX models.

#2673 Copper chelation overcomes the immunosuppressive neuroblastoma microenvironment to potentiate anti-GD2 antibody therapy.

J. R. C. Rouaen[1], A. Salerno[1], F. Luciani[2], J. Murray[1], T. Shai-Hee[1], N. Tedla[2], M. Haber[1], T. N. Trahair[1], O. Vittorio[2];
[1]Children's Cancer Institute Australia, Sydney, Australia, [2]University of New South Wales, Sydney, Australia

Neuroblastoma is the most frequent extra-cranial pediatric cancer with high-risk disease possessing a dismal five-year survival rate <50%. Antibody-based therapies targeting the surface disialoganglioside GD2 have shown promising anti-tumor activity in patients however efficacy is strongly hampered by immunosuppressive mechanisms present in the tumor microenvironment. Neuroblastomas typically feature low mutational burdens, limited major histocompatibility complex class I expression, increased immune checkpoint markers, sparse immune infiltration, and soluble mediators which drastically limit anti-tumor immunity. Given the emerging link between elevated copper levels and tumoral immune evasion, we explored copper chelation as a therapeutic strategy using the agents tetraethylenepentamine (TEPA) and the clinically approved analogue triethylenetetramine (TETA). Using the immunocompetent TH-MYCN model, we performed single-cell RNA sequencing supported by OPAL multiplex immunohistochemistry and cytokine profiling of resected tumors to assess cellular and molecular changes occurring after one week of TEPA treatment. Therapy was observed to successfully deplete intratumoral copper and reinvigorate anti-tumor immunity with increased infiltration and activity of pro-inflammatory immune cells, and was specifically found to induce egress and N1-polarisation of neutrophils. Further mechanistic studies in vitro revealed the sequestration of copper by neuroblastoma cells attenuated neutrophil function, which could be successfully reversed upon TEPA treatment. Findings propose a novel mechanism of immune evasion, highlighting copper chelation as a therapeutic strategy to counteract immunosuppression. Using the TH-MYCN model, TEPA was employed as a priming agent to effectively potentiate anti-GD2 antibody therapy and achieve durable tumor control. Importantly, this was associated with increased Fc-receptor-bearing natural killer and myeloid cells, which elicit tumor clearance via antibody-dependent cellular cytotoxicity. Currently indicated for the treatment of copper overload disorder Wilson's disease, TETA was evaluated for potential repurposing as a novel immunomodulatory agent. Using the syngeneic NXS2 model, TETA exhibited an exceptional safety profile and combination therapy achieved durable tumor control with no relapses occurring after treatment cessation. This result was similarly associated with the infiltration of pro-inflammatory immune cells, including N1 neutrophils. Collectively, this study credentials copper chelation as a non-toxic strategy to disrupt the immunosuppressive tumor microenvironment and reinvigorate anti-tumour immunity. Findings provide crucial translational evidence for repurposing TETA to potentiate anti-GD2 antibody therapy and improve neuroblastoma patient responses.

#2675 A new dual-targeting anti-immune checkpoint therapeutic approach for the treatment of “hot” and “cold” tumors.

M. M. Moutuou[1], N. DeLuce[2], E. Creton[2], H. Lucchi[2], J. Accolas[1], A. Savatier[1], **M. Leonetti**[1];
[1]CEA, Saclay, France, [2]Blue Bees Therapeutics, Parc Club-Orsay Universite, Orsay, France

Anti-Immune Checkpoint (ICP) antibody approaches provided a major breakthrough in the field of cancer therapy. However, their efficiency is mainly restricted to patients with “hot” tumors characteristics, which limits the breadth of their use. To tackle this limit, we developed a new strategy aimed at amplifying anti-ICP antibody ability to activate immune cells. This approach is based on antibodies engineered to make them able to target both an ICP receptor and a co-receptor often involved in receptor-mediated activation, namely Heparan Sulfate Proteoglycan.
The dually-targeting engineered anti-ICP antibodies were produced in eukaryotic cells. They were purified to homogeneity using two chromatographic steps and remain stable for months in frozen conditions. A first engineered antibody-derived construct was assessed for its ability to impact immune cell activation and tumor-growth. It is able to stimulate subsets of immune cells from mouse splenocytes as well as from human peripheral mononuclear cells, *in vitro*. In addition, its injection in healthy mice triggers activation of T-cells. Last, in mice previously implanted with different types of cancer cells it impacts growth of “hot” as well as “cold” tumors. Immune profiling in a “cold” cancer model shows that the treatment decreases the proportion of MDSCs and increase that of $CD8^{+}$ T-cells and NK-cells in tumor microenvironment making it close of that found in “hot” tumors. Altogether, our data indicate that our first engineered antibody-derived construct presents an attractive immunotherapeutic potential for a large variety of cancers paving the way for its evaluation in clinical phases.

IMMUNOLOGY: Innate Immunity in Cancer
Poster Session

#2679 Myeloid olfactory receptors in melanoma.
E. M. Benson, K. Ley, M. Orecchioni, C. C. Hedrick;
Immunology Center of Georgia, Augusta, GA

Olfactory receptors are commonly found in the nasal cavity and function to detectodorants. However, very recent studies have determined that innate immune cells,including monocytes and macrophages, express olfactory receptors. OLFR2 (OR6A2 inhumans), was recently linked to atherosclerosis development through interaction with itsligand, octanal. Increased levels of octanal are considered as a risk factor foratherosclerosis. Conversely, octanal levels are associated with lower cancer incidence,suggesting that OLFR2 may play a protective role in cancer. Indeed, data from TheCancer Genome Atlas for liver and brain cancers show that OLFR2 expression isassociated with increased patient survival. Here, we utilized an orthotopic melanomamouse model using B16 cancer cells in C57/BL6 mice that had been transplanted witheither wild type or OLFR2 knockout bone marrow to directly test the role of OLFR2 onimmune cells in regulating tumor growth. We found that hematopoietic deletion of OLFR2exacerbated melanoma tumor growth in these mice; again, supporting the notion thatOLFR2 is anti-tumoral. The OLFR2+ cells present in the tumor were myeloid cells.Monocytes, non-classical monocytes specifically, function to detect cancer cells in tumorseeding sites, and recruit NK cells for tumor cell destruction. OLFR2-deficientmacrophages were found to migrate less to tumor cells in an in vitro assay, suggestingthat OLFR2 is involved in the sensing of newly seeding tumor cells, likely through sensingoctanal. Studies are ongoing to determine the exact functions of OLFR2+ monocytes andmacrophages in the tumor microenvironment. OLFR2 may be one of several olfactoryreceptors that is utilized by myeloid cells as a defense mechanism for detection of newlyseeding or metastatic tumor cells. As olfactory receptors are easily druggable targets,understanding their role in cancer prevention could lead to emerging newimmunotherapies for cancer.

#2680 Knockout on enhancer of zeste homolog 2 in triple-negative breast cancer model alters immune signaling and decreases tumor progression and lung metastasis.

L. Monterroza[1], M. Parrilla[2], S. Samaranayake[1], D. Rivera[1], B. Dobosh[1], P. Selvaraj[1], R. Tirouvanziam[1];
[1]Emory University, Atlanta, GA, [2]Georgia State University, Atlanta, GA

Triple-negative breast cancer (TNBC) is an aggressive and highly metastatic subtype of breast cancer. Lack of known targets, patient-to-patient variations of target antigens and resistance to immune checkpoint inhibitors make TNBC one of the most challenging cancers to treat. TNBC is enriched in tumor-infiltrating neutrophils (TINs). TINs are key contributors to pro-tumorigenic processes linked to “immunologically cold” tumors, in part by preventing recruitment of T-lymphocytes (TILs). Prior studies identified the Enhancer of zeste homolog 2 (EZH2) as a prominent methyltransferase expressed in primary and metastatic TNBC cells. EZH2 is an upstream regulator of the stimulator of interferon genes (STING), a critical innate sensor mediating anti-tumor responses that is inhibited in cold tumors. To date, EZH2/STING signaling in TINs is relatively unknown. Here, we hypothesized that EZH2 inhibition and subsequent STING activation could exert anti-tumor activity by modulating TINs. We derived EZH2-knockout (KO) and EZH2-overexpressed (OX) cell lines from the well-established 4T1 TNBC mouse cell line. We demonstrate a 10-fold decrease in lung metastasis and significant reduction of 4T1 EZH2 KO tumor growth compared to the parent 4T1 cell line. Concomitantly, the TIN:TIL ratio was significantly reduced in 4T1 EZH2 KO vs. control tumors. Overexpression of EZH2 in 4T1 TNBC cells did not affect the primary tumor growth or lung metastasis. A therapeutic study using the repeated injection of the STING agonist MSA-2 after tumor engraftment in vivo also demonstrated a decrease in lung metastasis and tumor growth in MSA-2 vs. vehicle injection with both 4T1 parent and EZH2 KO cell lines. Together, our findings suggest a key role for STING pathway modulation and TIN/TIL poise in primary TNBC progression and lung metastasis.

#2681 Blockade of SIRPα in glioblastoma cells inhibits mitochondrial fatty acid β-oxidation and increase immune cell mediated cytotoxicity.

Y.-T. Tsai, G. Lesser, D. Soto-Pantoja;
Wake Forest University School of Medicine, Winston Salem, NC

Glioblastoma (GBM) is the most malignant brain tumor with limited immunotherapeutic options, likely due to significant GBM-associated systemic and intra-tumoral immunosuppression. The binding of SIRPα on myeloid cells to CD47 on cancer cells restricts immuno-phagocytosis against cancer cells. However, less attention has been given to SIRPα is also expressed in cancer cells, and the role of SIRPα on cancer cells is still unclear. Immunohistochemistry (IHC) staining was used to examine the expression of SIRPα in normal brain tissues and GBM. A single-cell database on the Broad Institute Portal was utilized to analyze the SIRPα expression in different cell types. SIRPα antisense morpholino was applied for gene knockdown. Established stable SIRPα overexpressed GBM cell lines were used to examine the mitochondrial function through the Seahorse Mito Stress test. In vitro, immune cell-mediated cytotoxicity was measured by Agilent xCELLigence Real-Time Cell Analysis. Patient biopsies show a 2-fold increase in SIRPα expression in GBM tumors compared to the normal adjacent ($n=14-21$; $p < 0.01$). Single-cell RNA-seq data on GBM tumors shows that SIRPα is expressed not only in the myeloid compartment but also in malignant cells. Studies have shown that mitochondrial function and fatty acid β-oxidation (FAO) play a critical role in GBM progression. Respirometry data revealed that blocking SIRPα in murine GBM cell line (CT2A) decreases mitochondrial ATP production. Seahorse Mito Stress test combined with fuel inhibitors showed that SIRPα expression mainly affects the usage of FAO (approximately 50%). In addition, stably, the GFP-tagged SIRPα overexpressed GBM cell line showed an increase of mitochondrial respiration with enhanced FAO ratio compared to the GFP control cell line. These suggested that SIRPα regulates mitochondrial FAO. Studies have shown that tumor-intrinsic FAO confers cell resistance to immune cell-mediated cytotoxicity. Interestingly, by coculturing with microglia, the innate immune population in the brain, our data showed that SIRPα blockade on GBM enhanced microglia-mediated cytotoxicity. Our data showed that targeting SIRPα on GBM may be a prospective therapeutic option by inhibiting FAO in mitochondria and increasing immune cell-mediated cytotoxicity.

#2684 Pan-cancer neutrophil profiling illuminates anti-tumor antigen-presenting potency.

Y. C. Wu, J. Ma, Q. Gao;
Fudan University, Shanghai, China

Neutrophils, the most abundant and efficient defenders against pathogens, exert opposing functions across cancer types. However, given their short half-life and fragile proliferation, it remains challenging to explore how neutrophils adapt to specific fates in cancer. Here we generated and integrated single-cell neutrophil transcriptomes from 17 cancer types (225 samples, 143 patients). Neutrophils exhibited extraordinary complexity, with 10 distinct cell states along differentiation paths including inflammation, angiogenesis, and antigen presentation. Notably, the antigen-presenting program was associated with favorable survival in most cancers and could be evoked by leucine metabolism and subsequent histone H3K27ac modification. These neutrophils could further invoke both (neo)antigen-specific and antigen-independent T-cell responses. Neutrophil delivery or leucine diet fine-tuned the immune balance to boost anti-PD-1 therapy in various murine cancers. In summary, these data not only unravel the neutrophil divergence across cancers, but also offer therapeutic opportunities such as antigen-presenting neutrophil delivery.

#2685 Activated phenotype of intraepithelial type 1 innate lymphoid cells is enriched in HPV-positive head and neck cancers.

H. Takahashi[1], S. ida[2], H. Tada[2], K. Chikamatsu[2];

[1]Ai Komagata Clinic, Maebashi, Japan, [2]Gunma Univ. Grad. School of Medicine, Maebashi, Japan

Innate lymphoid cells (ILCs) and natural killer (NK) cells are a heterogeneous family of innate immune cells that regulate inflammation, immune tolerance and tissue homeostasis in infection, chronic inflammation, metabolic diseases and cancer. The ILC family lacks the expression of antigen-specific receptors and demonstrate effector function by generating cytokines and secreted proteins. In tumor microenvironment, ILCs play a dual role including both tumor regression and tumor promotion, suggesting their diverse phenotypes and functional states. Among the ILC family, ILC1s and NK cells share some features, including the expression of the transcription factor T-bet and the ability to produce IFN-γ. In the present study, we analyzed single-cell RNA sequencing (scRNAseq) data to investigate the landscape and functional status of ILC families in patients with head and neck squamous cell carcinoma (HNSCC). The GSE164690 dataset, including pre-processed scRNAseq data and clinical data, was obtained from Gene Expression Omnibus. A total of 17 pairs of tumor-derived CD45-positive cells and peripheral blood lymphocytes, consisting of 6 HPV-positive HNSCCs and 11 HPV-negative HNSCCs, were analyzed using the Seurat v4 R package. After quality control, a total of 95,809 cells were obtained and clustered into 16 immune cell clusters. Next, a total of 7,278 NK cells were extracted and sub-clustered into 11 clusters. To characterize the 11 clusters, the abundances of NK subsets were estimated by CIBERSORTx. This approach identified eight NK cell clusters, two intraepithelial ILC1 (ieILC1) clusters, and one ieILC1-NK-intermediate (ieILC1-NK-int) cluster. Single-sample GSEA (ssGSEA) analysis was performed to further characterize each subset. ieILC1 clusters expressed tissue-resident markers *ITGA1*, *CD69*, and *CXCR6*, whereas ieILC1-NK-int cluster expressed ILC1 markers *CCR7*, *IL7R*, and *SELL*. Principle component analysis (PCA) based on ssGSEA indicated that ieILC1 clusters and ieILC1-NK-int showed the different PCA distribution from NK clusters. Inflammation and effector function-related pathways, including inflammatory response, interferon-gamma response, and interferon-alpha response, were enriched in ieILC1 clusters compared with the others. Among ieILC1 clusters, several pathways, including hypoxia, TNFA signaling via NFKB, allograft rejection, TGF beta signaling, were more enriched in ieILC1-1 than in ieILC1-2, suggesting that ieILC1-1 is the most immunologically active phenotype among NK subclusters. Of note, ieILC1-2 mainly comprised cells isolated from HPV-negative tumors, whereas ieILC1-1 mainly comprised cells isolated from HPV-positive tumors. In conclusion, we have demonstrated the diverse landscape of NK and ieILC1 cells in patients with HNSCC. Further characterization of the ILC family would lead to a novel therapeutic approach against HNSCC.

#2686 Glycolysis-stimulated lactate production by tumor-associated macrophages promotes their M2-like phenotype.

K. Kurylowicz[1], K. Chakraborty[1], C. Cui[1], G. Davanzo[2], G. Zhou[1], X. Tang[1], K. Q. Schoenfelt[1], N. Pulliam[3], C. A. Reardon[1], S. Kulkarni[3], T. Vaisar[4], P. M. Moraes-Vieira[2], Y. Zhao[1], L. Becker[1];

[1]The University of Chicago, Chicago, IL, [2]University of Campinas, Campinas, Brazil, [3]Northwestern University, Chicago, IL, [4]University of Washington, Seattle, WA

Tumor-associated macrophages (TAMs) are the predominant immune cells within the tumor microenvironment (TME), and their phenotypic modulation is influenced by environmental cues in the TME. In early tumors, TAMs adopt a pro-inflammatory M1-like phenotype, characterized by the secretion of immunogenic cytokines and the ability to kill cancer cells, thus opposing tumorigenesis. However, as tumors progress, TAMs mainly transition to an anti-inflammatory M2-like phenotype, promoting angiogenesis, suppressing anti-tumor immunity, and supporting metastasis. Importantly, a high M2-like/M1-like TAM ratio correlates with poor survival and decreased treatment responses.Despite the significance of TAMs, the molecular mechanisms driving their pro-tumorigenic M2-like phenotype remain unclear. One potential mechanism is metabolic reprogramming, where, traditionally, M1 macrophages favor glycolysis, and M2 macrophages rely on oxidative phosphorylation. However, this paradigm is primarily derived from in vitro experiments using well-defined polarization cocktails, which may not accurately replicate the complex TME. For instance, while in *in vitro* experiments IL4 and IL13 can induce oxidative phosphorylation and an M2-like phenotype, these cytokines do not seem essential for M2-like TAM polarization *in vivo*.Our studies reveal that, relative to M1-like TAMs, M2-like TAMs exhibit heightened glycolysis, intracellular lactate accumulation, and increased histone lysine lactylation - an epigenetic mark directly stimulated by lactate. Importantly, we demonstrate that TAM glycolysis and the M2-like phenotype are positively associated with hypoxia within a single tumor (GEM model and human tumors) and across various tumor types (syngeneic models). Inhibition of glycolysis-stimulated lactate production in TAMs through myeloid cell-specific deletion of lactate dehydrogenase A (mLdha-/-) reduces the M2-like:M1-like TAM ratio. This intervention increases tumor-infiltrating CD8+ T cells and reduces tumor growth in pre-clinical models, particularly in highly hypoxic environments. Moreover, to exclude the role of cancer cell-derived lactate on TAMs' phenotypic changes, we reduced glycolysis in cancer cells by deleting pyruvate kinase muscle isozyme M2 (PKM2). This resulted in decreased lactate production and suppressed tumor growth. However, the M2/M1 ratio remained unaffected, suggesting that the intrinsic lactate production by TAMs is crucial for their phenotype modulation.Our findings underscore the pivotal role of hypoxia-induced glycolysis and lactate production in TAMs, shaping their M2-like phenotype and impacting tumor progression. This understanding not only advances our knowledge of macrophage metabolism and phenotype dynamics in the context of cancer but also in other diseases.

#2687 NK cell plasticity in SCLC is linked to tumor transcriptional diversity.

J. Malin, S. Zhuang, A. K. Sharma, J. Clara, A. Thomas;
NIH-NCI, Bethesda, MD

Natural Killer (NK) cells are innate lymphoid cells that are pivotal in the body's response to cancer. To harness their cytotoxicity in clinical interventions, it is critical to understand their biology, which is highly tissue- and tumor-specific. In Small Cell Lung Cancer (SCLC), reports have described widely divergent levels of NK activity in neuroendocrine (NE) and non-neuroendocrine (non-NE) subtypes. Diminished self-antigen presentation by MHC-I is a classic trigger of NK cell activity but, counter-intuitively, NK cells exhibit reduced cytotoxicity in MHC-I downregulated NE SCLC.

To explore potential causes for depressed NK activity in NE SCLC relative to non-NE, we applied scRNA-Seq to 45 SCLC patient biopsies and rapid autopsies, and identified 4000 NK cells based on gene expression signature. There was a notable dip in NK cell infiltration in NE tumors compared to non-NE tumors. Tumor cell-surface ligands recognized by activating and, unexpectedly, inhibitory NK cell receptors were generally both more highly expressed in non-NE tumors. While inhibitory NK receptors were comparable in NE and non-NE tumors, activating NK receptors were expressed significantly, though modestly, higher in non-NE. We observed tumor site-specific gene expression patterns in NK cells from different metastatic sites. Overall, there were a remarkably high number of differentially expressed genes (>1k) between NK cells from NE and non-NE tumors, even after controlling for tumor site. Together, our work suggests that NK cell plasticity is manifest at the level of SCLC transcriptional subtypes.

#2688 Age-associated changes in macrophage function and phenotype affects cancer development, and the efficacy of macrophage targeted anticancer therapies in murine melanoma model.

M. Suresh, X. Li, S. Noonepalle, N. Gajendran, M. Durr, D. Quiceno-Torres, K. Tan, A. Villagra;
Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC

Introduction: Aging of the immune system is a critical risk factor for chronic diseases, including cancer. Globally, cancer incidence is higher between 45 to 75 years of age and declines thereafter. However, the implications of aging in cancer are understudied, and aged populations are underrepresented, both in preclinical and clinical studies. The role of macrophages in cancer progression has gained attention as a tool and target for anticancer therapies. Tumor-associated macrophages (TAMs) mainly exhibit an anti-inflammatory M2 phenotype, promote an immunosuppressive tumor microenvironment (TME), and contribute to developing resistance against immunotherapies. Therefore, several strategies targeting the phenotype and function of TAMs are being explored, including inhibitors of histone deacetylases (HDACis), adoptive macrophage cell therapy, and CAR macrophages. Studies from our group have shown that ultra-specific HDAC6is can switch macrophages from anti-inflammatory, M2, to pro-inflammatory and antitumoral M1 phenotype with minimal cytotoxicity to cancer cells. However, it is unknown if age-related changes in macrophages affect such therapeutic strategies and the TME.
Objective: To characterize the changes in macrophage function and phenotype with aging and study its implications on the TME and the efficacy of macrophage-based anticancer therapies.
Methods: Wildtype mice of ages 6-8 WKS, 3-6 MO, 10-12 MO, and 20-24 MO were injected with SM1 melanoma cells to study tumor growth kinetics. Bone marrow-derived macrophages (BMDMs) isolated from tumor-bearing and healthy mice were polarized to M1 and M2 phenotype treated with HDAC6i to study age-associated changes in phagocytic activity, antigen presentation, and gene expression. Pathways associated with macrophage polarization were examined by flow cytometry, qRT-PCR, western blot, and single-cell proteomics. Immune cells in TME were characterized in flow cytometry and single-cell RNA and secretome analyses.
Results: Tumor growth in SM1 murine melanoma model was significantly slower in older mice when compared to younger mice. Aged macrophages demonstrated significant defect in polarization to M1 and M2 phenotypes that was more pronounced in BMDMs from tumor-bearing mice. Tumor-associated macrophages showed inefficient monocyte-to-macrophage transition, as also reflected in the single-cell secretome analysis. The ability of HDAC6i to enhance macrophage function was reduced among older mice.
Conclusions: The functional and phenotypic characteristics of macrophages change with age and can significantly affect tumor growth and the effectiveness of macrophage-targeted anticancer therapies. Our study highlights the importance of studying aging in macrophages and better representation of aged populations in preclinical and clinical studies.

#2689 Mass cytometry analysis of CXCR3 expression in tumor-infiltrated myeloid cells as a predictive biomarker For immunotherapy response.

G. A. Valentin-Guillama, N. Chatterjee, A. Alimadadi, C. C. Hedrick;
Augusta University, Augusta, GA

Monocytes have emerged as important regulators of cancer progression. We have recently found that $CXCR3^{\pm}$ circulating monocytes in humans are associated with better response to immunotherapy. Here, we aimed to study the functions and heterogeneity of $CXCR3^{\pm}$ monocytes in two different triple negative breast cancer (TNBC) tumors in mice, using either AT3 or EO771 tumor cell lines. AT-3 tumors exhibit higher resistance to anti-PD-1 and anti-CTLA-4 therapy in C57BL/6 breast cancer mouse models compared to EO771 tumors. We evaluated 36 surface protein markers on tumor-infiltrated myeloid cells in tumors isolated from each model using CyTOF mass cytometry. Analysis of monocytes, macrophages and dendritic cells in the tumors using unsupervised clustering identified 13 cell subsets. Significant differences were discovered between the two tumor types in frequencies of nine of 13 identified subsets. However, 3 of these subsets displayed relatively high expression of CXCR3 in EO771 tumors when compared to AT-3 tumors. The significant CXCR3 positive subsets were identified as $CXCR3^{\pm}$ early macrophages, $CXCR3^{\pm}$ $Ly6C^{+}CD11b^{lo}$ classical monocytes and $Trem2^{\pm}$ $CXCR3^{\pm}$ dendritic cells. We observed higher expression of CXCR4, Trem2, and CCR1 in $CXCR3^{\pm}$ myeloid cells when compared to their $CXCR3^{-}$ counterparts in both tumor models. To elucidate the role of these $CXCR3^{\pm}$ cells, we performed low-input bulk RNA sequencing of $CD115^{+}/CD11b^{+}$ cells from blood and spleen of EO771 tumor bearing mice with a wild type or $CXCR3^{KO}$ genotype. Ingenuity Pathway Analysis (IPA) of the differentially expressed genes suggests a significant inhibition of the IL-10 signaling pathway of $CXCR3^{KO}$ cells. These differentially expressed markers and genes suggest a functional importance in this subset in migration to the tumor and antigen presentation, both of which are anti-tumoral functions. Ongoing studies are aimed towards understanding the role of $CXCR3^{\pm}$ myeloid cells in regulating response to immunotherapies.

#2690 The role of PCNA tyrosine phosphorylation in evading innate immune surveillance.

C.-C. Lee[1], W.-R. Wu[2], Y.-C. Shen[1], F.-C. Chung[2], Y.-L. Wang[1], Y.-Z. Lin[2], C.-H. Lu[3], W.-C. Cheng[2], H. Chang[1], L.-C. Liu[1], J.-A. Liang[1], C.-F. Chiu[1], M.-C. Hung[2], S.-C. Wang[2];

[1]China Medical University Hospital, Taichung, Taiwan, [2]China Medical University, Taichung, Taiwan, [3]National Yang-Ming Chiao Tung University, Taipei, Taiwan

Cancer cells are continually exposed to intrinsic and extrinsic proliferative stresses that can send the genome stability awry. The aberrant DNA metabolism, evolving through deregulated replicative growth in cancer cells, is increasingly recognized as a major mechanism bridging the crosstalk between the immune microenvironment and tumor tissue, thereby either promoting or suppressing tumor progression. However, the triggering and regulation of these mechanisms remain largely unknown. Proliferating cell nuclear antigen (PCNA) and its homologs are the evolutionarily conserved central components of the DNA replication machinery. In eukaryotic cells, PCNA forms homotrimeric rings encircling the DNA double helix to coordinate the complex processes of DNA replication and damage repair, directed at least in part by differential post-translational modifications of the PCNA protein. In cancer cells, growth signal-stimulated phosphorylation at tyrosine 211 of PCNA (pY211-PCNA) is known to play an important function for active proliferation. Here, we demonstrate that inhibition of pY211 disrupts the processivity of replication forks. This disruption triggers single-stranded DNA (ssDNA) production catalyzed by the MRE11 nuclease, activating the cGAS-STING axis to launch an anti-tumor immune response by natural killer (NK) cells. We further show that the pY211 regulates site-specific post-translational modifications of MRE11, and loss of pY211 promotes the endonuclease mode of MRE11. This causes ssDNA generation in the cytosol, subsequently inducing type I interferon-activated cytotoxicity by NK cells and fostering an anti-tumor immunity that abrogates distant metastasis. Mechanistically, the pY211 determines the recruitment of the writer or eraser of the modification on MRE11, thus tuning the nucleolytic modes of MRE11 and, consequently, ssDNA generation. Therapeutic measures promoting MRE11-dependent ssDNA enhance the response of triple-negative breast cancer to cytotoxic killing mediated by endogenous or allogenic NK cells in mice. In breast cancer patients, the level of cytosolic ssDNA is inversely correlated with the expression of the eraser and pY211-PCNA, which is associated with poor overall survival in cancer patients. Our studies shed new light on the shaping of the tumor immune microenvironment and demonstrate the potential to develop therapeutic approaches that proactively leverage genomic instability and immune activation to target malignant tumors.

#2691 Mapping the landscape of innate immune pattern recognition receptors in pancreatic cancer.

B. Kashgari[1], L. McLeod[1], L. J. Gearing[1], D. Croagh[2], **B. J. Jenkins**[3];
[1]Hudson Institute of Medical Research, Melbourne, Australia, [2]Monash University, Melbourne, Australia, [3]University of Adelaide, Adelaide, Australia

Pancreatic ductal adenocarcinoma (PDAC) accounts for 90% of all pancreatic cancer cases, and is among the most aggressive and lethal malignancies worldwide. PDAC is driven by genetic alterations in the pancreatic epithelium (e.g. *KRAS*, *TRP53*) coupled with a dysregulated innate immune response, the latter leading to an inflammatory tumor microenvironment enriched in innate immune cells (e.g. macrophages). However, immune-based treatment regimens for PDAC patients have primarily focused on immunotherapy with adaptive immune checkpoint inhibitors (e.g. PD-1) which disappointingly have yielded minimal clinical benefit. Thus, there is an unmet clinical need to identity disease-associated innate immune regulators as therapeutic targets in PDAC. Innate immune responses depend on a series of cell surface, endosomal and cytosolic pattern recognition receptors (PRRs) that are expressed in immune and non-immune cells. PRRs are classified into several structurally and functionally conserved subfamilies, including Toll-like receptors (TLRs), Absent in melanoma 2 (AIM2)-like receptors (ALRs), and Nod-like receptors (NLRs). A subset of NLRs and AIM2 are also well documented for their formation of multiprotein complexes called 'inflammasomes' - comprising the adaptor ASC and Caspase-1 - which direct the maturation and release of bioactive pro-inflammatory cytokines, IL-18 and IL-1β. However, the role of these critical innate immune regulators in PDAC has been underexplored, and is virtually unknown. By coupling endoscopic ultrasound-guided fine needle aspiration (EUS FNA) to capture tumor biopsies from all stages of PDAC, with whole transcriptome profiling of PDAC patient primary tumors, we reveal specific enrichment of the innate immune TLR2 and ASC inflammasome molecular pathways. Augmented TLR2 and ASC expression was prognostic for low survival, and a "TLR2 activation" signature was also predictive for chemoresistance. Antibody-mediated anti-TLR2 therapy suppressed tumor growth in human PDAC tumor xenografts (patient and cell line) in both immunocompromised and 'humanized' mice. With respect to ASC, using the genetically engineered KPC PDAC mouse model, we show that Caspase-1 activation, a read-out for inflammasome activation, is upregulated in pancreatic tumors. Moreover, genetic ablation of ASC in KPC mice markedly suppressed the development of pancreatic tumors, which was associated with significant reductions in levels of both Caspase-1 activation and inflammation. Transcriptome profiling further identified unique downstream molecular networks associated with a range of oncogenic cellular processes. Taken together, our results support innate immune TLR2- and ASC inflammasome-based therapeutic targeting in PDAC, with further clinical utility that ASC inflammasome and TLR2 activation is prognostic, with TLR2 also predictive for chemoresponsiveness.

#2692 ELK3 is a key regulator as the response of natural killer cell therapy in triple-negative breast cancer.

H.-Y. Jung, Y. Lee;
Korea Institute of Radiological & Medical Sciences (KIRAMS), Seoul, Korea, Republic of

Triple-negative breast cancer (TNBC) is the most challenging subtype of breast cancer because of its aggressive behavior and the limited therapeutic strategies available. In the last decade, immunotherapy has become a promising treatment to prolong survival in advanced solid cancers including TNBC. However, the efficacy of immunotherapy in solid cancers remains limited because solid tumors contain few tumor-infiltrating lymphocytes. Here, we show that targeting an ETS transcription factor ELK3 (ELK3) enhances the response of nature killer (NK) cells through intracellular and extracellular signaling. In extracellular signaling, ELK3 depletion increases CXCL16 expression level and promotes NK cell cytotoxicity through CXCL16-mediated NK cell recruitment in TNBC. In intracellular signaling, ELK3 depletion controls mitochondrial fission-fusion status to induce NK cell-mediated cell death. In silico analysis showed that ELK3 is negatively correlated with CXCL16 or MID51 expression in breast cancer patient samples. Low expression of ELK3 and high expression of CXCL16 or MID51 were associated with a better prognosis. Low expression of ELK3 and high expression of CXCL16 or MID51 were associated with increased expression of NK cell-related genes. Our findings demonstrate that ELK3-CXCL16 axis controls NK cell recruitment to target cancer cells and ELK2-MID51 axis triggers mitochondrial dysfunction-mediated apoptosis during NK cell therapy, suggesting that targeting the ELK3 gene could be an adjuvant strategy for increasing the efficacy of immunotherapy in TNBC

#2693 MicroRNA manipulation of macrophage polarization in DLBCL to augment antibody immunotherapy.

J. Longley, R. Foxall, S. Thirdborough, S. Beers, M. Cragg;
University of Southampton, School of Medicine, Southampton, United Kingdom

Background: CD163 positive tumor associated macrophages (TAM), have been associated with poor response to immunochemotherapy in DLBCL. Targeting these TAMs to reverse immunosuppression is one approach for improving treatment response rates. MicroRNAs have the potential to modify hundreds of genes by interacting with multiple mRNA targets, thereby altering the global transcriptional profile of cells. Manipulation of microRNAs may prove an effective means of switching the transcriptomic profiles of TAMs to more activated, anti-tumor states resulting in the reversal of immune resistance and enhancement of treatment efficacy.

Methods: MicroRNAs differentially expressed in DLBCL and associated with poor response were identified using whole gene correlated network analysis of DLBCL datasets. Peripheral blood mononuclear cells (PBMCs) were obtained from normal blood donors and differentiated into macrophages following cell culture with MCSF. Macrophages were polarized using immunosuppressive (IL4 + IL13) or immunostimulating (LPS + IFNγ) cytokines and microRNA expression measured using RT-qPCR. To assess antibody dependent cellular phagocytosis (ADCP), macrophages were generated and polarized as above and transfected with microRNA inhibitors (Thermofisher) prior to co-incubation with target cells. Human Chronic Lymphocytic Leukemia (CLL) cells were labelled with CSFE and used as target cells with Rituximab as the ADCP-inducing monoclonal antibody (mAb) and Herceptin as an isotype control. The percentage of Fc gamma receptor IIIA (FcγRIIIA)-expressing macrophages taking up target cells was determined using flow cytometry and analyzed using Flowjo software. Diagnostic biopsies from patients were then analyzed for microRNA 142-5p and CD206 expression using miRNAScope assays and immunohistochemistry.

Results: There was significant upregulation of microRNA 142-5p in macrophages polarized with IL4 plus IL13 compared to macrophages polarized with LPS plus IFNγ and non-polarized macrophages. Inhibition of microRNA 142-5p in IL4 plus IL13 polarized macrophages led to a significant increase in FcγRIIIA, CD40 and CD47 expression resulting in enhanced phagocytosis of CLL cells opsonized with Rituximab plus anti-CD47 mAb when compared with controls. High microRNA 142-5p expression in combination with high CD206 expression predicted poor response to immunochemotherapy in 38 treatment naïve human DLBCL samples (median PFS 12 months v NR p=0.0096).

Discussion: Transfection of a microRNA 142-5p inhibitor can repolarize immunosuppressive macrophages to a more anti-tumor phenotype leading to enhanced ADCP. CD206 positive TAM infiltration in combination with high microRNA 142-5p expression predicted poor outcome following treatment with immunochemotherapy in DLBCL. It may be possible to use microRNA directed therapies targeting the tumor microenvironment to enhance treatment efficacy.

#2694 The role of innate lymphoid cells and innate like T cells in hepatocellular carcinoma.

P. Huang, B. Ruf, R. Trehan, D. Soika, C. Ma, T. F. Greten, F. Korangy;
National Cancer Inst. - Bethesda Campus, Bethesda, MD

The major focus of cancer immunotherapy has been on conventional T cells due to their unique recognition of specific peptide antigens. Despite advances in the cancer immunotherapy field, including the use of atezolizumab and bevacizumab as first-line therapy for unresectable hepatocellular carcinoma (HCC), the overall mortality rate of HCC continues to rise. Innate lymphoid cells (ILC) and innate-like T cells (ILTC) are broadly categorized within the innate lymphoid population as playing an important role in inflammation, tissue repair and immune tolerance. Their ability to react rapidly to stimulants in their local tissue environment as well as to recruit and activate a variety of other immune cells makes these cells attractive targets for anti-tumor therapy. However, previous studies looking at ILCs and ILTCs in cancer have revealed both pro- and anti-tumor functions. Furthermore, the complex interplay between these cell populations in the tumor microenvironment is not well understood, particularly over the natural course of tumor development. In this study, we aim to better elucidate the role of ILC and ILTC populations in HCC progression in terms of both their kinetics and role as potential therapeutic targets. We performed hydrodynamic tail vein injections in mice with two different plasmid combinations to alter expression of commonly mutated oncogenes and tumor suppressors in human HCC (MYC;TP53 and MYC;CTNNB1). Histologic analysis of the livers was performed to determine appropriate time points to assess ILC and ILTC populations. We then designed a comprehensive 29-plex spectral flow panel to assess broad kinetic changes in the frequency of ILC, ILTC, and conventional T cell populations. We show that in early time points (4-7 days post-injection) when neoplastic transformation of hepatocytes has already occurred, mucosal-associated invariant T (MAIT) cells, group 1 ILCs, ILC2s, and ILC3s expand in frequency for both tumor models. Cytokine analysis shows a generalized decreased trend across timepoints in effector cytokine production in MAITs and group 1 ILCs, suggesting gradual dysfunction over time. Taken together, these preliminary findings show that ILC and ILTC populations expand early during tumor progression but gradually decrease in functionality with tumor progression.

#2695 A higher percentage of M2 macrophages in non-tumor part predict the tumor recurrence in patients with hepatocellular carcinoma after surgical resection.

P.-T. Lin[1], W.-T. Ku[2], T.-H. Wu[1], C.-H. Wu[1], C.-K. Yang[1], W. Teng[1], Y.-C. Lin[1], C.-Y. Lin[1];
[1]Chang Gung Memorial Hospital - Taoyuan Branch, Taoyuan, Taiwan, [2]Chang Gung University, Taoyuan, Taiwan

The primary hurdle in improving outcomes for hepatocellular carcinoma (HCC) patients after curative treatment is the high early recurrence rate. The existing literature indicates the presence of type 2 macrophages (M2), renowned for their immunosuppressive capabilities, has been implicated in creating a microenvironment conducive to tumor growth and recurrence. However, the intricate interplay involving M2 macrophages and the recurrence of HCC is underexplored. Therefore, we conducted an analysis involving HCC patients who underwent hepatectomy at our hospital between 2013 and 2017. We collected samples from both the tumor and non-tumor regions and subjected them to bulk RNA sequencing for comprehensive molecular profiling. The proportion of immune cells was calculated by CIBERSORTx.In our study, we enrolled fifty patients, with sixty percent presenting with cirrhosis and seventy-three percent having viral hepatitis. Twenty-three patients experienced tumor recurrence, with a median time to recurrence of 12.6 months. First, we found no correlation between five TIMR subtypes defined by TIMELASER (Xue R, Nature, 2022) and recurrence. However, as for the proportions of immune cell, a significantly lower NK/Treg ratio (p= 0.0163) and high within the resected tumor section in recurrent group was found. On the other hand, the ratio of M2 macrophages to total macrophages (M2/M) was significantly higher within the non-tumor region in patients experiencing tumor recurrence after hepatectomy (p=0.0357). Furthermore, the expression of the ACGT2 gene in non-tumor part, which strongly correlates with Treg function, was significantly higher (p=0.0056) in recurrent group. In addition, the innate T cells score was increased in non-tumor pat in recurrent group but with borderline significance (p=0.0628). However, in multivariable analysis, only a higher M2/M ratio within the non-tumor region (HR 3.756, p=0.0072) were identified as independent risk factors for tumor recurrence. We also found that patients with a higher M2/M ratio had a lower percentage of cirrhotic patients (p=0.0049) and less association with TIME-IA (immune activation) subtype of HCC by TIMELASER classification (p=0.0030). In conclusion, a higher M2/M ratio within the non-tumor region predict the tumor recurrence in patients with hepatocellular carcinoma.

#2696 Tumor organoid and immune cells co-cultures to study myeloid cells-targeting immunotherapy.

L. Spagnuolo, F. Morales-Rodriguez, A. Merenda, C. Oyarce, F. Pourfarzad, R. G. J. Vries, S. F. Boj;
HUB Organoids B.V., Utrecht, Netherlands

Cancer immunotherapy is one of the main pillars of oncology treatment due to the clinical success of approaches that enhance anti-tumoral T cell responses. Nonetheless, many patients do not benefit from these approaches, highlighting the need to develop novel immunomodulatory strategies. Exploiting the anti-tumor capacity of innate immune cells is a promising approach that can overcome specific limitations of T cell-targeting therapies and complement existing immunotherapies. Still, promising therapeutic developments face hurdles in translating preclinical findings into treatment since conventional 2D cancer models hold low clinical predictive value. HUB developed an innovative alternative, building on the discovery that adult stem cells proliferate and organize into three-dimensional organotypic structures. Patient-specific organoids are generated from healthy and disease tissues and recapitulate complex characteristics of the original parental tissue, including molecular heterogeneity and morphological and functional traits. To assess the efficacy of therapies that engage innate immune cells, we developed an assay in which organoids derived from colorectal (CRC) or breast cancer patients are co-cultured with PBMC-derived macrophages or monocytes to evaluate the cytotoxic potential of exogenously activated myeloid cells. We tested the ability of macrophages to phagocyte human CRC organoid cells in response to anti-CD47 antibody. The pro-phagocytic function of anti-CD47 was detected by several methods (i.e., flow cytometry, imaging), indicating the platform's suitability to evaluate ADCP-modulating compounds.
Moreover, to assess whether our PBMC-organoids co-culture platform is suited to detect monocyte-mediated effects, Lipopolysaccharide (LPS) plus IFN-γ were used to activate monocytes in the co-culture assays. We observed an increase in cytokines secretion (i.e., CXCL10), immune cell activation and organoid killing, indicating that our assay allows the detection of monocyte activation through different types of readouts. In summary, our organoid-immune cell co-culture platform allows to study the response of tumor organoids to innate immune cells, holding significant value for the preclinical development of immunotherapies based on innate immune cells.

#2697 Simultaneous activation of innate immune suppressive components impairs antitumor efficacy of immunotherapy against the innate immune system.

H. Nishinakamura[1], S. Shinya[2], T. Irie[3], S. Sakihama[4], T. Ioroi[1], T. Naito[3], K. Watanabe[1], D. Sugiyama[5], M. Tamiya[6], T. Yoshida[1], T. Hase[5], T. Yoshida[7], K. Karube[5], Y. Maeda[1], S. Koyama[3], H. Nishikawa[1];

[1]National Cancer Center Japan, Tokyo, Japan, [2]Discovery Research Alliance, Ono Pharma USA, Inc., Massachusetts, MA, [3]National Cancer Center Japan, Chiba, Japan, [4]Graduate School of Health Sciences, University of the Ryukyus, Nishihara, Japan, [5]Nagoya University Graduate School of Medicine, Nagoya, Japan, [6]Osaka International Cancer Institute, Osaka, Japan, [7]Ono Pharmaceutical Co., Ltd., Osaka, Japan

Cancer immunotherapy has shown noticeable clinical efficacy in many cancer types, while clinical benefits are only observed in 20-40% of treated patients. Therefore, combination cancer immunotherapy targeting multiple factors that limit antitumor immunity has been tested in the clinic. Accumulating evidence reveals that cancers that harbor limited immune cell infiltration (so-called immunologically cold tumors) respond poorly to current immunotherapy. Preclinical studies using animal models have shown that activation of innate immunity by TLR agonists or STING agonists can successfully remodel the TME to effectively induce antitumor immunity in those immunologically cold tumors. However, unexpectedly, all TLR agonists and STING agonists tested have not shown clinical efficacy in combination with immune checkpoint blockade therapy, including PD-1/PD-L1 blockade therapy. Hence, we addressed the mechanism(s) why stimulators of innate immunity failed to elicit effective antitumor immunity in cancer patients. We then employed OK-432, which reportedly stimulates TLR-2, TLR-4, and/or TLR-9, as OK-432 is widely used in Japan in the clinic. In vitro OK-432 treatment accelerated the maturation DCs, and efficiently induced CD8+ T cells in humans. However, the combination treatment with anti-PD-1 mAb and OK-432 failed to augment antitumor immunity in animal models using anti-PD-1 mAb monotherapy-resistant tumors; the data mirrors the failure of clinical trials of combination therapy with immune checkpoint blockade and TLR agonists or STING agonists in humans. Therefore, using the animal models, we explored the acquired resistance mechanism developed after combination treatment. While OK-432 treatment effectively stimulated DCs, innate immune suppressive cells, such as MDSCs, were concurrently accumulated in the TME. The accumulation of PMN-MDSCs after OK-432 treatment was induced in a CXCL1-CXCR2-dependent fashion. Accordingly, triple combination treatment with a PMN-MDSC inhibitor along with OK-432 and anti-PD-1 mAb attenuated the accumulation of PMN-MDSCs in the TME and improved the antitumor effect of the combination treatment. Taken together, we propose that successful combination treatment stimulating innate immunity against immunogenically cold cancers requires controlling the unwanted co-activation of innate immune suppressive cells. This study clearly demonstrates the mechanism of acquired resistance after administration of reagents that activate innate immunity, such as TLR agonists or STING agonists, and provides the basis for future successful combination therapy.

#2698 TCF-1 is a critical regulator of intraepithelial lymphocytes in colorectal carcinoma.

M. H. Yakou[1], S. Ghilas[1], K. Tran[1], Y. Liao[1], S. Afshar-Sterle[1], A. Kumari[1], K. Schmid[1], C. Dijkstra[1], C. Inguanti[1], S. Ostrouska[1], J. Wilcox[1], M. Smith[2], P. Parathan[1], A. Allam[1], H.-H. Xue[3], G. T. Belz[4], J. M. Mariadason[1], A. Behren[1], G. R. Drummond[5], R. Ruscher[2], D. S. Williams[1], B. Pal[1], W. Shi[1], M. Ernst[1], D. Raghu[1], L. A. Mielke[1];

[1]Olivia Newton-John Cancer Research Institute, Heidelberg, Australia, [2]Australian Institute of Tropical Health and Medicine, Cairns, Australia, [3]Center for Discovery and Innovation, Hackensack University Medical Center, Nutley, NJ, [4]University of Queensland Frazer Institute, Woolloongabba, Australia, [5]La Trobe University, Bundoora, Australia

Tissue-resident immune cells reside within the gastrointestinal tract known as intraepithelial lymphocytes (T-IELs), including αβ and γδ T-IELs. This unique population of T cells constantly survey and are critical in maintaining the gastrointestinal epithelium. We show that T-IELs in various regions of the gastrointestinal tract have distinct features. T-IELs in the small intestine exhibit high expression of cytotoxic molecules important for cancer defense while colon T-IELs are distinctively regulated by the transcription factor, *TCF-7*/TCF-1, which suppresses their effector and cytotoxic properties, including reduced expression of granzymes, and their abundance is dependent on the microbiome. Targeted deletion of TCF-1 in γδ T-IELs using pre-clinical mouse models resulted in a distinct effector profile and reduced colon tumor burden. Furthermore, TCF-1 expression was significantly reduced in γδ T-IELs present in human colorectal cancers compared with normal healthy colon, strongly correlating with an enhanced γδ T-IEL effector phenotype and improved patient survival. Further investigation aims to elucidate diverse mechanisms by which TCF-1 controls tissue-specific anti-tumor immunity and uncover the important factors controlling TCF-1 expression. Our study underscores the necessity to consider tumor and organ microenvironment-specific factors in optimizing immunotherapy, advancing our understanding of T cell function in the colon to pave the way for innovative CRC treatments.

#2699 Application of whole genome loss of function CRISPR screen in primary natural killer cells.

M. Sheffer, I. E. Kaplan, E. Bobilev, Y. Z. Abdulhamid, R. Romee;
Dana-Farber Cancer Institute, Boston, MA

Natural killer cells (NKs) are cytotoxic lymphocytes of the innate immune system, operating against infections and cancer. NKs act in an antigen independent manner, preventing graft versus host disease in allogeneic settings. NKs can be isolated from healthy donors, activated, expanded and safely administered to cancer patients. Although NKs are highly cytotoxic against cancer cells *in vitro*, they lose viability and functionality in the suppressive tumor microenvironment (TME).

Until recently, viral transduction of primary NKs was considered a technical hurdle. The latest progress using Baboon Lentiviral (BaLV) pseudotyping substantially increased transduction rates and facilitated the use of chimeric antigen receptor (CAR) NKs for cancer immunotherapies. Due to this challenge, most genetic manipulations were performed in single genes with limited capabilities. Large-scale functional manipulation of NKs using CRISPR-cas9 editing was not implemented, leaving a gap in our understanding of NK suppression.

We generated a whole genome library of 55,548 guide RNAs (gdRNAs, 4 per gene), targeting 13,749 genes that were determined to be expressed in NKs and 138 (10%) olfactory receptor genes that are not expressed in NKs as control gdRNAs. The gdRNA plasmid was optimized based on our CAR-NK backbone, to express the gdRNA scaffold under U6 promotor and GFP under EF1α promotor. The library plasmids were sequenced and their gaussian distribution was verified, with high representation of all the different gdRNAs.

Primary NKs were isolated from 3 healthy donors and transduced at 25% transduction rates using our optimized BaLV system. After a week expansion *in vitro*, NKs were electroporated with protein cas9-RFP using the maxCyte electroporator. RFP levels at 6 hours after electroporation were at least 80%.

The cells were profiled after electroporation for cytotoxicity and for functionality against the K562 target cell line. IFNγ production and degranulation (CD107a) were similar before and after electroporation. Genomic DNA was extracted from the transduced NKs and the gdRNA barcodes were amplified by PCR and sequenced. The distribution of the gdRNA barcodes after sequencing exhibited high representation of almost all gdRNAs, with minimal loss of gdRNAs. Several gene knockouts were identified as important for survival/proliferation of NKs and are being validated using single gdRNAs *in vitro* and *in vivo*.

NK cell immunotherapy is a promising approach for cancer treatment. Although recent clinical trials with CAR-NK present exciting results, many solid tumors do not benefit from NK immunotherapies due to the inactivation of NKs in the immune-suppressive TME. Here, we successfully implemented an unbiased genome wide loss-of-function CRISPR screen as an effective and informative method to identify novel candidates for NK cell suppression.

#2700 Therapeutic IL-33 enhances the antigen presentation function of ILC2s to exert anti-tumor immune activity.

J. Liu, Z. Feng, H. Wei, C. Li, X. Li, W. Chen, Y. Ke, M. Wang, L. Liu, C. Zheng, Q. Liu;
Southern University of Science and Technology, Shenzhen, China

IL-33 regulates the function of ILC2s through ST2. However, the role of IL-33, especially exogenous IL-33, on ILC2s in tumors is controversial depending on the cytokines they secrete. Here we report that exogenous, but not endogenous, IL-33 significantly inhibits the progression of a variety of mouse solid tumors, including melanoma, colorectal cancer, lung adenoma, and breast cancer. By inoculating tumor cells in *Il1rl1*$^{-/-}$ and NSG mice, we found that the tumor-suppressive effect of IL-33 on tumors was dependent on the expression of ST2 receptors and the presence of lymphocytes. Regarding tumor-infiltrating immune cells, exogenous IL-33 significantly increases the proportions of ST2^{+} Tregs (1.10 ± 0.20% vs. 1.74 ± 0.36%), eosinophils (6.00 ± 1.33% vs. 22.73 ± 6.51%), Granzyme B^{+} CD8^{+} T cells (4.32 ± 2.77% vs. 11.53 ± 6.81%), and bulk ILC2s (0.08 ± 0.04% vs. 5.31 ± 1.33%) and IA/IE^{+} ILC2s (0.02 ± 0.01% vs. 3.67 ± 1.03%) . In draining lymph nodes, IL-33 also significantly increases the proportions of ILC2s (0.03 ± 0.02‰ vs. 6.37 ± 1.71‰) and IA/IE^{+} ILC2s (0.003 ± 0.003‰ vs. 4.38 ± 1.21‰). Importantly, single-cell transcriptomic analysis on tumor-infiltrating ILC2s highlights the expression of genes related with antigen processing and presentation including *H2-K1*, *H2-Q7*, *B2m*, *Hspa1a*, *Hspa1b*, *Creb1*, *Hspa4*, *Tap1* and *Tap2*. We testified this finding by DQ-OVA experiment and found that IL-33 could promote ILC2s to up-take and process exogenous antigens (17.78 ± 0.75 fold vs. 22.02 ± 0.75 fold). The antigen presentation function of ILC2s was further established by mixed lymphocyte culture where BALB/c ILC2s potently stimulated C57BL/6 CD8^{+} T cell proliferation, which was further augmented by IL-33 treatment. Taken together, our data demonstrate an anti-tumor function of therapeutic IL-33 that elevates the number and antigen presentation function of ILC2s.

#2701 EREG reprograms M2-tumor-associated macrophage and suppresses colorectal cancer cell proliferation and migration.

A.-R. Yu, S. Kim, Y. Jeong, H. Hong, Y. Shin, **Y. Cho**;
Samsung Medical Center, Seoul, Korea, Republic of

Colorectal cancer (CRC) represents a common malignancy within the digestive system, linked to significant morbidity and mortality rates. Tumors exert diverse effects on immune modulation, facilitating progression and metastasis. Amid the abundant immune cell populace within the tumor microenvironment (TME), tumor-associated macrophages (TAMs) play a pivotal role. M2-type TAMs actively foster tumor growth and engage in immune suppression by fostering angiogenesis and tissue restructuring. In a previous study, we analyzed single-cell RNA-sequencing (scRNA-seq) data derived from colorectal cancer patients. We observed an enrichment of the secreted phosphoprotein 1 (SPP1)+ macrophage fraction in both the tumor core and border when compared to normal tissues. Additionally, epiregulin (EREG), an epidermal growth factor receptor (EGFR) ligand, was found to be upregulated in SPP1+ macrophages, correlating with tumor growth and metastatic tendencies. Research on EREG is important because it has been found to play a significant role in cancer progression, including colorectal cancer. Understanding the mechanisms by which EREG contributes to tumor growth and metastasis can provide valuable insights into the development of targeted therapies for cancer treatment. Our hypothesis centered around the impact of EREG from TAMs on tumor progression. To identify TAM-specific EREG and its functional significance, we isolated tumor-associated macrophages from CT26 (mouse colorectal carcinoma)-bearing tumors and cultured them with conditioned and normal mediums. Subsequently, we examined EREG expression at the gene level using quantitative PCR. Our findings indicated significantly higher levels of EREG in the conditioned medium compared to the normal medium, suggesting an association between EREG and cancer cells. Remarkably, our investigation also confirmed that EREG has the capacity to reshape macrophage signatures. Notably, the surface marker CD206, characteristic of M2 macrophages, exhibited a significant decrease, while iNOS, a marker for M1 macrophages, showed an increase upon EREG depletion. We evaluated the interaction between CT26 cancer cells and TAMs using indirect co-culture methods. EREG-depleted TAMs were plated in the top chamber, while CT26 colorectal cancer cells were seeded at the bottom. Our results validated that knocking down EREG in TAMs not only hindered the proliferation of cancer cells but also affected the behavior of TAMs. Additionally, the reduced EREG expression in TAMs hindered the migration of cancer cells. These findings strongly suggest that targeting EREG could effectively restrain the growth and metastasis of colorectal cancer cells by reprogramming macrophage polarization in the TME. Consequently, this indicates its potential as a promising therapeutic target in colorectal cancer.

#2702 Hyperprogression due to myeloid mimicry in renal medullary carcinoma treated with nivolumab plus ipilimumab.

M. Soeung[1], **X. Yan**[1], L. Zhang[1], L. Perelli[1], J. Chen[1], B. Slack Tidwell[1], H. Khan[1], C. N. Le[1], T. N. A. Lam[1], N. Bhattacharya[1], R. Shah[1], I.-L. Ho[1], Z. Chen[1], S. R. K. Lundgren[1], N. Feng[1], C. Zanca[1], M. Karki[1], N. Millward[1], R. He[1], R. A. Sheth[1], B. K. Tharakeswara[1], P. Rao[1], N. C. Daw[1], D. N. Tripathi[2], C. L. Walker[2], G. Han[1], Y. Chu[1], R. Wang[1], M. Dang[1], E. Dai[1], F. Peng[1], Y. Liu[1], A. S. Jadhav[1], W. Lang[1], C. A. Arrechedera[1], L. Campos Clemente[1], E. R. Parra-Cuentas[1], H. Lu[1], C. Haymaker[1], I. I. [1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor college of Medicine, Houston, TX

Renal medullary carcinoma (RMC) is a rare but highly aggressive SMARCB1-deficient kidney cancer that mainly afflicts young individuals of African descent and has few treatment options. Despite the advancements in immune checkpoint therapy (ICT) for other kidney cancers, its efficacy against RMC remains elusive. The majority of RMC patients treated with ICT have experienced aggressively progressive disease as the best response. This hyperprogression was confirmed in our prospective clinical trial of nivolumab plus ipilimumab specifically designed for RMC patients (ClinicalTrials.gov identifier: NCT03274258). To elucidate the mechanisms of resistance to ICT in RMC, we generated high-quality single-cell RNA sequencing data on 23,880 cells from 7 patients at baseline and 2 patients exhibiting hyperprogression after ICT intervention. Our analysis revealed that RMC tumor cells undergo a distinct transcriptional reconfiguration following ICT therapy. This reconfiguration is manifested by upregulation of S100A9 and activation of the MEK/ERK pathway, indicating that RMC tumor cells adopt myeloid-affiliated transcriptional circuits, potentially promoting cell proliferation and leading to hyperprogression. Using a mouse model of RMC, we further demonstrated in a controlled setting that ICT causes hyperprogressive disease via activation of MEK/ERK pathway and an increase of S100A9 positive tumor cells. This process can be reversed by inhibiting master regulators of this “myeloid mimicry” mechanism, such as the CEBPB/p300 complex in our mouse model of RMC, thus restoring sensitivity to ICT. These findings provide novel insights into RMC resistance to ICT and suggest valuable directions for the development of therapeutic strategies.

#2703 Targeting STING pathway as a therapeutic strategy against β-catenin driven immune escape and resistance to anti-PD1 therapy in hepatocellular carcinoma..

Qingmei Zhang[1], Jiacheng Bi[2], Oscar Wai-Ho Yeung[1], Tao Ding[1], Wing-Lim Chan[3], yueqin Zhu[1], Jiang Liu[1], Kevin Tak-Pan Ng[1], Kwan Man[1]

[1]Surgery, The University of Hong Kong, Hong Kong, Hong Kong,[2]The CAS Key Laboratory of Quantitative Engineering Biology, Shenzhen Institute of Synthetic Biology, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, China, Shen Zhen, China,[3]School of Biomedical Sciences, The University of Hong Kong, Hong Kong, Hong Kong

β-catenin mutation occurs in around 40% of hepatocellular carcinoma(HCC); yet no precision therapies are available to treat this tumor subset. Immune checkpoint inhibitors (ICIs) are now widely used for the treatment of patients with advanced HCC. Unfortunately, preliminary evidence showed that β-catenin mutation drives resistance to anti-PD1 immunotherapy in HCC. In this study, we studied the molecular mechanisms underlying β-catenin mutation during HCC pathogenesis to develop novel therapeutics targeting β-Catenin-driven HCC. Firstly, three HCC cohorts were examined, including 70 untreated, 20 treated patients with nivolumab, and patients from a public TCGA database. By single-cell RNA sequencing analysis, we identified that anti-PD-1 treatment displayed effectiveness with the increase of CD27+CD8+ T-cell infiltration, correlating to improved prognosis with longer progression-free survival (PFS) and OS. Importantly, multiplex IHC staining showed that β-catenin activation is associated with significantly reduced CD8+CD27+ T cell infiltration in tumors (n=70), demonstrating that β-catenin promoted immune escape and resistance to anti-PD-1 treatment involved defective cytotoxic T-cell activity. Subsequently, we found that the interaction of β-Catenin with sirtuin 1 (SIRT1) mediated suppression of IRF3/IRF7 activity, resulting in inhibition of Type I interferon (IFN-I) production. However, by CRISPRi screening, we found that disruption of β-catenin-SIRT1 interaction via STING caused persistent high-level IFN-I response which increased the transcription of T-cell costimulatory molecule CD27 via IL10/STAT3/BATF signaling on infiltrated CD8+ T cells. This effect was also confirmed in the STING null mice, emphasizing that STING signaling is a therapeutic target to overcome β-catenin driven immune escape. Further, using hydrodynamic tail-vein injection murine HCC models, we found that the STING agonist inhibited β-catenin-SIRT1 activity, restored IFN signaling to rescue T-cell cytotoxic capacities, and enhanced the anti-PD-1 therapy efficacy. In conclusion, we demonstrated that STING reprogrammed β-Catenin mutated the HCC tumor microenvironment and a combination of STING and anti-PD-1 treatment represents an effective novel therapeutic strategy for HCC patients with β-Catenin mutation.

#2704 cGAS-STING drives myeloid inflammation in chromosomally unstable esophageal cancer.

B. Beernaert, E. Erdal, R. Clark, T. Liu, E. M. Hammond, E. E. Parkes;
University of Oxford, Oxford, United Kingdom

Esophageal adenocarcinoma (EAC) is an aggressive disease characterized by chromosomal instability (CIN), whereby cells continuously acquire chromosomal abnormalities that promote therapeutic resistance, immune evasion and metastasis. CIN in cancers also fuels the misplacement of genomic DNA in the form of structural abnormalities of the nucleus, such as micronuclei (MN), that lead to chronic activation of the cytosolic DNA sensing cGAS-STING pathway. However, how chronic cGAS-STING pathway activation is tolerated and shapes the tumor landscape of CIN^{high} EAC cancers is poorly understood. Using publicly available RNA-seq and genome sequencing data of EAC tumours and esophageal cancer cell lines as well as a panel of EAC cell lines, we demonstrate that the core cGAS-STING pathway machinery is rarely inactivated in EAC despite high levels of baseline CIN and aneuploidy. Through transcriptomic profiling of an isogenic EAC precursor cell line model of variable CIN and $cGAS^{KO/WT}$ EAC cell lines we show that both chronic and transient CIN-driven cGAS-STING activation converge on the expression of CXCR1/2 ligands and other pro-inflammatory cytokines and chemokines rather than typical anti-tumor type I interferon signalling in EAC cells. Indeed, a novel transcriptional signature of $cGAS^{+}$ micronuclear burden-correlated genes correlates with orthogonal measures of CIN in EAC tumours and esophagogastric cancer cell lines and is associated with an enrichment in myeloid-derived cells as well as poor prognosis. Correspondingly, using multiplexed immunofluorescence (IF) we find that a high preponderance of $cGAS^{+}MN$ and STING expression in human EAC samples is associated with decreased tumor purity, increased myeloid cell and macrophage infiltration, and increased peripheral blood neutrophil counts, indicative of tumor-promoting myeloid inflammation. Ongoing multiplexed IF and single-nuclei RNAseq analysis of $cGAS^{+}MN^{high}$ and $cGAS^{+}MN^{low}$ EAC tumors will further help characterise the components that comprise the CIN-EAC tumor microenvironment (TME) and the CIN- and cGAS-STING-dependent cell-cell interactions that govern it. Taken together, our findings provide an explanation for the observed maintenance of cGAS and STING in EAC and identify disruption of cGAS-STING-dependent myeloid cell inflammation and recruitment as a potential therapeutic target for CIN^{high} EAC.

#2705 Hyaluronic acid impairs NK killing towards breast tumor spheroids despite elevated cytotoxicity.

B. C. H. Cheung[1], A. T. Li[1], J. E. Segall[2], M. Wu[1];
[1]Cornell University, Ithaca, NY, [2]Albert Einstein College of Medicine, Bronx, NY

The tumor microenvironment (TME) is often regarded as a critical component in tumor progression and metastasis. Among the main structural components of the TME, such as collagen and glycosaminoglycans (GAGs), hyaluronic acid (HA) is highly elevated in the breast TME, and is associated with poor prognosis. In recent years, immunotherapy has gained tremendous success in the battle against hematological cancers. Yet, solid tumors have remained a significant clinical challenge for immunotherapy due to the physical constraints they impose on immune cells. Mechanically, our previous work has shown that the abundance of high molecular weight (HMW) HA significantly reduces matrix pore sizes and softens the collagen and HA cogel, and impairs breast tumor invasion. However, it is still unclear how modulating tumor invasion through the mechanics of the TME may correlate with the efficacy of immunotherapy. In this study, we aim to investigate the effect of HMW HA on natural killer (NK) cell-based immunotherapy using a tumor spheroid model (GFP-labeled MCF-7). We introduced NK-92 MI cells into tumor spheroid embedded collagen gels with or without HA, and followed spheroid-NK cell interactions through live cell imaging. Preliminary data shows that while tumor spheroids were still able to invade in the collagen only gel, they underwent apoptosis in the presence of NK cells. More importantly, the presence of HA within the ECM reduced NK cells' ability to kill tumor spheroids. Specifically, when surrounded by NK cells, tumor spheroids remained intact and viable in the collagen-HA cogel, while they underwent apoptosis in collagen only gels. In a parallel experiment, multicolor flow cytometry data showed that HA increased NK activation and certain cytotoxic markers (interferon-gamma, perforin, and granzyme-B), despite the fact that spheroids appeared to be more resistant towards NK cells in the presence of HA. Taken together, we speculate that the presence of HMW HA in the TME may protect solid tumors from immune attacks by modulating the mechanical environment.

#2706 Identification and characterization of cancer-associated polymorphonuclear cell subsets in mice.

Marco A. De Velasco, Yurie Kura, Kazuko Sakai, Takashi Kikuchi, Yasunori Mori, Takafumi Minami, Kazuhiro Yoshimura, Kazutoshi Fujita, Kazuto Nishio, Hirotsugu Uemura

Kindai University Faculty of Medicine, Osaka-Sayama, Japan

Background: Neutrophils are the main type of polymorphonuclear cells (PMN) and comprise most immune cells in the body. PMN cells are upregulated in cancer and accumulate in the tumors. Tumor-associated PMNs comprise a heterogeneous population consisting of immunologically active mature neutrophils and immature polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs). The phenotype of these cells evolves with disease progression and is implicated in modulating immune response. However, there is yet to be a consensus to define PMN populations in tumors and blood.
Methods: Here, we used single-cell RNA-seq, bulk RNA sequencing, flow cytometry, and immunohistochemistry (IHC) analysis to characterize cancer-associated PMN-MDSCs in tumor-bearing mice.
Results: Single-cell RNA-seq data from lung tumors and healthy individuals revealed five metaclusters (MC): MCA, MCB, MCC, MCD, and MCE. MCA and MCB made up 34.4 and 65.1% of PMNs in healthy tissues, respectively. MCA, MCB, MCC, MCD, and MCE comprised 3.8%, 23.5% 3.3% 14.6%, and 54.7% of PMNs in tumors, respectively. Genes enriched in MCA and MCE were associated with MDSCs and myeloid progenitor cells. MCB and MCC were associated with inflammatory responses mediated by TNF-alpha signaling and neutrophil degranulation. MCD was associated with a CD33 myeloid cell phenotype and had high expression levels of *CD274*, *Pdcd1lg2*, *Havcr2*, and *Tigit* genes. Cells from MCE were associated with protein translation signatures and had elevated levels of *Nt5e*. Gene expression signatures from single-cell RNA-seq data were compared with bulk transcriptomic data from healthy mouse prostates and *Pten*-null prostate tumors characterized by high PMN cell infiltration. Gene set enrichment analysis showed enrichments after androgen deprivation therapy and Cluster MCE was associated with castration-resistant tumors. Flow cytometric and IHC analysis confirmed the enrichment of PMN cells expressing elevated levels of proteins identified from gene expression analysis including CD73, PD-L1, and PD-L2.
Conclusion: This study offers further insights into the distinct subsets of PMN-MDSCs present in tumors.

IMMUNOLOGY: Single Target and Bispecific Antibodies
Poster Session

#2710 Combination CXCR4 and PD-1 blockade increases T cell infiltration and effector function in fibrolamellar carcinoma (FLC).

L. K. Dickerson[1], R. van den Bijgaart[2], X. Jiang[1], S. K. Daniel[3], J. A. Carter[1], A. Farghli[4], K. M. Sullivan[5], Y. Liu[1], H. L. Kenerson[1], R. S. Yeung[1], T. S. Kim[1], I. N. Crispe[1], P. Sethupathy[4], K. C. Barry[2], V. G. Pillarisetty[1];

[1]University of Washington, Seattle, WA, [2]Fred Hutchinson Cancer Center, Seattle, WA, [3]Stanford University, Stanford, CA, [4]Cornell University College of Veterinary Medicine, Ithica, NY, [5]City of Hope Medical Center, Duarte, CA

Introduction: Fibrolamellar carcinoma (FLC), a rare liver cancer affecting young patients without cirrhosis, has a poor prognosis and few systemic therapy options. Current evidence implicates an immunosuppressive tumor microenvironment (TME), including our preliminary data suggesting preferential localization of T cells in stromal bands. We hypothesized that dual blockade of C-X-C chemokine receptor type 4 (CXCR4) and programmed cell death protein (PD-1) would enhance T cell infiltration and activation, respectively, and thereby increase tumor killing.

Methods: Flow cytometry and single-nuclear RNA sequencing (snRNA-seq) were used to analyze immune cells and evaluate gene expression, respectively, in patient-derived FLC and non-tumor liver (NTL). Immunohistochemistry (IHC) was used to assess $CD3^{\pm}$ T cell localization in relation to CXCL12, the chemokine ligand of CXCR4. Tumor slice cultures (TSCs) from fresh FLC resection specimens (n=11) were treated with control (IgG1), a small molecule CXCR4 inhibitor (AMD3100), anti-PD-1 blocking antibody (αPD-1), or combination CXCR4 and PD-1 blockade (AMD3100/αPD-1). IHC, RNA expression (Nanostring), and live microscopy were used to evaluate T cell mobilization and function.

Results: Flow cytometry analysis demonstrated fewer $CD45^{\pm}$ cells (16% vs 54% of live cells, p=0.01) and heterogenous PD-1 expression on T cells in FLC compared with NTL. SnRNA-seq analysis showed that CXCR4 expression is upregulated in FLC lymphocyte and macrophage populations relative to NTL (15% vs 10% and 20% vs 5% expressed), and CXCL12 is expressed primarily in stellate cells. $CD3^{\pm}$ T cells colocalized with CXCL12 in the FLC stroma on IHC. Multiplex IHC of treated TSCs revealed more T cells in the carcinoma ($CK7^{\pm}$) than the stromal ($SMA^{\pm}$) compartment after AMD3100 compared with IgG1 (63% vs 34% T cells in $CK7^{\pm}$ compartment, p=0.05). Nanostring indicated upregulation of effector pathways (apoptosis, cytotoxicity, lymphocyte activation) after AMD3100/αPD-1 compared with IgG1. Time-lapse live microscopy revealed a greater percentage of apoptotic carcinoma cells ($SR\text{-}FLICA^{\pm}CK7^{\pm}$) colocalized with $CD3^{\pm}$ T cells (37% vs 18%, p=0.005) and longer $CD3^{\pm}$ T cell track length (27 vs 22 μm, p=0.03) after AMD3100/αPD-1 than before treatment. Cleaved caspase-3 (CC3) IHC demonstrated significantly increased tumor apoptosis after AMD3100/αPD-1 compared with IgG1 and monotherapy (53% vs 32% (IgG1), 39% (AMD3100), and 42% (αPD-1) $CC3^{\pm}$ cells, p=0.002, p=0.03, p=0.04).

Conclusion: The CXCR4/CXCL12 axis mediates T cell exclusion in the FLC TME. Combination CXCR4 and PD-1 blockade overcomes immunosuppression in FLC by mobilizing T cells into the carcinoma compartment and activating their effector function, with resultant tumor apoptosis. These findings support consideration of clinical trials testing drugs targeting CXCR4 and PD-1 in FLC.

#2711 A novel bispecific antibody to reprogram the immune suppressive GBM TME.

T. Wong[1], J.-S. Leu[1], X. Fan[2], R. Kang[1], N. Abdelfattah[1], F. Leonard[1], N. Zhang[2], K. Yun[1];
[1]Houston Methodist Research Institute, Houston, TX, [2]Texas Therapeutics Institute, Brown Foundation Institute of Molecular Medicine, The University of Texas Health Science Center at Houston, Houston, TX

GBM (glioblastoma) is the most common and aggressive primary brain tumor in adults. Immunotherapy is an emerging and promising treatment modality for GBM. Unfortunately, most immunotherapy trials have provided only modest benefit to GBM patients thus far. A significant barrier that limits efficacy of immunotherapy in GBM is the paucity of tumor infiltrating lymphocytes and abundance of immune suppressive myeloid cells. A critical step in enhancing the efficacy of immunotherapy for GBM requires approaches that enhance T cell infiltration and reprogram the myeloid cells to a more pro-inflammatory state. S100A4 is a major regulator of stemness, epithelial-mesenchymal transition, and immunosuppression in glioma stem cells and a critical regulator of immune suppressive myeloid and T cell phenotypes in GBM. Targeting S100A4 in either glioma cells or stromal cells is sufficient to reprogram the tumor immune landscape and extend survival of glioma bearing mice, indicating that S100A4 is a promising immunotherapy target. Since S100A4 has both intracellular and extracellular function as well as cytokine-like function, we developed a S100A4 blocking antibody. While the anti-S100A4 antibody blocks breast cancer metastasis efficiently, it did not cross the BBB. Hence, we generated a bispecific S100A4-TfR antibody (BsA) that allows robust BBB penetration. Using ELISA, confocal immunofluorescent microscopy, and multiplexed flow cytometry, our preliminary results suggest that systemic administration of the S100A4-TfR BsA results in accumulation of BsA in the brain and glioma tissue, increased T cell infiltration and immune remodeling. Furthermore, the BsA is taken up by glioma cells and accumulates intracellularly, which is correlated with decreased nuclear SOX2 expression. These results suggest that S100A4-TfR BsA is a promising agent to treat GBM to reprogram the GBM immune landscape and reduce stemness. We are currently performing single cell RNA-sequencing to elucidate molecular and cellular changes induced by the bispecific antibody treatment in different cell types and performing long term survival analyses to evaluate its therapeutic potential.

#2712 Development of GB268, a tri-specific antibody targeting PD-1/CTLA-4/VEGF, with enhanced anti-tumor efficacy and reduced toxicity in pre-clinical studies.

Q. Du, Y. Lv, J. Xu, F. Peng, H. Cao, X. Yang, Z. Qian, X. Li, Y. Cao, Q. Ding, Y. Tan, **S. Han**;
Genor Biopharma Co. Ltd., Shanghai, China

Background: Immunotherapy using immune checkpoint modulators such as anti-PD1/PD-L1 have been widely used in cancer therapy. Combination of checkpoint inhibition using anti-PD1 and anti-CTLA4 has improved therapeutic efficacy but is also accompanied by severe immune related adverse events (irAEs) which limited their clinical use. Bi-specific antibody targeting PD-1/CTLA-4 such as cadonilimab has shown improved clinical benefits with reduced irAEs in cervical cancer. Vascular endothelial growth factor (VEGF) is overexpressed in various solid tumors and anti-VEGF agents inhibit neovascularization and shrink tumor with time. Combined application of bevacizumab and PD-1/PD-L1 blockade displays durable and improved anti-tumor effects. We have recently developed a novel tri-specific antibody GB268, specifically targeting PD-1, CTLA-4 and VEGF with fine-tuned activity & potency for each arm to simultaneously block PD-1/CTLA-4 mediated immune-suppression and VEGF mediated tumor angiogenesis.
Methods: GB268 is a hexavalent antibody with symmetrical structure, composed of anti-PD-1 VHH antibody, anti-CTLA-4 VHH antibody, and anti-VEGF conventional antibody. The Fc part is silenced by introducing L234A/L235A mutations. Comprehensive in vitro and in vivo characterization of GB268 have been carried out. Along with in vivo efficacy studies, toxicity has also been evaluated with a murine arthritis model in hPD1/hCTLA4 double-KI mice to assess immune related AEs.
Results: GB268 specifically bound to PD-1, VEGF, and CTLA-4 with high affinity and completely blocked PD-1 and VEGF pathways in reporter systems. To reduce the CTLA4 inhibition-induced AEs, the CTLA-4 arm was intentionally designed to only partially block the interaction of CTLA4 to its ligands CD80/CD86, and furthermore, the blockade of CTLA-4 was highly dependent on PD-1 expression. GB268 displayed robust anti-tumor efficacy with attenuated toxicity in murine models. In multiple PBMC-humanized models including A375 melanoma model, HT29 colorectal cancer model, and NCI-H460 NSCLC model, etc., GB268 exhibited significantly better anti-tumor efficacy, compared to PD-1/CTLA-4 bsAb and PD-1/VEGF bsAb, or in the combination of monoclonal antibodies to PD-1, CTLA-4 or VEGF. In arthritis induction model using hPD1/hCTLA4 double KI mice, GB268 had improved tolerance than cadonilimab and at least 20-fold better safety profile than ipilimumab combined with nivolumab.
Conclusions: GB268 is a first-in-class anti-PD-1/CTLA-4/VEGF tri-specific antibody with innovative design. Preclinical data demonstrated GB268 is very effective in provoking anti-tumor responses. At the meantime, immune-related AEs is alleviated. Thus, GB268 may emerge as a promising novel therapeutics for cancer treatment.

#2713 Novel anti-PD-L1-IL-15 diabody immunocytokine in combination with radiation therapy improves response rates in immune-resistant murine head and neck cancer.

Abhay R. Sheeri, Robert S. Edinger, Harikrishnan Rajkumar, Ravi B. Patel

Radiation Oncology, University of Pittsburgh, Pittsburgh, PA

Purpose: The purpose of this study was to develop a new anti-programmed death-ligand 1 (αPD-L1) interleukin-15 (IL-15) diabody (Db) immunocytokine to improve the efficacy of combination radiation therapy (RT) and immune checkpoint inhibition (ICI) treatment in head and neck cancer.
Background ICI has revolutionized cancer care by increasing survival in patients with metastatic cancer, yet many patients with poorly immunogenic tumors have limited response to this therapy. To improve the efficacy of ICI, we developed a new immunocytokine combining an αPD-L1 Db with an effector immune cell agonist, IL-15. We hypothesized that our αPD-L1-IL-15 Db construct in combination with immunostimulatory radiation will lead to improved tumor responses and survival from ICI-resistant tumors.
Methods: Production in-vitro: αPD-L1-IL-15 Db construct was transfected into Expi-CHO™ cells and isolated with HiTrap™ Protein L affinity column. The molecular weight was confirmed via SDS-PAGE, and surface plasmon resonance sensorgram kinetics revealed high affinity of the immunocytokine to mouse isoform PD-L1 (K_D < 10 nM). Splenocyte proliferation and HEK-Blue™ reporter assays showed the IL-15 component to be functionally active. Testing in-vivo: 80-100 mm^3 mouse oral carcinoma-2 (MOC-2) tumors were established in C57BL/6 mice. Groups of 6 mice with tumors were treated with rat IgG isotype control, αPD-L1 Db, and αPD-L1-IL-15 Db w/wo 8 Gy of tumor-localized beam RT to upregulate PD-L1. Mice were tracked for tumor growth via tumor measurements and overall survival until the tumor burden endpoint was reached.
Results: We found αPD-L1 Db w/wo RT had an insignificant impact on survival or tumor growth delay in this tumor model in comparison to IgG w/wo RT. However, αPD-L1-IL-15 Db significantly improved survival compared to αPD-L1 Db treatment ($p = 0.004$) and IgG ($p = 0.0013$) in the presence of RT. We also saw significantly increased mean tumor growth delay with αPD-L1-IL-15 Db treatment compared to αPD-L1 Db ($p = 0.0164$) and IgG ($p = 0.0252$), on days 25 and 18 respectively, in the presence of RT. However, in the absence of RT, αPD-L1-IL-15 Db yielded no significant difference in mean tumor growth delay or survival when compared to IgG and αPD-L1 Db w/o RT.
Conclusion: Our results demonstrate that our αPD-L1-IL-15 Db immunocytokine with RT significantly improved tumor response and increased survival in aggressive, ICI-resistant mouse oral carcinoma, as compared to αPD-L1 Db with RT. However, this observation no longer persisted in the absence of RT. Hence, this suggests a synergy between radiation therapy and ICI-cytokine therapy in immunotherapy-resistant tumors. Further correlative and mechanistic tumor microenvironment profiling studies are underway to further elucidate mechanisms of immune activation with our combination of αPD-L1-IL-15 Db and radiation treatment.

#2714 Developing an mRNA encoded therapeutic antibody platform to simplify manufacturing and reduce time to clinic.

Roxana Redis[1], Dan Rocca[2], Rachel Pooley[3], Matthew Benson[3], Namrata Jayanth[1], Eva Oswald[4], Alexander Hale[1], **Louise Brackenbury**[2], Maxim Mashric[5], Christian Cobaugh[5], Michael Shaw[5], Justin Bryans[3]

[1]Charles River Laboratories, Leiden, Netherlands,[2]Charles River Laboratories, Bristol, United Kingdom,[3]Charles River Laboratories, Cambridge, United Kingdom,[4]Charles River Laboratories, Freiburg, Germany,[5]Vernal Biosciences, Colchester, VT

The manufacturing of therapeutic antibodies requires expensive production, often challenging purification, lengthy stability optimization and complex protein characterization that despite continual improvement, keeps the cost of treatment in the clinic high. Alternatively, leveraging gene-based approaches such as mRNA to express therapeutics circumvents many of the manufacturing challenges and instead rely on *in situ* production of antibodies within a patient, improving the developability and cost of sophisticated, disease-modifying antibodies. Crucially, recent work demonstrates that therapeutic antibodies translated *in vivo* from mRNA can be readily detected within hours following infusion into pre-clinical models and can persist up to several days or weeks. Peak levels of circulating mRNA-encoded antibodies are comparable to infused recombinant equivalents dosed to patients and have been shown to be within favorable therapeutic ranges in phase I trials. Here we outline an mRNA-LNP based platform to encode and deliver therapeutic antibodies *in vivo* that can overcome costly and challenging manufacturing and that demonstrates both robust PK/PD kinetics and potency. We describe how to effectively encode a standard-of-care anti-HER2 antibody - Trastuzumab - using LNP-encapsulated modified mRNA and validate using *in vitro* as well as *in vivo* efficacy models. Initial *in vitro* characterization of mRNA encoded antibodies demonstrates robust translation in producer cell lines, reproducible expression kinetics, retention of antigen specificity and HC:LC integrity when analyzed by ELISA and WB. To evaluate whether Trastuzumab-encoding mRNA-produced protein is detectable *in vivo*, antibody levels were measured in mouse serum after IV administration of a single dose of mRNA formulated LNPs. Peak plasma concentrations of mRNA-encoded trastuzumab were benchmarked against circulating recombinant Trastuzumab in parallel groups, and pharmacokinetics interrogated. Of note, the majority of mRNA encoded antibody was likely produced in the liver as shown by bioluminescence imaging. To demonstrate the efficacy of the platform, the potency of mRNA-encoded Trastuzumab isolated from producer cell lines will be assessed using *in vitro* cytotoxicity assays with human PBMCs and HER2+ tumor lines to dissect ADCC or direct tumor growth inhibition. Additionally, to determine whether mRNA-encoded Trastuzumab is able to retain anti-tumor activity *in vivo*, a mouse tumor xenograft model will be established and the mRNA antibody-dependent effects on tumor volume, growth and morbidity-free survival will be examined. Overall, the data demonstrate that mRNA-encoded therapeutic antibodies could provide an effective, alternate strategy for solid tumor treatment and may unlock a strategy to deliver lead biologics at reduced cost and with improved developability.

#2715 Preclinical characterization of SM2248: A dual-action bispecific antibody enhancing immunotherapy for solid tumors.

X. Liu, H. Zhou, S. Lu, H. Geng, W. Song, S. Xie, Y. Wei, X. Zhang, S. Yang, S. Zhou, **Y. Liang**;
Beijing StarMab BioMed Technology, Ltd., Beijing, China

Background: Innate immune cells, such as macrophages and myeloid-derived suppressor cells (MDSCs), dominate the immune landscape within "cold" solid tumors, which typically exhibit poor responses to immune checkpoint inhibitors (ICIs). The dearth of tumor-infiltrating T cells and the prevailing immunosuppressive microenvironment contribute to this ineffectiveness. To bolster immunotherapy against such tumors, we developed SM2248, a bispecific VHH antibody. SM2248 simultaneously obstructs the CD47-SIRPα phagocytosis checkpoint pathway and conditionally activates CD40 on tumor-infiltrating innate immune cells. CD47/SIRPa blockade enhances macrophage and dendritic cell (DC) phagocytosis and cross-presentation of antigens to cytotoxic T cells. CD40 activation fosters DC licensing, reprograms macrophages, and guides MDSC differentiation towards DCs and macrophages. The combined action of CD47 blockade and CD40 stimulation remodels the tumor microenvironment, fostering T cells infiltration and activation.
Methods: SM2248 was developed by fusing a highly selective CD47-blocking VHH module - minimizing binding to human erythrocytes and platelets, with a conditional CD40 agonistic VHH module - selectively activating immune cells upon CD47 engagement, incorporated into an inactivated IgG1 Fc backbone. The specificity and affinity of SM2248 binding to human CD47 and CD40 were assessed via ELISA and flow cytometry assays. CD47 and SIRPα interaction blockade was confirmed through a competitive ligand binding assay. Target-dependent CD40 activation was evaluated via a CD40-NFκB-Luc reporter assay. In vivo anti-tumor efficacy was determined using a syngeneic transplantation model of MC38-hCD47 cancer cells in B-hCD40 humanized mice. Binding to erythrocytes and platelets, compared with magrolimab, was assessed using flow cytometry. Hemolysis toxicity was evaluated through an in vitro erythrocyte lysis assay.
Results: SM2248 effectively inhibits cell surface CD47-SIRPα interaction at nanomolar concentrations and activates CD40-NF-κB-luciferase reporters at picomolar concentrations in a target-dependent manner. In contrast to the CD47 monoclonal antibody magrolimab, SM2248 does not bind to human erythrocytes or platelets and does not induce hemolysis. In murine syngeneic tumor models, SM2248 completely halts the growth of MC38-hCD47 tumors in humanized B-hCD40 mice and does not induce dose-dependent hepatotoxicity at doses up to 10 mg/kg.
Conclusions: SM2248, a humanized bispecific tetravalent VHH antibody targeting CD47 and CD40, exhibits promising in vivo efficacy and a favorable safety profile in preclinical studies, offering the potential for enhancing immunotherapy in solid tumors.

#2716 The O-glycan epitope targeting anti-human carcinoma monoclonal antibody (mAb) NEO-201 can also target human regulatory T cells (Tregs).

A. Tanaka[1], M. Fantini[2], P. M. Arlen[2], C. M. Annunziata[3], K. Y. Tsang[2], S. Sakaguchi[1];
[1]Frontier Research Center, Osaka University, Osaka, Japan, [2]Precision Biologics, Inc., Bethesda, MD, [3]National Cancer Institute, National Institutes of Health, Bethesda, MD

Introduction:NEO-201 is a humanized IgG1 mAb that targets Core 1 and/or extended Core 1 O-glycans expressed by several human solid and blood tumors, as well as neutrophils, but it does not bind to most normal tissues and human immune cell subsets (B cells, $CD4^{\pm}$ T cells, $CD8^{\pm}$ T cells, NK cells, monocytes). Functional analysis revealed that NEO-201 mediates the killing of its target cells through ADCC and CDC. Previous study has shown that approximately 4.6% of $CD4^{\pm}$ T cells express NEO-201 target antigen and that those $CD4^{\pm}$ T cells have Tregs phenotype. In addition, in a recent published phase 1 study we observed that NEO-201 binds to $CD4^{\pm}$/ $CD25^{\pm}$/, $CD127^{-}$/, $Foxp3^{\pm}$/, $CD15s^{\pm}$ cells from peripheral blood mononuclear cells (PBMCs) from cancer patients with solid tumors. The purpose of this study was to further characterize the phenotype of the specific subset of $CD4^{\pm}$ T cells expressing the NEO-201 target antigen.
Experimental Design: Human PBMCs were obtained from 7 healthy donors (HD) collected at Osaka University and 6 cancer patients from our ongoing phase II clinical trial (Clinical Trial NCT03476681) evaluating the efficiency of the combination of NEO-201 with pembrolizumab in adults with solid tumors resistant to checkpoint inhibitors. Phenotypic analysis was performed by flow cytometry using NEO-201 and antibodies CD3, CD4, CD25, CD45RA, FoxP3, and CD15s. The same gating strategy was applied for both normal donors and patients to evaluate which fraction of $CD4^{\pm}$ T cells is recognized by NEO-201. Fraction (Fr) 1 is naïve Treg, Fr II is effector Treg, Fr III is non-Treg, Fr IV is effector CD4 T cells and Fr V is naïve CD4 T cells.
Results: Flow cytometry analysis of PBMCs revealed that NEO-201 recognizes naïve Tregs (nTregs: $CD3^{\pm}$/$CD4^{\pm}$/$CD45RA^{\pm}$/$Foxp3^{low}$ cells) while it does not bind to effector Tregs (eTregs: $CD3^{\pm}$/$CD4^{\pm}$/$CD45RA^{-}$/$Foxp3^{high}$ cells) in both HD and cancer patients. The % of nTregs in cancer patients was higher than HD. Preliminary results from the ongoing Phase II clinical trial showed that subjects with durable SD had a reduction of circulating nTregs after treatment with NEO-201 compared to baseline levels.
Conclusions: NEO-201 binds to human Tregs with significantly higher % of binding to Fr I and a greater % of Tregs expressing NEO-201 target antigen in cancer patients compared to HD. It is conceivable that naïve Tregs in cancer patients express high levels of Core 1 O-glycans. Furthermore, when subjected to TCR stimulation, naïve Tregs undergo proliferation and differentiate into eTregs. eTregs can then infiltrate into tumor microenvironment (TME). These data suggest that depletion of circulating nTregs in cancer patients after NEO-201 treatment may prevent the differentiation of nTregs into eTregs and their accumulation in the TME. This study suggests the potential use of NEO-201 to reduce the Treg-mediated suppression of anticancer immunity.

#2717 Bifunctional fusion protein PDL1sFv/MICAe for cancer immunotherapy.

J. Li, Y. Wei;
Clemson University, Clemson, SC

Many cancer cells upregulate the expression of programmed death ligand 1 (PD-L1) to surpass T-cell mediated immune response. Immune checkpoint blockers targeting PD-L1 or its receptor PD1 have been shown to suppress the inhibitory signals and enhance T cell function. As a new immunotherapy, immune checkpoint blockers have been used to treat multiple cancers. However, most clinically available blockers only engage with one type of immune cell: the T cells. Natural killer (NK) cells, on the other hand, play a significant role in anti-cancer immune responses. It will represent an advancement in anti-cancer immunotherapy if NK cells are engaged with immune checkpoint blockers. In this study, we designed a unique bifunctional fusion gene, *PDL1sFv/MICAe*, consisting of the variable regions of an anti-PD-L1 antibody and the extracellular domain of stress protein MICA and hypothesized that fusion protein PDL1sFv/MICAe will simultaneously bind to PD-L1 on tumor cells to block the inhibitory signal and extend T cells activity, and to NKG2D to activate NK Cells. cDNA sequence of fusion gene *PDL1sFv/MICAe* was designed based on the variable region of an established clinically used antibody, Atezolizumab, and the extracellular domain of *MICA* with linkers in between. After a computational confirmation of its structure and binding affinities, the fusion gene was synthesized and cloned into an expressing vector, and the fusion protein was produced for evaluation. Western blotting and fluorescent microscopic analyses confirmed that the protein binds to PD-L1 of human tumor cells, including MCF7 and MDAMB231, and NKG2D of KHYG1 cells. Preliminary results also show that the fusion protein enhances NK cell cytotoxicity against tumor cells. Studies on confirming the fusion protein's activities on other tumor cells, NK cell IFN-γ production, T cell function, etc., are underway. In summary, fusion protein PDL1sFv/MICAe represents an improved version of the immune checkpoint blockers and could treat cancer patients quickly and effectively.

#2718 A novel TROP2-targeted immune stimulating antibody conjugate (ISAC) with potent anti-tumoral activtiy and accpetable safety.

Ye Chen[1], Fei You[2], Chenchen Zhu[1], Yao Xiong[1], Li Li[1], Nana Luo[1], Shuaixiang Zhou[1], Fushuai Wang[1], Chenyang Xu[1], Fan Fei[1], Chang Li[1], Jianglu Wang[1], Jinling Xu[1], **Huizhong Xiong**[1]

[1]Innovent Biologics, Suzhou, China, [2]Innovent Biologics, Rockville, MD

Immune stimulating antibody conjugates (ISACs) are a unique class of ADC in which antibodies recognizing tumor antigens are conjugated with immune agonists. ISACs target tumor tissue and specifically activate intra-tumoral myeloid cells, unleashing downstream immune response. Like the other immune agonists, balance between efficacy and safety remains a challenge for ISACs.

Here we describe a potential first-in-class TROP2 ISAC with rationally selected antibody and TLR7/8 agonist linker-payload. The anti-TROP2 antibody elicited robust ADCP of TROP2+ tumor cells by macrophages. *In-vitro,* TROP2 ISAC mildly activated myeloid cells only in the presence of TROP2+ tumor cells. *In-vivo,* the molecule potently suppressed tumor growth in different TROP2+ xenograft tumors, and effectively enhanced killing of an ADC. In terms of safety, the ISAC was tolerated in both WT and hTROP2KI mice, and, importantly, in monkeys. Taken together, our data demonstrate a novel TROP2 ISAC with outstanding efficacy and manageable safety profile, which may benefit patients with TROP2+ tumors.

#2719 Papiliximab, a bispecific nanobody targeting CD47 and PDL1 retards tumor growth without hemolysis.

B. Baek[1], M. Kim[2], J. Kim[1], I. Jang[1], S. Kim[1], J. Kim[1], S. Lee[1], **H. Kim**[1], S.-Y. Seong[2];
[1]Shaperon Inc., Seoul, Korea, Republic of, [2]Seoul National University, Hongcheon, Korea, Republic of

Cancer cells are known to express immune checkpoint proteins, enabling them to evade immune surveillance. In response, anti-cancer therapies targeting these proteins have been developed. While immune checkpoint inhibitors targeting PD-L1 have been clinically approved, their effectiveness as standalone therapies is limited, with only a 20% response rate. To improve responsiveness, bispecific monoclonal antibodies (MoAbs) targeting both CD47 and PD-L1 have been developed. These bispecific antibodies activate both the innate (by blocking CD47) and adaptive (by blocking PD-L1) immune systems simultaneously. However, conventional antibodies targeting CD47 have been dropped during development due to the risk of hemolysis. In this study, we developed a bispecific single-domain antibody (nanobody, Nb) that targets both CD47 and PD-L1 with a minimal hemagglutination risk. Using phage display libraries from alpacas immunized with recombinant antigens, we screened for an anti-CD47 Nb and an anti-PD-L1 Nb. The affinities (Kd) of these Nbs for their antigens were 7.0×10^{-9} and 9.7×10^{-9}, respectively. To maximize affinity for both antigens, a bispecific antibody (Papiliximab) was designed to tandemly array anti-CD47 and PD-L1 Nbs with the Fc region of IgG4. Papiliximab has a lower affinity for RBC (up to 3 μM) than conventional anti-CD47 MoAbs reported earlier. Papiliximab successfully inhibited interactions between CD47/SIRP-α and PD-L1/PD-1, with IC_{50} values of 7.09 nM and 2.67 nM, respectively. Papiliximab induced the expression of IFN-γ by inhibiting the PD-L1/PD-1 interaction in the PBMC-based MLR (Mixed Lymphocyte reaction) assay. In addition, Papiliximab demonstrated the induction of a phagocytosis effect through CD47 blocking and its IgG4 Fc domain. Therefore, Papiliximab is a multifunctional hybrid bispecific antibody that modulates both innate and acquired immunity. Papiliximab exhibited no cross-reactivity with mouse antigens, but did with cynomolgus antigens. We tested its efficacy on the growth of human B cell lymphoma (Raji cells) and human breast cancer (MDA-MB-231 cells) in humanized NSG mice. Papiliximab was more effective in inhibiting tumor growth than mono-specific Abs and Nbs for PD-L1 or CD47, and their combination. These observations suggest that Papiliximab might be able to improve clinical remission more effectively than the combination of monotherapies without the risk of anemia associated with anti-CD47 MoAbs. We are now working to elucidate the mechanisms behind Papiliximab's superior efficacy and safety compared to the combination of monotherapies.

#2720 Engineering sweeping antibodies for the clearance of tumor-derived, pro-tumorigenic cytokines.

J. M. Baker, N. J. Singh, T. Luetkens;
University of Maryland, Baltimore, Baltimore, MD

Soluble, tumor-derived, pro-tumorigenic (STP) cytokines have been shown to contribute to cancer cell proliferation and drug resistance. But therapeutic targeting of STP cytokines by monoclonal antibodies is limited by high concentrations and persistent production of antigen. We hypothesize that the ability of sweeping antibodies (swAbs) to actively clear soluble antigens will overcome these limitations. SwAbs differ from conventional antibodies via (1) pH-dependent binding of antigen, and (2) increased binding to the neonatal Fc receptor (FcRn). SwAbs facilitate clearance of soluble antigens by releasing antigen in the low pH environment of FcRn-expressing cells. SwAbs are then recycled via FcRn for repeated clearance of antigen.We are developing swAbs against four STP cytokines contributing to cancer cell proliferation, survival, migration or intra-tumoral angiogenesis: hepatocyte growth factor (HGF), vascular endothelial growth factor (VEGF), transforming growth factor-β (TGF-β) and interleukin 16 (IL-16). We selected four existing neutralizing antibodies against these cytokines with available crystal structures and generated a second antibody targeting interleukin 16 with high affinity (clone 3B6; K_D = 13 nM) *de novo* using phage display. We are using bio-layer interferometry and custom recycling/clearance assays for antibody characterization and pre-clinical validation. To introduce pH dependency into the four antibodies with crystal structures, we performed targeted histidine mutagenesis of residues at the interface with the respective target antigens. For the *de novo*-generated interleukin-16 antibody, we performed an unbiased histidine scanning approach by mutating residues across all six complementarity-determining regions (CDRs), which resulted in slight increases in pH sensitivity. We then performed a second round of mutagenesis of the most pH-sensitive 3B6 variants by replacing additional residues considered developability liabilities with histidine residues. We found that this approach significantly increased expression and affinity at pH 7 of the resulting 3B6 variants but only modestly increased pH sensitivity. In contrast, replacing a single residue in the heavy CDR1 in clone 14.1, a pre-clinical anti-IL-16 antibody, resulted in substantially increased pH sensitivity ($K_{D(pH=7)}$ = 2 nM; $K_{D(pH<6)}$ = n.b.). We are currently performing pH-sensitivity screenings for the three additional STP-specific antibodies. Our findings indicate that the ability to introduce pH sensitivity is largely dependent on the parental antibody and that some antibodies may not be amenable to this process. In addition, we show that histidine mutagenesis can be an effective approach to enhance expressibility and binding, while also increasing pH sensitivity. This project will answer the question whether anti-STP cytokine swAbs are an effective approach to treat patients with cancer.

#2721 FF01: a novel humanized heavy chain antibody targeting endogenous retroviruses with anti-lymphoma activity.

F. Spriano[1], L. Cascione[1], J. Sgrignani[2], N. Bendik[1], S. Napoli[1], G. Sartori[1], E. Cannas[1], T. Gongo[2], A. J. Arribas[1], D. Rossi[1], D. F. Robbiani[2], A. Cavalli[2], F. Bertoni[1];

[1]Institute of Oncology Research, Faculty of Biomedical Sciences, USI, Bellinzona, Switzerland, [2]Institute for Research in Biomedicine, USI, Bellinzona, Switzerland

Background: Human endogenous retroviruses (HERVs) are transposable elements (TE) derived from retrovirus infections that occurred millions of years ago. Despite constituting 8% of our genome, their biological role still needs to be explored. HERV-K (HML-2), a subgroup of HERVs, represents the most recent retroviruses integrated into the human germline DNA. Members of the HML-2 subgroup retain complete ORF with coding potential and have garnered the most attention in disease-related studies. HERVs exhibit physiological expression in embryonic stem cells but are heavily methylated and remain almost silent in normal adult tissues. Although the mechanisms underlying HERV-K contribution to tumor cell growth and survival remain poorly understood, aberrant expression of HERVs has been demonstrated in various human tumor tissues and lymphoma. These findings led us to explore HERV-K as a potential therapeutic target in B cell lymphomas

.Methods: RNA data were analyzed with Telescope. Validations were performed by qPCR, Western blot, flow cytometry, and ELISA. Env structure was obtained with AlphaFold and peptides were purchased from GeneScript. Antibody-dependent cellular cytotoxicity (ADCC) was performed with the ADCC Reporter Bioassay (Promega). Internalization was assessed using the Incucyte Fabfluor-pH Antibody labeling reagents.

Results: We assessed the TE expression in RNA-seq datasets of diffuse large B cell lymphoma (DLBCL) and B cells from healthy individuals. An MDS plot showed that TEs could separate neoplastic from healthy samples, demonstrating that tumoral and normal specimens have distinct TE and HERV expression profiles. Focusing on tumor samples, DLBCLs were divided into four clusters with different prognoses. Similar results were obtained in a 47 B-cell lymphoma cell line panel. Focusing on the HML-2 family in lymphoma patients, we identified many of them upregulated in tumors. We validated RNA and protein expression of the HML-2 envelope (env) in seventeen lymphoma cell lines, and in two of them, we also proved the protein surface expression. Env-specific siRNA reduced env expression determined a decrease in cell proliferation, suggesting a contribution to lymphoma cell growth. In silico examination of the env identified four linear regions with potential for antibody binding, and peptides covering them were synthesized. We screened 150 lymphoma patients' serum samples for IgG antibodies binding to the peptides, and all peptides showed positive hits. We used a phage display screen to obtain one nanobody, FF01, binding one peptide. FF01 induced ADCC in the cell line with high surface env expression and not in a negative one. FF01 was internalized in an expressing cell, proving the principle for using it as a component of an antibody-drug conjugate.

Conclusions: Our data demonstrate that HERVs are in DLBCL patients and propose FF01 as a new candidate to target HERV Env+ lymphomas.

#2722 CTN001, a first Twin Fc-immune cell engager, with a superior potency against Her2+ and Her2-low cancers by engaging multiple Fc-mediated mechanisms.

D. Lee, S. Yoon, J. Bae, M. Kim, K.-J. Lee, E. Kim, H. Park, E. S. Choi, G.-H. Yang;
Centenaire Biosciences Inc., Seongnam-si, Korea, Republic of

Many therapeutic monoclonal antibodies mediate the immune effector functions through the engagement of their fragment crystallizable (Fc) domain and Fcγ receptors on the immune cells. However, these functions are limited due to the low affinity of their interactions and the requirement of abundancy of antigens for the avidity effects. Recently, mutation-based Fc engineered antibodies showed their enhanced immune effector functions mostly through the NK cell-mediated ADCC. To overcome the limited improvement of current Fc engineering, we developed an innovated platform, Twin Fc-Immune Cell Engager (Twin Fc-ICE) composed of a single Fab domain and two Fc domain with drug-like properties. Here we demonstrated the superior efficacy of CTN001, a first Twin Fc-ICE, in *in vitro* and *in vivo* Her2+ tumor models. CTN001 bound to various types of Fcγ receptor-expressing immune cells with stronger affinity, supported by its better *in vitro* affinity to all types of Fcγ receptors than wild type and Fc-engineered antibodies. To evaluate the pharmacological efficacies, CTN001 was tested for its functions of *in vitro* antibody-dependent cellular cytotoxicity (ADCC), antibody-dependent cellular phagocytosis (ADCP) and complement-dependent cytotoxicity (CDC) and *in vivo* efficacy with Her2+ xenograft models. In Her2+ models, both CTN001 and trastuzumab induced ADCC-mediated effects, but CTN001 showed better anti-tumor cytotoxicity through ADCP and CDC than trastuzumab. Importantly, CTN001 also showed cytotoxic effects on Her2-low tumor cells. Consistently, CTN001 showed better anti-tumor efficacy than trastuzumab or its combination with pertuzumab in Her2+ tumor xenograft model and, surprisingly, even in Her2-low or resistant models. These results suggest that CTN001 can provide new therapeutic options for treating Her2-low patients differentiated from antibody-drug conjugates (ADCs), and that the Twin Fc-ICE can be an innovative platform to overcome limitations of existing therapeutics.

#2724 BCG020, a novel bispecific antibody targeting EGFR and CD70, is effective against EGFR and CD70 high expressed tumors.

Y. Yang, X. Sun, Z. Li, Y. Yan, L. Xu, X. Wu, L. Du, Y. Zhu, **C. Guo**, W. An;
Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

The epidermal growth factor receptor (EGFR) is highly expressed across a wide range of different cancers, and is a known driver of cancer growth; EGFR upregulation is frequently associated with adverse prognosis. Many patients undergoing EGFR-TKI (tyrosine kinase inhibitors) treatment will acquire resistance, which can be accompanied by increased expression of CD70 in some cancers. Simultaneous engagement of both EGFR and CD70 with a bispecific antibody (bsAb) is a potential strategy to overcome such resistance and achieve greater efficacy. To explore this strategy, we developed a novel IgG1 bsAb, BCG020, targeting EGFR and CD70. The parental EGFR antibody and CD70 antibody were developed from fully human common light chain antibody mice (RenLite®). When compared to EGFR benchmarks, the parental EGFR antibody exhibits similar affinity to both human and cynomolgus monkey EGFR, similar internalization activity in EGFR+ tumor cell lines, and superior blocking activity of EGF to EGFR *in vitro*. Furthermore, the EGFR parental antibody demonstrates good stability. The parental CD70 antibody exhibits high affinity to both human and monkey CD70, with superior internalization activity to benchmark antibody in CD70+ tumor cell lines, as well as superior blockade of CD70-induced signaling of CD27-Luc when compared to benchmark antibodies. When assembled into a bsAb, BCG020 exhitibs the same high affinity as both parental antibodies, with higher internalization activity than parental antibodies and benchmark antibodies. To evaluate the efficacy of BCG020 *in vivo*, we established cell line-derived xenograft (CDX) models in immunodeficient (B-NDG) mice. We observed that BCG020 treatment (10 mg/kg) potently inhibited growth of EGFR+CD70+ tumors. Taken together, these data indicate that BCG020 is a first-in-class bispecific antibody with potential to treat solid tumors with high expression of EGFR and CD70.

#2726 A novel trispecific antibody HC010 targeting PD-1/CTLA-4/VEGF for the potential treatment in anti-PD-1 antibody resistant NSCLC patients.

D. Jiang, Y. Xi, C. Xu, X. Wang, Q. Yin, Z. Li, **T. Yang**;
HC Biopharma Inc., Shanghai, China

Background and Aim: Immune checkpoint inhibitors (anti-PD-1 /CTLA-4 antibody) have been approved and widely used for the first line treatment of non-small cell lung cancer (NSCLC). However, most patients are experiencing resistant to PD-1 blockade. In recent clinical trials, anti-VEGF antibody has shown to improve the clinical outcomes of anti-PD-1 antibodies and overcome resistance to checkpoint blockade. We developed a PD-1/CTLA-4/VEGF trispecific antibody (HC010) by site-specifically fusing anti-PD-1 scFv and anti-CTLA-4 nanobody to the defined site of anti-VEGF antibody. The aim of this study was to evaluate the potential use of HC010 for treatment of anti-PD-1 antibody resistant NSCLC patients.
Method: Humanized mice were established in NCG mice by reconstituting human PBMC before inoculating the PDX tissue, which was derived from a NSCLC patient treated with two cycles of an anti-PD-1 antibody sintilimab. When tumors were approx. 170mm3, mice were dosed with HC010 twice weekly for 3 weeks. Pembrolizumab, sintilimab and a Standard of Care (SoC) agent docetaxel were included as reference. For IHC analysis, tumor samples were harvested 24h post final dose and fixed with 10% NFB overnight and subsequently stained with CD31 and CD8 to explore the change in tumor microenvironment after HC010 treatment. For preclinical toxicity assessment, HC010 was intravenously administered once weekly for four weeks in naïve cynomolgus monkeys and immunogenicity/local tolerance/clinical pathology were evaluated during the dosing and recovery phase.
Results: HC010 showed a significant tumor inhibition (TGI=81%) when compared with the vehicle control. Pembrolizumab and sintilimab alone exhibited limited anti-tumor effect. Docetaxel only showed a partial response during the dosing phase. By analyzing tumor samples, there was a significant increase in CD8+ positive T cells in HC010 treated tumors in contrast to the vehicle group and pembrolizumab/sintilimab treated groups, suggesting that HC010 can significantly improve CD8+ T cell infiltration. Expression of CD31 as an angiogenic and vasculogenic marker, was significantly reduced in HC010 treated tumors. In the toxicity study, HC010 at selected doses showed no obvious toxicity in cynomolgus monkeys.
Conclusion: Our trispecific antibody HC010 targeting PD-1/CTLA-4/VEGF showed a superior anti-tumor effect in a sintilimab resistant PDX animal model when compared with pembrolizumab and sintilimab as well as SoC. By analyzing tumor microenvironment , HC010 overcame acquired resistance by modulating tumor microenvironment such as increase in intra-tumoral cytotoxic T cell infiltration and normalization of blood vessels. Together with preclinical efficacy and safety data, HC010 showed potential benefits in treatment of anti-PD-1 antibody resistant NSCLC patients.

#2727 Pre-clinical development of a novel anti-GPRC5D inducing potent anti-tumor effect through enhanced antibody-dependent cell-mediated cytotoxicity (ADCC) for multiple myeloma.

H. Bonnevaux, E. Remy, T. Pizette, S. Bouvier, K. Desrumeaux, L. Bassinet, C. Nicolazzi, P. Rettman, Z. Klippel, M. Meloni, M. Chiron, A. Virone-Oddos; Sanofi-Aventis, Vitry-sur-seine, France

Multiple myeloma (MM), characterized by clonal accumulation of malignant plasma cells in the bone marrow, is the second most prevalent hematopoietic malignancy. Despite emerging therapies, MM remains an incurable disease with a 5-year overall survival of 56% for relapsed and/or refractory disease (RRMM) patients. Thus, innovative approaches that would be safe and potent are required. GPRC5D (G Protein-Coupled Receptor Class C Group 5 Member D) is an orphan GPCR protein involved in keratin synthesis with limited expression in healthy tissues. GPRC5D is expressed at very high prevalence among MM patients and its expression on tumor cells is maintained after treatments with standard of care agents such as anti-CD38, or BCMA-targeting therapies. The ability of NK cells to kill tumor cells leaving other cells unharmed and to induce minimal pro-inflammatory cytokine release as compared to T cell-based therapies, makes NK cells ideal immune cells for a safe and efficacious therapeutic approach. Like Sarclisa®, other therapies engaging NK cells and mediating tumor cell killing through antibody-dependent cell-mediated cytotoxicity (ADCC) mechanism have demonstrated their efficacy in clinic. Here we report the design, preclinical characterization, and development of a novel anti-GPRC5D antibody inducing potent cytotoxic activity against MM cells. SAR446523 is an IgG1-based antibody with an engineered Fc domain for enhanced ADCC function and targeting human GPRC5D on tumoral plasma cells. SAR446523 demonstrated high affinity for GPRC5D target and increased affinity for both high and low affinity FCGR3A-158V and 158F variants of CD16a receptor. The ability of SAR446523 to induce ADCC *in vitro* was assessed in a panel of MM cell lines exhibiting low, medium, and high GPRC5D expression. SAR446523 induced strong potency against all tested cell lines (picomolar range), regardless of the levels of GPRC5D. In addition, SAR446523 induced higher cytotoxic activity compared to a clinical benchmark compound. This anti-tumor activity was associated with very low IL-6, TNFa and IFNg pro-inflammatory cytokine release, much lower compared to a CD3xGPRC5D T-cell engager in *in vitro* assay using human peripheral blood mononuclear cells (PBMC) in presence of GPRC5D positive cells. In addition, the *in vivo* anti-tumor activity of SAR446523 was investigated in a NK humanized NOG huIL15 transgenic mouse model bearing disseminated MM cells. SAR446523 led to a robust antitumoral efficacy with a significant improved mouse survival. These data demonstrating potent anti-tumor activity and favorable safety profile of this novel anti-GPRC5D antibody suggest that SAR446523 may be a promising therapy for patients with RRMM and provide consistent support for clinical development.

#2728 Discovery of a multispecific CD73/PD-1 targeting drug Fc-conjugate (DFC), which improves tumor reduction compared to PD-1 monotherapy in a humanized mouse model.

J. Levin, S. Dohrmann, N. Dedeic, A. Almaguer, D. Zuill, E. Abelovski, J. N. Cole, J. B. Locke, J. Fortier, Q. Zhao, M. Hernandez, K. Amundson, M. Moniz, H. Chen, D. Panickar, T. Lam, T. Brady, A. Borchardt, G. Hough, L. W. Tari;
Cidara Therapeutics, Inc., San Diego, CA

Background: The approval of immune checkpoint therapies has revolutionized cancer treatment and established immuno-therapy as an additional treatment option. However, while anti-PD-(L)1 therapies have demonstrated durable responses, only a small subset of patients respond. One mechanism of tumor escape is via the release of immunosuppressive metabolites such as adenosine. CD73, an extracellular enzyme expressed on immune cells and some tumors, catalyzes the conversion of AMP to adenosine, the rate limiting step in adenosine production. As a strategy to improve response rates we developed a first in class CD73/PD-1 targeting DFC, comprised of a multivalent conjugate of a small molecule CD73 inhibitor stably linked to a proprietary human IgG1 Fc-fusion with a PD-1 inhibitor peptide. This multispecific DFC has the potential for differentiation and increased therapeutic potency compared to approved PD-(L)1 inhibitors.

Methods: Binding of CD73/PD-1-001 to biotinylated hPD-1 was determined using ELISA and to human $CD8^{\pm}$ T cells by flow cytometry. CD73 inhibition was measured in cell-free and cell-based assays. Efficacy was determined in a humanized mouse model optimized for PD-1 activity against a transgenic MC-38 colon cell line expressing hPD-L1 (Genoway, France). Tumor volumes were recorded and statistical analysis was conducted by t-test (Mann-Whitney) or two-way ANOVA.

Results: In vitro, CD73/PD-1-001 demonstrated potent activity against both checkpoint targets. CD73/PD-1-001 bound to hPD-1 with an IC_{50} of < 1 nM and demonstrated functional inhibition of CD73 with an EC_{50} of <10 nM, which is on par with respective single agent molecules. Importantly, addition of the CD73 targeting moiety resulted in no significant loss in PD-1 binding relative to PD-1-001, a DFC containing only the PD-l inhibitor peptide. Efficacy was determined in a humanized mouse model against a transgenic MC-38 cell line. Both CD73/PD-1-001 and PD-1-001 DFCs were highly potent in this model with tumor growth inhibition (TGI) of >70% at dose concentrations of 3 mg/kg or greater ($p \leq 0.01$). However, at the lowest test concentration of 1 mg/kg, only CD73/PD-1-001 retained significant potency with a TGI of 56.0 % ($p \leq 0.05$). Tumor reduction in the 1 mg/kg PD-1-001 group did not reach statistical significance (36.5%, $p > 0.05$).

Conclusions: This work demonstrates that a multispecific CD73/PD-1 targeting DFC, is a potent inhibitor of tumor growth in a humanized mouse model. Furthermore, CD73/PD-1-001 was more potent than PD-1 monotherapy, demonstrating the therapeutic benefit of targeting two important checkpoints with a single agent molecule. Collectively, preclinical testing of a CD73/PD-1 DFC has validated the benefits of targeting the PD-(L)1 axis in combination with adenosine suppression, resulting in improved anti-tumor effects.

#2729 Discovery and characterization of LILRB2XPD-L1 bispecific antibody SPX-303.

A. Haight[1], Q. Chen[1], B. William[1], D.-D. Nguyen[1], R. Cai[1], J. Ma[1], M. White[1], J. Jin[1], J. Shen[1], M. Siekierzycki[1], V. Hall[1], H. Jin[1], R. Meier[1], J. Moser[2]; [1]Sparx Biopharmaceutical Corp, Mount Prospect, IL, [2]HonorHealth Research Institute, Scottsdale, AZ

The advent of immunotherapy has led to deep and sometimes durable remissions in certain cancers. However, the variable response rates and development of resistance mechanisms pose significant challenges to the current therapies. The immunosuppressive nature in the tumor microenvironment (TME) can drive many of these observations. Reversing this immunosuppression is a promising avenue for enhancing and broadening the applicability of IO therapies. Macrophages are critically modulated by LILRB2, a pivotal receptor in their maturation and polarization to the M2 immunosupressive phenotype. We report the discovery and development of a novel anti-LILRB2/PD-L1 bispecific antibody, SPX-303, designed using an anti-LILRB2 IgG4 derived from a mouse hybridoma screen and linked with an anti-PD-L1 epitope. SPX-303 demonstrates sub-nanomolar binding affinity to both LILRB2 and PD-L1 targets, effectively blocking the interaction between LILRB2 and its ligand, as well as inhibiting PD-1 binding to PD-L1. In *in vitro* functional assays, SPX-303 exhibits effects comparable to the parental monomeric anti-LILRB2 (SPX-104) in redirecting macrophage polarization from M2 to M1 stage, as observed in both cultured PBMC and human monocyte-derived macrophage (HMDM) models. Furthermore, SPX-303 demonstrates a synergistic effect in inducing T cell activation in the autologous mixed lymphocyte reaction assay (auto-MLR), surpassing the effects of the anti-LILRB2 epitope (SPX-104) and the anti-PDL1 fragment (single-domain anti-PDL1) alone or in combination. *In vivo* experiments reveal that SPX-303 significantly inhibits tumor growth. Collectively, these results support SPX-303 as a novel therapeutic antibody that effectively enhances anti-cancer immunity in the treatment of advanced solid tumors. The pre-clinical data as well as the clinical plan of SPX-303 will be presented.

#2730 Beyond antibodies and CAR-T: Topologically-engineered, super-dimeric antibody-like molecules with dual Fc domains for trispecific, bivalent targeting of CD19, CD20, and Fcgamma receptors.

D. J. Capon, N. L. S. Chan, L. Troitskaya, M. Fomin, U. Edman, B. Frank, B. Z. Capon, B. Law, S. J. Chapin, G. M. Lewis, M. L. Gefter, J. Punnonen; Hinge Bio, Inc., Burlingame, CA

Background: Depletion of B cells has resulted in major therapeutic benefits in autoimmune diseases and hematological malignancies. Several FDA-approved B cell-depleting antibody-based therapies are available, including antibody-drug conjugates, T cell engagers, CAR-T cells, and antibody variants with enhanced effector functions through Fc engineering. However, a significant unmet need remains in both oncology and autoimmune disease. All currently approved B cell-depleting therapies target a single B cell antigen, increasing potential for incomplete depletion and emergence of escape mutants that give rise to relapse and treatment failure.

Methods: Here we describe trispecific antibody-like molecules generated using GEM-DIMER technology. In addition to bivalent target binding of both CD19 and CD20, the GEM-DIMER candidates are designed to have two Fc domains to enable powerful effector functions via cooperative binding of Fcgamma receptors. The approach is based on incorporation of a super-dimerization domain into the hinge region of an immunoglobulin heavy chain, enabling the combination of all of the components of two IgG antibodies into a single molecule. Using this approach, we generated GEM-DIMER candidates from rituximab and FMC63, the parental anti-CD19 antibody for anti-CD19 scFv used in approved CAR-T cell therapies.

Results: CD19/CD20-targeting GEM-DIMER molecules demonstrated binding to both CD19 and CD20 with affinities comparable to the individual parent antibodies. Importantly, CD19/CD20-targeting GEM-DIMER molecules demonstrated robust depletion of human B cells in overnight cultures of whole blood. Moreover, antibody-dependent cellular cytotoxicity (ADCC) was demonstrated in co-cultures of the human B cell lymphoma cell line Raji and human peripheral blood mononuclear cells (PBMC). As expected, due to the presence of dual Fc domains, CD19/CD20-targeting GEM-DIMER molecules exhibited enhanced binding to Fcgamma receptors, further explaining the robust effector functions observed.

Conclusions: CD19/CD20-targeting GEM-DIMER molecules are promising candidates to provide efficient depletion of both CD19+ and CD20+ cells, providing potential for broad and deep depletion of B cells with reduced risk of emergence of antigen escape variants. These data support the advancement of CD19/CD20-targeting GEM-DIMER molecules in multiple indications where depletion of CD19+ and/or CD20+ B cells is needed. Preparations for clinical investigation are ongoing.

#2731 CCR5-001, a novel drug Fc-conjugate (DFC) targeting CCR5, demonstrates potent efficacy in a colorectal cancer mouse model.

S. Dohrmann, J. Levin, N. Dedeic, A. Almaguer, D. Zuill, E. Abelovski, J. B. Locke, J. Fortier, M. Hernandez, Q. Zhao, K. Amundson, M. Moniz, H. Chen, D. Panickar, T. Lam, G. Hough, T. P. Brady, A. Borchardt, J. N. Cole, L. W. Tari;
Cidara Therapeutics, San Diego, CA

Background The approval of immune checkpoint inhibitors (ICI) such as PD-(L)1 inhibitors has revolutionized cancer therapy and established a role for immune effector cells, most notably $CD8^+$ T cells, in tumor control and destruction. While anti-PD-(L)1 therapy has demonstrated durable responses, only a small subset of patients benefit and respond to therapy. CCR5 is expressed on multiple immune cells (e.g. myeloid-derived suppressor cells) and CCR5-dependent migration of these cells contribute to an immune-suppressive tumor microenvironment (TME) thereby limiting response to ICI therapy. In addition, expression of CCR5 on cancer cells has been linked to increased metastasis and resistance to ICI therapy. Upregulation of CCL5/CCR5 has been associated with poor outcomes in multiple solid tumor indications, including colorectal cancer (CRC). Therefore, targeting CCR5 has the potential to increase response rates to ICI therapy and improve outcomes. Herein, we describe a first-in-class CCR5 targeting DFC, CCR5-001, a multivalent conjugate of a potent, small molecule CCR5 antagonist conjugated to an immune-silent proprietary human IgG1 Fc. This CCR5 targeting DFC has the potential to improve responses to ICI therapy by preventing pro-tumorigenic reprogramming of the TME induced by CCL5/CCR5 expressing tumor and myeloid cells.

Methods Binding of CCR5-001 to hCCR5 was measured by surface plasmon resonance (SPR) and to $CCR5^+$ PathHunter cells (DiscoverX) by flow cytometry. Functional activity was determined in $CCR5^+$ PathHunter β-arrestin assay with CCL3 to induce CCR5 signaling according to manufacturer's instructions. Efficacy was determined in an immune-competent syngeneic mouse model using the CRC cell line, MC38. CCR5-001 was dosed at 20 mg/kg twice per week for two weeks. Tumor volumes were recorded and statistical analysis was conducted by t-test (Mann-Whitney) or two-way ANOVA in Prism.

Results CCR5-001 displayed a KD of 4.2 nM to immobilized hCCR5 by SPR and IC_{50} of 0.63-0.98 nM for binding to engineered $CCR5^+$ PathHunter cells. This high affinity binding translated to potent functional inhibition of CCL3-induced CCR5 signaling with an IC_{50} of 12.7 nM in $CCR5^+$ cell-based assay. CCR5-001 demonstrated potent, statistically significant ($p = 0.0052$) tumor growth inhibition of 76% by day 13 in a syngeneic mouse model.

Conclusions CCR5-001 demonstrated potent CCR5 binding and functional inhibition of CCR5 signaling in cell-based assays. The *in vitro* activity translated to robust efficacy as a monotherapy in a syngeneic mouse model. Based on these results and other emerging data, CCR5-001 represents an exciting new avenue for targeting CCR5 with DFCs in solid cancers where the pathology is driven by the CCR5/CCL5 axis.

#2732 NB203: A Novel therapeutic bispecific antibody targeting CEACAM1/VEGF for tumor immunity and angiogenesis modulation in the tumor microenvironment.

J. Dong, B. Wang, D. Wang, J. Ni, T. Bu, H. Wang, B. Nayak, B. Wang, X. Dong, **Y. Zhang**;
NeoLogics Bioscience Co. Ltd., Suzhou, China

The carcinoembryonic antigen cell adhesion molecule 1 (CEACAM1) is detected on leukocytes, epithelia and endothelia, and involved in cell adhesion through homophilic or heterophilic binding. In various gastrointestinal cancers, NSCLC (non-small cell lung cancer), and melanoma, CEACAM1 is highly expressed on tumor cells and tumor stroma, with its levels increasing as the disease progresses. Notably, CEACAM1 has been found to dampen T and NK cell functions while promoting tumor angiogenesis and metastasis. In this study, we present NB203, a novel CEACAM1/VEGF bispecific antibody developed using Neologics CEACAM-*plus*, a bifunctional molecule engineering platform designed to target and modulate the tumor microenvironment (TME). NB203 effectively accumulated in the TME and hindered the homophilic or heterophilic interactions of CEACAM1. It demonstrated a significant enhancement in T cell activities and NK cell-mediated killing of CEACAM1-expressing tumor cells, and the inhibition of tumor cell migration and polyploidy through macrophages. More importantly, NB203 was specifically designed to impede tumor angiogenesis. It exhibited an increased binding capacity to both CEACAM1 and VEGF in pro-angiogenic TME, and undermined intratumoral vessel maturation by blocking VEGF and negatively regulating myeloid cell-dependent tumor angiogenesis. In summary, our preclinical data indicate that NB203 exhibits effective anti-tumor activity by mediating NK and cytotoxic T cell activities, improving the immune-suppressive TME, and suppressing tumor angiogenesis. The use of NB203 holds promise in overcoming resistance to anti-VEGF therapy and substantially improving the safety of therapeutic targeting of angiogenesis in cancer treatment.

#2733 NB202: A bispecific anti-PD1/TIM-3 antibody for cancer immunotherapy.

J. Dong, **Y. Zhang**, B. Wang, D. Wang, T. Bu, J. Ni, B. Nayak, X. Dong;
NeoLogics Bioscience Co. Ltd., Suzhou, China

Despite the remarkable efficacy of PD-(L)1 therapy, a significant proportion of cancer patients fail to respond or develop resistance over time. Co-expression of T-cell immunoglobulin and mucin domain containing-3 (TIM-3) with PD-1 on primed T cells has been observed in patients exhibiting resistance to PD-1 blockade. Moreover, TIM-3 is also expressed on other immune cells, including NK and DC, and plays a negative regulatory role in these immune cells. Therefore, the dual blockade of PD-1 and TIM-3 holds potential for enhanced clinical benefits. NB202 is a bispecific anti-PD1/TIM-3 antibody that has been designed to optimize the therapeutic response of anti-PD1 therapy by maximizing TIM-3 blockade on antigen-experienced T cells, enhancing NK cell activity, and improving antigen presentation ability of antigen-presenting cells (APC). NB202 has demonstrated high affinity binding to human TIM3 and PD-1 in the low nanomolar range. Moreover, it can simultaneously bind to TIM-3 and PD-1 receptors through a trans-manner, suggesting its potent capacity to enhance the interaction between T cells and dendritic cells (DCs). In classic MLR (mixed lymphocyte reaction) and T cell stimulation assays, NB202 has exhibited superior efficacy compared to the combination of anti-PD1 mAb and anti-TIM3 monoclonal antibodies as it significantly enhances the secretion level of interferon-gamma (IFN-gamma), and particularly interleukin-2 (IL-2). Moreover, in an anti-PD1 resistant mouse model, NB202 has shown promising efficacy results.

#2734 RC148, a novel bispecific antibody targeting PD-1 and VEGF for cancer immunotherapy.

Jianmin Fang[1], **Dong Li**[2], Kaiyue Wu[2], Sisi Wang[2], Du Li[2], Guorui Zhao[1], Shenjun Li[1], Jing Jiang[1]

[1]RemeGen Co., Ltd., Shandong, China,[2]Shanghai RemeGen Biotechnology Co., Ltd., Shanghai, China

Vascular endothelial growth factor (VEGF) is one of the most important pro-angiogenic factors in modulating tumor microenvironment (TME), and the concentration of VEGF in TME is significantly higher than that of peripheral. Inhibiting VEGF can improve immunotherapy efficacy by modulating the TME, preventing angiogenesis and regulating immune cell populations. Combined anti-VEGF and anti-Programmed cell death protein 1 (PD-1)/Programmed cell death ligand (PD-L1) therapies have exerted potent antitumor effect in preclinic and clinic studies. Therefore, we developed a novel humanized IgG1 silenced bispecific antibody RC148 to target VEGF and PD-1. RC148 allows dimeric VEGF crosslinking and gradually enhances PD-1 binding activity, potentially reduces systemic toxicity of anti-VEGF therapy and enhances antitumor potency via VEGF trigged enrichment in tumor areas. In preclinical studies, RC148 blocks the binding of VEGF to VEGFR and PD-1 to PD-L1, prevents the growth and migration of human umbilical vein endothelial cells, enables efficient T cell activation, exhibited synergistic antitumor effects in rodent models and showed safety profiles in non-human primate studies.

#2735 High affinity and potent anti-tumor efficacy of Nivo813, an anti-PD-1/ALK-1 bispecific antibody, in pre-clinical studies for solid tumors.

Qingqing Zhou[1], **Rong Tang**[1], Lanfang Zhuang[2], Jianyu Huang[1], Jiang Qian[1], Zhihua Ren[1], Youzhi Tong[1]

[1]Kintor Pharmaceutical Limited, Suzhou, China,[2]Kintor Pharmaceutical (Guangdong) Co., Ltd., Zhuhai, China

Background: The activin-like kinase receptor 1 (ALK-1, encoded by ACVRL1) is a member of the transforming growth factor β (TGF-β) superfamily. Combination treatment using anti-PD-1/PD-L1 agents with anti-angiogenetic reagents might bring additional benefits, such as establishing a favorable TME leading to better responses towards immunotherapy. In the phase II clinical trial (NCT03893695) of combination therapy of ALK-1 (GT90001) and Nivolumab for the second line therapy in patients with metastatic hepatocellular carcinoma (“HCC”) in Taiwan, among the 20 evaluable patients, the overall response rate is 40%, and the side effects were well tolerated and manageable. Nowadays, the combination of GT90001 and nivolumab shows a remarkable long-tail effect, since 7 patients are still alive as of March 30, 2023, 6 of them had received no further systematic anti-tumor therapy after trial completion. Among them, 4 patients are still on progression free status. Our pre-clinical data demonstrated that Nivo813 has improved cell-binding potency and potent anti-tumor effects, lighting up its potential capacity as a therapeutic drug in the treatment of human cancers.

Methods: The antigen binding activity of Nivo813 with PD-1 and ALK-1 were assessed by ELISA, Fortebio and flow cytometry. Endothelial cell tube formation assay was performed to identify the anti-angiogenesis function of Nivo813. The anti-tumor activity of Nivo813 was investigated in PBMC implanted with MDA-MB-231 breast cancer cells.

Results:Nivo813 could specifically bind to human PD-1 and ALK-1 with high affinity. Intriguingly, Nivo813 was found to have much higher affinity (40-fold, nM) to cell surface PD-1 than that of nivolumab. Meanwhile, Nivo813 exhibited dose-dependent anti-angiogenesis activity in vitro. Nivo813 demonstrated greater anti-tumor efficacy compared to nivolumab in mice model.

Conclusions: Nivo813, a dual-blocking anti-PD-1/ALK-1 bispecific antibody, shows improved binding potency to cell surface PD-1 and ALK-1 simultaneously, and displays dose-dependent anti-angiogenesis in vitro and great anti-tumor efficacy in vivo, supporting its clinical potentials for the treatment of human cancers.

#2736 Ligand-independent targeting of tumor cells for antibody-dependent cell-mediated cytotoxicity.

M. L. Aliru, N. R. Sultanpuram, K. Au, T. Zhang, A. Z. Wang;
University of Texas Southwestern Medical Center, Dallas, TX

Introduction: Biological targeting is a key concept in cancer treatment utilized by most therapeutics. Targeted agents that selectively treat diseased tissues while reducing off-target effects to normal tissues are widely used for cancer therapies. However, key hurdles include: (i) a limited number of tumor-specific biomarkers expressed in sufficiently high levels for targeted therapy, (ii) lack of specific biomarkers amenable to targeting, and (iii) current technologies rely on largely protein-based targeting ligands limiting the applications of these therapies due to final conjugates with low payloads. We developed a novel method for tumor-specific delivery by combining metabolic glycoengineering and nanomedicine to engineer targetable chemical groups on cancer cells and enable directed treatments. We hypothesize that increased Fc fragments on the surface of tumor cells can enable antibody-dependent cell mediated cytotoxicity (ADCC) response to tumor cells, providing innate immunotherapy.

Materials/Methods: We formulated nanoparticles (NPs) using polyethylene glycol-ply lactic acid-co-glycolic acid (PEG-PLGA). Using the Dolomite microfluidic device, we formed NPs by nanoprecipitation of PEG-PLGA with tetraacetylated N-azidoacetyl-D-mannosamine (Ac_4ManNAz), a sialic acid analogue containing a click chemistry group. We targeted this reactive group by functionalizing the Fc fragment with dibenzylcyclooctyne (DBCO). We characterized the NPs using dynamic light scattering (DLS), charge measurements and transmission electron microscopy (TEM). We evaluated toxicity using a cell viability assay and assessed preliminary efficacy with a tumor growth delay study.

Results: NP characterization revealed a size of 30-40 nm via DLS, congruent with TEM imaging. Charge measurements ranged from -4 to +4 mV. Toxicity studies revealed no differences in cell viability amongst different treatment groups. Preliminary efficacy studies demonstrated improved tumor growth delay in the cohort of mice treated with a combination of NPs and Fc-DBCO conjugate, as well as a survival benefit. Median OS was 31.5 days for the control groups vs 57.5 days for the combination treated group ($p = 0.0067$).

Conclusion: There is growing interest in harnessing the power of the innate immune response to shape anti-tumor immunity. This is because clinical data demonstrates tumor cells can evade the adaptive immune system through mutations as well as downregulate MHC receptors. One of the most effective innate immune responses is ADCC. To this end, we developed a novel method for tumor-specific delivery of Fc fragments to enhance ADCC. While this data reveals improved tumor growth delay and a survival benefit, the sample size is limited, and a larger study is needed to evaluate the potential benefits of this strategy. Furthermore, correlative studies are needed to identify the mechanism for treatment response.

#2737 LIS22, a first in class polyclonal antibody immunotherapy in T cell blood cancers.

C. Ciron, F. Shneiker, O. Dauphouy, J. Rousse, P.-J. Royer, G. Evanno, O. Duvaux, **F. Bassissi**;
Xenothera, Nantes, France

Background: Several approaches such as antibody drug conjugate (ADC), chimeric antigen receptor T cells (CAR-T) and recently bispecific antibodies are being introduced as innovative weapon in B-Cell lymphoma treatment. In the opposite, very limited therapeutic options are available for the treatment of rare refractory T cell malignancies such as PTCL. The 5-year survival rate of PTCL is lower than 30% according to the recent clinical data. Developing new effective treatment strategies for PTCL is an urgent problem. LIS22, is a first in class glyco-humanized polyclonal antibody (GH-pAb), targeting multiple tumor-associated antigens simultaneously. In this study, we characterized the safety and efficacy of LIS22 in preclinical models of T cell malignancies.
Material and Methods: LIS22 ability to induce Antibody-Dependent Cell Cytotoxicity (ADCC), Antibody-Dependent Cellular Phagocytosis (ADCP), Complement Dependent Cytotoxicity (CDC), and apoptosis was tested in a panel of hematologic malignancy cell lines and peripheral blood mononuclear cell (PBMC). To assess the targeting and recognition of LIS22 in PTCL patients, we evaluated the immunolabelling of LIS22 on patients' biopsies (n=119) using tissue microarray. LIS22 efficacy in vivo were evaluated in NMRI nude mice and SRG rats using T1301 and Jurkat cancer cell lines. Pharmacokinetics and safety of this drug were assessed in cynomolgus monkeys after single and repeated IV dosing up to 50mg/kg.
Results: LIS22 acts via several mechanisms, at 30µg/ml, it induced cytotoxicity via CDC (in 70%), ADCP (in 49%), ADCC (in 41%) and apoptosis (in 30%) of HPB-ALL human T blood cancer cell line but not in PBMC. LIS22 showed a potent in vitro antitumor activity in a panel of hematologic malignancy cell lines, it induced specific tumor cell CDC (EC50=41.4±28.9µg/mL). In both CDC and apoptosis cytotoxicity assays, LIS22 displayed a significantly higher potency on T cell blood cancers and no toxicity on healthy blood cells compared to PTCL clinically active drug Alemtuzumab (Anti-CD52). It was able to kill up to 100% of the cancer cells without affecting PBMC. In immunolabeling assay, LIS22 demonstrated cross-reaction to PTCL patient biopsy (staining up to 93%). In vivo efficacy studies in different mice and rat xenograft models, LIS22 induced a significant reduction of tumor growth up to 90% across several tested tumors. LIS22 was also characterized by high tolerance profile and satisfactory exposure in monkeys after repeated dosing (up to 250mg/kg of cumulative dose).
Conclusion: LIS22 appeared as a novel and promising cancer immunotherapy against T Cell hematologic malignancies. It has already been administered to human in another indication and showed a satisfactory PK and safety profile (no signs of immunotoxicity or systemic cytokine release). LIS22 is now ready to enter Phase I/II in the coming months for the treatment of peripheral T cell lymphoma (PTCL).

#2738 XON7, a new Glyco-Humanized Polyclonal Antibody, first in class immunotherapy against several solid tumors.

C. Ciron, G. Evanno, P. Morice, P.-J. Royer, F. Shneiker, O. Duvaux, B. Vanhove, **F. Bassissi**;
Xenothera, Nantes, France

Introduction: Cancer immunotherapy has recently generated much excitement after the success of the immunomodulating anti-CTLA-4 and anti-PD-1 antibodies against various types of cancers. However, for many cancers, there is still a lack of effective treatment that can result in long-term cancer-free survival and lower metastatic and relapse risks. The emergence of cancer resistance could be minimized by drug combination or by multi-targeting of tumor cells. Polyclonal antibodies can target several tumor-associated antigens simultaneously and would be more efficient than a conventional mAbs. Here we evaluate the safety and efficacy of XON7, a first in class glyco-humanized polyclonal antibody (GH-pAb), in cancer preclinical models.
Material and Methods: XON7 ability to induce Complement Dependent Cytotoxicity (CDC) and apoptosis was tested in a panel of cancer cell lines and PBMC. XON7 was also evaluated in sphere formation assay to predict its effects on cancer resistant. Specific binding to human tumors and healthy tissues was assessed by immunochemistry on tissue micro-array. Cross-cancer activity was evaluated on biopsies from patients with solid tumor such as CRC, NSCLC, osteosarcoma, and breast cancers. In vivo XON7 efficacy was evaluated in NMRI nude mice using A549: NSCLC, HCT-116: colon cancer, LNCaP: prostate cancer and MDA-MB-231: breast cancer cells. A human NSCLC chorio-allantoic membrane (CAM) model was used to evaluate the efficacy of XON7 + anti PD-1 on tumor growth and metastasis. Pharmacokinetics and safety of this drug were assessed in marmoset after single and repeated IV dosing up to 60mg/kg.
Results: XON7 showed a potent in vitro antitumor activity in a panel of cancer cell lines, it induced specific tumor cell CDC (EC50=50ug/mL) and apoptosis (IC50= 100ug/mL). it was able to kill up to 100% of the cancer cells without affecting PBMC. In addition, it induced a striking decrease of tumor sphere formation in HCT116, A549 and MDA-MB-231 cancer cell lines. XON7 showed preferential recognition of tumor cells as compared to normal cells, it demonstrated cross-reaction to tumor patient biopsy without staining of the healthy tissues. In vitro XON7 potency was translated into in vivo efficacy in different mice xenograft models. XON7 induced a significant reduction of tumor growth ranging from 40 to 90% across several tested tumors. Furthermore, it showed, significant increase of anti-tumor response rate and decrease of metastasis when it is associated with anti PD-1 in vivo CAM model (>90%, p=0.001). XON7 was also characterized by high tolerance and satisfactory exposure in marmoset.
Conclusion: Based on its safe toxicity profile and potent activity, XON7 appeared as a novel and promising cancer immunotherapy to fight against recurrent solid tumor, it is now aimed to reach clinical development, FIH in patients is planned to start before the end of 2023.

#2739 XON27, a novel and potent immunotherapy against hematologic malignancies.

C. Ciron, P. Morice, F. Shneiker, O. Duvaux, **F. Bassissi**;
Xenothera, Nantes, France

Background: Over the past decades, intensive research has led to the development of innovative therapies (monoclonal and bispecific antibodies, CAR T cells) that have increased the survival rate of patients with multiple myeloma (MM) and B cell lymphoma. However, despite this progress, the majority of patients relapse and become refractory due to the development of resistance. Polyclonal antibodies, with their ability to target multiple antigens, can counteract this resistance. Here we evaluate the safety and efficacy of XON27, a first-in-class glyco-humanized polyclonal antibody (GH-pAb), in MM and other blood cancers.
Material and Methods: The ability of XON27 to induce antibody-dependent cellular phagocytosis (ADCP), complement-dependent cytotoxicity (CDC) and apoptosis was tested in a panel of hematological malignancy cells and peripheral blood mononuclear cells (PBMC). Specific binding to human blood cancers was assessed using tissue microarrays. To study resistance mechanisms, MM cell lines were cocultured with macrophages in the presence or absence of XON27 and macrophage. To study relapse mechanisms and tumorigenicity, repeated in vitro administration of XON27 was evaluated in KMS-12-BM. The in vivo efficacy of XON27 was evaluated in KMS-12-BM NMRI nude mice model. Pharmacokinetics and safety of this drug were assessed in non-human primate after repeated IV dosing up to 60mg/kg.Results: XON27 induces potent and specific cytotoxicity in several blood malignancy cell lines including human MM cells via multiple mechanisms: CDC (EC50=35.84 ug/ml), apoptosis (IC50=100 ug/ml) and ADCP (up to 40% of cell death at 50 ug/ml). The cytotoxicity induced by XON27 in the KMS-12-BM was significantly more potent compared to daratumumab (anti-CD38) in both CDC and apoptosis assays, XON27 was able to kill up to 100% of cancer cells without affecting PBMC. XON27 showed cross-reactivity with blood cancer patient biopsies without staining healthy tissue. In addition, repeated administrations of XON27 demonstrate its ability to effectively kill tumor cells after each administration. No resistance is induced after repeated treatments. Interestingly, XON27 blocked the proliferation of residual tumor cells for up to 45 days after the second treatment at 50 ug/ml compared to the control condition, demonstrating sustainable effect of XON27 on tumorigenicity. The in vitro efficacy of XON27 was translated into in vivo efficacy in a murine MM xenograft model. It induced a significant reduction in tumor growth of up to 75%. XON27 was also characterized by a high tolerability profile and satisfactory exposure in primates.
Conclusion: Although many therapeutic advances have been made in the field of blood cancers, myeloma remains an incurable disease with a real need for new innovative therapies. XON27 represents a promising and selective immunotherapy which may provide an effective and safe treatment against refractory myeloma.

TUMOR BIOLOGY: Biomarkers and Expression Differences in Metastatic Progression
Poster Session

#2743 Molecular characterization and prognostic evaluation of disseminated cancer cell subpopulations detected in bone marrow of non-small cell lung cancer patients.

Daniel Spitzl[1], Tobias Mederer[1], Julius Zank[1], Severin Gutter[1], Michael Ried[2], Hans-Stefan Hofmann[3], Christoph A. Klein[1]

[1]Chair of Experimental Medicine and Therapy Research, University of Regensburg, Regensburg, Germany,[2]Department of Thoracic Surgery, University Hospital Regensburg, Regensburg, Germany,[3]Department of Thoracic Surgery, Krankenhaus Barmherzige Bruder Regensburg, Regensburg, Germany

Introduction: Disseminated cancer cells (DCC) can be detected years before metastatic manifestation in bone marrow of lung cancer patients. Although a consensus protocol has been established, the impact of markers and methods for DCC detection are still not settled. We recently found that $EpCAM^{\pm}$ DCC detected by immunofluorescence (IF) outperform the classical immunocytologic (IC) detection by cytokeratin (CK) antibodies regarding prognostic impact. However, it remained unclear whether this difference resulted from biological traits associated with $EpCAM^{\pm}$ *vs* $CK^{\pm}$ DCC or from methodological reasons. We therefore performed a side-by-side comparison of IC *vs* IF for CK and EpCAM.

Methods: We prospectively collected bone marrow (BM) aspirates from 56 non-metastasized NSCLC patients that underwent tumor resection with curative intention. After density gradient centrifugation, we analyzed the mononucleated cells by (i) IC using the anti-CK antibody A45-B/B3 and (ii) by IF using the anti-CK antibody A45-B/B3 and the anti-EpCAM antibody HEA-125. IF signals were captured and objectively quantified using ImageJ, whereas IC was evaluated by two independent observers. Marker-positive cells were isolated and subjected to Whole Genome Amplification (WGA) and whole genome sequencing for assessment of copy number alterations (CNA). Survival analysis was performed for progression-free survival (PFS), tumor-specific survival (TSS) and overall-survival (OS) after a median follow-up time of 72.5, 78.7, 78.7 months, respectively.

Results: IC and IF revealed the presence of $CK^{\pm}$ DCCs in 37.5% and 41.1% of cases, respectively (P=0.34). IF identified $EpCAM^{\pm}$ DCCs in 55.4% of patients, resulting in a 63.8% DCC-positivity rate found by IF, when combined with CK. The average number of DCCs per million MNC, the DCC density (DCCD), was 0.92, 0.93 and 1.44 for CK_{IC} and CK_{IF} and for $EpCAM_{IF}$, respectively. No association was found between $CK_{IC}^{\pm}$ DCCs and PFS, TSS or OS. In contrast, detection of $EpCAM_{IF}^{\pm}$ and/or $CK_{IF}^{\pm}$ DCCs showed a trend towards reduced PFS (P=0.055), TSS (P=0.225) and OS (P=0.155). Subgroup analysis revealed that both $EpCAM_{IF}^{\pm}$ and $CK_{IF}^{\pm}$ cells were correlated with worse PFS (P=0.016 and P=0.040, respectively) and TSS (P=0.033 and P=0.008, respectively). CK_{IF}-positivity was also associated with worse OS (P=0.014), whereas EpCAM was not. $CK_{IF}^{\pm}$ DCCs remained an independent prognostic variable for TSS and OS upon multivariate testing (hazard ratio: 6.45 and 3.31, respectively), while $EpCAM_{IF}^{\pm}$ was not. The IF-marker-defined cell phenotypes exhibited comparable frequencies and distributions of CNAs across the entire genome (~50% of cells).

Conclusions: Detection of $CK^{\pm}$ DCC by quantified IF analysis apparently outperforms CK detection by IC in survival analysis. The impact of CK and EpCAM expression levels on outcome are under investigation.

#2744 Exploring the role of the MSLN/MUC16 interaction in cancer progression via the in situ proximity ligation technique.

S. Bodbin, **D. Raykova**, A. Zieba-Wicher;
Navinci Diagnostics AB, Uppsala, Sweden

Introduction: Mesothelin (MSLN) is a glycoprotein present on the surface of mesothelial cells, sometimes used as a tumor marker. Its overexpression in various cancers, including mesothelioma, ovarian, pancreatic, and lung, is linked to increased tumor aggressiveness, evasion of apoptosis, metastasis, and resistance to treatments. Mucin16 (MUC16) belongs to a family of proteins that play a crucial role in cell adhesion, signaling, and immune responses. In cancer, alterations in mucin expression and structure may contribute to tumor progression and metastasis by enhancing cell survival and immune evasion. Mesothelin is known to interact with mucins, influencing tumor cell behavior and metastatic potential. More specifically, the MSLN/MUC16 interaction facilitates tumor cell invasion and peritoneal spread in ovarian cancer. However, reliable molecular tools to study protein interactions have been scarce. Here, we relied on the Naveni® *in situ* proximity ligation technology to identify MSLN/MUC16 in various cancer samples. The method detects proteins located within interaction range (<40 nm) by means of antibodies conjugated to oligonucleotides that create amplified fluorescent signal. Since the technique does not compromise the structural integrity of tissues, communication between proteins can be studied in their native environment.

Materials & Methods: Human FFPE tissue microarrays (TMA) with ovarian primary carcinoma and matched metastatic cancer (80 cores) and ovarian cancer tissue with normal tissue (100 cores) were deparaffinized and subjected to standard heat-induced antigen retrieval and blocking. Staining against the MSLN/MUC16 interaction was performed with the NaveniFlex Tissue MR Atto647N kit (Navinci Diagnostics). Co-staining antibodies against pan-Cytokeratin and Ki67 were included in the detection mix. Immunofluorescence (IF), using the same MSLN and MUC1 primary antibodies, was completed on an additional slide of each TMA, and then secondary antibodies conjugated to Alexa Fluor™ 488 and 594 were used for detection. Imaging was performed on an Olympus scanner VS200.

Results & Discussion: In this study, we showed that the interaction is abundant in ovarian cancer, with a distinguishable difference in the signal presence between cancerous and normal adjacent tissue. Furthermore, the additional tumor marker co-stainings give insights into the tumor invasion and growth. When comparing the Naveni® signal of MSLN/MUC16 against IF staining of each, the Naveni® signal shows true interactions, as opposed to expression patterns. Understanding the roles of mesothelin and mucin in cancer, both individually and in interaction, is crucial for developing targeted therapies and diagnostic tools. Further research on their interaction and specific molecular pathways triggered by it is essential for devising effective strategies to combat cancer progression.

#2745 Sequential tracking of PD-L1 expression on circulating epithelial tumor cells (CETCs) in men with primary non-metastatic prostate cancer.

D. Schott, M. Pizon, U. Pachmann, K. Pachmann, M. Maurer;
Laboratory Dr. Pachmann, Bayreuth, Germany

Background: Radiotherapy (RT) is an essential component of multimodality therapy in the primary or postoperative treatment of prostate cancer with curative intent by preventing local recurrence and distant metastases, indicating its impact on residual occult tumor, such as circulating tumor cells. Immunogenic changes in cancer cells induced by RT can lead to adaptive up-regulation of PD-L1 expression. As immune checkpoint inhibition plays an increasingly important role in prostate cancer, radiogenic PD-L1 upregulation may be of therapeutic importance. The aim of this study was to determine PD-L1 status on CETCs before and during RT.

Methods: Peripheral blood samples were collected from 52 primary non-metastatic prostate cancer patients. CETCs were enumerated and analyzed for PDL-L1 expression prior to (baseline), 3 and 6 weeks after the start of RT using fluorescence scanning microscopy.

Results: PD-L1 expression was detectable in CETCs and localized in the membrane and/or cytoplasm. We found a correlation between PD-L1 status in CETCs and aggressiveness of cancer disease prior to RT. The frequency of PD-L1 positive CETCs depended on the grading and Gleason score of the primary tumor. Patients with a high Gleason score and G3 tumors had significantly more PD-L1 positive CETCs compared to patients with a low Gleason Score and G1 tumors. Moreover, patients in stage I/II had significantly less PD-L1 positive CETCs compared to patients in stage III/IV (mean 54.25 vs. mean 69.65; $p<0.05$). A higher number of PD-L1 positive CETCs were detected in patients who had radical prostatectomy before start of RT than in those who had no surgical intervention (mean 66.24 vs. mean 47.46; $p<0.01$). Interestingly, the fraction of PD-L1 positive CETCs decreased significantly during RT only in patients with G3 tumors and a high Gleason Score.

Conclusion: Our results indicated that PD-L1 in CETCs is closely related to the aggressiveness of the primary tumor and may be a co-factor associated with the progression of prostate cancer. PD-1/PD-L1 blockade combined with RT represents a novel and promising treatment strategy that could contribute to improve the treatment efficacy of prostate cancer.

#2746 MAGE-A3 co-expression with IDH1-R132H and IL-1β in colon cancer.

Andy /Xi Han[1], Rachel Gonzalez[1], Jina Yom[1], Zhaoying Guo[1], Bailey Gilmore[1], Eden Zewdu[1], Tianli Qu[1], Hailey /YiChen Guo[1], Qi Ren[2], Xiaomin Hu[2], Ranran Zhang[2], Zhaohui Wu[2], Xuan Liu[1], Wei Fu[1]

[1]OriGene Technologies, Inc., Rockville, MD,[2]OriGene Wuxi Biotechnology Co., Ltd., Binhu District Wuxi, China

Colorectal cancer (CRC) remains a significant cause of cancer death worldwide with an estimated 52,000 deaths in 2023. Over the past few decades, the incidence rate of CRC in individuals younger than 50 has been steadily increasing. Currently, diagnostic biomarkers play an important role in the detection and treatment of CRC. MAGE-A3 has been shown to be expressed in many tumor types, including colon cancer by RNA expression. Due to their high sequence homology, members of the MAGEA family have been difficult to evaluate and screen for their protein expression. However, in a previous study, highly specific antibodies were identified using CytoSections for MAGE-A3 immunohistochemistry. IL-1β is a cytokine that induces inflammatory responses and when localized to the nucleus in colon cancer cells it can promote stemness. IL-1β expression has been shown to be increased in wildtype IDH1 positive glioblastoma. However, the relationship between IL-1β and IDH1 has not been studied in colon cancer. In this study, the difference in the expression of MAGE-A3, IL-1β, and wildtype IDH1 compared to mutant IDH1-R132H in colon cancer tissues was evaluated. The results show that IL-1β, wildtype IDH1, and MAGE-A3 were co-expressed in 27 of the 38 colon cancer tumors. However, IDH1-R132H expression was only seen in 20% of the tumors. This study suggests that MAGE-A3, IL-1β, and IDH1 are candidate biomarkers for immunotherapy due to their high expression in colon cancer tissues.

#2747 Chaperonin-containing TCP-1 promotes the release of exosomes from prostate and breast cancer cells.

A. R. Khaled[1], L. Truong[1], C. Frank[1], C. Dang[1], J. Velazquez[1], P. Gopalan[2], S. Litherland[1];
[1]University of Central Florida, Orlando, FL, [2]Orlando VA Healthcare System, Orlando, FL

Coping with cancer recurrence and assessing metastatic risk are challenges for cancer patients that could be addressed with an effective diagnostic predictor. Exosomes, a subpopulation of extracellular vesicles released by tumor cells, can promote distal metastatic site development and could have promising diagnostic applications. However, the mechanisms controlling exosome secretion by cancer cells remain to be determined, which impedes clinical development. The actions of protein-folding chaperones could facilitate tumor exosome formation, payload loading, and extracellular release. Protein folding complexes link the expression of tumor-promoting oncogenes with the proteins driving oncogenic cancer behavior. Of these, the eukaryotic type II chaperonin, Chaperonin-Containing TCP-1 (CCT), folds many of the oncoproteins (e.g., KRAS, MYC, CDKs, STAT3, etc.) responsible for cancer growth and invasion. CCT is a complex machine composed of eight subunits, each encoded by a unique gene (cct1-8), which folds proteins in an ATP-dependent fashion. We and others showed that CCT is upregulated in breast, lung, and prostate cancer cells as well as neuroblastoma, leading to alterations in apoptosis, migration, cell morphology, and proliferation. Using T47D breast cancer and PC3 and 22rV1 prostate cancer cells, we exogenously expressed or depleted the second subunit of the CCT complex (CCT2). With these cells, we isolated exosomes from culture media by membrane-based affinity binding and examined exosomal RNA and protein content. In exosomes from prostate and breast cancer cells, we found abundant CCT2 subunit mRNA and protein in CD63+ exosomes ranging from 50 to 120 microns in size. When CCT2 was exogenously expressed in breast and prostate cancer cells, CCT2 mRNA and protein were higher in exosomes than other CCT subunits, and CCT2 was randomly distributed throughout the size range of exosomes. Of interest, an increase in CD63+ small exosomes (50-75 microns) was evident in cancer cells exogenously expressing CCT2 compared to mock-transfected and parental controls, suggesting a role for CCT2 in the exosomal secretory pathway. FACS-sorted CD63+ exosomes subjected to mass spectrometry yielded distinct protein content based on CCT2 expression. These findings are the first report of CCT2 driving exosome secretion in cancer cells and suggest that exosomes containing CCT2 RNA and protein are associated with metastatic potential. Exosomal CCT2 thus represents a promising diagnostic indicator for a liquid biopsy approach to monitor cancer recurrence and metastasis.

#2748 Single cell biomechanical profiling of the metastatic potential of MDA-MB-231 cells.

Zeina Habli[1], Ahmad Zantout[2], Nadine Al Hajj[3], Raya Saab[4], Marwan El-Sabban[3], Massoud L. Khraiche[1]

[1]Neural Engineering and Nanobiosensors Group, Biomedical Engineering Program, American University of Beirut, Beirut, Lebanon,[2]Biomedical Engineering Program, American University of Beirut, Beirut, Lebanon,[3]Department of Anatomy, Cell Biology, and Physiological Sciences, Faculty of Medicine, American University of Beirut, Beirut, Lebanon,[4]Department of Pediatrics, Stanford, Palo Alto, CA

Cancer metastasis is a multistep complex process accompanied by changes in the mechanical properties of cancer cells, such as adhesion, viscoelasticity, deformability, and motility. Connexin 43 (Cx43), a gap junction protein with a putative tumor suppressor function, plays a pivotal role in Epithelial to Mesenchymal transition (EMT). It affects cell motility indicators and promotes cytoskeleton reorganization and, ultimately, metastasis when downregulated, corroborating resistance to chemotherapy. The lack of universal markers that can predict the metastatic ability of cancer cells necessitates the evaluation of parameters, such as cell adhesion, viscoelasticity, and stiffness, to serve as unique biophysical metrics that predict cancer cell metastatic potential and elucidate how metastasis and cell mechanics are coupled. Therefore, we utilized fluidic-based single-cell force spectroscopy (SCFS) and Quartz Crystal Microbalance with Dissipation Monitoring (QCM-D) to measure the mechanical properties of single cancer cells with different metastatic potential. To explore the relationship between cell mechanics and metastatic cell behavior, we quantitatively demonstrate the progression of cancer cell biomechanics across different metastatic states using MDA-MB-231 breast cancer cells with varying connexin 43 (Cx43) expression as a model of cells with varying metastatic potential. We measured, at a single-cell level and in real-time, the adhesion and viscoelastic properties of MDA-MB-231 cells and their response to chemotherapy. Our data show that cells with higher metastatic potential (down-regulated Cx43 expression) exhibited a softer, less adherent, and more viscoelastic phenotype, consistent with their metastatic state when in clusters compared to cells at the lower spectrum of metastatic potential (up-regulated Cx43 expression). These mechanical biomarkers are significantly absent in single cells outside of a cluster. Of particular interest, we also observed significant cellular stiffening upon treatment with docetaxel (DTX), a chemotherapeutic agent that targets microtubules, with a rapid and profound response of highly aggressive cells when compared to cells with attenuated metastatic potential. Such treatment schemes could render cancer cells less deformable, potentially impeding their ability to invade and metastasize to other tissues. Our study demonstrates a unique quantitative metric that unfolds biomechanical markers for discerning the metastatic state of cancer cells. Our data represents a stepping stone to understanding how mechanical changes in cancer cells may determine how cancer progresses and responds to chemotherapeutic agents and may provide novel modalities to inhibit metastasis.

#2749 DHX36 may promote the growth and metastasis of lung cancer.

T. Li, N. Luo, J. Fu, C. Wei, **J. Fu**;
Southwest Medical University, Luzhou, China

Introduction: Helicase is a kind of protein molecular motor that widely exists in eukaryotic cells, viruses and bacterial cells, and participates in DNA replication, transcription and other life activities. DHX36, a kind of helicase, is a new homologous gene of human DNA/RNA helicase cloned by our laboratory by homologous molecular cloning which used the sequence of the maleless gene (mle) of Drosophila. Studies have shown that DHX36 upregulates the expression of proto oncogene and promotes the occurrence of cancer. At present, there are few studies on DHX36 in lung cancer. This study aims to clarify the relationship between DHX36 and lung cancer and provide a new molecular target for the diagnosis, treatment and prognosis of lung cancer.
Methods: Twenty-eight pairs of clinical tumor samples from lung adenocarcinoma and adjacent tissues were collected, and the protein expression of DHX36 in different tissues was detected by western blot. Correlation between DHX36 expression and survival prognosis of lung cancer patients was analyzed by online database. Over-expression of DHX36 in A549 and H460 cells and knockdown of DHX36 in A549 and H1975 cell lines, then the migration, invasion and growth index of cells were analyzed by real-time cell analyzer. After DHX36 stable knock-down cell line was established in H1975 cells, they were injected into nude mice by subcutaneous injection and tail vein injection respectively at the same time as the control cells, and the growth of subcutaneous tumors and the metastasis of lung tissues in nude mice were recorded and collected respectively. The tissues were analyzed by histology, immunohistochemistry, and western blot.
Results: In 28 pairs of clinical lung cancer tumor samples, we found that DHX36 was higher in cancer tissues than in adjacent tissues in 23 pairs, which indicated that DHX36 might be a kind of proto oncogene to promote the occurrence and development of lung cancer. Bioinformatics analysis revealed that the high expression of DHX36 was related to the low survival of lung cancer patients. The results of RTCA showed that the abilities of growth, invasion and migration of cells in the over-expressed DHX36 groups were higher than those in the control groups. After DHX36 was knocked down, the growth, invasion and invasion of lung cancer cells were inhibited.
Conclusion: DHX36 is expected to be a new molecular target of lung cancer. Next, we will knock out DHX36 in lung cancer cells to observe the tumor growth and lung metastasis in mice.

#2750 Leveraging machine-learning approaches to dissect drivers of clinical metastatic dynamics in lung adenocarcinoma.

Tyler Aprati[1], Michael Manos[1], Giuseppe Tarantino[1], Marc Glettig[1], Maryclare Griffin[2], Alexander Gusev[1], Kenneth Kehl[1], David Liu[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]University of Massachusetts Amherst, Amherst, MA

Background: Non-small cell lung cancer (NSCLC) survival is closely linked to metastatic progression. 5-year survival rates drop from >65% when localized to ~9% when distant metastases occur. Despite this impact on mortality, drivers of overall metastasis and site-specific organotropism are not well understood in NSCLC. To investigate these questions, we focused on Lung adenocarcinoma (LUAD), the most common subtype of NSCLC. Although previous efforts have been made to examine LUAD organotropism, we sought to expand upon longitudinal modeling approaches and explore associations in an independent large clinical and genomic annotated cohort.

Methods: Using the artificial intelligence model from (Kehl et al. 2021), we annotated a clinico-genomic cohort of 2777 patients with lung adenocarcinoma, resulting in 59,177 annotated imaging reports. This resulted in time to metastatic site annotations for each patient, with median of 2 years follow up. Metastatic sites included brain, bone, adrenal, liver, lymph node, and mesentery. All patients were evaluated at the Dana-Farber Cancer Institute, and each patient had at least one tumor biopsy sequenced with targeted panel sequencing of 400+ cancer related genes. To infer genomic and clinical correlates of site-specific metastasis, we performed cause-specific and Fine-Gray hazard modeling in this cohort. We used the recurrent event Andersen-Gill model to infer predictors of longitudinal metastasis rates.

Results: Site-specific analyses yielded genes whose mutant status were significantly associated with a change in risk and/or rate of certain metastatic sites. We found that NOTCH1 is significantly associated with an increased rate and risk of brain metastases (HR=2.46, P<0.001). SETD2 is associated with decreased incidence of brain (HR=0.42, P<0.001). SMARCA4 is significantly associated with increased incidence and rate of adrenal metastasis (HR=1.64, P<0.01), while NF1 is significantly associated with decreased rate of adrenal metastasis (HR=0.72, P<0.01). In a multivariable model, Female patients and younger patients had a lower rate of new metastatic sites. As previously seen, TP53 and SMARCA4 mutations associated with higher rates of new metastatic sites (HR=1.17, P<0.001; HR=1.36, P<0.001 respectively), and SETD2 is associated with a lower rate of new metastatic sites (HR=0.71, P<0.001).

Conclusions: By using time-to-event analysis with longitudinal metastatic annotations, we identify potential drivers of overall metastasis and site-specific organotropism in LUAD patients. Identification of new associations and concordance of our results with previous studies also supports the utility of artificial-intelligence-annotated datasets, allowing for larger cohorts without the need for manual annotation.

#2751 Functional assessment of STK11 C-terminal domain variants.

G. Nandagopal, S. Lenahan, H. Ross, H. Sarausky, D. Seward, P. Deming;
University of Vermont, Burlington, VT

STK11 mutations in KRAS-driven lung adenocarcinomas (LUADs) are associated with aggressive tumor phenotypes characterized by increased risk of metastasis and lower overall and progression free survival. STK11 is a serine-threonine kinase that is comprised of an N-terminal domain containing a nuclear localization signal, a kinase domain, and a C-terminal domain (CTD). In LUAD, STK11 loss of function impacts many aspects of coordinated cell motility and promotes alterations characteristic of metastasis including cell polarity and adhesion. Both kinase activity and subcellular localization are important for STK11 tumor suppressor function. Our objective was to develop a reliable method to identify pathogenic STK11 mutations. Using archival data from the University of Vermont Medical Center, we identified 28 STK11 missense variants that had not yet been functionally characterized. We evaluated the functional impact of these variants on STK11 kinase activity through detection of autophosphorylation using an in-vitro kinase assay, as well as their ability to induce p53 activity through a luciferase reporter. Of the variants studied, 5 were CTD mutations. These variants retained kinase activity and the ability to bind STK11's partners STRAD-alpha and MO25 in co-immunoprecipitation assays. Although the CTD of STK11 has no catalytic activity, it is thought to be integral for translocation to the cytoplasm where it can colocalize with actin and the cell membrane. STK11 dependent regulation of directional migration requires both proper localization to the actin cytoskeleton and kinase activity. Moreover, it has been reported that the C-terminal polybasic motif of STK11 (aa403-426), consisting of 3 Lysine and 5 Arginine residues is key for its localization and activation of AMPK at the plasma membrane. Therefore, when ascertaining functional status of STK11 in vivo, it is important to consider kinase independent STK11 functions. In LUAD cell lines, we show through immunofluorescent microscopy that expression of a truncated construct encoding STK11 with a CTD deletion results in nuclear sequestration. Additionally, point mutants in 3 of the polybasic motif residues (R409W, K416E and K423E) retain kinase activity and STRAD-alpha binding, but also lead to nuclear sequestration - highlighting the importance of a multipronged approach when assessing STK11 function. Future studies will assess the ability of these C-terminal domain mutants to phosphorylate cytoplasmic substrates, and their impact on cell migration and invasion. Additionally, we will utilize the TurboID proximity ligation system to assess the effect of C-terminal domain point mutations on binding partner accessibility.

#2752 ICA1 promotes prostate cancer progression and metastasis via AR down-regulation.

F. Wang, Y. He, X. Huang, M. Chang, X. Zhang, X. Li, X. Ye, **Y. Lu**;
Southern University of Science and Technology, China, Shenzhen, China

Cancer metastasis, one of the main characteristics in malignancy, contributes to high mortality in cancer patients. Prostate cancer (PCa) is the most common cancer among men and the second leading cause of cancer-related death in Europe and the United States. In China, its incidence has been dramatically increased over past years. However, the mechanism of PCa progression and metastasis remains unclear. The androgen receptor (AR) has been demonstrated to play an important role in PCa progression and metastasis. We have previously established mouse models of PCa bone metastasis and PCa lung metastasis. We have obtained cell clones with bone-specific or lung-specific metastatic capability. By transcriptomic analysis of highly metastatic cell clones and their parental cells, we found a gene group including islet cell autoantigen 1 (ICA1) that are highly expressed in both metastatic cell clones. We further compared these results with RNA array data in clinical samples. Data comparison and correlation analysis showed that ICA1 was negatively correlated with AR expression. Survival analysis of PCa and lung cancer patients showed higher expression of ICA1 but with shorter overall survival. Down-regulation of ICA1 expression in highly metastatic tumor cells significantly inhibited cell growth, colony formation, migration, and invasion. ICA1 overexpression in parental RM1 cells apparently increased cell growth, migration, and metastasis. Interestingly, down-regulation of ICA1 also significantly activated AMPK/mTOR signaling pathway. These findings are anticipated to shed light on the novel pathogenic mechanism underlying PCa and propose a compelling theoretical basis for the application of ICA1 in PCa. This work supported by the NSFC projects (81972420, 81972766, 82173336), as well as grants from the Science and Technology Project of Shenzhen (JCYJ20210324104214040, JCYJ20190809161811237).Keywords: prostate cancer, metastasis, ICA1, androgen receptor

#2753 Muc4 is a biomarker of metastasis in TNBC and its downregulation by blocking soluble TNF prevents metastasis in combination with immunotherapy.

F. L. Mauro[1], S. Bruni[1], A. Dupont[2], G. Inurrigarro[2], S. Figurelli[3], S. Barchuk[3], D. Lopez Della Vecchia[3], R. Cordo Russo[1], E. Gil Deza[4], M. Mercogliano[1], R. Schillaci[1];

[1]IBYME-CONICET (Institute of Biology and Experimental Medicine), Buenos Aires, Argentina, [2]Sanatorio Mater Dei, Buenos Aires, Argentina, [3]Hospital Juan A. Fernandez, Buenos Aires, Argentina, [4]Instituto Oncologico Henry Moore, Buenos Aires, Argentina

Triple negative breast cancer (TNBC) accounts for about 10-15% of all breast cancers and has the worst survival rate. Immunotherapy is a new treatment option but resistance is frequent. We have demonstrated that TNF induces trastuzumab resistance through mucin 4 (MUC4) upregulation and it is an independent biomarker of poor response to therapy in HER2+ breast cancer. MUC4 is a transmembrane glycoprotein involved in metastasis (MTS) dissemination. Here, we evaluated the impact of the axis TNF/MUC4 on the invasive capacity of TNBC cell lines and in a preclinical model of spontaneous MTS. Finally, we assessed the clinical impact of MUC4 expression in TNBC patients. TNF blockade was achieved with etanercept (E), which blocks the soluble (sTNF) and transmembrane isoform of TNF, or with the dominant negative protein INB03 (DN) which neutralizes only sTNF. BT-549 and MDA-MB-231 human TNBC cell lines treated with E or DN exhibit a decrease in MUC4 expression. To assess the impact of TNF blockade on tumor cells and its effect on the tumor microenvironment, we collected conditioned media (CM) from MDA-MB-231 and BT-549 cells treated with E or DN which were used to evaluate the invasive capacity of the TNBC cell lines. The invasion of BT-549 and MDA-MB-231 was impaired with CM-Eta ($p \leq 0.01$) and CM-DN ($p \leq 0.01$ and $p \leq 0.05$, respectively). Female BALB/c mice bearing the TNBC LMM3 tumors were treated with IgG, DN, anti-PD-1 antibodies or DN+anti-PD-1 for two weeks. After the treatments we performed surgery to remove the primary tumor and the animals were sacrificed 2 weeks later. No effect on tumor growth was observed. However, the DN+anti-PD-1 group was the only one with less of 3 MTS per lung ($p \leq 0.05$). We obtained tumor extracts and found that the tumors of the animals treated with DN or DN+anti-PD-1 had decreased MUC4 expression measured by Western blot. We determined the presence of TILs by H & E and the expression of MUC4, Ki67, PD-L1 (SP142), androgen receptor (AR) and cytokeratin 5 by immunohistochemistry in a cohort of 56 early TNBC patients. MUC4 expression was inversely correlated with TILs presence ($p=0.0003$). Since TILs are associated with good prognosis, we evaluated the effect of BT-549-CM and MDA-MB-231-CM on T cell migration. CM-DN from both cell lines increased T cell migration compared to control CM ($p \leq 0.01$). MUC4 expression was inversely correlated with Ki67 ($\geq 30\%$, $p=0.036$), PD-L1 ($p=0.001$) and AR ($p=0.047$) in our cohort. Moreover, MUC4 proved to be an independent predictor of poor overall survival ($p=0.02$), and is associated with a higher MTS risk ($p=0.005$). MUC4 is associated with poorly-infiltrated TNBC, and sTNF blockade downregulates its expression decreasing MTS when combined with anti-PD-1. We propose the TNF as a new target for the treatment of TNBC, and MUC4 as a predictive biomarker to guide a combined treatment of TNF blockers with immunotherapy.

#2754 Uncovering the role of TEADs in treatment induced small cell or neuroendocrine prostate cancer.

L. G. Brown[1], I. M. Coleman[2], T. L. H. Chu[2], D. W. Lin[1], J. K. Lee[2], E. Sayar[2], L. D. True[1], R. Dumpit[2], E. Corey[1], P. S. Nelson[2], M. C. Haffner[2], **C. Morrissey**[1]; [1]University of Washington, Seattle, WA, [2]Fred Hutchinson Cancer Center, Seattle, WA

Study Purpose: Determine the role of the transcription factor TEAD1 in promoting the neuroendocrine phenotype in castration-resistant prostate cancer (CRPC).
Experimental Procedures: We quantitated YAP-pathway associated transcripts, protein abundance, and splicing events in androgen receptor (AR) positive prostate adenocarcinoma (ARPC) and small cell or neuroendocrine prostate cancer (SCNPC) using RNAseq, scRNAseq, qPCR, immunohistochemistry (IHC), CpG methylation, and western blot analyses on patient samples, patient-derived xenograft (PDX) models, and cell lines. In addition, we tested the impact of the pharmacological inhibition and knockdown of proteins and genes associated with TEAD1 activity in ARPC and SCNPC cell lines on TEAD1 expression, cell number, and tumor cell differentiation.
Results: Transcriptomic analyses revealed a decrease in YAP1, TAZ, LATS2, and TEAD2 and an increase in LATS1, TEAD1 and RBFOX2 transcript levels in SCNPCs compared to ARPCs in SU2C, rapid autopsy metastases, and PDX models. Similar results were observed in ARPC and SCNPC cancer cell lines, in the transplantable LTL331 prostate cancer transdifferentiation model, and scRNAseq of liver CRPC metastases from patients. The decrease in YAP1, TEAD2 and LATS2 expression correlates with increased methylation and the increase in TEAD1 correlates with decreased methylation in SCNPC PDX models, suggesting epigenetic control. The changes in YAP and YAP-associated proteins (most importantly TEAD1) at the epigenetic and transcriptional level were confirmed by IHC analysis comparing ARPC to SCNPC PDX models. Of the four TEAD proteins, TEAD1 expression was increased, with a concomitant decrease in TEAD2 and TEAD3, whereas low levels of TEAD4 transcript are maintained in the SCNPC phenotype. Notably, RBFOX2 was increased in the SCNPC datasets. RBFOX2 is a pre-RNA splicing regulator that promotes the inclusion of exon 6 in TEAD1 mRNAs associated with increased TEAD1 activity. The RBFOX2 spliced TEAD1 was observed in the SCNPC PDX models, while not detected in the ARPC PDX models.
Conclusions: The conversion of ARPC to SCNPC involves the loss of transcriptional regulators: AR, YAP, and REST inactivation in SCNPC. It also involves the expression of ASCL1 or NEUROD1, well described master regulators that are implicated in the conversion to and maintenance of the SCNPC phenotype. Our work suggests TEAD1 is another transcriptional regulator in SCNPC that warrants further investigation.

#2755 Characterizing breast cancer cells following immune pruning in mice.

S. McElduff, D. Bronder, M. Duran, S. Bakhoum;
Memorial Sloan Kettering Cancer Center, New York, NY

In cancer patients, metastasis is the leading cause of death. Indeed, primary tumors which are diagnosed early and treated in a timely manner have the highest rate of success. In contrast, metastatic disease and late diagnosis of tumors portend poor outcomes. Thus, understanding the underlying biology and developing novel therapeutic approaches for metastatic cancers is pivotal. Most cancer-based mutational characteristics are tissue-dependent, and cancers with higher mutational load are generally more susceptible to immunotherapy. We observed that poorly metastatic, murine breast cancer cells established a clear phenotypic difference in lung metastasis formation assays. Upon injection of these cells into immune-proficient mice, few, large metastases developed, whereas in immuno-deficient mice, many small metastases grew instead. To determine the molecular features which enable escape under immune editing, we designed the following workflow. We intravenously injected immune-proficient and immune-deficient mice with our poorly metastatic, murine breast cancer cells. As expected, cells readily engrafted in the lungs, causing a significant reduction in survival of immune-deficient mice. Furthermore, liver metastases were observed only in immune-deficient mice. Upon euthanasia, we resected and dissociated both organs. To isolate the tumor cells from these samples, we flow-sorted and subjected them to next-generation sequencing. To elucidate the epigenomic, genomic, and transcriptomic differences between metastases of each background, we performed ATAC, WGS, and RNAseq, respectively. By dissecting the evolutionary mechanisms which allow cancer cells to evade immune detection in metastasis, we can develop targeted immunotherapy strategies to diminish the spread (and lethality) of metastatic cancers. In the future, we plan to examine the descriptive discrepancies between the tissues reared with and without immune pruning in order to put forward innovative therapeutic strategies.

#2756 Single cell analysis reveals treatment response-associated plastic cell state and lineage switching in aggressive variant prostate cancer.

Shuai Guo[1], Elavarasan Subramani[2], Daniel E. Frigo[2], Patrick G. Pilie[3], Sangeeta Goswami[3], Rama Soundararajan[4], Ana Aparicio[3], Wenyi Wang[1]

[1]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Cancer Systems Imaging, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Department of Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX

Prostate cancer (PCa) is a common malignancy in men over 65, ranking as the second leading cause of cancer-related deaths among men in the United States. While most prostate cancers respond to androgen receptor (AR) targeting therapies, Aggressive Variant Prostate Cancers (AVPCs), characterized by RB1, Tp53, and/or PTEN alterations, do not. AVPCs exhibit lineage plasticity in preclinical models, enabling the expression of non-prostate epithelial lineage markers to adapt to therapeutic pressures. However, a measurable definition of lineage plasticity as a potential therapeutic target for clinical trials is currently lacking. To arrive at said definition, we perform single-nuclei RNA sequencing (snRNA-seq) on lymph node metastases from twelve AVPC patients with matched sample pairs of both pre- and post-treatment. Additionally, we include snRNA-seq data from eight non-AVPC patients as a baseline. Expanding upon our prior establishment of tumor-specific total mRNA expression (TmS) as an indicator of tumor cell lineage plasticity (*Nature Biotechnology*, PMID: 35697807), we employ unique molecular identifier (UMI) counts from individual cells to quantify this plasticity. We reveal a distinct cluster of tumor cells with notably high UMI counts in resistant samples, indicative of a less differentiated state and increased transcriptional diversity. This high-UMI cluster is marked by significant enrichment in pathways associated with epithelial-mesenchymal transition (EMT), stemness, one-carbon metabolism, and arginine metabolism pathways. Concurrently, there is a reduction in activity within the androgen receptor (AR) and DNA damage repair pathways. These characteristics suggest an enhanced capacity for lineage switching in AVPC tumor cells, potentially contributing to evasion from targeted therapies. Moreover, immune components within resistant samples consistently display lower UMI counts, indicating a diminished propensity for lineage plasticity. In conclusion, we present a better understanding of lineage switching in therapeutic resistance in AVPCs, paving the way for novel treatment strategies in PCa management.

#2757 Investigating regulatory drivers of prostate cancer metastasis in circulating tumor cells.

A. Zheng[1], A. Obradovic[2], K. Ronaldson-Bouchard[1], G. Vunjak-Novakovic[1], A. Califano[2], P. A. Sims[2], C. Abate-Shen[2], A. Giacobbe[2];
[1]Columbia University, New York, NY, [2]Columbia University Irving Medical Center, New York, NY

Prostate cancer is the most common cancer in men and the second-leading cause of death. Most prostate cancer deaths are due to metastasis, particularly to the bone. Metastasis occurs when cells from the primary tumor travel through the blood as circulating tumor cells (CTCs) and settle in metastatic sites. CTCs are difficult to collect from patients, and understanding the relationships between CTCs and the tumor phenotypes of origin could reveal mechanisms of cancer metastasis. Hence, we utilized several genetically engineered mouse models (GEMMs) of metastatic prostate cancer to evaluate tumor phenotypes and CTCs. We compared the tumor phenotypes of several GEMMs of metastatic prostate cancer and identified a level of heterogeneity among tumors, particularly focusing on a GEMM that demonstrated severe metastasis, especially to the bone. Next, we analyzed CTCs from this GEMM and focused our analysis on transcriptional states that are regulated by proteins called master regulators (MRs). MRs control the expression of groups of genes called regulons, and pharmacologically inhibiting these MRs may lead to reversal of cancer phenotypes. We hypothesized that these MRs may be mechanistic drivers of CTC cell state in prostate cancer metastasis. We investigated MRs enriched in CTCs from mice and screened and validated Lap2, the lamina-associated polypeptide 2 protein, as a regulatory driver in mice with metastatic prostate cancer. Analysis of bulk RNA-seq profiles from primary and metastatic prostate samples in The Cancer Genome Atlas and Stand Up to Cancer cohorts, respectively, revealed that the regulon-based activity of Lap2 was significantly higher in the latter group. Moreover, analysis of single-cell RNA-seq profiles of CTCs isolated from prostate cancer patients confirmed aberrant Lap2 activity. Finally, the role of Lap2 was assessed in human tissue from an engineered multi-organ-on-a-chip model of metastasis. Silencing of Lap2 production in cells dissociated from mouse CTC-derived organoids inhibited extravasation to the bone in the model, suggesting a critical role for Lap2 in metastasis. Our findings illustrate the unique transcriptional profile of prostate cancer CTCs associated with their metastatic potential. We identified Lap2 as a novel driver of CTC dissemination and metastasis in mice and validated its activity in human prostate cancer, which can aid future therapies to prevent metastatic progression in patients.

#2758 Stemness subtype gastric cancer accelerate hematogenous metastasis.

Seungho Lee[1], Jaeun Yoo[2], Seungbok Lee[3], Hyun Myong Kim[4], Kyoungyun Jeong[4], Yie-Ri Yoo[4], Ji-Yeon Shin[4], Kyoung Un Park[5], Hye Seung Lee[6], Seong-Ho Kong[1], Do Joong Park[1], Hyuk-Joon Lee[1], Han-Kwang Yang[1]

[1]Department of Surgery, Seoul National University Hospital, Jongro-gu, Korea, Republic of,[2]Cancer Research Institute, Seoul National University, Jongro-gu, Korea, Republic of,[3]Department of Genomic Medicine, Seoul National University Hospital, Jongro-gu, Korea, Republic of,[4]Cancer Research Institute, Seoul National University Hospital, Jongro-gu, Korea, Republic of,[5]Department of Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of,[6]Department of Pathology, Seoul National University Hospital, Jongro-gu, Korea, Republic of

Oncogenic progression and metastasis correlate with the acquisition of stem cell-like characteristics and the loss of differentiated phenotype. Poorly differentiated primary tumors often lead to unfavorable oncologic outcomes due to a heightened likelihood of metastasis to distant organs across various cancers. However, the relationship between stemness traits and metastasis in gastric cancer (GC) remains insufficiently explored. In this investigation, we analyzed bulk RNA-sequencing from microdissected primary tumor specimens and clinical data to pinpoint molecular subtypes linked to distant organ metastasis. Transcriptomic data from patient-derived xenograft (PDX) samples and available single-cell RNA datasets validated our bulk RNAseq findings. Comprehensive analysis highlighted the molecular traits of GC tied to hematogenous metastasis. Microdissection of primary tumor FFPE samples facilitated bulk RNA sequencing, encompassing samples from 33 metastatic and 31 metastasis-free patients, with 8 paired normal samples. Most samples contained less than 10% of tumor microenvironment (TME) components like fibroblasts, endothelial cells, and immune cells. Using non-negative matrix factorization (NMF) clustering, we achieved unsupervised subtyping of the gastric cancer gene expression matrix. Permutation tests based on subsampling indicated consistent high-level cophenetic coefficients at k=2, suggesting robust bifurcation of transcriptomic data into two clusters. One showed augmented stemness traits while the other emphasized differentiated mucosal genes, labeled as stemness and differentiated subtypes, respectively. GSEA highlighted a significant boost in the Hallmark angiogenesis score in the stemness subtype, not attributed to endothelial cell infiltration as verified by CIBERSORTx. This subtype also exhibited a marked decrease in hematogenous metastasis-free survival (HMFS) ($p=0.008$, log-rank test). Further, PDX samples were scrutinized. Post classification of the PDX graft expression matrix via logistic regression, we examined the endothelial cell fraction, determined by CIBERSORTx. Stemness subtype PDX grafts revealed a significant elevation in the host (mouse) endothelial cell fraction ($p<0.05$). In addition, stemness PDX patient showed significant decreased HMFS ($p = 0.03$). We also categorized the pseudobulk expression matrix of malignant cells into stemness or differentiated subtypes using GSE183904 scRNA cohort. scRNA sample analysis consistently presented an elevated endothelial cell fraction in the stemness GC subtype. The outcomes suggest a propensity for angiogenesis in the TME of the stemness subtype of GC. In conclusion, our findings demonstrate that the stemness subtype of GC accelerates hematogenous metastasis, as evidenced through clinical data, bulk RNAseq, PDX, and scRNAseq data.

#2759 Transcriptional intra-tumoral heterogeneity of putative therapeutic targets in colorectal cancer peritoneal metastases.

J. J. Zhao[1], J. C. Ong[2], D. K. Chia[3], M. C. Teo[2], Q. Tan[2], G. Ng[2], J. W. Tan[2], H. Ma[4], X. Ong[4], S. Tay[4], P. Tan[4], R. Sundar[1];
[1]National University Cancer Institute, Singapore, Singapore, [2]Division of Surgery and Surgical Oncology, National Cancer Centre Singapore, Singapore, Singapore, [3]University Surgical Cluster, National University Health System, Singapore, Singapore, [4]Duke-NUS Medical School, Singapore, Singapore

Background: The poor prognosis of peritoneal metastasis (PM) in colorectal cancer (CRC) is typically attributed to, and characterized by, resistance to systemic chemotherapy and immunotherapy. The evolutionarily conserved plasma-peritoneal barrier as well as reduced tumor tissue vascularity contributes to poorer responses to systemically administered antineoplastic therapy. Beyond these, we sought to understand transcriptomic variations of important therapeutic targets implicated in peritoneal organotropism and by extension, resistance to systemic regimens in CRC PM.
Methodology: FFPE tissue samples from CRC patients were collected during oncological surgical resection of the synchronous PM (cytoreductive surgery [CRS] with or without hyperthermic intra-peritoneal chemotherapy [HIPEC]), or exploratory laparotomy for palliative surgery, with the majority of patients receiving systemic therapy prior to surgery. Samples were sequenced with whole transcriptomic sequencing. Paired and unpaired T-tests between PT and PM samples were undertaken with log2(fragments per kilobase of exon per million mapped [FPKM]) gene expression values.
Results: Fifty-six (22 primary tumor [PT], 34 peritoneal metastases [PM]) samples from 35 patients, comprising 21 paired PT-PM samples, were included in this analysis. TEAD1 (unpaired T-test, p=0.087; paired T-test, p=0.041), FGFR1 (unpaired T-test, p=0.003; paired T-test, p<0.001), PIK3CA (unpaired T-test, p=0.034; paired T-test, p=0.003), SMAD4 (unpaired T-test, p=0.095; paired T-test, p=0.010), and HAVCR2 (unpaired T-test, p=0.009; paired T-test, p=0.007) were found to be upregulated in the PM. Conversely, MET was found to be downregulated in PM samples (unpaired T-test, p=0.004; paired T-test, p=0.002). There were no significant differences in gene expression profiles of BRAF, RHOA, CD274, CTLA4, PDCD1 and TIGIT between PT-PM (all p>0.05).
Conclusion: Through CRC PT-PM comparisons, we identify potential therapeutic targets implicated in transcoelomic metastasis and provide rationale for development of immunotherapeutic biology and drug discovery for CRC PM. These findings underscore an exigent need to develop intra-peritoneal therapeutic strategies to overcome resistance to systemic regimens.

#2760 Novel GPCR recombinant monoclonal antibodies for cancer biology research.

A. Ball, Y. Hsieh, C. Huang, S. Huang, S. Wu, Y. Chang, J. Liu, P. Peng, C. Lin;
GeneTex, Inc., Irvine, CA

Recombinant technology is becoming the preferred production mechanism for creation of antibody reagents used in academic and clinical cancer biology research. Recombinant antibodies (rAbs) are superior to standard polyclonal and hybridoma-generated monoclonal reagents as they offer reproducible performance and consistent, scalable supply. A major focus of antibody manufacturers is to leverage rAb production strategies to generate antibodies against challenging targets for which there are few, if any, reliable antibodies. G-protein coupled receptors (GPCRs) are encoded by more than 820 human genes and represent the largest membrane protein superfamily in the genome. These seven-pass transmembrane domain receptors are involved in a multitude of physiological and pathophysiological processes related to various chronic diseases, including an array of malignancies. Perhaps 30-40% of all therapeutics are directed against GPCR activity, and ~350 of the non-olfactory GPCRs are thought to be potential candidates for drug development. However, for a slew of technical reasons, the development and validation of high-quality antibodies against GPCRs has proven difficult. In an effort to facilitate further research into GPCRs, GeneTex is combining its recombinant antibody production platform with enhanced validation techniques to make specific monoclonal antibodies against GPCRs with direct relevance to cancer and other diseases. GeneTex's rAb production protocol employs a multi-parameter fluorescence-activated single cell sorting (FACS)-based methodology to identify and select antigen-specific IgG+ memory B cells from an immunized rabbit (Starkie *et al.*, 2016). The heavy and light chain variable region genes from single cells are amplified, cloned, and co-expressed in mammalian cells to generate a monoclonal IgG. Application-specific testing is performed in conjunction with knockout/knockdown (KO/KD), differential expression comparison in cells and tissues, cell fraction enrichment (i.e., membrane extracts versus whole cell extracts), and other methodologies. Antibodies directed against extracellular GPCR domains are validated for specificity using GPCR arrays (CDI Labs, Baltimore, MD). This workflow has resulted in the production of specific antibodies for a number of GPCRs studied by cancer biologists. These include novel recombinant monoclonal antibodies to the dopamine D2 receptor (DRD2), retinoic acid-induced protein 3 (RAI3), CXC motif chemokine receptor 2 (CXCR2), CXCR4, and CXCR7. All of these antibodies were validated for at least two applications, while the specificity of three (i.e., RAI3, CXCR4, and CXCR7) is supported by KO/KD data. GPCR array data argues for the specificity of the other two antibodies (i.e., DRD2 and CXCR2). This same production/validation approach will be applied as GeneTex targets the remaining GPCRs.

#2761 Activating RET mutations promotes osteoblastic bone metastasis by inhibiting osteoclastogenesis and stimulating osteoblast activity via regulation of osteoprotegerin.

R. Bagheri-Yarmand, J. L. Kidd, G. M. Pagnotti, T. Trivedi, L. Guerra, X. Wan, J. Song, S.-H. Lin, T. Guise;
UT MD Anderson Cancer Center, Houston, TX

Bone metastases (BM) are a source of increased mortality and significant morbidity in patients with medullary thyroid cancer (MTC), with ~50% survival at five years post-diagnosis. MTC causes osteoblastic, osteolytic, or mixed lesions, yet the underlying mechanisms are unknown. The *RET* proto-oncogene encodes a transmembrane tyrosine kinase receptor and is the driver oncogene in ~60% of MTC cases where a germline or somatic activating mutation results in ligand-independent constitutive activation of the receptor. However, the role of RET mutations in the genesis of bone metastasis lesions is unknown. We show that activating *RET* mutations promotes an osteoblastic phenotype in mice implanted with patient-derived MTC cells by increasing bone formation and decreasing bone resorption. We found that the radiographic appearance of osteoblastic lesions differed between the types of RET mutations (C634W and M918T). MTC cells with RET^{C634W} mutation showed a four-fold increase in bone mineral density, trabecular bone volume, number, and thickness with a decreased number of osteoblasts compared to the non-tumor-bearing femur. TRAP staining revealed that osteoclast numbers per long bone were reduced in the injected femur compared to the control. In contrast, the MTC-RET^{M918T} mutation showed an increased cortical thickness and porosity with reduced medullary area and increased bone formation rate compared to the non-tumor bearing femur. MTC cells formed tumors with extensive mineralized tissue, composed of bone matrix surrounded by osteoblast-like cells and osteoid. The knockdown of RET in the MTC-RET^{M918T} model significantly reduced cortical thickness and increased the number of osteoclasts per bone surface. We observed increased osteoprotegerin (OPG) expression in MTC-bearing femurs compared to controls, suggesting decreased bone resorption. The factors secreted by MTC cells, including OPG, inhibited osteoclast formation from primary bone marrow cells and Raw264 cells. In addition, RET knockdown by shRNA in MTC cells decreased OPG expression. Moreover, the MTC-conditioned media (CM) increased osteoblast differentiation and mineralization of the primary culture of pre-osteoblasts isolated from calvarial bone, long bones, and MC3T3 cells. The conditioned media of RET-depleted cells inhibits osteoblast differentiation and mineralization. The expression of alkaline phosphatase, osteocalcin, OPG, and osterix increased in pre-osteoblast incubated with MTC-CM. Compared to primary non-metastatic tumors, the OPG expression increases in tissues of sporadic MTC bone metastases harboring RET^{M918T} mutation. These results suggest that MTC with RET-activating mutations induces osteoblastic bone metastasis due to decreased bone resorption and increased bone formation.

#2762 Spatial proteomics of lung adenocarcinoma mouse models with divergent propensities for metastasis.

P. Ramkissoon, N. Mitchell-Hutchinson, J. Wells, R. Maser, T. Stodola, B. Hoffmann, A. Marchini, E. Bechtel, R. Doty, C. J. Bult;
The Jackson Laboratory, Bar Harbor, ME

Introduction: Lung cancer is the leading cause of cancer deaths worldwide with most deaths attributed to metastasis. Metastases in existing mouse models of lung adenocarcinoma (LUAD) is sporadic and often requires several months of aging. These factors limit these models for basic and pre-clinical research aimed at identifying mechanisms of metastatic disease. We have recently developed two novel mouse models of LUAD that feature constitutively active *Kras*, loss of *Trp53* function and truncated *Dicer1* in different cell types. The observed survival and metastatic phenotypes of the models are dependent on the cell type in which the genetic alterations are made. We applied spatial proteomics and metabolomics to investigate molecular drivers underlying the phenotypic differences in our models.

Methods and Results: Mouse models were generated by adding mutations in *Dicer1*, an RNAse III enzyme within the microRNA (miRNA) biosynthesis pathway, to a mouse model of *Kras*-driven LUAD. For both models, tumorigenesis was induced by conditional expression of an oncogenic allele of *Kras*, deletion of both alleles of *Trp53* and deletion of one allele of *Dicer1* in one cell type and the expression of a truncated *Dicer1* allele in a different cell type. Mice expressing $Kras^{G12D}$ and deleted *Trp53* in club cells without *Dicer1* truncation have a reported median survival of 28.6 weeks after tumor induction. We observed accelerated development of LUAD and lymph node metastasis (12.1 weeks) only when we induced tumorigenesis in club cells and truncate *Dicer1* in alveolar type II (ATII) cells. Induction of tumorigenesis in ATII cells and truncation of *Dicer1* in club cells did not accelerate tumorigenesis or lead to detectable metastasis. Prelminary spatial proteomic analysis revealed significant upregulation of proteins associated with mitochondrial respiratory chain complex I in the tumors of both models which is consistent with processes of bioenergetic adaptation of tumor cells to hypoxic conditions. Gene Ontology annotation term enrichment revealed that the tumors of the two models have distinctive molecular function profiles. Both models show significant disruption of amino acid metabolism but only the model with increased metastatic potential showed apparent disruption in metabolites associated with steroidogenesis.

Conclusions: Through cell type specific truncation/deletion of *Dicer1* we have generated a mouse model that rapidly develops *Kras*/*Trp53* driven LUAD and metastatic disease. Our findings suggest that tumorigenesis and metastasis are influenced by miRNA-mediated communication between different cell types. Additional studies are underway to link miRNA expression in these models to the results reported here for spatial proteomics and metabolomics. We will continue to develop this model to investigate the molecular mechanisms underlying metastasis.

#2763 A specific ribomethylome pattern in lung cancer is associated with increased risk of metastasis.

C. Pauli[1], D. Heid[1], C. Rohde[1], N. Krall[1], S. Delaunay[2], M. Kienhoefer[1], C. Tischer[3], M. Allgauer[1], M. Blank[1], F. Zhou[1], M. Kardorff[1], M. Thomas[4], H. Winter[4], S. Sandmann[5], M. Kriegsmann[1], M. Schneider[6], T. Muley[6], A. Brobeil[1], N. Baumer[5], S. Baumer[5], S. Raffel[1], A. Stenzinger[1], P. Schirmacher[1], J. Lu[1], J. Zaugg[3], M. Frye[2], C. Muller-Tidow[1];

[1]Heidelberg University Hospital (UKHD), Heidelberg, Germany, [2]DKFZ Heidelberg, Heidelberg, Germany, [3]European Molecular Biology Laboratory, Heidelberg, Germany, [4]Thoraxklinik, Heidelberg University Hospital (UKHD), Heidelberg, Germany, [5]University Hospital of Muenster, Muenster, Germany, [6]Thoraxklinik, Heidelberg University Hospital, Heidelberg, Germany

Non-coding RNAs drive cancer phenotypes and are associated with patients' outcome. SnoRNAs are required for the 2'-O-methylation (2'-O-Me) and pseudouridylation of ribosomal RNA (rRNA) thus being essential for ribosomal biogenesis and function. So far, the role of rRNA methylation (ribomethylation) for non-small cell lung cancer (NSCLC) pathogenesis is unknown. To investigate the role of ribomethylation we included samples from 92 patients with lung adenocarcinoma (pathological stage IA to IIB) for comprehensive multi-omics profiling. Amongst transcriptomics, small RNA sequencing, proteomics, and whole exome sequencing, ribomethylation as epitranscriptomic dimension was analyzed using RiboMethSeq. We focused the analysis on complete tumor resection samples. Here 47 out of 106 2'-O-Me sites were fully methylated in all tumor samples suggesting a crucial role for methylation at this position. Surprisingly, 59 sites had a dynamic methylation pattern. By combining ribomethylation sequencing data of dynamic sites with whole-exome-sequencing as well as transcriptome and proteome analyses using a multi-omics factor analysis (MOFA), we discovered a 2'-O-Me signature in a subset of NSCLC patients with a high risk of metastasis and poor prognosis. We termed the patient subset, with underlying ribomethylation signature, epitranscriptomic pro-metastatic phenotype (EPROMET). This phenotype was not associated with genetic mutations as analyzed by exome sequencing. Analysis of gene sets in both transcriptomics and proteomics showed an upregulation of secreted and extracellular matrix proteins in EPROMET patients. Alongside, the ribomethylation site with major contribution to the EPROMET signature; 18S-Um799, mediated through SNORD105/105B, was found to be the most dynamic within the dataset. It also showed the largest difference between EPROMET and non-EPROMET patients. For functional validation, lung cancer cell lines with knockout of snoRNAs contributing to EPROMET signature were generated using CRISPR/Cas9. Lung cancer cells lacking the corresponding rRNA modifications migrated slower *in vitro,* failed to grow at a distant site *in vivo* and were impaired in metastasis. Functionally, it was shown that the modulated ribomethylation signature effected translation of secreted proteins by altered mRNA binding to ribosomes. This study indicates the presence of a ribomethylome-associated phenotype of NSCLC related to metastasis and poor prognosis. Altered ribomethylation affects the ribosome function towards differential expression patterns of secreted proteins. Taken together, an epitranscriptomic pattern of 2'-O-Me is associated with invasion/migration properties of NSCLC cells and with development of metastasis. The ribomethylome may present a suitable biomarker and a potential therapeutic target.

#2764 Ubiquitin-specific peptidase 22 controls integrin-dependent cancer cell stemness & metastasis.

Q. Gao[1], K. Liu[1], Y. Jia[1], J. Wei[1], S. M. Chaudhuri[1], S. Wang[1], A. Tang[1], N. L. Mani[1], R. Iyer[1], Y. Cheng[1], B. Gao[1], W. Lu[1], Z. Sun[2], H. Liu[1], D. Fang[1]; [1]Northwestern University - Chicago, Chicago, IL, [2]Dalian Medical University-Dalian, Dalian, China

Integrins play critical roles in connecting the extracellular matrix and actin skeleton for cell adhesion, migration, signal transduction, and gene transcription. While the upregulation of integrins is thought to promote cancer stemness and metastasis, the mechanisms underlying their upregulation in cancer stem cells (CSCs) remain poorly understood. Herein, we show that the death from cancer signature gene, USP22, is essential in maintaining breast cancer cell stemness by promoting the transcription of a group of integrin family members, in particular, integrin β1 (*ITGB1*). Both genetic and pharmacological inhibition of USP22 largely impaired breast cancer stem cell self-renewal and prevented their metastasis. Reconstitution of Integrin β1 partially rescued USP22-null breast cancer stemness and their metastasis. At the molecular level, USP22 functions as a bona fide deubiquitinase to protect the proteasomal degradation of the forkhead box M1 (FoxM1), a transcription factor for tumoral *ITGB1* gene transcription. Importantly, unbiased analysis of the TCGA database revealed a strong positive correlation between USP22 and *ITGB1* in more than 90% of human cancer types, implying that USP22 functions as a key factor in maintaining stemness across a broad spectrum of human cancer types possibly through regulating *ITGB1*. To support this notion, immunohistochemistry staining detected a positive correlation among USP22, FoxM1 and integrin β1 in human breast cancers. Collectively, our study identifies the USP22-FoxM1-integrin β1 signaling axis as critical for cancer stemness and offers a potential target for antitumor therapy.

#2765 Novel WNT-RIP1-GDF15 pathway promotes migration and invasion of colorectal cancer cells.

A.-R. Kang, D. Kim, **J. Park**;
Korea Institute of Radiological & Medical Sciences (KIRAMS), Seoul, Korea, Republic of

Growth-differentiation factor 15 (GDF15) is a member of the transforming growth factor β (TGF-β) family protein, also known as NSAID-activated gene 1 (NAG-1) or macrophage inhibitory cytokine 1 (MIC-1), and is a major cause of cancer cachexia, cardiovascular disease, and various inflammatory diseases. Roles of GDF15 as major inflammatory response factor also have been demonstrated in animal models, and it has also showed various malignant functions such as regulating metabolism, promoting metastasis by inducing EMT in cancer. Here, we revealed a novel potential role for RIP1 in colorectal cancer (CRC) in enhancing metastasis by controlling WNT-RIP1-GDF15 signaling. We showed that WNT3A treatment increased the expression of GDF15 and GFRAL. Immunohistochemical analysis of human CRC tissue arrays consisting of primary cancer and metastatic cancer also confirmed that the expression of GDF15 and GFRAL was increased in metastatic cancer. Human XL cytokine assay, western blot, and ELISA results confirmed that GDF15 expression was reduced in cell lines in which RIP1 was knocked down. Reduction of GDF15 expression and secretion by RIP1 knockdown showed suppression of EMT induction resulting to decrease of migration and invasion of CRC cells. Taken together, these results suggest a novel EMT-enhancing role for RIP1 in the WNT pathway and suggest a novel WNT-RIP1-GDF15 pathway contributing to CRC malignancy by promoting EMT.

#2767 Exploring ADAR1 dependencies in breast cancer brain-metastases.

T. Sposito, E. E. Klacking, A. W. Ruiz, J. Pham, C. Jamieson;
University of California San Diego - UCSD, La Jolla, CA

Background: Adenosine deaminase acting on double-stranded RNA (ADAR1) is a recognized driver of epitranscriptomic (post-transcriptional) remodeling and tumor progression. Changes in amino acid sequence, mRNA splicing, and/or polyadenylation sites are only some of the adenosine-to-inosine (A-to-I) RNA editing effects. Under physiological conditions, ADAR1 activity prevents autoinflammation by inhibiting the accumulation of endogenous immunostimulatory double-stranded RNA and by suppressing the Z-RNA sensor ZBP1. Such mechanisms are exploited by cancer cells to desensitize tumor response to therapies, therefore augmenting aggressiveness. Approximately 10 to 20% of patients diagnosed with breast cancer (BC) will develop metastatic disease, which remains the leading cause of death in individuals with BC. We have hypothesized that ADAR1 and its interferon-inducible p150 isoform, play a pivotal role in promoting BC metastases since high levels of ADAR1 are associated with a worse prognosis in patients with high grade BC, especially in the triple-negative BC subgroup (TNBC), which is the most likely to develop brain metastases.

Methods: We established a humanized mouse model of breast cancer brain metastases (BC-BrM) using neonatal intracerebroventricular inoculation of MDA-MD-231 TNBC cells and primary patient derived metastatic cells in $Rag2^{-/-}\gamma c^{-/-}$ mice. Before implantation, MDA-MD-231 cells were transduced with a nanoluc-GFP reporter for tracing ADAR1 enzymatic activity in the brain metastatic niche. Lentiviral shRNA knockdown vectors targeting ADAR1, combined with over-expression vectors of full-length ADAR1 or the p150 deleted isoform were adopted to detect editing changes in the metastatic model through RNA-sequencing of BC-BrM.

Results: BrM derived from MDA-MD-231 implants display upregulation of ADAR1 p150 and activation of the WNT/β-catenin pathway compared to the non-implanted cell lines. Upon shRNA knockdown of ADAR1, decreased expression of BC stem cell markers was detected via FACS in MDA-MD-231 ADAR1 knocked-down versus control BC-BrM isolated cells. We are now exploring molecular pathways affected by ADAR1 loss/overexpression in establishing BrM.

Future Directions: We have developed a biorepository of primary patient-derived metastatic breast cancer samples and have begun the process of tracking metastatic kinetics and ADAR1 activation with the ADAR1 reporter in an orthotopic mouse model. Overall, this study will provide new insights into the molecular role of ADAR1 deaminase activity in establishing and maintaining metastatic niches.

#2768 Ribosome biogenesis score: Prognostic insights and drug responses in cancer.

A. R. Elhamamsy, R. S. Samant, L. A. Shevde;
University of Alabama at Birmingham, Birmingham, AL

Ribosome biogenesis, a crucial cellular process responsible for creating the cellular machinery required for protein synthesis, is vital for cell growth and proliferation. Cancer cells have dysregulated ribosome biogenesis, which contributes to uncontrolled cell growth and proliferation. Aberrant ribosome biogenesis not only drives the increased need for protein synthesis in rapidly developing cancer cells, but it also orchestrates tumor-related signaling cascades. We developed a robust scoring method for ribosome biogenesis and applied it to a broad range of TCGA tumor samples. By categorizing TCGA samples into distinct groups based on their ribosome biogenesis scores, we unveil significant prognostic associations in various cancer types. We used the scoring method and compared the scores with ssGSEA analysis using different ribosome biogenesis signatures in several databases to confirm these predictions. Furthermore, our research goes beyond predictive implications, delving into the biochemical complexities of ribosome biogenesis's impact on drug responses and resistance. This thorough investigation sheds light on the molecular complexities of ribosome biogenesis in tumors, providing useful insights with potential implications for refining strategies for cancer therapy.

#2769 Long non coding RNA H19/cell adhesion molecules circuitry as novel target and diagnostic tool for metastatic prostate cancer.

V. Pecci[1], A. Aiello[2], S. De Martino[2], C. Ripoli[1], D. Rotili[3], F. Pierconti[1], F. Pinto[4], C. Grassi[1], C. Gaetano[5], A. Pontecorvi[1], L. Strigari[6], A. Farsetti[2], S. Nanni[1]; [1]Universita' Cattolica del Sacro Cuore, Roma, Italy, [2]Consiglio Nazionale delle Ricerche, Roma, Italy, [3]Universita Sapienza, Roma, Italy, [4]Fondazione "Policlinico Universitario A. Gemelli IRCCS, Roma, Italy, [5]Istituti Clinici Scientifici Maugeri, Pavia, Italy, [6]S. Orsola Malpighi University, Bologna, Italy

In the complex tumor biology of prostate cancer (PCa), we previously contributed by demonstrating that estrogen receptor and hypoxia signaling promoted transcription of progression-associated genes. Notably, combined treatment, estrogens plus hypoxia, caused a significant down regulation of the long noncoding RNA H19, one of the most sensitive to these pro-tumoral stimuli. Mechanistically, H19 acts as transcriptional repressor: H19 over-expression decreases E-cadherin (CDH1) level causing epithelial-to-mesenchymal transition whereas H19 reduction promotes the expression of E-cadherin and β4 integrin (ITGB4) switching the tumor dissemination program toward an alternative mechanism, specifically the cohesive metastatic phenotype. We focused on this H19/cell adhesion molecules circuitry by investigating its role as: 1.Novel prognostic biomarker at the time of biopsies. eNOS, HIF2a and β4 integrin expression was evaluated by immunohistochemistry, H19 and CDH1 transcripts by Droplet Digital PCR on FFPE-biopsies in a retrospective cohort of PCa patients [n = 30; Gleason score GS≤ 7(3+4) n= 17, GS ≥7(4+3) n= 13; biochemical, local, or metastatic recurrence defining disease progression (n=8/30; time of recurrence: range 2-6 years)]. Importantly, multivariate analysis of combined biomarkers, named “Bioscore”, defined by the presence of at least 3 among HIF-2α, eNOS, CDH1, β4 integrin ≥cut off or H19≤cut off revealed its prognostic value for progression and Progression-Free Survival determined using the ROC analysis (p=0.003) and Kaplan Meier curve (p= 0.005), respectively. 2.Master regulator of metastatic program in vivo and ex vivo PCa experimental models. Upon H19 silencing, mimicking combined estrogens plus hypoxia treatment, luciferase-positive PC-3 and 22Rv1 cells led to increased E-cadherin and β4 integrin expression, enhanced tumor growth and metastasis formation at bone, lung, and liver in PCa mouse models. Further, treatment with H3K27 demethylase inhibitor, GSK-J4, rescued cell adhesion molecules expression by modulating H3K27me3 level at gene promoters, reduced metastasis number and size, and induced cell death in PCa-derived Organotypic Slice Cultures. Additionally, treatment with JQ1 and dBET6 BET protein family inhibitors) markedly reduced both E-cadherin and β4 integrin levels, cell proliferation and in vivo tumor growth. Intriguingly, H19 silencing increased BRD3 and BRD4 levels, implicating H19 in BRD transcription. Overall, this research enhances our understanding of the molecular mechanisms driving aggressive prostate cancer phenotypes, providing a foundation for new diagnostic and therapeutic strategies in prostate cancer management.

#2770 A novel MIRO2/MYO9B/RhoA signaling axis controls tumor cell invasion and metastasis.

Dillon P. Boulton[1], Connor J. Hughes[1], Valentina Vaira[2], Ajita Jindal[3], Masoom Raza[1], Stephen Connor Purdy[1], Shilpa Sant[4], Heide L. Ford[1], M. Cecilia Caino[1]

[1]University of Colorado Anschutz Medical Campus, Aurora, CO,[2]Universita degli Studi di Milano, Milan, Italy,[3]University of Pittsburgh, Pittsburgh, PA,[4]University of Illinois Chicago, Chicago, IL

Metastasis of cancer cells to vital organs remains the leading cause of cancer related deaths, emphasizing a strong need for actionable targets in advanced stage cancer. To address this, we study novel dysregulated mitochondrial signaling mechanisms that cells utilize to metastasize. Here, we focus on how outer mitochondrial membrane protein—Mitochondrial Rho GTPase 2 (MIRO2)—promotes tumor cell invasion and metastasis. Our previous work identified higher MIRO2 mRNA expression in cancer vs. normal patient samples in a multitude of cancer types, which correlated with worse patient outcomes. Furthermore, we demonstrated that MIRO2 was critical for prostate cancer cell growth and survival *in vitro* and *in vivo*. However, it remains unknown if MIRO2 only affects primary tumor growth or if this protein is important throughout tumor progression. Using siRNA mediated knockdown (KD) of MIRO2 we find MIRO2 KD ubiquitously reduces tumor cell invasion in breast, melanoma, pancreatic, and prostate cancer cells. Utilizing metastatic prostate and breast cancer models, we demonstrate that mice injected with MIRO2 shRNA cells have significantly lower metastatic burden compared to mice injected with control shRNA cells. To determine the mechanism that MIRO2 controls invasion and metastasis, we looked at which of the top protein-binding partners for MIRO2 may regulate tumor cell invasion. Of our top hits, we found that depletion of atypical myosin IXB (MYO9B) by siRNA most significantly reduced tumor cell invasion and phenocopied MIRO2 depletion. MYO9B has a well-defined role in controlling cell motility via inactivation of RhoA. Excitingly, we have found 1) MIRO2 KD results in increased active RhoA, phenocopying MYO9B KD, 2) dual ablation of MIRO2 and RhoA fully rescues tumor cell invasion, and 3) MIRO2 is required for MYO9B driven invasion. Taken together, we propose a novel signaling mechanism by which MIRO2 broadly promotes invasion and metastasis through MYO9B dependent inactivation of RhoA.

#2771 Increased mtDNA copy number via EPOR signaling: A potential mechanism for metastatic dissemination in head and neck squamous cell carcinoma.

A. Chauhan[1], G. S. Boora[1], S. Ghosh[2], S. K. Patra[2], R. K. Verma[1], J. Bakshi[1], D. Chatterjee[1], R. Srinivasan[1], S. Ghoshal[1], A. Maitra[2], A. Pal[1];
[1]Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India, [2]National Institute of Biomedical Genomics, Kalyani, Kolkata, India

Introduction: Head and Neck Squamous cell carcinoma (HNSCC) is characterized by high degree of invasion, locoregional metastasis, relapse which leads to overall poor prognosis. The molecular mechanism responsible for aggressiveness is poorly understood. A better understanding of molecular pathways involved shall precede the identification of newer diagnostic tools and therapeutic targets. We explored EPOR signaling pathway in Circulating tumor cells (CTCs) and HNSCC cell lines.

Methods and Results: By using a validated in-house CTC isolation protocol, which addresses various drawbacks of currently available techniques and isolates CTCs suitable for various downstream molecular analysis, we isolated CTCs from HNSCC patients. The whole transcriptome analysis was performed from CTCs using ultra-low cell number RNA sequencing and corresponding primary tumors in 24 paired samples. We found a significant transcriptomic heterogeneity in CTCs, which are associated with overall disease outcome in HNSCC patients. To explore the plausible molecular pathways, we also identified 521 differentially expressed genes in CTCs with respect to primary tumors and various canonical pathways including oxidative phosphorylation, TCA cycle, cytokine-cytokine receptor interaction signaling, and ECM receptor interaction were enriched in CTC samples. Overexpression of erythropoietin receptor (EPOR) along with various genes encoded by mitochondrial genome and genes involved in maintenance of mtDNA in CTCs as compared to primary tumors was an important finding from our data. When analyzed in depth, there was a significant positive correlation between various genes involved in mtDNA maintenance (ABAT, NT5M) and encoded by mitochondrial genome (MT-ND1, MT-ND2, MT-ND4, MT-ND5, MT-ND6, MT-CO1, MT-CO2, MT-ATP6, MT-CYTB) with EPOR expression in our RNA seq data which is also substantiated by analyzing TCGA data. We confirmed these findings experimentally in HNSCC cell lines Cal 27 and FaDu. It was also observed that metastatic cell line FaDu has significantly higher mtDNA content as compared to non-metastatic cell line Cal 27, which was correlated with EPOR expression. Treatment with low dose Erythropoietin (0.1IU/mL) which a natural ligand for EPOR, enhanced mtDNA content in both the cell lines at low doses and boosted the metastatic capability while minimal effect on cell proliferation was observed.

Conclusion: EPOR signaling might promote the metastatic ability of cancer cells and may act as a potential target for cancer dissemination and metastasis.

#2772 Mechanisms linking STK11 loss with metastatic potential in KRAS-mutated lung adenocarcinoma.

C. M. Royer, L. K. Bialek, H. M. Sarausky, S. M. Prior, G. Nandagopal, P. B. Deming, D. J. Seward, M. N. Scheiber;
University of Vermont, Burlington, VT

Metastasis is one of the major determinants of worsened patient prognosis and occurs in roughly 50% of lung adenocarcinoma (LUAD) patients at the time of diagnosis. Late-stage diagnosis of LUAD often results in the accumulation of a wide range of mutations in tumor cells, with altered *KRAS* being the most frequently encountered oncogenic driver. Co-mutation of the tumor suppressor *STK11* is also common and occurs in 10-15% of KRAS-driven LUAD. Retrospective patient studies have demonstrated that concurrent oncogenic *KRAS* and *STK11* loss-of-function mutations are associated with metastatic disease, poorer patient survival, and inferior therapy response. The purpose of this study was to identify molecular mechanisms by which STK11 loss results in a greater metastatic potential in *KRAS*-driven LUAD in hopes of exploiting that knowledge to improve patient outcomes. For our studies, we utilized the *KRAS*-mutated, STK11-intact human LUAD cell line NCI-H2009. Both parental and ΔSTK11 (generated by CRISPR/Cas9) H2009 cells were seeded in Transwell® inserts coated with fibronectin. As expected, H2009 ΔSTK11 cells displayed a 1.6-fold increase in trans-well migration compared to the parental line (SEM 14393 ± 877.3 cells, n=6; $p<0.0001$). To assess the invasive properties of parental and ΔSTK11 cells in a three-dimensional environment, spheroids generated by hanging drop culture were embedded in Matrigel and imaged by light microscopy at zero and 24-hours post-embedding. Analysis demonstrates a 2.4-fold increase in invasion in ΔSTK11 cells compared to parental cells (SEM 0.03 ± 0.01 mm^2, n=19-21; $p<0.0001$). Three-dimensional LUAD spheroids have been reported to more closely recapitulate *in-vivo* tumor transcriptomes compared to two-dimensional monolayer cultures. qRT-PCR analyses of our spheroids demonstrate that loss of *STK11* promotes a significant increase in the expression of lung cancer stem cell markers CXCR4, NANOG, CD44, and OCT4 (n=3-6; $p<0.002$). These markers are known to support stem cell maintenance, chemoresistance, as well as metastatic potential, suggesting a mechanistic link between STK11 and their transcriptional regulation. To assess the impact of *STK11* loss on early and late-stage metastasis *in-vivo*, we will use an embryonic zebrafish xenograft model. Zebrafish represent a tractable metastasis model due to the number of conserved human homologs - most notable being the CXCR4/CXCL12 axis which models cross-communication between zebrafish endothelium and cognate human tumor ligands. Current and future studies focus on investigating the role of STK11 in regulating stem cell markers; thereby identifying potentially novel therapeutic targets for *STK11* and *KRAS* co-mutated LUAD patients.

TUMOR BIOLOGY: Cancer Stem Cells and Their Microenvironment
Poster Session

#2776 Exploring the differences between brain tumor initiating cell extracellular vesicles and secreted factors that influence the tumor microenvironment.

M. Russo, M. Ulloa Navas, E. Norton-Ramos, A. Quinones Hinojosa, H. Guerrero Cazares;
Mayo Clinic Florida, Jacksonville, FL

Glioblastoma (GBM) is the most common and lethal primary brain tumor in adults. Within the tumor, there is a subtype of cells deemed brain tumor initiating cells (BTICs), which contribute to tumor progression, therapy resistance, and tumoral heterogeneity. The tumor microenvironment, surrounding tumors, contains an ecosystem of cells in which BTICs can interact with and further promote tumor progression. In the lateral wall of the lateral ventricles, the neurogenic niche of the subventricular zone (SVZ), contains neural progenitor cells (NPCs) that self-renew and generate highly migratory neuroblasts. Interestingly, GBM tumors proximal to the SVZ are more proliferative, migratory, and negatively impact the survival of patients. We have previously observed that the presence of GBM induces reciprocal changes to the SVZ altering its neurogenic capacity and resulting in a more proliferative tumor. BTICs share similar self-renewal capacity to NPCs and may exert intercellular communication resulting in increased malignancy features. The mechanisms of intercellular communication, present in the SVZ include paracrine, autocrine, direct cell contact, gap junctions, nanotubes, and more recently extracellular vesicles (EVs). However, the exact mechanisms of how BTICs communicate with NPCs is not well understood. EVs are a heterogenous group of cell-derived membranous structures that serve as means of intercellular communication, allowing for cells to exchange proteins, lipids, RNA, and other genetic material. Cancer cells release higher amounts of EVs than non-malignant cells, and these EVs help communicate with other nearby cells, leading to promotion of tumorigenesis. We have observed that BTICs-derived EVs increase the proliferation of human NPCs, while altering their morphology and expression of stem cell markers. These effects are not observed when NPCs are treated with vesicle-free BTIC-derived secreted factors. To investigate the distinctions between BTIC secreted factors and protein cargo contained in BTIC-EVs, we employ the proximity protein labelling system, TurboID, and express this system in BTIC-EVs. The overarching goal of this project is to characterize BTIC-derived EV cargo to identify proteins that modify the GBM tumor microenvironment. **We hypothesize that the phenotype of non-cancer NPCs is altered by distinct protein cargo contained in BTIC-derived EVs.** The results of these experiments will help us to elucidate what BTIC-specific EV cargo impacts the tumor microenvironment, with the potential of revealing therapeutic targets for GBM.

#2777 A unique sub-population of PDGFRB+ glioma-associated mesenchymal stem cells constitute the perivascular niche in murine glioblastoma.

M. F. Zaman, S. K. Singh, A. Hossain, L. M. Phillips, J. Gumin, D. Ledbetter, B. Milutinovic;
The University of Texas MD Anderson Cancer Center, Houston, TX

Microvascular proliferation (MVP) and spatial heterogeneity are defining histological features of glioblastoma (GBM). Using *ex vivo* culture method to analyze human GBMs we have previously identified mesenchymal stem cell (MSC)-like cells, called glioma-associated-MSCs (GA-MSCs) in the heterogenous tumor-microenvironment (TME) of GBMs. Like pericytes, fibroblastic cells and smooth muscle cells (SMCs), these GA-MSCs reside in the perivascular niche (PVN) within GBM, and their presence correlates with MVP, decrease in immune cell counts, and poor prognosis. However, the impact of GA-MSCs on the TME remains correlative, and to date, a causative role of GA-MSCs in MVP and immune evasion has not been established *in vivo*. We hypothesize that recruited GA-MSCs promote MVP and enhance immune evasion in the GBM-TME. To begin to address this hypothesis, we first identified and characterized GA-MSCs at single-cell resolution in an immunocompetent murine GBM model. We sorted tumor, immune, and non-tumor-non-immune (NTNI) cells from GFP-labelled GSC005 tumors in C57Bl/6 mice and performed scRNA-seq. Tumor cells (GFP^+ cells) clustered together into 13 distinct cell states. Of the immune cells ($CD45^+$), the most abundant cell types were microglia (33.9%), macrophages (31.9%), T cells (10.3%), dendritic cells (7.5%) and B cells (1.4%), mimicking human GBM. In the NTNI compartment, we identified 17 clusters, which mapped to endothelial cells, oligodendrocytes, astrocytes and other cell types. Interestingly, there were 4 distinct cell clusters that exclusively expressed platelet-derived growth factor receptor beta (PDGFRB). Three of these clusters mapped to pericytes, SMCs and fibroblastic cells. The fourth cluster expressed both adipose tissue and bone marrow MSC markers, identifying for the first time, GA-MSCs in murine GBM. Next, to define the spatial organization of GA-MSCs and their relationship to immune cells in the GBM TME, we conducted spatial proteomics. GA-MSC counts were significantly higher in the PVN compared with the avascular niche (AN) ($p= 0.009$) and GA-MSCs were absent in contralateral non-tumor regions. Interestingly, GA-MSCs co-localized with SMCs, fibroblastic cells and pericytes as well as pro-tumorigenic macrophages/microglia ($Iba1^+/CD163^+$) in the PVN indicating potential interactions between these cell populations. In conclusion, we have identified for the first time, MSC-like cells in the PVN of murine GBM. Our results suggest that these GA-MSCs are recruited to the TME where they may promote MVP, a hallmark of GBM, and interact with immunosuppressive immune cells. Building on these observations, future experiments will investigate the extent to which GA-MSCs drive MVP formation and immune evasion in GBM.

#2778 Influence of the differentiation strategy on the phenotypic and genotypic features of iPSC derived NK cells.

M. Huyghe, C. Desterke, J. Imeri, N. Belliard, **A. G. Turhan**, A. Bennaceur Griscelli, F. Griscelli;
INSERM U1310, Villejuif, France

The iPSC-derived NK (iNK) cells offer new perspectives to produce large-scale of homogeneous immunotherapeutic cellular products and open the way towards manufacturing off-the-shelf cancer immunotherapies. Numerous strategies and protocols of differentiation of iPSCs toward NK lineage have been published in the last decade. Nevertheless, the embryological development of the NK cells and the impact of the differentiation strategy on the activity of the NK cells are still not clearly understood. Furthermore, very few studies have compared different NK differentiation strategies from iPSC. this study, we compared two previously reported protocols for NK cell generation from the same iPSC line, one feeder-based and the other feeder-free. In the first protocol, 3D hematopoietic differentiation was followed by lymphoid differentiation, using an OP9 DLL4 expressing feeder cell line. The second protocol employed a clinical-grade approach, utilizing the “spin embryoid body” method to generate primitive hematopoietic progenitors. Subsequently, these progenitors were differentiated towards the NK lineage in a feeder-free environment. Hematopoietic progenitors produced by these protocols have distinct phenotypes, suggesting variations in their maturity levels. Furthermore, the protocols have different kinetics of differentiation revealed by CD56 and CD7 phenotypes. Although, both protocols were able to efficiently generate functional and mature NK cells, characterized by the expression of activating and maturity ligands but with a distinct transcriptomic profile. iNK cells generated using feeders exhibit a more pronounced inflammatory profile with the expression of hallmark NFKB and STAT3 signaling pathways. In contrast, feeder-free iNK cells have a more proliferative profile as evidenced by increased expression of cell cycle factors such as E2F or Myc. Feeder-based iNK cells exhibit increased expression of transcription factors involved in NK cell differentiation, such as GATA2, STAT1, and IRF1. These transcriptional variances are reinforced by superior functionality observed in feeder-based NK cells compared to feeder-free NK cells, evidenced by increased degranulation (p-value < 0.0001) and cytotoxicity (p-value = 0.0004) at a 1:2 (effector-to-target) ratio against the K562 cell line. Our findings indicate that, despite the advantages of the feeder-free strategy, the feeder-based protocol remains more efficient and produces iPSC-derived NK cells with an enhanced cytotoxic profile in vitro. Our comprehensive transcriptional analysis offers significant insights into the biological and functional properties of iNK cells. This information has the potential to oncover novel mechanisms for NK differentiation strategies from iPSCs.

#2779 The significance of TIMP-1 and hypoxia in cancer stemness: A synergistic role in chemoresistance.

I. Thirusenthilarasan[1], W. Xiao[2], M. V. Rojiani[1];
[1]Penn State University, Hershey, PA, [2]Augusta University, Augusta, GA

Chemotherapeutic resistance in non-small-cell lung cancer (NSCLC) poses a formidable clinical challenge. Numerous studies have highlighted the critical role of tissue inhibitor of matrix metalloproteinase-1 (TIMP-1) in tumorigenesis and, increasingly, in the development of chemoresistance. We have studied multiple aspects of the MMP-independent, tumor-promoting function of TIMP1 in human NSCLC. Our recent studies have found a pivotal role for TIMP1 in chemoresistance. In order to gain an enhanced comprehension of the mechanisms underpinning TIMP-1-mediated chemoresistance, we have sought to determine the contribution of CSCs and hypoxia. TIMP-1 plays a role in propagating stemness, although relatively unexplored in the context of CSCs within NSCLC. A second crucial factor in the development of chemoresistance in NSCLC is the interplay between intratumoral hypoxia and CSCs. As the tumor grows, metabolic demand for oxygen increases and hypoxic regions are seen in areas furthest from the blood vessels. We have shown TIMP1 levels to increase under experimentally-induced hypoxia. In the present study, we cultured NSCLC cell lines and their TIMP1 KD clones in an assay with serum-free media and found a significant decrease in spheroid size in TIMP1 KD clones. Postulating a reduction in CSC population in KD clones, we determined the NSCLC CSC markers CD133 and ALDH's expression in the NT and KD TIMP1 clones. Flow cytometry results showed that $CD133^{pos}$ and $ALDH^{high}$ populations were significantly decreased in TIMP1 KD clones relative to NT clones. Moreover, KD clone of TIMP1 showed a decrease in the levels of CSC-specific Transcription factors Oct 4A and Nanog. Taken together, our findings confirm that reduction in TIMP1 expression negatively impacts CSC populations. Furthermore, we determined the mRNA levels of CD44, another CSC marker also expressed in lung cancer is upregulated under hypoxia (1% O_2) in both the NT and KD clones of TIMP1. Thus, we postulate that TIMP1 enhances chemoresistance by promoting CSC propagation within a hypoxic tumor microenvironment.

#2780 Induced pluripotent stem cell (iPSC) based vaccines potentializes anti-CTLA4 immune response in a murine lung carcinoma model.

F. Griscelli, D. Chaker, N. Oudrhiri, C. Desterke, **A. G. Turhan**, A. Bennaceur Griscelli;
INSERM U1310 Universite Paris Saclay, Villejuif, France

Despite the development of new immunotherapy strategies, lung cancer remains the leading cause of cancer-related deaths. One of the reasons is attributed to the persistence of cancer stem cells (CSCs) within the tumor, contributing to drug resistance, dormancy and metastatic spread. To eradicate CSCs, iPSC-based vaccination represents a novel approach based on the paradigm that CSCs and iPSCs share common tumor associated antigens (TAAs) with the ability to elicit a strong anti-tumor immune response.We previously showed that induced allogeneic pluripotent stem cells (miPSCs), combined with a histone deacetylase inhibitor (HDACi), induced a major reduction of tumor growth and metastatic spread to lungs in an aggressive triple negative breast cancer model (4T1) in syngeneic mice. We report here the use of the same protocol in a lung carcinoma model using LLC1 cell line in combination with an anti-CTLA4 antibody. We compared the effectiveness of allogenic miPSCs treatment alone or with an anti-CTLA4 mouse antibody on mice-bearing LLC1-Luc tumors (mean+se: 17,5+0,6 mm^3). Five mice received 5 subcutaneous (SC) injection of $2x10^6$ miPSCs, 5 mice received 3 intraperitoneal injections of anti-CTLA4 antibody at 5mg/kg and 5 mice were treated with the combinatory regimen (miPSCs and anti- CTLA4) with the same doses. In addition, all treated mice received a HDACi in the drink water throughout the experience.After 24 days, all tumor volumes from the 3 groups were significantly reduced compared to the control mice receiving only PBS. We obtained a reduction of 72% (p=0.007) and 74% (p=0.009) respectively for the mice treated solely with miPSCs or anti-CTLA4. An important synergic effect was obtained for the mice treated with miPSCs and anti- CTLA4 with a reduction of the tumor size by 92% (p=0.005) compared to the control mice. We also found a significant inhibition of metastatic spread to lungs for the 3 groups that was more pronounced in mice receiving the combination treatment with a significant reduction of 91 % compared to the control group. All these therapeutic effects were correlated with a significant increase of CD4+ and CD8+ cells that was more pronounced in mice receiving the combinatory regimen.We also have performed single-cell RNA sequencing analysis (10x Genomics) of LLC1 tumors treated with miPSCs and anti- CTLA4 compared to mice treated with monotherapy and untreated mice. T-distributed stochastic neighbor embedding plot reveals distinct clusters of stromal and immune cells across tumors with a significant upregulation of CD8+ and CD4+ T cells in mice receiving the combinatory regimen.Overall, these results demonstrate for the first time the clinical relevance of using an off-the-shelf allogeneic iPSC-based vaccine combined with an anti-CTLA4 antibody as a new anti-cancer immunotherapy strategy against aggressive non-small cell lung cancer (NSCLC) with metastatic potential.

#2781 GBM cells mimic regulatory T cell function to protect the CSC pool from immune surveillance in recurrent GBM.

H. Lopez-Bertoni[1], S. Sall[2], H. Khela[2], J. Korleski[2], K. Luly[1], M. Johnson[2], B. Lal[2], A. Johnson[1], S. Tzeng[1], J. Green[1], J. Laterra[1];
[1]Johns Hopkins School of Medicine, Baltimore, MD, [2]Hugo W Moser Institute at Kennedy Krieger, Baltimore, MD

Glioblastoma (GBM) is the most lethal and aggressive form of brain cancer, with incredibly high recurrence rates and virtually no long-term survival. Despite our growing understanding of GBM at the molecular level, we still don't fully comprehend the molecular mechanisms driving recurrence in GBM. Current knowledge indicates that Glioma Stem Cells (GSCs) drive a resistant cell phenotype in GBM. Understanding the molecular events coordinated by GSCs leading to therapy-resistance can provide key advancements on how we treat recurrent GBM (rGBM). Mechanisms of GSC immune escape are considered fundamental to clinical GBM growth and recurrence. The cross talk between cancer cells and the immune system is now classified as a hallmark of cancer. The current dogma is that cancer cells, including GSCs, influence recruitment of immune-suppressive cell subsets to tumor tissue, *however how subsets of GSCs mimic this immune-suppressive effect within the tumor microenvironment remains to be elucidated.* Single-cell RNA sequencing analysis of GBM neurospheres revealed a previously unrecognized Oct4/Sox2^{high}/FOXP3^{-} cell subpopulation with high expression of TGFβ1, CD39, CD73, PD-L1, and Galectin-1, a gene expression fingerprint typically associated with regulatory T cell (Tregs) and their immune suppressive functions within the tumor microenvironment. Bioinformatics analysis of public databases shows that the above-mentioned genes are enriched in the mesenchymal GBM subtype and highly correlated with TGFβ type II receptor (TGFBR2) expression in clinical GBM. Mechanistically, we show that blocking TGFBR2 or XBP1 signaling, key intermediary of this process, counteracts the immune-suppressive phenotype of rGBM cells by restoring CD4 and CD8 tumor killing capacity and reversing exhaustion in co-culture experiments. siRNA-mediated knock-down of TGFBR2 in rGBM cells also decreased CD206 expression and reduced release of anti-inflammatory chemokines in THP1 cells. By combining miRNA-based network analysis and advanced nanoparticle formulation for miRNA delivery we show that miR-16/124-3p effectively target all nodes of this immunosuppressive axis successfully blocking the immunosuppressive nature of rGBM cells. This research provides the first description of such neoplastic cells in any malignancy and has high potential translational impact since targeting these tumor cell subsets and their immunosuppressive mechanisms may be critical to the successful development of GBM immunotherapies.

#2782 Characterization of quiescence-associated secretory profile (QuASP) in cancer: A novel defining feature and therapeutic target.

Q. Jiang[1], S. Panesso- Gomez[1], D. Natesan[1], M. L. MacDonald[2], R. J. Buckanovich[3];
[1]Magee-Womens Research Inst. & Foundation, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Magee-Womens Research Inst. & Foundation, UPMC Hillman Cancer Center, Pittsburgh, PA

Senescent cells have a unique senescence-associated secretory profile (SASP) and understanding SASP has contributed to numerous advances in knowledge on aging and cancer biology. Quiescence, which is an important yet poorly understood mechanism for chemoresistance, is related but distinct from senescence. Quiescence shares a non-proliferative feature with senescence but is a reversible state in which quiescent cells can reenter the cell cycle. We hypothesized that, analogous to senescent cells, quiescent cells have a distinct quiescence-associated secretory profile (QuASP) and that defining the QuASP will uncover new genes and pathways associated with cancer cell viability and therapeutic resistance. Indeed, suggesting quiescent cells have a unique and biologically important secretome, we found that tumor conditioned medium (TCM) from quiescent ovarian cancer cells (qOvCa) vs. TCM from proliferating cancer cells increased chemoresistance. Similarly, TCM from quiescent cancer cells vs. TCM from proliferating cancer cells suppressed T cell proliferation and INF-gamma/Granzyme B secretion, suggesting a QuASP immunosuppressive effect. RNASeq analysis of qOvCa cells revealed the secreted factor Follistatin (FST) is upregulated in qOvCa and acted as a paracrine pattern to induce chemoresistance. Furthermore, FST was found to be upregulated in peritumoral fluid following chemotherapy and FST levels in patients with OvCa predicted poor prognosis. To identify additional QuASP factors, we used an ER-BIOID labeled system and LC-MS/MS to characterize the secreted proteins from qOvCa induced by serum starvation compared with normal cells in three OvCa cell lines (PT412, PT340, HEY1). Quiescent OvCa cells indeed have a secretome that is highly unique from proliferating cells, with 137/577 upregulated proteins (LFC>1) and 65/577 downregulated proteins (LFC<-1 or no detection in quiescence). Several proteins identified as upregulated have been linked to immunosuppression and/or chemoresistance, oncogenesis and cell cycle were selected for validation and further analysis (CLU, VGF, SERPINE1). In conclusion, we find quiescent cells have a unique quiescence associated secretory profile and that the QuASP induces chemoresistance and immunosuppression. As such, this study has important implications for cancer therapy.

#2783 The exosomes from cord blood stem cells, containing novel miRNAs, induce apoptosis in melanoma cells and enhance T cell anticancer function.

M. Mojgan Najafzadeh[1], A. Baumgartner[2], S. Jafarinejad[1], Z. Karimi[1], M. Isreb[1], P. Akhbari[3], N. Ghaderi[4], F. Sefat[1], S. Heidari Keshel[5], P. Naeem[1], R. Ghaderi[6], J. E. Gomez[1], D. Anderson[1], A. Wright[4];

[1]University of Bradford, Bradford, United Kingdom, [2]York St John University, York, United Kingdom, [3]University of Exeter, Exeter, United Kingdom, [4]Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom, [5]Shahid Beheshti University, Tehran, Iran, Islamic Republic of, [6]Imperial College London, London, United Kingdom

Regulatory T (Treg) cells expressing FOXP3 play a critical role in suppressing immune responses against anti-tumor immune responses. However, their presence in tumor tissues is often associated with poor prognosis. Cord blood stem cell-derived exosome vesicles (CBSC-EV) constitute a valuable source of lipids, microRNAs, and proteins, that are essential for cell-to-cell communication and provide therapeutic benefits.

This study aimed to investigate the contents of CBSC-EV, identifying several known miRNAs (from *Let7* and *Let5* families) and two unknown miRNAs. Healthy lymphocytes, fibroblasts, and CHL1 amelanotic melanoma cell lines were transfected with these two novel miRNA inhibitors, and the changes before and after treatment compared to CBSC-EV and H_2O_2 were examined. Following treatment, the cells underwent a 24-hour incubation period, during which the level of cytotoxicity was assessed using CCK8, and the degree of DNA damage incurred was quantified with the Fast Microplate DNA damage assay. To further investigate the effects of treatment, RNA sequencing was conducted on both healthy and cancerous cells. The results demonstrated that CBSC-EV and novel miRNAs induced cytotoxicity in cancer cells, while in healthy cells, the DNA damage was repaired and cell viability was significantly increased ($p<0.001$). RNA sequencing revealed that following treatment with CBSC-EV and both CBSC-EV+N1 and N2 inhibitors in malignant melanoma cells, the expression of genes involved in the cytokine-mediated signaling pathway, cytokine-cytokine interaction, and cytokine activity were enhanced. In healthy cells treated with CBSC-EV and novel miRNA inhibitor transfection, the MT-CO1 gene was upregulated, contributing to cytochrome-c oxidase activity.

This study presents evidence of the potential use of novel miRNAs as genetic material for cancer therapeutics in the future. Additionally, the findings suggest that these miRNAs could be used as an immune system modulator against melanoma. These findings demonstrate that miRNAs can effectively suppress resistance to anticancer cytotoxic therapy, which is a common feature of cancer cells. This suggests that miRNAs can potentially enhance current cancer therapies.

#2784 Fatty acid synthase enhances stem-like properties of normal intestinal and colorectal cancer cells via an increase in notum expression and secretion.

C. O. Kelson, J. Weber Tessmann, D. He, C. Wang, Y. Zaytseva;
University of Kentucky, Lexington, KY

Introduction: Overexpression of lipogenic enzymes has been associated with a poor clinical outcome in colorectal cancer (CRC). Fatty acid synthase (FASN) synthesizes palmitate which can be utilized for post-translational modifications of various proteins. Notum, a palmitoleoyl-protein, prevents the downstream activation of Wnt signaling by de-palmitoylating Wnt ligands. Notum is also a CRC stem cell marker, and its expression correlates with poor prognosis in CRC. We found that upregulation of FASN is associated with an increase in Notum expression in mouse adenoma tissues. Therefore, the purpose of this study is to elucidate the mechanisms and contribution of FASN/Notum axis in CRC.

Methods: Adenoma and normal intestinal organoids, established from Apc^{Min}/VillinCre-ERT2 and Apc/VillinCre-ERT2 mouse models with hetero- and homozygous deletion of FASN. 4-hydroxytamoxifen (4-OHT) and TVB-3664 (FASN inhibitor) treatments were used to assess the effect of FASN deletion/inhibition on organoid growth and viability. LIVE/DEAD™ Viability/Cytotoxicity and Cell Titer-Glo® 3D Cell Viability Assays were used for quantitative analysis of growth. Human NOTUM/Protein notum homolog ELISA Kit was used to analyze Notum secretion. CRC cells, NTC and FASN shRNA, and control and FASN overexpression, were used for Notum analysis.

Results: The TCGA data analysis shows that Notum is significantly upregulated in CRC and its expression correlates with expression of FASN in tumor tissue. Utilizing qRT-PCR and Western blot analyses, we show that downregulation of FASN leads to a decrease in expressions of active β-catenin, Notum, and other stem cell markers in transgenic mouse models. Moreover, 4-OHT-mediated inhibition of FASN results in decrease viability and size in Apc^{Min}/ FASN/VillinCre-ERT2 and Apc/FASN/VillinCre-ERT2 organoids. Consistently, shRNA-mediated deletion of FASN decreases expression of Notum in CRC cells. In contrast, overexpression of FASN increases the expression levels of active and total β-catenin, Notum, and other stem cell markers in SW480 cells. We show that normal epithelial cells exposed to CRC cell medium exhibit stem-like phenotype which is reduced when cells are exposed to medium collected from Notum shRNA knockdown cells. Moreover, the addition of recombinant Notum restores this phenotype.

Conclusion: In summary, downregulation of FASN leads to a decrease in expression of Notum and is associated with morphological changes and significant decrease in viability in organoid models. Conversely, FASN overexpression upregulates Notum expression suggesting a potential cross talk between *de novo* lipid synthesis and Notum. Delineating the role of FASN regulation of stem-like properties via upregulation of β-catenin signaling and expression of Notum and other stem cell markers will provide the rationale for targeting the FASN/Notum axis in CRC.

#2785 Beyond the role of transcobalamin 1 (TCN1) as a vitamin B12-binding protein in hepatocellular carcinoma.

G. Muliawan, C. Leung, T. Lee;
Hong Kong Polytechnic University, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) is a common form of primary liver cancer and is associated with poor prognosis. Although sorafenib and lenvatinib have shown promising results in HCC treatment, their clinical benefits for patients have been limited owing to drug resistance and tumor relapse. This may be associated with the presence of tumor-initiating cells (T-ICs), which require further investigation to identify the key pathways or molecules involved in their regulation. Through *in vitro* enrichment of liver T-IC populations via a series of sphere passages under treatment with chemotherapeutic drugs, subsequent bulk RNA sequencing analysis identified a vitamin B-12 binding protein, transcobalamin 1 (TCN1), as the most upregulated molecule in such enriched T-IC populations. This result was consistent with the enrichment profiles of the stem cell signature in $TCN1^{High}$ HCC samples in the clinical dataset.
TCN1 is a secretory protein expressed at high levels in salivary glands and glandular cells; however, its function beyond its native role as a vitamin B12-binding protein in the regulation of T-ICs is unclear. Using lentiviral shRNA overexpression and knockdown approaches, we identified a critical role for TCN1 in regulating the properties of T-ICs, including self-renewal, invasiveness, tumorigenicity, and drug resistance, through *in vitro* and *in vivo* assays. Clinically, we also observed a substantial increase in TCN1 mRNA signatures in HCC samples, which was associated with poor prognosis of HCC patients. By analyzing the TCGA-LIHC dataset with confirmation by immunoprecipitation, we report, for the first time, that TCN1 directly interacts with integrin subunit alpha 3 (ITGA3), thereby regulating the Notch signaling pathway. Furthermore, ELISA results revealed the presence of the secretory form of TCN1 in HCC cells, which exerts a T-IC-enhancing effect on HCC cells via autocrine regulation.
In conclusion, our study provides novel insights into how TCN1 functions in HCC via a non-canonical mechanism, which goes beyond its conventional role as a vitamin B12-binding protein and uncovers a potential novel therapeutic target for HCC.

#2786 Seizure related 6 homolog (SEZ6), a cancer stem cell-specific secreted protein, is a novel GBM therapeutic target.

A. Mukherjee, S. Sengupta, A. Chowdhury, A. Srivastava, K. Somasundaram;
Indian Institute of Science, Bengaluru, India

Cancer Stem Cells (CSCs) are known to initiate a tumor, resist chemotherapy and radiotherapy, and also cause tumor recurrence. A deeper understanding of CSC biology is needed for a more effective therapeutic response. An integrative study of regulated transcriptome of human patient-derived Glioma Stem-like Cells (GSCs) using Gene Ontology (GO) analysis and Gene Set Enrichment Analysis (GSEA) identified a potential role for GSC in tumor angiogenesis. We chose Seizure Related 6 Homolog (SEZ6), one of the Wnt target genes, for further study, as its downregulation inhibited the potential of GSCs to induce angiogenesis without impacting GSC growth. SEZ6, a transmembrane protein, is shed upon cleavage by Beta-site APP cleaving enzyme 1 (BACE 1) and is known to be involved in normal neuronal functions; however, its role in cancer has not been studied yet.

SEZ6 silencing inhibited GSC-initiated tumor growth in an intracranial orthotopic mouse model due to reduced tumor angiogenesis and increased the mouse survival. Pre-treatment with a pharmacological inhibitor of BACE1 (BACE1i) prevented SEZ6 shedding from GSCs and inhibited the ability of the GSC-secretome to induce angiogenesis. Further investigations are ongoing to establish the use of BACE1i or BACE1-silencing as a novel therapeutic strategy to inhibit SEZ6-mediated tumor angiogenesis.

We also carried out a protein array-based investigation, which revealed that SEZ6 induced IL8 in endothelial cells to induce angiogenesis. Additional investigation showed that SEZ6 activated the TGFβ pathway in endothelial cells to induce IL8. SEZ6 interacted with TGFβRII as seen by confocal microscopy and co-immunoprecipitation. Generation of various deletion mutants of SEZ6 revealed that three Sushi [also known as complement control protein (CCP) module or the short consensus repeat (SCR)] domains, 3, 4, and 5, interacted with TGFβRII. Molecular docking and dynamic simulation studies identified Sushi-3 domain as the mediator of the interaction between SEZ6 and TGFβRII extracellular domain. Based on the above results, experiments are underway to design specific inhibitors of this interaction. We are also developing an improved BACE1 inhibitor that would inhibit the shedding of SEZ6 into the extracellular milieu to inhibit SEZ6 functions.

Thus, this study establishes that GSC-secreted SEZ6 activates the TGFβ pathway in endothelial cells to induce tumor angiogenesis and proposes a novel therapeutic target.

#2787 Heme oxygenase 1 pulls the brake on stemness-induced properties by prostate cancer-bone crosstalk.

A. A. Sabater[1], I. Achinelli[2], P. Sanchis[1], N. Anselmino[3], J. Bizzotto[1], G. Pascual[2], R. Seniuk[2], J. Cotignola[2], E. Vazquez[2], G. Gueron[2], A. Toro[2]; [1]CONICET - IQUIBICEN; Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), CABA, Argentina, [2]CONICET - IQUIBICEN, CABA, Argentina, [3]Department of Genitourinary Medical Oncology and the David H. Koch Center for Applied Research of Genitourinary Cancers, The University of Texas MD Anderson Cancer Center, Houston, TX

Prostate cancer (PCa) is the second most diagnosed cancer in men globally, and it is positioned as the fifth leading cause of cancer-related death in males. PCa aggressiveness and mortality is intricately linked to the metastatic disease, which is propelled by PCa stem cells (PCSCs). We have previously showcased the strong antitumoral role heme oxygenase-1 (HO-1) exerts in PCa. However, little is known about the association of HO-1 with the stemness capacity of PCa cells. In this work, we first performed clonogenic assays in PCa cells (PC3 and C4-2B) to assess colony formation, which evidenced a reduction on the stem-like properties of tumor cells treated with hemin (FDA approved drug and specific HO-1 inducer and activator). Next, we employed an indirect co-culture system of PCa cells (PC3) grown with bone progenitors (MC3T3) to emulate the dynamic PCa-bone crosstalk. PC3 cells were pre-treated or not with hemin. We performed comprehensive RNA-seq analyses and assessed the transcriptome of PC3 cells focusing on genes associated with stemness (*CD44, CD133* and other pluripotency markers), metastasis and a stem-like signature previously identified by our group (*ADAM15*, *BCL2L1*, *LTBR*, *MBNL2*, *SPINT1*). PC3 cells that were co-cultured with MC3T3 displayed upregulated PCSC and pluripotency markers, as well as *BCL2L1* and *LTBR*, when compared with PC3 cells cultured alone. Intriguingly, pre-treatment of PC3 cells with hemin prior to the co-culture impaired the upregulation of these genes, including the PCSC marker *CD44*, underscoring the protective effect of HO-1 induction against the pro-stemness effect triggered by bone progenitors secreted factors. Furthermore, we extended our analysis using PCa patients' survival and transcriptomic publicly available data (TCGA-PRAD (n=565), SU2C-PRAD (n=444), FHCRC-PRAD (n=176)), which revealed that *ADAM15, BCL2L1, LTBR and SPINT1* expression was higher in bone metastases *vs*. primary PCa ($p<0.001$). Moreover, *POU5F1, ALDH1L2, ADAM15, BCL2L1, LTBR* and *SPINT1* presented higher expression in bone metastases *vs*. other sites of metastasis ($p<0.01$). We also performed multiple survival analyses including progression-free, metastasis-free, biochemical relapse-free and overall survival (TCGA-PRAD, GSE116918, GSE70770) which revealed that *CD44* expression is associated with increased risk of metastasis ($p<0.05$), while patients with high expression of *SOX2*, *ALDH1B1* and *ALDH1L2* showed shorter times to biochemical relapse ($p<0.05$) Altogether, HO-1 expression modulates stemness and metastasis-related genes in PCa cells, steering tumor cells towards a more differentiated state and counteracting the pro-stemness effect inherent to the communication with bone progenitors. These findings support the antitumoral role of HO-1 in PCa and underscores *CD44* as an HO-1-modulated compelling candidate for further investigations.

#2788 Immunological targeting of integrin β1^{high}/β3^{high} melanoma.

Feng Wang[1], Ying Xin[2], James J. Moon[3], Alfred E. Chang[1], Max Wicha[2], Qiao Li[1]

[1]Department of Surgery, University of Michigan, Ann Arbor, MI,[2]Department of Internal Medicine, University of Michigan, Ann Arbor, MI,[3]Department of Pharmaceutical Sciences, University of Michigan, Ann Arbor, MI

We previously reported two integrin β4 (ITGB4)-targeted immunologic strategies, e.g., ITGB4 protein-pulsed dendritic cells (ITGB4-DC) for vaccination and adoptive transfer of anti-CD3/anti-ITGB4 bispecific antibody (ITGB4 BiAb)-armed tumor draining lymph node (TDLN) T cells. Both immunotherapies significantly demonstrated efficacy in inhibiting local tumor growth and lung metastases. We found these therapeutic efficacies were closely associated with the T cell as well as humoral anti-integrin β4^{high} cancer stem cells (CSCs) in breast (4T1) and head and neck squamous cell carcinoma (SCC7) tumor models. Recently, we further found that integrin subunits β1 (ITGB1) and β3 (ITGB3) are expressed at significantly high level in melanoma cells. In culture cell lines, integrin β1 and β3 are highly expressed on approximately 98% and 95% of the two mouse melanoma cell lines F10 and D5. We confirmed the expression of these two integrin subunits in newly harvested fresh melanoma tumors *in vivo*, which is very similar to the findings in cell lines. We then assessed ITGB1 and/or ITGB3-pulsed dendritic cell (DC) vaccines using F10 mouse model and demonstrated that ITGB1-DC or ITGB3-DC vaccine both exhibited significant antitumor efficacy inhibiting tumor growth, and ITGB1-DC + ITGB3-DC showed an additive/synergistic anti-tumor effect. Notably, we found that ITGB1 and ITGB3 loaded on separate DCs demonstrated more potent antitumor efficacy than loaded on the same DCs as vaccine. In addition, anti-PD-L1 significantly augmented the antitumor efficacy of ITGB1-DC/ITGB3-DC vaccine to inhibit tumor growth. Considering the crucial role of CSCs in tumor initiation, progression, metastasis, and recurrence, we further evaluated the expression of ITGB1 and ITGB3 on F10 and D5 ALDH^{high} CSCs. We detected significantly higher expression of ITGB1 on ALDH^{high} F10 CSCs (83.3%) and ALDH^{high} D5 CSCs (87.1%) *vs*. ALDH^{low} F10 non-CSCs (0.2%) and ALDH^{low} D5 non-CSCs (2.0%), suggesting that ITGB1 and ITGB3-targeted vaccine-conferred anti-melanoma effects may have significantly involved targeting of ITGB1^{high}/ITGB3^{high} melanoma CSCs. Furthermore, recent studies suggested that bone marrow (BM)-DCs expressing dysfunctional integrin β2 (ITGB2) exhibited more potent antigen presentation function than WT BM-DCs. We found that ITGB2 highly (63.3%) expressed on the surface of BM-DC, but not on F10 or D5 tumor cells. On-going experiments include the investigation of experimental evidence to verify that ITGB1 and ITGB3-targeted vaccines have induced targeting of ITGB1^{high}/ITGB3^{high} melanoma CSCs; and both the cellular and humoral mechanisms underlining the anti- ITGB1^{high}/ITGB3^{high} melanoma CSC immunity. At the same time, generation and use of ITGB2 deficient DCs for the vaccine preparation to improve the efficacy of DC vaccine targeting integrin ITGB1^{high}/ITGB3^{high} melanoma and melanoma CSCs warranty further investigation.

#2789 NCAPG promotes triple-negative breast cancer stemness by a positive feedback loop with HIF-1α.

H. Zhang[1], P. Xie[2], R. An[2];

[1]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China, [2]Xi'an Jiaotong University, Xi'an, China

Objective: Triple-negative breast cancer (TNBC) is life-threatening because of limited therapies and lack of effective therapeutic targets. NCAPG, an oncogenic marker, might be served as a new target for TNBC treatment. Here, we aimed to elucidate the role of NCAPG played in TNBC and the underlying mechanism.
Design: GEO data was used to investigate the potential targets for TNBC. Patient samples and TCGA data were used to demonstrate the clinical significance. Cell migration, self-renewal ability, chemoresistance and expression of pluripotency factors were tested to detect the stemness of TNBC cells. Immunoprecipitation, ubiquitination assay and chromatin immunoprecipitation assay were utilized to investigate the mutual regulation mechanism of NCAPG and HIF-1α.
Results: NCAPG was significantly overexpressed in TNBC compared with other subtypes of breast cancer and was positively correlated with poor overall survival. Elevated NCAPG expression could enhance cancer stem-like cell properties of TNBC cells. Mechanically, NCAPG positively regulated HIF-1α protein stability by interacting with HIF-1α and competitively abrogating the E3 ligase FBXW7-mediated ubiquitination and degradation towards HIF-1α. NCAPG, as a direct target gene of HIF-1α, could be in turn transcriptionally upregulated by HIF-1α.
Conclusion: NCAPG promotes TNBC stemness by a HIF-1α/NCAPG positive feedback loop. NCAPG is a promising target for TNBC treatment.

#2790 Hematopoietic stem cells tropism and conditioned media for targeting the triple negative breast cancer stem cells and associated mechanism: An in vitro study.

S. Mallick, S. Shenoy P, B. Bose;
Yenepoya University, Mangaluru, India

Triple-negative breast cancers are the most challenging to treat with targeted therapy because of their non-expression of cell surface receptors, unlike other types of breast cancer. However, conventional therapies such as chemotherapy, radiotherapy, and surgery are standard treatment modalities. Moreover, drug encapsulation strategies to deliver drugs at the targeted site have been sought-after alternatives. Hematopoietic Stem Cells (HSCs) have unique features to migrate towards inflammatory sites and other body organs during any injuries and release various cytokines, which lead to interaction with molecular pathways and results in reduced inflammation and tissue injuries. From this characteristic, we have hypothesized that hematopoietic stem cells can show tumor tropism and modulate the metabolic alteration in cancer and cancer stem cells, mainly focusing on Triple Negative Breast Cancer Stem Cells (TNBC CSCs). In this study, we have sorted both cancer stem cells and hematopoietic stem cells from TNBC and hematological cell lines, respectively. Sorted HSCs were cultured in specific conditions to prepare conditioned media. Then, both cell' types were used for co-cultured assay and conditioned media cultured with TNBC-CSCs were performed. Metabolomics studies were performed to decipher the molecular interactions and TNBC-CSCs metabolic alterations. The result indicates that the HSCs are showing positive tropism towards TNBC stem cells. Furthermore, HSCs-derived conditioned media (CM) interact with the cell cycle pathway by downregulating the CDK genes and causing DNA breakage in the TNBC-CSCs. Moreover, the Metabolomics studies further confirmed that HSCs CM-derived cytokines interact with various pathways, dysregulating the TNBC-CSCs proliferation and altering the metabolic activities.

#2791 Establishment of immortalized endometrial cell lines using Sendai virus.

K. Hikino, H. Komatsu, G. Hichiwa, K. Kazuki, Y. Kazuki, H. Kugoh, M. Okawa, Y. Ida, M. Hosokawa, M. Sawada, A. Kudoh, S. Sato, F. Taniguchi;
Tottori University School of Medicine, Yonago City, Japan

Objective: To establish endometrial immortalized cell lines using the Sendai virus and analyze their characteristics.
Methods: The study included patients with benign ovarian tumors and endometrioid carcinoma who had regular menstrual cycles. Endometrial cells were collected and separated into epithelial and non-epithelial cells using flowcytometry (FCM) (CD326 (EpCAM) antibody). Furthermore, the isolated cells were infected with Sendai virus carrying three immortalization genes (Bmi-1, hTERT, and SV40T) to create immortalized cell lines. The cells were characterized as epithelial cells by immunocytochemistry (ICC), and receptor expression was assessed by reverse transcription PCR (RT-PCR) and ICC. Non-epithelial cells from the patients with endometrial carcinoma were evaluated using ICC.
Results: The immortalized cell lines were capable of more than 20 passages. Immortalized endometrial epithelial cells tested positive for anti-Keratin antibodies and negative for anti-Vimentin antibodies by ICC. Additionally, FCM detected these cells as positive for anti-EpCAM antibody, confirming that they were epithelial cells. RT-PCR confirmed mRNA expression of estrogen α-receptor and progesterone receptor after 20 passages and ICC confirmed protein expression of them after 10 passages, establishing an endometrial epithelial immortalized cell line. Non-epithelial cells isolated from patients with endometrial carcinoma tested positive for anti-α-smooth muscle actin and anti-Vimentin antibodies by ICC, indicating their characterization as cancer-associated fibroblasts.
Conclusion: We successfully established an immortalized cell line of endometrial epithelial cells using Sendai virus and generated cancer-associated fibroblasts.

TUMOR BIOLOGY: Microbiome and Cancer
Poster Session

#2794 Consumption of dietary fiber correlates with a significant increase in a-diversity in the intestinal Microbiome of allo-HCT recipients and with lower GVHD-lethality in pre-clinical models.

Jenny Paredes[1], Anqi Dai[1], Ruben J. Faustino Ramos[1], Peter Adintori[1], Teng Fei[1], Chi Nguyen[1], Harold Elias[1], Kristen Victor[1], Romina Ghale[1], Charlotte Pohl[1], Ana Gradissimo[1], Justin Cross[1], Oriana Miltiadous[1], Jonathan Peled[1], Marina Burgos da Silva[1], Marcel RM van den Brink[2]

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]City of Hope Los Angeles, Los Angeles, CA

Background: Graft-versus-host disease (GVHD) is associated with a decrease in intestinal microbiota and beneficial short-chain fatty acids (SCFAs). Dietary fiber can modulate the intestinal microbiome and SCFA production which effect intestinal epithelium health and immunity. Therefore, we hypothesized that a high-fiber diet in recipients of an allogeneic hematopoietic cell transplantation (allo-HCT) could result in an increase of beneficial commensals, concentrations of SCFAs, and decreased risk of GVHD.

Methods: We evaluated dietary data and fecal samples of allo-HCT patients receiving unmodified grafts (n=95) at MSKCC (day -10 to day +30 relative to allo-HCT) and correlated microbial α-diversity (16s rRNA, n=568 samples) with fiber intake and acute GVHD in No-GVHD (n=30), Non-LGI-GVHD (GVHD except lower gastrointestinal tract, n=41), and LGI-GVHD patients (lower gastrointestinal tract GVHD, n=24).We tested concentrations of cellulose fiber (0%, 6%, 12% and 40%) in a GVHD mouse model (C57BL/6J into BALB/c) to assess survival, microbial composition (shotgun sequencing n=180; n=30 per group), cecal SCFAs concentrations (GC-MS n=24, n=8 per group), and lastly, T cell subsets (Th1/Th17/Tregs) and colonic epithelial MHC-II expression (flow cytometry n=54, n=18 per group).

Results: In allo-HCT patients, fiber intake correlated positively with microbial α-diversity (R=0.3, p=0.04), especially in the LGI-GVHD group (p=0.007). Additionally, patients with high fiber intake had higher microbial α-diversity compared to the low fiber cohort (p<0.0001).GVHD mice receiving a fiber-rich diet (12%), compared to 0% and 6%, had a higher microbial α-diversity (p=0.01); reduced GVHD lethality (p=0.02); and a decrease in the *Enterococcus sp.* (p=0.004) and *Akkermansia sp.* (p=0.01) abundance; taxa which are associated with worse overall survival and increased risk of lethal GVHD. In contrast, compared to 12%, the 40% fiber diet resulted in worse survival (p=0.002), lower α-diversity (p=0.05) and a higher abundance of *Bifidobacterium sp.* (p<0.0001).Cecal butyrate in GVHD mice was higher in response to the 12% vs. the 0% (p=0.01) and 6% (p=0.05) fiber diets. Mice treated with12% fiber displayed higher number of Tregs (CD4+CD25+FOXP3+), than those with 0% (p=0.001) and 6% (p=0.02); and a lower expression of MHC-II in epithelial cells (EpCAM+CD45-) vs. 0% fiber (p=0.02).

Conclusions: We demonstrated that a higher fiber intake in allo-HCT patients is associated with an increase in α-diversity; especially in LGI-GVHD patients. In a pre-clinical GVHD-model, optimal fiber consumption (12% cellulose) leads to an increase in α-diversity, a decrease in pathogen relative abundance, increased T-regulatory cells, and a decrease in GVHD lethality. These results suggest that dietary fiber could be utilized to prevent GVHD.

#2795 An investigation to identify the phylogeny of bacterial communities in the pancreatic cancer microbiome by 16SrDNA sequencing and bioinformatic analysis.

H. N. Banerjee[1], C. Hunter[1], N. BANERJEE[1], K. Perry[1], K. Dia[1], A. Banerjee[1], S. Bhattacharya[2], H. Rachamala[3], E. Wang[3], S. Dutta[3];
[1]Elizabeth City State University under University of North Carolina, Elizabeth City, NC, [2]Mayo Clinic, Jacksonville, NC, [3]Mayo Clinic, Jacksonville, FL

The microbiome refers to the diverse community of microorganisms, including bacteria, viruses, fungi, and other microbes, that inhabit various parts of the human body, such as the skin, mouth, gut, and other mucosal surfaces. The role of the microbiome in cancer is a complex and evolving area of research. While much is still being learned, there is evidence suggesting that the microbiome can influence cancer development and progression in several ways. Some bacteria within the microbiome can produce substances that may be either carcinogenic or protective against cancer. For instance, the conversion of certain dietary components by gut bacteria can produce metabolites that may either promote or inhibit cancer development. Different cancers may be associated with specific alterations in the microbiome, for example, the gut microbiome has been extensively studied in relation to colorectal cancer, with certain bacterial species potentially contributing to the development of this cancer. However, the role of microbiome in Pancreatic cancer is still not extensively studied, henceforth, we did a preliminary study to identify novel bacterial communities around pancreatic cancer microbiome by 16SrDNA sequencing in human pancreatic cancer xenograft model mice. Isolating total genomic DNA from the pancreatic model mice feces, 16SrDNA PCR was done using specific primers and the amplicon obtained as PCR product was confirmed by standard DNA gel electrophoresis with a 1 kb standard ladder to be 1.5kb in size universal for all bacterial 16SrDNA. The amplicon was then sent for Next Generation Sequencing at Zymo Research Corporation (CA). The resultant DNA sequences were analyzed by bioinformatics studies and their phylogeny identified by comparing with 16SrDNA data base. Differential abundance of the bacteria's of the genera Lachnoclostridium, Robinsoniella, Alistipes, Akkermansia and Lactobacillus were observed analyzing the data along with other bacterial communities. We are currently continuing the project to identify more bacterial communities of significance in the pancreatic cancer microbiome and investigating the role and significance of these bacterial communities in pancreatic cancer tumor microenvironment. Acknowledgement This study was done by a joint collaboration between scientists and students of Elizabeth City State University (ECSU) campus of the University of North Carolina Systems and Mayo Clinic, Jacksonville. This research is supported by the NIH-NIGMS grant#T34GM100831-10 to Dr. H. Banerjee and a University of North Carolina General Administration Grant to Dr. Colby Hunter at ECSU.

#2796 Colibactin mutation signatures are associated with younger age of onset in colorectal cancer.

S. Gerstberger[1], M. Lumish[2], S. Hartner[3], F. Shah[1], S. Choi[1], A. Luthra[1], Q. Jiang[1], H. Woo[1], A. Mahmoud[1], H. Walch[1], S. Asawa[4], M. Donoghue[1], A. Cercek[1], R. Yaeger[1], A. McPherson[1], F. Sanchez-Vega[1], K. Ganesh[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Department of Hematology and Oncology, University Hospitals Cleveland Medical Center, Cleveland, OH, [3]McGill University, Montreal, QC, Canada, [4]ETH Zurich, Zurich, Switzerland

Escherichia coli (E. coli) strains carrying the polyketide synthase (pks) island produce the genotoxin colibactin associated with pathogenesis of colorectal cancer (CRC). Colibactin binds directly to DNA, causing alkylating damage leading to double stranded DNA breaks. Colibactin mutagenesis results in mutations in hexameric A-T rich DNA motifs that can be identified by whole genome sequencing (WGS) as mutation signatures SBS28 and SBS88 (SBS-pks). Since WGS is not routinely used clinically, we developed an approach to specifically identify SBS-pks using a clinical targeted exon capture assay, MSK-IMPACT. In an institutional pan-cancer clinical cohort of 78,905 tumors we identified 15,967 samples with > 20 mutations detected by MSK-IMPACT. We identified 150/1,884 samples with microsatellite stable CRC with >10% mutations attributable to SBS-pks. Examining clinicopathologic and genomic features of SBS-pks+ compared to SBS-pks- CRC tumors, we found that SBS-pks+ signatures are significantly enriched in younger age of onset compared to SBS-pks- CRC patients (median age 55 vs median age 59, p= 0.0028). SBS-pks+ CRC exhibit similar driver mutations and tumor mutational burden (TMB) compared to SBS-pks- CRC but are associated with increased fraction of genome altered (FGA). To mechanistically investigate colibactin-associated damage we developed a novel long-term human colon organoid-microbe co-culture model system that takes advantage of reversal of polarity in suspension culture. WGS of human CRC organoids co-cultured for three months with pks+ and delta-pks E. coli NC101 confirmed induction of pks+ specific SBS-pks signatures, validating the model. Leveraging this model and a biobank of normal colon organoids from donors aged </> 50 years, we are investigating the molecular mechanisms underlying the association of SBS-pks with younger age of onset CRC.

#2797 *Fusobacterium nucleatum* antigens drive tumor-associated macrophage-like cells in an engineered oral squamous cell carcinoma on-a-chip.

M. G. C. Sousa, Sr.[1], A. Athirasala[1], M. A. Fraga[1], D. Higashi[2], J. Merrit, Sr.[2], L. Bertassoni, Sr.[1];
[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]Oregon Health and Science University, Portland, OR

Oral squamous cell carcinoma (OSCC) is the sixth most prevalent cancer, representing 90% of all head and neck cancers. Oral cancers are expected to cause 11000 deaths in the US in 2023. OSCC comprises a complex microenvironment involving a 3D collagenous matrix, innate and adaptative immune cells, fibroblasts, and opportunistic microorganisms. *Fusobacterium nucleatum,* for instance, is related to OSCC development in different aspects, such as inducing epithelial-to-mesenchymal transition and coordinating the immunological response in the tumor microenvironment (TME). Although some advances were achieved in understanding the OSCC TME, there is an urge to develop advanced *in vitro* models to investigate the immunosuppressive role of opportunistic microorganisms in OSCCs. Offering a promising avenue for studying OSCCs, organs-on-a-chip serve as microphysiological platforms that closely emulate the complexities of biological tissues within the highly controllable microfluidic, cellular communication, and extracellular matrix. Here, we developed an OSCC on-a-chip to understand the immunomodulatory profile of *F. nucleatum* on macrophages in the TME. We cultivated oral squamous carcinoma cells in 3D in a collagen matrix (2.5 mg/mL) in a microfluidic device that has a central chamber (1mm in width) and two lateral channels connected by triangular pillars (space between pillars of 115 µm). Our tested groups were collagen matrix containing OSCC (5.10^5 cells/mL) in the presence or absence of heat-killed antigens (1.10^6 CFUs/mL) from *F. nucleatum* (ATCC 23726). *F. nucleatum* cells were integrated with collagen gels and oral squamous carcinoma cells for three days. On the fourth day, we added 2.10^3 THP-1 derived macrophages (differentiated with PMA 100 ng/mL) in the lateral channel to evaluate their chemoattraction to the 3D matrix in the presence or absence of *F. nucleatum* for 48 hours. We noticed a significantly higher number of macrophages invading the 3D matrices that had heat-killed antigens when compared to the groups containing just OSSCs. By immunofluorescence, we stained the cells with markers for M1 (CD86) and M2 (CD163) and observed a significantly lower number of CD86 and a higher number of CD163-positive cells in the *F. nucleatum* stimulated group. When cytokines and chemokines were measured from these chips by Luminex assay, we found that the presence of heat-killed bacteria upregulated TNF-α, MCP-1, IL-6, VEGF, and CCL5 significantly, showing that the presence of *F.nucleatum* might stimulate tumor-associated macrophages-like cells. These results enable us to understand how the early interactions between opportunistic microorganisms and the immune system modulate the suppression responses in the tumor microenvironment.

#2798 Oral fungal infection tweaks the innate immune tumor microenvironment promoting.

X. Li[1], N.-Y. Song[2], A. K. Singh[1], J. Badger[3], C. Jiang[4], F. Zhu[1], D. Tross[1], Y. Zhao[5], B. Tran[5], Y. Hu[1];
[1]National Cancer Institute, Frederick, MD, [2]Yonsei University College of Dentistry, Seoul, Korea, Republic of, [3]National Cancer Institute, Bethesda, MD, [4]National Heart, Lung, and Blood Institute, Bethesda, MD, [5]Leidos Biomedical Research Inc, Frederick, MD

It is yet unknown how a fungus and tumor interplay impairs innate immunity, modulating tumorigenesis. Here, we found that oral infection with *Cladosporium cladosporioides* of mice with *Ikka* deficiency in epithelial stem cells enhanced STAT3-dependent oral squamous cell carcinoma (SCC) development and fungal colonization. In wild-type mice infection was cleared up, suggesting a synergic tumor-fungus loop involved in the accelerated carcinogenesis. *C. cladosporioides*-mediated EGFR activation stimulated intratumor STAT3-led pathways to generate an acidic oral milieu, which disrupted bacterial compositions and suppressed neutrophil's ROS but increased *Il1b* expression, dampening neutrophil's fungitoxicity and allowing oral fungal and bacterial overgrowth. In addition, fungus-induced IL-1β/IL-17A augmented STAT3 activity in SCC cells, contributing to local and distal carcinogenesis. Significantly, fungal signals were greater in human head and neck SCCs (HNSCCs) and SCC-adjacent tissues than in healthy controls and were co-localized with *IL1B*-expressing neutrophils in HNSCCs. These similar traits of oncogenic pathways, microbiota dysbiosis, and defective neutrophils in HNSCC patients with poor survival highlight the importance of increased fungal infection for human malignant development and therapy.

#2799 Intestinal *Akkermansia muciniphila* complements the therapeutic efficacy of PD1 therapy by reshaping the immunosuppressive microenvironment in nonalcoholic fatty liver disease (NAFLD)-induced hepatocellular carcinoma.

Xueqian Wu, Fan Ying, Katherine Po Sin Chung, Carmen Oi Ning Leung, Terence Kin Wah Lee

Applied Biology and Chemical Technology, Hong Kong Polytechnic University, Hong Kong, Hong Kong

Objectives: Nonalcoholic fatty liver disease (NAFLD)-induced hepatocellular carcinoma (HCC) is an emerging malignancy in the developed world. However, immune checkpoint inhibitors (ICIs) are ineffective for patients with this disease. Advances in research have shown that gut-liver communication contributes to NAFLD progression. Therefore, identifying a key gut microbiota for predicting ICIs response and an effective combinatorial strategy is urgently needed.
Design: 16S rRNA sequencing was employed to identify key gut microbiota crucial in developing the mouse NAFLD-induced HCC model. The *in vivo* roles of *Akkermansia muciniphila* (*Akk*) were evaluated by immunofluorescence staining, qPCR, mass spectrometry analysis, ELISA assay, and single-cell RNA sequencing (scRNA-seq) coupled with immune profiling analysis. The clinical and therapeutic value of *Akk* alone in combination with PD1 treatment was investigated.
Results: *Akk* was decreased from healthy to HCC tissues during HCC tumor development, and daily administration of *Akk* not only ameliorates liver steatosis and cholesterol biosynthesis but could effectively attenuate the development of NAFLD-induced HCC. *Akk* repairs the intestinal lining, with a concurrent decrease in the serum concentration of *lipopolysaccharide* (LPS) and bile acid metabolites. Using scRNA-seq coupled with immune profiling analyses, we found that *Akk* suppressed the populations of immunosuppressive cells, including monocytic myeloid-derived suppressor cells (m-MDSCs) and M2 macrophages, by suppressing the differentiation of these cells from monocytes, which leads to T cell proliferation and activation. Consistent with this finding, *Akk* administration, combined with PD1 treatment, exerted a maximal growth-suppressive effect, accompanied by increased infiltration and activation of T cells. Clinically, the fecal level of *Akk* in HCC patients was decreased in NAFLD-induced HCC patients and serves as a potential biomarker for predicting PD1 response in HCC patients.
Conclusions: *Akk* regulates the immune tumor environment by regulating two key immune suppressive cells via regulation of the LPS flux to develop NALFD-induced HCC. This finding provides a solid therapeutic basis for a rational combination with PD1 for the treatment of this deadly disease. Interestingly, *Akk* may serve as a predictive biomarker for PD1 response in HCC patients.

#2800 Shotgun metagenomics of COPD-associated lung cancer tissue microbiome.

Atsushi Matsuoka[1], Kazuhiko Shien[2], Shuta Tomida[3], Daisuke Mizuno[1], Masayoshi Ohki[1], Ryo Yoshichika[1], Tomohiro Higashihara[1], Naohiro Hayashi[1], Fumiaki Mukohara[1], Mao Yoshikawa[1], Ken Suzawa[2], Hiromasa Yamamoto[2], Shinichi Toyooka[1]

[1]Thoracic, Breast and Endocrinological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan,[2]Thoracic, Breast and Endocrinological Surgery, Okayama University Hospital, Okayama, Japan,[3]Center for Comprehensive Genomic Medicine, Okayama University Hospital, Okayama, Japan

The gut microbiome plays a crucial role in the development of multiple chronic diseases. Several solid tumors including lung cancer are also implicated in the gut microbiome in cancer initiation and progression, possibly affecting signaling pathways in the tumor microenvironment. However, the microbiome in the peripheral lung tissue is unexplored and their relationship to the lung tumor microenvironment is still unknown. Thus, to explore the relationship between the microbiome and the tumor microenvironment of lung cancer, we performed shotgun metagenomic sequencing of the lung cancer tissue, especially in lung cancer patients accompanied by chronic obstructive pulmonary disease (COPD). We confirmed the presence of a diverse microbiome in peripheral lung cancer tissue. Next, we focused on individual species. We observed significant differences in the relative abundance of several species between COPD and non-COPD patients, and cancer and non-cancer tissue. Then, we focused on the metagenomic diversity between samples. The number of species in COPD patients and cancer tissue were decreased. And the bacterial total abundance in each sample were observed similar trend. On the other hand, alpha diversity in each sample were showed different trend to them. In the analysis of beta diversity using Principal Coordinate Analysis (PCoA), clusters were formed in each group. These findings suggest that microbiome imbalance known as dysbiosis in the peripheral lung tissue may affect the tumor microenvironment resulting in cancer progression.

#2801 Identifying gut microbial determinants of clonal hematopoiesis of indeterminate potential (CHIP) in immunotherapy treated melanoma patients..

E. A. Fallon[1], S. Urrutia[1], R. Ayabe[1], M. Chelvanambi[1], A. Damania[1], S. Johnson[1], T. Tanaka[1], Z. Li[1], Y. Seo[1], S. Cass[2], M. C. Wong[1], N. Ajami[1], J. Wargo[1], K. Takahashi[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]University of Texas Medical Branch, Galveston, TX

INTRO: Clonal hematopoiesis (CH) of indeterminate potential (CHIP) is associated with poor outcomes in those with non-hematologic cancers. CH mutated macrophages and neutrophils have increased capacity to home to peripheral tissues, driving local inflammation; they are also implicated in immunotherapy related toxicity. The relationship between CH and the microbiome in those treated with immunotherapy is not well understood.

RESULTS: 35 patients with stage IV melanoma treated with upfront immunotherapy; treatment and cohort characteristics are below (Table 1). We performed error corrected duplex sequencing on peripheral blood mononuclear cells using a panel previously validated for CH mutations. With a cutoff of 0.5% variant allele frequency (VAF), among 10 CHIP positive patients, we found mutations in TET2 (8/10), DNMT3A (7/10), PPM1D (2/10), and JAK2 (1/10). There was no difference in either survival or response based on CHIP status (Log-Rank Chi-Square p=0.44); however, CHIP positivity was associated with greater microbiome richness as measured by alpha diversity (p=0.0012 Shannon diversity) and distinct structural/compositional diversity vs CHIP negative patients as measured by beta diversity (p=0.032, R-Squared= 0.045). We inferred KEGG pathway activity from whole genome sequencing and identified that CHIP positive patients were enriched for exopolysaccharide biosynthesis while CHIP negative patients had higher expression of nucleotide sugars biosynthesis and amino acid metabolism pathways.

DISCUSSION: In patients treated with immunotherapy for melanoma, microbiome diversity signatures correlate with presence of CHIP. The analysis suggests that there are distinct taxonomic and functional features defining CHIP positivity. The effect of these cells in the tumor microenvironment and their role in immunotherapy response requires further exploration.

#2802 *Enterococcus faecalis*-derived X facilitates pancreatic tumor by regulating immune microenvironment.

B. Wang, C. Yang, Y. Xie, T. Zhou, J. Yu, J. Hao;
Pancreas Center, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer; Tianjin Key Laboratory of Digestive Cancer; Tianjin's Clinical Research Center for Cancer, Tianjin, China

Previous research in human samples has found a link between the intratumoral microbiome and the development and progression of pancreatic cancer. Nevertheless, the bacterial strains that may have an effect, and the underlying mechanisms, are largely unknown. To identify potential bacterial species, microbiome sequencing was performed on fecal and tumor samples obtained from KPC mice and patients with pancreatic tumors in this study. To identify metabolites associated with bacteria, untargeted metabolomics were analyzed on serum and tumor samples. Furthermore, advanced and high-throughput techniques, such as single-cell RNA sequencing, tumor organoids, engineered bacteria and germ-free mouse models, were used to elucidate the specific influence on the immune microenvironment of pancreatic tumors. Our findings reveal an increased abundance of *Enterococcus faecalis* (*E. faecalis*) in the gut during the development of pancreatic cancer, accompanied by its accumulation in the tumor. Patient-derived *E. faecalis* strain and its metabolite X, facilitated pancreatic tumor growth, reduced the recruitment of $CD8^{\pm}$T cells, and caused their dysfunction in the tumor, relying heavily on *E. faecalis* intratumoral colonization. We found that X inhibits the production of anti-tumor chemokines like CCL21 and CCL8 in tumor cells, reducing peripheral $CD8^{\pm}$ T cell infiltration into the tumor. Furthermore, X was found to inhibit glycolysis and compromise the function of tumor-infiltrating $CD8^{\pm}$ T cells by decreasing the activity of lactate dehydrogenase (LDH) in $CD8^{\pm}$ T cells. Additionally, oral doxycycline, an antibiotic that targets intratumoral *E. faecalis*, effectively enhanced the therapeutic effect of gemcitabine in pancreatic cancer. Finally, we present evidence that X may predicts efficacy and survival in pancreatic cancer patients. Together, our findings provide new insights into the role of *E. faecalis* in mediating the immune environment of pancreatic tumors, highlighting *E. faecalis* and X as potential therapeutic targets for pancreatic cancer patients.

#2803 Identification of microbiome and predictive immune biomarkers in patients with advanced non-small lung cancer treated with pembrolizumab with or without chemotherapy.

J. Lee[1], S.-J. Choi[1], G.-T. Lee[1], J. Yang[2], H.-S. Oh[2], A. Min[2], B.-E. Kwon[2], S.-s. Kang[3], S. Baek[1], D. Kim[1], J. Kim[1], S. Lim[1], M. Hong[1], K.-H. Pyo[1], B. Cho[1]; [1]Yonsei University College of Medicine, Seoul City, Korea, Republic of, [2]CJ Bioscience Inc., Seoul City, Korea, Republic of, [3]JEUK Institute for Cancer Research,JEUK Co., Ltd., Gumi City, Korea, Republic of

Background: Recent studies have shown that gut microbiota modulates antitumor immunity, and affect clinical efficacy of immune checkpoint inhibitors, including anti-programmed death-1 (PD-1) and programmed death-ligand 1 (PD-L1) inhibitors. We aimed to explore the metagenomic profiles of previously untreated, treatment naïve, stage IV non-small cell lung cancer (NSCLC) treated with pembrolizumab, an anti-PD1 agent with or without platinum-based chemotherapy and identify distinct ecological niche between responder and non-responder groups.

Methods: We performed metagenome sequencing, whole exome sequencing (WES), and RNA sequencing (RNA-seq) on 50 patients with stage IV NSCLC, including adenocarcinoma (N=31) and squamous cell carcinoma (N=22). We employed Dirichlet Multinomial Mixtures (DMM) community typing to cluster microbial community profiling data at the genus level and analyzed the changes in microbial composition and diversity between enterotype 1 (E1, N=27) and enterotype 2 (E2, N=23). Mutation landscape including genomic alterations in relation to immune response was analyzed between responders and non-responders using WES data. Differentially expressed genes (DEGs), Gene Set Enrichment Analysis (GSEA), and immune deconvolution analysis were carried out using RNA-seq data to analyze molecular profiling of two enterotypes between the responder (N=15) and non-responder (N=35) groups.

Results: The two enterotypes exhibited distinct microbial abundances and alpha diversity indices. Abundances of members of *Bacteroidaceae* (P=0.011) and *Oscillospiraceae* (P<0.001) were higher in E2 members, and enrichment of *Lactobacillaceae* (P=0.006) and *Bifidobacteriaceae* (P=0.041) were higher in E1. Compared to E1, the number of observed bacterial species (P<0.001) and Shannon index (P<0.001) was significantly higher in E2, indicating a healthier gut environment. The proportion of responders was higher in E2 than in E1 cluster. Comparison between responders and non-responder groups within each enterotype revealed that *Lactobacillaceae* showed an association with the response in E2 cluster. Mutation landscape revealed *TP53* mutation as the most common mutation, more frequently observed in the E2 (100%) than in the E1 (56%) cluster.

Conclusion: We explored the association between the gut microbiome and clinical response to pembrolizumab with or without combination with chemotherapy and found that E2 cluster enriched with *Lactobacillaceae* is associated with treatment response. Further analysis with larger cohort is ongoing.

#2804 Comparative analysis of microbial diversity and abundance in colorectal cancer patients before and after surgery.

H. Park[1], M. Kim[2], J. Park[2], S.-Y. Jeong[2], A. Shin[1], S.-Y. Cho[3], E. Jung[4], D. Suh[4], S. Lee[4], Y. Park[4];

[1]Seoul National University College of Medicine, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Seoul, Korea, Republic of, [3]Seoul National University, Seoul, Korea, Republic of, [4]HEM Pharma Inc., Suwon, Korea, Republic of

Background: Previous studies have indicated differing patterns of the microbiome in colorectal cancer (CRC) patients compared to healthy individuals. Yet, the changes in microbial features of CRC patients before and after surgery remain underexplored. This study aims to investigate the impact of surgical intervention on the gut microbial diversity and abundance at the patient level.

Methods: This hospital-based study analyzed data from 36 CRC patients who underwent CRC surgery at the Department of Surgery, Seoul National University Hospital between January 2020 and May 2022. Fecal samples from these patients were collected twice, both before surgery and during the post-surgery follow-up period. DNA extraction from stool specimens was performed using the MAG-Bind Universal Pathogen kit. This was followed by amplification and sequencing of the 16S rRNA gene V3-V4 region, with subsequent bioinformatics analyses conducted using QIIME 2. To compare the alpha diversity indices of patients before and after surgery, we employed both the paired t-test and the Wilcoxon signed-rank test.

Results: Out of the 36 patients, 21 were male and 15 were female, with a mean age of 63.8 years. The average duration between surgery and post-surgery fecal sample collection was 2.3 years. Post-surgery, the alpha diversity indices decreased compared to pre-surgery, but the differences were not significant, except for Faith's PD. At the phylum level, *Firmicutes* and *Actinobacteriota,* both recognized as beneficial bacteria, increased in abundance after surgery, while *Bacteriodota,* typically considered harmful, significantly decreased. At the genus level, variations in microbial abundance also showed an increase in *Blautia*, *Bifidobacterium*, and *Collinsella*, and a decrease in *Enterococcus*, *Romboutsia*, and *Faecalibacterium*. The rise in *Bifidobacterium* abundance following surgery suggests a gut environment altered by the surgery to favor beneficial bacteria. However, a specific species decline in *Bifidobacterium adolescentis* was observed, highlighting that CRC surgery may have distinct impacts on different bacterial species.

Conclusions: Our study indicates a slight decline in gut microbiome diversity following surgery. At the phylum level, there was an observed increase in beneficial bacteria and a decrease in harmful bacteria post-surgery, suggesting potential health improvements in CRC patients. Further research, particularly with a larger sample size and encompassing a broader range of bacteria, is needed to better understand the patterns and implications of microbiome variation in relation to surgical outcomes. Such insights could be pivotal in optimizing patient care and recovery strategies post-surgery.

#2805 Shotgun sequencing of serial fecal microbiome samples in patients with colorectal cancer reveals distinct bacterial species and metabolic pathways associated with tumor sidedness and age at diagnosis.

M. Lumish, N. Waters, J. Leinwand, A. Saxena, A. Dai, T. Fei, M. Fox, A. Chavez, J. Bermeo, D. Ismailgeci, E. Benitez, C. Cowley, J. Garcia-Aguilar, M. Weiser, A. Cercek, L. A. Diaz, M. van den Brink, J. Peled, K. Ganesh;
Memorial Sloan Kettering Cancer Center, New York, NY

Background: The incidence of early onset (EO) colorectal cancer (CRC) (age <50) is rising with a left-sided predominance. Response to chemotherapy and anti-EGFR therapies differ in left- and right-sided colon cancers after accounting for genomic differences. The intestinal microbiome may contribute to CRC pathogenesis and response to therapy; how organisms drive metastasis and treatment resistance is not known.
Purpose: To define the microbiome contribution to EO-CRC and response to treatment by analyzing longitudinal samples from previously untreated patients with CRC.
Methods: We designed a prospective biospecimen collection platform and selected patients with previously untreated CRC. We collected stool, biopsy or surgical tissue, and peripheral blood mononuclear cells at baseline and serially throughout treatment. Stool samples were analyzed using shotgun sequencing. Alpha diversity was calculated using the inverse Simpson index and compared between groups using the Wilcoxon signed-rank test. Beta diversity was analyzed using the Bray-Curtis dissimilarity matrix and compared using PERMANOVA. Multivariate associations between species abundance, metabolic pathway abundance and clinical covariates were performed using MaAsLin2 R package.
Results: We analyzed a total of 132 stool samples from 65 patients with CRC including up to 5 samples from a single patient over time. Mean alpha diversity did not differ significantly by primary site, stage or age at diagnosis. Beta diversity was significantly different between samples from right- compared with left-sided CRC (P=.011) and pre- and post-surgery (P=.001). Beta diversity also differed significantly by diagnosis age (<50 vs. > 50) (P=.001 all samples, P=.032 baseline samples). When CRC baseline samples were examined at the species level, *Blautia glucerasea* was associated with right-sided primary (P<.001, Q=.1). Considering non-metastatic cases, recurrence was associated with increased *Enteroscipio rubneri, Actinomyces oral taxon 448, Bacteroidales sp.* and *Lancefieldella parvula* (P<.01, Q>0.1). We further investigated metabolic pathway associations. The superpathway of L-threonine metabolism was significantly increased in samples from patients with right-sided colon cancer at baseline (P<.001, Q=.03). Considering samples across all time points, right-sided colon cancer was associated with increased abundance of pathways associated with propanoate degradation, L-threonine metabolism, yeast NADPH production, and hydroxyphenylacetate degradation (all P<.001, Q<.05).
Conclusions: The functional effects of the intestinal microbiome may underlie the distinct biology of right-sided colon cancer. Composition of the intestinal microbiome differs by age at diagnosis. Updated recurrence data will be presented.

#2806 A single dose of perioperative cefazolin disrupts the gut microbiome and immunity in patients (pts) with early-stage melanoma.

E. Fernandez, S. Cass, Y. D. Seo, A. V. Damania, X. Meng, P. V. Sahasrabhojane, J. Liu, W. Liu, Y. Chen, R. L. Bassett, Jr., S. Shelburne, H.-Y. Chang, K. R. Somaiya, K. S. Mungovan, J. C. Malke, B. Matejka, S. B. Fisher, A. Lucci, J. E. Lee, M. I. Ross, J. E. Gershenwald, P. Sharma, N. J. Ajami, C. L. Roland, J. A. Wargo, E. Z. Keung;
UT MD Anderson Cancer Center, Houston, TX

Background: Perioperative antibiotic prophylaxis is routinely utilized to reduce surgical site infections (SSIs). However, the rate of SSIs following a clean surgical procedure is <3%. Overuse of antibiotics is associated with potential adverse effects, including disruption of the composition and function of the native gut microbiota. Numerous studies have shown a negative impact of antibiotics on response and survival in patients with cancer treated with immune checkpoint blockade. The primary objective of this study was to determine the impact of a single dose of perioperative cefazolin on the gut microbiome and immunity. Methods: In this pilot trial (NCT04875728), 22 eligible pts diagnosed with clinical stage I or II melanoma undergoing wide excision with or without sentinel lymph node biopsy were enrolled between October 2021 and January 2023. Pts were randomized 1:1 to receive a single dose of cefazolin as standard-of-care (ABX, n=11) or no antibiotics (No ABX, n=11) at the time of surgery. Stool samples were collected before surgery, on post-operative day (POD) 14 and POD90 for metagenomic sequencing (WMS). Bulk RNA-sequencing of peripheral blood mononuclear cells (PBMCs) collected at the same timepoints was performed and data processed using DESeq2, log-transformed, and standardized for subsequent analysis. Immune pathway enrichment scores were calculated using GSVA for each sample with gene lists from 3 immune pathways (ADAPTIVE_IMMUNE_SYSTEM, INNATE_IMMUNE_SYSTEM, and CYTOKINE_SIGNALING_IN_IMMUNE_SYSTEM) from REACTOME (https://reactome.org) and immune cell gene signatures from Danaher P et al, 2017. Results: Treatment with a single dose of perioperative cefazolin was associated with a decrease in the alpha diversity of the gut microbiome 2 weeks postoperatively in pts who received perioperative cefazolin versus those who did not receive antibiotics (p=0.057, R2=0.0526); this persisted to POD90 (p=0.021, R2=0.0948). WMS showed prominent and persistent decreases in Akkermansia muciniphila (POD14: Log2FC=-8.38, q<0.001) and Alistipes communis (POD90: Log2FC=-4.47, q<0.001) in the ABX group compared to No ABX, respectively. RNA-seq analysis of PBMCs from pts revealed differences in immune subsets at POD90 between ABX and No ABX groups including decreased IFN-γ signatures (p=0.02) in pts who received perioperative cefazolin. Conclusions: Perioperative antibiotic prophylaxis is associated with profound and persistent reduction in microbiome diversity and composition, particularly of bacterial species associated with protective metabolic and inflammatory effects. Further studies will seek to assess the functional impact of this reduction on the immune response in a murine model, evaluate the generalizability of our findings across broader cohorts of patients undergoing surgery, and apply these findings to guide clinical management decisions.

#2807 Distinctive microbiome signatures in colorectal cancer: A comparative metagenomic analysis.

Z. Chen[1], B. Nie[2], B. Luo[1], Z. Wang[1], **X. Wang**[3],

[1]Shanghai Municipal Hospital of Traditional Chinese Medicine, Shanghai University of Traditional Chinese Medicine, Shanghai, China, [2]Nanjing University of Traditional Chinese Medicine, Nanjing, China, [3]University of California, San Diego, San Diego, CA

The human gut microbiome is increasingly recognized for its role in colorectal cancer (CRC) pathogenesis. This study aims to delineate the microbiome characteristics of CRC patients compared to healthy individuals, using a comprehensive metagenomic approach.

We utilized a cohort of 80 CRC patients and an equal number of matched healthy controls. Fecal samples were collected and subjected to in-depth metagenomic sequencing, targeting both structural and functional profiles of the microbiome. Data analysis involved advanced bioinformatics techniques. Key observations were subsequently validated in an independent cohort to bolster the findings.

Our analysis revealed significant alterations in the microbiome composition of CRC patients versus healthy individuals. Notably, there was an increased prevalence of pathogenic bacteria, such as Bacteroides Vulgatus in CRC patients. These bacteria are implicated in promoting inflammation and carcinogenesis. Conversely, there was a noticeable depletion of beneficial microbes like Lactobacillus in the CRC group. Functionally, the microbiome in CRC patients was characterized by enriched pathways related to DNA repair, cell cycle control, and metabolism pathways like Citrate cycle and Galactose metabolism. Validation in an independent cohort confirmed these distinctive microbiomic patterns.

Our study provides compelling evidence of altered microbiome landscapes in CRC patients, highlighting potential roles in disease development and progression. These findings pave the way for further investigation into microbiome-based diagnostics and therapeutic interventions in colorectal cancer.

#2808 Levels of isobutyric acid from gut butyrate-producing taxa are associated to Delta-24-RGDOX efficacy against malignant glioma.

N. M. Melendez-Vazquez[1], X. Fan[2], J. Fueyo[2], C. Gomez-Manzano[2], F. Godoy-Vitorino[1];
[1]University of Puerto Rico - Medical Sciences Campus, San Juan, PR, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Glioblastoma (GBM) is the most aggressive malignant primary brain tumor worldwide. Current standard-of-care treatments allow for a median survival of 12 to 18 months. GBM has a poor survival prognosis, observing less than 6% of patients surviving 5 years post-diagnosis. Among recent treatment advancements, the oncolytic adenovirus Delta-24-RGDOX armed with the T-cell activator OX40L is promising. Studies have unveiled a relationship between the gut microbiome and high levels of short-chain fatty acids (SCFA), such as isobutyric and propionic acid, to immunotherapy response. Changes in the gut microbiome and metabolome associated to viroimmunotherapy efficacy remain unclear. Here, we assessed the gut microbial changes in addition to isobutyric and propionic acid levels regarding viroimmunotherapy efficacy. Immunocompetent C57BL/6 mice were intracranially implanted GL261-5 GBM cells and received intratumoral injections of PBS (control) or Delta-24-RGDOX. A naïve group with no tumor nor treatment was also included. Fecal pellets were collected at three different time points: (1) before tumor implantation, (2) before treatment, and (3) 14 days after the first dose of treatment. Genomic DNA was isolated with the QIAGEN DNeasy Powersoil Pro Kit from fecal pellets (n=75), followed by sequencing with the Illumina platform of the 16S ribosomal RNA V4 region. Quality assessment of the sequences was executed in QIITA. Bacterial community analysis with a sequencing depth of 1,470 reads, while using the taxonomic database SILVA, was followed downstream with QIIME2 and R. Metabolic profiling of SCFA of the fecal pellets was performed through Gas Chromatography. Results showed significant differences in bacterial community structure of viroimmunotherapy-treated mice with survival of >100 days compared to controls (ANOSIM p-value=0.006). Alpha diversity metrics showed significant differences in richness between the naive and tumor-implanted mice of the PBS (KW p-value=0.049) and Delta-24-RGDOX (KW p-value=0.019) groups, highlighting that tumor presence alters the gut microbiota. Additionally, viroimmunotherapy-treated mice with survival of >100 days had a significant increase of *Lactobacillus* and the butyrate-producing bacterias *Erysipelatoclostridium* and *Ruminococcaceae*. Also, we found significantly higher levels of isobutyric acid and lower levels of propionic acid in viroimmunotherapy-treated mice with survival of >100 days (p-value<0.05). These findings suggest that butyrate-producing bacteria coupled with higher levels of isobutyric acid may be important in the efficacy of Delta-24-RGDOX. This highlights the microbial and metabolic changes associated with oncolytic viral therapy efficacy. *Sponsored by an award within The University of Puerto Rico/UT MD Anderson Cancer Center Partnership for Excellence in Cancer Research Grant (2U54CA096297-17).*

#2809 Bifidobacterium species BB_003 identified through metatranscriptomic analysis with experimentally validated antitumor actions.

Kyungchan Min[1], Xuan-Mei Piao[2], Young Joon Byun[2], Chuang-Ming Zheng[2], Seon-Kyu Kim[3], Seong-Hwan Park[3], Sungmin Moon[4], Kyeong Kim[4], Ho Won Kang[5], Won Tae Kim[5], Seok Joong Yun[5], Hansoo Park[1]

[1]Gwangju Institute of Science and Technology, Gwangju, Korea, Republic of,[2]College of Medicine, Chungbuk National University, Cheongju, Korea, Republic of,[3]Department of Bioscience, University of Science and Technology, Daejeon, Korea, Republic of,[4]Department of Urology, Chungbuk National University Hospital, Cheongju, Korea, Republic of,[5]Department of Urology, Chungbuk National University College of Medicine, Cheongju, Korea, Republic of

Introduction & Objectives: A host's microbiome influences both gene expression and phenotype. Whole transcriptome sequencing (WTS) provides information about the microbiome in addition to gene expression. This research probes the correlation between microbial abundance, host gene transcription, and therapeutic efficacy, pinpointing a beneficial microbial strain and its mechanism of action.
Materials & Methods: Bladder tissue biopsies from NMIBC patients underwent WTS and subsequent bioinformatic analysis. After in silico evaluation, in vitro assays including WST, quantitative PCR, and immune cell profiling were performed on mouse splenocytes. These assays were followed by in vivo assessment in both subcutaneous and orthotopic murine tumor models.
Results: Among 59 biopsies, non-recurrence correlated with heightened presence of Lactococcus species LC_001 and Bifidobacterium species BB_003. Notably, BB_003 was associated with an extended recurrence-free survival (RFS). Gene set enrichment analysis (GSEA) implicated BB_003 in mediating a pro-inflammatory cascade, accentuating macrophages and interferons. In vitro WST assays showed the antitumor potential of BB_003_β, characterized by upregulated pro-inflammatory gene transcription. This strain increased effector CD8 T cells and M2 macrophages. In vivo, direct live BB_003_β introduction into subcutaneous tumors curtailed tumor proliferation. An increase in effector CD8 T cell populations within tumors and elevated cDC1 and M1 macrophage counts in tumor-draining lymph nodes were observed. Intravesical administration of live bacteria markedly decreased bladder weight, amplifying interferon alpha and beta gene expressions compared to controls.
Conclusions: According to this study, BB_003_β inhibits tumor growth and is involved in immune response. Our study confirmed the antitumor properties of BB_003_β and suggested that cytokine and immune cell stimulation play a key role in its mechanism of action. Augmented insights warrant further exploration, particularly in synergy with intravesical BCG treatment.

#2810 Intracellular tumor microbiota promotes metastasis and drives an immunosuppressive phenotype in ovarian cancer.

A. Kumar, N. M. Bardhan, A. M. Belcher;
Massachusetts Institute of Technology (MIT), Cambridge, MA

Background: The tumor microenvironment has immense potential to change a patient's prognosis and therapeutic response. One of the emerging components of interest in the tumor microenvironment is the presence of intracellular microbes. Numerous studies have focused on colon and pancreatic cancer because of their proximity to the commensals in the gut. The female reproductive system is another site in our body where the rich vaginal microbiome has the potential to affect nearby organs and impact diseases. However, there is still little investigation done to understand the impact of microbes on Ovarian Cancer (OC).
Objective: To understand the role of the microbiome in OC metastasis, to develop new therapies to target the tumor microbiome
Methods: We used a co-culture study, the parameters of which were optimized to study the infection of microbes in different cell lines. Using a wide array proteome profiler, we looked for cytokines and chemokines to understand changes in signaling post-infection. Protein levels in the conditioned media using ELISA. Changes in actin, paxillin, and LC3B (autophagy marker) were monitored using immunofluorescence microscopy and western blots. Migration was studied by using transwell assay and spheroid cultures.
Results: We have identified two species of bacteria preferentially enriched in human ovarian tumors based on recent findings in the literature. We have demonstrated that these microbes are better at infecting OC cells in vitro over non-specific bacteria, can reside intracellularly, and are metabolically active. Upon infection, this intracellular uptake drives the release of pro-inflammatory cytokines and chemokine signaling by cancer and normal ovarian surface cells. We have also observed increased autophagy, changes in the actin cytoskeleton and reduced Paxillin foci on cancer cells infected with OC-associated microbes. This has led to increased migration in them; however, inactivated microbes did not change their migratory behavior. The infection also caused individual tumor cells to form more numerous and larger colonies when seeded into soft agar, suggesting an effect on cancer cell migration. Furthermore, we have shown that these microbes also elicit a more robust reaction in immune cells like Dendritic cells and macrophages, causing them to secrete chemokines like CCL 2,3,4,5, which also cause the cancer cells to migrate and have the potential to recruit neutrophils to drive the tumor microenvironment towards an immunosuppressive phenotype.
Conclusion: Most ovarian cancer patients are diagnosed at Stage III/IV, where cancer has metastasized, and is unresponsive to immunotherapy as the cancer is considered "cold". Through functional studies, we were able to gain insights into the role of the microbiome, which is associated with the clinical outcomes of OC, hoping to potentiate the existing therapies by probing the tumor microbiome.

TUMOR BIOLOGY: Modeling Cancer in Mice
Poster Session

#1130 Leveraging the IVIS imaging technologies for drug potency testing in orthotopic and metastatic tumor models.
J. Huang, J. Jin, H. Duan, X. Yang, W. Jin, Y. Zhang, L. Zhang, G. Xu, L. Xie, W. Li;
Pharmaron, Inc., Beijing, China

Assessing anti-tumor drug potency is significantly enhanced using orthotopic and metastasis mouse tumor models. These models imitate the tumor's native environment, biological complexities, and challenges of drug delivery via blood perfusion, thereby providing a high predictive value for clinical outcomes. In this poster, we demonstrate how the IVIS optical imaging technology is employed to determine the effects of two drugs on two tumor models: •The KRAS (G12C) inhibitor, AMG510, was evaluated on the luciferase-expressing Miapaca-2 pancreatic orthotopic model •The third-generation EGFR inhibitor, AZD9291, was tested on the luciferase-expressing NIC-H1975 intracranial metastatic model Both drugs showed significant anti-tumor activity. In addition to potency testing, each drug was administered in single doses for pharmacodynamic analysis, evaluating pERK/ERK and DUSP6 levels. The pERK levels decreased after treatment, which is in line with the mechanism of action of the inhibitors. Our research illustrates that IVIS imaging offers a robust method for monitoring anti-tumor activity of drugs in orthotopic and metastatic tumor models, empowering scientists to assess new drug candidates by using biologically relevant animal models.

#2814 Rectal implantation paves the path to evaluate the metabolic machinery responsible for CRC metastasis.

Said M. Afify, Chen Shen, Siva B. Merugu, Daniel T. Wynn, Anmada Nayak, Wenhui Lu, Ricardo M. Calderin, Evan Pannkuk, Sung H. Hong, Nagi G. Ayad, David J. Robbins

Department of Oncology, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC

Introduction: Colorectal carcinoma patients die most often from distant metastases in liver and lung. It is crucial to develop metastatic models for the CRC in order to better understand the process, which will help in treatment.
Method: Using orthotropic transplantation techniques, we tried to test whether rectal implantation could produce spontaneous metastases in-vivo mimicking colorectal cancer. The rectum was injected orthotopically with 0.2 X 106 HCT116 cells. In order to confirm metastasis, histopathological examinations were performed. Further, we generated cancer organoids to evaluate population susceptibility to CRC metastasis and metabolic mechanisms responsible for metastasis process.
Results: We found that rectal implantation was an effective method for simulating CRC cancer metastasis using H&E staining and immunohistochemistry. In less than four weeks after the implant, HCT116 spontaneously metastasized to the liver, lungs, and D lymph node. When compared with cancer organoids derived from primary tumors, liver and lung metastases organoids proliferated more often, were more aggressive, and displayed distinct characteristics. Using non-targeting metabolomic analysis, it was found that metastases derived organoids and primary tumors derived organoids were distinguished by novel metabolites.
Conclusion: By implantation in the rectal cavity, we can evaluate the metabolic machinery that leads to CRC metastasis. In the future, implantation of patient-derived samples will become increasingly important.

#2815 Immunotherapy development landscape for bone metastasis - need of predictive preclinical efficacy evaluation for de-risking clinical development.

T. E. Kahkonen[1], J. M. Halleen[2], G. MacRitchie[3], R. M. Andersson[3], J. Bernoulli[4];
[1]OncoBone Ltd, Aura, Finland, [2]OncoBone Ltd, Kiviniemi, Finland, [3]BioSeeker Group AB, Stockholm, Sweden, [4]University of Turku, Institute of Biomedicine, Turku, Finland

Most cancer deaths are due to metastases, and bone metastases are challenge especially in breast and prostate cancer, being developed in 70-90% of advanced-stage patients. Bone metastases remain incurable causing high mortality, skeletal-related effects and decreased quality of life. Currently used immunotherapies are ineffective in bone metastases. This creates a need to improve understanding immune microenvironment in bone metastases, namely interactions between tumor, immune and bone cells according to the osteoimmuno-oncology (OIO) concept, and ultimately to develop immunotherapies that primarily target bone metastases.

We used 1stOncology database, a cancer drug development resource to identify novel immunotherapies in development for breast and prostate cancer bone metastasis. Twenty-four immunotherapies that included evaluation of effects on bone metastasis were identified. Efficacy of only three of the identified therapies had been evaluated in preclinical bone metastasis models, one reason being that such models have not been commonly available. The use of clinically relevant and predictive preclinical bone metastasis models would significantly de-risk decision making when moving to clinical development in bone metastasizing cancers.

To support predictive preclinical evaluation of immunotherapies for bone metastatic cancers, we describe a preclinical bone metastasis technology platform for evaluating efficacy of immunotherapies. The platform utilizes tumors growing in bone microenvironment, mimicking growth of bone metastases in patients, and generates tumor-induced bone effects in a cancer-type specific manner. Syngeneic and/or humanized mouse models with tumor and immune cells of the same species are needed for development of immunotherapies, allowing interactions of tumor and immune cells in the bone metastatic microenvironment to support mode-of-action studies. The platform is clinically predictive, as demonstrated with observed effects that align with clinical findings. As an example, anti-PD-1 antibody had no effects on breast and prostate cancer bone metastases, predicting recent clinical findings that demonstrate lack of efficacy in clinical prostate cancer trials.

We conclude that tumor microenvironment in bone metastases has unique characteristics and is understudied as a potential primary cause of lack of efficacy of many immunotherapies, especially in breast and prostate cancer. It is prime time to focus on bone metastases by increasing understanding of the immune landscape in the bone tumor microenvironment according to the OIO concept. The biologically relevant and clinically predictive preclinical bone metastasis technology platform should be routinely used to study the mechanism-of-action and efficacy of therapies before entering clinical development in bone metastasizing cancers.

#2816 Comparison of MB-49_luc bladder carcinoma cell clones in the orthotopic superficial bladder tumor model in C57BL/6 female mice.

M. McArthur, **M. Tran**, A. Koznecki, H. Ketteringham, C. Silvio, S. Wenzel, C. Davis, S. Nadaraia-Hoke, C. Holding, L. Salem, V. Caruso, B. Hoerner, M. Spencer, M. Josey, A. Tannu;
Reaction Biology Corporation, Hummelstown, PA

In preclinical research, cell inoculation via bladder wall injection is a standard for studying invasive bladder cancer into the bladder muscle wall. However, a subset of patients presents with non-muscle invasive (superficial) disease. The standard of care for these patients is excision coupled with BCG treatment via catheterization. There is a need to further establish mouse models of cell inoculation via bladder catheterization for early drug development. While the injection places cells into the bladder wall, catheterization coats the inside of the bladder by first instilling Poly-L-Lysine. After instilling Poly-L-Lysine, instillation of luciferase-tagged cell suspension occurs.
MB49-luc cell lines were generated to determine the optimal cell lines for use in analyzing treatments for superficial bladder carcinoma. MB49-luc cells display varying degrees of luciferase activity and growth *in vitro.* A subset of cell lines were selected for further analysis *in vivo,* via bioluminescent imaging, survival analysis, flow cytometry and necropsy. The data provides a preclinical reference for the selection of a cell line for analysis of new drug candidates in C57BL/6 female mice inoculated via bladder catheterization.

#2817 Establishment of KRAS G12C mutant brain metastasis models for pre-clinical evaluation of KRAS G12C targeted anticancer therapy.

Q. Chen, G. Wang, Y. Yin;
Shanghai ChemPartner Co., Ltd., Shanghai, China

KRAS is one of the most frequently mutated oncogenes in cancers, especially in lung cancer. Clinical research has shown that about 14% of non-small-cell lung cancers (NSCLCs) carry the KRASG12C mutation, and brain metastases are a relatively common occurrence in KRASG12C-mutated NSCLC. Approximately 30% of patients with KRASG12C mutations develop brain metastases, and those with KRAS-mutated NSCLC and untreated brain metastases have limited treatment options and poor clinical outcomes. AMG510 (Sotorasib) is a small molecule inhibitor of KRASG12C that specifically binds to inactive GDP-bound KRASG12C, preventing its oncogenic signaling. It has been approved for NSCLC by the FDA. Recent clinical studies have shown that Sotorasib exhibits some activity against KRASG12C NSCLC brain metastasis. To evaluate the in vivo activity of AMG510 for NSCLC brain metastasis treatment and provide insights for the preclinical development of new KRAS targeted inhibitors, we established advanced orthotopic models, including intracranial, intracarotid, and intracardiac metastatic models, using the NCI-H358-luc cell line, which harbors the KRASG12C mutation. We validated these models with AMG510 as a single agent or in combination with radiation, which is commonly used in brain tumor therapeutic strategies, to reveal the efficacy and brain concentration of AMG510 in KRASG12C brain metastasis models. Tumor growth and metastasis incidences were assessed using bioluminescence imaging (BLI). All animal studies were performed in an AAALAC accredited facility and aligned with animal welfare regulations. Our preliminary results reveal that AMG510 could penetrate the blood-brain barrier (BBB) and show therapeutic activity for KRASG12C brain metastatic tumors. These models represent powerful tools for clinically relevant assessment of the efficacy of novel KRAS G12C inhibitors and can be expanded for other KRAS mutations-associated brain metastasis or inhibitors.

#2818 Investigating the role of TNIK in the pathogenesis of lung squamous cell carcinoma.

J. Chang[1], D. Dutta Chowdhury[1], D. N. Council[1], T. Nguyen[2], S. Jagtap[1], A. Chan[1], M. Ajmal Khan[1], N. Connis[3], P. Torres-Ayuso[4], J. Brognard[5], M. Rezaee[3], A. Lafargue[1], C. Hann[3], P. T. Tran[1],

[1]University of Maryland, Baltimore, Baltimore, MD, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [3]Johns Hopkins School of Medicine, Baltimore, MD, [4]Temple University Lewis Katz School of Medicine, Philadelphia, PA, [5]National Cancer Institute, Frederick, MD

Lung squamous cell carcinoma (LSCC) is the second most prevalent type of lung cancer with no FDA-approved targeted therapies. Platinum-based chemotherapy and immunotherapy remain the cornerstone of current treatments for advanced LSCC, and the 5-year survival rate is less than 10%. Despite abundant knowledge of the mutational landscape of LSCC, there is a paucity of effective targeted therapies. Amplification of chromosome 3q26 is the most common genomic alteration in LSCC and this leads to the overexpression of oncogenic kinases like TNIK. *TNIK* amplification occurs in approximately 50% of LSCC cases and is associated with tumorigenesis and therapy resistance in other cancers. Recent studies showed that TNIK maintains the survival of LSCC cells and drives LSCC progression. Furthermore, inhibiting the kinase eradicates tumor growth in TNIK-high preclinical models. These findings highlight the potential of TNIK as a therapeutic target in a subset of LSCC patients with 3q amplification. However, one major limitation of previous studies is the lack of animal models with squamous histology and patient-relevant genotypes. Therefore, we have created a novel conditional TNIK-overexpressing genetically engineered mouse model (GEMM) to better understand the roles of TNIK in tumor progression and therapy resistance in LSCC and elucidate mechanisms underlying LSCC pathogenesis. We are also producing a novel TNIK-overexpressing LSCC GEMM based on the simultaneous activation of $Kras^{G12D}$ and deletion of *Fbxw7* (KF model). We will present validation studies such as histological and molecular profiling of our conditional TNIK GEMM and initial data on the TNIK overexpressing LSCC transgenic mouse model (KF (LSCC control) vs KF-TNIK (LSCC-TNIK)).

#2819 Novel drug resistant CDX models for anti-cancer drugs discovery.

Hai-Ting Dai, Tie-Jun Bing, Zhi-Da An, Jie Yang, Tian-Yu Pang, Jia-Wei Gao, Yun-Yi Bo, **Wen-Jen Yu**

ICE Bioscience Inc., Beijing, China

Oncogene BRAF is located on chromosome 7q34, consisting of 766 amino acids and 22 exons, encoding a serine/threonine protein kinase belonging to the RAF family and plays a critical role in the MAPK signaling pathway. The mutation of BRAF was documented in nearly 8% of all human cancers including melanoma (60%), thyroid (60%), and lung adenocarcinoma (10%). The most common mutation of BRAF is V600E (Class I), which was found in more than 70% in these cancers. Despite the clinical success of approved small molecule inhibitors of BRAF V600E (vemurafenib, dabrafenib and encorafenib), this remains an area of unmet medical need because of primary or acquired drug resistance. The construction of BRAF drug-resistant cell lines plays a pivotal role in cancer research. It serves as a crucial tool for discovery of the mechanisms of drug resistance. In this study, we have developed a systematic approach for constructing drug-resistant cell lines, inducing resistance through the gradual escalation of drug concentrations. The validation of drug resistance involves morphological recordings of parent and drug-resistant cell lines, drug resistance index in vitro through IC50 measurements and in vivo through the inhibition of tumor growth (TGI) which compare to those in the parental cell line. We successfully established Vemurafenib and Dabrafenib resistant A375 cell lines (A375 Vemurafenib R, A375 Dabrafenib R) with 21 and 31.5 folds of resistance index, respectively. The in vivo drug resistance efficacy was also tested by implanting Vemurafenib resistant cells subcutaneously into NOD-SCID mice and showed that A375 Vemurafenib R exhibited robust tolerance to 50 mg/kg Vemurafenib treatment (P.O.21 days, 50mpk, TGI=17.4%), whereas the parental cells were nearly completely inhibited (P.O.21 days, 50mpk, TGI=92.3%). In addition, single-cell sequencing of A375 Vemurafenib R revealed significant gene expression differences in the MAPK and EGFR signaling pathways, aiding in the identification of new targets, and signaling pathways associated with drug resistance, thereby providing potential targets for new drug development.

#2820 The effect of *Pten* haploinsufficiency on genomic and transcriptomic profiles in combined genetically-engineered mouse models for colonic neoplasia based on *Apc* inactivation.

H. Sada[1], H. Niitsu[2], H. Nakahara[3], N. Sakamoto[4], H. Tashiro[1], H. Ohdan[4], T. Hinoi[3];
[1]Kure Medical Ctr. & Chugoku Cancer Ctr., Kure, Japan, [2]Aichi Cancer Center Research Institute, Nagoya, Japan, [3]Hiroshima University Hospital, Hiroshima, Japan, [4]Hiroshima University, Hiroshima, Japan

Background and Aim: We have reported genetically-engineered mouse models for colonic neoplasia by using our novel *CDX2P-Cre* mice, in which Cre is restrictedly expressed in colonic epithelial cells. Although colonic tumors are generated in *CDX2P-Cre;Apc*$^{flox/+}$ (*CPC;Apc*) mice with highly penetrant rate, greater number and deeper invasion of colonic tumors were observed in *CDX2P-Cre;Apc*$^{flox/+}$*;Pten*$^{flox/+}$ (*CPC;Apc+Pten*), possibly resulting from haploinsufficiency of *Pten* gene. We have also confirmed shorter lifespan in *CPC;Apc+Pten* than that in *CPC;Apc* (AACR Annual Meeting 2018). Here, we test if these phenotypes come from one copy loss of *Pten* itself or secondary genetic and/or transcriptomic alterations induced by *Pten* loss by using whole genome sequence (WGS) and RNA sequence from macroscopically-dissected colonic tumors (bulk RNA-seq).
Methods: WGS for five tumors and five livers as counterpart controls in each mouse model was performed by DNBSEQ platforms. Bulk RNA-seq was performed for three tumors in each model.
Results: In the analysis using B-allele frequency, copy-neutral LOH occurred in chromosome 18 including *Apc* loci specifically in colonic neoplasia in both *CPC;Apc* and *CPC;Apc+Pten* mice. In contrast, LOH was not observed in chromosome 19 including *Pten* loci in *CPC;Apc+Pten* mice. We also confirmed remarkably decreased coverage of reads in reference mapping in *Apc* locus, and there was a slight decrease of coverage in *Pten* locus. There were no additional driver gene mutations in *CPC;Apc* or *CPC;Apc+Pten* in WGS. All these results suggested just one copy loss of *Pten* resulting in aggressive tumor phenotype in *CPC;Apc+Pten* mice. In RNA-seq and subsequent GSEA comparing colonic tumors in *CPC;Apc+Pten* with those in *CPC;Apc* revealed upregulation of some signal pathways including mTORC1. Supporting this observation, number of colon tumors, especially adenocarcinomas, were decreased by rapamycin administration to *CPC;Apc+Pten*. Similarly, rapamycin was more effective in tumorids from *CPC;Apc+Pten* those from *CPC;Apc*.
Conclusion: WGS reveals one copy loss of *Pten* locus is the only genetic alteration *in CPC;Apc+Pten* when compared with *CPC;Apc*. One copy loss of *Pten* is sufficient to upregulate mTORC1 pathway in a *CPC;Apc+Pten* mouse model, resulting in promotion of tumor formation and invasion.

#2821 Development of therapeutic monoclonal antibodies against DKK1 peptide-HLA-A2 complex to treat human cancers.

J. Qian, W. Qiang, L. Xiao, W. Xiong, M. Xian, C. Zhang, Y. Li, Q. Yi;
The Houston Methodist Research Institute, Houston, TX

Immunotherapy is a promising option for cancer treatment. Targeted immunotherapy with monoclonal antibodies (mAbs) is an effective and safe method for the treatment of malignancies. In recent years, efforts have been made to identify potential therapeutic mAbs by defining alternative or novel target antigens. We reported that Dickkopf-1 (DKK1) is a good target for immunotherapy of human cancers based on its wide expression in different cancers but not in normal tissues. As DKK1 is a secreted protein, mAbs directly binding to DKK1 may have limited effects on cancer cells in vivo. Our previous studies demonstrated that DKK1 peptide (such as P20 and P66v, which bind with HLA-A*0201 (HLA-A2) molecule) specific cytotoxic T cells specifically kill myeloma and other cancer cells that express DKK1 and HLA-A2, but not HLA-A2$^{\pm}$ normal cells, indicating that DKK1$^{\pm}$ tumor cells naturally express these peptides, in the context of HLA-A2 molecules, on their surface. To develop cancer therapeutic antibodies, DKK1 peptide P20-HLA-A2 monomer was synthesized and used to immunize mice. Hybridomas secreting mAbs recognizing cell surface-expressed DKKl P20-HLA-A2 complex (DKK1-A2) were obtained and analyzed. In this study, we generated novel (DKK1-A2) mAbs recognizing DKK1 (P20) peptide in the context of human HLA-A*0201 (HLA-A2) molecules (DKK1-A2 complexes) that are naturally expressed by HLA-A2$^{\pm}$DKK1$^{\pm}$ cancer cells. These mAbs bound to HLA-A2$^{\pm}$DKK1$^{\pm}$ hematologic (myeloma, lymphoma, and leukemia) and solid (breast, pancreatic, and prostate) cancer cells and directly induced apoptosis in the cancer cells by activating the caspase-9 cascade. DKK1-A2 mAbs also effectively lysed cancer cells in vitro by mediating CDC and ADCC activities. Furthermore, DKK1-A2 mAbs were therapeutic against established hematologic and solid cancers in their xenograft mouse models. To enhance the therapeutic efficacy of DKK1-A2 mAbs, we investigated the effect of combination treatment of DKK1-A2 mAbs with lenalidomide. Our results showed that there is an additive therapeutic effect between DKK1-A2 mAbs and lenalidomide in vivo, underscoring a potential clinical development strategy for combining DKK1-A2 mAb with lenalidomide to treat cancer patients. As DKK1 is not detected in most human tissues, DKK1-A2 mAbs did not bind to or kill HLA-A2$^{\pm}$ blood cells in vitro nor caused tissue damage in vivo in tumor-free or tumor-bearing HLA-A2-transgenic mice. Thus, our study suggests that DKK1-A2 mAbs may be a promising therapeutic agent to treat human cancers and warrants further preclinic studies to determine their translatability to clinic.

#2822 Heterogeneity of CD56+ circulating tumor cells and derived xenografts and response to treatment in small cell lung cancer.

L. Martinetti[1], **P. Montagne**[2], M. Davilma[1], U. Jarry[2], A. Chatziioannou[3], M. Aubry[1], C. Ricordel[4], R. Pedeux[1];

[1]OSS (Oncogenesis Stress Signaling), UMR_S 1242, CLCC Eugene Marquis, Univ Rennes 1, Rennes, France, [2]Biotrial, Rennes, France, [3]Centre of Systems Biology, Biomedical Research Foundation of the Academy of Athens, Athens, Greece, [4]OSS (Oncogenesis Stress Signaling), UMR_S 1242, CLCC Eugene Marquis, Univ Rennes 1; CHU Rennes Service de Pneumologie, Rennes, France

Small cell lung cancer (SCLC) represents the most aggressive subtype of lung cancer, comprising 15% of all cases. Clinical advancements in SCLC have been hindered by slow progress, attributed to significant tumor heterogeneity and early metastasis. The majority of patients experience relapse within a few months post-treatment, with 20% exhibiting chemorefractory characteristics. Recent identification of molecular subtypes in SCLC, dependent on predominant transcription factors ASCL1, NEUROD1, and POU2F3, has opened avenues for potential therapeutic targets. Preliminary studies on these transcriptomic subtypes suggest distinct therapeutic susceptibilities, and intriguingly, chemotherapy may induce alterations in transcriptomic subtypes.In the context of SCLC, diagnosis reveals a substantial presence of circulating tumor cells (CTCs) in the patient's bloodstream, which can be efficiently isolated. A previously published method allowed us to isolate CD56+ CTCs with high specificity (Ricordel et al., 2023). Our overarching hypothesis posits a connection between chemosensitivity and the heterogeneity of CTCs, leading us to seek bioclinical markers predictive of chemotherapy response. The clinical study, named CTC-CPC, is a monocentric prospective non-interventional investigation involving treatment-naïve SCLC patients. Blood samples were collected at the time of diagnosis for subsequent analysis. In our study, whole exome sequencing data from isolated CD56+ CTCs of 22 SCLC patients were analyzed. Various methods were employed to characterize inter-tumoral heterogeneity, including the identification of genetic alterations (SSMs and Indels), mutational signatures, and disrupted pathways. Prominently affected pathways included ECM organization, axon guidance, Rho GTPases, and Wnt signaling. Additionally, we unveiled substantial intra-tumoral heterogeneity using PhyloWGS, a technique for reconstructing subclonal composition and evolution from tumor sample sequencing. To further explore the impact of treatment, we aimed to clarify the expression of ASCL1, NEUROD1, and POU2F3 transcription markers in xenografts generated from patient CTCs at the time of diagnosis. Immunohistochemical studies were performed to identify potential changes in molecular subtypes at the protein level. The molecular subtypes of the four CDX we generated were characterized, revealing heterogeneity in the intratumoral expression of transcription markers for some xenografts. Subsequently, CTC-derived xenografts were subjected to chemotherapy, with observations indicating a change in the number of cells positive for ASCL1 and NEUROD1 after treatment, particularly in the CEM51.01 line treated with carboplatin, suggesting a potential modification in the tumor subtype induced by the treatment

#2823 Development of an *in vitro* blood-brain barrier model of CCR7/CCL19 induced invasion of the central nervous system.

A. Rodriguez, C. I. Cardona, C. A. Bill, C. M. Vines;
The University of Texas at El Paso, El Paso, TX

Pediatric T-cell acute lymphoblastic leukemia (T-ALL), an aggressive hematological malignancy, is characterized by abnormal thymocyte proliferation, frequently with mutations of the Notch-1 gene and has an overall 10-year survival rate of ~27%. A marker of poor prognosis is the presence of T-ALL within the central nervous system (CNS), which is treated with intrathecal chemotherapy and cranial irradiation; two toxic treatments with high morbidities. Gene-expression profiling of Notch-1-induced adhesion regulators showed that C-C chemokine receptor 7 (CCR7) was highly expressed and was associated with leukemic T-cell invasion of the CNS. Normal functions of CCR7 include lymph node homing and immune cell trafficking in response to CCR7 ligands, CC-chemokine ligand 19 (CCL19) or CCL21. In several studies CCL19 has been linked to T-cell invasion of the CNS across the blood-brain barrier (BBB). We hypothesize that antagonizing CCR7 binding to CCL19 will block migration of T-ALL into the CNS and thereby alleviate the need for toxic therapies. To test our hypothesis, we are using receptor internalization assays, calcium mobilization assays, transwell migration assays and an *in vitro* model of an intact human BBB. We have used flow cytometry-based CCR7 internalization assays ± CCR7 antagonist and found that we can completely block CCL19-induced receptor internalization in human CCR7-expressing CCRF-CEM, and HuT-78 T-ALL cells, and chemotaxis via β1 integrins across a fibronectin-coated transwell membrane. Our BBB employs HBEC-5i, human cerebral microvascular endothelial cells, in transwell chambers coated with gelatin and fibronectin for the adhesion of endothelial cells. HBEC-5i cells are a suitable cell line to make a 3D model of the BBB, as they form an endothelial monolayer with tight junctions (TJ), which is crucial to maintaining the integrity and inhibiting permeability of the BBB. We are establishing a transwell migration assay to assess the migration of CCRF-CEM T-ALL cells across the HBEC-5i cell monolayer. The integrity of the HBEC-5i cell monolayer is assessed by trans-epithelial electrical resistance (TEER), which measures the electrical resistance across the HBEC-5i monolayer, a measure of TJ integrity. Using TEER measurements, we observe that HBEC-5i form a monolayer that reaches an intact monolayer functioning with TJs over 72-96 hours. We are using this model system to investigate the migration of CCR7-expressing CCRF-CEM cells through the BBB ± CCL19. Subsequently, we will add the CCL19 antagonist (CCL197-77) to determine if inhibiting CCR7 is sufficient to eliminate migration of the CCRF-CEM cells through the BBB. If successful, this model will allow us to test the contribution of CCR7 signaling to integrins, the contribution of other immune cell types and the overall molecular mechanisms that mediate invasion of the CNS in a 3-D model of the BBB.

#2824 Establishing prostate cancer models for orthotopic and bone metastatic growth using the 22Rv1cell line.

J. Zdrojewska, **K. Fagerlund**, J. H. E. Maki-Jouppila, M. I. Suominen;
Pharmatest Services Ltd., Turku, Finland

Prostate cancer is the second most common cancer in men with new cases diagnosed in 1.4 million men each year. Luckily the 5-year survival rates in developed countries are high reaching over 90%. However, approximately one third will develop a metastatic disease. In metastatic patients, prostate cancer almost always progresses despite the androgen deprivation therapy and is then referred to as “castration-resistant (mCRPC)”. Bone is involved in 80% of patients with metastasis, and the bone lesions are typically osteoblastic. The 22Rv1 human prostate carcinoma cell line is androgen sensitive and shown to express androgen receptor (AR). They also express low levels of prostate-specific membrane antigen (PSMA). The aim of this study was to establish orthotopic and intratibial preclinical in vivo prostate cancer models that can be used in drug development when targeting cancer cells and their local environment. Male athymic nude mice (5-6 weeks old) and NOG mice (over 20 weeks old) were used in the study. 2.5×10^5 22Rv1 cells (ATCC) were inoculated orthotopically into the prostate of NOG mice, and 5×10^5 cells were inoculated intratibially into the bone marrow cavity of athymic nude mice. Tumor growth was followed by PSA measurements every second week using Human PSA ELISA assay. In addition, in the intratibial model, tumor-induced bone changes were monitored by X-ray imaging of the hind limbs. Prostates and hind limbs were collected at sacrifice, fixed in 10% NBF, and processed to paraffin blocks for further histological analysis. Sections of prostate were stained with hematoxylin-eosin (HE) and AR. Tumor-bearing and contralateral (healthy) tibias were stained with HE - OrangeG, MGT, TRAP, and AR. The observed tumor take rate was 92% in the orthotopic and 100% in the intratibial models. Confirmed by IHC, tumors formed in both the orthotopic and intratibial models expressed AR. 22Rv1 cells formed osteoblastic - lytic mixed bone lesions in the intratibial model. Based on lesion areas, randomization of the tumor bearing mice in the intratibial model can be done after 2 weeks from cancer cell inoculation. Taken together, the 22Rv1 prostate cancer models are relatively fast growing, express AR and present good take rates. Furthermore, the intratibial model represents robust tumor-induced changes in bone with strong osteoblastic component. Thus, these models have several advantages in efficacy studies of novel drug candidates for prostate cancer.

#2825 Experimental hyperthermic intraperitoneal chemotherapy in mice: Establishment of a novel ovarian cancer xenograft model.

K. Fleten, Y. Andersson, E. Lovstakken, T. M. Herud, S. Waagene, K. Flatmark;
Oslo University Hospital, Oslo, Norway

Introduction: The peritoneum is a common metastatic site for several abdominal cancers, including ovarian and colorectal cancer. Peritoneal metastasis is associated with poor prognosis and poor response to therapy. A potentially curative treatment is cytoreductive surgery (CRS) to remove all visible tumor tissue, followed by perfusion with hyperthermic intraperitoneal chemotherapy (HIPEC) to eliminate small residual tumors and free-floating tumor cells. Hyperthermia can enhance the cytotoxic effect of the drug, inhibit DNA repair and activate the immune system. At the current time, there is no standardized protocol for performing HIPEC, and there is a large variation regarding key parameters, such as choice of drug, drug concentration, treatment duration, carrier solution, volume and temperature. The impact of these parameters is unknown, and in vivo models can be a helpful tool to better understand some of these parameters to improve this treatment strategy.
Methods: HIPEC was established in a murine xenograft model of ovarian cancer to evaluate the response to intraperitoneal perfusion of cisplatin and mitomycin C for 30 min at 41.5°C (HIPEC) and 37°C (NIPEC) compared to no treatment or intraperitoneal perfusion with saline at 41.5°C. The luciferase transfected B76 ovarian cancer cell line was injected intraperitoneally and treatment was performed on day 4 when the tumors were < 2 mm. Treatment efficacy was assessed by weekly luminescence measurement, tumor weight at an early time point (day 17), and overall survival.
Results: Intraperitoneal perfusion with cisplatin or mitomycin C significantly inhibited tumor growth as assessed by luminescence, tumor weight on day 17, as well as increased overall survival of the mice compared to control treatment from 25-27 days to 36 days for cisplatin and 37 days for mitomycin C. No significant differences in tumor growth or survival were observed by the addition of hyperthermia. However, a slight reduction of tumor weight at day 17 was observed in the HIPEC groups.
Conclusion: We have established a functional closed HIPEC model in mice bearing peritoneal metastases from the B76 ovarian cancer cell line which accurately mimics many features of the procedure in patients. Intraperitoneal perfusion of both cisplatin and mitomycin C efficaciously inhibited tumor growth and improved overall survival of the mice. Addition of hyperthermia caused an additional modest, temporary growth inhibition which did not translate into improved long-term outcome.

#2826 Examples of translational preclinical models to mimic cancer drug resistance.

M. Hillairet de Boisferon, N. Hoffmann, E. Rajon, I. Benzaid;
Oncodesign Services, Dijon Cedex, France

Drug resistance is becoming a major obstacle when treating patients with cancer. Cancer is characterized by an uncontrolled growth of abnormal cells with permanent genome alterations, which lead to severe mutations including resistance mechanisms. Mutations can occur in different resistance pathways, such as inhibition of drug transport, DNA damage repair, drug efflux, EMT (epithelial-mesenchymal transition), drug target alteration and cell death inhibition.
Resistance mechanisms are now well studied in vitro, based on mutated cell lines for specific resistance pathways. There is however a gap in our knowledge of resistance mechanisms observed in patient tumor cells. We are challenged to discover cancer resistance treatments in patients and need predictive models of clinical situations. Animal tumor models are the best translational tools to study cancer drug resistance, especially when they closely mimic human pathologies. Such models can bridge the gap between our understanding of cancer resistance in vitro and in tumor patients. In this poster we show different pre-clinical experiments, simulating clinical translational approaches, that led to novel and unique tumor resistant models.
Patient Derived Xenograft (PDX) models: Using our breast cancer PDX collection we showed that after repeated treatment with a spindle poison, tumor-bearing mice started to develop resistance and continued tumor growth under drug pressure. Following this successful approach, we initiated the development of a novel ER2-expressing PDX breast tumor model, resistant to hormone therapy by repeated Fulvestrant treatment. Using our colon cancer PDX collection we were able to recapitulate clinical situations by correlating PDX molecular profiles and drug sensitivity. We confirmed the key role of a *KRAS* mutation in cetuximab resistance.
Syngeneic model: In this model, animals were dosed with anti-PDL1 as first line of treatment. All animals were then defined as initial responders or non-responders at the end of the dosing schedule. Following this, a new treatment protocol was initiated with a Tyrosine Kinase inhibitor to study the effect of second line drug treatment in responder and non-responder arms.
Human model: In this experiment, we performed a first line Avastin treatment on human colon carcinoma tumor-bearing mice. A tumor resistance to Avastin was observed. During the second line of treatment with a tyrosine kinase inhibitor, we observed an antitumor activity on Avastin resistant animals.
In each of these case studies, we developed a novel tumor-resistant mechanism model. In some tumor models, we showed the added value of treating animals with new drugs as second line treatment, after establishing resistance to the first line standard of care treatment.

#2827 Characterization of acute myeloid leukemia PDX models with hotspot gene mutations for therapeutic evaluation.

Q. Liu, J. Wang, J. Liu, L. Zhang, L. Bourre, **J. Wang**;
Crown Bioscience, Inc., San Diego, CA

Introduction: Acute myeloid leukemia (AML) is the most common acute type of leukemia in adults characterized by chromosomal abnormalities and gene mutations. While inhibitors have shown promise targeting FLT3 mutations, resistance to these inhibitors can emerge. Similarly, inhibitors targeting IDH1 and IDH2 mutations showed promise, yet the emergence of drug resistance poses a significant challenge. In this study, a panel of AML PDX models with multiple gene alterations was established to support the development of new therapies.

Methods: The systemic AML PDX models were established using patients' peripheral blood (PB) or bone morrow (BM) injected intravenously and expanded *in vivo* by using splenic tumor cells. One AML PDX model derived from patient skin was established subcutaneously. Expression of human CD45+ in PB cells for systemic models or tumor volume for the subcutaneous model was used to monitor the tumor burden. Leukemic loads (hCD45+ cells) were measured in PB, spleen (SP), and BM. Tumors were categorized following tumor immunophenotyping, histology, and RNA sequencing/Whole Exome Sequencing. For *in vivo* efficacy studies, animals were grouped 3-5 weeks after systemic tumor cells inoculation and treated with AC220 (1, 2 or 10 mg/kg, p.o., QD), Cytarabine (Ara-c, 2mg/kg, i.p., QD), 5-azacytidine (2mg/kg, i.p., QD), Sorafenib (10mg/kg, i.p., QD) and Gilteritinib (10 or 30mg/kg, p.o., QD).

Results: Nine systemic and one subcutaneous AML PDX models carrying hotspot mutations (e.i. FLT3-ITD or TKD, IDH1-R132H and IDH2-R140Q) were established, showing comparable features to the clinic. Systemic AM8231 PDX model harboring FLT3-ITD mutation treated with AC220, a type II FLT3i, showed significant tumor burden reduction in PB at different time points and in SP and BM at termination, as well as a survival increase. Similarly in systemic model AM7577 with FLT3-ITD mutation treated with AC220, significant tumor burden reduction in PB was observed. Whereas using systemic model AM9626 (model with Sorafenib pretreatment history) with coexisting-FLT3-ITD/D835H TKD mutation, no significant efficacy was observed with AC220i, suggesting a FLT3-TKD mediated resistance mechanism. To overcome the resistance, Gilteritinib, a type I FLT3i, was tested in AM9626 and showed significant reduction of hCD45+ cells in PB compared to the control group, even at a lowest dose. As model AM9626 PDX also carries IDH1 mutation, the level of serum 2-HG correlated with the tumor burden. The functional effect of IDH1 inhibitor on the tumor inhibition and 2-HG level is under investigation.

Conclusion: The results presented in this study showed the establishment of a panel of AML PDX models, including different subtypes and genomic features reflecting the clinic. Those models will support the preclinical evaluation of new treatments or combination modalities as well as a better understanding of drug resistance mechanisms.

#2828 Combining neratinib with trastuzumab deruxtecan to treat HER2;TP53 co-mutated breast cancers.

X. Cheng, M. Highkin, J. Hsia, J. L. Prior, I. S. Hagemann, R. Bose;
Washington University in St. Louis, St. Louis, MO

In metastatic breast cancer, *HER2* activating mutations frequently co-occur with mutations in the *TP53* gene and patients with these two co-occuring mutations have a lower response rate to neratinib. In order to address this clinical problem, we bred HER2 activating mutant transgenic mice with two different alleles of TP53. We used mice with the TP53 R172H mutation, which is the murine homolog of the human hotspot TP53 R175H mutation, and mice with TP53flox/flox allele, which mimics TP53 truncating mutations seen in human breast cancers.

Abbreviation	Genotype	Median tumor formation (weeks)	Neratinib IC50 (nM)	Neratinib +T-DXd
H	$HER2^{V777L}$	28	10	Not determined
$H53^{null}$	$HER2^{V777L}$;$TP53^{flox/flox}$	10	240	Synergy
$H53^{172/WT}$	$HER2^{V777L}$;$TP53^{R172H/WT}$	11	100	Synergy
$H53^{172/null}$	$HER2^{V777L}$;$TP53^{R172H/flox}$	6	150	Synergy

All three H53 genotypes ($H53^{null}$, $H53^{172/WT}$, and $H53^{172/null}$) developed breast cancers faster than H mice, with $H53^{172/null}$ mice developing breast tumors the fastest, at just 6 weeks after adenoviral-Cre injection into the mammary fat pad. We developed organoids from these murine breast cancers and found that all H53 genotype organoids were less sensitive to neratinib compared to H, however, neratinib was able to synergize with trastuzumab deruxtecan (T-DXd), likely through neratinib mediated increased internalization of T-DXd. Prior literature studies suggest TP53 mutant cancer cells may have therapeutic vulnerabilities to the topoisomerase 1 (Top1) inhibitors. Organoids from all three H53 genotypes were sensitive to the Top1 inhibitor, exatecan. $H53^{172/WT}$ behaved like H organoids with G1 phase cell cycle arrest and induction of p21 expression after exatecan treatment. In contrast, $H53^{null}$ and $H53^{172/null}$ failed to induce p21 and arrested at late-S/G2 phase. Additional animal experiments with these H53 genotypes are in progress and results will be presented at the AACR Annual Meeting.

#2829 Strategies to overcome challenges in randomization and grouping methodologies in *in vivo* studies using the power of animal study workflow software.

Raghu Ramachandra

Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA

Preclinical research in Oncology requires using a wide variety of animal models. Robust, clinically relevant distribution methods including randomized and non-random methods appropriate to the model are essential to ensure unbiased group assignments and reliable experimental outcomes. This presentation will explore flaws and inconveniences in prevalent randomization methods and strategies to overcome them using animal study workflow software and demonstrate the power of each with unique examples. Strategies for randomizing individual animals into groups and randomizing mouse cages into groups will be explored. Strategies for exclusion criteria, robust documentation, multi-parameter randomization, re-randomization, and clinical relevance of these strategies will be discussed. Standardization and automation of distribution methods help improve process integrity, research quality, and reproducibility.

#2830 Intravital multiphoton microscopy of bone metastatic renal cell carcinoma.

S. Maksimovic[1], N. Boscolo[1], S. Barrios[1], A. Mikos[2], M. T. Campbell[1], E. Dondossola[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Rice University, Houston, TX

Clear cell renal carcinoma (ccRCC) represents 80% of renal neoplasms, with bone as a major site for distant spread (35-40% of patients). These secondary lesions cause a variety of skeletal-related complications, including pain, spinal cord compression, hypercalcemia, mobility issues and fractures, posing a significant negative impact on patient quality of life and survival. Furthermore, bone is well-known as a site of therapy resistance, which confers to patients treated with systemic therapies significantly worse time-to-treatment failure and progression-free and overall survival compared to those without bone metastases. Because of the complexity of the bone microenvironment and the paucity of suitable models, preclinical investigation of bone metastasis and therapy response is challenging. Preclinical models of bone metastasis that integrate tissue engineering and advanced imaging techniques can facilitate the study of the mechanism of tumor progression and therapy response. We recently developed a window model amenable to intravital multiphoton microscopy (MPM) to longitudinally monitor human ccRCC lesions in tissue engineered bone constructs (TEBCs) in immunodeficient mice. TEBCs were generated by functionalizing polymeric polycaprolactone scaffolds with bone morphogenetic protein 7. Human ccRCC lesions, after implantation into the bone cavity, were longitudinally monitored for growth and niche development, using multi-parameter recording of collagen/bone matrix (SHG), bone surface (THG), blood vessels/stromal phagocytes (fluorescent dextran), and tumor cells (GFP). However, this model lacked key components of the immune system (including B and T-cells), which are of major interest in the study of tumor progression and (immune) therapy response. Therefore, we developed a tissue-engineered preclinical model that incorporate species-specific interactions between cancer and bone stromal cells, and account for an intact immune system. To this purpose, we optimized TEBC formation in C57BL/6 fluorescent reporter mice (Sp7-mCherry, osteoblasts; Trap-td-Tomato, osteoclasts; GFP, immune cells, αSMA-RFP fibroblasts; and Flk1-GFP, blood vessels), coupled to detection by intravital or *ex vivo* multiphoton microscopy analysis, to monitor the evolution and fate of the TEBC. Interestingly, the bone marrow in the core of the TEBC was replaced by a desmoplastic tissue with features like the foreign body response, including foreign body giant cells, which was not present in immunodeficient mice. By applying dual color GFP/αSMA-RFP mice, which expressed red fluorescence in activated fibroblasts, we confirmed the fibrotic nature of this core. To avoid its formation, we generated scaffold-free ossicle, by direct implantation of BMP7 and VEGF in the subcutaneous tissue. To conclude, we established a protocol for generating ectopic ossicles in immunocompetent mice.

#2831 Development and application of the NCG-hIL2 mouse model: A humanized platform for enhanced NK cell evaluation in ADCC efficacy testing.

Y. Fang, H. Sun, H. Wang, J. Xing, J. Fan, J. Zhao, X. Gao, C. Ju;
Gempharmatech Co., Ltd., Nanjing, China

Natural Killer (NK) cells play a pivotal role in immune surveillance and antitumor responses, making them valuable targets in cancer immunotherapy. The assessment of therapeutic antibodies' efficacy, particularly in the context of Antibody-Dependent Cell-Mediated Cytotoxicity (ADCC), necessitates models that faithfully recapitulate human NK cell responses. Here, we introduce the NCG-hIL2 mouse model, designed to address these requirements and advance our understanding of NK cell development.

The NCG-hIL2 mouse model was engineered to express human Interleukin-2 (IL2) cytokine, a critical factor in NK cell development and activation. This humanized platform allows for the robust reconstitution of human NK cells through the transplantation of peripheral blood mononuclear cells (PBMCs) or hematopoietic stem cells (HSCs).

In this study, we validate the NCG-hIL2 model's exceptional capability in supporting the reconstitution of human NK cells, highlighting the indispensable role of IL2 in NK cell development. Moreover, we demonstrate its utility in the evaluation of therapeutic antibodies, specifically Trastuzumab and the ADCC-enhanced Margetuximab, in the context of ADCC efficacy testing. Our findings reveal that the NCG-hIL2 model provides a unique advantage for assessing the impact of IL2 on NK cell development, thus facilitating a deeper understanding of the complex interplay between NK cells and therapeutic antibodies.

The NCG-hIL2 mouse model serves as a valuable tool for studying NK cell development and evaluating the efficacy of immunotherapies, particularly in ADCC. By reconstituting human NK cells and leveraging the role of IL2, this model offers an enhanced platform for preclinical evaluation of therapeutic antibodies, ultimately advancing our ability to harness NK cell-mediated antitumor responses. It is poised to contribute significantly to the field of cancer immunotherapy and drug development.

#2832 Mouse models advancing cancer research - The Jackson Laboratory.

J. Beckwith, J. Merriam, A. Valenzuela, D. Pomerleau, J. Kelmenson;
The Jackson Laboratory, Bar Harbor, ME

Genetically defined mice are a cornerstone of cancer research. The Jackson Laboratory (JAX) offers more than 13,500 unique mouse lines to the scientific community, many useful in advancing cancer research. Available are mouse models for specific cancers, xenograft recipients, immunodeficient platforms for PDX studies and multi-purpose tool strains having CRISPR/Cas9 utility, conditional/inducible expression (Cre-lox, FLP-frt, Tet-On/-Off), optogenetic function and calcium-sensing technologies. This poster will highlight some recently added models, more than 100 of which have cancer research applications. The portfolio of strains useful for transplantation/engraftment and “humanized” mouse research continues to expand and complement the NSG (NOD scid IL2rγc-/-) model as ideal tools for engraftment with a wide range of malignant or non-malignant human or mouse tissues. Fluorescent protein-expressing strains include Traffic Light Reporters for tracking of DNA repair pathways, Gene Editing Reporters for detection of homology directed repair (HDR) and non-homologous end joining (NHEJ) repair events, as well as several CRISPR Editing, Bxb1 Integrase Editing, Base Editor and Prime Editor tools. For example, the Rosa26^{PE2} mouse has Cre-inducible expression of a prime editor enzyme and a fluorescent reporter, allowing viral delivery of prime editing guide RNAs to introduce cancer mutations into the genome. Recently added CRISPR Array Repair Lineage Tracing (CARLIN and DARLIN) component strains allow researchers to achieve high barcode diversity in targeted cell populations. In addition to safeguarding each strain by cryopreservation, JAX has a comprehensive genetic quality control program that confirms mutation identity and genetic background, and screens for unwanted alleles (such as stray GFP, Cre, neo, etc.). Search the comprehensive collection of innovative mouse models using our improved JAX Mouse Search site (mice.jax.org). This resource includes models created by many generous donating institutions. Researchers are encouraged to donate their mouse lines via a very short Strain Submission form (jax.org/donate-a-mouse). Please also visit the JAX Oncology webpage for cancer research related strains and resources (jax.org/jax-mice-and-services/solutions-by-therapeutic-area/oncology). JAX is supported by the NIH, The Howard Hughes Medical Institute and other private charitable foundations.

#2833 Validating cancer biomarker expression on mouse cell-derived xenograft models of human cancer.

M. Huang, A. E. Wiggins, D. Marroquin, M. Liu, L. Tsai;
HD Biosciences, Inc.,a WuXi AppTec company, San Diego, CA

Background and Objective: The target antigen expression level is critical for the potency of immune therapies like ADC, mRNA-LNP, and CAR-T. Selecting an appropriate cancer model remains a challenge to the pre-clinical drug testing. HD Biosciences offers over 1000 cell lines and 150 CDX mouse models of human cancers. Furthermore, we have validated the expression of three therapeutic targets Nectin-4, Trop2, and PD-L1 in various CDX tumor tissues. This poster will highlight some recently established models as well as the antigen validation result. Our study provides a reference that guides the model selection of efficacy studies targeting Nectin-4, Trop2, or PD-L1. In addition, we offer a platform to validate the expression of target antigens in CDX mouse models covering numerous cancer types.

Method and Result: Biomarker surface expression of Nectin-4, Trop2, and PD-L1 on xenograft tumors was validated by IHC staining and FACS analysis. We highlight these models with high expression of each marker. These models are available to support further efficacy studies of anti-cancer drugs targeting the marker. We also analyzed the biomarker surface expression in vitro using cell pellets via FACS analysis to compare with the in vivo expression level. Hence, the biomarker gene expression level was confirmed by FACS. Interestingly, the result indicates biomarker expression in mouse tumor tissues is often inconsistent with in vitro cell expression. For example, the A375 CDX model on humanized immunodeficient mice is commonly used for anti-PD-1/PD-L1 drug efficacy tests. However, the surface expression of PD-L1 is only detected in the A375 tumor tissues and is undetectable in the A375 cell pellet. This finding could explain the inconsistency of in vitro and in vivo drug test results. The in vivo CDX model-based biomarker would better predict the drug's efficacy, as the model better mimics the clinical situation of tumor burden in patients.

Conclusion: In vitro gene expression and protein expression of cell surface biomarkers may not be relevant to the in vivo tumor surface expression level, resulting in inconsistent efficacy data in vitro and in vivo. Thus, validating targeted biomarkers in vivo is crucial for choosing the best cancer tumor model with high target expression for drug efficacy validation. HD Biosciences provides validated 150 CDX models expressing Nectin-4, Trop2, and PD-L1 and have in vivo capability for target validation and drug efficacy study.

#2834 Establishment of orthotopic high grade glioma xenograft model using zebrafish embryos.

E. Winter da Silva[1], A. De Loose[2], Y. Chernyavskaya[1], A. Rodriguez[2], J. Blackburn[1];
[1]University of Kentucky, Lexington, KY, [2]University of Arkansas for Medical Sciences, Little Rock, AR

High grade glioma (HGG) is the most common malignant brain tumor in adults. These tumors represent a lethal group of brain tumors characterized by a remarkable level of genetic, epigenetic, and environmental heterogeneity, which can significantly affect therapy response and patient outcomes. Patient-derived xenograft (PDX) models of glioma are a central tool for neuro-oncology research and drug development, enabling the detection of patient-specific differences in growth and drug response. Mouse xenografts of HGG are well-established, but the time required to generate these models is not practical for integration into clinical paradigms. Patient derived organoids cannot mimic the physiologic aspects of an in vivo system, such as the blood-brain barrier or metabolism of drugs, which can affect how tumor cells respond to treatment. In this context, zebrafish are emerging as a time-efficient and cost-effective *in vivo* model. We investigated a rapid zebrafish-based PDX model that can recapitulate key aspects of different gliomas and enable treatment response evaluation within 8 days. We engrafted one GBM cell line (U-87), two patient-derived glioblastoma (GBM) cells, and one patient-derived IDH mutant grade 4 astrocytoma into the midbrain region of 2-day-old zebrafish embryos. Survival of transplanted larvae were monitored over 8 days post-transplantation and the engraftment was analyzed. Therapy response was evaluated through tumor size. One day post-transplantation, animals received 10 and 25 Gy radiation with or without 50 and 100 μM of temozolomide, a common GBM therapeutic, and tumor size was measured after 3 days by imaging. Results showed that GBM and astrocytoma cells had 100% and 80% of engraftment, respectively. GBM cell induced a median survival of 7 days in transplanted animals while 87 % of astrocytoma-injected animals were alive 8 days post transplantation. GBMs also varied in their drug and radiation response. Although both samples were classified as high-grade GBM and MGMT unmethylated, PDX derived from a younger patient with no alterations in PTEN and MDM2 genes responded better to temozolomide and radiation . Tumor responsiveness to therapy is often a combination of genetic and non-genetic factors that are difficult to clinicians to predict. By combining tumor-specific models and drug testing, a patient's treatment plan could be tailored based on the sensitivity of each sub-clone to targeted therapeutics. In conclusion, we showed that the zebrafish-based PDX model provides a novel, high throughput avenue to assess the impact of tumor heterogeneity on drug response.

#2835 Comparison of xenograft and syngeneic cancer cachexia models for preclinical drug testing.

K. Draheim, D. Gietl, K. Shinn, W. Durham, F. Zhao, C. Thompson, A. Baldwin, G. Harris, C. Hall, **P. Fadden**, A. Avrutskaya;
Charles River Laboratories, Inc., Durham, NC

Cancer cachexia is a wasting syndrome characterized primarily by loss of skeletal muscle and adipose tissue mass and contributes greatly to overall cancer-related mortality (for recent review see Argiles 2023). An estimated 25-75% of cancer patients develop cachexia which leads to impacts on therapeutic tolerability, well-being, and eventually overall survival (Bossi 2021). Some preclinical mouse and rat cancer models manifest cachexia as they progress. In this study we established a syngeneic (immune competent) and a xenograft (immune incompetent) tumor model of cachexia with the intention of comparing the models with respect to typical study endpoints and to provide a platform for testing novel therapeutic agents aimed at inhibiting or reversing the effects of cachexia. The Colon26 syngeneic mouse colon adenocarcinoma model was reported as an experimental cancer cachexia model by Tanaka, et. al. in 1990. The model was developed in male BALB/c × DBA/2 F1 (first generation cross) mice. We typically implant Colon26 in female BALB/c mice for preclinical drug testing of anticancer agents and noticed a strong tendency for mice bearing Colon26 tumors to develop signs of cachexia on study, but not always consistently. A review of the literature showed there are clear gender differences with male cancer patients having higher prevalence of cachexia and greater muscle loss compared with female patients (Zhong 2020). Based on this we implanted Colon26 tumors in male BALB/c mice to establish the cachexia model. The HT1080 human fibrosarcoma model HT1080 was characterized as a cachexic model by Bernardo, et. al. in female severe combined immunodeficiency disease (SCID) mice. We developed the HT1080 model in male SCID mice based on the literature and previous experience. Both models were characterized by multiple endpoints including overall body weight loss, skeletal muscle weight loss, reduction of adipose tissue, and cardiac muscle loss, as well as tracking a broad panel of relevant cytokine levels at study endpoint. Both models generate robust wasting of skeletal muscle and adipose tissue providing an opportunity to assess novel anti-cachexia therapies.

#2836 Assessment of therapeutic antibody efficacy without the interference of murine Fc receptors allows for investigation of human antibody-dependent cellular cytotoxicity mediated by NK cells in the FcResolv™ hIL-15 NOG mouse model.

S. Rhein[1], M. Stecklum[1], M. Buczek[2], J. Richardson[2], **J. Hoffmann[1]**;
[1]Experimental Pharmacology and Oncology Berlin-Buch GmbH, Berlin, Germany, [2]Taconic Biosciences, Rensselaer, NY

Targeted antibody therapy is applied to treat various cancer types. In addition to the primary mode of action (MOA), which involves direct binding to the tumor antigen, indirect MOA acting through the constant region (Fc) of the antibody can enhance anti-tumor efficacy. Indirect mechanisms engage the innate immune system, mediated by both the complement system (complement-dependent cytotoxicity (CDC)) and immune cells (antibody-dependent cellular phagocytosis (ADCP) and antibody-dependent cellular cytotoxicity (ADCC)). These indirect mechanisms can complicate the evaluation and accurate assessment of antibody-induced ADCC by human NK cells in current mouse models. In immune-deficient mouse strains (e.g. NOG), false positives and/or negatives may occur due to interactions with murine Fc receptors. These can either result in anti-tumor responses via activation of the murine innate immune system or can interfere with the human-targeted therapy's primary MOA. To study the response to anti-cancer antibodies without the interference of these murine Fc receptor interactions and to investigate ADCC mediated by human NK cells, a novel mouse model deficient in Fc receptors and expressing human IL-15 (FcResolv™ hIL-15 NOG) was employed for testing antibody therapies. Methods: Patient-derived xenograft (PDX) tumor models were transplanted into hIL-15 NOG and FcResolv™ hIL-15 NOG mice. A human head and neck squamous cell carcinoma and a lung adenocarcinoma PDX model were both treated with cetuximab. Treatment with pertuzumab and trastuzumab was applied in a breast ductal carcinoma PDX model. Rituximab treatment was tested in two diffuse large B cell lymphoma PDX models. Based on growth kinetics, the lung cancer PDX model was chosen for further testing of ADCC in the NK cell-humanized FcResolv™ hIL-15 NOG mouse. Results and Conclusion: There was no difference in percent tumor growth inhibition between the FcResolv™ hIL-15 NOG and hIL-15 NOG mice with regards to cetuximab treatment in the lung and head and neck cancer or for trastuzumab treatment of breast ductal carcinoma. However, pertuzumab treatment revealed a false positive efficacy, with the false positive effect more pronounced in hIL-15 NOG mice than in FcResolv™ hIL-15 NOG mice. In one of the lymphoma models, a false negative result was observed. Here, rituximab did not show notable tumor inhibition in the hIL-15 NOG mice but did in the FcResolv™ hIL-15 NOG mice. These results demonstrate that FcResolv™ hIL-15 NOG mice serve as a suitable mouse model for a more accurate assessment of the therapeutic efficacy of anti-tumor antibodies. Additionally, evaluation of human-mediated ADCC of therapeutic antibodies in NK cell-humanized FcResolv™ hIL-15 NOG allows detection of effects specifically mediated by human NK cells.

#2837 Conservation of JAK-STAT signaling in canine lymphocytes responding to human IL-6, IL-7, and IL-1 alpha.

K. Fung, M. L. Breiner, J. B. Mitchell II, R. E. Parchment;
FNLCR, Frederick, MD

Dogs share physiological similarities with humans, positioning them as valuable models for studying the efficacy and safety of drugs and their underlying mechanisms of action. The JAK-STAT pathway, a highly conserved signaling pathway across species, including humans and dogs, presents an opportunity to investigate the therapeutic potential of cytokines that utilize this pathway.

In this study, we aimed to evaluate the functional activity of three canine cytokines on canine cells. To assess stimulation of the JAK/STAT pathway, we used a flow cytometry assay that measures phospho-STAT in activated canine or human lymphocytes in whole blood specimens. Testing of commercially available human and canine IL-6 proteins revealed that canine lymphocytes respond poorly to most canine IL-6 products, whereas all recombinant human IL-6 products stimulated STAT phosphorylation in canine lymphocytes, despite sharing low sequence similarity with canine IL-6. In human T cells, both canine IL-6 and human IL-6 stimulated STAT phosphorylation, demonstrating biological activity from the canine IL-6 products. Several JAK inhibitors inhibited cytokine-induced STAT phosphorylation in both canine and human CD4 T-cells, consistent with JAK inhibition, but targeting the IL-6 receptor with tocilizumab only blocked IL-6-induced STAT phosphorylation in human but not canine CD4 T-cells in whole blood. These findings demonstrate the potential of our assay system to assess cross-species cytokine reactivity, determine if JAK/STAT inhibitors used clinically might be useful in treating inflammatory conditions in dogs, and identify novel canine-specific inhibitors.

Additionally, we explored the induction of IL-8 by human and canine IL-1 alpha in IL-1 alpha sensitive human cells. Human IL-1 alpha failed to stimulate a canine IL-1 alpha sensitive cell line, suggesting species-specific differences in IL-1 alpha activity. Furthermore, we discovered that canine IL-7 and human IL-7 are species-specific.

In summary, this proof-of-concept study highlights the capability to assess the activation of STATs and pathway inhibition by JAK inhibitors in canine whole blood using flow cytometry. We confirmed that human IL-6 stimulates JAK/STAT signaling in canine CD4 T-cells. Our results also revealed significant differences in species cross-reactivity of human IL-6, IL-7, and IL-1 alpha, underscoring the importance of species-specific investigations. Leveraging the similarities and differences between canine and human cytokines targeting the JAK-STAT pathway can enhance drug development efforts and contribute to the advancement of safer and more effective therapies for both humans and pet dogs with similar diseases. This study was funded by NCI Contract No. 75N91019D00024.

#2838 ZNFX1 is a master regulator and tumor suppressor in epigenetically induced pathogen mimicry, mitochondrial dysfunction and STING-dependent signaling in cancer.

L. Stojanovic[1], R. Abbotts[1], K. Tripathi[1], C. M. Coon[2], S. Liu[3], J. Wan[3], M. Topper[4], S. Baylin[4], K. Nephew[2], F. Rassool[1];
[1]University of Maryland, Baltimore, Baltimore, MD, [2]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Bloomington, IN, [3]Indiana University, Bloomington, IN, [4]Johns Hopkins University, Baltimore, MD

Immunomodulatory agents are an important recent advance in cancer therapy, but utility is often limited by tumor immune evasion mechanisms. Strategic therapeutic activation of intracellular antiviral immune responses offers an opportunity to reverse immune evasion mechanisms and improve treatment outcomes. Anti-cancer agents such as, DNA methyltransferase inhibitors (DNMTis) induce re-expression of endogenous retroviruses (ERVs), leading to cytosolic double-stranded RNA (dsRNA) accumulation that activates interferon/inflammasome signaling. Moreover, poly (ADP ribose) polymerase inhibitors (PARPi) increase cytosolic dsDNA, activating stimulator of interferon (IFN) genes (STING). We reported that DNMTis in combination with PARPis induce STING-dependent signaling in a process termed pathogen mimicry response (PMR). Mitochondria (mt) are an important gateway for antiviral inflammasome signaling, but are not fully understood in cancer. Our studies of the little-known gene, NFX1-type zinc finger-containing 1 (ZNFX1), show that it acts as a master nucleic acid (dsRNA/DNA) sensor for mt gateway function. Bioinformatics analysis in primary ovarian tumors from TCGA and clinical trial RNAseq datasets, shows that increased ZNFX1 expression tracks with tumor stage and grade but inversely correlates with a mt dysfunction signature. **I**n studies of high-grade and endometrial serous carcinoma (OC) cell lines (N=3), transfection of dsRNA/DNA mimics or DNMTi azacytidine (AZA) and PARPi (talazoparib [TAL]) treatments induce increased ZNFX1 expression and binding to mt antiviral protein (MAVs) localized on the mt outer membrane. Functional studies of mt dysfunction in OC cells, show that dsRNA/DNA as well as above viral mimicry drugs increase mt reactive oxygen species (ROS) as measured by mitosox flow cytometry. AZA and TAL treatments also increase fragmented mtDNA and oxidative mtDNA base damage, as measured by long range PCR and 8-oxoguanine (8-oxoG) ELISA assays. These drug treatments also increase release of mtDNA into the cytosol, resulting in STING-dependent inflammasome signaling and cytokine release. Notably, ZNFX1 knockout (KO) attenuates these dynamics, including in bioinformatics of RNA seq data, thus defining this gene as essential for IFN/inflammasome signaling induced by mtDNA damage. Further pathway analysis of ZNFX1 KO vs wild-type (WT) RNAseq data suggest increased proliferation and epithelial to mesenchymal transition (EMT) that was validated by in vitro and in vivo assays. Not only is ZNFX1 a master regular of the above mt dynamics, but it is a tumor suppressor in OC. Abrogating ZNFX1 expression in OC cells triggers increased cell proliferation, invasive capacity and, in-vivo, increased tumor growth. This work then suggests novel approaches to improve immune therapy responses in OC through manipulating ZNFX1.

#2839 The mouse models of human cancer database (MMHCdb).

D. A. Begley, D. M. Krupke, E. Jocoy, S. B. Neuhauser, **C. J. Bult**;
The Jackson Laboratory, Bar Harbor, ME

The laboratory mouse plays a pivotal role as an experimental system for investigations into the genetic and genomic basis of cancer susceptibility, initiation, and progression and for preclinical research on novel treatment strategies for cancer. Advances in mouse models include humanized mice, transplant compliant mouse strains, and panels of genetically diverse mice (e.g., Diversity Outbred and Collaborative Cross). The distributed and heterogenous nature of information about these model systems presents a significant challenge to finding and aggregating information about mouse models and to identifying the most relevant models for a particular research question. The Mouse Models of Human Cancer database (http://tumor.informatics.jax.org) is an expertly curated FAIR-compliant knowledgebase that applies community annotation standards and nomenclature standards for genes, alleles, and strains to support accurate and comprehensive search results for mouse models of human cancer. The data in MMHCdb are curated from peer-reviewed scientific publications and direct data submissions from individual investigators and large-scale programs. A primary focus of the resource is to reflect the impact that genetic background has on the cancer-related characteristics of mouse models. The database includes information on spontaneous and genetically engineered cancer models as well as Patient Derived Xenografts and diversity panels. The database supports faceted searching for models by multiple criteria including, tumor type, genetic background of the mouse model, somatic mutations, and publication. Model descriptions include summaries of observed frequencies of tumors observed in the model and histopathology images. Information in MMHCdb is linked to cancer model data from other bioinformatics resources including the Patient Derived Cancer Models database (PDCM), PathBase, the Gene Expression Omnibus (GEO), and ArrayExpress.

MMHCdb is supported by NCI R01 CA089713

#2840 Development, characterization, and validation of a systemic human mantle cell lymphoma model utilizing luciferase expressing Jeko-1 tumor cells.

D. Harris, A. Wong, E. Rainbolt, N. Westrick, J. Avery, J. Kolb, A. Vunnava, Z. Ward, C. Hall, **B. John**;
Charles River Laboratories, Inc., Durham, NC

Mantle cell lymphoma (MCL) is an aggressive subtype of B-cell non-Hodgkin lymphoma that is clinically and biologically heterogenous. MCL murine models are scarce and reliable *in vivo* models are necessary for pre-clinical testing and identification of improved novel therapeutics. To address this need, we established and characterized a human MCL *in vivo* model by systemic implantation of the luciferase-expressing Jeko-1 cell line (Jeko-1-luc) into immunodeficient NCG mice. Tumor growth kinetics was evaluated by testing multiple cell inoculums, and disease progression was monitored by *in vivo* serial bioimaging, three-dimensional optical imaging (3D), and *ex-vivo* endpoint analyses. Jeko-1-luc tumor growth profile revealed moderate latency with a median survival of 40 days post implant. Subsequently, we utilized 3D optical imaging and *ex-vivo* imaging that confirmed the localization of tumor growth predominantly in lungs, spleen, and skeletal regions. Additionally, we determined the surface expression of selected B-cell lineage markers including CD19, CD20, and CD22. Next, we evaluated the efficacy and effect on survival in response to various standard of care agents including Vincristine, Rituximab, Palbociclib, Temsirolimus, and Cyclophosphamide. The quantification of tumor burden by *in vivo* and *ex-vivo* bioluminescent imaging demonstrated that the highest therapeutic activity and overall survival was achieved by Palbociclib and Vincristine. Flow cytometric analyses further demonstrated that tumor cells obtained from blood and selected tissues including spleen and bone marrow showed reduced tumor burden in treatment groups relative to the control group. Taken together, these results illustrate the translational value of the Jeko-1-luc model and provides a platform for evaluating novel treatment modalities for mantle cell lymphoma.

#2841 Development and validation of a systemic human multiple myeloma model utilizing luciferase expressing MM1.S tumor cells.

B. John, C. Currie, N. Westrick, T. Rowe, A. Wong, E. Rainbolt, Z. Ward, C. Hall, D. Harris;
Charles River Laboratories, Inc., Durham, NC

Multiple Myeloma (MM) is a complex hematologic malignancy characterized by clonal proliferation of transformed plasma cells leading to overproduction of monoclonal immunoglobulins and subsequently end-stage organ damage. Despite therapeutic advances, MM is an incurable disease with poor prognosis in high-risk patients, and thus relevant preclinical models are necessary to develop novel treatment strategies. We developed a Multiple Myeloma *in vivo* model by systemic implantation of the luciferase-expressing glucocorticoid sensitive tumor cell line MM1.S (MM1.S-Luc) into immunodeficient NCG mice. First, we generated a MM1.S-Luc monoclonal cell line from a polyclonal pool of stable luciferase-expressing cells by limiting dilution. Single cells from the stable pool were expanded under selective pressure and four MM1.S-Luc monoclonal lines were selected based on *in vitro* growth properties and bioluminescence intensity. Next, we determined the *in vivo* tumor growth profile by testing the monoclonal lines at two different cell inoculums, and disease progression was monitored by *in vivo* serial bioimaging. MM1.S-Luc tumor growth kinetics revealed a long latency and based on our *in vivo* imaging results, the tumor preferentially localized to the long bones, lungs, and mandible. For validation of the MM1.S-Luc *in vivo* model, we determined the efficacy and survival benefit in response to various clinically relevant standard of care agents including Dexamethasone, Daratumumab, Cyclophosphamide, Vincristine, Panobinostat, and Bortezomib. The quantification of tumor burden by bioluminescent imaging showed reduced tumor burden and prolonged survival with Panobinostat and Cyclophosphamide. In summary, we have developed a systemic MM1.S-Luc model that recapitulates the disease dissemination and invasiveness of multiple myeloma for evaluating novel therapeutic approaches to treatment.

#2845 Novel genetic risk loci for B-cell acute lymphoblastic leukemia in African American children: Findings from the Admixture and Risk of Acute Leukemia (ADMIRAL) Study.

C. Im[1], A. Raduski[1], L. J. Mills[1], R. A. Johnson[1], A. DeWan[2], X. Ma[2], J. L. Wiemels[3], C. Metayer[4], J. J. Yang[5], H. H. Nelson[1], T. Yang[1], S. Basu[1], L. M. Turcotte[1], N. Pankratz[1], M. E. Scheurer[6], L. G. Spector[1];
[1]University of Minnesota, Minneapolis, MN, [2]Yale University, New Haven, CT, [3]University of Southern California, Los Angeles, CA, [4]University of California, Berkeley, Berkeley, CA, [5]St. Jude Children's Research Hospital, Memphis, TN, [6]Baylor College of Medicine/Texas Children's Hospital, Houston, TX

Background: Racial and ethnic disparities in incidence and outcomes for childhood B-cell acute lymphoblastic leukemia (B-ALL) are well established. While genome-wide association studies (GWASs) among children of European (EUR) genetic ancestry have identified robust risk loci, comparable studies in children of African (AFR) genetic ancestry do not exist. Here we report on results from the first GWAS of B-ALL exclusive to AFR children.
Methods: A total of 840 AFR cases (diagnosis age <21y) and 3360 sex-/ancestry-matched controls (from ADMIRAL and ZOE 2.0, a childhood caries study) were evaluated. We used 656 cases from the Children's Oncology Group (COG) ALL frontline trials for discovery and 184 non-COG cases for replication. Samples were genotyped with the Illumina Global Diversity Array and imputed with the TOPMed reference panel. Ancestry was ascertained with RFMix-inferred global ancestry values and principal components analysis. Logistic regression models adjusted for cryptic population substructure evaluated variant risk associations. Discovery and replication results were meta-analyzed using an inverse variance-weighted fixed effects model.
Results: We identified 7 genome-wide significant (GWS, $P<5x10^{-8}$) variants, including 2 novel B-ALL risk loci with replication evidence ($P<0.05$) and striking per allele effect sizes: *CNTN4* (meta-analysis odds ratio [OR]=2.09, $P=1.4x10^{-11}$) and *FAM174A* (OR=2.94, $P=1.2x10^{-15}$). Established B-ALL EUR risk loci were corroborated in these data (*ARIDB*5, *IKZF1*; $P<5x10^{-8}$). Five additional novel loci were GWS after meta-analysis including at *SLC37A4* (OR=2.02, $P=1.1x10^{-8}$) and *CBWD1* (OR=2.69, $P=2.7x10^{-9}$), with suggestive associations in discovery data ($P<5x10^{-6}$) and nominal replication ($P<0.05$). Notably, all novel risk alleles were low-frequency in reference AFR populations and AFR-specific (minor allele frequencies of 2-9% in 1000 Genomes AFR and <0.1% in non-AFR). Top variants had relevant *in silico* annotations; variants at *CNTN4* and *SLC37A4* had high predicted functional probability (>0.8, RegulomeDb). For example, annotations for a top *CNTN4* signal suggest a potential leukemogenesis mechanism, overlapping a ChIP-seq peak for CEBPA in transdifferentiated B cells. In our replication data, a polygenic risk score (PRS) with 5 novel AFR-specific GWS variants from discovery had an appreciably stronger B-ALL risk association (top 25% vs rest: OR=2.03, $P=1.2x10^{-4}$) compared to a published B-ALL PRS from a GWAS in EUR children (top 25% vs rest: OR=1.59, P=0.014).
Conclusions: Despite the modest number of AFR B-ALL cases, we successfully detected and replicated genotype risk associations with considerable effect sizes. These results demonstrate the critical importance of increasing diversity in genomic studies of childhood ALL to promote discovery and reduce disparities.

#2846 Investigation of mechanisms that result in health disparity for Hispanic/Latino patients with B acute lymphoblastic leukemia.

J. W. Schramm, B. He, Y. Ding, C. Singh, D. Bogush, K. Dovat, D. Bastihalli Tukaramrao, R. Bhalodia, S. Dovat;
Penn State Health Milton S. Hershey Med. Ctr., Hershey, PA

Although social determinants of health have a large impact on health disparity, biologic vulnerabilities - particularly in cancers that impact at-risk populations are important. Amongst children with Acute Lymphoblastic Leukemia (ALL), the Hispanic/Latino (H/L) population is vulnerable given since the risk of developing ALL is 1.2-1.75 that of Non-Hispanic White children. After corrections for socioeconomic impacts, the mortality for H/L children is 40% higher than NHW. H/L children have a higher rate of high-risk genetic variations: 2-fold rate of heterozygous IKZF1 deletion (IKZF1-del) and a 4-fold rate of CRLF2 translocation. IKZF1 deletion and CRLF2 translocations are associated increased risk of relapse and chemotherapy resistance in B ALL. IKZF1 is an important transcriptional factor and epigenetic regulator that affects global gene transcription in hematopoietic cells. Simultaneous IKZF1-del and CRLF2 translocation represented 94% of H/L children with CRLF2 translocation. Although only 49% of all H/L patients with IKZF1-del had a CRLF2 translocation. Transcriptomics were analyzed for 42 H/L and 18 NHW patient samples using RNAseq. Gene expression from H/L patients was compared to expression in NHW patients and differentially expressed genes were analyzed. Gene set enrichment analysis (GSEA) revealed downregulation of processes responsible for genome maintenance including DNA replication, DNA templated transcription elongation, double strand break repair, and recombinational repair. Ingenuity pathway analysis (IPA) revealed upregulated pathways in stress related translation, histone deacetylases, interferon, and FLT3 signaling compared to NWH. H/L specimens resulted in decreased expression for FGF pathways, ceramide, and FAK signaling. We performed the same analysis in H/L and NHW with wildtype IKZF1 to compare these two population without high risk structural variants. GSEA analysis showed downregulated Intra S DNA Damage checkpoint signaling, DNA replication checkpoint signaling, glutamine amino acid synthesis, and aspartate amino acid synthesis. IPA showed upregulated interferon, histone deacetylases, TREM1 signaling, and Tec Kinase signaling. IPA showed downregulated Ephrin and CDK5 signaling. DNA methylation patterns were compared between 8 H/L and 8 NWH B ALL samples which showed differential methylation patterns affecting multiple cancer relevant genes.In conclusion, these data represent biologic vulnerability in H/L patients with B ALL in comparison to NWH regardless of high-risk genetic variants. H/L B-ALL shows deregulated maintenance of the genome via replication and repair pathways as well as potential vulnerabilities related to regulation of glutamate/aspartate synthesis. These findings give insight into potential mechanisms that can explain increased frequency of high-risk genetic variants in H/L B ALL.

#2847 Study of spatial and temporal epigenetic heterogeneity in neuroblastoma suggests role of H3K27me3-mediated repression.

C. Butterworth[1], A. Saint-Charles[1], Y. Iddir[1], J. Bhalshankar[1], A. Bellini[1], C. Bobin[1], E. Wecht[2], Y.-G. Park[2], C. Louis[1], V. Raynal[1], D. Plantaz[3], H. Sartelet[4], V. Combaret[5], G. Pierron[1], I. Janoueix-Lerosey[1], K.-O. Henrich[2], O. Delattre[1], F. Westermann[2], G. Schleiermacher[1];

Introduction: Trimethylation of Histone 3 Lysine 27 (H3K27) is widely understood to be a mark associated with gene repression and linked to gene silencing during development. Neuroblastoma, a developmental pediatric extracranial solid malignancy, has a relatively silent mutational landscape. Therefore, epigenetic modifications, including H3K27me3 mediated repression, could explain underlying developmental origins and the wide clinical heterogeneity observed. While previous studies have focused on the role of distinct super enhancer histone marks and their core regulatory circuits, less is understood about repressive control. We aimed to therefore investigate the role of H3K27me3-mediated repression in Neuroblastoma patients.
Methods: Genome-wide H3K27me3 ChIP-Seq profiles were obtained from 48 diagnostic tissue biopsies covering all clinical and molecular patient subgroups. Transcriptome sequencing, ChIP-Seq of additional histone marks and WES/WGS was also performed on the same samples and on a panel of Neuroblastoma cell line models, with multiomics integrative analysis to validate findings. HMCAN, deepTools, DiffBind and ROSE packages were used to analyze the ChIP-seq data.
Results: A comparison of H3K27me3 regions across all patient ChIP-Seq profiles, identified commonly repressed genes specific to Neuroblastoma. These genes are enriched in development and differentiation pathways, with significantly lower RNA expression levels than other publicly available pediatric tumor datasets. When compared to publicly available single cell RNAseq of the healthy adrenal medulla, we can further highlight a potential role of H3K27me3-mediated repression in regulating cell lineage commitment and differentiation ability. In addition, we identified that patient samples cluster into their clinical subgroups based on H3K27me3 patterns and differentially repressed genes, specifically between *MYCN*-amplified and non-amplified high-risk groups. A CRISPR screen to further validate the functional role of these repressed genes is being carried out.
Conclusions: To our knowledge, this study shows for the first time that understanding of H3K27me3 mediated repression in Neuroblastoma, can uncover new insights into both disease development and clinical subclassifications. This knowledge will be important when considering future potential novel treatment options.

#2848 MYC and TGFβ promote group 3 medulloblastoma tumor resistance through deregulation of Polycomb targets.

Z. A. Qadeer[1], S. Westelman[1], M. O. Johnson[1], E. Hou[1], S. Grele[1], K. Smith[2], L. Hendrikse[3], L. Wang[1], S. Husain[1], M. Beytagh[1], C. Schmidt[1], M. Huang[4], M. D. Taylor[5], P. Northcott[2], W. A. Weiss[1];

[1]UCSF - University of California San Francisco, San Francisco, CA, [2]St. Jude's Children, Memphis, TN, [3]Hospital for Sick Children, Toronto, ON, Canada, [4]Children's Hospital of Los Angeles, Los Angeles, CA, [5]Texas Children's Hospital, Houston, TX

Medulloblastoma (MB) is one of the most prevalent malignant brain tumors in children, with tremendous cognitive and neuroendocrine disability among survivors. Group 3 (G3) MBs have poor overall survival at <50%, few recurrent mutations, higher frequency of metastasis, and no targeted therapies. Amplification of *MYC* and activation of TGFβ signaling are frequent in G3MB. Remarkably, some MB tumors have no reported mutations, suggesting roles for epigenetic mechanisms in driving disease. We hypothesize that the TGFβ pathway and MYC contribute to the intrinsic resistance of G3MB through deregulation of key genes and pathways. We previously established humanized models for SHHMB by introducing MYCN or *PTCH1* deletions into neuroepithelial stem cells (NESC) derived from normal human induced pluripotent stem cells (hIPSCs). In this study, we transduced NESCs with TGFb effectors activated in G3MB alone and/or in combination with MYC, prioritizing combinations observed in patients. Excitingly, both MYC and TGFβ effectors drove tumor formation *in vivo* with the combination of TGFβ effectors with MYC leading to more aggressive tumors. Moreover, they clustered with human G3/G4MB samples, indicating they phenocopy the relevant tumor of interest. We next found that NESCs expressing MYC with either TGFβR1 or TGFβ1 showed resistance to clinical TGFβR1 inhibitors, compared to cells driven by either TGFβR1 or TGFβ1 alone. To decipher mechanisms of resistance, we integrated CUT&RUN to probe for MYC genomic localization and relevant histone PTMs with RNA-seq analysis and discovered a subset of genes upregulated in MYC and TGFb-driven lines that are targets of the histone demethylase KDM2B. Loss of function mutations in *KDM2B* occur in G3MB patients, indicating that KDM2B deregulated genes are critical in G3MB. We postulate that epigenetic remodeling via MYC and recruitment of other MYC-interacting cofactors to PRC targets culminates in transcriptional changes that lead to aggressive disease. Work from others suggests that PRC-mediated chromatin regulation is critical in many adult and pediatric brain tumors. Overall, our studies provide important insight on identifying new therapeutic avenues for patients with *MYC* and TGFβ driven G3MB.

#2849 Palbociclib as a novel therapeutic for desmoplastic small round cell tumor.

J. W. Magrath, S. Sampath, D. A. Flinchum, A. B. Hartono, I. N. Goldberg, J. R. Boehling, S. D. Savkovic, S. B. Lee;
Tulane University School of Medicine, New Orleans, LA

Desmoplastic small round cell tumor (DSRCT) is an aggressive, pediatric cancer caused by the EWSR1-WT1 fusion oncoprotein. Targeted therapies are lacking and the current standard of care, multimodal therapy, is insufficient, leading to a 5-year survival rate of less than 25%. While the EWSR1-WT1 oncoprotein is critical to growth *in vitro*, its importance has yet to be examined *in vivo*. Further, the set of EWSR1-WT1 downstream targets critical to oncogenesis and the mechanism by which the two EWSR1-WT1 isoforms regulate them remain underinvestigated. Here we generate a toolkit of DSRCT cell lines that deplete EWSR1-WT1 in a doxycycline (dox)-inducible manner. This toolkit enabled us to establish the essentiality of EWSR1-WT1 not only *in vitro* but also for the first time *in vivo*. Using this toolkit, we performed RNA sequencing on four DSRCT cell lines and established the most comprehensive analysis of EWSR1-WT1 downstream targets to date. We discovered novel mechanistic insights into EWSR1-WT1 functionality including the uniqueness of its transcriptional alterations as compared to native WT1, the direct role of EWSR1-WT1 binding in gene upregulation, and the dominant role of the E-KTS isoform in transcription. Given the rarity of DSRCT, we focused on downstream targets with existing inhibitors and perform a drug screen that identified the CDK4/6 inhibitor palbociclib as a novel DSRCT therapeutic. We found that the E-KTS isoform of EWSR1-WT1 binds to the CCND1 promoter, leads to CCND1 expression, and stimulates DSRCT growth through the CCND-CDK4/6-RB axis. Palbociclib treatment conversely reduced DSRCT growth by preventing retinoblastoma phosphorylation and blocking the transition from G1 to S phase. Palbociclib treatment was effective not only *in vitro* but also *in vivo* where it significantly reduced tumor growth in two xenograft models of DSRCT. Given these novel findings and palbociclib's previous approval by the FDA for the treatment of breast cancer, we advance palbociclib as an exciting DSRCT therapy that warrants urgent clinical investigation.

#2850 Noncoding regulatory mutations as driving event for the oncogenic core regulatory circuitries of neuroblastoma.

M. Capasso[1], V. Aievola[1], V. Lasorsa[2], A. Montella[1], F. Bonfiglio[1], M. Avitabile[1], T. Maiorino[1], M. Tirelli[3], G. D'Alterio[3], M. Fischer[4], F. Westermann[5], A. Iolascon[1];

[1]University of Naples Federico II, Naples, Italy, [2]CEINGE Biotecnologie Avanzate Franco Salvatore scarl, Naples, Italy, [3]University of Milan, Milan, Italy, [4]University of Cologne, Cologne, Germany, [5]Hopp-Children's Cancer Center at the NCT Heidelberg (KiTZ), Heidelberg, Germany

Background and Aim: Neuroblastoma (NB) is the most aggressive solid tumor of infancy and arises from neural-crest-derived progenitor cells. It is composed by cell types reflecting developmental stages of the adrenergic lineage: mesenchymal (MES) and adrenergic (ADRN) cell types. These cell identities result from the activity of NB specific Core Regulatory Circuitries (CRCs), transcription factor (TF) sets that co-occupy regulatory regions together impacting the expression of their own genes and those of lineage-specific ones governing cell state transitions and cellular identities. Our hypothesis is that noncoding somatic single nucleotide variants (SNVs) located in NB CRCs TF binding sites (TFBSs) underlie NB CRCs activity, affecting cellular differentiation and promoting tumor onset. We aim to investigate such pattern of regulatory elements and identify putative driver SNVs, exploring their role and characterizing their action mechanism.
Methods: Transcriptionally active TFBSs (aTFBSs) bound by ADRN CRC TFs (GATA3, HAND2, ISL1, TBX2, MYCN, PHOX2B, ASCL1 and LMO1) were identified integrating 27 ChIP-seq and 11 ATAC-seq experiments in 6 NB ADRN cell lines (SKNBE2C, Kelly, NGP, COGN415, LAN5 and NB1643). In particular, aTFBSs were defined as ChIP-seq peaks overlapping ATAC-seq signals in the same cell line. SNVs from 317 NB whole genomes were mapped on aTFBSs and the enrichment of mutations in core regions respect to flanking ones was tested using Fisher test. Observed mutation rate in aTFBSs was compared with background mutation rate due to local sequence context. SNVs in mutated aTFBSs were selected and their impact on TF binding affinity was evaluated with FABIAN-variant and motifbreakR tools. aTFBSs target-genes were identified through promoter capture HiC (CHiC) in ADRN NB cells (SKNBE2C and SHSY5Y).
Results: We found a significant (FDR < 0.05) mutation enrichment in aTFBSs of ISL1, PHOX2B, TBX2, GATA3 and MYCN, suggesting a common somatic mutation burden for a subset of ADRN CRC TFBSs in ADRN NB cells. Starting from 839 SNVs falling in significantly mutated aTFBSs, we selected 269 mutations impacting the binding of ADRN CRC TFs. This mutations subset mapped in aTFBSs interacting with genes that significantly enriched pathways involved in neuronal development and migration (FDR < 0.05), thus suggesting their possible role in affecting cell identity definition. As an example, chr6:137753475:G>T mapped in aTFBSs interacting with the promoter of *OLIG3*, which takes part in neuronal differentiation. Interestingly, chr6:137753475:G>T was predicted to break the binding to ISL1 (FABIAN score: -0.24), a key regulator of ADRN CRC.
Conclusions: These results demonstrate that somatic noncoding SNVs can act synergistically to promote NB onset, affecting CRCs activity and, in turn, the normal cell identity definition.

#2851 Characterization of neogenes in desmoplastic small round cell tumors.

D. Truong[1], J. Magrath[2], S. Lee[2], J. Ludwig[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Tulane University School of Medicine, New Orleans, LA

Desmoplastic Small Round Cell Tumor (DSRCT) is a rare, soft tissue sarcoma caused by the EWS::WT1 fusion protein (FP). The FP acts as an aberrant transcription factor with oncogenic properties. Recently, oncogenic chimeric transcription factors (OCTF), such as EWS::WT1, were discovered to induce the expression of novel transcripts in otherwise silent genomic regions. These neogenes (NGs) are highly specific to each OCTF and not detected in normal tissue. 37 NGs were found to be associated with the EWS::WT1 FP.We explored the NGs to characterize their expression and regulation in a cohort of MD Anderson Cancer Center patients. We annotated and counted the NGs from the bulk RNA-seq data of 37 specimens. After fusion detection, only 22/37 specimens harbored the EWS::WT1 FP. We found that only the same 22 specimens robustly expressed DSRCT-specific NGs. Interestingly the NGs were heterogeneously expressed, suggesting that there may be patient-specific differences. Single-nucleus RNA-sequencing (snRNA-seq) of Ewing sarcoma (ES), CIC::DUX4 sarcoma (CDS), DSRCT, and osteosarcoma revealed that only the three sarcomas driven by an OCTF robustly expressed NGs. Notably, the DSRCT-specific NGs were only expressed in DSRCT. Similarly, ES and CDS only expressed their subtype-specific NGs. Given the robust expression of the DSRCT-specific NGs in DSRCT, we asked if the EWS::WT1 FP regulated the expression of the NGs. Knockdown (KD) of the EWS::WT1 FP in four DSRCT cell lines showed a consistent reduction in DSRCT-specific NGs. While there was variability in NG expression and EWS::WT1 FP KD sensitivity, we identified seven NGs decreased by at least 75% in all four cell lines and an additional eight NGs with 75% reduction across three cell lines. BOD-DSRCT and SK-DSRCT2 had the largest number of NGs reduced after KD, with 25/37 and 20/37 NGs with 75% expression reduction, respectively. EWS::WT1 FP has two known isoforms generated by alternative splicing in the WT1 domain that includes or excludes three amino acids, lysine, threonine, and serine (KTS) between zinc fingers 3 and 4, producing E+KTS and E-KTS isoforms. By transducing one or both isoforms into the mesothelial cell line LP9, we found 3/37 NGs were induced by the E+KTS isoform and 17/37 were induced by the E-KTS isoform, suggesting that the E-KTS isoform is primarily responsible for NG expression. Current work is underway investigating the relationship between EWS::WT1 FP binding and NG expression and the potential for NG to produce novel peptides that could serve as DSRCT immunotherapy targets.

#2852 Novel combination therapy with a KAT6A/B inhibitor together with retinoids induces irreversible differentiation of neuroblastoma cells.

N. Weichert-Leahey[1], A. Berezovskaya[1], M. Zimmerman[1], B. J. Abraham[2], A. W. Durbin[3], A. Look[1];
[1]Dana-Farber Cancer Institute, Boston, MA, [2]St. Jude Children's Research Hospital, Memphis, TN, [3]St. Jude Children's Research Hospital, Memphis, MA

Neuroblastoma is a pediatric tumor of the peripheral sympathetic nervous system derived from migratory neural crest cells that have committed to become sympathetic neuroblasts, but their definitive differentiation is blocked. Neuroblastoma cell identity depends on the adrenergic core regulatory circuit (CRC) of transcription factors that collaborate with MYCN to drive cell proliferation and the oncogenic gene expression program. Retinoic acid is used as differentiation therapy for patients with high-risk neuroblastoma, with the goal to block proliferation and drive sympathetic neuronal differentiation. We recently showed that retinoic acid re-organizes the enhancer landscape of neuroblastoma and promotes a new retino-sympathetic cell state characterized by MYCN downregulation, proliferative arrest, and sympathetic neuronal differentiation. However, the effects of retinoic acid on epigenetic rewiring of the adrenergic CRC and suppression of MYCN expression are reversible *in vitro* and *in vivo*, leading to tumor re-growth when the retinoic acid is withdrawn. Therefore, we sought to determine if retinoid-induced differentiation can be forced to progress to irreversible neuronal maturation by the addition of inhibitors of epigenetic modifying enzymes. Here, we conducted a drug screen of epigenetic modifying drugs alone and in combination with retinoic acid to determine their effects on neuroblastoma cell growth and differentiation. In this screen, we found that an inhibitor of the histone H3K23 acetyltransferases KAT6A/B, PF-9363, synergistically inhibits neuroblastoma cell growth in combination with retinoic acid. Moreover, retinoid-resistant neuroblastoma cell lines can be sensitized to retinoic acid when combined with a KAT6 inhibitor. Importantly, this combination treatment renders the differentiated cell state irreversible, such that it is maintained after retinoic acid is withdrawn, with continued suppression of the adrenergic CRC and MYCN expression. In conclusion, the retino-sympathetic differentiated cell state induced by retinoic acid in neuroblastoma becomes irreversible when the cells are also treated with an inhibitor of the KAT6A/B histone H3K23 acetyltransferases, implicating the essential role of these enzymes in restoring the proliferative immature progenitor phenotype in adrenergic neuroblastoma cells.

#2853 Comparison of methods for detection of hemispheric gliomas of infancy and their characteristic oncogenic tyrosine kinase gene fusions.

T. Pietsch[1], G. Gielen[1], A. Waha[1], E. Dorner[1], V. Dreschmann[1], C. Kramm[2], C. Vokuhl[1];

[1]University of Bonn Medical Center, Bonn, Germany, [2]University of Gottingen Medical Center, Gottingen, Germany

Introduction High grade hemispheric gliomas in infancy (IHG) are characterized by a more favorable outcome compared to high grade gliomas in older children. We have shown in previous studies that these tumors are characterized by a stable genome. The occurrence of tyrosine kinase gene fusions in high-grade hemispheric gliomas of infancy may represent therapeutic targets.

Methods: 33 high-grade hemispheric gliomas occurring in children younger than three years were retrieved from the archives of the Brain Tumor Reference Center, Institute of Neuropathology, University of Bonn. DNA and RNA were extracted from FFPE tumor samples. Methylation-based classification was done by hybridization to Illumina methylation arrays and subsequent use of the Heidelberg brain tumor classifier versions v11b4, v12.5 and v12.8. In addition UMAP plots were used to visualize similarities of methylation profiles. Gene fusions were identified on the DNA level by FISH using break-apart probes for *ALK, NTRK1, -2, -3, ROS1* and *MET* and Molecular Inversion Probe (MIP) methodology. On the RNA level, fusion transcripts were detected by targeted RNA sequencing as well as Nanostring assay with fusion-specific probes.

Results: 32 IHG occurred in the first year of life, one at the age of two years. 23/33 IHG were classified as such by methylation arrays; 6 further cases could be annotated to the IHG group by UMAP plots. 18/33 cases (54.5 %) showed fusions of *ALK* to different partners; all occurred in the first year of life. Fusions of *ROS1* were found in 4, *MET* in 2, *NTRK1* and *-3* in 7 cases. 2 cases showed no fusions. The different methods for fusion detection led to comparable results. Only recurrent fusions with known fusion partners were detectable with Nanostring probes designed for the fusion sequence, and library construction for targeted RNA sequencing was not successful in a fraction of cases. Break-apart FISH led to reliable results on the next day, and MIP technology represented the most sensitive method for analysis of FFPE samples.

Conclusions: Gene fusions involving the tyrosine kinase genes *ALK, MET, ROS1* and *NTRK1* and *-3* occurred in 93 % of high grade hemispheric gliomas of infancy; the most frequent were *ALK* fusions occurring in children younger than 1 year. DNA-based MIP technology represented the most robust and sensitive assay. A combination of RNA- and DNA-based methods to detect these fusions with high reliability is recommended.

#2854 Delineating mediators of oncogenesis in *FOXR2*-expressing cancers.

J. W. Tsai[1], M. Coppola[1], P. Arounleut[2], J. B. Collins[3], P. Hart[4], H. Keshishian[4], D. T. W. Jones[5], P. Bandopadhayay[3], T. N. Phoenix[2];
[1]Children's Hospital Los Angeles, Los Angeles, CA, [2]University of Cincinnati, Cincinnati, OH, [3]Dana-Farber Cancer Institute, Boston, MA, [4]Broad Institute of MIT and Harvard, Cambridge, MA, [5]German Cancer Research Center, Heidelberg, Germany

Background: Pediatric brain tumors are associated with the highest rates of morbidity and mortality of all childhood cancers. Diffuse midline gliomas (DMGs) are universally fatal pediatric tumors with a median survival of less than one year. DMGs are thought to arise from stalled developmental programs in the context of histone mutations (*H3* K27M) which are thought to be a critical initiating event. However, these histone mutations alone are insufficient for gliomagenesis and cooperate with other alterations, including mutations in the *TP53* pathway (TP53, PPM1D), growth factor receptor pathway activation (PDGFRA, EGFR, PIK3CA), and MYC amplifications (MYC, MYC-N) to induce tumor formation. There is a high degree of genetic heterogeneity amongst DMGs, and other alterations are also critical to DMG pathogenesis. This work is focused on Forkhead Box R2 (FOXR2), a forkhead family TF that we have found to be aberrantly expressed in many cancers, including DMGs. Expression of FOXR2 is sufficient to enhance glioma formation, and we have shown that regulation of FOXR2 occurs through a previously unrecognized epigenetic mechanism. Expression of FOXR2 is regulated by novel promoters, and we have demonstrated that these promoters are necessary for FOXR2 expression in several cancer lineages using CRISPR interference technology, including DMGs, melanoma, neuroblastoma, and non-small cell lung cancers.
Methods: We applied an integrative approach using transcriptomics, epigenetics, proteomics, *in vitro* cancer models, and *in vivo* mouse models to systematically evaluate how FOXR2 mediates gliomagenesis.
Results: We have found that FOXR2 is activated across multiple cancer lineages, including DMGs. FOXR2 is required for proliferation *in vitro*, and it is sufficient to enhance gliomagenesis using an *in utero* electroporation *in vivo* mouse model. FOXR2 enhances MYC protein stability, even in the presence of cycloheximide. However, FOXR2 also exerts its oncogenic effects through MYC independent functions. FOXR2 is highly enriched at E26-transformation (ETS) motifs and specifically activates ETS transcriptional gene sets. To determine protein-protein interactions of FOXR2, we have performed immunoprecipitation and mass spectrometry to identify FOXR2 protein interactors. Moreover, we have performed both proteomic and phospho-proteomic analyses of *FOXR2*-expressing human neural stem cells. These proteomic studies have allowed us to identify proteins and phospho-sites that are highly enriched in FOXR2-expressing cells, and that could be potential therapeutic targets in FOXR2-expressing cancers.
Conclusion: Taken together, this study elucidates how FOXR2 protein interactors mediate oncogenesis in FOXR2-expressing diffuse midline gliomas. These studies proposed here have broad applicability across a range of cancers as FOXR2 is aberrantly expressed in 8% of all cancers.

#2855 ETS1, a target gene of the EWSR1::FLI1 fusion oncoprotein, regulates the expression of the focal adhesion protein TENSIN3.

V. J. Ebegboni, T. L. Jones, T. Brownmiller, E. Pehrsson, P. Zhao, S. Sundara Rajan, N. J. Caplen;
National Cancer Institute, Bethesda, MD

Ewing sarcoma (EWS) is an aggressive bone and soft tissue tumor that affects children and young adults. Ewing sarcomas harbor few mutations beyond the chromosomal translocation that initiates disease, and the mechanistic basis for the metastasis of these tumors remains poorly understood. The epigenome of EWS cells reflects the regulatory state of genes associated with the DNA binding activity of the fusion oncoproteins EWSR1::FLI1 or EWSR1::ERG. In this study, we examined the EWSR1::FLI1/ERG's repression of transcription factor genes, particularly those encoding transcriptional regulators of cell differentiation. To examine EWSR1::FLI1/ERG's regulation of gene expression, we assayed DNA binding using ChIP-seq or CUT&RUN, RNA using RNA-sequencing (RNA-seq) or qRT-PCR, and protein using immunoblotting or immunofluorescence. We depleted the expression of EWSR1::FLI1/ERG proteins using RNAi and overexpressed ETS1 using a full-length cDNA or CRISPR activation.RNA-seq analysis of control and *EWSR1::FLI1*-silenced TC-32, TC-71, and A673 EWS cells identified 67 genes encoding proteins with DNA binding activity that exhibited significant increases in expression following depletion of EWSR1::FLI1. Comparison of the expression of these 67 transcription factor genes in EWS cell lines (n=41) and tumors (n=79) showed 37 expressed at a wider range in tumors relative to cell lines ($p < 0.01$). This more variable expression in EWS tumors suggests that one or more of these transcription factors could exert a phenotypic effect. Focusing on one of the EWSR1::FLI1-repressed target genes, *ETS1*, we detected EWSR1::FLI1 binding and an H3K27me3 repressive mark at this locus. Depletion of EWSR1::FLI1 results in ETS1's binding of promoter regions. Analysis of EWS cells in which we profiled ETS1 binding and assessed the effects of ectopically expressed ETS1 defined 265 genes as positively regulated by ETS1 of which 103 also exhibited an increase in expression following depletion of EWSR1::FLI1. Of these 103 genes, we focused on ETS1's regulation of TNS3, as assessment of multiple EWS tumor expression profiles, showed positive correlation of *ETS1* and *TNS3* expression. *TNS3* encodes TENSIN3, a focal adhesion protein that regulates cytoskeletal reorganization and contributes to cell migration by connecting the cytoplasmic tail of integrins to the actin cytoskeleton. EWS cell lines (SK-N-MC (*EWSR1::FLI1*) and ES-5838 (*EWSR1::ERG*), in which we activated *ETS1* expression (CRISPRa) exhibited a migratory phenotype and increased TNS3 expression. Critically, the activated ETS1 EWS cell lines show TNS3 accumulation at leading cell edges, with F-actin cytoskeletal reorganization, a phenotype associated with cell migration. Our study demonstrates that EWS cells expressing ETS1 exhibit a more migratory phenotype, which, has the potential to promote the dissemination of cells and, thus, metastasis.

#2856 Multi-omics approaches for biomarker discovery and target therapy in pediatric germ cell tumors.

A. Souza Peres[1], I. Vieira Cardoso[1], J. Soares Galvao[1], A. Santarosa Vieira[1], M. Nunes Rosa[1], I. Tosi[1], D. Antunes Moreno[1], A. Laus[1], A. van Helvoort Lengert[1], S. Aparecida Teixeira[1], A. Feijo Evangelista[1], R. Manuel Reis[2], L. Lopes[3], **M. Tomazini Pinto**[1];

[1]Barretos Cancer Hospital, Barretos, Brazil, [2]University of Minho, Braga, Portugal, [3]Barretos Children's Cancer Hospital, Barretos, Brazil

Pediatric germ cell tumors (GCT) are rare and heterogeneous, presenting various histologies. There are no specific markers for diagnosing GCT, and 30% of patients are resistant to standard cisplatin-based chemotherapy, which can be related to epithelial-mesenchymal transition (EMT). Therefore, this study aims to elucidate markers for classifying GCTs, evaluate the molecular mechanisms related to drug resistance, and search for new therapeutic approaches. The expression of miRNAs was assessed for 42 GCT-pediatric patients through miRNA Panel - Nanostring technology. Whole Exome Sequencing (WES) was performed for 16 GCT-pediatric patients to assess somatic mutations. *In silico* analysis of epithelial-mesenchymal transition (EMT) markers was performed using the cBioPortal database. The expression of EMT markers was evaluated *in vitro* in parental and cisplatin-resistant models (NTERA-2R). Xenograft model-derived NTERA-2R was established and EMT markers were also assessed. We identified specific miRNA expression signatures for each histology, including 34 miRNAs for dysgerminomas, 13 for embryonal carcinomas, 25 for yolk sac tumors, and one for immature teratoma. We identified 26 miRNAs that were commonly expressed in malignant tumors, with six miRNAs (miR-302a-3p, miR-302b-3p, miR-371a-5p, miR-372-3p, miR-373-3p, miR-367-3p) showing significant overexpression. MiR-302b-3p had a significant association with all the evaluated clinical features. WES analysis showed that Single Base Substitution signature 39 was observed in 68.75% of samples and SBS22 in 12.5%. Copy number alterations were identified in 4, 7, 8, 10, 12, 21, and 22 chromosomes, with amplification of *CDKN1B*, *KRAS*, *CCND2*, *ETV6*, and *KDM5A* genes and deletions of *KIT* and *PTEN* genes. Somatic mutations in *NYAP2, RHBDF2*, *MTOR*, *KIT*, *ATM*, *KRAS*, and *PIK3CA* were frequent among the samples. *KIT* (Asp816Val, Ala829Pro) and *KRAS* (Gln61Leu) mutations were classified with potential clinical significance and were validated. *In silico* analysis showed that different histologies had distinct expression profiles for EMT markers. Patients with $SNAIL^{low}SLUG^{low}$ expression had higher PFS than those with $SNAIL^{high}SLUG^{high}$ (p=0.006). The median PFS of patients with $SLUG^{low}$ was 46.4 months, while $SLUG^{high}$ was 28.0 months (p=0.022). *In vitro* analysis using NTERA-2R showed overexpression of EMT markers. The same result was obtained in the xenograft model derived from NTERA-2R. Our study offers vital insights into pediatric GCTs' molecular landscape, using *in silico*, *in vitro*, *in vivo* analyses, and genetic assessments, highlighting three points: 1) The miRNA signatures for each histology may have robust diagnostic and prognostic potential, besides clinical implications as biomarkers. 2) *KIT* and *KRAS* genes are possible therapeutic targets of pediatric GCTs. 3) EMT is related to cisplatin resistance and SLUG is a potential molecular target.

#2857 Perspectives from a systematic review of kinase fusion oncogenes and access to corresponding kinase inhibitor clinical trials in pediatric, adolescent, and young adult solid malignancies.

L. Lazo de la Vega[1], S. K. Eder[2], E. Sukharevsky[1], Z. A. Kahn[1], M. O'Connell[1], F. Wachter[1], E. P. Anderson[3], M. C. Trissal[1], J. J. LaBelle[1], K. Carpenter[4], L. Kager[2], M. G. Filbin[1], K. A. Janeway[1];

[1]Dana-Farber Cancer Institute, Boston, MA, [2]St. Anna Children's Cancer Research Institute, Vienna, Austria, [3]Massachusetts General Hospital, Boston, MA, [4]Boston Children's Hospital, Boston, MA

Oncogenic kinase fusions (KFs) have been reported in pediatric, adolescent, and young adult (P-AYA) brain tumors, sarcomas, and rare solid malignancies. Molecularly targeted therapy (MTT) matched to KFs generally produce objective responses even in advanced P-AYA malignancies. KFs occur across a broad age range of P-AYA cancer diagnoses (dx) so data on KF prevalence and the relationship between KFs and clinical characteristics including response and resistance to MTT is distributed across many studies. To address resulting knowledge gaps, we conducted a systematic review of KFs reported in P-AYA cancers and assessed the availability of clinical trials (CTs) for P-AYA patients with KF malignancies. A systematic literature search was conducted with PubMed using publication date 2013-2022, search terms for dx, age, and gene names of interest (BRAF, RAF1, NTRK1-3, ALK, FGFR1-4, MET, RET, ROS1). Known P-AYA cancer sequencing studies were also reviewed. Papers were included if they reported ≥1 patient <18 yo with a KF cancer of any type or ≤30 yo with a KF P-AYA cancer dx. Data abstracted included paper type, KF gene and partner, dx, fusion breakpoints, age, stage, MTT received, response to MTT, and CT enrollment. Clinicaltrials.gov was queried for interventional CTs in the U.S. assessing relevant MTTs. We identified 531 studies (299 case reports/series; 119 P-AYA sequencing studies) reporting 4,329 patients with a KF P-AYA solid tumor. Brain tumors had, in decreasing order of frequency, BRAF, NTRK, FGFR, ALK, ROS1, RAF1, MET, and RET fusions. Dx in which KFs were reported were LGG (n=2451), HGG (n=298), embryonal tumors (n=16), ependymomas (n=8), meningioma (n=1), and other (n=16). Extracranial solid tumors (EST) had, in decreasing order of frequency, NTRK, RET, ALK, BRAF, ROS1, MET, FGFR, and RAF1 fusions. Dx in which KFs were reported were thyroid cancer (n=607), sarcoma (n=546), melanoma and spitz tumor (n=183), renal tumor (n=90), carcinoma (n=57), rhabdomyosarcoma (n=12), neuroblastoma (n=11), osteosarcoma (n=9), and other (n=24). As of Aug 23, 2023, 476 CTs were assessing 65 inhibitors relevant for these KFs, of which only 20 are currently FDA-approved. Patients <18 yo were only eligible for 16% of CTs. RET (47%), RAF/BRAF (33%), and NTRK (32%) inhibitors had the highest percent of CTs enrolling patients <18 yo while ERK (4%) and FGFR (6%) inhibitors had the least. Notably, while 467 P-AYA patients identified in our review were <18 yo and had an ALK- or ROS1-fusion positive tumor, only 24% of ALK or ROS1 inhibitor CTs allowed enrollment of patients <18 yo. To our knowledge, this is the first systematic review of KFs in P-AYA solid tumors. Oncogenic KFs are common and occur across P-AYA solid and brain tumor dx demonstrating a need for CTs of relevant MTTs including patients <18 yo, particularly for drugs targeting ALK, ROS1, and FGFR.

#2858 Phenotypic screens identify genetic regulators of nanoparticle delivery to pediatric brain tumors.

M. Coppola[1], J. Kenny-Serrano[2], J. G. Doench[3], P. Hammond[4], P. Bandopadhayay[2], J. W. Tsai[1], J. Straehla[5];
[1]Children's Hospital Los Angeles, Los Angeles, CA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Broad Institute of MIT and Harvard, Cambridge, MA, [4]Massachusetts Institute of Technology, Cambridge, MA, [5]Koch Institute for Integrative Cancer Research, Cambridge, MA

Pediatric central nervous system tumors are the leading cause of cancer death in children. Diffuse midline glioma (DMG) is a universally fatal pediatric brain tumor and despite many clinical trials over the past decades, less than 10% of patients are long-term survivors. The clinical standard of care is radiotherapy, however it only provides limited symptom relief. There is a clear need to develop creative treatment strategies for patients with DMG. Nanomedicine has the potential to address this challenge, allowing the encapsulation of difficult to deliver therapeutic cargoes, and selectively targeting them to tumors while crossing innate biological barriers. However, a deep understanding of disease-specific nano-bio interactions is crucial to leverage the full potential of these therapies.
To functionally validate the role of candidate biomarkers in nanoparticle delivery to DMGs, we performed pooled genetic perturbation screens using a flow based phenotypic output. We developed a lentiviral all-in-one CRISPR/Cas9 knock-out library paired with fluorescence-activated cell sorting to probe the functional impact of 700 genes on the delivery of nanoparticles to DMG. Layer-by-layer electrostatic assembly was used to generate liposomal nanoparticles with a polymer surface coating of hyaluronic acid. Two patient-derived neurosphere models of DMG were transduced with the pooled all-in-one CRISPR/Cas9 library. Following antibiotic selection, cells were incubated with hyaluronic acid or polymeric nanoparticles for 4 or 24 hours and sorted into populations based on nanoparticle affinity. A dynamic cell-sorting strategy was optimized to separate cells infected with inert DNA barcodes based on their degree of nanoparticle-association. DNA was isolated from sorted cells and subjected to next generation sequencing. The enrichment of each single guide was determined relative to matched controls. We found strong agreement between biologic replicates, and determined which genes, when knocked down, shifted nanoparticle uptake into DMG cells.
Our pooled phenotypic screen revealed strong biologic regulators of nanoparticle uptake. These can be categorized as formulation dependent and independent, as well as time-dependent. We identified several negative regulators of nanoparticle uptake including members of the mitogen-activated protein kinase (MAPK) and mammalian target of rapamycin (mTOR) pathways. The top target genes are currently being validated in DMG and human neural stem cell models. In ongoing work, we are leveraging genetic and chemical inhibition to sensitize DMG cells to nanoparticle therapeutics. We plan to leverage our screening technique to develop novel combination therapy approaches that could be implemented across multiple administration routes (intravenous, intraventricular, or intratumoral) to enhance the use of nanomedicine for DMG and other pediatric brain tumors.

#2859 The Single-cell Pediatric Cancer Atlas: Open-source data and tools for single-cell transcriptomics of pediatric tumors.

A. G. Hawkins[1], J. A. Shapiro[1], S. J. Spielman[1], D. S. Mejia[1], D. Venkatesh Prasad[1], N. Ichihara[1], A. Yakovets[1], K. G. Wheeler[2], C. J. Bethell[3], S. M. Foltz[4], J. O'Malley[1], C. S. Greene[5], J. N. Taroni[1];

[1]Alex's Lemonade Stand Foundation, Bala Cynwyd, PA, [2]Reify Health, Boston, MA, [3]UTHealth Houston Graduate School of Biomedical Sciences, Houston, TX, [4]Children's Hospital of Philadelphia, Philadelphia, PA, [5]University of Colorado Anschutz Medical Campus, Aurora, CO

The Single-cell Pediatric Cancer Atlas (ScPCA) Portal (https://scpca.alexslemonade.org/), developed and maintained by the Childhood Cancer Data Lab, is an open-source data resource for single-cell and single-nuclei RNA sequencing data of pediatric tumors. Originally comprised of data from 10 projects funded by Alex's Lemonade Stand Foundation, the Portal currently contains summarized gene expression data for over 500 samples from a diverse set of over 50 types of cancers and is growing to include community-contributed datasets. In addition to gene expression data from single-cell and single-nuclei RNA sequencing, the Portal holds data obtained from bulk RNA sequencing, spatial transcriptomics, and feature barcoding methods, such as CITE-seq and cell hashing.

ScPCA data are available for download in formats ready for downstream analysis, such as SingleCellExperiment or AnnData objects. Objects include raw counts and normalized gene expression data, PCA and UMAP coordinates, unsupervised clustering assignments, and cell type annotations. Additionally, all downloads include two summary reports for each library. The quality control report is a general overview, including processing information, summary statistics, and general visualizations of cell metrics. The cell type annotation report includes an overview of cell type annotation, comparisons among cell type annotation methods, and diagnostic plots to assess annotation quality. Comprehensive documentation about data processing and the contents of files on the portal, including a guide to getting started working with an ScPCA dataset, can be found at scpca.readthedocs.io.

All data on the Portal were uniformly processed using scpca-nf, a Nextflow-based open-source pipeline developed by the Childhood Cancer Data Lab. The scpca-nf workflow uses alevin-fry for fast and efficient processing of all data currently available on the portal, including single-cell RNA-seq data and any associated CITE-seq or cell hash data, spatial transcriptomics data, and bulk RNA sequencing. The workflow and associated documentation are freely available at https://github.com/AlexsLemonade/scpca-nf, allowing researchers to leverage this pipeline for their own datasets.

Providing an open-source workflow has allowed researchers to process their own single-cell or single-nuclei datasets for their own research. Furthermore, any data sets processed with scpca-nf are then eligible for inclusion on the ScPCA Portal. The continuous growth of the ScPCA Portal will help pediatric cancer researchers spend less time finding and processing data and more time answering their pressing research questions.

#2860 High-resolution mapping of oncogenic structural changes in osteosarcoma.

A. S. Clugston[1], S. Leung[1], E. Fuentes[1], L. Sayles[1], M. Ostrowski[2], C. Wu[2], C. Curtis[3], Z. Ma[4], Y. Zhao[3], G. K. Marinov[3], V. Ramani[2], M. Breese[1], A. Sweet-Cordero[1];

[1]UCSF - University of California San Francisco, San Francisco, CA, [2]Gladstone Institute for Data Science & Biotechnology, San Francisco, CA, [3]Stanford University School of Medicine, Stanford, CA, [4]Stanford Cancer Institute, Stanford, CA

We have leveraged long-read and spatial sequencing modalities to identify cancer-specific oncogenic alterations for treatment of osteosarcomas. Osteosarcoma is archetypal of cancers driven by aneuploidy and structural rearrangement rather than point mutations. The functional consequences of many SVs stem from their effect on multidimensional genome organization. SVs can enable enhancer hijacking, alter boundaries of topologically associated domains (TADs), and move gene loci to different regulatory compartments to affect gene expression. SVs can also lead to the formation of extrachromosomal DNA amplicons (ecDNA), which can be megabases in size and can incorporate both genes and regulatory elements to result in substantial increases in gene transcription and intratumor heterogeneity. Complex SVs may have profound implications for prognosis and treatment in OS and other cancers yet they remain poorly understood. By incorporating long-read optical genome mapping (OGM) and chromatin conformation capture sequencing (HiC), we studied SVs in osteosarcoma with the goal of elucidating their contribution to cancer development.

We used a unique panel of 11 OS patient-derived xenograft (PDX) cell lines which have been previously characterized regarding response to targeted therapies as well as genomically via whole genome (WGS), RNA (RNA-seq), and chromatin accessibility (ATAC-seq) sequencing. To understand the complex genomic reorganization that occurs in osteosarcoma, we integrated OGM and WGS data for all 11 cell lines to describe detailed genome-wide SVs including ecDNA formation. PDX lines assayed using OGM exhibited between 106 and 704 translocations each (versus zero detected in germline controls) and we identified dozens of potential ecDNA amplicons, including one amplicon which may explain exceptionally high expression of YAP1 and BIRC3 transcripts. Further, we used HiC to describe the topological environment resulting from these SVs and observed potential enhancer hijacking events affecting dozens of known oncogenes including MYC and CDK4. HiC interaction maps among six cell lines reveal genomic compartments and TAD boundaries in detail, with 4,167 unique TAD boundaries identified among six cell lines using 50kb genomic bins. Despite the observed complexity of these genomes, we note that 71% of TAD boundaries are consistent in at least four of the six HiC assayed cell lines, and 44% are present in all six lines. Changing TAD boundaries are associated with numerous SVs and/or copy number discrepancies, and are associated with genomic regions that contain genes with dysregulated RNA transcript levels. Overall, OGM and HiC modalities add considerably to our ability to detect oncogenic SVs and the genes they affect.

#2861 Rhabdomyosarcoma fusion-oncogene alters the chromatin landscape to initially drive a neural signature *in vivo*.

J. Kucinski, C. Taslim, A. Tallan, M. Cannon, K. Silvius, B. Stanton, G. Kendall;
Nationwide Children's Hospital, Columbus, OH

Fusion-positive rhabdomyosarcoma is an aggressive pediatric cancer lacking curative therapies, and outcomes for children with this disease have not improved in decades. The chimeric transcription factor PAX3::FOXO1 is the most common and lethal driver of fusion-positive rhabdomyosarcoma, and it consists of the DNA binding domains of PAX3 fused to the transactivation domain of FOXO1. Despite its well-established essentiality for tumorigenesis, how PAX3::FOXO1 initially generates a tumorigenic cell state has been challenging to study due to the lack of in vivo models expressing the fusion-oncogene at accessible early developmental time points. Here, we developed a novel zebrafish mRNA injection model that ubiquitously expresses PAX3::FOXO1 during gastrulation representing all three germ layers. Using this high-throughput model, we used ChIP-seq to identify initial in vivo PAX3::FOXO1 binding sites and targets. PAX3::FOXO1 has pioneering activity, where it can utilize partial-motif recognition to bind to inaccessible chromatin and alter chromatin structure. With biochemical and 2D chromatin sequencing approaches in our model, we find evidence for in vivo PAX3::FOXO1 pioneering activity. PAX3::FOXO1 consists of two DNA binding domains, a paired and homeobox domain, and we demonstrate a new mode of pioneering activity driven by its homeobox domain given a strong enrichment of homeobox-related motifs at PAX3::FOXO1 binding sites. PAX3::FOXO1 activity in developing zebrafish embryos results in an arrested development phenotype and transcriptional signatures enriched for pathways such as an inhibition of segmentation and myogenic development. Critically, we find that PAX3::FOXO1 directly activates neural-related gene targets by increasing chromatin accessibility and re-distribution of the active histone mark H3K27Ac to these loci. These discoveries are particularly striking because rhabdomyosarcoma is traditionally associated with skeletal muscle characteristics. With our findings, we hypothesize neural gene activation is a critical mechanism for fusion-positive rhabdomyosarcoma tumor initiation and could be a critical pathway across various stages of rhabdomyosarcoma tumorigenesis. This hypothesis agrees with our previous discovery of a novel PAX3::FOXO1 cooperating neural transcription factor, HES3, which we find is directly activated by PAX3::FOXO1 in our mRNA injection model. Our long-term goal is to utilize this versatile model to functionally evaluate cooperation between PAX3::FOXO1 and both canonical rhabdomyosarcoma and neural transcription factors. Our approach will employ a cross-species comparative analysis across this injection model, our zebrafish tumor models, other model systems, and patient data. This work will identify conserved targets and mechanisms of PAX3::FOXO1 tumorigenesis that could become new therapeutic vulnerabilities.

#2862 Evolution of clinically relevant variants in advanced pediatric sarcomas.

H. Y. Comeau[1], L. Lazo De La Vega[1], A. J. Church[2], L. D. Maese[3], N. Pinto[4], M. E. Macy[5], M. A. Applebaum[6], A. J. Sabnis[7], A. Kim[8], S. I. Colace[9], F. Dela Cruz, Jr.[10], S. G. DuBois[1], N. B. Collins[1], K. A. Janeway[1];

[1]Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA, [2]Boston Children's Hospital, Boston, MA, [3]University of Utah/Primary Children's Hospital, Salt Lake City, UT, [4]University of Washington/Seattle Children's Hospital, Seattle, WA, [5]University of Colorado/Children's Hospital Colorado, Aurora, CO, [6]University of Chicago/Comer Children's Hospital, Chicago, IL, [7]University of California San Francisco/Benioff Children's Hospital, San Francisco, CA, [8]George Washington University/Children's National Hospital, Washington, DC, [9]The Ohio State University/Nationwide Children's Hospital, Columbus, OH, [10]Memorial Sloan Kettering Cancer Center, New York, NY

Objective Few pediatric sarcoma studies have investigated how gene alterations detected by targeted sequencing change in the same patient over time. We leveraged targeted somatic DNA next-generation sequencing (NGS) data from a large cohort of young patients with osteosarcoma (OS), Ewing sarcoma (EWS), or rhabdomyosarcoma (RMS) to identify changes in known oncogenic variants with the aim of addressing the clinical utility of resequencing at recurrence.
Methods The iCat2/GAIN Consortium Study is a cohort study involving 13 US institutions evaluating outcomes after receipt of matched targeted therapy (MTT) in young patients with advanced extra-cranial solid tumors. Tumors are sequenced using OncoPanel, a targeted DNA NGS test performed in a CLIA/CAP certified laboratory assessing single nucleotide variants (SNV), copy number variants (CNV) and structural variants (SV) in up to 447 cancer genes and rearrangements in up to 60 cancer genes. In 2 cases, similar targeted NGS tests were performed. For OS, EWS, or RMS patients with at least 2 OncoPanels from different timepoints (initial diagnosis or relapse) and/or tumor sites (metastatic or primary), we assessed oncogenic variants in genes previously known to be recurrently altered in the respective diagnosis. For each variant, we assigned patterns of change as emergence, disappearance, or persistence.
Results Of 784 iCat2/GAIN patients, there were 157, 107, and 100 patients with OS, EWS, and RMS respectively. The analytic cohort consisted of 34, 20, and 15 OS, EWS, and RMS patients respectively with at least 2 tumor sequenced samples. The median number of sequenced samples per patient was 2 (range 2 to 6). In EWS, 9 (45%) patients had an oncogenic variant (other than an expected fusion) in at least one sample. In 4 patients, the predominant pattern of change was emergence. Specifically, a new pathogenic SNV in STAG2 (N=1) or TP53 (N=3) were observed. In OS, all 34 patients had an oncogenic variant in at least one sample. In RMS, 12 (80%) patients had an oncogenic variant in at least one sample. There was no predominant pattern of change in OS and RMS. In OS, 41% percent of variants persisted in all samples; 32% of variants disappeared in subsequent samples; 22% of variants emerged in subsequent samples; 5% of variants were variably present over time. Interestingly, while TP53 was most often persistent over time, there were also 7 cases with emergence of TP53 variants and 8 cases with disappearance of TP53 variants. In RMS, 26% percent of variants persisted in all samples; 31% of variants disappeared in subsequent samples; 43% of variants emerged in subsequent samples. Interestingly, in three cases there was emergence of a new variant activating the RAF/MAPK or AKT pathway.
Conclusion Pediatric sarcomas display a range of genomic changes over time. Given the observed changes in oncogenic alterations, there may be utility to repeat sequencing of relapsed tumor biopsies to understand these changes.

#2863 *CDKN1A* prevents IR-induced apoptosis in rhabdomyosarcoma tumor via repressing the pro-apoptotic factor NOXA in a novel apoptotic regulatory axis.

P. S. Modi, M. Ignatius, L. Wang, P. Sreenivas;
UTHSA, San Antonio, TX

Rhabdomyosarcoma (RMS) is a tumor of the muscle and is the most common soft tissue cancer in children and teens, with approximately 400 to 500 new cases every year in the United States. While we have a good understanding of the interplay between pro- and anti-apoptotic regulators, much remains to be learned about how the decision to trigger apoptosis or not is controlled at the transcriptional level in RMS tumors. We strive to elucidate how pathways that drive apoptosis avoidance are epi-genetically pre-programmed in cells. We have discovered that SNAI2, a transcriptional repressor, acts as a master switch to either activate or dampen apoptosis in response to ionizing radiation (IR). While elevated SNAI2 results in transcriptional repression of the pro-apoptotic factor *BIM* and protection from apoptosis post-IR, a small number of SNAI2 null cells survive radiation to reproliferate in vivo, revealing the existence of hitherto unappreciated mechanisms that support the survival of irradiated cells. Hence, we hypothesized that there are additional genes or pathways in cells lacking SNAI2 that are co-opted to drive relapse disease. We have identified that CDKN1A or p21 expression is robustly increased in SNAI2 null cells. *CDKN1A* is thought to be a tumor suppressor. However, our preliminary data indicate that *CDKN1A* is an oncogene, and in RMS patients, high tumor expression is associated with poor outcomes. We found that *CDKN1A* expression in combination with SNAI2 can predict resistance to radiation across RMS cell lines. We next developed control RD, Rh30, and Rh18 cells, either *CDKN1A* or both *CDKN1A* and *SNAI2* ablated using CRISPR/Cas9 reagents with control cells expressing control gRNAs. Ablation of *CDKN1A*, while not affecting proliferation, led to a significant increase in apoptosis post-radiation, and this effect was increased in *SNAI2/CDKN1A* double knockout cells. Further, in colony-forming assays, we find that double-ablated cells form significantly fewer colonies than control and single knockout cells. Loss of *CDKN1A, SNAI2, or CDKN1A/SNAI2* led to a G2/M cell cycle block, indicating that the cell cycle effects of p21 might not be responsible for the phenotypes observed. Ongoing xenograft experiments have determined the effect we observe *in vitro* will also translate *in vivo*. Given that SNAI2 and *CDKN1A* are heterogeneously expressed, respectively, we will interrogate CDKN1A for its role in protecting differentiated cells from apoptosis. We will determine if *CDKN1A* prevents apoptosis by repressing the pro-apoptotic factor NOXA in a novel apoptotic regulatory axis specific to differentiated cells. Our study will show that critical primary and alternative apoptosis resistance mechanisms are epi-genetically pre-programmed in cells by SNAI2.

#2864 Transcriptional repressor REST controls autophagy in Sonic Hedgehog medulloblastoma through the VHL-HIF1α axis..

A. Singh, D. Cheng, J. Swaminathan, Y. Zheng, N. Gordon, V. Gopalakrishnan;
UT MD Anderson Cancer Center, Houston, TX

Introduction: Medulloblastoma (MB) is the most common malignant brain tumor in children. It is categorized into four molecular subgroups, each with unique genetic and epigenetic alterations, molecular signatures, and differences in clinical features and treatment responses. Targeted therapy for MB has failed in the clinic, prompting new studies of mechanisms involved in MB tumorigenesis and progression.
Experimental Procedure: The transcriptomic information of the MB patients was obtained from the publicly available RNAseq datasets and was analyzed for differential expression and clustering analysis. Patient-derived orthotopic xenografts of medulloblastoma tumors with high- and low-REST expression were histologically and biochemically studied for autophagy markers. Furthermore, the SHH-MB cell lines were studied to get a mechanistic understanding of the REST-driven autophagy in this MB subgroup.
Summary: Our data showed that autophagy, a process responsible for cellular recycling, and genes associated with this pathway exhibit distinctive expression patterns in human MB subgroups. Specifically, we demonstrate that autophagy is induced in one of the MB subgroups (Sonic Hedgehog-SHH) in response to elevated expression of the RE1-silencing transcription factor (REST), a transcriptional repressor and a canonical regulator of neuronal differentiation genes. REST is also a driver of SHH-MB metastasis. Pharmacological inhibition of autophagy decreases MB cell growth, suggesting it is a pro-survival pathway in REST-driven SHH MBs. In mechanistic studies, we found REST-dependent autophagy induction to involve upregulation of the hypoxia-inducible factor 1-alpha (HIF1α) due to REST-mediated silencing of the von Hippel-Lindau (VHL) gene. The VHL gene product promotes HIF1α ubiquitination and proteasomal degradation, and its loss in SHH-MBs with elevated REST expression drives HIF1α stabilization and nuclear localization to activate target autophagy-related genes.
Conclusion: Our work is the first to link VHL to MB pathology. VHL loss of function in cancers has been mainly attributed to mutational events. Here, we report a novel mechanism of VHL loss, namely its epigenetic silencing by REST. Our findings provide the foundation for future pre-clinical investigations to examine the feasibility of autophagy blockade as a therapeutic strategy for REST-driven SHH MBs.

#2865 Efficacy of MDM2 and epigenetic inhibitors treatments for neuroblastoma.

T. Momenah[1], U. Natarajan[2], S. Jaganathan[2], A. Rathinavelu[3];

[1]Nova Southeastern University, Barry & Judy Silverman College of Pharmacy, Fort Lauderdale, FL, [2]Nova Southeastern University,Barry & Judy Silverman College of Pharmacy, Fort Lauderdale, FL, [3]Nova Southeastern University,, Fort Lauderdale, FL

Pediatric Neuroblastoma (NB) is one of the most prevalent solid tumors in children that arise from embryonic neural crest cells and poses a significant challenge in the field of oncology. There are about 700 to 800 new cases of neuroblastoma diagnosed each year in the United States, and accounts for approximately 15% of all childhood cancer mortalities. Since this malignancy predominantly affects infants and young children, it is imperative to decipher the underlying molecular factors driving its pathogenesis. The novel molecular therapeutic approach includes the use of epigenetic modifiers as drugs. This approach aims to reverse significant epigenetic events underlying cancer pathogenesis, particularly abnormalities in histone modifications and DNA methylation. The reduction of both DNA and histone methylation levels leads to the reactivation of tumor suppressor genes and inhibits cancer cell proliferation and cell growth. In this study, we used selective and reversible small molecule agents such as MDM2 inhibitor (RG7388) and epigenetic modifiers (CM272 and SAHA) to block cell proliferation by inducing cell cycle arrest via enforcing Epigenetic alterations. Our initial experiments were designed to understand the effects of RG7388, CM272, and SAHA treatments on NB and their impact on cell cycle progression. It was hypothesized that the decrease in DNA methylation and increase in histone modification-augment p21 expression *via* the use of MDM2 inhibitors and epigenetic modifiers. To test this hypothesis, the NB cells (SK-N-SK and IMR-32) were treated with RG7388, CM272, and SAHA for 24 hours. The extent of Cell death was determined for NB cells by using the Trypan Blue Dye Exclusion (TBDE) method, and CellTiter-Glo® Luminescent Cell Viability Assay. Induction of apoptosis was determined by using the Immunofluorescence staining method with DEVD-*amc* substrate. The results of our study suggested that RG7388, CM272, and SAHA were able to induce cell death in the SK-N-SH cells following 24-hour treatment. Furthermore, we analyzed the levels of Tumor suppressor (p53), cell cycle arrest (p21, p27, AurkB, CDC25A, CyclinD) cell death (Bax, Bcl2, LC3, Beclin, PARP, Cleaved PARP, RIP1, RIP3, MLKL, p-AKT), and Epigenetic biomarker (DNMT1, DNMT3A, DNMT3B, acetyl histoneH3, H4, and H2b) protein expression levels using western blot analysis. The results showed significant elevation of p53, p21, p27, and acetylation of histone family biomarkers after treatment when compared with the control group. In summary, our results indicate that RG7388, CM272, and SAHA treatments can effectively induce cellular responses and prevent cell growth and progression by enforcing epigenetic changes in the NB cells. (This research was supported by the National Pediatric Cancer Foundation, Tampa, Florida, and the Royal Dames of Cancer Research Inc. of Ft. Lauderdale, Florida)

#2866 *NAPRT*silencing in rhabdomyosarcoma confers therapeutic vulnerabilities to NAD^+depletion.

S. J. Zhao[1], K. J. Noronha[1], P. Bhardwaj[1], K. N. Lucas[1], R. K. Sundaram[1], C. D. Heer[1], R. Morotti[1], J. Spurrier[2], M. Raponi[2], R. S. Bindra[1], **J. C. Vasquez**[1]; [1]Yale School of Medicine, New Haven, CT, [2]Alphina Therapeutics, New Haven, CT

Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma among children, and new treatments are needed to improve survival. Cells primarily synthesize nicotinamide adenine dinucleotide (NAD) through the Preiss-Handler and Salvage pathways driven by nicotinic acid phosphoribosyltransferase (NAPRT) and nicotinamide phosphoribosyltransferase (NAMPT), respectively. NAMPT inhibitors (NAMPTi) have been tested in clinical trials, but their efficacy has been limited by (a) lack of appropriate biomarkers for patient selection, and (b) significant dose-limiting toxicities (DLTs), including myelosuppression and retinal toxicity, although the latter has been described only in preclinical studies. Previous work from our group indicates that loss of NAPRT expression by tumor-specific promoter CpG island methylation may provide a novel biomarker for sensitivity to NAMPTi in a variety of tumors. Here, we sought to determine if RMS harbors NAPRT silencing that confers a synthetic lethal interaction with NAMPTi. We probed methylation data within the Cancer Dependency Map (DepMap) and found a high frequency of NAPRT gene promoter hypermethylation in RMS models. Predicted NAPRT silencing was confirmed at the protein level by western blot in a panel of RMS cell lines. In vitro growth delay assays demonstrated that NAPRT-silenced cells are exquisitely sensitive to NAMPTi even in the presence of nicotinic acid (NA) supplementation, while NAPRT-expressing cells were completely rescued. This sensitivity to NAMPTi was further mirrored by changes in NAD levels. In vivo, NAMPTi induced significant tumor regression in a NAPRT-silenced RMS xenograft model. To further establish the translational relevance, NAPRT protein expression in a TMA of 51 human RMS tumors was assessed via IHC staining using a newly validated NAPRT monoclonal antibody (4A5D7). Based on a semi-quantitative scoring system accounting for the percentage of positive tumor cells and staining intensity, 28% of RMS samples demonstrated loss of NAPRT protein expression. Overall, these data suggest that NAPRT loss may serve as a therapeutic target in RMS by inducing a synthetic lethal interaction with NAD^+ depleting agents. Future studies in patient-derived xenograft (PDX) models will determine the optimal cut-off of NAPRT expression that portends NAMPTi sensitivity, paving the way for the development of biomarker-driven clinical trials in RMS. Ongoing studies will also evaluate the efficacy of combining NAMPTi with existing cytotoxic and DNA damaging chemotherapy in these difficult-to-treat tumors.

TUMOR BIOLOGY: Radiation Science

#2870 Analysis of cancer cells response to radiotherapy activated NBTXR3 nanoparticles.
J. Da Silva, C. Bienassis, **S. Paris**;
Nanobiotix, Paris, France

In 2011, NBTXR3 emerged as the first-in-class radioenhancer used in clinical practice for treating patients with locally advanced soft tissue sarcoma (LA-STS). NBTXR3 became the first radioenhancer to receive CE mark approval after successfully completing a phase II/III clinical study for LA-STS with a doubling of the pCR rate in the NBTXR3 arm compared with the control arm. NBTXR3 nanoparticles consist of a functionalized core of hafnium oxide, a high atomic number element, specifically designed to amplify the effects of radiotherapy (RT) within cells without additional side effects on healthy tissues. Leveraging this physical mechanism, RT-activated NBTXR3 (NBTXR3+RT) has demonstrated superior efficacy in destroying tumor cells and controlling tumor growth in numerous preclinical models and in human, surpassing the effects of RT alone, while maintaining a favorable safety profile. Preclinical studies have revealed that the benefits of NBTXR3 extend beyond mere radioenhancement and improved cancer cell destruction. Specifically, NBTXR3 has been reported to possess immunomodulatory properties through 1) improved induction of DNA damage, leading to better activation of the cGAS-STING pathway, 2) promotion of immunogenic cell death, 3) enhancement of immunopeptidome presentation, 4) generation of an antitumor immune response leading to the production of an abscopal effect mediated by CD8+ cytotoxic lymphocytes. Notably, a series of recent studies using a two-tumor mouse model of anti-PD1-resistant lung cancer that the addition of NBTXR3 significantly improved the efficacy of various treatment regimens (RT+anti-PD1 and combinations with other check-point inhibitors) in terms of tumor growth, abscopal effect, and survival. It has been demonstrated that same benefits can be achieved when NBTXR3 was combined with proton therapy. Moreover, all these studies (X-ray and proton) reported a robust activation of the antitumor immune response, restoration of the effectiveness of anti-PD1 therapy, and the induction of memory response in cured mice. However, our understanding of the biological events leading to these effects remains limited. To address this question, we conducted a series of in vitro studies that employed cytometry, microscopy, and RNA sequencing on various cancer models, both human and murine. We reported that NBTXR3 nanoparticles primarily accumulate within lysosomes following their uptake by tumor cells, leading to the activation of genes associated with the biogenesis, structure, and contents of these organelles. Upon activation by RT, NBTXR3 within lysosomes induces lysosomal membrane permeabilization (LMP), resulting in an increase in lipid peroxidation, inducing regulation of fatty acid oxidation genes, and impacting mitochondrial genes expression, such as respirasome. These findings provide a deeper insight into the early biological effects of NBTXR3+RT in comparison to RT alone.

#2871 Co-targeting asparagine and glutamine metabolism is a viable treatment strategy for PI3K/PTEN mutated cervical cancer.

Nishanth Noel Gabriel, Naoshad Muhammad, Kevin Cho, Kay Jayachandran, Jin Zhang, Gary Patti, Julie Schwarz

Washington University in St. Louis, St. Louis, MO

Purpose Statement: Alterations in the PI3K/AKT signaling pathway are common in cervical cancer. The most commonly observed mutations are in *PIK3CA* (26%) and *PTEN* (8%). However, the biological and metabolic implications of acquiring these mutations in the cervical cancer genome are poorly characterized.
Materials/Methods: Isogenic cell lines with *PIK3CA E545K* and *PTEN* null mutations were generated using Crispr/CAS9. Cell viability and clonogenic cell survival assays were performed in the presence and absence of inhibitors of glutamine and asparagine metabolism. Glucose and glutamine metabolism was evaluated by stable isotope labeling with U13C glucose and13C5 glutamine in presence of glutamine antagonist DON. RNA-seq was employed to evaluate transcriptomic alterations.
Results: Introduction of the PIK3CA E545K mutation and PTEN mutation in cervical tumor cells leads to an increase in AKT signaling compared to the parental (wild-type) cells. Notably, RNASeq and mass spectrometric analysis of both the tumor cells and their culture media revealed heightened dependencies on glucose and glutamine in the tumor cells carrying the PIK3CA E545K and PTEN mutations as compared to the wild-type cells. Treatment with glutamine antagonists (DON, JHU-083) and GLS inhibitors (CB-839 and IACS-6274), resulted in reduced cell viability and clonogenic survival in tumor cells with PI3K/PTEN mutation compared to wild-type. Additionally, we observed a metabolic reliance on the amino acid asparagine in tumors with PI3K/PTEN alterations when treated with DON. Asparaginase in combination with DON effectively inhibited the proliferation of human and mouse cell lines derived from primary tumors with PTEN mutations. Furthermore, the incorporation of a glutamine antagonist and asparaginase into conventional chemoirradiation further enhanced the therapeutic efficacy in cervical tumors with PI3K/PTEN alterations which are otherwise treatment resistant.
Conclusions: Orthogonal evaluations using glutamine agonists, GLS inhibitors, and mass spectrometric point to a significant role played by *PI3K/PTEN* mutations in altering cervix tumor cell metabolism towards a more glutamine dependent phenotype. This study suggests a potential strategy for improving the treatment of PI3K-AKT-altered cervical tumors by targeting glutamine and asparagine metabolism in combination with standard therapies. These treatment strategies are currently being evaluated *in vivo* using a patient derived xenograft model with *PIK3CA E545K* mutation as well as an immunocompetent cervical tumor model in mice with *PTEN* deletion.

#2872 GLUT3 promotes metabolic plasticity that drives radiation resistance in glioblastoma.

L. Abdulrahman, J. Bailleul, H. Hoang, A. Tang, E. Vlashi;
UCLA - University of California Los Angeles, Los Angeles, CA

Glioblastomas (GBM) are the most common and malignant brain tumors in adults. While radiation therapy (RT) offers a significant advantage for GBM patients, improving long-term survival remains elusive largely due to the remarkable resistant nature of these tumors. We have shown that metabolic plasticity, especially rewiring of glucose metabolism, promotes radiation survival in GBM. In this study, we investigate the role of glucose transporter 3 (GLUT3) translocation to the cell surface in radiation resistance of GBM. The effect of radiation on GLUT3 total protein levels was determined in patient-derived gliomaspheres via westerns blots, while cellular localization of GLUT3 was determined via immunofluorescence, flow cytometry and cell fractionation assays. The role of the AMPK and αvβ3 integrin in the radiation-induced GLUT3 translocation to the cell membrane was probed via small molecule inhibitors and activators. To determine the role of GLUT3 in radiation survival, GLUT3 levels were knocked down via siRNA and shRNA, followed by functional *in vitro* and *in vivo* assays. We provide evidence that irradiated gliomaspheres translocate GLUT3 to the plasma membrane, in a radiation-induced oxidative stress-dependent manner, effectively increasing their glucose uptake and promoting radiation survival. Our data also suggest that GLUT3 translocation to the cell surface contributes to RT resistance. AMPK and αvβ3 integrin are linked to radiation-induced translocation of GLUT3 to the cell membrane, suggesting that targeting these pathways is a potential approach to sensitize GBM tumors to radiation therapy.

#2873 Radiation therapy promotes polyunsaturated fatty acid mediated ferroptosis in cervical cancer: Role of AMPK/xCT/GPX4 axis.

N. Muhammad, N. Gabriel, L. M. Bengtsson, T. McKinnish, N. Msengi, K. Cho, G. Patti, J. K. Schwarz;
Washington University School of Medicine in St. Louis, St. Louis, MO

Purpose: Previously, we found that mono-and di-unsaturated fatty acids can sensitize cervical cancer to radiotherapy (RT) through a p53 dependent apoptotic mechanism that is distinct from ferroptosis (Muhammad et al., *Cancer Res.* 2022; 82: 4515-27). Polyunsaturated fatty acids (PUFAs) enhance therapeutic response in preclinical tumor models by increasing lipid peroxidation (L-ROS) and induction of ferroptosis. Ferroptosis is a form of cell death that requires abundant cytosolic labile iron to promote membrane lipid peroxidation. The objective of the present study is to test whether the combination of RT + PUFAs promotes cell death via increased membrane lipid peroxidation and ferroptosis in cervical cancer, and to determine the impact of RT + PUFAs on cervix tumor cell metabolism and mitochondrial function.

Experimental Procedures: Cell viability and clonogenic cell survival assays were performed using 8 human cervical cancer cell lines including normal cervix epithelial controls incubated with PUFAs (EPA, DHA and AA), before and after RT. Western blotting, siRNA-mediated knockdown, pharmacologic inhibition and activation were performed to determine whether ferroptosis dependent signals were mediating PUFA-induced RT sensitivity. Oxidative stress parameters were quantified using mass spectrometry and fluorometric dyes. Flow cytometry was used to quantify total cell ROS, lipid ROS, mitochondrial ROS and labile iron pool. Mitochondrial morphology and function were characterized using microscopy and the Seahorse assay.

Summary: PUFAs + RT increased total ROS and LROS accumulation followed by a ferroptotic tumor cell death, which was iron-dependent and could be prevented by the addition of iron chelator and lipophilic antioxidants, Ferrostatin-1 and Liproxstatin-1. GPX4, a thiol dependent enzyme that eliminates lipid peroxides, and the cystine-glutamate antiporter (xCT) a key source of cystine for reduced glutathione (GSH) synthesis, were downregulated in response to PUFAs + RT. PUFAs + RT induced increased mitochondrial ROS and subsequent metabolic dysfunction. Mechanistically, the expression of AMPK, a key regulator of metabolic/energy homeostasis and mitochondrial biogenesis, was upregulated by PUFAs + RT. Pharmacological activation and inhibition of AMPK further enhanced and abrogated the effect of PUFA + RT, respectively.

Conclusions: PUFAs modify the RT sensitivity of cervical cancer cells by inducing cell death through ferroptosis and mitochondrial dysfunction via AMPK activation. In vivo experiments are ongoing in immunocompromised and immunodeficient mouse tumor models to confirm this finding and determine the impact of PUFAs on RT induced tumor cell death and anti-tumor immunity.

#2874 Cancer metabolism in radiation resistance: Complementary roles of O-GlcNAc transferase and PARP1.

E. E. Efimova, S. Averbek, D. J. Wolfgeher, D. Wu, Y. Liu, **S. J. Kron**;
University of Chicago, Chicago, IL

The efficacy of image-guided radiotherapy (RT) has been linked to directing increased chromosomal double strand breaks (DSBs) to tumor cells while sparing surrounding normal tissue. DSBs can block cell cycle progression and promote mitotic catastrophe, cell death and senescence. End processing of persistent DSBs releases single strand DNA (ssDNA), driving cGAS/STING signaling and anti-tumor immune response. DSB repair, whether by non-homologous end-joining (NHEJ) or homologous recombination (HR), is a resistance mechanism, supporting cell survival, repopulation and immune evasion. Decades of effort to block DSB repair to enhance benefits of RT has yet to produce approved agents. Toxicity due to lack of cancer specificity may prevent the current generation of targeted agents from reaching the clinic. An answer may come from examining cancer metabolic reprogramming as a determinant of intrinsic radiation resistance. Along with other glucose metabolites, the Warburg effect increases N-acetyl glucosamine (GlcNAc) biosynthesis, which not only supports N-glycosylation but also modification of nucleocytoplasmic proteins by O-GlcNAc transferase (OGT). OGT-dependent O-GlcNAcylation confers radiation resistance, in part by accelerating DSB repair. OGT regulates γH2AX, 53BP1 and BRCA1 foci kinetics and suppresses ssDNA formation at DSB ends, limiting HR but favoring NHEJ for S/G2 DSB repair. Blocking OGT induces radiation sensitization *in vitro* and *in vivo*. In cells, OGT inhibition results in hyperresection, persistent RPA and RAD51 foci and accumulation of cytosolic DNA. One mediator may be the histone methyltransferase EZH2, which is rapidly recruited to deposit H3K27me3 at DSBs, promoting NHEJ repair. Irradiation of EZH2 KO cells results in hyperresection that cannot be suppressed by O-GlcNAcylation. Cancer cells may also accumulate NAD+, a substrate for PARP1 incorporated into poly-ADP-ribose to initiate DSB repair. Much like OGT inhibition, blocking PARP1 induces hyperresection and shifts repair toward HR and away from NHEJ. Importantly, increasing O-GlcNAcylation can suppress ssDNA formation even in PARP1 KO cells. In turn, inhibiting PARP1 enhances hyperesection in EZH2 KO cells, leading to a marked increase in cytosolic ssDNA. Our data assign complementary roles for EZH2 and PARP1 in DSB repair pathway choice by independently limiting 5' end resection. This directs DSBs to rapid, imprecise repair by NHEJ over slow and precise repair by HR. An implication is that PARP inhibitor resistance due to the Warburg effect may be mediated by EZH2. Driving hyperresection by targeting O-GlcNAcylation or H3K27 trimethylation along with PARP inhibition may saturate the capacity of HR and produce irreversible damage in cancer cells. Targeting impacts of metabolic reprogramming on DSB repair may not only enhance the therapeutic index of radiation but also sharpen synthetic lethality with HR deficiency.

#2875 Resistance to conventional chemo and radiotherapy associated with increased DNA repair and stem cell-like phenotype in head and neck squamous cell carcinoma expressing HPV E5.

S. Roy, S. Miyauchi, R. Jones, S. Kim, **A. B. Sharabi**;
UCSD Moores Cancer Center, La Jolla, CA

Human papillomavirus-associated head and neck squamous cell carcinoma (HPV+ HNSCC) is one of the fastest-rising cancers in the US. While HPV+ HNSCC patients exhibit better responses to chemoradiation compared to HPV- HNSCC patients, a subset of HPV+ patients do not respond as well and develop recurrent/refractory disease. In this study, we investigated the potential role of HPV E5 in promoting resistance to conventional chemo- and radiotherapy, and the underlying molecular mechanisms. HPV E5 is a small hydrophobic viral oncoprotein with multiple functions including regulation of tumor cell differentiation and apoptosis, modulation of H+ ATPase responsible for acidification of late endosomes, and immune modulation. To test the impact of HPV E5 on therapeutic resistance, we generated HNSCC cell lines and normal keratinocytes expressing HPV16 E5. Upon treatment with radiation (2Gy, 4Gy, 8Gy) and/or cisplatin, HNSCC cells and keratinocytes expressing HPV 16 E5 had increased cell viability, decreased apoptosis, and increased colony-forming capacity compared to empty vector (EV) control lines. Specifically, treatment with 4Gy radiation, 4μM cisplatin, or the combination led to a ~2-fold decrease in % of apoptotic cells in HPV16 E5-expressing HNSCC cells compared to EV and HPV16 E6/E7 HNSCC cells ($p < 0.05$). Examination of DNA damage response and repair pathways indicated that while HPV16 E5 HNSCC cells initially had increased phosphorylation of H2AX 6 hours post treatment, at 24 hours post treatment H2AX phosphorylation in HPV16 E5 cells was significantly decreased compared to EV or HPV16 E6/E7 HNSCC cells. These findings indicate increased DNA repair capacity of HPV16 E5 HNSCC cells. To identify mechanisms underlying this phenotype, we performed RNA-seq and observed enhanced signaling pathways associated with epithelial development and increased expression of stem cell markers in HPV16 E5 HNSCC cells compared to EV control lines. Functionally, we observed a ~2.5-fold increase in sphere-forming capacity and increased expression of markers associated with stem cell phenotype in HPV16 E5 HNSCC cells compared to EV and HPV E6/E7 HNSCC cells. To determine whether these findings translated clinically, 18 HPV+ HNSCC patients from the GSE74927 dataset were grouped according to median expression level of HPV E5 (High vs Low). In support of our hypothesis, HPV E5-High patients exhibited enrichment of pathways associated with extrinsic apoptotic signaling, pluripotency of stem cells, and positive regulation of DNA repair. Taken together these results identify HPV E5 as a potential mediator of resistance to conventional radiation and chemotherapy in HNSCC and suggest that patient tumors expressing HPV E5 may have increased DNA repair capacity and cell survival after cytotoxic therapies.

#2876 Spatial immune cell atlas predicts the sensitivity to neoadjuvant PD-1 blockade treatment combined with radiotherapy in resectable esophageal squamous cell carcinoma.

X. Yin[1], K. Xu[2], S. Zheng[2], B. Li[3],

[1]The Affiliated Hospital of Qingdao University,, Qingdao, China, [2]The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China

Combination of radiotherapy and immunotherapy in neoadjuvant treatment seems a promising approach in resectable esophageal squamous cell squamous (ESCC). The clinical study of radiotherapy combined with PD-1 blockade therapy for neoadjuvant treatment of resectable ESCC shows good result. In order to investigate the underlying mechanism of the effectiveness of radiotherapy combined with immunotherapy in ESCC, we collected the pre and post neoadjuvant therapy samples from 5 responders and 5 non-responders ESCC patients and performed multiplexed tissue imaging using 28 markers. Using the detection measurements exported from QuPath, we performed the unsupervised clustering with Seurat and defined 20 cell types. Scimap was used to calculate the distance between different cell types. We found that CD4+ T, CD8+ T, cytotoxic CD8+ T cells and M1 macrophages showed an increase after treatment in both responders and non-responders. Tregs were decreased after neoadjuvant treatment in responder while there was no significant decrease in non-responder. And the distance between Tregs and cancer cells were increased in responders. Collectively, we provide an approach for investigating the underlying mechanism of the sensitivity to neoadjuvant PD-1 blockade treatment combined with radiotherapy in resectable ESCC using spatial multiplexed imaging.

#2877 Enhancing diagnostic precision in peritoneal cancer metastasis: Photodynamic diagnosis-guided laparoscopy in a rabbit model.

H.-I. Kim[1], A. Rivera-Piza[1], S. Lee[2];

[1]Yonsei University Health System, Seoul, Korea, Republic of, [2]CHA Bundang Medical Center, Bundang, Korea, Republic of

Introduction: Precise diagnostic workup is crucial for developing effective treatment strategies in cancer patients. Peritoneal carcinomatosis, often missed in preoperative CT scans and conventional laparoscopy, poses diagnostic challenges. This study aimed to assess the diagnostic accuracy of staging laparoscopy using photodynamic diagnosis (PDD) with the photosensitizer phonozen activated at 405 nm in a rabbit model of peritoneal carcinomatosis.
Methods: Female New Zealand white rabbits (16-20 weeks old) were utilized to establish the model through peritoneal inoculation of VX2 sarcoma cells, resulting in distinct solid-tumor nodules for laparoscopic evaluation. A customized dual-emission laparoscope, capable of both white-light and 405 nm blue-light, was employed for PDD. To minimize blue-light background interference, a 550 nm long-pass filter was placed between the laparoscope and the video camera, optimizing the process. The PDD-enhanced diagnostic laparoscopy comprised a tripartite approach: 1) initial peritoneal cavity exploration under white-light and labeling of suspect nodules, followed by 2) utilization of blue light with the long-pass filter to identify red-light emissions from distinctly labeled tumor cells, and 3) open laparotomy served to palpate the peritoneal surface and identify additional or missed tumor nodules.
Results: Analysis of data from 12 rabbits with 267 tumor nodules revealed that sensitivity and specificity of diagnostic laparoscopy for detecting tumor nodules increased from 84.9% and 18.8% with white light alone to 90.8% and 25.0% when aided by PDD, respectively. These findings underscore the substantial improvement in diagnostic accuracy achievable by combining the rabbit model of peritoneal carcinomatosis with PDD in laparoscopic procedures.
Conclusion: The heightened sensitivity and specificity observed in this study hold significant promise for positively impacting clinical practice, providing a more accurate and effective approach to the diagnosis and management of peritoneal carcinomatosis.

#2878 Hyperthermia increases the efficacy of aminolevulinic acid-mediated photodynamic therapy in human osteosarcoma cells.

P. J. Baugher;
Pacific Univ., Forest Grove, OR

Osteosarcoma is a malignant osteoid tumor that arises from mesenchymal cells exhibiting osteoblastic differentiation. Common treatments for this neoplasm include limb-salvage surgery and/or amputation of the affected limb, either of which can substantially decrease quality of life. Therefore, other, less invasive treatments should be explored. Photodynamic therapy (PDT) represents a more targeted, less invasive treatment possibility for osteosarcoma. Previous data from my laboratory demonstrated that aminolevulinic acid-mediated photodynamic therapy (ALA-PDT) can be used to induce significant cell death in human osteosarcoma MG-63 cells *in vitro*. However, delivering high doses of drugs to deep osteosarcoma tumors could prove difficult, so we aim to explore the use of combination therapies to increase the efficacy of ALA-PDT in human osteosarcoma cells. Previous studies have shown that hyperthermia (increased temperature) can induce cell death in cancer cells. Furthermore, data suggest that combining PDT with hyperthermia can induce cell death in cancer cells synergistically by activating differential death-inducing pathways. However, hyperthermia in combination with ALA-PDT has not been explored in human osteosarcoma. Therefore, we aim to investigate the possibility that hyperthermia in combination with ALA-PDT can increase cell death in human osteosarcoma cells compared to ALA-PDT alone. Data from our lab show that compared to normal body temperature (37°C), cell death in MG-63 human osteosarcoma cells was not significantly increased by mild hyperthermia alone (40°C and 43°C respectively), while moderate hyperthermic temperatures alone (46°C and 49°C) did significantly increase cell death. We also found that at moderately hyperthermic temperatures, ALA-PDT does not increase cell death any further compared to moderate hyperthermia alone. Furthermore, we found that at the mildly hyperthermic temperature of 40°C, cell death was not significantly increased any further by ALA-PDT compared to ALA-PDT alone. However, our data do show that at a temperature of 43°C, hyperthermia plus ALA-PDT increased cell death compared to ALA-PDT alone. Therefore, our data suggest that inducing mild hyperthermia could increase the efficacy of ALA-PDT in human osteosarcoma cells.

#2879 Spatiotemporal fractionation: An innovative concept of fractionated radiotherapy.

I. Vetrugno[1], I. Telarovic[1], N. Torelli[2], J. Unkelbach[1], M. Pruschy[1];
[1]Universitat Zurich, Zurich, Switzerland, [2]University Hospital Zurich, Zurich, Switzerland

Impressive outcomes in therapeutic radiation oncology have been achieved in the past decade through the development of advanced computer technology and imaging methods, such as intensity modulated radiotherapy. Ideally, radiotherapy treatment delivers a high dose to the tumor while sparing the surrounding healthy tissues and organs at risk from radiation damage. Spatiotemporal Fractionated Radiotherapy has emerged as an innovative technique that delivers different dose distributions to different parts of the tumor in order to achieve high doses to the target while ensuring a low dose-bath in the surrounding normal tissue. Spatiotemporally fractionated regimens showed *in silico* up to 10 - 15% sparing of normal tissue from radiation damage, while ensuring isoeffective tumor control compared to conventionally fractionated regimens. However, prior to advancing spatiotemporal fractionation to the clinical level, it is important to probe the validity of the main assumption of spatiotemporal fractionation derived from the Biologically Effective Dose (BED) model: two different fractionation schemes that implement a high and a low dose will lead to equivalent clinical effects, regardless of dose-treatment sequence. A tumor growth delay study was performed in a subcutaneous immunocompetent murine tumor model (MC38-tumor cell derived) receiving two different fractionation regimens. Particularly, tumors belonging to the two treatment groups received the same dose combination - a high (12 Gy) and a low (6 Gy) dose fraction separated by 72 hours - with the doses delivered in opposite order in the two treatment groups. The same experimental outline was performed in a subcutaneous immunodeficient murine tumor model derived from the same tumor cells. Tumors were also characterized by immunophenotyping analysis seven days after first irradiation. Even though the two regimens deliver the same physical dose to the tumor - and would be considered equivalent according to the BED model - different tumor growth delays were observed in a time window of 30 days after first irradiation depending on the treatment group. Such differences were observed in the immunocompetent model but not in the immunodeficient model. The immunophenotyping results showed immunostimulatory vs immunosuppressive phenotypes of the tumor microenvironment depending on the order of the treatment doses. An additional tumor growth delay study including immune checkpoint inhibitors confirmed the fundamental role of the immune system with the differential efficacy outcomes of the two regimens. Overall, these intriguing results suggest that a differential radiotherapy-induced immune response to different doses of ionizing radiation plays an important role in the treatment outcome and asks for re-evaluation of the BED model taking scheduling-dependent parameters into consideration.

#2880 Radiation induces myofibroblast differentiation of pericytes.

T. Yamazaki, K. R. Jordan, M. R. Crittenden, M. J. Gough, K. H. Young;
Providence Cancer Institute, Portland, OR

Radiation not only kills cancer cells directly through DNA damage, but also indirectly by inducing vascular changes. Endothelial cells (ECs) in small blood vessels and capillaries connect with pericytes, a type of mural cells which are important for vascular stability and structure. Effects of radiation on tumor vasculature are critical for the therapeutic efficacy, however, its impacts on pericytes remain largely unknown. In this study, we focused on the effect of radiation on pericytes and sought to elucidate the mechanism by which radiation affects pericytes. We show 20Gy for C3H10T1/2 (10T1/2) mouse embryonic mesenchymal pericyte precursor cells and 10Gy for human pericytes from placenta (hPC-PL) cells induces pericyte differentiation and activation of adhesion molecules. Radiation enhanced lymphocyte adhesion and decreased permeability in co-culture of ECs and pericytes primarily through endothelial cells, not via pericytes. Furthermore, radiation promoted transdifferentiation of pericytes into myofibroblasts. Supernatant from irradiated cells in combination with a TGFβ inhibitor showed that TGFβ signaling is involved in pericyte differentiation by radiation but not all pericyte marker genes are regulated by TGFβ. Therefore, we performed phospho-kinase array analysis and revealed Akt signaling pathway activation 10 minutes following radiation, which was verified by the phosphorylation of GSK3β and PRAS40. Along with this, generation of intracellular reactive oxygen species (ROS) occurs as early as 5 min following radiation. Inhibitors of Akt and ROS suppress the expression of myofibroblast markers increased by radiation.

To investigate whether radiation induces pericyte differentiation into myofibroblast in tumors, we employed NG2DsRedBAC (NG2DsRed) transgenic mice where DsRed is expressed under the control of NG2 promoter to trace pericytes. The endogenous expression of DsRed was detected in pericytes in the tumors implanted to NG2DsRed mice. Flow cytometry analysis of tumors harvested 7 days after radiation shows radiation increased vimentin^{+} cells and decreased DsRed^{+} cells, which indicates radiation induced pericyte differentiation into myofibroblast. In conclusion, radiation promotes pericyte maturation and transdifferentiation into myofibroblast via Akt signaling. Further study using Akt inhibitor with radiation to tumor-bearing N2DsRed mice will be warranted.

#2881 Comparing the effects of proton and photon therapy on promoting cancer aggressiveness in ovarian cancer and glioblastoma.

Y. Jung[1], A. Morcos[2], A. Keniston[1], A. Antonissen[1], S. Asariah[3], A. Bertucci[4], M. Vazquez[4], J. Unternaehrer[2];
[1]California State University, San Bernadino, San Bernardino, CA, [2]Loma Linda University, Loma Linda, CA, [3]California Baptist University, Riverside, CA, [4]Canadian Nuclear Laboratories, Chalk River, ON, Canada

Ovarian cancer is the 12th most common cancer among women in the United States and the 5th leading cause of cancer-related death for women. About 80% of the patients are diagnosed at stages III or IV, classified as High-Grade Serous Ovarian Cancer (HGSOC). HGSOC is highly aggressive, exhibiting an 80% recurrence rate within 24 months after cancer treatment. Brain and nervous system cancer ranks as the 10th leading cause of cancer-related death in the U.S., with Glioblastoma Multiforme (GBM) accounting for 47.7% of all brain cancer cases. GBM is the most aggressive primary brain cancer, with a 90% recurrence rate and a 4% 2-year survival rate. Patients with these cancers encounter limited treatment options, and the recurrence of cancer exacerbates these challenges. Therefore, a deeper understanding of the factors contributing to cancer treatment-induced aggressiveness is greatly needed. In our study, we first examined the treatment efficacy of proton and photon radiation by conducting apoptosis assays. Our findings demonstrate that proton radiation is significantly more effective at eliminating both HGSOC and GBM cells compared to photon radiation. Subsequently, we assessed the level of cancer aggressiveness in the surviving cells after radiation exposure by measuring stemness and epithelial-mesenchymal transition (EMT) levels. While proton radiation proved to be more effective in eliminating a greater number of cancer cells, we hypothesize that both proton and photon irradiation promote cancer aggressiveness in the surviving cells of HGSOC and GBM. To assess the stemness and EMT level of cancer cells following radiation, we integrated a SORE6-GFP reporter to identify the cancer stem cell population expressing SOX2/OCT4 and a 3' UTR-ZEB1-GFP reporter to detect the cell population with mesenchymal traits. Cells transduced with the reporters were treated with 0, 1, 2, 4, and 8 Gy of 250 MeV proton and 6 MeV photon beams, and at 72 hours post-radiation, GFP levels were measured via flow cytometry. Our data demonstrated a dose-dependent increase in stemness and EMT levels in live cells after both types of radiation. Furthermore, cancer cells exposed to radiation were harvested at 72 hours and 240 hours post-radiation for RT-qPCR analysis. Our preliminary data indicate an upregulation of stemness genes including POU5F1 and SOX2, as well as EMT transcription factor genes ZEB1, SNAI1, and TWIST1 in response to both types of radiation in most cell lines. These findings indicate that both proton and photon radiation therapies promote cancer aggressiveness in the surviving cancer cells.

#2882 Investigating mechanisms of radioresistance in TYK2 knockout head and neck cancer cells.

N. M. Constante, V. Kelley, J. Contessa;
Yale University, New Haven, CT

Radiation therapy is the primary form of treatment of head and neck squamous cell carcinoma (HNSCC). However, more than half of patients experience disease progression with standard of care treatment. To investigate novel therapeutic targets, a CRISPR screen was done to identify genes that are associated with radioresistance. The screening results indicated that JAK1 and TYK2 knockout (KO) resulted in radioresistance in HNSCC. Preliminary data suggests that loss of JAK1 causes an enhanced G2/M arrest phenotype and enhanced genome stability that contribute to radioresistance. To investigate whether TYK2 KO caused changes to the cell cycle and genome stability as observed in JAK1 KO, Western blots, cell cycle assays, and micronuclei staining experiments were performed. Cal27, a HNSCC cell line, was used. Cal27 cells were transduced with a non-targeting control (NT2) guide RNA (gRNA) or two different gRNAs targeting TYK2 to generate TYK2 KO cells. Western Blot analysis was performed to determine changes in signaling upon TYK2 KO. Additional conditions included radiation and treatments with Interferon gamma, Interferon alpha and Interleukin-6 to activate the canonical JAK-STAT pathways. Overall, there were minimal changes in downstream signaling between the treatments and the knockouts. Cell cycle analysis via flow cytometry revealed no changes between the NT2 and TYK2 KO cells, potentially corroborating signaling results. Forty percent of TYK2 KO cells were arrested at the G2/M checkpoint at 8 hrs and 24 hrs after radiation treatment, but twenty percent returned to the G1 phase at 24 hrs. This indicates that loss of TYK2 is not responsible for cell cycle arrest. Lastly, micronuclei formation was observed to measure genomic instability. Twenty thousand Cal27 NT2 and TYK2 KO cells were seeded. They were allowed to incubate for 48 hrs before treatment with 4 Gy. Micronuclei staining revealed minimal differences between NT2 and TYK2 KO cell lines, although there were significant differences between the control and the radiation groups. Overall, radioresistance by TYK2 KO is not caused by changes in cell cycle or genomic instability as demonstrated with JAK1 KO. To understand how TYK2 is causing radioresistance in HNSCC, next steps would be to see if there are changes in proliferation. If MTT assays demonstrate significant changes, downstream signaling in growth pathways will be measured. If there is no increased proliferation, we will examine changes in DNA damage repair.

#2883 HDAC6 mediates the radioresistance of NSCLC through LSD1, independent of its own deacetylation activity.

S. Ha[1], H. Kim[1], H. Lee[1], S. Choi[1], H.-y. Lee[2], W.-Y. Kim[1];

[1]Sookmyung Women's University, College of Pharmacy, Seoul, Korea, Republic of, [2]Seoul National University, Seoul, Korea, Republic of

Resistance to radiation therapy significantly affects the prognosis of solid tumors. Histone deacetylase 6 (HDAC6) is a stress-responsive lysine deacetylase that has emerged as a promising target for cancer therapy, with numerous clinical trials investigating interventions to modulate its activity. While HDAC6 appears to be linked to responses to DNA-damaging therapeutics, the reported responses and underlying mechanisms remain intriguing and varied. In this study, we elucidate a novel mechanism of radioresistance mediated by HDAC6 in non-small cell lung cancer (NSCLC). We classified nine NSCLC cell lines into three groups based on their radioresistance using survival assays and correlated this resistance with the induced expression of six deacetylases. We conducted gain-of-function experiments (GOF) using plasmid transfection and loss-of-function experiments (LOF) employing inhibitors or RNAi. Furthermore, we quantified the repair of damaged dsDNA through FACS-based GFP assays and assessed the mechanism of homologous recombination repair (HRR) end-resection via single-strand quantitative PCR. Co-immunoprecipitation assays, cancer stem cell enrichment, DNA damage-induced senescence assays, reverse-phase protein assays (RPPA), and RNA sequencing were also performed to investigate gene expression changes resulting from the loss of HDAC6. Our findings revealed that HDAC6 induction by radiation is strongly correlated with NSCLC resistance to radiation leading to CSC survival and escape from radiation led senescence LOF of HDAC6 through RNAi or inhibitors suppressed resistance, while GOF achieved through wild-type or deacetylase activity-deficient mutant transfection, induced resistance. Importantly, this resistance mechanism was independent of deacetylation activity. RNAi-mediated loss of HDAC6 reduced both HRR and non-homologous end-joining, whereas pharmacological inhibition of HDAC6 activity did not. Notably, DNA end-resection, a critical step in HRR, was decreased by RNA interference but not affected by the inhibitors. RPPA assays demonstrated that Histone demethylase 1A (LSD1/KDM1A) levels decreased significantly upon HDAC6 RNA interference but remained unaffected by pharmacological intervention. Loss of LSD1 alone resulted in decreased HRR and end-resection, likely mediated through HDAC6-induced ubiquitination. Moreover, overexpression of LSD1 rescued the HDAC6 loss-induced sensitization of NSCLCs. In summary, our study unveils a novel mechanism by which HDAC6 mediates HRR after radiation through the stabilization of LSD1. This mechanism operates independently of deacetylase activity. Therefore, our findings suggest that interventions targeting both deacetylation and non-deacetylation roles of HDAC6 should be considered to overcome HDAC6-derived radioresistance in NSCLCs and enhances the radiation therapy efficacy.

#2884 Resistance to pan-FGFR inhibition is determined by the EMT phenotype associating with clinical outcome in HNSCC.

F. Broghammer[1], M. Gouda[2], I. Korovina[3], C. Brunner[4], R. P. Coppes[5], O. Gires[2], M. Seifert[1], **N. Cordes**[3];
[1]Technische Universitat Dresden, Dresden, Germany, [2]Ludwigs-Maximilians-University University Hospital, Munich, Germany, [3]Helmholtz Center Dresden - Rossendorf, Dresden, Germany, [4]Ulm University Medical Center, Ulm, Germany, [5]University of Groningen, Groningen, Netherlands

Receptor tyrosine kinases (RTK) and integrins coalesce at focal adhesions. These cell membrane areas serve as huge signaling hubs critically contributing to central aspects of cancer cell survival and therapy resistance. Despite the fact that these receptors mutually interact, co-dependencies between these receptors and associated therapeutically exploitable vulnerabilities remain largely unclear in HPV-negative head and neck squamous cell carcinoma (HNSCC). Here, we evaluated the cytotoxic and radiochemosensitizing potential of targeting 10 RTK and β1 integrin in up to 20 different 3D matrix grown HNSCC cell models. RNA sequencing and protein-based biochemical assays were performed for molecular and pathway characterization. Bioinformatically identified transcriptomic signatures were applied to patient cohorts to show clinical relevance. Our observations demonstrate that fibroblast growth factor receptors (FGFR 1-4) present with the strongest cytotoxic and radiosensitizing potential, both as monotherapy and in combination with β1 integrin inhibition, surpassing the efficacy of the other investigated RTK. Pharmacological pan-FGFR inhibition elicited a variable response spectrum ranging from cytotoxicity/radiochemosensitization to resistance/radioprotection. Transcriptomic characterization revealed an association of these contrasting responses to FGFR inhibition with a mesenchymal-to-epithelial transition (MET) for sensitive cell models and a partial epithelial-to-mesenchymal transition (EMT) for resistant cell models. Accordingly, deactivation of EMT associated kinases like EGFR, PKC and PAK proved effective in diminishing the adaptive FGFR-driven resistance. Importantly, the translation of the adaptive resistance profiles to HNSCC patient cohorts showed its prognostic value and provided conclusive validation of the presence of EMT-related vulnerabilities that can be strategically used for therapeutic intervention. In conclusion, our study demonstrates that pan-FGFR inhibition induces both a highly beneficial radiochemosensitizing and a detrimental radioprotective effect in HNSCC cell models. Adaptive EMT-associated resistance appears to be of clinical importance, and we provide effective molecular approaches to exploit this therapeutically.

#2885 O-carborane-entrapped polymeric Micelles for Proton Boron Capture Therapy.

Q.-X. Teng[1], G. Zhang[1], H. Chen[1], F. Mendes[2], N. Sahoo[1], C. Fernandes[2], A. Paulo[2], C. Li[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Lisboa, Lisbon, Portugal

Introduction: Proton boron capture therapy (PBCT) has the potential to enhance the biological effectiveness of proton therapy, based on proton-boron fusion reactions ($^{11}B + p \rightarrow 3\alpha + 8.7$ MeV), which produce 3 α particles. In this study, we formulated *o*-carborane, a high boron content cage-like compound, into a polymeric micelle (M-carb) as a delivery tool to achieve effective delivery of the boronated compound to cancer cells and validated the enhancement of the biological effectiveness of proton therapy promoted by the uptake of *o*-carborane-entrapped in the micelle.
Methods: *O*-carborane was effectively entrapped into an amphiphilic block copolymer to yield a stable polymeric micelle. The size and surface charge of the resulting M-carb were characterized by dynamic light scattering (DLS) and the uptake of M-carb in MIA PaCa-2 pancreatic cancer cells was measured by inductively coupled plasma mass spectrometry (ICP-MS). A colony formation assay was employed to assess the impact of M-carb on the survival of MIA PaCa-2 cells irradiated with a proton beam at the entrance and distal Spread-Out Bragg Peak (SOBP) positions at doses ranging from 0, 2, 5, and 8 Gy. The γH2AX foci were quantified by immunofluorescence to assess treatment-induced DNA double-strand breaks. Boron phenylalanine (BPA) was used as a control boron-carrying agent.
Results: *O*-carborane-entrapped polymeric micelles (M-carb) had a diameter of about 60 nm and a relatively narrow size distribution (polydispersity index ~0.15) and possessed a slight negative charge. After 6 h incubated with M-carb at an equivalent concentration of 200 μM boron, MIA PaCa-2 cells were found to have taken up ~45 ng ^{11}Boron per million cells. The colony formation assay demonstrated a significant decrease in the survival rate of MIA PaCa-2 cells after 8 Gy proton irradiation in the presence of 40 ppm of boron (corresponding to 4.61 μM BPA or 0.46 μM carborane) compared to irradiation treatment alone ($p<0.05$). At 8 Gy, the survival rates were 0.10, 0.07, and 0.04 for the following irradiation conditions: i) irradiation alone; ii) in the presence of BPA; in the presence of M-carb. At 2 and 5 Gy, these survival rate values were 0.78, 0.69, and 0.69 and 0.33, 0.19, and 0.16, respectively. Importantly, M-carb alone at the concentration used in proton irradiation experiments displayed no cytotoxicity. Immunofluorescence assays revealed that at both 2 Gy and 5 Gy, BPA and M-carb significantly increased γH2AX foci compared to irradiation alone ($p<0.0001$).
Conclusion: M-carb was efficiently taken up by MIA PaCa-2 cells. PBCT mediated by M-carb or BPA enhanced the relative biological effectiveness of proton therapy with consequent improvement of its cell-killing efficacy in pancreatic cancer cells. This approach holds promise for advancing proton therapy as a new treatment modality for pancreatic cancer.

#2886 Osteoclast and neuronal cross-talk as a mechanism for chest-wall pain caused by thoracic radiosurgery for lung cancer.

S. Park, M. Peters, J. Moore, K. Reno, M. Farris, C. Peters, J. Willey;
Wake Forest University, Winston-Salem, NC

Radiation therapy (RT)-induced chest wall pain (CWP) is a severe complication after thoracic stereotactic body radiation therapy (SBRT) for lung tumors; with increased survivorship, ~30% of patients develop severe CWP. The causes of CWP are unknown, but could involve: 1] damage to intercostal peripheral nerves; 2] bone loss from affected osteoclast activity, or 3] both (secreted factors from activated osteoclasts can affect nerves). This study tested the potential for radiation to affect osteoclasts and/or sensory neurons to induce pain. Mature osteoclasts differentiated from RAW264.7 cells plated on Osteoassay surfaces were exposed to an acute 10 Gy Cs137 γ-rays and bone resorption was assessed. We collected conditioned media (CM) from these cells at 48h and applied to cultured primary mouse dorsal root ganglia neurons (irradiated and non-irradiated neuron), assessing neurite growth and pain-associated marker (CGRP, SP) expression through immunohistochemistry and RT-qPCR. Risedronate (50μM), an anti-resorptive agent, was administered pre-radiation to inhibit osteoclast activity. Unpaired t-tests were utilized for statistical analyses (α=0.05). Osteoclast resorption activity was increased by 48h after irradiation. These irradiated, activated osteoclasts exhibited increased mRNA expression of differentiation (RANK) and activity (CTSK, MMP9) markers. Neurons treated with CM from irradiated osteoclasts exhibited elevated levels of CGRP (+38.5%) and SP (+29.5%) compared to cells treated with CM from non-irradiated cells. Consistently, in co-cultures of osteoclasts and neurons exposed to radiation, irradiated neurons exhibited significantly increased neuropeptide levels. Risedronate not only reduced osteoclast activity but also inhibited neuropeptide expression in irradiated neurons within these co-cultures. Moreover, neuropeptide levels were similar between directly irradiated neurons and non-irradiated neurons. However, irradiated neurons exposed to CM from either irradiated or non-irradiated osteoclasts showed a marked 4-fold increase in neuropeptide levels vs neurons that were non-irradiated and then received osteoclast CM. Our findings indicate that radiation activates osteoclasts and leads to direct bone loss *in vitro* and signaling between irradiated osteoclasts and non-irradiated neurons increases pain responses. Importantly, this response is enhanced when neurons were also previously irradiated. During SBRT, intercostal nerves may be influenced by adjacent irradiated osteoclasts, increasing expression of pain-related neuropeptides as the osteoclasts break down bone, thus enhancing the risk of CWP as treatment progresses across time. Understanding these interactions could reveal potential targets for preventing CWP, allowing higher tumor radiation doses with less toxicity. Support: The Milton Raben Foundation.

#2887 Impact of ionizing radiation on the energy metabolism of normal and tumor cells in the brain.

Marvin Kreuzer[1], Pascal Imseng[2], Matthias Wyss[2], Thomas Look[3], Tobias Weiss[3], Bruno Weber[2], Martin Pruschy[1]

[1]Department of Radiation Oncology, University Hospital Zurich, Zurich, Switzerland,[2]Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland,[3]Department of Neurology, Clinical Neuroscience Center, University Hospital Zurich, Zurich, Switzerland

This study aims to analyze irradiation-induced metabolic alterations in glioblastoma cells and astrocytes to enhance understanding of cellular responses and facilitate the development of more effective radiotherapeutic strategies. Metabolic reprogramming of tumor cells is considered one of the hallmarks of cancer. Studies have shown that abnormal activation of oncogenes and cancer-related signaling pathways, as well as the inactivation of tumor suppressor genes can induce metabolic reprogramming. These metabolic aberrations facilitate rapid proliferation, continuous growth, invasion, metastasis, and immune evasion. Following the application of radiotherapy, the activity of several metabolic pathways significantly changes, potentially leading to the development of radioresistance. However, a differential effect of ionizing radiation on tumor and normal cells is not well understood. Hence, quantifying irradiation-induced metabolic changes in glioblastoma cells and astrocytes is of high importance. We have developed a novel approach to measure dynamic metabolite changes upon irradiation, in vivo, in situ, and in real-time. This tool combines imaging of recently developed fluorescent biosensors via 2-photon microscopy and millimeter-scaled irradiation. Murine glioblastoma cells and astrocytes were generated with stable expression of biosensors for the quantification of intracellular concentrations of various metabolites, including lactate. Cytosolic concentrations of lactate depend on the balance between glycolytic production, mitochondrial consumption of pyruvate and lactate, and the exchange with the extracellular lactate pool via monocarboxylate transporters. Many cancer cells are characterized by an excessive conversion of glucose to lactate even under normoxic conditions. We quantified this so-called Warburg Effect in glioblastoma cells and astrocytes as the ratio between basal lactate production and the lactate increase after OXPHOS inhibition and determined irradiation-induced metabolic changes on the single-cell level. Complementarily, we used metabolomics and Seahorse analyses before and after irradiation. Our data indicate that irradiation increases oxygen consumption in glioblastoma cells but not in astrocytes. Also, we established an orthotopic glioblastoma mouse model via injection of sensor-expressing tumor cells for *in vivo* measurements of metabolite changes during and after irradiation. These data are expected to significantly advance the understanding of the cellular response to irradiation on a molecular level in situ and in real-time. This knowledge will help to develop combination treatments and increase the efficiency of radiotherapy.

#2888 Sensitization of radiation resistant colon cancer - The oxygenated microbubble hydrogel approach.

A. Jose, C. H. Chong, J. Jaiswal, Z. Wu, S. S. Thakur;
University of Auckland, Auckland, New Zealand

Background: Hypoxia, a state of reduced oxygen that develops within the tumor due to its irregular vasculature, could result in treatment resistance. Mounting evidence suggests that reoxygenation of the tumor could improve outcomes of conventional cancer therapies. Our approach combats hypoxia using oxygenated lipid microbubbles (OMB) loaded in a temperature sensitive gel. The OMB would carry the oxygen while the gel would sustain its release into the tumor microenvironment.
Objectives: To formulate an oxygen loaded MB dispersed in a temperature sensitive poloxamer hydrogel for intratumoral administration.
Methods: OMB were generated by first preparing a liposomal mixture DSPC:DSPE-PEG2000, which was dispersed in a thermosensitive poloxamer hydrogel (P407:P188). This was pressurized with oxygen and vortexed in a gas-tight vial. Characterizations included OMB size distribution, injectability, thermosensitivity, oxygen loading and release, and the impact of the formulation on efficacy of radiotherapy against a colon cancer cell line (HCT116) was evaluated.
Results: DSPC:DSPE-PEG2000 liposomes at a molar ratio of 94:6 dispersed in P407:P188 (21:6.5 %w/w) generated OMB with a size distribution in the acceptable range of 0.8-8 µm. Formulations were within the established limits of injectability (F<38N) at room temperature, and gelled near physiological temperatures enabling a sustained release of oxygen. . The formulation co-treatment enhanced radiotherapy significantly as evidenced by the remarkable reductions of clonogenic survival rates in both hypoxic and normoxic HCT116 cells (reduction by 78% vs 68% compared to just their respective radiated controls; $p<0.0001$ for both cases).
Conclusion: Reoxygenation with a newly developed OMB hydrogel formulation effectively sensitized HCT116 to radiotherapy *in vitro*. Studies are underway to explore the importance of reoxygenation rate and extent for optimal tumor sensitization.

#2889 Cartilage oligomeric matrix protein as a potential biomarker and therapeutic target of radiation resistance in NSCLC.

K. E. Reno, S. H. Park, M. K. Farris, R. T. Hughes, J. E. Moore, C. M. Patel, J. S. Willey;
Wake Forest University School of Medicine, Winston Salem, NC

Despite recent advances in lung cancer treatment, the survival rate of non-small cell lung cancer (NSCLC) is ~57% largely due to treatment resistance. Cartilage Oligomeric Matrix Protein (COMP) has previously been implicated in promoting metastasis and is associated with poor survival outcomes in breast, prostate and colorectal cancers. Patients with prostate cancer and osteoarthritis (a condition characterized by elevated circulating COMP) had both increased tumor COMP expression and rate of metastasis. Additionally, elevated COMP expression, among others, was observed in a study that investigated the gene expression of invasive NSCLC cell lines, though association with COMP was not further studied. Therefore, COMP could potentially increase the metastatic potential for NSCLC and thus serve as a therapeutic target to reduce tumor aggressiveness. We performed proliferation and migration assays on NSCLC cell lines, A549 and NCI-H1975, treated with 2 µg/mL COMP to identify COMP's role in NSCLC progression. Plated cells in monolayer were treated with either COMP (2µg/mL) or PBS (control), and then within each group received either: 1] one of two different inhibitors of COMP signaling (either the α_v integrin antagonist cilengitide (1µM), or the Src inhibitor PP2 (1µM)), or 2] no additional treatment. Replicates from each group then received 2Gy Cs137 γ-radiation, or no irradiation. Proliferation and migration were monitored via the IncuCyte ZOOM live-cell imaging system over a 48hr interval. Radiation alone reduced both proliferation (-22%, $p<0.0001$) and migration (-40%, $p<0.01$) of A549 cells. However, exogenous COMP treatment attenuated the effects of radiation, maintaining both A549 proliferation (19% vs irradiated control, $p<0.05$) and migration (91% vs irradiated control, $p<0.0001$). While the overall pattern for NCI-H1975 cells with/without COMP treatment was similar, the magnitude of the responses was reduced vs A549 cells and non-significant. In contrast, radiation resistance with COMP treatment was abrogated by exogenous treatment of both COMP inhibitors. Cilengitide treatment resulted in lower proliferation rates of the COMP treated, irradiated A549 (-16%, $p<0.05$) and NCI-H1975 cell lines (-58%, $p<0.0001$) vs COMP treatment alone, while PP2 reduced proliferation and migration rates for both irradiated and non-irradiated COMP treated cell lines ($p<0.0001$). PP2 treatment alone did not reduce migration rates of either irradiated control cell lines. In conclusion, COMP serves to radioprotect NSCLC in an undetermined manner, and could serve as both a prognostic biomarker for and therapeutic target against radiation resistance in patients with NSCLC. Support: Milton Raben Foundation

TUMOR BIOLOGY: The Tumor Microenvironment as a Drug Target
Poster Session

#2893 Inhibition of ADAMTS4 and 5 to regulate the tumor microenvironment.
C. Lee, S. Kim, S. Kim, Y. Kim, S. Lee, S. Ha, Y. Lee, J. Yang;
Cellus, Seoul, Korea, Republic of

Background: Triple-negative breast cancer accounts for approximately 10~15% of all breast cancers and is characterized by the absence of ER, PR, and HER2 receptors, making targeted therapies challenging due to the lack of biomarkers. ADAMTSs (ADAM metallopeptidase with thrombospondin) are complex extracellular proteases known for their roles in facilitating cancer cell proliferation and safeguarding tumor functions. This enzyme is secreted by cancer cells and various immune cells, influencing the tumor microenvironment. ADAMTSs modulate cellular adhesion, migration, proliferation, and vascular development by cleaving components of the extracellular matrix and regulatory factors such as chemokines and cytokines. Our aim is to positively manipulate the tumor microenvironment of triple-negative breast cancer by inhibiting ADAMTSs, presenting a new strategy for treating this challenging type of breast cancer that lacks targeted therapeutic options.
Results: To confirm the anticancer effects of a protease inhibitor concurrently targeting ADAMTS4 and 5, a co-culture of triple-negative breast cancer cells (MDA-MB-157) and THP-1 was established to artificially create a tumor microenvironment. Subsequently, a wound healing assay was conducted, revealing that treatment with the ADAMTS4 and 5 dual inhibitor effectively inhibited cancer cell migration. This observed anticancer effect is attributed to the inhibition of CXCL16 secretion by the ADAMTS4 and 5 dual inhibitor. To verify the anti-tumor mechanisms of ADAMTS4 and 5, MDA-MB-157 cells, a triple-negative breast cancer cell line, were treated with IFNγ and TNFα to promote CXCL16 secretion artificially. Upon treatment with varying concentrations of the ADAMTS4,5 dual inhibitor, it was confirmed that the secretion of CXCL16 was inhibited in a dose-dependent manner. In a mouse model with transplanted 4T1 breast cancer cells, treatment with the ADAMTS4,5 dual inhibitor resulted in the suppression of CXCL16 secretion, leading to an increase in M1 macrophages. Additionally, it was observed that the inhibitor induced $CD8^{+}$ T cell activation. These regulation and changes of immune cells through inhibition of ADAMTS4 and 5 control the TME to resist tumor cells.
Conclusion: ADAMTSs are known as protein-degrading enzymes responsible for the degradation, modification, and regulation of proteins. Recent research has revealed that ADAMTSs play a crucial role in the proliferation and survival of cancer. Activation of ADAMTS4 and 5 has been shown to promote the secretion of CXCL16, leading to the differentiation of macrophages into tumor-associated macrophages. Specifically, ADAMTS4 and 5 convert membrane-bound CXCL16 into a soluble form, exacerbating the tumor microenvironment of triple-negative breast cancer. Therefore, inhibiting ADAM4,5 is intended to change or maintain TME in a suitable state for anti-cancer therapy, which could lead to a new strategy for anti-cancer therapy.

#2894 Targeting NOS2 and the tumor microenvironment in endometrioid ovarian cancer: Implications for treatment and survival.

G. Melone[1], M. Li[1], I. Uzair[1], M. Chervo[1], K. Ortega[1], W. Qian[1], J. Zhou[1], L. Guzman[1], S. Hynes[2], S. Glynn[2], C. Thomas[1], P. Matre[1], L. Francis[3], J. Chang[1];
[1]Houston Methodist Research Institute, Houston, TX, [2]University of Galway, Galway, Ireland, [3]Swansea University, Swansea, United Kingdom

Purpose of the study: The final aim of the study is to disrupt the deleterious effect of the tumor microenvironment by targeting inducible Nitric Oxide Synthase 2 (NOS2). NOS2 has a role in cancer cell proliferation and immune cells inactivation. It is upregulated by cytokines released from the tumor proinflammatory environment and the adipose tissue. By targeting and reverting NOS2 functions, we want to develop a therapeutic modality that inhibits endometrioid ovarian cancer (EOC) progression and reactivates the immune response in the ovarian cancer tumor microenvironment (OC-TME).
Experimental procedures: We analyzed ovarian cancer patients' cohorts using TNMPlot, Kaplan-Meier Plotter and The Human Protein Atlas. We simulated the tumor proinflammatory microenvironment by administering Interferon-gamma (IFN-Y, 25 ng/mL), Interleukin 1 Beta (IL1-β, 10 ng/mL), Tumor Necrosis Factor-alpha (TNF-α, 10 ng/mL) on A2780 EOC human cell line. We also administered conditioned media (CM) from breast fat adipose tissue to assess the influence of lipid components on cytokines release. After upregulating NOS2, we tested the efficacy of Cisplatin in combination with L-NMMA, a NOS2 inhibitor, on A2780 cells through proliferation assays using RealTime-Glo™ MT Cell Viability Assay (Promega®). In addition, to assess the immune landscape in ovarian cancer, we developed a syngeneic model administering ID8 cells (murine OC cell line) through intraperitoneal injection (IP) in C57BL/6 mice.
Results: The findings indicated higher NOS2 RNA expression levels in tumors than in normal samples according to TNMPlot ($p = 6.84e-01$). KMPlotter analysis revealed that patients with high NOS2 expression treated with Cisplatin had a significantly shorter survival rate (10.64 months) compared to those with lower NOS2 expression (25 months, $p = 0.0088$). Patients untreated with Cisplatin and exhibiting high NOS2 expression also showed lower survival rates (11 months) than those with lower NOS2 expression (34 months, $p = 0.056$). Furthermore, cytokine treatments increased NOS2 protein levels in A2780 cells after 48 hours, and CM similarly elevated NOS2 protein levels. Subsequent administration of Cisplatin and Cisplatin + L-NMMA to cytokine-treated A2780 cells notably reduced cell proliferation by 85% and 89%, respectively.
Conclusion: Taken together, our results showed the importance of a proinflammatory environment and adipose tissue in NOS2 upregulation. These findings show a potential correlation between endometriosis, obesity, and endometrioid ovarian cancer. With the development of an in vivo and in vitro model, we can gain a better understanding of the role of NOS2 in immune inactivation as well as in cell proliferation in EOC.

#2895 ILRAP blockade mediates anti-fibrotic effects in pancreatic cancer-associated fibroblasts.

N. I. Nissen[1], N. Hansen[2], E. Jaensson Gyllenback[3], C. R. Millrud[3], M. Jaras[2], D. Liberg[3], M. A. Karsdal[1], **N. Willumsen**[1];
[1]Nordic Bioscience, Herlev, Denmark, [2]Lund University, Lund, Sweden, [3]Cantargia, Lund, Sweden

Introduction: Pancreatic cancer (PDAC) patients have poor prognosis partly due to excessive activity of cancer-associated fibroblasts (CAFs). CAFs drive the fibrosis that causes excessive type III collagen and extracellular matrix deposition that in turn reduces drug response resulting in poor survival. In support, high levels of the type III collagen serum biomarker PRO-C3 correlates with poor survival in PDAC. TGF-β is thought to be the main driver of PRO-C3 and tumor fibrosis. Cytokines such as Interleukin 1 (IL-1) play a key role in the pancreatic tumor microenvironment and may play a role in tumor fibrosis as well. In this study, we first investigated the potential of IL-1 in activating fibroblasts to drive fibrosis and produce PRO-C3. Subsequently, we established a co-culture of pancreatic cancer cells and pancreatic CAFs to investigate the anti-fibrotic properties of nadunolimab, an antibody that blocks IL-1 signaling by targeting IL-1 Receptor Accessory Protein (IL1RAP). Nadunolimab is currently in phase I/IIa clinical development for treatment of pancreatic cancer (CANFOUR, NCT03267316). Methods: Human primary pancreatic cancer-associated fibroblasts (CAFs) were cultured in Ficoll-media (Scar-in-a-jar, SiaJ) supplemented with TGF-β, IL-1α or IL-1β. The fibrotic activity of the fibroblasts was investigated by measuring the formation of type III collagen (PRO-C3) at days 3, 6, 9 and 12. Then, pancreatic cancer cells (BxPc3) and pancreatic CAFs were cultured either alone or in a co-culture. Nadunolimab or isotype control were added at the start of these cultures and supernatants were collected after three days. The level of PRO-C3 was measured by ELISA. Results: Both IL-1α or IL-1β were equipotent to TGF-β in inducing PRO-C3 in the SiaJ monoculture, indicating that IL-1 is pro-fibrotic. In addition, when cancer cells and CAFs were co-cultured, PRO-C3 levels increased compared to single-cell cultures (1.5-6-fold). When co-cultures were treated with nadunolimab, the induction of PRO-C3 was blocked to levels similar to monocultures, whereas the isotype control had no effect on PRO-C3 levels. Conclusion: IL-1 activated fibroblasts and induced type III collagen formation (PRO-C3), suggesting that IL-1 is a driver of tumor fibrosis. In support, pancreatic tumor cells induced collagen type III formation (PRO-C3) in pancreatic CAFs and blockade of IL1RAP with nadunolimab inhibited this collagen formation. Thus, nadunolimab may have anti-fibrotic properties and PRO-C3 could potentially be used for prognostic/predictive enrichment and as a pharmacodynamic marker in future studies evaluating anti-IL-1 modalities in PDAC.

#2896 Elucidating the role of transglutaminase 2 (TGM2) in pancreatic ductal adenocarcinoma pathogenesis and its therapeutic implications.

P. Wright, A. Atfi;
Virginia Commonwealth University - VCU, Richmond, VA

Pancreatic cancer remains one of the deadliest malignancies, with limited therapeutic options and a poor prognosis due to delayed symptom presentation and disease detection. Pancreatic ductal adenocarcinoma (PDAC) has a 5-year survival rate of less than 8%, predominantly attributed to oncogenic KRAS mutations and loss-of-function mutations in TP53, SMAD4, and P16. Our lab is interested in studying Transglutaminase 2 (TGM2), a multifunctional enzyme involved in protein cross-linking and cellular signaling, because it is highly correlated with cancer cell survival, malignancy, metastasis, and treatment resistance. Clinically, overexpression of TGM2 is associated with poorer survival in patients with Pancreatic Ductal Adenocarcinoma so it is imperative to understand the mechanism of its action in disease progression. To elucidate the role of TGM2 in PDAC, we studied the targeted deletion of TGM2 in the context of a mouse model of PDAC and saw a significant reduction in PDAC incidence and precursor lesion formation, suggesting that TGM2 has a role in the tumor microenvironment. Using single cell sequencing, we found TGM2 levels to be elevated in certain cell populations, specifically endothelial cells and cancer cells. We discovered high TGM2 levels in TIE2-GFP mouse vessels and subsequently found high TGM2 levels in patient tumor vasculature. Further studies aim to conditionally ablate TGM2 in endothelial cells to assess its mechanistic involvement in PDAC initiation and progression. Additionally, we are studying concurrent conditional TGM2 and SMAD4 deletions in mice to investigate pancreatic cancer precursor lesion formation and are further evaluating the protective mechanisms of a TGM2 deletion in a more aggressive mouse model of PDAC. Our preliminary findings substantiate TGM2 as a critical player in PDAC pathogenesis, opening avenues for targeted therapeutics to ultimately improve patient prognosis.

#2897 Cancer associated fibroblasts targeted photoimmunotherapy improves drug delivery.

S. Nishimura[1], K. Noma[1], T. Matsumoto[1], T. Takahashi[1], Y. Takeda[1], H. Matsumoto[1], T. Kunitomo[1], K. Kawasaki[1], H. Kashima[1], T. Kato[1], S. Kikuchi[1], T. Ohara[1], H. Tazawa[2], T. Fujiwara[1];

[1]Okayama Univ. Graduate School of Med., Okayama, Japan, [2]Okayama Univ., Okayama, Japan

Introduction: Desmoplasia is often associated with adverse outcomes in cancer, particularly in esophageal cancers characterized by stroma-rich environments and poor prognoses. The dense extracellular matrix (ECM) within the stroma hinders effective drug delivery, primarily due to elevated interstitial pressure. Cancer-associated fibroblasts (CAFs) of the tumor microenvironment deteriorate this issue by promoting cancer proliferation and ECM production. We have developed a photoimmunotherapy targeting these CAFs via fibroblast activation protein (FAP-PIT), which has demonstrated notable antitumor efficacy in CAF-rich tumors that are typically chemoresistant. This study explores the potential of FAP-PIT to enhance drug delivery in CAF-rich tumors.

Methods: We have conjugated Sibrotuzumab, a clinically-trialed FAP antibody with the photosensitizer IR700DX for application in FAP-PIT. We compared the protein expression levels of ECM components—collagen I (Col I) and hyaluronic acid (HA)—between CAFs and normal fibroblasts (NFs) in vitro. Spheroid models, both CAF-poor (solely cancer cells) and CAF-rich (cancer cells plus fibroblasts), were employed to assess drug uptake. Additionally, 140 esophageal cancer cases from 2008 to 2010 were retrospectively analyzed. In vivo, we induced bilateral subcutaneous tumors to apply FAP-PIT, monitoring drug uptake using in vivo imaging systems (IVIS) and immunohistochemistry (IHC).

Results: Initially, we determined how significantly CAFs impede the drug delivery. In vitro, CAFs secreted higher levels of Col I and HA compared to NFs. Clinically, the expression of Col I and HA consistently showed a positive correlation with α-smooth muscle actin (αSMA) and FAP. CAF-rich spheroids exhibited significantly reduced uptake of fluorescently labeled chemotherapy compared to CAF-poor spheroids. Conversely, FAP-PIT enhanced drug penetration in CAF-rich spheroids through CAFs depletion and ECM remodeling. In vivo studies further demonstrated that FAP-PIT significantly increased Panitumumab and nab-Paclitaxel accumulation in CAF-rich tumors, leading to superior antitumor efficacy. IHC analysis validated the significant reduction of CAFs and Col I.

Conclusion: The ECM, including CAFs, poses a barrier to drug delivery. Our findings indicate that FAP-PIT can effectively enhance drug penetration in CAF-rich tumors, presenting a novel therapeutic strategy to overcome drug resistance.

#2898 Development of the lipid kinase PIKfyve PROTAC degrader against neuroendocrine prostate cancer.

Y. Qiao[1], C. Li[2], Y. Zheng[1], X. Jiang[1], S. N. Yee[1], C. Cheng[1], Y. Bao[1], Y. Zhang[1], Y. Wang[3], Z. Wang[2], K. Ding[2], A. Chinnaiyan[1];
[1]University of Michigan Medical School, Ann Arbor, MI, [2]Shanghai Institute of Organic Chemistry, Chinese Academy of Sciences, Shanghai, China, [3]The Vancouver Prostate Centre, The University of British Columbia, Vancouver, BC, Canada

Therapies targeting the androgen receptor (AR) as the main driver of prostate cancer (PCa) can lead to various mechanisms of resistance and promote progression to castration-resistant PCa (CRPC), which has a median survival of only 13-23 months. Amongst recurrent CRPC, 17%-30% of patients develop neuroendocrine prostate cancer (NEPC), which is a PCa subtype characterized by a unique histology. NEPC exhibits a loss of AR signaling during neuroendocrine transdifferentiation which results in resistance to AR-targeted therapies and gain of cell characteristics resembling poorly differentiated neuroendocrine tumors. Despite advances in the understanding of NEPC development, treatment options remain limited, with platinum-based chemotherapy as the first-line treatment for both de novo and treatment-induced NEPC. However, response to first-line chemotherapy in NEPC is short, with a median survival of only seven months. The poor prognosis of NEPC is attributed in part to late diagnosis and a lack of effective therapeutic agents. Our previous work demonstrated that NEPC and AR-negative PCa exhibit higher dependency on the lipid kinase PIKfyve than AR-positive CRPC. Thus, development of PIKfyve inhibitory therapies targeting the emergent vulnerabilities of NEPC or AR-negative forms of PCa is a promising approach.
Using a proteolysis targeting chimera (PROTAC) technology, we designed a class of PIKfyve specific degrader. The *in vitro* degradation efficiency were determined by immunoblotting, and DC50s (degradation concentration at 50%) were calculated for top candidates. Pharmacokinetic and pharmacodynamic were evaluated for *in vivo* study. In summary, we have developed a class of PIKfyve specific degrader using the E3 ligase von Hippel-Lindau (VHL) as a ligand via a diverse set of linkers. Mechanistic studies revealed that it induced PIKfyve degradation in a VHL- and proteasome-dependent manner.

#2899 Combined inhibition of RAF, MEK and FAK increases PDAC responsiveness to cytotoxic- and immune therapy.

X. Liu[1], J. Baer[1], B. Knolhoff[1], G. Hogg[1], F. Ahmad[1], S. Coma[2], J. Pachter[2], K. Lim[1], D. DeNardo[1];
[1]Washington University in St. Louis, Saint Louis, MO, [2]Verastem Oncology, Needham, MA

Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal malignancy with poor response rate to therapy. An immune suppressive tumor microenvironment (TME) and oncogenic mutations in KRAS have been implicated as drivers of resistance to both conventional and immune therapies. As such, targeting RAS/MAPK signaling is an attractive strategy. However, RAS/MAPK inhibition has not yet shown clinical efficacy for PDAC, likely due to rapid acquisition of resistance in PDAC cells. Tumor intrinsic mechanisms of resistance to RAS/MAPK have been studied, however, the unique PDAC TME may also be a key driver in resistance. Previous studies have shown that FAK inhibition can reprogram the PDAC TME and delay PDAC progression in animal models. Herein, we found that long-term FAK inhibitor treatment led to hyperactivation of the RAS/MAPK pathway in both genetically engineered mouse models and in post-treatment PDAC tissues from FAK inhibitor clinical trials. Concomitant inhibition of both FAK (VS-4718) and RAF/MEK (avutometinib) signaling dramatically suppressed tumor growth, leading to increased survival across multiple PDAC mouse models. The mechanisms of synergy include both changes in tumor-intrinsic signaling and modulation of tumor/stroma interactions that drive avutometinib resistance. In the TME, we found that cancer associated fibroblasts (CAFs) can impair the downregulation of cMyc by RAF/MEK inhibition in PDAC cells. This resulted in de-novo resistance to RAF/MEK inhibition in fibrotic conditions. By contrast, FAK inhibitors reprogramed CAFs to suppress the production of key growth factors, including FGF1, that drove resistance to RAF/MEK inhibition. While combined FAK and RAF/MEK inhibition only led to disease stasis, the addition of chemotherapy to the combination led to tumor regression and improved long-term survival in PDAC mouse models. Analysis of tumor immunity showed that the combination of FAK and RAF/MEK inhibition improved anti-tumor immunity and improved priming of T cell responses, which was further improved with the addition of chemotherapy. These findings led to testing of FAK (defactinib) plus RAF/MEK (avutometinib) inhibition in combination with gemcitabine and nab-paclitaxel in advanced front-line pancreatic cancer patients (RAMP 205; NCT05669482). Finally, we tested whether addition of immunotherapy could enhance the efficacy of FAKi + RAF/MEKi + chemotherapy and found that addition of either PD-1 or CTLA4/PD-1 blockade led to long term disease control in PDAC animal models. Together, these studies identified FAK inhibition as a novel approach to overcome both tumor intrinsic and stromal-derived resistance to RAS/MAPK inhibition and showed that this combination can be exploited to increase the efficacy of cytotoxic and immunotherapy approaches.

#2900 BRAFi-induced epigenetic switch drives the reprogramming of resistant cancer-associated fibroblasts.

Y. Xiao, L. Zhou, Y. Zhang;
University of Cincinnati, Cincinnati, OH

Cancer-associated fibroblasts (CAFs) are a potential target for optimizing therapeutic strategies against melanoma. However, a major unknown still exists in CAFs, which is how CAFs maintain and even reinforce their functions in drug therapy and influence melanoma cell drug sensitivity. Yes-associated protein 1 (YAP1) is the master regulator that shuttles between the cytoplasm and nucleus in CAFs. Apparently, proteins associated with nuclear YAP1 in CAFs when treated with BRAF inhibitor (BRAFi) can potentially influence tumor drug response. Here we unveil that CAFs require the YAP1 function to proliferate, migrate, remodel the cytoskeletal machinery and matrix, and promote cancer cell invasion. Ablating YAP1 in CAFs increases the response of BRAF-mutant melanoma cells to BRAFi and MEK inhibitor (MEKi) *in vivo* and *in vitro*. Using an approach termed RIME (Rapid Immunoprecipitation Mass Spectrometry), we purified nuclear YAP1 and identified protein arginine methyl transferase 1 (PRMT1) as a major YAP1 binding partner in BRAFi-treated CAFs. Binding PRMT1 to YAP1 was confirmed by Co-immunoprecipitation and proximity ligation assay, and YAP1 deficiency in CAFs diminishes the nuclear accumulation of PRMT1, suggesting BRAFi-induced nuclear translocation of PRMT1 in CAFs requires the formation of YAP1 and PRMT1 complex. Silencing PRMT1 expression in CAFs not only deprives them of their ability to proliferate and to induce BRAF mutant melanoma cell resistance to BRAFi and MEKi. PRMT1 is a type I R-methyltransferase that mediates arginine methylation in human cells, which was known to be recruited to chromatin and exert its enzymatic activity to methylate Arg3 of histone H4 (H4R3). Using Histone H4 Modification Multiple Assay, we observed a global increase in Histone H4 methylation, especially H4R3 methylation, in CAFs in response to BRAFi stimulation, suggesting increased chromatin unfolding and accessibility and transcription activation. When YAP1 or PRMT1 expression was silenced, H4R3 methylation was notably suppressed, indicating BRAFi-induced H4R3 methylation was indeed driven by the YAP1 and PRMT1 signaling axis. In conclusion, our data disclose a novel BRAFi-induced YAP1-PRMT1-mediated epigenetic mechanism that reprograms CAFs through H4R3 methylation-directed transcriptional activation to reinforce their drug-resistant functions and modulate melanoma cell drug sensitivity. Moreover, the discovery of PRMT1 as a key player in the intricate molecular mechanisms that govern epigenetic regulation in CAFs in response to BRAFi treatment suggest PRMT1 as a potential CAF target in cancer therapy.

#2901 The apoptotic peptide TB511 targets activated CD18 and suppresses solid tumor progression.

Ilsoeb Choi[1], Ik-Hwan Han[1], Soyoung Kim[1], Juwon Yang[2], Hye Yeon Kim[1], Daehwan Park[1], Hongseo Choi[3], Jeongyoon Choi[3], Heekyung Lee[3], Jin Sun Shin[3], Jinho Kim[2], Jihwan Moon[2], Hyunsu Bae[1]

[1]Department of Physiology, College of Korean Medicine, Kyung Hee University, Seoul, Korea, Republic of,[2]Department of Korean Medicine, College of Korean Medicine, Kyung Hee University, Seoul, Korea, Republic of,[3]R&D Center, Twinpig Biolab Inc., Seoul, Korea, Republic of

Tumor-associated macrophages (TAMs) primarily exist in the M2-like phenotype in the tumor microenvironment (TME). M2-TAMs contribute to tumor progression by establishing an immunosuppressive environment. However, TAM targeting is hindered, mainly owing to a lack of specific biomarkers for M2-TAMs. Herein, we verified that TB511, a fusion peptide comprising a TAM-targeting peptide and the pro-apoptotic peptide dKLA, could preferentially bind to active CD18 in M2-TAMs, inducing apoptosis; it was less toxic to other tissue-resident macrophage lineages. TB511 suppressed tumor progression in various cancer models and humanized mouse models. Removal of M2-TAMs by TB511 significantly increased the infiltration of tumor-killing cells, such as granzyme B-positive $CD8^+$ T cells and natural killer cells, in the TME. Collectively, our findings suggest that targeting CD18 in M2-TAMs using peptide drugs is a potential strategy for immunotherapy in various tumors, including non-small cell lung cancer, colorectal cancer, hepatocellular carcinoma, renal cell carcinoma, and prostate cancer.

#2902 CA-4948 (emavusertib) improves treatment response of preclinical metastatic brain melanoma to anti-PD-1 immune checkpoint blockade.

Christina A. von Roemeling[1], Bently P. Doonan[1], Amanda M. Acevedo[1], Jeet A. Patel[1], Savannah L. Carpenter[1], Alisha Bhatia[1], Reinhard W. von Roemeling[2], Jamison Hoffman[2], **Maureen Lane**[2], Duane A. Mitchell[1]

[1]University of Florida College of Medicine, Gainesville, FL,[2]Curis, Inc., Lexington, MA

Background: Although recent advances in immunotherapy for metastatic melanoma have transformed the treatment paradigm for a disease that once carried a grim prognosis, nearly 50% of patients fail to reach a complete response to immune checkpoint blockade (ICB) due to multiple mechanisms of tumor-induced immune resistance. These challenges are amplified in the CNS tumor microenvironment (TME) where metastatic brain melanoma (MBM) demonstrates diminished clinical benefit to ICB treatment. A deeper understanding of these mechanisms are required to improve therapeutic response to ICB for these patients. Our group has previously identified that aberrant activation of the myddosomal cascade through downstream interleukin (IL)-1 receptor-associated kinase (IRAK-4) signaling results in chronic stimulation of MAPK and NF-κB in MBM. Further investigation reveals myddosome signaling emanates in large part from the TME, resulting in reflexive immune suppression. CA-4948 (emavusertib), a small molecule inhibitor of IRAK-4, is capable of reaching therapeutic dose levels in the brain where it demonstrates on-target inhibition of this pathway. These data highlight a unique therapeutic opportunity where selective inhibition of immune-suppressive signaling via targeted IRAK-4 blockade may sensitize MBM to anti-PD-1 ICB.

Methods Multispectral imaging of patient MBM samples were analyzed for myddosome expression in the TME. Melanoma preclinical models, including both primary site (cutaneous) and metastatic brain disease, were evaluated for tumor burden and survival in response to CA-4948 treatment alone and in combination with anti-PD-1 ICB. Immunological responses of tumor to treatment were evaluated in two transgenic reporter models, $CCR2^{RFP}CX3CR1^{GFP}$ and $IFN\gamma^{IRES\text{-}EYFP}$, to determine both the distribution and activation of infiltrating immune cells. Tumor-associated myeloid cells were assessed for phenotypic markers by multiparameter flow cytometry.

Results Myddosome signaling was found to be elevated in tumor-associated immune cells in patient MBM specimens. Treatment of preclinical melanoma with CA-4948 combined with anti-PD-1 ICB resulted in significantly reduced tumor growth and improved survival in three independent models. CA-4948 treatment was associated with reduced tumor recruitment of peripherally derived tumor-associated macrophages, as well as increased lymphocyte infiltration and improved pro-inflammatory signaling measured by increased IFNγ expression in the combinatorial setting.

Conclusion Targeted inhibition of IRAK-4 with CA-4948 improves immune surveillance and activation in preclinical models when combined with anti-PD-1 ICB, resulting in reduced tumor growth and increased survival. Thus, CA-4948 may be an effective adjuvant treatment strategy alongside anti-PD-1 ICB for the treatment of metastatic melanoma.

#2903 CTHRC1 induces PSCs (pancreatic stellate cells) into myCAFs (myofibroblast-like cancer-associated fibroblasts).

J. Lee[1], M. Kang[1], F. Jiang[1], K. Ryu[1], J. Kim[2], Y.-Y. Park[1], S. Koh[2];

[1]Prestige BioPharma IDC Co., Ltd., Busan, Korea, Republic of, [2]Department of Biomedical Sciences, Dong-A University, Busan, Korea, Republic of

Collagen triple helix repeat containing-1 (CTHRC1) is a secreted protein that contributes to the progression of various cancers, including pancreatic cancer. The higher expression of CTHRC1 in tumor tissues is associated with poorer survival outcomes. However, its specific roles in tumor extracellular matrix (ECM) remodeling remain unclear. Our study aims to investigate the influences of CTHRC1 on pancreatic stellate cells (PSCs), a main source of ECM production in pancreatic cancer. The analyses of the publicly available pancreatic cancer patient data revealed that CTHRC1 is mainly expressed in cancer stroma and highly correlated with ECM-related genes. An in vitro study showed that more than 40% of these genes can be upregulated by CTHRC1. CTHRC1 specifically activated PSC into myofibroblast-like cancer-associated fibroblasts (myCAFs), which are characterized by a significantly upregulated POSTN gene expression. Periostin (coded by the POSTN gene) has a central role in the CTHRC1-PSCs-cancer metastasis axis. Furthermore, CTHRC1 promoted pancreatic cancer cell proliferation through PSC activation to a greater extent than via direct stimulation. Proof-of-concept experiments showed that the long-term (4-week) inhibition of CTHRC1 led to significant tumor suppression and ECM reduction, and also resulted in an unexpected shift in the CAF subtype from myCAFs to inflammatory CAFs (iCAFs). PSC activation was demonstrated to be the key molecular mechanism responsible for the tumor-promoting effects of CTHRC1, and CTHRC1 has a critical role in CAF subtype differentiation and tumor microenvironment (TME) remodeling. The inhibition of CTHRC1 as a therapeutic strategy for the treatment of pancreatic cancer warrants further investigation.

#2904 Small molecule inhibitor targeting DDR represents a novel therapeutic strategy for the treatment of pancreatic ductal adenocarcinoma (PDAC).

T. Do[1], J. Prochnau[1], P. P. Venkata[1], S. Khan[1], S. Timilsina[1], D. Singh[1], D. Medina[1], R. Amaradhi[2], D. Zhou[1], M. Hart[3], S. McHardy[2], M. Rao[1];
[1]UT Health Science Center at San Antonio, San Antonio, TX, [2]UT San Antonio, San Antonio, TX, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: Pancreatic ductal adenocarcinoma (PDAC) is ranked as the second leading cause of cancer-related mortality with a 5-year survival rate of merely 12%. The complexity of PDAC lies in its intrinsic resistance to treatment, attributable to the desmoplastic tumor microenvironment, characterized by an abundance of tumor-promoting extracellular matrix (ECM) and stromal cells. We hypothesize that Discoidin Domain Receptors (DDR), members of the receptor tyrosine kinase family known for their affinity to fibrillar collagens within the ECM, play an important role in promoting PDAC growth and progression. While several drugs targeting DDR proteins have been developed, no inhibitors to DDR proteins are specific or approved for PDAC treatment, thus necessitating the development of novel therapeutic interventions.

Methods. A comprehensive high-throughput screening approach employing small molecule inhibitors was executed to identify authentic inhibitors targeting DDR. Subsequently, a rigorous evaluation of specificity of these small molecules was conducted through structural activity relationship (SAR) analyses and reference-based assessments. The efficacy of candidate inhibitors was assessed through functional assays, while mechanistic insights were gleaned using a multifaceted approach, including RNA-seq, real-time PCR, western blot analysis, in vivo experimentation, and Phospho-Receptor Tyrosine Kinase (RTK) profiling to discern any unintended off-target effects.

Results: Using an unbiased screening approach, we identified 13 inhibitors that specifically target DDR. SAR studies and cellular thermal shift assay validated CIDD-0108633 (8633) as a bona fide DDR2 inhibitor. Functional assays and RNA-seq analyses demonstrated 8633's capacity to inhibit PDAC growth, metastatic potential, and expression of DNA replication, cell-cycle, and DNA damage repair genes. Combination therapy of 8633 with gemcitabine synergistically reduced PDAC cell viability and metastatic potential. Mechanistic studies revealed the role of ABC transporters in mediating gemcitabine resistance. RTK profiling shows moderate kinase selectivity. *In vivo* studies affirmed its antitumor effects.

Conclusions: The results indicate that the selective inhibition of DDR with small molecule inhibitors suppresses PDAC cell growth and progression, implying that DDR inhibitors have the potential to be developed as safe and efficacious therapeutics for the treatment of pancreatic cancers.

#2905 Spatial analysis of neuropilin 2 expression in the microenvironment of melanoma.

A. Dimou[1], R. M. Moore[1], C. Ward[2], A. Leontovich[1], R. Guo[1], C. Wang[1], S. Suman[1], B. Dicke[1], J. M. Schimke[1], N. A. Stueven[1], C. A. Atherton[1], W. Nevala[1], S. N. Markovic[1];

[1]Mayo Clinic, Rochester, MN, [2]University of Minnesota, Minneapolis, MN

Background: Neuropilin 2 (NRP2) is a co-receptor that enhances signaling of growth factor and cytokine receptors and is expressed in tumor and microenvironment (TME) cells in melanoma and other tumors. Neuropilin 2 expression in tumor cells is associated with more aggressive tumors. Expression in tumor associated macrophages enhances efferocytosis and immunologically silent tumor cell death.

Methods: Whole excisional lymph node biopsies were obtained from 10 treatment naïve patients with metastatic cutaneous melanoma who subsequently received anti-PD1 treatment. A single 5mm formalin-fixed paraffin embedded tissue section was used to assess a panel of 39 analytes by cyclic multiplex immunofluorescence (MxIF). Fields of view (~1mm2, n=288) were selected from pathologist-annotated regions of the tumor core, tumor-immune interface and adjacent lymphoid tissue. Pixel-based single cell segmentation and a supervised classifier approach was applied to resolve 12 distinct tumor, stromal and immune cell phenotypes and functional states (NRP2 positive or negative) in 1.5 million cells.

Results: Tumor recurrence was observed in 6 patients (relapsed) , whereas 4 patients were recurrence-free (non-relapsed) during follow up. Among the different cell types, NRP2 expression was more frequent in macrophages (44%), tumor cells (40%), dendritic cells (40%), followed by Tregs (31%) and T helper cells (29%), and less frequent in neutrophils (24%), cytotoxic T cells (23%) and B cells (15%). In colocalization permutation analysis, NRP2 expressing macrophages clustered away from tumor cells in non-relapsed patients while a random spatial distribution of NRP2 expressing macrophages with respect to tumor cells was observed in relapsed patients. In comparing the odds of tumor cell interactions with NRP2-expressing macrophages to those with NRP2 non-expressing macrophages, we found in the tumor:stromal interface (10% tumor cells) that cells from both non-relapsed and relapsed patients were more likely to interact with NRP2 non-expressing macrophages (OR = 0.73, 95% CI = [0.71, 0.75] and OR = 0.56, 95% CI = [0.55, 0.58] for non-relapsed and relapsed patients, respectively). However, in the tumor core (90% tumor cells), tumor cells from relapsed patients had significantly higher odds of interacting with NRP2 expressing macrophages, (OR = 1.15, 95% CI = [1.12, 1.18]), and this was not seen for non-relapsed patients (OR = 0.68, 95% CI = [0.66, 0.71]). In FOVs dominated by tumor cells (75% tumor), tumor cells from relapsed patients had 4.97 times the odds of expressing NRP2 compared to tumor cells from non-relapsed patients (95% CI = [2.23, 11.09], p = 0.0001).

Conclusions: These spatial analytics suggest complex interactions among NRP2 expression in tumor and TME of melanoma determining risk for relapse with anti-PD1 treatment.

#2906 Inducing and disabling COX-2 S-nitrosylation to investigate its role in breast cancer progression.

R. J. Hoffmann, A. Bensen, E. de Wilde, J. E. Korkola, P. Schedin;
OHSU, Portland, OR

Background: We aim to assess the effect of S-nitrosylation of COX-2 on tumor attributes in models of early breast cancer. COX-2 is involved in tumor progression in many solid cancers. It is a known oncogene in murine breast cancer models, and targetable by NSAIDs. In women, its clinical correlation to breast cancer progression as well as its efficacy as a therapeutic target have yielded mixed results. These incongruities may be due, in part, to a post-translational modification, as COX-2 undergoes S-nitrosylation on Cys-526. Commercially-available antibodies selectively bind to either the S-nitrosylated (SNO-COX-2) or non-nitrosylated (nCOX-2) forms, and immunohistochemical staining of human tissue reveals that the two forms of COX-2 localize to different cellular sites in normal breast tissue and have opposite associations with breast cancer progression (PMID 33298921).
Hypothesis: S-Nitrosylated and non-nitrosylated COX-2 have distinct roles in cancer progression.
Approach: MCF10DCIS.com is a human breast cancer cell line chosen due to its ability to form DCIS-like (“stage 0”) lesions in culture and xenografting, which can progress to invasion when induced by signals from the tumor microenvironment (TME).
Approach 1: Detect extracellular matrix (ECM) and ligand factors that upregulate SNO-COX-2, independently or in ECM/ligand pairs. We utilized a 2D microenvironment microarray (MEMA) and tested 357 TME conditions.
Approach 2: Validate TME conditions in 3D culture.
Approach 3: Develop a mutant MCF10DCIS.com line in which COX-2 cannot be S-nitrosylated by inducing a single disabling missense mutation at Cys-526 via CRISPR.
Results: The MEMA revealed several conditions in which SNO-COX-2 was upregulated, including fibular collagens and SSP1. In 3D culture, increased SNO-COX-2 was associated with the presence of markers for EMT and an invasive growth phenotype, whereas nCOX-2 was not. Following CRISPR transformation, 59 individual MCF10DCIS.com clones were isolated and the target site of each sequenced. We identified 10 heterozygotic clones with the desired mutation, including a classical heterozygote that also retained the WT allele.
Ongoing: Current studies include a second round of CRISPR to produce a homozygous mutant cell line as well as validation of the mutant protein. The resulting cell lines will model the loss of COX-2 S-nitrosylation in breast cancer cells while retaining otherwise-functional COX-2.

#2907 Therapeutic targeting miR-146a and miR-21 induce malignant cell death and regulate CD8$^{\pm}$ T-cell function in mycosis fungoides with large-cell transformation.

Z. Han, P. Swiderski, X. Wu, Y.-C. Yuan, J. Wu, C. Su, H. Qin, S. T. Rosen, C. Querfeld;
City of Hope, Duarte, CA

Large cell transformation of mycosis fungoides (LCT-MF) occurs in 20-50% of advanced MF and is associated with an aggressive clinical course and poor survival not to overcome by any standard treatment regimen. We have previously identified a distinct miRNA expression profile in LCT-MF from that of non-transformed MF with significant upregulation of miR-21 and miR-146a. Our analyses demonstrated the involvement of genes for immune checkpoint pathways such as ICOS-ICOSL and PD1-PDL1 signaling (Di Raimondo C et al. Cancers 2021). Here, we aimed to investigate the efficacy of antagomiR-146a and -21 (amiR-146a, and -21) on the tumor growth and CD8$^{\pm}$ tumor infiltrating lymphocyte exhaustion in LCT-MF. The amiR-146a, and -21 were synthesized in our DNA/RNA Synthesis Core by linking CpG-D19. *In vitro*, CTCL cell lines (Myla and HH) were treated with amiR-146a and -21, the cell viability was assessed by the 2,5-diphenyl-2H-tetrazolium bromide assay and cell apoptosis was evaluated using apoptosis assay. We found that amiR-146a, and -21 synergistically inhibited the proliferation of MyLa and HH cells due to the activation of apoptosis through Caspase3/7 pathways and inducing cell cycle arrest by blocking STAT3/ CDK1/Cyclin B1 pathway. Our RNA-seq data indicated that the exhausted CD8$^{\pm}$ T cells express elevated amounts of STAT3, IRF4, and BATF in LCT-MF compared with non-LCT MF. To evaluate the functional importance of amiR-146a, and -21 on CD8$^{\pm}$ T cell exhaustion, we induced an exhausted state of CD8$^{\pm}$ T cells with high level of immune checkpoints and dysfunctional cytokine production by continues anti-CD3/DC28 beads and culture supernatant (MyLa or HH cell) exposure. Our data revealed that amiR-146a and -21 attenuated the CD8$^{\pm}$ T cell exhaustion by blockade of immune checkpoints and STAT3/IRF4/BATF pathway to trigger the cytotoxic immune response. Collectively, the findings of our study suggest that targeting miR-146a and -21 is a promising and novel therapeutic strategy for LCT-MF.

#2908 EDB^{+}FN is an attractive therapeutic target in oncology: Insights from protein expression analysis of solid tumors.

S. Lewandowski, L. Diao, A. Quigley, M. Crochiere, J. Pinkas;
Pyxis Oncology, Boston, MA

Stroma plays a major role in the initiation, growth, survival, and drug-resistance of solid tumors, yet few therapeutics specifically target tumor-associated stroma. Extra-domain-B fibronectin (EDB^{+}FN) is an oncofetal splice variant of fibronectin upregulated in solid tumor stroma, which is associated with tumor growth, angiogenesis, and metastases. Here we developed an immunohistochemistry (IHC) assay to assess EDB^{+}FN protein expression in the stroma of tumor and normal tissues to characterize the potential of EDB^{+}FN as a therapeutic target for solid tumors with high unmet need. We validated a primary detection antibody and titrated assay conditions to achieve specificity and a broad dynamic range of EDB^{+}FN expression levels across indications, including thyroid cancer, head and neck squamous cell carcinoma, hepatocellular carcinoma, soft tissue sarcoma, pancreatic cancer, non-small cell lung cancer, ovarian cancer, and renal cancer. Considering the stroma-specific expression pattern of EDB^{+}FN, we developed a scoring algorithm weighting both the intensity and distribution of EDB^{+}FN expression specifically in the stroma compartment and separately in tumor cells. Using this assay and scoring approach, we screened more than 200 tumor samples from 10 solid tumor indications and found EDB^{+}FN to be highly differentially expressed in tumor-associated stroma with little to no expression on tumor cells and trace to undetectable levels in healthy tissue. EDB^{+}FN was expressed across the indications evaluated with a wide range of expression both within and between indications. Stromal EDB^{+}FN expression was not correlated with stromal density, which also varied widely within and across indications. In parallel, we developed an algorithm using digital pathology to approximate pathologist scoring of stromal density and EDB^{+}FN expression, allowing streamlined screening of preclinical samples for in vivo studies and indication selection. The disease-specific expression pattern of EDB^{+}FN and high incidence of expression across indications make EDB^{+}FN an ideal target for high-unmet-need solid tumors. The specificity and dynamic range of our IHC assay for detection of EDB^{+}FN protein expression position it as a robust potential biomarker assay for EDB^{+}FN-targeting therapeutics.

#2909 ST101, a clinical CEBPβ antagonist peptide, promotes an immune-active tumor microenvironment by multiple cellular mechanisms.

C. Scuoppo, J. Diehl, R. Ramirez, M. Koester, E. Gallagher, S. Leong, J. Gonzales, K. Mendelson, Z. Mattes, L. Ghamsari, G. Merutka, A. Vainstein-Haras, B. J. Kappel, **J. A. Rotolo**;
Sapience Therapeutics, Inc., Tarrytown, NY

CCAAT/Enhancer Binding Protein β (C/EBPβ) is a transcription factor that is an established driver of cellular transformation in several cancer types with poor prognosis, including glioblastoma (GBM), triple negative breast cancer (TNBC) and non-small cell lung cancer (NSCLC). These cancers' growth is often supported by an immunosuppressive (IS) tumor microenvironment (TME), characterized by high expression of TAMs, MDSCs, Tregs, and in the case of GBM, IS microglia. In addition to its cell-autonomous role of promoting survival and proliferation in cancer cells, C/EBPβ is also critical for IS M2 macrophage polarization, while its role in other TME populations is less understood. ST101 is a peptide antagonist of C/EBPβ that is being evaluated in a Phase 2 clinical study in patients with recurrent and newly diagnosed glioblastoma (NCT04478279). Here we explored the impact of ST101 on IS TME cell populations and on activation of cytotoxic T-cells in macrophage co-culture systems. ST101 increased the M1:M2 ratio up to 40-fold in hPBMC-derived macrophages cultured under conditions that typically drive M2 polarization. Further, ST101 promoted M2 repolarization to the M1 cell type, demonstrating that C/EBPβ is required for maintenance of the M2 program. When added to co-cultures of T cells with M2 macrophages, ST101 induced a 3-4-fold increase in intracellular IFN-γ staining indicating enhanced T cell activation. Notably, in M1 cultures ST101 further enhanced expression of the immune activity marker CD80 and T cell activation. Similar to its effect on M2 repolarization, ST101 induced activation of iPs-derived IS human microglia cultures toward an M1-like program. ST101 also impacted IS cell populations in vivo, as demonstrated in an orthotopic TNBC model in which ST101 exposure was associated with a reduction of the TAM fraction, increased intratumoral M1/M2 ratios, reduction of Tregs, increase of CD8:Treg fraction, and enhanced activity in combination with anti-PD-1. Similar observations were observed in clinical samples, where following ST101 exposure a significant decrease in expression of factors involved in M2 polarization, including CD209, SIGLEC5, and IL-24, and T cell suppression, including FoxP3 and inhibitory KIR proteins, were observed. Gene expression analysis suggests that ST101 induced a decrease in the intratumoral Treg:TIL ratio, indicating a shift towards a more immune-active TME. Overall, these results provide novel evidence for the contribution of C/EBPβ to the expression of multiple IS cancer-associated cell types and support the use of ST101 to antagonize C/EBPβ and promote an immune-active TME. Further, these data provide rational for evaluating the clinical impact of ST101 in combinations with immune checkpoint inhibitors.

#2910 Targeting thioredoxin reductase 1 (TrxR1) suppresses TAZ-driven glioblastoma progression.

M. Tang[1], K. Dirks[2], S. Kim[1], J. Thorpe[1], W. Li[1];
[1]Penn State College of Medicine, Hershey, PA, [2]Colorado State University, Fort Collins, CO

Glioblastoma (GBM) is the most common and aggressive primary brain malignancy in adults. Poor outcomes for traditional treatments demand targeted therapies based on identified mechanisms that drive tumor development and sustain its malignancy. Molecular pathology studies have classified GBM into subtypes differing in treatment responses and survival rates. Among these subtypes, the mesenchymal (MES) group is associated with the worst prognosis. The Hippo pathway transcriptional co-activator with PDZ-binding motif (TAZ) is one of the three transcriptional regulators that drive the GBM MES gene expression program. Studies from our lab and others have previously shown that TAZ activation is able to promote GBM MES differentiation and progression. Therefore, finding vulnerabilities of TAZ-driven tumors may help to develop targeted therapeutic methods for MES GBM. In an orthotopic GBM mouse model, we found that TAZ-driven tumors show increased expression of thioredoxin reductase 1 (TrxR1), which is responsible for catalyzing the reduction of thioredoxin and maintaining the cellular redox balance. In searching for the cause of increased expression of TrxR1, we found that glucose deprivation can induce TrxR1 expression, suggesting TrxR1 may be an adaptive mechanism for tumor cells to survive in glucose deprivation conditions. Indeed, either depleting TrxR1 genetically or inhibiting TrxR1 pharmacologically can promote tumor cell death under glucose deprivation. Furthermore, knockout TrxR1 in a TAZ-driven mouse GBM model significantly decelerated tumor progression. Collectively, our studies revealed that inhibition of the Trx redox system under glucose deprivation conditions leads to a synergistic cell death induction in GBM cells, therefore making targeting TrxR1 a potential therapeutic strategy for TAZ-driven MES GBM.

#2911 Prevalence of potential antibody drug conjugate targets and co-expression with PD-L1 in breast cancer and lung cancer patients with clinical response information.

M. Cumberbatch[1], W. Kim[2], M. Bhagat[1], J. Cogswell[1];
[1]TriStar Technology Group LLC, Washington DC, DC, [2]Seoul National University Medical College, Seoul, Korea, Republic of

Breast and non-small cell lung cancer (NSCLC) are two of the most important diseases for antibody drug conjugate (ADC) development. ADCs targeting HER2 and TROP2 are currently approved in select breast and lung subgroups with ADC's to many other tumor targets currently in clinical development. Based on TCGA mRNA expression data, ADC tumor targets currently under investigation for treatment of solid tumors have variable overlap in breast and lung cancers, however little is known about the overlap of ADC targets with PD-L1 which is a predictive biomarker in TNBC and for pembrolizumab monotherapy. In the current study, the prevalence and co-expression of ADC targets (HER2, TROP2, Nectin-4, B7-H3, B7-H4, HER3, FOLR1) were investigated in the context of PD-L1 status and clinical response data for standard-of-care (SOC) and immunotherapy, in breast and NSCLC cancer subtypes. Tissue microarrays (TMAs) comprising treatment naïve tumor samples (1mm cores) and including TNBC (26 patients), ER+ BC (90 patients), and NSCLC (adeno & squamous subtypes; 146 patients), all with full clinical follow-up information, were examined by immunohistochemistry (IHC) in serial sections for each ADC target and PD-L1, applying widely used and well optimized IHC assays on the Ventana and Dako Link 48 platforms. Established scoring methods were employed for analysis of PD-L1 and HER2, except for the addition of an exploratory ultra-low score for HER2. All other ADC targets were scored by digital image analysis to deliver percentage positive tumor expression at high (3+), moderate (2+), weak (1+) and negative (0) intensities. Taken together, this analysis revealed variable prevalence for each target in breast and lung cancer histologies by subtype, including differing overlap between ADC targets within tumor indications. In addition, prevalence of each ADC target in breast cancer characterized by HR status and HER2 subgroups (HER2-positive, low, ultra-low, negative) indicated potential opportunities for ADC clinical development in these subgroups. Co-prevalence of the selected ADC targets with PD-L1 CPS>10 (predictive for Pembrolizumab response in TNBC) and PD-L1 CPS categories of interest for NSCLC revealed patterns of expression in support of combination therapies. Furthermore, expression and co-prevalence data for each ADC target +/- PD-L1 was characterized in association with response to immunotherapy or other SOC. In summary, these data provide better understanding of which breast and lung cancer subtypes express the selected ADC targets uniquely and competitively which may be key to future clinical and diagnostic development.

#2912 SFRP2 and CD38 colocalize in triple negative breast cancer microenvironment.

L. Hsu, P. Nasarre, R. Mukherjee, E. Hilliard, M. Romeo, E. O'Quinn, W. Christians, N. Klauber DeMore;
The Medical University of South Carolina, Charleston, SC

Introduction: A promising target for breast cancer is secreted frizzled-related protein 2 (SFRP2), and a humanized monoclonal antibody to SFRP2 (hSFRP2 mAb) inhibits primary triple negative breast cancer (TNBC) in vivo. CD38 is a known cause of PD-1 inhibitor resistance in some tumors, and in metastatic osteosarcoma hSFRP2 mAb overcomes PD-1 mAb resistance by reducing CD38 in tumor infiltrating lymphocytes (TILs). Could this phenomenon be replicated in TNBC? This is unknown as the expression of CD38 in TNBC has not been studied. This study will establish the presence of SFRP2 and CD38 in the TNBC microenvironment.

Methods: Immunohistochemistry (IHC) was performed on an 88 core human TNBC tissue microarray (TMA) with antibodies to SFRP2 and CD38. Spatial analysis software was used to determine percent positivity. Each core was categorized using the scoring system for the estrogen receptor in breast cancer (<1% negative, 1-10% low positive, and >10% positive). Multiplex IHC was performed on 4 human triple TNBCs sections. Tissues were stained with antibodies to CD38, CD68 (macrophage), CD3 (T-cell), CD19 (B-cell), CytoKeratin (tumor), and SFRP2. Percent positivity of each marker was analyzed with a software package. For flow cytometry of tumor associated macrophages (TAMs), 1 million EO771 cells were injected into the mammary fat pad of female C57/BL6 mice. After 4 weeks tumors were extracted and a cell suspension was incubated in a mastermix with antibodies to SFRP2, CD38, PD1, CD11B and F480. Cells were fixed and conjugated to a fluorochrome secondary antibody. TAM gated cells were analyzed for the presence of SFRP2 and CD38.

Results: For the TNBC TMA, 83 cores were positive and 4 cores were low positive for SFRP2, 1 not evaluable; 87 cores were positive and 1 low positive for CD38. For multiplex IHC there was a total of 1,753,544 individual cells in all 4 human TNBC tumors that were stained. 94% of cells stained positive for SFRP2, and 65% stained positive for CD38. Of the cells that were positive for SFRP2, 70% were also positive for CD38, 15% were positive for CD68, 1% were positive for CD19, 77% were positive for CytoKeratin, and 10% were positive for CD3. Of the cells that were CD38 positive, 99% were also positive for SFRP2, 15% were positive for CD68, 1% were positive for CD19, 81% were positive for CytoKeratin, and 9% were positive for CD3. Flow cytometry analysis of TAMs confirmed the presence of SFRP2, CD38 on TAMs. TAMs that were negative for PD1 and CD38 (pro-inflammatory) had a 56% reduction in SFRP2 compared to TAMs that were double positive for PD1 and CD38 (anti-inflammatory).

Conclusion: SFRP2 and CD38 are prevalent in human TNBC and colocalize in the TNBC microenvironment in tumor cells, TAMs and TILs, but not B-cells. The presence and co-localization of SFRP2 and CD38 in TAMs was confirmed with flow cytometry. This confirms that SFRP2 is a therapeutic target in TNBC and provides a mechanistic rational for combination therapy with PD-1 inhibitor.

#2913 Co-expression of extracellular matrix enzymes heparanase or PH-20 augments the anti-tumor efficacy of folate receptor 1-targeting CAR T cells in an ovarian cancer model.

B. L. Steimle, P. Hu, N. Tran, J.-J. Lee, K. Baysac, K. Luo, X. Wang, G. Liang, S. Nurmukhambetova, T. Tran, P. Dash, D. Schneider;
Lentigen Technology Inc., a Miltenyi Biotec Company, Gaithersburg, MD

Introduction: The tumor extracellular matrix (ECM) is a physical barrier which obstructs trafficking of CAR T cells to tumors. We hypothesize that co-expressing ECM remodeling/degrading enzymes heparanase (HPSE) or PH-20 with a CAR directed against folate receptor 1 (FolR1) will overcome the physical tumor microenvironment barrier and improve anti-tumor efficacy of anti-FolR1 CAR in a human ovarian cancer model.

Methods: ECM CARs were constructed by combining anti-FolR1 ScFv with a CD8 hinge and transmembrane domain, 4-1BB, and CD3ζ endodomains, followed by a P2A element and full-length HPSE or GPI-anchored PH-20 sequence. CAR T cells were prepared from CD4+ and CD8+ T cells of healthy donors by lentiviral transduction. CAR expression was evaluated by flow cytometry; HPSE and PH-20 expression were measured via ELISA and Western blotting, respectively. CAR-mediated killing and cytokine release were observed in overnight co-culture assays with FolR1-expressing tumor cells. ECM CARs' migration through Cultrex™ and sodium hyaluronate matrices were assessed for HPSE and PH-20 function, respectively. ECM CARs' efficacy was evaluated *in vivo* using a FolR1-expressing subcutaneous OV90 ovarian cancer xenograft model in NOD SCID Gamma (NSG) mice, and representative OV90 tumors were harvested at day 7 post-CAR T treatment for immunohistochemical staining.

Results: FolR1 expression was confirmed in ovarian cancer cell lines and substrates targeted by HPSE (perlecan, glypican 3, CD138) and PH-20 (hyaluronan) were detected by immunofluorescence in human ovarian tumors' sections. Lentiviral transduced primary T cells yielded robust expression of FolR1 CAR and ECM enzymes. Anti-FolR1 CAR and ECM CARs secreted pro-inflammatory cytokines IL-2, TNFα, IFNɣ and lysed OVCAR3 tumor cells with similar efficacy. ECM CARs with HPSE or PH-20 exhibited enhanced migration through ECM-rich matrices as compared to anti-FolR1 CAR alone. *In vivo*, all anti-FolR1 CAR T cells rejected OV90 tumors and extended survival compared to tumor alone or untransduced T cells (UTD). However, ECM CARs co-expressing HPSE or PH-20 accelerated tumor regression as compared to anti-FolR1 CAR alone. Tumor histology revealed CAR T cell infiltration (CD3+, CD8+) in mice treated with anti-FolR1 CARs but not UTD, indicating that anti-FolR1 CARs can effectively infiltrate OV90 tumors. Imaging studies are underway to evaluate the function of ECM CARs in the tumor microenvironment.

Conclusions: The anti-FolR1 CARs boosted with ECM enzymes HPSE or PH-20 demonstrated specific lysis of FolR1-expressing cell lines, improved penetration through ECM-rich matrices *in vitro*, and accelerated tumor regression in an ovarian cancer model *in vivo*. Therefore, ECM CARs may help improve clinical outcomes in patients with ovarian tumors.

#2914 AI/ML-driven discovery of CTHRC1, collagen triple helix repeat-containing 1, a novel proteoglycan for stroma + tumor targeting and delivery of 4-1BB costimulation.

Christopher Harvey[1], Elizabeth Koch[2], Amanda Hanson[1], Lindsey Rice[1], Amy Berkley[2], Kerry White[1], Reza Saberianfar[2], Nikolai Suslov[1], Sam Cooper[2], **Michael Briskin**[1]

[1]Phenomic AI, Waltham, MA,[2]Phenomic AI, Toronto, ON, Canada

Background: While checkpoint inhibitors have demonstrated efficacy in a number of solid tumor indications, those with high stromal presence have been difficult to treat with minimal objective responses observed. Phenomic has developed a proprietary machine learning/artificial intelligence platform to identify novel stromal targets with superior expression profiles that enable selective targeting of immune activating agents that will relieve these immunosuppressive barriers in difficult to treat indications.

Methods: Using our single cell RNA Atlas, we assessed cancer-associated fibroblasts (CAFs) in several solid tumor indications for identification of novel targets, including proteoglycans. Our Atlas was also used to identify immune activating payloads whose cognate receptors were present in indications of interest. Antibodies were generated, and lead clones who demonstrated potent ligand binding and cell staining were used to generate fusion proteins to immune activating ligands. Efficacy and PD were assessed in multiple syngeneic tumor models.

Results: Bioinformatic analysis identified a unique subset of pathogenic CAFs, which are TGF beta responsive, secrete several ECM proteins, and their presence tracks with poor outcome and resistance to immunotherapy in several solid tumor types. CTHRC1 was identified as a novel matrix protein highly expressed in this CAF subtype as well as tumor epithelium and is highly selective in a range of tumor types such as ovarian cancer, triple negative breast cancer, and pancreatic ductal adenocarcinoma. While secreted, CTHRC1 is complexed on the cell surface and affords the opportunity to drug this target in a variety of ways. We identified an absence of 4-1BBL expression across indications of interest, and fusion proteins were generated to deliver 4-1BBL via CTHRC1 targeting. In checkpoint-resistant tumor models, we observed significant increases in CD8 T cells and robust anti-tumor activity with anti-CTHRC1-targeted 4-1BBL. Biodistribution studies were conducted using our targeting mAb and demonstrate uptake only in sites of primary and metastatic tumors, even at doses 20-fold higher than those that achieve maximal therapeutic activity, suggesting the potential to minimize the toxicity that has been observed with other 4-1BB agonists.

Conclusions: We have identified CTHRC1 as a novel proteoglycan expressed by both pathogenic CAFs and tumor cells that is highly selective for tumors, enabling the therapeutic targeting of immune activating payloads with the potential for safely delivering payloads while limiting toxicity. Given the specificity and selectivity afforded by CTHRC1 expression, ADC and CD3 engager approaches are also being pursued. These data represent novel approaches aimed at breaking down stromal barriers in tumors previously unresponsive to immunotherapies.

#2915 Targeting complement factor H renders STK11-mutant lung adenocarcinoma sensitive to anti-PD-1 therapy in mice.

S. Suzuki[1], A. Khan[1], T. Giridharan[1], C. Ting[1], R. Bushey[2], E. Gottlin[2], M. Campa[2], E. F. Patz[2], E. H. Yau[1], B. Segal[1];
[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Duke University Medical Center, Durham, NC

STK11 mutations occurs in 15-20% of lung adenocarcinoma (LUAD) and is associated with KRAS mutations, poor survival and resistance to immune checkpoint inhibitors (ICI). We observed tumor cell lines and primary human STK11-mutant LUAD upregulates of expression of C3 and complement factor H (FH). Deletion of C3 in STK11 knock-out tumor cells resulted in reduced FH expression. FH is a co-factor of Factor I, which converts C3b to proteolytically inactive iC3b thereby limiting activation of the alternative pathway (AP) C3 convertase. FH binds to proteoaminoglycans on the cell membrane and protects cells from AP complement-dependent cytotoxicity. With increased C3 generation by STK11-mutant tumor cells, we reasoned that systemic or tumor-derived FH protects tumor cells from complement attack. We hypothesized that tumor-derived C3 would promote STK11-mutant LUAD growth in immune intact mice by promoting immune evasion and would drive ICI resistance. Based on the expected tumor-protective effects of FH, we also hypothesized that anti-FH antibodies would control tumor growth and render tumor more sensitive to ICI. We evaluated growth of subcutaneously administered CMT167-STK11KO with and without C3 deletion (CMT167-STK11KO is murine $KRAS^{G12V}$ LUAD with CRISPR/Cas9 deletion of STK11). Deletion of C3 in CMT167-STK11KO (CMT167-STK11KO/C3KO) resulted in dramatic inhibition of tumor growth and in sensitivity to anti-PD-1 therapy *in vivo*. In contrast, deletion of C3 in STK11-KO tumors had no effect on tumor growth in nude mice or following CD8 depletion in WT mice. These findings support a role of tumor-derived C3 in evasion of T cell anti-tumor immunity and as an obstacle to anti-PD-1 therapy. GT103 is a therapeutic antibody that binds tumor cell-attached CFH, causes complement activation, kills tumor cells, initiates a shift from a pro- to an anti-tumor immune microenvironment, and is currently being evaluated in a Phase 1b-2 clinical trial in combination with pembrolizumab (NCT05617313). We observed that single agent GT103 or anti-PD-1 has limited efficacy in CMT167-STK11KO tumor in WT mice. However, the combination of GT103 and anti-PD-1 was very effective in limiting tumor growth. Our results support a role of tumor-derived C3 in suppressing CD8 T-cell immunity and in driving ICI resistance and that the addition of GT103 renders STK11-KO tumors sensitive to anti-PD-1 in mice. These studies establish rationale for evaluating this combination in patients with STK11-mutant LUAD.

#2916 Discoidin domain receptor 1 (DDR1) expression is associated with degree of immune exclusion across epithelial tumors.

X. Sher[1], F. D. Gootkind[1], T. Schurpf[1], F. Peyraud[2], J.-P. Guegan[3], A. Italiano[2], G. T. Clifton[1], **L. A. Dillon**[1];
[1]Incendia Therapeutics, Boston, MA, [2]Institut Bergonie, Bordeaux, France, [3]Explicyte Immuno-Oncology, Bordeaux, France

Background: Discoidin domain receptor 1 (DDR1) is highly expressed in epithelial cancers and has been implicated in tumor growth, invasion, and lack of response to therapy. DDR1 contributes to immune exclusion by promoting tumor collagen alignment in *in vivo* models. However, it is unclear how DDR1 expression impacts immune cell infiltration in human tumors. A first-in-human trial of PRTH-101, a DDR1-targeted therapeutic antibody, is underway. Establishing a correlation between DDR1 expression and immune infiltration in the tumor microenvironment (TME) will shed light on the role of DDR1 in the TME and inform indication and patient selection strategies for DDR1-targeted therapies.

Methods: Adjacent formalin fixed paraffin embedded slides from colorectal (CRC), non-small cell lung (NSCLC), ovarian (OC), pancreatic (PDAC), and triple-negative breast cancers (TNBC) were stained by H&E and a multiplex immunofluorescence (mIF) panel containing DDR1 and immune cell markers CD8 and CD45. Tumor-stromal segmentation and cell identification was done from H&E using AI-powered models developed by PathAI (PathExplore™) or from mIF by image analysis using QuPath. *DDR1* mRNA expression was measured by bulk RNA-sequencing, while DDR1 protein expression was measured by mIF. Immune Exclusion Scores (IESs) were calculated for each tumor based on lymphocyte density (from H&E), CD8+ T cell density (from mIF), or CD45+ cell density (from mIF). Each IES is the orthogonal distance between the coordinate of immune cell density in tumor epithelium and stroma, and the regression line representing equal density in epithelium and stroma. Correlations between lymphocyte, CD8, and CD45 IESs and DDR1 mRNA or protein expression levels were evaluated.

Results: Both DDR1 mRNA and protein expression levels were significantly correlated with all Immune Exclusion Scores (IESs) measured by the distribution of lymphocytes (H&E), CD8+, or CD45+ cells (mIF) in tumor epithelium and stroma (R: 0.31-0.55, adjusted p: <0.001-0.01) at a pan-cancer level. While the degree of the correlation varied between tumor indications by IES immune cell type, pancreatic cancer exhibited the strongest correlation between the lymphocyte-based IES and DDR1 mRNA and protein expression (R: 0.48-0.54, adjusted p: 0.04-0.07). *DDR1* mRNA was also moderately correlated with lymphocyte IES in NSCLC and TNBC (R: 0.37-0.48, adjusted p: 0.12-0.14).

Conclusions: We developed a continuous scoring method to quantify the degree of immune exclusion in tumors based on the spatial distributions of lymphocytes, CD8+ T cells, and CD45+ immune cells from H&E and mIF images. DDR1 mRNA and protein expression are correlated with immune exclusion at both the pan-cancer and specific indication level. This adds additional insight into the role of DDR1 in human cancers and may be useful in selecting indications and stratifying patients for DDR1-targeted therapies.

#2917 Purifying cancer-associated fibroblasts (CAFs) from glioblastoma and defining their role in therapeutic resistance.

A. Sati, A. Mathur, M. Lad, A. Saha, M. K. Aghi;
University of California San Francisco, San Francisco, CA

Glioblastoma (GBM), a challenging brain tumor, necessitates the development of new therapies due to poor patient prognoses, with a median survival of 14-16 months. Standard of care, as established almost 20 years ago, remains to be surgical resection followed by chemotherapy and radiation and till date there is no defined standard of care for recurrent GBM, highlighting the urgent need for the development of novel therapies. Recent studies have implicated the tumor microenvironment in these poor prognoses. While cancer associated fibroblasts (CAFs) are a key cellular component of the microenvironment of many systemic tumors, their presence in GBM had been doubted until we recently developed intriguing data identifying cells in GBM that express fibroblast markers, have fibroblast-like morphology, and, most importantly, transcriptomically resemble CAFs from systemic cancers rather than other stromal cells that express similar surface markers such as pericytes (Jain et al. 2023). Similar to other solid cancers, GBM CAFs increase tumor growth and drive immunosuppression. The role of CAFs in regulating these processes could have significant implications in response to standard of care therapy as well as novel immunotherapies. While our initial CAF isolation had just 50% purity, we have developed a novel flow-sorting algorithm for CAF enrichment driven by our bioinformatic data. Through this protocol, we have successfully established, the first of its kind, a biobank of patient derived GBM CAFs with greater than 90% purity. These CAFs are now being utilized to investigate their contribution in conferring resistance to chemotherapy (Temozolomide) and radiotherapy. The CAFs are also being assessed for their role in suppressing T cell function and resistance to immunotherapies. In parallel, the origin of GBM CAFs and their development trajectory is being analyzed to find molecular markers to specifically target CAFs in the GBM microenvironment. The work put together will provide insight on mechanisms employed by CAFs in altering the GBM microenvironment and a basis for developing novel combination approaches, alleviating therapeutic resistance caused due to the presence of CAFs in the GBM microenvironment. The results of this study have the potential to significantly attenuate therapeutic resistance in GBM and provide much needed treatment options and improvement in survival, for what remains one of the most dismal diagnoses in the clinic.

#2918 Potential for a novel therapeutic target: Effects of lactate & lactylation in expression of key regulatory cancer proteins.

Christos P. Costeas[1], Connor Purcell[2], Wafik S. El-Deiry[3]

[1]Warren Alpert Medical School, Legorreta Cancer Center at Brown University, Providence, RI,[2]Legorreta Cancer Center at Brown University, Providence, RI,[3]Pathology and Laboratory Medicine, Legorreta Cancer Center at Brown University, Warren Alpert Medical School, Providence, RI

The purpose of our study is to investigate the immunologic, metastatic, and gene regulation effects of lactate in the context of cancer in normoxic and hypoxic conditions to identify novel biomarkers and potential therapeutic targets. We aim to modify the in-vitro cancer microenvironment to show how lactate and lactylation can be exploited using existing cancer treatments. While hyperlactatemia is defined as lactate levels between 2 mmol/L and 4 mmol/L (Foucher et al 2023), tumor biopsies have demonstrated extracellular concentrations as high as 40 mM (Pérez-Tomás et al 2020). Through CTG viability assays we identified lactate concentrations that PANC1 cells can survive, which are in agreement with the in-vivo findings of Brizel et al (2001). We observed pancreatic cancer cells achieving over 50% viability for 5 days at 50 mM lactate concentrations while at 30 mM on day 5 they proliferated past their initial plating numbers. Furthermore, Brizel et al (2001) found that patients with high tumor lactate concentrations had a significantly higher incidence of metastatic relapse. Through our scratch assay, we show qualitative evidence of increased mobility and inferred migration potential of PANC1 at 7.5mM [lactate] compared to the absence of lactate. We have also observed increased migration at higher lactate concentrations for which we are pursuing quantitative measurements to evaluate significance. Migration experiments will be followed by the investigation of gene regulation (eg. mRNA seq, lactylation profile) involved in the observed increased mobility. Lactate has been shown to affect immune regulation, namely suppression of iNKT (Fu et al, 2020), macrophages (Yang et al, 2020), dendritic cell differentiation and antigen recognition/presentation (Wang et al, 2022), however not much is known about its effect on NK cells and their cytokine expression. Through NK92MI/PANC1 cocultures we show the effects of lactate concentration on the killing ability of NK cells (in the works). And plan on investigating the cytokine profile leading to the phenotypic killing differences. Lastly, via lactate-titrated incubation of PANC1 cells in normoxia we have demonstrated a positive correlation of HIF1a expression, pan-lactyllysine lactylation, and microenvironment lactate concentration. We speculate HIF1a inhibition post-lactate-sensitization may induce cancer killing and we will investigate this theory in normoxia and hypoxia using existing treatment options.

#2919 Targeting regulatory T cells to boost immunity against melanoma.

W. Miao[1], Y. J. Jin[1], V. Jain[2], S. Gregory[2], J. Y. Zhang[1];
[1]Duke University Medical Center, Durham, NC, [2]Duke university, Durham, NC

Tumor-infiltrated regulatory T-cells (Treg) restrict the function of effector T-cells and thereby promote tumor growth. Disrupting the immunosuppression of Treg cells presents an attractive strategy for cancer immunotherapy; However, the risk of autoimmunity, resulting from systemic Treg depletion, limits its therapeutic effectiveness. Here, we show that genetic depletion of Ube2n in Treg cells inhibits tumor growth which is correlated with a markedly enhanced infiltration of cytotoxic immune cells. Notably, the deletion of Ube2n in a fraction of Treg cells was sufficient to produce a long-lasting anti-tumor effect, without apparent systemic autoimmune responses. The antitumor effect persists following adoptive T-cell transfer to an otherwise immunodeficient mouse tumor model. Through flow cytometry, immunostaining and T-cell targeted single-cell sequencing analyses, we demonstrate that the loss of Ube2n dampens Treg suppressive function, as indicated by markedly increased numbers of cytotoxic CD8 T-cells in the tumor microenvironment (TME). Further, differentially expressed genes analyses show a downregulation of Mki67 and an upregulation of Ifng in Ube2n deficient Tregs, concomitant with amplification and activation of effector T-cells. Our findings uncover a hitherto unexplored role of Ube2n in orchestrating the differentiation and functions of Treg in TME, highlighting the therapeutic potential of targeting this pathway to enhance and reprogram anti-tumor immunity.

#2920 *In vitro* assays for investigating the effects of cancer therapeutics on bone.

J. H. E. Maki-Jouppila, M. Ristola, J. Rissanen, **K. Fagerlund**;
Pharmatest Services Ltd., Turku, Finland

Bone microenvironment is an important factor in regulating bone metastasis. When cancer cells home to bone they secrete factors that stimulate osteoclast activity leading to increased bone resorption. Stimulatory factors released from the resorbed bone matrix in turn promote proliferation of cancer cells and this process, referred as the vicious cycle, often leads to osteolytic lesions in bone when osteoclastic bone resorption exceeds osteoblastic bone formation. The vicious cycle observed in osteolytic disease occurs also in osteoblastic metastases, and in addition cancer cells produce osteoblast-stimulating factors. Cancers with bone metastases often include both osteolytic and osteoblastic lesions. Our aim was to establish *in vitro* cell culture models to study the effects of cancer therapeutics on osteoblast and osteoclast differentiation and activity. In the osteoclast differentiation assay, human osteoclast precursor cells (Lonza) were cultured on bovine bone slices for 7 days. Denosumab was added in the cultures at day 0, and tartrate-resistant acid phosphatase isoform 5b (TRACP 5b) activity was measured from the culture medium collected at day 7. Osteoclast activity was studied by allowing osteoclasts resorb bone after 7 days' maturation period for additional 3 days in the presence of odanacatib. The amount of C-terminal cross-linked telopeptides of type I collagen (CTX-I) was measured in the culture medium collected at day 10 to quantitate osteoclast activity. Denosumab and odanacatib showed strong concentration dependent inhibition of osteoclast differentiation and activity, respectively. A mouse osteoblast progenitor cell line KS483 (Pharmatest Services) was used to study differentiation and activity of osteoblasts with test compounds bone morphogenetic protein 2 (BMP-2) and estradiol (E2). In the osteoblast differentiation assay, the activity of cellular alkaline phosphatase (ALP), a marker of osteoblast differentiation, was measured at day 8. In the osteoblast activity assay, the cells were cultured for 13 days. N-terminal propeptide of type I procollagen (PINP) secreted into the culture medium was determined at day 11 to indicate the effects on organic bone formation and calcium deposition was determined at the end of the study as a marker of inorganic bone formation. BMP-2 and E2 stimulated osteoblast differentiation and activity indicated by the increase in ALP activity, PINP and calcium levels. We conclude that these culture systems can be used for studying the effects of cancer therapeutics and identifying new potential compounds affecting the disease process of bone metastases with different mechanisms of action.

#2921 Extended treatment with IAP inhibitor xevinapant post radiotherapy improves therapeutic efficacy and promotes antitumor immunity in preclinical models.

T.-L. Yeung[1], F. Jiang[1], H. Huang[1], H. Yu[1], L.-Y. Chiu[1], M. Bonnemaison[1], B. Marelli[1], R. Ferretti[1], R. Lindemann[2], C. Esdar[2];
[1]EMD Serono, Billerica, MA, [2]The Healthcare Business of Merck KGaA, Darmstadt, Germany

Background: Xevinapant is a first-in-class, oral IAP (inhibitor of apoptosis protein) inhibitor designed to restore cancer cell sensitivity to apoptosis induced by radiotherapy (RT) and chemotherapy. In a randomized phase 2 study of patients with unresected locally advanced squamous cell carcinoma of the head and neck, xevinapant + chemoradiotherapy (CRT) significantly improved locoregional control at 18 months, 3-year progression-free survival and nearly doubled 5-year overall survival vs. placebo + CRT (53% vs. 28%). Two phase 3 trials, in which patients receive 6 cycles of xevinapant or placebo monotherapy (3 cycles in combination with standard-of-care (C)RT followed by 3 cycles of monotherapy), are ongoing. Based on the roles of IAPs in apoptosis and tumor immunity, continual dosing of xevinapant post RT may deliver additional therapeutic benefit through modulation of multiple tumor microenvironment (TME) compartments. Methods: The impact on antitumor efficacy of xevinapant dosing duration was evaluated in A1419 (head and neck), LLC (lung) and MC38 (colorectal) syngeneic tumor-bearing mice treated with vehicle control, RT alone (3.6Gy, QD, 5 days), or RT + xevinapant (100 mg/kg, QD, 1, 2, or 4 weeks). To assess treatment-mediated TME modulation in MC38 tumors, RNAseq and FACS-based immune profiling was performed, followed by functional validation with ex vivo ELISpot assays, in vitro immunogenic cell death assays, T cell activation assays, and macrophage polarization and viability assays. To evaluate the effect of xevinapant on RT-induced cancer associated fibroblast (CAF) activation and CAF-modulated immune phenotype, activation assay and cytokine profiling was performed. Results: In the tumor models tested, RT in combination with extended xevinapant dosing markedly improved efficacy and prolonged survival compared to treatment arms of RT with shorter xevinapant dosing durations, RT alone, and vehicle control. RNAseq and FACS analyses suggested a TME with enhanced antitumor immunity, while ELISpot and in vitro T cell assays confirmed that extended xevinapant dosing promoted antigen-specific T cell response and T cell activation. Furthermore, macrophage polarization and viability assays suggested that xevinapant reduced the viability of M2 macrophages which may have contributed to the increased M1:M2 macrophage ratio and the improved antitumor immune response observed in vivo. In addition, via the suppression of RT-mediated CAF activation, xevinapant may promote M1 polarization of macrophages and recruitment of T cells by upregulating GM-CSF and CXCL10 in CAFs. Conclusions: Extended dosing of xevinapant post concurrent RT improved antitumor efficacy and prolonged survival of tumor-bearing mice. Mechanistic investigation suggested that such benefit may be, in part, modulated by xevinapant enhanced antitumor immunity.

#2922 Sensory innervation as a novel driver of ovarian cancer progression.

M. Knarr[1], K. Cummins[1], D. Racordon[1], H. Reavis[1], T. Lippert[1], R. Hausler[1], P. Rawat[1], S. Ryu[2], J. Moon[2], D. Hoon[2], R. Greenberg[1], P. Vermeer[3], R. Drapkin[1],

[1]Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA, [2]Saint John's Cancer Institute, Santa Monica, CA, [3]Sanford Research Institute, Sioux Falls, SD

One of the main challenges currently faced in ovarian cancer treatment is that the primary platinum/taxane therapy used to treat patients does not meaningfully extend survival. The overall survival for ovarian cancer patients with advanced disease is less than 30% with most patients recurring within 5 years of initial therapy. Once resistant disease develops there are few second line therapy options, which inevitably leads to disease progression. Thus, there is a critical need to identify new therapies that can overcome ovarian cancer chemoresistance and produce meaningful increases in patient survival. In recent years, new efforts have focused on targeting the tumor microenvironment (TME), the complex mixture of non-cancer cells that surround and support the cancer cells within the tumor. Different strategies have evolved to target the TME, such as immune checkpoint inhibitors or angiogenesis inhibitors. However, these TME targeting therapies have limited effect when used to treat ovarian cancer patients. Most ovarian tumors have a microenvironment that is highly immunosuppressive and do not respond or are resistant to angiogenesis inhibitors. Thus, new TME targeting therapies must be developed that can induce a therapeutic effect in ovarian tumors and can be used to treat most ovarian cancer patients. A novel TME component ripe for therapeutic targeting are the nerve fibers that infiltrate tumors in a process termed tumor innervation. Recent studies in several cancers have shown that tumor innervation can promote tumor growth/metastasis. However, in ovarian cancer the role of innervation in promoting cancer progression remains undefined. Here we show that Transient Receptor Potential cation channel subfamily V member 1 (TRPV1)+ sensory innervation plays a significant role in driving ovarian cancer growth and metastasis. Analysis of patient samples shows that sensory nerve fiber innervation is much higher in ovarian tumors vs benign reproductive tissue. In addition, ablation of TRPV1 sensory nerve fibers in vivo causes reduced tumor burden and prolongs survival in a syngeneic mouse model of ovarian cancer metastasis. Taken together, our results establish TRPV1+ sensory innervation as a novel driver of ovarian cancer growth/metastasis and a potential therapeutic target for ovarian cancer treatment.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Advances in Genomic Sequencing Platforms, Methodologies, and Interpretation 2
Poster Session

#2926 The effect of cancer research autopsy parameters on DNA and RNA sequencing quality.

P. Fessas[1], S. Hessey[1], C. Richard[1], C. Naceur-Lombardelli[1], S. Ward[1], D. A. Moore[1], K. Nowakowska[2], B. Trujillo[2], I. Lobon[3], S. T. C. Shepherd[3], F. Byrne[3], S. Turajlic[3], G. Attard[2], C. Swanton[4], M. Jamal-Hanjani[1];

[1]University College London Cancer Institute, London, United Kingdom, [2]University College London, London, United Kingdom, [3]The Francis Crick Institute, London, United Kingdom, [4]Cancer Evolution and Genome Instability Laboratory, London, United Kingdom

Background: Cancer research autopsy genomic studies offer insight into the metastatic cancer landscape but come with complexities that relate to the sampling and processing of post-mortem tissue. Clarifying the effect of autopsy variables on pre- and post-sequencing quality control (QC) is an unmet need that may inform tissue collection strategies.

Methods: The effect of age, sex, post-mortem interval (PMI), and sample type (primary, metastatic, or normal) on pre-sequencing QC (nucleic acid concentration and integrity) was examined in 2678 samples (88.6% metastatic, 8.0% primary, 3.4% normal) from 83 patients with melanoma, lung, renal, or prostate cancer in the PEACE study. In the lung cohort, 160 surgical samples were also included through the TRACERx study, allowing surgery-autopsy tissue comparisons. Post-sequencing QC metrics were evaluated for lung samples that underwent DNA (n=522) or RNA (n=366) sequencing.

Results: RNA concentration and RIN were greater in surgical samples than those collected at autopsy. Across cohorts, metastatic autopsy samples had greater nucleic acid concentrations than primary or normal autopsy samples, but not integrity. DNA and RNA concentration and integrity differed significantly between primary tumor types. When comparing samples of different metastatic sites from the whole cohort, concentration was lowest in bone (DNA) or the digestive tract (RNA), while integrity was greatest in the brain and lowest in the digestive tract (DIN, RIN). Although autopsy variables like age, sex and PMI correlated with pre-sequencing QC metrics in univariate analysis, they were not found to significantly correlate with these metrics in multivariate analysis, which identified that only primary cancer type and metastatic site were independent determinants of concentration and integrity. Similarly, for post-DNA (whole exome) sequencing QC, only the metastatic site was found to independently influence sequencing QC metrics like total number of sequences, average sequence length, and FastQC score. For RNA sequencing, only the metastatic site was found to influence sequencing QC metrics like total number of sequences, percentage of non-duplicated sequences, one hit-one genome percentage, and the alignment percentage on the human genome.

Discussion: The lack of influence of PMI on QC in the largest QC-focused autopsy cancer study to date suggests that quality tissue can be obtained from non-rapid autopsy programs, which are more feasible and less resource-intensive than rapid programs.

#2927 Optimization of sample preparation for single-cell RNA-sequencing using accumulated collection of preclinical and clinical specimens.

K. Lim[1], J. Lee[2], K.-H. Pyo[3], B. Cho[4];

[1]JEUK Institute for Cancer Research, JEUK Co., Ltd, Gumi, Korea, Republic of, [2]Department of Research Support, Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: The heterogeneity of tumors became apparent with the introduction of single-cell RNA-sequencing technology, enabling the discovery of rare and novel cell types that were not attainable with bulk RNA-sequencing. Numerous papers have been published, and the data from single-cell RNA-sequencing are publicly available. While current literatures provide detailed guidance on effectively analyzing single-cell RNA sequencing data, documentation for sample preparations is less frequently reported in easily accessible protocols. Additionally, researchers hold diverse opinions on sample handling and practical information is scattered across multiple sources.

Method: A total of 233 cases were included in the study, comprising 150 cases of clinical and 83 cases of preclinical samples. Among the 150 clinical samples, 58 were freshly obtained (32 biopsies and 26 surgical resections), and 92 were frozen. Of the 83 preclinical samples, 70 were fresh, and 13 were frozen. Sample preparations for 10X Genomics Chromium single-cell RNA-sequencing were carried out using the methods of 'Red blood cell lysis', 'Straining', and 'Dead cell removal using magnetic beads' with clinical specimens. Each method was applied based on specific situations involving the presence of red blood cells, cell aggregates, dead cells and debris.

Results: There was a variation in the usage of red blood cell lysis, straining, and dead cell removal methods across different sample types. Specifically, 40.6% of clinical biopsy samples were primarily conducted with red blood cell lysis and/or straining without the removal of dead cells. Whereas, 96.2% of clinical surgical resections and 100% of clinical frozen samples predominantly utilized dead cell removal. The frequency of a double application of dead cell removal was higher in frozen samples, at 34.8% due to low viability as expected. For surgical resections, in comparison, only 15.4% required a second round of dead cell removal. In preclinical samples, both fresh and frozen, removal of dead cells was essential and implemented in 100% of cases. Among these, 62.9% of the fresh preclinical samples and 76.9% of the frozen preclinical samples underwent a second round of dead cell removal.

Conclusions: The utilization of the methods red blood cell lysis, straining, and dead cell removal proved to be adequate in meeting the stipulated criteria of the 10x Genomics guidelines, demonstrating efficiency in terms of time. We have outlined a workflow for each sample type, accompanied by images illustrating pre- and post-conditions for plausible occurrences. Additionally, approximate cell numbers required, or percentages of cell loss are provided for each situation. We anticipate that this protocol will be beneficial for those new to the field, enabling them to generate samples for single-cell RNA-sequencing independently.

#2928 Solving the cancer mutation conundrum: A single cell, massively parallel approach for cancer mutation discovery, genome modelling and functional characterization.

S. M. Grimes, H. Kim, S. Roy, A. Sathe, B. T. Lau, **H. P. Ji**;
Stanford University, Stanford, CA

Large scale genomic studies are cataloguing tens of thousands of cancer mutations across a wide spectrum of tumor types. Conventional DNA sequencing methods have limitations in terms of identify mutations at high resolution among single cells. Moreover, determining cancer mutations' phenotype and function remains an enormous challenge - most mutations are assigned to the category of variants of unknown significance. In-silico functional predictions of cancer mutations are frequently used as a stopgap solution. However, these computational methods lack the ability to make refined biological and functional predictions. We demonstrated a new single cell experimental strategy that accelerates the discovery of cancer mutations and their characterization. This genomic technology framework does the following: (1) identify disease-related mutations at the resolution of individual cells from tumors or cell lines; (2) genome engineer these candidate mutations into cellular experimental systems for further biological characterization. First, we developed a single cell approach to identify cancer somatic mutations and even gene fusion rearrangements found in coding regions of mRNAs. Primary tumors are processed into single cell RNA-seq libraries and analyzed with nanopore long read sequencing. Across thousands of cells from primary tumors, we identified single cell mutations from the nanopore long reads that covered cancer gene transcripts. This approach allows us to even identify cancer rearrangements at single cell resolution. Next, we used short-read single cell transcriptomes to characterize the cell type and determine the gene expression characteristics of those cells with mutations. For single cell phenotypic studies, we developed a highly multiplexed technology using CRISPR base editors to directly engineer hundreds of mutations into their original genes among single cells and determine their transcriptional phenotype. Among specific individual cells, nanopore-based long-read sequencing identifies these modelled mutations directly from a target's transcript sequence. Then, we integrate this single cell mutation data with the short-read transcriptome profile from the same individual cell. Therefore, we determine both the genotype and phenotype of a given engineered mutation from an individual cell. In summary, our work demonstrates a new, direct and highly scalable method for identifying, modelling and functionally assessing cancer mutation phenotype at single cell resolution. This approach enables the broader assessment of cancer mutations impact on tumor biology and clinical ramifications.

#2929 Multiplexed somatic genome editing to model and investigate advanced colorectal cancer.

M. Mastel[1], R. Jackstadt[1], J. Meier[2], G. Diamante[1];

[1]DKFZ German Cancer Research Center, Heidelberg, Germany, [2]Heidelberg Institute for Stem Cell Technologies and Experimental Medicine, Heidelberg, Germany

Colorectal cancer (CRC) is among the deadliest cancers worldwide, with advanced CRC being the leading cause of death. For the development of novel therapy options, it is crucial to investigate mechanisms of advanced CRC in a bona fide way. However, little is known about the impact of distinct genomic alterations on cancer progression. The assessment of the function and role of the putative drivers in tumor progression via sequencing data remains challenging, due to the complexity and possible combinations of the candidates. Hence, genetically engineered mouse models (GEMMs) represent the mainstay for the investigation of the role of oncogenes and tumor suppressor genes in cancer progression. However, particularly in CRC, they are limited by imprecise modeling of cancer-associated changes, challenging scalability, and development of tumors in anatomically incorrect places. To tackle these issues, we developed SOmatic CRISPR-mediated genome Alterations of Tumor suppressors with Exploratory single cell Sequencing (SOCRATES) to analyze advanced CRC. We multiplexed CRISPR-Cas systems, packaged them into lentiviral particles, and delivered them to enterocytes via colonoscopy-guided submucosal injection. With this innovative approach, SOCRATES enables rapid and direct *in vivo* genome engineering for the modeling of advanced CRC with distinct mutational patterns and the investigation of the cancer cell states and tumor microenvironment (TME) upon editing the genes of interest. Similar to the Greek philosopher Socrates, who established a form of argumentized dialogue between individuals, SOCRATES facilitates the understanding of previously undiscovered communication between cancer cells and TME. We analyzed the influence of the most recurrent tumor suppressor mutations (*Fbxw7, Ptprt, Arid1a, Atrx, Atm, Smad4, Pten*) on the cancer cell state and TME in advanced CRC. Further, we created a TS-TME interaction atlas and revealed novel mechanistic insights into how the TS mutations rewire cell states and cell-cell communications. With this generated knowledge, SOCRATES will contribute to our understanding of complex tumor ecosystems and foster the improvement of diagnostic and therapeutic approaches.

#2930 Recovery of limited viable cells from low-quality precious samples for scRNA-seq.

Camila Egidio, Dinesh Bhosale, Lanxin Shen, Susana Jett, Amir Malek, Teddy de Groot, Suzanne Weaver, Gang Sun, **Josh Mahlios**, Kevin Travers, Geoff Facer

LevitasBio, Menlo Park, CA

Biomarker discovery is a critical milestone in pursuing personalized and targeted cancer treatments, yet it faces formidable challenges hindering success rates. Limited access to high-quality samples restricts in-depth biological investigation, with scarce and compromised viable cells acting as barriers to progress. Levitation Technology™ addresses these challenges by significantly improving sample quality and preserving maximum viable cells for single-cell RNA sequencing (scRNA-seq). This innovative approach overcomes limitations in sample quality and availability and heralds a new era of possibilities, propelling significant advancements in biomarker discovery for personalized cancer treatment.

To assess the performance of Levitation Technology using the LeviCell® 1.0 system, 105 cryopreserved samples derived from diseased human tissues were processed by Discovery Life Sciences™. This diverse sample set covered 20 disease indications, including 17 types of cancer. A staggering 70% of the samples (n=74) exhibited cell viability ranging between 14-69%, underscoring the need for enhanced viability for effective scRNA-seq analysis. Notably, 45 of these samples presented fewer than 500,000 cells, a scenario marked by low quality and limited viable cells. Traditional methods fail to recover viable cells from such samples without considerable or complete viable cell loss. After processing the samples with the LeviCell 1.0 system, all samples had improved quality, with an impressive 90% of the most difficult samples (n=40) presenting a viability increase to 70-94%, meeting the minimum quality criteria for scRNA-seq. A notable success story was a particular breast cancer sample with only 31,000 cells and 14% viability. Processing with the LeviCell 1.0 system yielded 13,300 viable cells and a substantial 4.5-fold increase in viability to 64%. Such enhancements in sample quality translate into significant improvements in scRNA-seq data quality, enabling more single-cell data extraction from each invaluable sample.

Levitation Technology represents a paradigm shift in sample processing, rescuing even the most challenging samples. This groundbreaking technology maximizes the retention of viable cells while efficiently eliminating dead cells and debris, factors that have traditionally compromised scRNA-seq data quality. By revolutionizing this aspect of sample preparation, Levitation Technology opens up unparalleled opportunities to explore deeper into disease biology, providing a leap forward in biomarker discovery.

#2931 Utilizing an extracellular matrix-embedded 3D tumor model of NSCLC to identify novel cancer dependencies via genome-scale CRISPR screen.

Pranay Agarwal, Soon Youn Choi, Xin Liu, Jina Song, Maya Tureez, Un Jae Baek, Aashka Mehta, Kyuho Han, Hong-Pyo Lee

MEDiC Life Sciences Inc., Mountain View, CA

INTRODUCTION: Non-small cell lung cancer (NSCLC) is a prevalent and deadly cancer type. Despite advances in targeted therapies in NSCLC, one-third of adenocarcinomas lack actionable oncogenes, limiting targeted therapy options. To address these challenges, CRISPR screening has emerged as a tool to unveil cancer dependencies. However, current genome-scale studies rely heavily on 2D monolayer cancer models that fail to replicate in vivo tumor biology due to altered gene/protein expressions, absence of cell-extracellular matrix (ECM) signaling, and rewired metabolic pathways. To overcome these limitations, we developed a high-throughput 3D extracellular matrix (ECM) based hydrogel culture platform suitable for conducting genome-scale CRISPR screening. Leveraging this platform, we performed genome-wide CRISPR loss of function screens in 3D tumor models in ECM (3D-ECM). These results were compared with the screening outcomes from 3D cultured cells lacking an extracellular matrix (3D-spheroids) and traditional 2D monolayer (2D-monolayer) cells to identify new genes that might be crucial in driving NSCLC tumor cells.

METHODS: Three NSCLC cell lines (NCI-H358, PC-9, and EKVX) were utilized for CRISPR screens. A genome-wide CRISPR library containing 60,000 sgRNAs targeting 20,000 genes was prepared. To create genome-scale 3D tumor models in ECM, cells were encapsulated in sub-millimeter microcapsules made of alginate and an extracellular matrix protein-hydrogel mix. Encapsulated cells were cultured for up to 4 weeks. 3D-spheroids were cultured on ultra-low attachment plates in viscous growth media and split every 3-4 days over 4 weeks.

RESULTS: Cancer cells' proliferation and metabolic activity notably increased in 3D-ECM compared to 3D-spheroids. The CRISPR screens in 3D-spheroids and 3D-ECM revealed numerous positive growth phenotypes in contrast to the conventional 2D monolayer culture model. Specifically, we found 79 additional genes exhibiting positive-growth phenotype in 3D-ECM. Moreover, prominent oncogenic drivers, such as KRAS and EGFR were ranked considerably higher in both 3D-ECM and 3D-Spheroids compared to the 2D-monolayer. Interestingly, the pathway-enrichment analysis revealed that Notch signaling (CREBBP, EP300, APH1A), FoxO signaling (STK11, TGFBR2, MAPK14), and Citrate cycle signaling (MDH2, SDHC, PDHA1) were enriched in 3D-ECM when compared to 3D-spheroids.

CONCLUSION: Our results reveal significant distinctions between the 2D monolayer model, the 3D spheroid model lacking extracellular matrix, and the 3D tumor model incorporating ECM. These differences underscore the importance of conducting CRISPR screens with 3D tumor models within the extracellular matrix to unveil novel cancer dependencies.

#2932 Computational discovery of paralog dependencies drives target identification in lung cancer.

S. O'Brien, A. H. Berger;
Fred Hutchinson Cancer Center, Seattle, WA

Lung cancer is the leading cause of cancer-related death in the United States, and worldwide, with the 5-year survival rate of non-small cell lung cancer at 24%. Treatment options are limited, and even in cancers that harbor druggable biomarkers, resistance is near-universal. Identifying novel treatment strategies is essential to improve the outcomes of patients with lung cancer and provide secondary strategies for those who acquire resistance to first-line therapeutics. Identifying targeted therapies based on the genotype or expression pattern of cancers is an ongoing endeavor. In lung cancer, treatment of patients that harbor activating mutations in EGFR with specific EGFR inhibitors has improved progression-free survival rates and extended the lifespan of patients diagnosed with this aggressive cancer, demonstrating the utility of targeted therapies based genetic-based vulnerabilities, or synthetic lethal interactions. A rich source of synthetic lethal genetic interactions are paralogous genes. Paralogs result from gene duplication events through evolutionary history, and many paralogs share both sequence homology and functional redundancy. Co-targeting of some paralogous genes induces a fitness defect that is synergistic compared to individual paralog loss alone. Nearly 70% of genes in the human genome are considered paralogs, and until recent efforts from the Berger lab and others, this buffering effect has caused them to be under-represented in lethality studies. Identifying frequently-inactivated paralog genes in lung cancer will provide a platform to identify new vulnerabilities in lung cancer and other cancer types that share mutational backgrounds. To identify patterns of mutation and expression of paralog genes in lung cancer, we have accessed publicly available data sets for both cell line and patient tumor samples. Using TCGA and CCLE data sources, and a set of 1030 paralog pairs identified previously by the Berger lab as potential drug targets, we have identified paralog genes that harbor high mutational frequencies in lung cancer. Using these candidates, we next asked whether genetic inactivation or transcriptional repression of one paralog influences the essentiality of its paired gene using CERES scores generated by the Cancer Dependency Map. Preliminary results identifies several paralog pairs with distinct dependency profiles in cell lines for which expression of one paralog is lost, including *MAGOH/MAGOHB* and *TLK1/TLK2*. Further work to characterize these dependencies in relevant cell line models is ongoing. Additionally, the druggability of these targets will be tested using targeted degradation using the dTAG system. This work will uncover a new set of paralog synthetic lethality targets, and further validate the utility of targeting known synthetic lethal paralogs for the treatment of highly lethal lung cancer.

#2933 Use of artificial intelligence to facilitate reporting of comprehensive genomic profiling tests.

H. Kage[1], T. Aoki[2], A. Shinozaki-Ushiku[1], K. Watanabe[1], N. Akiyama[1], H. Isago[1], M. Ogawa[1], K. Ishigaki[1], H. Kobayashi[1], T. Miyagawa[1], J. Omatsu[1], Y. Saito[1], K. Sasaki[1], Y. Sato[1], Y. Sato[1], N. Suzuki[1], S. Tanaka[1], M. Kato[1], M. Tanabe[1], K. Tatsuno[3], T. Ushiku[1], K. Nishimura[2], H. Aburatani[3], K. Oda[1];
[1]The University of Tokyo Hospital, Tokyo, Japan, [2]Xcoo, Inc., Tokyo, Japan, [3]The University of Tokyo, Tokyo, Japan

Background: Comprehensive genomic profiling (CGP) tests have been nationally reimbursed in Japan since 2019, and all test results must be discussed by molecular tumor boards (MTBs). More than 60,000 patients have taken the CGP tests at over 200 government-designated hospitals by November 2023. Streamlining decision-making by MTBs and standardizing interpretation of test results is important. We evaluated the performance of Chrovis, an annotation algorithm for reporting CGP tests.
Methods: We retrospectively reviewed the reporting process of all approved CGP tests done at The University of Tokyo Hospital and its 12 affiliated hospitals between December 2019 and November 2023. Chrovis referenced several public knowledge databases and used natural language processing to annotate each genetic variant and generated reports using the automated program. The MTB reviewed all reports with the addition of clinical information and made any necessary changes Recommendations on disclosure of germline findings were made in accordance with the national guideline.
Results: Among the 2,819 Chrovis reports created, 1,927 were tumor-only FoundationOne CDx (F1CDx), 483 were tumor/normal paired NCC Oncopanel (NOP), and 409 were FoundationOne Liquid CDx (F1Liquid) panels. Among them, 603 changes in 496 reports (17.6% of all reports) were made by the MTB. The most common type of change was germline disclosure with 208 changes (7.4%), followed by clinical trial information (196 changes, 7.0%) and pathogenicity (107 changes, 3.8%). Gene alterations that led to most changes in germline disclosure were *TP53*, *SMAD4, CDKN2A, TERT*, and *NF2* (42, 22, 16, 13, and 13 changes, respectively). Changes in clinical trial information were frequently observed in *TP53*, *NF1*, *BRAF*, *ERBB2*, and *KRAS* (25, 20, 19, 16, and 16 changes, respectively). F1CDx required the greatest number of changes (404/1927, 21.0%) followed by F1Liquid (53/409, 13.0%) and NOP (39/483, 8.1%) ($p < 0.001$). Changes to germline disclosure were made in 9.1% of F1CDx reports, 5.4% of F1Liquid reports, and 2.1% of NOP reports ($p < 0.001$). Changes to clinical trial information were made in 8.3%, 4.4%, and 3.9%, respectively ($p < 0.001$).
Conclusions: Chrovis-generated CGP reports did not require any changes in 82%s, suggesting that artificial intelligence reporting may lessen the burden of MTBs while contributing to its standardization. Recommendation for germline disclosure requires manual supervision, and improvements in clinical trial databases are required to correctly recommend genomically matched trials to patients.

#2934 Somatic variant workflow with HiFi sequencing provides new insights in highly challenging cancer cases.

K. Chua[1], I. McLaughlin[1], O. Hofmann[2], K. P. Stewart[2], P. Baybayan[1], J. Bibliowicz[1], S. Grimmond[2], Z. Kronenberg[1], M. A. Eberle[1];
[1]PacBio, Menlo Park, CA, [2]University of Melbourne, Melbourne, Australia

Tumor evolution is a highly heterogeneous process where multiple oncogenic pathways can lead to host defense evasion. Advancements in genome sequencing are allowing us to better understand these processes and their impact. However, critical genomic variations that could be pivotal to the development of tumors may have remained undetected due to technological constraints of short-read sequencing. PacBio HiFi sequencing generates accurate (>99.9%) long reads (>15 kb) with native 5-methylcytosine information that can comprehensively delineate many variations, including ones which were previously inaccessible with short-read sequencing. Unlike standard whole-genome analysis, cancer variant calling must account for somatic variation, where the assumptions of a diploid genome are violated. We have developed and optimized a bioinformatics workflow for somatic variant detection with HiFi sequence data. To validate this pipeline, we sequenced two well-studied cancer cell lines (COLO829, HCC1395) to 60-fold depth and their matched normal lymphoblast cells (40-fold to 60-fold depth) and called all classes of variations (SNVs, INDELS, and structural variants). Next, we compared our calls against the Valle-Inclan (structural variants) and SEQC2 (small variants : SNV/INDEL) datasets. We achieved 92% F1 score for small variants across all variant allele frequencies (VAF) in the HCC1395 experiment. We observed a maintained accuracy (F1=91%) even at lower variant frequencies (10-20), highlighting the ability of HiFi sequencing to detect subclonal mutations. The workflow calls structural variants with high sensitivity, capturing 57/62 (92%) of all previously validated SVs in COLO829 at all VAF. Lastly, we applied our pipeline to five diverse tumor samples that exhibit complex oncogenic phenotypes including homologous recombination deficiency (HRD) and high genomic instability, e.g. unresolved rearrangement breakpoints in repetitive regions and unknown oncogenic drivers when prior sequencing efforts did not provide full clarity as to the molecular drivers of tumorigenesis. Notably, we were able to identify and phase 5mC methylation of promoters together with large-scale structural variants in cancer genes involved in HRD. Taken together, we demonstrated the high accuracy of HiFi reads in resolving somatic variants and its potential to provide novel insights in complex cancer samples. The ability for long reads to resolve complex genomics aberrations and epigenetic markers that underly the tumorigenesis process will become indispensable in the realm of precision oncology.

#2935 NGS panel customization for comprehensive genomic profiling.

M. Ruvolo, A. Khare, N. Matcha-Balaguruvappa, K. Wilkins, L. Forsmark, S. Gupta;
Agilent Technologies, Santa Clara, CA

Introduction: We have developed a custom SureSelect Cancer design pipeline for the creation of target enrichment gene panels for comprehensive profiling of single nucleotide variations (SNP/INDEL), gene-level copy number variations (CNV), and DNA translocations (TL) as well as content for measuring of microsatellite instability (MSI) and tumor mutational burden (TMB).

Methods: The performance of individual probes was measured for the 679-gene SureSelect Cancer CGP panel and the information used to generate a reference database. When creating a new design, the gene list is cross-referenced with the database and when applicable, the probe information is applied to the new design. If genes are included in the custom design that are not present in the database, a second design algorithm selects the optimal probe based on its sequence characteristics (% GC, homology, etc.). Content is selected based on the biomarker to be measured and can be defined based on gene name (SNV/indel and CNV) or genomic coordinates (SNV/indel, TL). Pre-defined content for MSI measurement can be added to any design to cover 288 microsatellite sites. The performance of these sites in determining MSI status was demonstrated by comparing to the MSI-PCR reference method. To assess the performance of the design methodology, designs of various sizes (50 to 650+ genes) and content type were generated and assayed on reference samples and FFPE with known biomarkers. Sequencing metrics were evaluated for capture specificity and coverage of the target regions.

Results: The design methodology allowed for sub-selection of content present in the 679-gene SureSelect Cancer CGP assay as well as addition of de-novo content. The design algorithm uses empirical data on probe performance to provide robust and reproducible results for the range of supported design sizes. Biomarkers were reliably detected with SNV detection down to 1% allele frequency, detection of gene amplifications and translocations concordant with FISH, and MSI and TMB determination concordant with PCR and Exome sequencing respectively. The design workspace was implemented in the SureDesign platform, providing a web-based interface for creating the designs.

Conclusions: We demonstrated full customization capability of the SureSelect Cancer target enrichment platform that pairs user-defined content with an optimized probe design methodology to enable the sensitive detection of the common types of DNA alterations found in FFPE samples.

#2936 Nanopore adaptive sampling detects nucleotide variants and improves large scale rearrangement characterization for diagnosis of cancer predisposition.

S. Chevrier[1], C. Richard[1], M. Mille[2], D. Bertrand[2], M. Blum[2], N. Philippe[2], **R. Boidot**[1];
[1]Ctr. Georges-Francois Leclerc, Dijon, France, [2]SeqOne Genomics, Montpellier, France

Molecular diagnosis has become highly significant for patient management. Facing new challenges to generate more comprehensive data in reduced time and cost, we tested Nanopore (ONT) adaptive sampling to analyze a gene panel for germline predisposition to cancer.
We tested 30 clinical germline samples carrying known alterations on BRCA1, BRCA2, PALB2 and MLH1 genes to detect large scale rearrangements (LSR) and single nucleotide variants (SNV). We used adaptive sampling to enrich the full sequence (from promoters to 3'UTR) of 152 cancer predisposition genes on ONT R10.4.1 MinION flowcells and the Q20 chemistry. The analysis was performed using the long-read bioinformatics pipeline developed by SeqOne Genomics. We observed a mean enrichment of 7.85 (3.91-9.85) and a mean coverage on target genes of 14.73X (4.71-35).
In our cohort, 11 samples had LSR that were all detected with ONT sequencing. In addition to perfectly detect the locus of the LSR (starts and stops always in intronic regions), we discovered that a known MLPA amplification of exon 13 in the BRCA1 gene was in fact an amplification of both exons 12 and 13. This 2-exon duplication was also confirmed on a patient's relative, originally diagnosed with an exon 13 duplication as well. Another LSR was a total deletion of the BRCA1 gene. ONT sequencing highlighted this complete deletion of BRCA1 was the consequence of a large deletion of almost 140 kbp carrying 5 different genes (BRCA1, IFI35, NBR2, RND2, and VAT1).
ONT sequencing was also able to detect all class-5 SNVs (point mutations and small indel) present in 16 patient samples at low coverage (between 6 and 27X). We faced bioinformatics detection issues for 3 mutations located in homopolymer regions using standard pipelines. These were all confirmed correctly when visualizing the raw data.
As we analyzed complete genes and more genes than with short read sequencing, we detected novel unknown variants. To check the reliability of those novel variant by ONT, we wondered whether we could confirm results obtained at a low coverage (10X) with average quality (Phread score >/= 15). For that we randomly selected 8 new variants we analyzed by Sanger sequencing, and all of these were confirmed, suggesting that variants detected with ONT, even at a 10X coverage and a Phread score higher than 15, could be considered as real variants.
In conclusion, we showed that ONT adaptive sampling sequencing is suitable for the analysis of germline alterations. It improves the characterization of LSR and is able to detect SNV even at low coverage. Nevertheless, an improvement of bioinformatics detection of variants located in homopolymer regions should be considered. A larger comparison study between ONT adaptive sampling and short read sequencings should be performed on hundreds of samples to adapt international guidelines to third generation sequencing for germline diagnosis.

#2937 Accurate detection of human papillomavirus breakpoints in cervical cancers using a novel library preparation strategy for nanopore sequencing technology.

P. Parida[1], N. Mukherjee[2], A. Singh[2], A. Singh[3], K. Sharan[1], M. Rao[4], S. Lewis[1], S. Radhakrishnan[2], R. R. Damerla[1];
[1]Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, India, [2]National Centre for Biological Sciences, Tata Institute of Fundamental Research, Bengaluru, India, [3]Manipal School of Life Sciences, Manipal Academy of Higher Education, Manipal, India, [4]Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal, India

Introduction: Integration of human papillomavirus (HPV) DNA into the human genome is considered as a key event in cervical carcinogenesis. Different methods have been employed in exploring HPV integration sites, such as APOT, DIPS-PCR, and NGS. However, these methods have their drawbacks. APOT heavily relies on the quality of the sample due to its dependence on RNA, while DIPS-PCR mostly identifies known sites and has limited capability in uncovering new integration sites. Although the detection sensitivity of virus infection status increased significantly through the Illumina sequencing platform, there were still disadvantages remain for further improvement, including the detection accuracy and the complex integrated genome structure identification, etc. Also, it requires large amounts of sequencing data, and thus is not applicable in clinical usage, which requires fast and accurate results. Therefore, the development of a new method for HPV integration detection with high accuracy and prompt reporting capacity is crucial for future clinical application.
Methods: We established a novel library preparation strategy for the detection of HPV integration in the human genome using Oxford Nanopore sequencing. Using this novel technology, Nanopore libraries were prepared from HPV positive cell lines HeLa and SiHa followed by sequencing on the Oxford Nanopore. We also determined HPV integration sites in five patients with cervical cancer patients with HPV positive tumors using Ilumina WGS. HPV integrations and breakpoints in human genome from both Nanopore and Ilumina WGS were extracted using Minimap and ViFi tool respectively. All HPV integration sites from cell lines and patient samples were validated using Sanger sequencing.
Results: The novel library preparation approach for detection of HPV integrations with Nanopore sequencing technology were sensitive and efficient in detection of commonly reported HPV breakpoints in HPV positive cell lines HeLa and SiHa. Additionally, we applied this method to clinical samples from five patients subjected to Whole Genome Sequencing, consistently yielding concordant results.
Conclusion: Our Nanopore based assay for detecting HPV integrations without the need for WGS demonstrated high efficacy. These data highlight the sensitivity and efficiency of this methodology in detecting HPV integrations events, emphasizing its potential as a reliable diagnostic tool in understanding pathophysiology of HPV-related malignancies and its use as prognostic markers in clinical settings.

#2938 Comprehensive genomic profiling of solid tumor patients with the OncoDEEP assay for broad analysis in clinical diagnostics.

E.-J. M. Speel[1], P.-J. Volders[2], J. Van der Meulen[3], A. De Cock[3], S. Vermeire[4], J. Van Huysse[4], M. De Barsy[5], G. Beniuga[5], W. de Leng[6], A. Jansen[6], S. Thijssen[1], **H. Dubbink**[7], Z. Ozgur[8], W. van Ijcken[8], B. Maes[2], G. Froyen[2];

[1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Jessa Hospital, Hasselt, Belgium, [3]Ghent University Hospital, Ghent, Belgium, [4]AZ Sint-Jan Brugge AV, Bruges, Belgium, [5]Institute of Pathology and Genetics (IPG), Gosselies, Belgium, [6]University Medical Center Utrecht, Utrecht, Netherlands, [7]Erasmus MC Cancer Institute, Rotterdam, Netherlands, [8]Erasmus University Medical Center, Rotterdam, Netherlands

Somatic multi-gene analysis by Next Generation Sequencing (NGS) becomes standardly integrated in medical oncology for clinical decision making. However, with the fast-growing number of recommended and required genomic biomarkers, small panels have become vastly insufficient for most tumor types. Comprehensive Genomic Profiling (CGP) is amenable to screen for single nucleotide variants (SNVs) and subtle insertions and deletions (indels) in several hundreds of genes. Moreover, it provides information on copy number variations (CNVs) and gene fusions of the most relevant genes for optimal patient management. Currently, most comprehensive panels also allow for screening of tumor-agnostic genomic biomarkers, including microsatellite instability (MSI), tumor mutation burden (TMB) and homologous recombination deficiency (HRD), which are implemented as prognostic and therapeutic signatures in a wide variety of solid tumors. So far, only a handful of CGP assays have been validated for their diagnostic utility in routine laboratory practice for the care of cancer patients. In this study we report on an extensive multicentric analysis across multiple centers in Belgium and The Netherlands comparing the novel OncoDEEP CGP assay (OncoDNA) with the diagnostically validated TSO500 assay (Illumina). We describe the technical differences between both assays as well as their outcome and shortcomings. Detection of clinically relevant SNVs, indels and CNVs was very similar and differences were often due to assay-specific settings. Similarly, TMB, MSI and HRD data were concordant for most samples but those with scores close to the cut-offs could deviate. For fusion detection, concordance was found for the limited number of 11 clinically-actionable driver genes covered by the OncoDEEP kit. The uniformity of coverage was much higher with the OncoDEEP assay thereby allowing to pool 2- to 3-times more samples per NGS run. For the diagnostic implementation of the OncoDEEP assay we then performed an extensive validation with clinical samples representing a wide variety of solid tumor types, as well as reference samples. All performance metrics passed the validation criteria. In conclusion, the OncoDEEP kit can be used for reliable diagnostic comprehensive profiling of solid tumors, but currently, extensive fusion analysis requires an additional screening method.

#2939 Harnessing *in vivo* CRISPR screen to uncover metabolic dependencies during cancer progression.

S. Ng[1], Z. Wu[1], J. A. Lidster[2], W. Tam[1];

[1]Genome Institute of Singapore, Singapore, Singapore, [2]Cancer Science Institute of Singapore, Singapore, Singapore

Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer, with the worst prognosis and limited treatment options. TNBC cells undergo metabolic reprogramming in response to nutrient limitations and changes in the tumor microenvironment throughout cancer progression. In the early stages, tumor cells are found to prioritize nutrient uptake and biosynthesis, but as they grow, intensified competition for nutrients fosters the emergence of subpopulations of cancer cells that excel in utilizing specific nutrients. The substantial metabolic pathways and genes that regulate each phase of cancer progression remain poorly understood. To address this, we have developed a stable integration, site-specific, and inducible CRISPR-Cas9 system that allows for temporal control of genetic perturbation. We conducted an unbiased *in vivo* loss-of-function CRISPR screen aimed at identifying metabolic vulnerabilities at different phases of cancer progression of TNBC. The inducible CRISPR system was activated only at the desired study period of each phase, thus capable of uncovering metabolic dependencies for TNBC proliferation at each distinct phase of cancer progression. As many large-scale CRISPR screens have previously been performed to identify gene dependencies for cancer progression *in vitro*, our CRISPR screen could address the shortcomings of *in vitro* screens by identifying novel essential metabolic genes that are significantly important for cancer growth *in vivo*. Preliminary data from our CRISPR screen revealed different pathways to be significantly important for tumor growth and proliferation at different phases of TNBC progression. For example, we find that ferroptosis is altered during the early lag phase of TNBC cancer progression, whereas, at the later stage of cancer progression, metastatic tumors upregulate serine metabolism, suggesting that secondary tumors could have distinct metabolism from the primary sites. Altogether, the findings from this study could provide valuable insights into stepwise metabolic dependencies arising from microenvironmental limitations and identify potential therapeutic targets at each phase of cancer progression. Moreover, our CRISPR-Cas9 model holds promise for dissecting the complex mechanisms of other cancer progressions.

#2940 A comparative analysis of library preparation technologies for RNA sequencing from FFPE samples.

J. Pavlica, T. Sanders, D. Gelagay, K. Reed, T. Harrison, **G. Corbet**, J. Haimes, A. Hanek, K. Giorda, B. Kudlow;
Watchmaker Genomics, Inc., Boulder, CO

Formalin-fixed, paraffin-embedded (FFPE) samples are an invaluable resource in the oncology space, providing access to a vast library of archived diseased tissue samples paired with relevant donor information. Despite the broad utility of these samples, RNA extracted from FFPE tissue is typically difficult to process due to the presence of residual crosslinks and its degraded nature. Further, these samples often vary widely in performance, as the fixation process, block age, block storage, and extraction method can impart large impacts on resulting template quality. As a result, robust and reproducible RNA sequencing from FFPE-derived RNA remains a challenge with unpredictable and high failure rates. We evaluated four commercially available WTA solutions to determine which performed best with this challenging sample type with respect to library complexity, inter-input and intra-sample concordance, and overall reproducibility. Matched fresh frozen and FFPE liver samples were used such that the fresh frozen data set serves as a comparative truth set for the FFPE data. RNA-Seq libraries were prepared from each sample at both 10 ng and 100 ng inputs. The higher input serves as a control while the lower input reflects achievable inputs from very challenging FFPE samples. For 10 ng FFPE-derived RNA, the Watchmaker RNA Library Prep Kit with Polaris Depletion detects more unique genes than other chemistries and has a much higher percentage of genes that overlap with the fresh frozen control libraries. Additionally, differential expression analysis between 10 ng and 100 ng FFPE libraries demonstrates that the Watchmaker solution better preserves the gene expression profile at low inputs, as fewer differentially expressed genes are identified.

The Watchmaker chemistry includes a number of features aimed at improving library complexity, including a novel FFPE decrosslinking step, a reverse transcriptase specifically engineered to improve conversion of RNA to cDNA, and fewer bead purification steps to prevent sample loss. The concordance between FF and FFPE samples at variable input masses observed when using the Watchmaker solution promotes a higher degree of confidence when making decisions based on lower quantity and quality samples and enables researchers to access more meaningful biological information.

#2941 A novel gene signature predicting fibroblast composition in the TME allows for an improved selection of patient-derived xenograft (PDX) models for preclinical studies.

Mara Gilardi, Gilad Silberberg, Hsiu-Wen Tsai, **Stefano Cairo**, Clare Killick-Cole, Michael Ritchie

Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

The Tumor MicroEnvironment (TME) plays a pivotal role in driving tumor progression, metastasis, and therapeutic resistance through diverse mechanisms. Notably, the TME influences the response to therapy by regulating immune surveillance evasion in tumor cells. Fibroblasts can play a significant role in resistance to therapy. In the context of cancer cancer-associated fibroblasts (CAFs) in the TME have been associated with resistance to various therapeutic approaches. CAFs can contribute to therapy resistance through multiple mechanisms, including extracellular matrix remodeling, immune modulation, angiogenesis and paracrine signaling. Understanding the intricate interactions between fibroblasts and cancer cells is crucial for developing more effective therapeutic strategies and overcoming resistance in cancer treatment. In the pre-clinical stages of therapy testing, the use of clinically and biologically relevant models is essential. However, current preclinical tumor models often lack a comprehensive characterization of the TME. To address this limitation, Champions Oncology utilized transcriptomic data from its exclusive TumorGraft models bank to develop a signature predicting TME composition. Validation involved confirming the predicted TME composition through histological analysis of Patient-Derived Xenograft (PDX) models grown in humanized mice. In an immune-competent host, the Tumor Microenvironment (TME) of the model more accurately replicates the conditions observed in cancer patients. PDX) models are recognized as accurate and clinically relevant for pre-clinical studies. Consequently, Champions Oncology built its pre-clinical research on a deeply characterized PDX bank, employing multi-omic datasets, including WES ,RNAseq, proteomics, phospho-proteomics, kinase activity, and patient treatment history. To identify molecular signatures predictive of fibroblast presence, Champions analyzed the data with xCell^{3} computational method. Concurrently, mice were humanized, and high and low infiltration predicted PDXs models were implanted. Tissues were collected and stained for fibroblast populations. Immunohistochemistry analyses confirmed a strong correlation between the infiltration predicted by the molecular signature and positive staining. The application of this method to Champions' model bank provided a comprehensive understanding of the TME profile, culminating in the definition of a gene signature predictive of fibroblast infiltration. Histological analysis validated the computational findings, creating a TME atlas of the PDX bank. This data support the use of the pre-defined molecular signature, facilitating the pairing of ideal model systems with appropriate humanized hosts for future preclinical studies.

#2942 Deciphering histological subtype-associated cellular and molecular characteristics of lung adenocarcinoma using single-cell RNA sequencing and spatial transcriptomics.

J. Lee[1], J. Jeong[2], M. Hong[2], H.-G. Kang[2], J. Choi[2], J. Kim[1], Y. Choi[1], J. Kim[1], **S. Lee**[2];
[1]POSTECH, Pohang, Korea, Republic of, [2]Kyungpook National Univ. School of Med, Daegu, Korea, Republic of

Lung adenocarcinoma (LUAD) is the most frequently observed subtype found in non-small cell lung cancer (NSCLC). Despite its high prevalence, the molecular and histological heterogeneity in LUAD pose a significant challenge for providing effective patient care and aiming to reduce the high mortality rate. The histopathological classification proposed by WHO in 2015 describes five histologic patterns of lung adenocarcinoma (lepidic, acinar, papillary, micropapillary, and solid), and it has been shown that the existence of high-grade subtypes (micropapillary and solid) is associated with poorer survival outcomes. Nevertheless, the specific cellular and molecular mechanisms responsible for these clinical outcome differences based on distinct histological patterns remain unclear. Here, we conducted single-cell RNA sequencing (scRNA-seq) to unveil insights into the tumor microenvironment (TME) and identify cancer cell biomarkers associated with distinct histological patterns. Our study involved 18 specimens from primary LUAD patients who underwent surgical resection, all of whom were previously untreated. These specimens were classified into three groups: acinar/papillary (A/P), micropapillary (MP), and solid. Remarkably, patients with solid-type tumors showed a notable enrichment of CD8+ T cell exhaustion, alongside a significant abundance of GPNMB-high macrophages in the myeloid compartment. Additionally, macrophages from the solid-type demonstrated cholesterol-efflux activation, particularly in alveolar macrophages. It is well-known that cholesterol efflux-activated macrophages display a tumor-associated macrophage phenotype, contributing to immunosuppression in the TME. In contrast, the A/P group exhibited a higher enrichment of mast cells compared to the solid-type. This suggests that the solid-type tumor landscape is more immunosuppressive than the A/P group. In the context of cancer cells, we identified that A/P cancer cells displayed a well-differentiated pattern with a high alveolar epithelial type II cell (AT2) signature. In contrast, solid-type cancer cells showed poorly differentiated states, coupled with a significant activation of the epithelial-mesenchymal transition (EMT) process. Remarkably, even within A/P patients, those with a small portion of solid patterns in the tumor tissue showed higher clonal complexity compared to patients without any solid pattern. Furthermore, we found that cancer cell plasticity can be regulated by cell-cell interactions in the TME. Collectively, this study unveils the relationship between histological patterns and the TME, encompassing distinct immune responses and molecular characteristics of cancer cells in LUAD. These findings provide valuable insights for potential targeted therapeutic strategies.

#2943 Investigation of microsatellite instability in RNA compared to DNA, using microsatellite targeted, anchored multiplex PCR and NGS.

R. Rogge, T. Patterson, A. Navetta, D. Legare;
Integrated DNA Technologies, Inc., Boulder, CO

MSI measurements are typically made on DNA, but it would be useful to make similar measurements from RNA or total nucleic acid inputs (TNA), so that MSI determinations could be made in parallel to interrogation of the RNA. Doing so requires characterizations of microsatellite lengths from those which are transcribed and untranscribed, because both will be detected following cDNA creation. Microsatellite instability (MSI) occurs when small unit repeats of DNA undergo incorrect replication resulting in the growth or contraction of the number of repeats in the newly synthesized DNA. This accumulation of errors at microsatellite DNA is usually mitigated by the mismatch repair (MMR) pathway which can correct these errors. MSI is of interest because it serves as a phenotypic readout of the status of the MMR machinery, and MSI status can correlate to tumor progression and response to agents that regulate these cellular mechanisms. We investigated the status of microsatellites using Anchored Multiplex PCR (AMP™) targeted panels (RUO) and compared results from TNA inputs using an AMP MSI module and both VARIANT*Plex*™ chemistry to interrogate DNA, and FUSION*Plex*™ chemistry to interrogate both RNA + DNA. Our results indicate differences in the diversity of lengths of microsatellites present in RNA, and the resulting stability calls which would be made at those sites. Microsatellite length diversity was highly dependent on the genomic context of the microsatellite. Microsatellites located within transcripts showed increased length diversity when examining the RNA + DNA results compared to DNA alone. Microsatellites located in intergenic regions, which are unlikely to be transcribed, showed no increase in diversity of lengths when comparing the RNA + DNA results to DNA alone. While these results suggest that MSI determinations could be made from RNA or RNA + DNA NGS data, the unique behavior of microsatellites in RNA is likely to require additional investigations and unique data analysis techniques to correctly categorize microsatellites as stable or unstable.

#2944 A high-throughput screening system for identifying therapeutic targets in immuno-oncology.

Dippal Parikh, Soon Youn Choi, Ki Eun Pyo, Hong-Pyo Lee, Kyuho Han

MEDiC Life Sciences Inc., Mountain View, CA

INTRODUCTION: Over the last decade, cancer immunotherapy has revolutionized cancer treatment. However, more than half of patients don't respond, and responders often lack lasting effects. Understanding how genetic variants in cancer cells influence their interaction with immune cells, especially T cells, is crucial to uncover underlying mechanisms. Genetic screens are powerful for uncovering responsible genes for various phenotypes, but challenges in obtaining ample samples to set up a proper immune and cancer co-culture system have limited their use for identifying immune modulators in cancer: primary mouse T cells expressing CD3 against a specific antigen (typically albumin) need to be extracted from transgenic mice and only syngeneic mouse cancer cell lines that match these T cells can be paired, restricting the utilization of human T cells and human cancer cells for this co-culture screening setup.
METHODS: Here, we present a highly scalable co-culture system that enables genome-wide CRISPR screens on a pair of human primary T cells and any allogeneic human cancer cell lines. This system utilizes the expression of a membrane-targeted protein in mammalian cells, named as ImBridge, which directly engages and activates CD3+ immune cells. This mechanism bypasses the need for matched MHC on target cancer cells.
RESULTS: We validated activation of CD3+ immune cells and selective cancer cell cytotoxicity by ImBridge. A genome-scale CRISPR screen utilizing the co-culture system unveiled known immune-oncology targets including PD-L1 and PTPN2 and revealed MEDiC_01 as a novel therapeutic target. Genetic loss of MEDiC_01 in cancer cells significantly sensitized them to cytotoxic cells, effectively eliminating cancers in the presence of human PBMCs.
CONCLUSION: We demonstrated a scalable and efficient approach for conducting high-throughput functional screens to uncover genes that modulate interactions between effector T cells and target cancer cells. This can facilitate the identification of new immuno-oncology therapeutic targets, insights into underlying mechanisms, and genetic factors influencing immune susceptibility and evasion.

#2945 Using pooled minimal genome-wide sgRNA libraries to drive oncology drug discovery.

S. Lukasiak[1], A. Kalinka[2], N. Gupta[2], K. Saeed[2], A. Papadopoulos[1], U. McDermott[1], G. J. Hannon[3], D. Ross-Thriepland[1], **D. Walter**[2];
[1]AstraZeneca, Cambridge, United Kingdom, [2]Cancer Research Horizons, Cambridge, United Kingdom, [3]Cancer Research UK Cambridge Institute, Cambridge, United Kingdom

The emergence of CRISPR technologies has enabled rapid and precise gene editing opportunities. The Functional Genomics Centre (FGC) - a joint venture between Cancer Research UK's (CRUK) drug discovery engine, Cancer Research Horizons, and AstraZeneca has been launched to better utilize and improve the CRISPR technology within cancer research. The FGC leverages the strengths of both CRUK's and AstraZeneca's world-class oncology research and drug discovery experience, with the potential to drive scientific innovation in how new drug targets are identified and validated, and uniquely democratize access to the latest cutting-edge research tools and expertise for many thousands of scientists and clinicians funded by CRUK.
Here, we will showcase how the FGC is leading the development and refinement of functional genomics technologies. Through independent evaluation of publicly available CRISPR tools and leveraging this data we have designed optimized, minimal genome-wide CRISPR libraries. These libraries permit a reduction of the experimental scale of CRISPR screens by 50% and enable our Target Discovery platform to impact more projects, faster, at a lower cost and importantly - more sustainably.

#2946 Characterizing the genomic landscapes of breast and lung tumors using cost-effective whole genome sequencing.

H. Benjamin[1], I. Soifer[1], D. Shem-Tov[1], M. Levy[1], I. Tuncay[2], B.-L. Oh[2], J.-Y. Shin[2], Y. Ju[2], S. Lee[2], O. Barad[1], D. Lipson[1];
[1]Ultima Genomics, Fremont, CA, [2]Genome Insight Inc., San Diego, CA

Whole Genome Sequencing (WGS) has emerged as a pivotal tool for unraveling the intricate genomic alterations underlying cancer, enabling the detection of a broad spectrum of somatic changes in cancer genomes, including single nucleotide variants, insertions, deletions, copy number variations, and structural rearrangements. Characterizing somatic variants across the entire genome significantly benefits from novel cost-efficient sequencing platforms, such as UG100. In the current study, we aim to demonstrate the utility of UG100 WGS in characterizing the landscape of somatic events in breast and lung cancer.
Over 35 tumor-normal cancer sample pairs were profiled using UG100 WGS (mean tumor coverage: >100x; normal: >50x). Variant calling was done using a somatic deep-variant algorithm, optimized to UG100 data. Results were compared to Illumina sequencing and high concordance was observed, with over 97% of SNVs and over 93% of indels detected by Illumina identified also by UG100. UG100 sequencing was deeper and allowed for identification of a larger number of genomic variations, including known driver events in cancer-related genes. The somatic mutational signatures by UG100 were concordant with the Illumina platform, with a cosine similarity higher than 99%. Copy number variation and structural variation analysis was performed on all sample pairs, revealing a wide range of genomic aberrations.
The integration of genetic sequencing into routine clinical oncology practices has proven instrumental in identifying actionable mutations, predicting treatment responses, and monitoring minimal residual disease. Moving from targeted sequencing to WGS provides a more comprehensive and unbiased assessment of the entire genome, uncovering rare or unexpected mutations that might be missed by targeted approaches. WGS allows for the simultaneous evaluation of both coding and non-coding regions of the genome, providing a deeper understanding of the regulatory elements influencing gene expression. This broader scope enhances our understanding of cancer biology and contributes to a more accurate assessment of the tumor's functional landscape.

#2948 Unveiling hidden genomic diversity: Exploring epigenetic potential and gene expression in African Pan Genome contig sequences.

R. Martini[1], K. Founta[2], S. Maurice[3], J. White[1], O. Balogun[4], N. Chambwe[2], M. Davis[1];

[1]Morehouse School of Medicine, Atlanta, GA, [2]Northwell Health, Hempstead, NY, [3]City College of New York, New York, NY, [4]Weill Cornell Medical College, New York, NY

An important consideration when studying cancer in diverse populations is the representativeness of the reference genome. Cancer genomics findings are largely based upon alignments to GRCh37 and GRCh38 references, and with the recent release of the telomere-to-telomere (T2T) and the Human Pangenome Reference Consortium references, analyses of sequences distinct from previous references in the cancer context provide exciting opportunities to identify novel targets that may be linked to cancer outcomes. Because GRCh38 and T2T are overwhelmingly Eurocentric, the question remains if these references have applicability outside the ancestral populations that comprise them. Prior to T2T and pangenome, whole genome sequencing of 910 individuals of African descent revealed 296.5 million distinct base pairs, which were assembled into 125,715 African Pan Genome (APG) contigs. These unique sequences represent African ancestry novel genomic sequences whose function was unclear. Here we present provisional efforts to determine the function of APG contigs, and whether they are represented in newer references. To determine the epigenetic potential of the 125,715 APG contigs, we used Emboss Cpgplot to predict CpG islands. We identified 8,353 potential CpG islands, where 6,352 contigs had at least 1 predicted CpG island, and 1 contig had 9. There was weak correlation between contig length, GC content and number of predicted CpG islands suggesting that these sequences represented potentially functional regions. Using unmapped transcriptomic reads from our published African ancestry triple negative breast cancer cohort, we sought to determine the expression potential of these contigs. Unmapped reads mapped to ~9% of the contigs, where ~1100 APG contigs had both predicted CpG islands and alignment of the unmapped transcriptomic reads. This strongly suggests that these APG contigs contain African ancestry-specific regulatory regions and functional gene coding sequences. Preliminary BLASTn queries of contigs with regulatory potential revealed that these sequences may be present in T2T. Mapping to T2T and visualization of expression and CpG islands showed that our predictions matched novel T2T sequences. We anticipated some contigs would map to T2T given one- or two-end placement in GRCh38 and wanted to determine if any of the ~1100 contigs mapped to T2T. Initial analysis of this contig subset shows ~15% fail to map to T2T, indicating that T2T may still fail to capture diversity across ancestry groups. These sequences represent previously unstudied expression and epigenetic potential not captured in the reference genome, and we are working to evaluate all 125,715 sequences. Capturing the diversity across the genome remains extremely important to contextualize these findings and build resources to continue moving precision medicine approaches forward across diverse ancestry groups.

#2949 A flexible and efficient approach for single-cell CRISPR perturbation screens combined with targeted RNA-seq expression analysis.

D. Tedesco, T. Liu, M. Makhanov, D. Hu, **N. Isachenko**, P. Diehl, A. Chenchik;
Cellecta, Inc., Mountain View, CA

This study presents a novel approach for performing 10X platform-based targeted single-cell RNA-seq analysis in combination with CRISPR perturbation screens. For the analysis, we constructed a custom sgRNA library focused on a small subset of genes associated with the TNFα response (i.e., NFκB pathway). We compared analysis of two targeted gene expression panels—the first, targeting all protein-coding genes (genome-wide) and the other, targeting a selected set of genes representing key hubs in signaling pathway modules. Narrowing down the analyzed gene set enhanced the efficiency of single-cell RNA-seq by reducing the associated next-generation sequencing (NGS) depth required for readout, and significantly streamlining data analysis. Comparing the analysis of the expression panels targeting all protein-coding genes with the smaller pathway-targeted set, we were able to assess the general flexibility of the novel approach for single-cell CRISPR perturbation screens. We evaluated the specific tradeoffs with regard to the size of the CRISPR library, the size of the panel of genes targeted for expression analysis, and NGS sequencing depth. This flexible, targeted approach not only refines the precision of RNA-seq but also provides a more cost-effective solution for comprehensive genomic analyses.

#2950 CRISPR/saCas9 and CRISPR/spCas9 systems for combinatorial genetic screens (CRISPR-KO, CRISPRa, CRISPRi).

N. Isachenko, G. Aleksanyan, P. Diehl, D. Tedesco;
Cellecta, Inc., Mountain View, CA

This study explores the utilization of orthogonal CRISPR-based gene editing/modulation systems for combinatorial genetic screens using CRISPR knockout (CRISPR-KO), CRISPR activation (CRISPRa), and CRISPR interference (CRISPRi) functionalities. *S. aureus* (sa)Cas9 is an alternative nuclease to *S. pyogenes* (sp)Cas9 in scenarios where the latter cannot be used, or when multiple independent CRISPR systems need to be simultaneously expressed in the same cell. In this study we set out to explore the feasibility of utilizing different combinations of saCas9 and spCas9 CRISPR systems to achieve the simultaneous inactivation (via CRISPR-KO or CRISPRi) and transactivation (via CRISPRa) of different target genes in the same host cell. For this purpose, a complete set of tools for CRISPR/saCas9 gene editing and gene modulation was developed, compatible with CRISPR/spCas9 co-expression. Specifically, we developed and validated optimized saCas9 and sg(sa)RNA lentiviral and AAV vectors, dual expression (sp)/(sa)sgRNA lentiviral library vectors, as well as (sa)CRISPR-KO, (sa)CRISPRi, (sa)CRISPRa fluorescence-based activity kits for the functional validation of saCas9 expressing cell lines. Results demonstrating the feasibility of the orthogonal screens will be presented, with different combinations of CRISPR-KO, CRISPRa, and CRISPRi systems in multiple cell lines.

#2954 Androgen deprivation therapy (ADT) and senescence-associated secretory phenotype (SASP) *in vitro*: Correlation with SASP in tumor specimens as well as in the serum of patients after ADT.

M. Schwermann[1], M. Hadfield[2], S. Lu[2], P. Srinivasan[1], V. Tajiknia[1], W. MacDonald[1], A. George[3], S. Zhang[1], L. Zhang[1], K. S. Meza[1], A. De Souza[2], D. Golijanin[2], E. Hyams[2], G. Lagos[2], S. Holder[2], A. Mega[2], J. Sedivy[1], H. Safran[2], W. El-Deiry[2], B. Carneiro[2];
[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]Legorreta Cancer Center and Lifespan Cancer Institute at Brown University, Providence, RI, [3]Yale School of Medicine, New Haven, CT

Introduction: Androgen Deprivation Therapy (ADT) is a highly effective treatment for prostate cancer. However, resistance to ADT develops in most patients, leading to a lethal state of castration-resistant prostate cancer (CRPC). Senescent prostate cancer (SPC) cells can arise after ADT and contribute to therapy resistance. SPCs can restore replicative function and alter the tumor microenvironment through pro-tumorigenic senescence-associated secretory phenotype (SASP). We aimed to characterize changes in SASP in prostate cancer cell lines and serum samples from patients receiving ADT.
Methods: SASP factors (Luminex 100/200 System, xMAP Instruments) were analyzed in patients undergoing ADT. To correlate SASP with the sensitivity to ADT, we sought to evaluate the regulation of SASP in vitro using PCa cell lines. The PC3 (AR resistant) and LNCaP (AR sensitive) cell lines were used in the experiments. We performed an analysis of archival tumor tissue (paired) from 18 patients with or without alterations in DNA repair genes (BRCA1, BRCA2, and CDK12). We performed immunohistochemical (IHC) staining of known SASP markers, such as P16, uPAR, gamma-H2AX, and Lamin B1.
Results: In a cohort of patients (n=8) with pre and post-ADT matched status, we demonstrate increased levels of SASP factors such as IL-6 (pre-ADT: 1.54±0.24 pg/ml, post-ADT: 5.23±1.3 pg/ml p=0.001), IL-7 (pre-ADT: 3.11±0.6 pg/ml, post-ADT: 13.5±2.7 pg/ml p=0.01), IL-1 alpha (pre-ADT: 1.06±0.3 pg/ml, post-ADT: 15.3±3.5 pg/ml p=0.001), IL-15 (pre-ADT: 15.6±3.1 pg/ml, post-ADT: 37.1±4.8 pg/ml p=0.002), MIF (pre-ADT: 1036±67.6pg/ml, post-ADT: 2362±55.5 pg/ml p=0.003), and IL-15 (pre-ADT: 5±2.1 pg/ml, post-ADT: 37.5±5.1 pg/ml p=0.002). In vitro, the AR-responsive LNCaP cell line, exposed to AR blockade, showed similar findings in upregulating IL-6, IL-7, and IL-15 but not the PC3 cell line. We also demonstrate measurable differences between the expression of u-PAR, gamma-2AX, p16, and loss of Lamin B1 expression in tumor specimens from patients with advanced castration-resistant prostate cancer (n=18). The expression of p16 was significantly upregulated post-treatment irrespective of DDR status (p=0.0417). Other SASP factors showed a trend in upregulation but were insignificant (u-PAR p=0.056, gamma-H2AX p=0.62, Lamin B1 p=0.72)
Conclusion: These results provide evidence of systemic increases in SASP-related cytokines following treatment with ADT. The in vitro results suggest that secretion of SASP is promoted by an AR-mediated mechanism. Preliminary results from tumor specimens suggest increased senescence marker p16 expression induced by therapy. Ongoing experiments are further characterizing the senescence markers in prostate tumor specimens and correlated to treatment effect.

#2955 HPV E6* and senescence-related gene expression in cervical cancer.

Louise Medina Bengtsson[1], Matthew Inkman[1], Naoshad Muhammad[1], Leahan Castillo[1], Naomi Msengi[1], Tyler McKinnish[2], Nishanth Gabriel[1], Jin Zhang[1], Julie Schwarz[1]

[1]Department of Radiation Oncology, Washington University In St. Louis, St. Louis, MO,[2]Department of Obstetrics and Gynecology, Washington University In St. Louis, St. Louis, MO

Previous work in our lab found that increased expression of the E6* variant of the HPV E6 viral protein was significantly correlated with worse response to standard-of-care chemoradiation (CRT) and progression-free survival, independently of HPV genotype. *In vitro* validation showed that overexpression of E6* induces senescence in an HPV 16-positive cervical cancer cell line. Given these findings, we hypothesized that increased E6* expression mediates resistance to CRT by inducing a reversible state of tumor cell senescence. We created a senescence score using ten genes that have been consistently reported in the literature as associated with senescence. Using an institutional cohort of 68 patients with cervical cancer with prospectively collected clinical outcome data, we performed bulk RNA sequencing to assess senescence scores before CRT and determine whether there is an association between senescence scores and E6* expression. Using a second institutional cohort of 35 patients with cervical cancer treated with CRT with pre and posttreatment tumor biopsies, we performed bulk RNA sequencing to evaluate the same relationship and determine whether expression of senescence-related genes was affected by CRT. Nine cervical cancer cell lines stratified into low- and high-E6* expression groups will be assessed regarding their senescence score, beta-galactosidase staining, and SASP expression before and after CRT. In our first cohort, there was no correlation between E6*:E6 expression ratio and senescence score, regardless of HPV genotype. In our second cohort, CRT increased senescence score in CRT-treated samples ($p < 0.01$), but $p16^{INK4a}$ expression significantly decreased compared to pre-treatment samples ($p < 0.01$). Increased senescence score was not associated with cancer recurrence. There was no significant difference in senescence scores between different HPV genotypes before therapy. Tumors that were positive for HPV 16 or HPV 18 had significantly lower senescence scores compared to HPV negative tumors ($p = 0.037$ and $p = 0.038$, respectively) after CRT. Among HPV 16-positive tumors ($n = 12$), there was no correlation between E6*:E6 expression ratio and senescence score before or after CRT. We found no association between senescence score and E6* expression, and between senescence score and cancer recurrence after CRT in our dataset. Additionally, our results suggest that $p16^{INK4a}$ might not be an appropriate senescence marker in tumors that have intrinsically high $p16^{INK4a}$ expression, such as in cervical cancer, reinforcing the need for a cervical cancer-specific senescence signature. We are currently testing beta-galactosidase and SASP expression *in vitro* and *in vivo* before and after CRT.

#2956 Chemotherapy-induced adipocyte senescence triggers bone loss through osteoclast activation.

G. K. Raut, T. Malachowski, T. Holt, R. Oliveira, X. Luo, D. Faget, Q. Ren, S. Stewart;
Washington University School of Medicine in St. Louis, St. Louis, MO

Despite breakthroughs in cancer treatment, chemotherapy-induced osteo-toxicity is a major problem that compromises the quality of life and overall survival of cancer patients regardless of cancer type. Recently we demonstrated that chemotherapy-induced senescence drives bone loss by both limiting mineralization of new bone and increasing bone resorption. However, the underlying mechanism of action remains elusive. Therefore, it is critical that we understand the mechanisms that drive these toxicities and develop approaches to mitigate their severity. To establish whether senescent bone resident cells or systemic responses to chemotherapy drove therapy-induced bone loss, we used a vertebral body transplant (vossicle) model. Using this approach, we found that the specific elimination of senescent cells in L4 and L5 donor vossicles (*INK-ATTAC*) implanted into wildtype mice, protects from chemotherapy-induced bone loss within the vossicles but not the femur of the recipient mice. This demonstrated that chemotherapy-induced senescence in resident bone cells is responsible for bone loss. To determine which bone resident cell(s) underwent senescence in response to chemotherapy and how their gene expression was impacted, we used the p16-Cre^{ERT2}-tdTomato mouse model and found that chemotherapy triggers senescence in bone marrow adipocytes. Subsequently, we observed that postnatal fat ablation in adipoqCre-inducible DTR transgenic mice (iDTR^{ADQ}) prevented chemotherapy-induced bone loss, indicating senescent adipocytes trigger bone loss. Furthermore, we observed chemotherapy-induced bone loss is attributed to RANKL-mediated high osteoclasts activity. Collectively, our data demonstrate that chemotherapy causes senescence in marrow adipocytes which in turn triggers bone loss via RANKL-mediated osteoclasts activation and bone loss can be protected by eliminating senescent cells.

#2957 Senescence of stromal, endothelial, and myeloid cells in the tumor microenvironment has distinct effects on cancer progression.

J. Rupert, Z. Gao, Y. Yu, **M. Kolonin**;
University of Texas at Houston, Houston, TX

Accumulation of senescent cells, undermining the function of vital organs, is a culprit of aging. The effects of senescence in different types of cells on tumor growth and metastasis remain incompletely characterized. Cell senescence has been shown to result from inactivation of Telomerase (TERT), an enzyme that maintains telomere length and has obscure roles in regulating gene expression and supporting mitochondrial function. As we reported previously, knockout (KO) of *Tert* gene in mesenchymal stromal cells (MSC) of *Pdgfra+* or *Pdgfrb+* lineages leads to premature replicative stromal cell senescence in adipose tissue. To assess the effect of senescence in endothelial and myeloid cells, we also created mice with *Tert* KO driven by the *Tie2e* promoter or the *LysM* promoter, respectively. Here, to investigate the effect of these three KOs on cancer, we used syngeneic graft models of breast, prostate, and pancreatic carcinoma. Overall, *Tert* KO in cells of *Pdgfra+*, *Pdgfrb+*, *Tie2e+*, or *LysM+* lineage had a suppressive effect on tumor growth. The strongest tumor suppression effect of *Tert* KO was observed in female mice orthotopically grafted with E0771 breast cancer cells. Intermediate suppressive effects of *Tert* KO were observed in mice orthotopically grafted with KPC pancreatic ductal adenocarcinoma cells, whereas the effect on RM1 prostate cancer cells grafts in male mice was the least significant. MSC *Tert* KO and myeloid *Tert* KO also suppressed the growth of breast and prostate cells grafts. Importantly, spontaneous metastases to the liver were induced by *Tie2e-Tert* KO in all mice with pancreatic KPC grafts. Analysis of adipose tissue in this endothelial senescence model revealed vasculature abnormality, leakiness, and tissue hypoxia, which provides a mechanistic explanation for increased tumor dissemination. In contrast, *LysM-Tert* KO did not promote KPC metastases, consistent with the lack of contribution of myeloid cells to the vasculature. *Pdgfrb-Tert* KO in the KPC model resulted in liver metastases observed for some but not all mice, consistent with the role of MSC in supporting vascular integrity. To test an independent model of replicative MSC senescence, we exhausted their pool by several cycles of ganciclovir treatment in mice expressing thymidine kinase under the control of *Pdgfrb* promoter. Upon KPC grafting in this model, reduced primary pancreatic tumor growth was also observed and liver metastases were also induced. We conclude that senescence of distinct cells in the tumor microenvironment affects early and late stages of cancer progression differently. Specifically, our data indicate that vascular cell senescence suppresses tumor growth but promotes metastases. These findings are important to consider as new approaches designed to mitigate cell senescence are investigated in the context of cancer.

#2958 Melphalan-treated multiple myeloma cells exhibit a senescent-like dormancy phenotype.

A. J. Guilatco[1], M. Diaz-del-Castillo[2], G. Alvares Borges[1], N. I. Sannuli[1], M. L. Ritting[1], S. M. M. Aalam[1], N. Kannan[1], T. Tchkonia[1], J. L. Kirkland[1], Y. Lin[1], T. Kourelis[1], M. T. Drake[1], T. L. Andersen[2], M. Weivoda[1];

[1]Mayo Clinic, Rochester, MN, [2]Aarhus University Hospital, Aarhus, Denmark

Multiple myeloma (MM) is an incurable plasma cell (PC) cancer in which all patients are expected to relapse. Cytotoxic agents such as high-dose melphalan (HDM), which is used as a myeloablative agent prior to autologous stem cell transplant (ASCT) in MM, drive therapy-induced senescence (TIS) in non-cancerous tissues. We hypothesized that HDM similarly activates TIS pathways in surviving MM cells and this response may correlate with patient outcomes post-ASCT. To test this, we developed an *in vitro* model in which 5TGM1 mouse MM cells are cultured with 10uM melphalan (HDM) or vehicle (Veh) for 6 hours, followed by co-culture in normal media with primary mouse bone marrow stromal cells. Cultures were maintained for 10 days and imaged to quantify cumulative population doublings (CPDs). 5TGM1 were then isolated by FACS to measure telomere-associated DNA damage foci (TAFs), sensitivity to senolytic drugs, and senescence gene expression (RT-qPCR and scRNA-seq). To translate these studies, scRNA-seq was used to analyze CD138+ PCs from MM patient bone marrow post-ASCT. Additionally, longitudinal bone biopsies from MM patients at diagnosis and post-ASCT were stained for CD138+ PCs; PC burden was quantified using artificial intelligence assisted histology (HALO). HDM-5TGM1 exhibited stable growth arrest (decreased CPDs) and sustained DNA damage (increased TAFs) compared to Veh-5TGM1. HDM-5TGM1 were also significantly more sensitive to senolytic ablation (Dasatinib+Quercetin or Fisetin). HDM-5TGM1 showed increased senescence (*Cdkn1a, Cdkn1c, Glb1)*, anti-apoptosis (*Bcl2l1)*, and senescence associated secretory phenotype (*Ccl5, Icam1, Mmp13*) genes, as well as myeloid markers found to be increased in MM dormancy (*Axl, Fcer1g, Mpeg1*). Analysis by scRNA-seq revealed that HDM-5TGM1 were G0/G1 arrested, and gene set enrichment analysis (GSEA) confirmed upregulation of senescence pathways with downregulation of DNA replication and cell cycle pathways. Consistent with RT-qPCR results, these cells exhibited myeloid gene expression. Analysis of patient CD138+ PCs post-ASCT by scRNA-seq also revealed a myeloid-like cluster. Of interest, of the 491 genes upregulated in this cluster, 268 were also upregulated in HDM-5TGM1. CD138+ PCs could also be detected in patient bone biopsies post-ASCT, although PC burden was significantly reduced post-ASCT. Surprisingly, the percent reduction in PC burden post-ASCT was greater in relapsed (≤3 years) vs non-relapsed patients. Further, in relapsed patients, PC burden post-ASCT positively correlated with time in remission. Altogether, these findings demonstrate that HDM can induce senescence features and a myeloid-dormancy signature in surviving MM cells. This phenotype is associated with longer durable response, suggesting that activation of TIS may be a strategy to extend PFS. Further, senolytic therapy may be a novel approach to eliminate dormant MM cells and prevent relapse.

#2959 Signatures of therapy-induced senescence in glioblastoma-derived extracellular vesicles.

V. DeLuca, P. Digumarti, K. Garcia-Mansfield, P. Pirrotte, M. E. Berens;
TGen (The Translational Genomics Research Institute), Phoenix, AZ

The recalcitrant nature of glioblastoma (GBM) may be due, in part, to the promotion of therapy-induced senescence (TIS) by standard of care treatments. TIS is a prolonged growth arrest associated with epigenetic, metabolic, and biochemical alterations, as well as a robust secretory phenotype. Despite an initial period of tumor stasis due to the loss of cell proliferation, TIS is associated with the development of stemness, increased drug resistance, and immune suppression. Our preliminary data demonstrate the prominent induction of TIS in GBM tumor cells and astrocytes following standard of care therapies for GBM in vitro. However, studies of TIS in GBM patients have been limited due to i) the impracticality of receiving multiple GBM biopsies post-treatment but prior to recurrence and ii) the lack of robust detection methods for TIS even with appropriate biopsy. These challenges argue the need for novel methods to survey TIS in patients. Extracellular vesicles (EVs) are small membrane-bound particles that readily cross the blood brain barrier, and convey information about originating cell identity and cell state through their cargo content. We hypothesize that TIS in host and tumor cells drives the elaboration of senescence-associated EVs (senEVs) with quantifiable senescence protein cargo signatures, and consequently, that EVs can serve as a liquid biopsy for senescence in patients. In a preliminary experiment, two patient derived xenografts grown as short-term in vitro cultures were exposed to 6GY irradiation, with supernatant collected prior to radiation (D0), at peak senescence (D7), and at late senescence (D10). EVs were isolated and subjected to unbiased mass spectrometry. Following unsupervised clustering, EVs were grouped by treatment rather than by cell line. Approximately 6000 proteins were identified across the entire data set, with 105 proteins unique to D7 samples, 162 proteins unique to D10 samples, and 688 proteins exclusive to D7 and D10 samples. Further, proteins from two established senescence gene sets were identified as unique to the D7 and/or D10 conditions. Current work to more robustly identify enrichment of senescence gene sets in EV cargo post-irradiation is underway. We have also established shRNA knockdown cell lines with abrogated TIS to equip validation studies of the TIS-EV cargo relationship. We anticipate that these studies will aid in the development of EVs as a novel reporter of senescence in the clinic.

#2960 Deciphering the role of miRNA146-a and its crosstalk with cellular redox state in senescence escape in breast cancer cells.

S. Pervaiz, A. Q. X. Liew, M.-V. Clement;
National University of Singapore (NUS), Singapore, Singapore

Senescence serves as a double-edged sword in cancer as studies revealed that senescence exhibits both tumor-suppressing and tumor-promoting effects. A subpopulation of cancer cells that enters senescence can evade senescence to proliferate, thereby resulting in tumor regrowth, which has been associated with chemoresistance and tumor aggressiveness. Unlike senescent cells, the senescence-escaped cells harbor low levels of reactive oxygen species (ROS), however, the mechanism(s) underlying this redox dichotomy in senescence and senescence evasion remains elusive. In this regard, recent reports have highlighted the pivotal role of miRNAs in regulating cellular senescence. To that end, miR-146a has been reported as a biomarker of senescence probably via modulating pro-inflammatory and antioxidant pathways. We set up a model of doxorubicin-induced senescence in MDA-MB-231 breast carcinoma cells to study the role and involvement of miRNA146a in senescence induction and its regulation. Senescence induction was confirmed by upregulation of p21, increase in senescence-associated beta galactosidase and C_{12}FDG staining, as well as propidium iodide positivity. We show that, following the initial phase of apoptotic cell death, as evidenced by increased γH2AX and cleaved caspase 3, a population of senescent cells escaped growth arrest to re-enter cell cycle and proliferate. Senescence-escaped cells harbored lower ROS levels compared to senescent cells, which correlated with upregulation of antioxidant enzymes such as MnSOD and CuZnSOD as well as increased transcription of *NRF2* and *NQO1*. Our results also provide evidence for a novel senescence associated redox state, which implicates intracellular peroxynitrite as a driver of cellular senescence. Interestingly, in our model system, p21 upregulation was not associated with intracellular ROS accumulation, which was reported in earlier findings. Interestingly, these changes coincided with a significant increase in *miR-146* expression (during senescence), which was previously shown to downregulate ROS in other model systems. While modulating *miR-146a* did not seem to change ROS levels upon doxorubicin-induced senescence in MDA-MB231 cells, the precise crosstalk between cellular ROS, *miR146-a* and senescence evasion is currently being pursued.

#2961 Investigating the role of aging and treatment-induced senescence in the metastatic liver cancer tumor microenvironment.

K. Gallant, A. Karpova, X. Li, M. Iglesia, A. Houston, D. Rapp, C.-W. Peng, C. Liu, J. Herdon, F. Chen, R. Fields, L. Ding;
Washington University In St. Louis, St. Louis, MO

Liver senescence, marked by the progressive decline in hepatic cell function and regenerative capacity, plays a vital role in the context of aging, chronic liver diseases, and cancer progression, particularly when influenced by anti-cancer therapies. This study is designed to extensively characterize liver senescence under two specific conditions: replicative aging and therapy-induced changes. We examined liver samples from 20 individuals, covering a wide age range (young, <40 years; old, >60 years), and 16 cases of colorectal cancer (CRC) liver metastasis (ages 37-66). Our integrative approach melds single-nucleus RNA-sequencing (snRNA-seq) and ATAC-sequencing (snATAC-seq) to investigate the transcriptomic and epigenetic landscapes across a spectrum of liver cell types, including hepatocytes, cholangiocytes, stellate cells, liver sinusoidal endothelial cells, and diverse immune cells. Key findings include an upregulation of senescence markers such as *CDKN1A*, *CDKN2A*, and *HMGB1*, particularly in specific hepatocytes from older individuals and various cell types in the CRC liver metastasis group. Furthermore, we noted a distinctive senescence-associated secretory phenotype (SASP) across multiple immune cell types in our treated CRC liver metastasis group and upregulation of treatment-induced senescence gene signatures, such as SenCan. Moreover, hepatic stellate cells from older subjects exhibited augmented senescence-related gene signatures (SenSig) and transcription factors (SenMayo), with myofibroblast-like and FAP+ stellate cells showing a marked senescence phenotype, evidenced by elevated SASP molecule expression (*CCL2*, *SERPINE1*, *GLB1*, *IGFBP7*, *IGFBP3*).Incorporating advanced high-resolution imaging techniques, our study delves into the detailed morphological characteristics and spatial distribution of senescence markers within the liver in the setting of replicative aging and treatment-induced senescence. This study sheds light on the heterogeneity and intricacies of senescence-associated gene expression within liver cell populations. By combining comprehensive multiomic data with advanced high-resolution spatial profiling, we aim to decipher unique senescence phenotypes in the context of both replicative and treatment-induced senescence. Our work highlights the significance of cellular senescence in liver pathologies and cancer progression, suggesting new directions for therapeutic interventions that target these complex dynamics.

#2962 Chemotherapy induced senescence drives peripheral neuropathy.

T. Malachowski, G. Kumar Raut, X. Luo, S. Mullick Bagchi, S. Stewart;
Washington University in St. Louis, Saint Louis, MO

Chemotherapy is a mainstay of cancer therapy. Unfortunately, while chemotherapy can profoundly impact disease free survival, it is often accompanied with devastating side effects including hair loss, bone loss, cognitive impairment (referred to as "brain fog"), and peripheral neuropathies. While many of these side effects may subside after the completion of chemotherapy, some persist for a lifetime, substantially compromising the quality of life for survivors. Particularly insidious is chemotherapy-induced peripheral neuropathy (CIPN), which can impair a patient's ability to care for themselves. Shockingly, in over 30% of patients, CIPN persists even after the cessation of chemotherapy, subjecting them to a lifetime of numbness and/or pain. Paclitaxel (PTX), a common treatment for breast cancer, induces CIPN in 61-92% of patients depending on the administered dose. Unfortunately, there are currently no preventative or curative measures for CIPN resulting in side effects that persist for months or even years after the cessation of chemotherapy. Considering chemotherapy can trigger cellular senescence, leading to the release of a diverse array of factors collectively known as the senescence-associated secretory phenotype (SASP) that are capable of negatively influencing neighboring cells. To determine if senescence played a role in CIPN we treated with PTX and found that animals displayed reduced axon innervation in the paws and diminished paw withdrawal responses during the von Frey assay, characteristic symptoms of CIPN. To determine if senescent drove PTX-induced CIPN, we utilized the INKATTAC (INK) mouse, a model in which a p16INK4a promoter drives an inducible suicide transgene to eliminate p16+ senescent cells following treatment with AP20187 (AP). Employing the INK mouse, we successfully prevented CIPN by eliminating PTX-induced senescent cells. Furthermore, through bone marrow (BM) transplant studies using BM from INK mice into wildtype recipients, we failed to prevent CIPN. This result establishes that senescent immune cells, do not contribute to CIPN. In an independent approach, we found that senolytic drugs (kill senescent cells), such as dasatinib and quercetin (DQ) or ABT737 (ABT), effectively prevented and reversed CIPN in mice. Additionally, since the p38MAPK pathway has been shown to regulate SASP mRNA stability, we treated with p38 and MK2 inhibitors and found that inhibition prevented CIPN in mice. To address the mechanism behind CIPN we have carried out single cell RNA sequencing (scRNA-seq) to identify the cell population senescing in response to chemotherapy. These analyses will allow us to understand the mechanisms that drive CIPN and may lead to new treatments for patients suffering from CIPN.

#2963 Dihydromyricetin is a senomorphic agent to promote therapeutic outcome of age-related conditions including cancer and Alzheimer's disease.

Q. Xu, Z. Li, Z. Jiang, J. Campisi, **Y. Sun**;
Chinese Academy of Sciences, Shanghai, China

Aging is characterized by a progressive decline of organ function and gradual rise of susceptibility to multiple chronic disorders, with cancer being a primary cause of human morbidity and mortality worldwide. Cellular senescence represents a state of permanent cell cycle arrest and contributes to chronological aging and age-related diseases including Alzheimer's disease (AD), mainly through development of a distinct secretome termed the senescence-associated secretory phenotype (SASP). By screening a natural medicinal agent library, we noticed Rattan tea extract (RTE) has a prominent antiaging potential, wherein dihydromyricetin (DMY), the most abundant natural flavonoid in RTE, played a central role in suppressing the SASP expression of senescent cells. DMY enhanced total antioxidant capacity (T-AOC), increased catalase (CAT) and glutathione peroxidase (GSH-Px) activity, upregulated the expression of HO-1, NQO1, nuclear Nrf2 and phospho-ERK (p-ERK), but decreased malondialdehyde (MDA) level in senescent cells. Furthermore, DMY regulates PI3K/Akt/mTOR signaling pathway, NLRP3 inflammasome formation, the NF-κB complex activity and ER stress-response, each responsible for a full spectrum SASP development. Transcriptomic profiling suggested that DMY can dampen the genome-wide upregulation of pro-inflammatory factors produced by senescent cells, resulting in abrogated progression of cancer malignancy including elevated proliferation, migration, invasion and chemoresistance. Importantly, combination of DMY with classic chemotherapy significantly enhanced therapeutic efficacy, causing remarkable tumor regression and extending posttreatment survival. Alzheimer's disease (AD) is marked by the presence of amyloid plaques, neurofibrillary tangles, damaged neuronal macromolecules and redox sensitive ions. We found that DMY restrains inflammatory injury in microglial cells, reduces their apoptosis and inflammation, and inhibits TLR4 and MD2 expression. Results of small molecule-protein docking and pull-down assays indicated that DMY binds MD2 to suppress the formation of TLR4 complex. In AD mice, DMY improved the cognitive disorder of animals, suppressed inflammatory injury in brain and reduced TLR4 expression. Together, DMY represents a valid natural candidate that has senomorphic activity and can be applied for treatment of malignancies or neurodegenerative disorders such as AD, pathologies that frequently arise in late life of humans.

#2964 Glutathione S-transferase omega 2 (GSTO2) suppresses the acquisition of the senescent tumor cells phenotype in lung adenocarcinoma.

H. Hatano[1], R. Sumiya[1], T. Hagiwara[1], H. Suzuki[2], K. Yamada[1], N. Kokudo[1], Y. Kawamura[1];
[1]National Center for Global Health and Medicine, Tokyo, Japan, [2]Sapporo Medical University, Hokkaido, Japan

Cellular senescence is a phenomenon characterized by the cell cycle arrest and the induction of inflammatory responses, and is known to contribute to the development and progression of various diseases. In cancerous tissues, some cancer cells acquire the senescent traits, which are referred to as senescent tumor cells (STCs) and contribute to tumor invasion and metastasis. We have previously demonstrated that the expression of glutathione S-transferase omega 2 (GSTO2), which regulates the glutathione redox balance, is exclusively expressed in cells with regenerative ability such as airway basal cells, Clara cells, and type II alveolar cells in the lungs. Contrastingly, the expression of GSTO2 was completely lost in squamous cell carcinoma of the lung (***Cancer Science***, 2022); however, we found that some of lung adenocarcinoma expressed GSTO2. In this study, we aimed to clarify the significance of GSTO2 in lung adenocarcinoma, especially in the regulation of senescence and STCs. To examine whether GSTO2 expression affects senescence marker expression, we prepared GSTO2-transfected and mock-transfected lung adenocarcinoma cell line PC-9. Forced GSTO2 expression resulted in significantly reduced expression of senescence markers, such as p21, p53, and p16. We performed double staining for GSTO2 with p16 and confirmed the inverse correlation between them in lung adenocarcinoma tissues, where GSTO2-positive cells tended to express lower p16 level compared with GSTO2-negative cells. Furthermore, GSTO2-transfected PC-9 cells showed lower expression of senescence-associated secretory phenotype factors, such as IL-6, TNFα, and IL-1β than mock-transfected cells. These results suggest that GSTO2 suppresses senescence in lung adenocarcinoma cells. We next examined whether GSTO2 expression affects tumor cell growth because senescence is involved in the cell cycle arrest. Expectedly, MTT assay revealed that GSTO2 overexpression in PC-9 cells significantly promoted cell growth compared with the mock transfected cells. Contrastingly, the scratching assay showed that the cell migration of GSTO2-transfected PC-9 cells was significantly delayed compared with that of the mock-transfected cells. In conclusion, we demonstrated that GSTO2 regulates senescence, resulting in the suppression of cell migration. The expression of GSTO2 in lung adenocarcinoma may contribute to the inhibition of the emergence of STCs, being a cause of invasion and resistance to radiotherapy and chemotherapy.

#2965 *GADD45B* as a mechanism for enhanced treatment response with the combination of copanlisib and romidepsin in colorectal cancer.

K. Maduscha, A. Schmitz, R. DeStefanis, C. Pasch, D. Deming;
University of Wisconsin - Madison, Madison, WI

Background: Treatment options for molecular subtypes of colorectal cancer (CRC) are urgently needed, including for *PIK3CA* mutant CRC. Previous work in our lab demonstrated enhanced activity of copanlisib in combination with romidepsin in *PIK3CA* mutant CRC models. Here we investigate the induction of *GADD45B* as a mechanism of the enhanced induction of apoptosis seen with this treatment strategy.

Methods: RNA sequencing was done on the CRC 2D cell line, SW48PK (Horizon Discovery, SW48 PIK3CA$^{H1047R/+}$ mutation) as well as *PIK3CA* mutant and wild-type patient derived cancer organoids (PDCOs) through the UW Biotechnology Center. All lines were treated with copanlisib, romidepsin, or combination and were compared with untreated controls. *GADD45B* gene expression was also confirmed on SW48PK, *PIK3CA* mutant, wild type, and *PIK3CA* and *KRAS* mutant PDCOs using RT-qPCR.

Results: RNA sequencing determined that there was an increase of *GADD45B* expression in the SW48PK 2D cell line as well as in *PIK3CA* mutant and wild-type PDCOs treated with the combination compared to untreated controls (average log2 fold change= 1.83). A significant increase in *GADD45B* expression was seen in the SW48PK combination treatment group compared to the control group at 6 hours (combination median fold change= 2.7, p= 0.045) and 24 hours (4.1, p< 0.001). For *PIK3CA* mutant PDCOs treated with the combination, there was significant increase in *GADD45B* expression at 6 hours (9.45, p= 0.005) and 24 hours (14.7, p= 0.002) compared to untreated control. In wild type PDCOs, there was a significant increase in *GADD45B* expression in the combination compared to untreated control at 6 hours (32.95, p=0.004) but not after 24 hours (2.6, p= 0.42). For KRAS mutant PDCOs, there was a significant increase in *GADD45B* expression in combination treated cells at 6 (9.9, p= 0.001) and 24 hours (3.3, p= 0.047), however, this increase was less than *PIK3CA* mutant PDCOs at 24 hours (3.3 vs 14.7).

Conclusions: Copanlisib in combination with romidepsin increases *GADD45B* expression in PDCOs and SW48PK. Further studies will determine if *GADD45B* is required for this treatment response.

#2966 Senescent cancer cell vaccines induce cytotoxic T cell responses targeting primary tumors and disseminated tumor cells.

Y. Liu, J. Pagacz, D. J. Wolfgeher, S. J. Kron;
University of Chicago, Chicago, IL

Diverse conventional cancer therapies, including genotoxic agents and cell cycle or cell division-targeting drugs, can trigger cancer cell senescence. Senescent cells (SnCs) induced by cancer therapy often display unrepaired chromosomal damage but persist indefinitely. SnCs remain metabolically active and display distinct alterations in transcription, secretion, and membrane protein expression/presentation. While initially viewed as a favorable outcome and likely tumor-suppressive mechanism, therapy-induced senescence has more recently been recognized as contributing to resistance, recurrence and metastasis. Adverse effects may be mediated in part by release of inflammatory mediators as components of the senescence-associated secretory phenotype (SASP). Recent studies have argued for reconsidering the potential benefits of therapy-induced senescence, especially in modulating the tumor microenvironment to potentiate anti-tumor immunity and potentiate immunotherapy. We have explored the potential for SnCs to serve as vaccines, building upon prior findings where we demonstrated the immunogenic senescence triggered by the combination of ionizing radiation (IR) and the PARP1/2 inhibitor veliparib. We find that SnCs are avidly taken up by type I conventional, CD11c+/CD103+ dendritic cells (DCs), promoting their activation and maturation. Thereby, SnCs promote DC function in T cell priming and stimulation. The capacity of SnCs to activate DCs depends on how the SnCs are formed, with our results confirming IR+veliparib induces high immunogenicity and implicating a distinct SASP in these effects. On the other hand, blocking STING signaling limits SnC activation of DCs. In vivo experiments with the murine tumor models CT26 and 4T1 suggest that both SnCs and SnC-pulsed DCs serve as effective anti-tumor vaccines. They not only confer protective immunity against tumor engraftment but also act as therapeutic vaccines, inhibiting both primary and disseminated tumor growth, and synergize with radiotherapy and immune checkpoint blockade. While direct administration of tumor-derived SnCs to patients may raise safety concerns, pulsing autologous DCs with tumor SnCs may help drive anti-tumor immune response, offering a promising path toward personalized cancer immunotherapy.

#2967 The mammalian 8-oxo-dGTPase, MTH1, as a novel targetable vulnerability in pancreatic ductal adenocarcinoma.

B. Mateo-Victoriano[1], L. Zhang[1], J. Samaranayake[1], Z. McGaughey[1], C. Due[1], C. Troccoli[1], M. G. Mohsen[2], N. Nagathihalli[1], O. G. McDonald[1], M. VanSaun[1], E. T. Kool[2], P. Rai[1];

[1]University of Miami Miller School of Medicine, Miami, FL, [2]Stanford University, Stanford, CA

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive KRAS-driven cancer that remains one of the most lethal of all human malignancies. Oncogenic KRAS relies on elevated reactive oxygen species (ROS) to support pro-tumorigenic signaling. However, these elevated ROS levels can also evoke tumor suppressive oxidative stress; thus KRAS-driven cancers must evolve protective redox adaptations to mitigate ROS-induced anti-tumor consequences. Here we report a unique adaptation centered on redox maintenance of nucleotide pool integrity, that supports aggressive PDAC tumorigenesis. MTH1 is the main mammalian 8-oxodGTPase that is known to be elevated in various RAS-driven cancers including PDAC. We have previously shown MTH1 is critical for ROS-mediated oncogenic signaling, and promotes escape from oncogene-induced senescence. We therefore hypothesized that MTH1 provides important redox support for aggressive PDAC tumor growth. Consistent with this, we found that elevated MTH1 expression was strongly correlated with poor disease-free survival in PDAC patients. These findings extended to KRAS-driven PDAC cell lines: highly proliferative human PDAC cells strongly expressed MTH1 ($MTH1^{high}$), and MTH1 deletion was selectively anti-tumorigenic against $MTH1^{high}$ cells. Furthermore, introduction of MTH1-null backgrounds into gold standard genetically engineered PDAC mouse models selectively decreased 8-oxodGTPase activity levels and slowed PDAC growth in aggressive, short latency $Ptf1a^{cre/+}$;LSL-$Kras^{G12D/+}$;$Tgfbr2^{flox/flox}$ (PKT) mice, but with no effect in longer latency $Pdx1^{Cre}$; LSL- $Kras^{G12D/+}$; LSL-$Trp53^{R172H/+}$ (KPC) mice. These selective anti-tumorigenic effects were accompanied by a reduction in circulating immunosuppressive cytokines in PKT mice, further suggesting that MTH1 potentially supports aggressive tumorigenesis through induction of systemic immunosuppression. Consistent with this, pancreatic-restricted MTH1 conditional deletion fully rescued PDAC growth in PKT mice. Our findings here thus suggest that MTH1-dependent redox protection of the nucleotide pool represents a unique TME adaptation that supports aggressive PDAC tumorigenesis. Further studies will investigate whether this adaptation is maintained through symbiotic tumor/stroma or tumor/immune cell crosstalk, as observed for other KRAS-driven traits. Ultimately, interventions designed to target MTH1-dependent protection of the nucleotide pool could hold promise as novel therapeutic strategies for this untreatable disease.

#2968 TWIST1-induced suppression of oncogene-induced senescence in non-small cell lung cancer requires the transactivation domain of TWIST1.

A. M. Lafargue[1], H. Wang[2], S. T. Chettiar[3], R. P. Gajula[3], A. C. Shetty[1], Y. Song[1], B. W. Simons[3], T. Nguyen[1], C. Lam[3], F. A. Carrieri[3], C. Smack[3], N. Connis[3], D. Chowdhury[1], J. Chang[1], D. Council[1], K. Nugent[3], I. Siddiqui[3], K. Taparra[3], M. Rezaee[3], N. Zachara[3], Z. S. Morris[4], C. McFarland[5], S. Abdulkadir[6], C. L. Hann[3], P. T. Tran[1];

[1]University of Maryland Baltimore, School of Medicine, Baltimore, MD, [2]GenoImmune Therapeutics, Wuhan, China, [3]Johns Hopkins University, School of Medicine, Baltimore, MD, [4]University of Wisconsin School of Medicine and Public Health, Madison, WI, [5]Case Western Reserve University, School of Medicine, Cleveland, OH, [6]Northwestern University Feinberg School of Medicine, Chicago, IL

Non-small cell lung carcinoma (NSCLC) is a major cause of cancer mortality. High expression of the epithelial-to-mesenchymal transition transcription factor TWIST1 is strongly associated with metastatic cancers and treatment resistance. Additionally, TWIST1 can upregulate O-GlcNAcylation which (1) is required to suppress fail-safe programs such as oncogene ($KRas^{G12D}$)-induced senescence (OIS) to accelerate tumorigenesis in primary NSCLC tumors, and (2) is a potential modulator of DNA repair/radiation response. To decipher the domains and transcriptional targets required for tumorigenicity and radioresistance, we created a novel genetically engineered mouse model (GEMM) allowing tetracycline-inducible expression in the lung epithelium (via lung specific CCSP-reverse tetracycline transactivator (C)) of $KRas^{G12D}$ (R) with $Twist1^{wt}$ (T) or with $Twist1^{F191G}$ transactivation-null mutant (F). CRT mice had shorter tumor-free survival and more aggressive tumors compared to CR/CRF mice indicating that the *Twist1* transactivation domain is required for *Twist1*-dependent tumorigenesis acceleration. Also, $Twist1^{wt}$ expression promoted radioresistance in cell lines and GEMMs. Contrary to CRT, CRF showed a progressive loss of $Twist1^{F191G}$ expression over time suggesting no functionality/no selective advantage. CRT lung tumors had higher proliferation (Ki67) and lower cell-cycle arrest (p16) compared to CR/CRF suggesting that the transactivation domain of *Twist1* is important for the suppression of OIS. Supporting these data, we observed in non-cancer Human Bronchial Epithelial Cell (HBEC) that the co-expression of human $TWIST1^{wt}$ (HBEC-$TWIST1^{wt}$) could suppress $HRas^{G12V}$-induced senescence while the transactivation-null $TWIST1^{F187G}$ mutant (HBEC-$TWIST1^{F187G}$) could not. Additionally, HBEC expressing $HRas^{G12V}$-$TWIST1^{wt}$ had enhanced tumorigenic/invasive programs. Interestingly, we observed that the inhibition of O-GlcNAcylation rescued OIS in HBEC-$HRas^{G12V}$-$TWIST1^{wt}$ while the stimulation of O-GlcNAcylation in HBEC-$HRas^{G12V}$-$TWIST1^{F187G}$ suppressed OIS. Furthermore, $TWIST1^{wt}$ expression with $HRas^{G12V}$ modulated MYC downstream targets and the inhibition of MYC activity using the novel MYC inhibitor MYCi975 in HBEC-$HRas^{G12V}$-$TWIST1^{wt}$ also rescued OIS induction. Altogether, these results suggest that TWIST1 may suppress OIS via MYC signaling and nominate MYCi975 as a means to activate latent OIS programs. In this context, MYC inhibiting strategies could serve as a therapeutic sensitizer for TWIST1-positive NSCLC. This work and our future studies on TWIST1 toward the control of OIS, O-GlcNAcylation and of mechanisms of radioresistance may help to identify new potential NSCLC therapeutic strategies.

#2969 Targeting novel senescence markers by conditionally active biologics eliminates senescence-associated secretory phenotype in *in vitro* and *in vivo* models.

J. Chen, J. Wang, H. Liu, C. Chang, W. J. Boyle, J. M. Short;
BioAtla, San Diego, CA

Clearing senescent cells has been shown to have promising effects against cancer and age-related pathologies in preclinical models as well as early human clinical trials. However, current senescent cell elimination strategies are focused on targets that do not distinguish between hyper-inflamed or SASP senescent cells versus relatively non-inflamed senescent cells. The use of senolytics in the clinic is still limited due to their cytotoxicity to either normal cells or potentially beneficial senescent cells. A more effective senescence cell targeted approach is needed to reduce side effects and increase the efficiency of senescence cell removal or reduction.

Conditionally Active Biologics (CAB) technology is a proprietary platform unique in its ability to be selectively active in the context of diseased tissues, but not normal tissues. The aberrant accumulation of senescent cells in aged and cancerous tissue triggers inflammatory signaling through a senescence-associated secretory phenotype (SASP), promoting aging and tumor progression. Since our CAB technology is currently being tested as a cancer therapy by targeting cell surface markers such as AXL, ROR2, and CTLA4 in clinical studies, we explored whether CAB technology allows selective removal of senescent cells in SASP-associated microenvironments.

In our previous report, we demonstrated several novel senescence-specific surface antigens upregulated in senescent cells (1). CAB antibodies targeting these senescence markers have no or very low binding to the target antigen on senescence cells in physiological, alkaline conditions, but have strong binding in glycolytic, acidic SASP conditions in *in vitro* binding assays. In *in vitro* antibody-dependent cell-mediated cytotoxicity assays, CAB antibodies were more potent against senescent cells compared to proliferating cells and displayed high selectivity for the glycolytic, acidic condition. To study whether CAB antibody reduces senescent cell occurrence *in vivo*, we developed a unilateral ureteral obstruction (UUO) mouse model to induce senescent cells, fibrosis, and inflammation in mouse kidney. The mice treated with CAB antibodies had a significant reduction of senescent cells and inflammatory cells infiltrated in the renal cortex, compared to the mice treated with benchmark and isotype antibodies in UUO kidneys. Thus, the CAB antibody-based therapeutic is a promising strategy for senescent cell removal in an inflammatory microenvironment. In conclusion, CAB technology provides a new generation of biologics with an increased safety margin and therapeutic index targeting SASP, acidic senescence cells in cancer and age-related diseases.

#2970 Anti-diabetic drug, semaglutide, prevents doxorubicin-induced endothelial cell toxicity.

S. Bakhit, C. Amaefuna, K. Ramana;
Noorda College of Osteopathic Medicine, LLC, Provo, UT

Doxorubicin (Dox) is part of the anthracycline drug family and is known for its broad and effective use as a chemotherapeutic agent. It is commonly used to treat solid tumors and malignancies such as leukemia, breast, lung, and ovarian cancers. Unfortunately, its use in treating advanced cancers is limited due to its cardiotoxic side effects. Therefore, various adjuvant approaches are required to increase Dox's efficacy and to reduce unwanted toxicities including cardiotoxicity. Semaglutideis a glucagon-like peptide-1 (GLP-1) receptor agonist commonly used to treat type-2 diabetes. In his study, the effect of Semaglutide in preventing Dox-induced endothelial cell toxicity was investigated. Our data indicate that Semaglutide prevents Dox-induced cell death in human umbilical vein endothelial cells (HUVEC) in a dose- and time-dependent manner. Similarly, live and dead cell staining assay also confirms Semaglutide prevents Dox-induced endothelial cell death. Semaglutide also prevented the Dox-induced apoptosis of HUVECs. It also prevented the Dox-induced reactive oxygen species and activation of caspase-3. Further, Semaglutide regulated the expression of various anti- and pro-apoptotic and inflammatory factors induced by Dox. Inconclusion, our current results suggests that the anti-diabetic drug, Semaglutide, could prevent Dox-induced endothelial cell death by regulating the expression of various pro-apoptotic, anti-apoptotic and inflammatory markers. Thus, our data indicate that Semaglutide could be used as a potential adjuvant drug to reduce the adverse effects of anthracycline chemotherapeutic drugs.

#2971 A cytosolic growth factor receptor serves as a convergent core of condensates for anabolic activity in cancer and senescence.

T. Kim, **H. Choi**, T. Yoon, C. Kang;
Seoul National University, Seoul, Korea, Republic of

Anabolic activity, driven by growth factor signaling, is essential for cellular activities, including cell growth, proliferation, and protein synthesis. Dysregulation of growth factor signaling has been implicated in numerous human pathological conditions, including cancer and aging. Interestingly, cancer cells and senescent cells - two completely different cell fates - are reported to have an increased anabolic activity. Here, we show endosomal condensation of a growth factor receptor as a molecular switch for such anabolic enhancement. Endosomal condensates of a growth factor receptor (ecGFR) exhibit liquid-liquid phase separation (LLPS), acting as a signaling hub locked in the 'ON' state by preventing their lysosomal degradation. Furthermore, we identify a regulatory circuit that operates in both cancer and senescence to facilitate the formation of ecGFR and its physicochemical properties. Pharmacological and genetic resolution of ecGFR corrects aberrant anabolism in cancer and senescence, thereby suppressing cancer growth and senescence-associated hyperinflammation *in vitro* as well as *in vivo*. Thus, our study provides a convergent anabolic core between cancer and senescence that could be exploited as a therapeutic vulnerability for human pathological conditions associated with aberrant anabolism.

#2972 Senescent macrophages drive tumorigenesis by limiting antitumor immunity.

L. I. Prieto;
Mayo Clinic, Rochester, MN

A big challenge in oncology is tumor heterogeneity, as the same type of tumor can manifest differently across patients. Our current cancer therapies focus on targeting malignant cells without considering how the tumor microenvironment influence tumorigenesis or changes in response to treatment. Therefore, identifying effective therapies that restrict tumor growth and progression while restoring optimal tissue and organ function is imperative. Here, we propose a potential strategy to delay the frequency of lung tumorigenesis and reduce progression by selectively targeting tumor-promoting senescent cells that arise with advancing age, prolonging antitumor immunity.

Using lung tumor-prone mice, we found that senescent cells, specifically senescent alveolar macrophages, accumulate early in hyperplastic lesions. Mechanistically, these macrophages upregulate the cell cycle regulator $p16^{Ink4a}$; express the cell surface protein CXCR1; they are distinct from other established subsets; are sensitive to senolytic interventions; have a tumor-promoting secretome, including SPP1; and express immunosuppressive factors that modulate the antitumor immune response. Selective clearance of senescent macrophages attenuates adenoma development, indicating they, at least in part, promote tumorigenesis. Importantly, we observed alveolar macrophages with these properties accumulating in treatment-naive human early-stage lung adenocarcinoma *in situ,* indicating that the cellular senescence program in macrophages is a conserved etiology. We also found that senescent alveolar macrophages accumulate in otherwise naturally aged normal mouse lungs and their persistence correlates with increased inflammation. Collectively, our findings suggest that targeting senescent macrophages may constitute a potential therapeutic intervention to postpone or attenuate lung cancer during the early stages of the disease.

#2973 Analysis of NBTXR3 nanoparticles recapture after release by dying cells.

J. Da silva, C. Bienassis, S. Paris;
Nanobiotix, Paris, France

In 2011, NBTXR3 emerged as the pioneering radioenhancer used in clinical practice to treat patients with locally advanced soft tissue sarcoma (LA-STS). Following the successful completion of a phase II/III clinical study for LA-STS, with a doubling of the pCR rate in the NBTXR3 arm compared with the control arm. NBTXR3 became the first radioenhancer to receive CE mark approval. NBTXR3 nanoparticles are composed of a functionalized core made of hafnium oxide, a high atomic number element. They were designed to enhance the effects of radiotherapy (RT) within cells without causing additional side effects on healthy tissues. Exploiting this physical mechanism, radiation-activated NBTXR3 (NBTXR3+RT) has exhibited superior efficacy in eradicating tumor cells and managing tumor growth in various preclinical models and in human studies. It surpasses the effects of RT alone while maintaining a favorable safety profile. Recent preclinical investigations have uncovered that the advantages of NBTXR3 go beyond mere radioenhancement and improved cancer cell destruction. Notably, NBTXR3 has been reported to possess immunomodulatory properties through several mechanisms, including 1) improved induction of DNA damage, leading to enhanced activation of the cGAS-STING pathway, 2) promotion of immunogenic cell death, 3) enhancement of immunopeptidome presentation, 4) generation of an antitumor immune response that results in the production of an abscopal effect mediated by CD8+ cytotoxic lymphocytes. Significantly, a series of recent studies using a two-tumor mouse model of anti-PD1-resistant lung cancer demonstrated that the addition of NBTXR3 significantly improved the efficacy of various treatment regimens (combinations of RT plus anti-PD1 and other checkpoint inhibitors) in terms of tumor growth, abscopal effect, and overall survival. Furthermore, similar benefits can be achieved when NBTXR3 is combined with proton therapy (PBT). Moreover, all these studies (both X-ray and PBT) reported a robust activation of the antitumor immune response, the restoration of the effectiveness of anti-PD1 therapy, and the induction of a memory response in cured mice. But our knowledge of the underlying biological processes that lead to these effects remains rather limited. For example, no information is available about the fate of these nanoparticles once they are injected into a tumor or when they are released by dying cancer cells. To gain a better understanding of these issues, we conducted a series of in vitro and in vivo experiments. We demonstrate that the endocytosis occurs similarly both in vivo and in vitro, at the level of tumor cells. Furthermore, we demonstrate in vitro that nanoparticles taken up by these tumor cells and subsequently released upon their death can be reinternalized by other tumor cells, thus facilitating their destruction by RT. These initial findings provide a deeper insight into the behavior of NBTXR3.

#2975 Vitamin D receptor signaling limits DNA damage at early stage of prostate tumorigenesis and prevents tumor aggressiveness.

K. Len[1], J. Gantzer[1], N. Le May[2], C. Thibault-Carpentier[1], D. Metzger[1], G. Laverny[1];
[1]IGBMC -CNRS UMR7104 - INSERM U1258 - Univ. of Strasbourg, Illkirch, France, [2]CRBS - INSERM U1112, Strasbourg, France

Prostate cancer (PCa) is the most common visceral neoplasm and the second leading cause of cancer-related deaths in male of western societies. Low circulating vitamin D levels and reduced expression of its receptor (VDR) correlate with PCa risk and severity, but the clinical use of vitamin D is limited by its pro-calcemic activities. To characterize the role of VDR in PCa, PTEN$^{(i)pe-/-}$ mice, that recapitulate the human disease and in which the tumor suppressor gene PTEN is selectively inactivated in prostatic epithelial cells (PECs) at adulthood, were compared to PTEN/VDR$^{(i)pe-/-}$ mice in which PECs are PTEN and VDR-deficient. Histological analysis showed that prostatic intraepithelial neoplasia (PIN) are formed between 1-3 months after gene inactivation (AGI). Importantly, VDR-deficiency increased by 2-fold the PECs proliferation rate as early as 1-month AGI. At this stage, RNA-seq and immunohistochemistry analysis revealed the presence of oxidative DNA damage selectively in VDR-deficient PINs. Moreover, a 4-week supplementation with the antioxidant N-acetyl cysteine reduced oxidative DNA damage in PTEN/VDR$^{(i)pe-/-}$ prostates, and normalized the number of Ki-67+ cells to the levels of PTEN$^{(i)pe-/-}$ ones. After 3 months AGI, both PTEN$^{(i)pe-/-}$ and PTEN/VDR$^{(i)pe-/-}$ tumors entered in a latency phase characterized by cellular senescence. However, the prostate weight in PTEN/VDR$^{(i)pe-/-}$ mice was 2-fold higher than in PTEN$^{(i)pe-/-}$ mice 12 months AGI. In addition, tumors of PTEN$^{(i)pe-/-}$ were mostly composed of non-invasive PIN-like adenocarcinoma, whereas invasive adenocarcinoma, sarcomatoid and squamous-cell carcinoma were observed in those of PTEN/VDR$^{(i)pe-/-}$ mice. Using single cell and spatial transcriptomics, we unraveled the presence of epithelial cells with epithelial-mesenchymal transition (EMT) hallmarks in PTEN/VDR$^{(i)pe-/-}$ prostate 10 months AGI. In addition, immunophenotyping revealed a higher infiltration of neutrophils, also termed as myeloid-derived suppressive cells and implicated in EMT and metastasis dissemination, in PTEN/VDR$^{(i)pe-/-}$ prostates compared to PTEN$^{(i)pe-/-}$ ones. Moreover, pan-cytokeratin-positive micro-metastasis were detected in lymph nodes and livers of PTEN/VDR$^{(i)pe-/-}$ mice, but not in those of PTEN$^{(i)pe-/-}$ mice, demonstrating that VDR-deficiency in PECs promotes aggressive PCa. Thus, VDR signaling exerts a protective role on PTEN-deficient PECs by limiting the oxidative-stress and proliferation during PINs initiation, and prevents PCa progression.

#2976 The potential use of butyrate and propionate to inhibit oncogenic phenotypes in oral squamous cell carcinoma and triple negative breast cancer.

A. J. Amaral Maisonet;
University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Background
Oral squamous cell carcinoma (OSCC) and triple-negative breast cancer (TNBC) are aggressive cancers with low survival rates, particularly in Hispanics. Since the underpinning mechanisms of oncogenesis for both OSCC and TNBC are multifactorial, the development of novel targeted therapies is limited. The tumor microbiome has been shown to modulate the microenvironment. The microbial product short-chain fatty acids (SCFA) may represent a putative target for treatment as they can potentially inhibit cell growth, proliferation, migration, and induce morphologic changes in cancer cells. We evaluated the impact of the SCFAs butyrate, acetate, and propionate on the oncogenic phenotypes of OECM-1 and MDA-231 cell line models for OSCC and TNBC respectively.
Methods
OECM-1 and MDA-231 cell lines were cultured in RPMI-1640 medium supplemented with 10% FBS. Cytotoxicity was determined using an alamarBlue assay by treating the cells with SCFA in a series of 7 concentrations starting at 125 mM (1:2 dilution factor) for 24, 48, and 72 hours (h). Proliferation quantification was performed using trypan blue dye after treatment with SCFA for 24h, 48h and 72h. Migration and invasion were measured after treatment for 24h with SCFAs. Comparative analysis of our results was performed using GraphPad Prism v10.
Results
Higher concentrations of all SCFA decreased cell viability in OSCC and TNBC at all time points. In OECM-1 cells, the average inhibitory concentration of 50% (IC50) was 3mM for butyrate, 382mM for acetate, and 64mM for propionate while in MDA-MB-231 cells, the average IC50 was 4.3mM for butyrate, 462mM for acetate, and 20mM for propionate. Both OECM-1 and MDA-MB-231 cells treated with butyrate and propionate at 5mM resulted in a slower migration after 24h of treatment. Additionally, there was a significant reduction of cell number and proliferation rate after 48h and 72h of butyrate treatment at the concentrations 1mM ($p=0.0425$) and 5mM ($p=0.0007$) in OSCC.
Conclusions
Our results show that butyrate and propionate can reduce oncogenic phenotypes in OSCC and TNBC and may represent a potential target for the development of alternative treatment strategies for both cancers. Future work includes measuring the impact of these SCFA in epithelial-mesenchymal transition, loss of adhesion, and cell death.

#2977 Novel HSP90 inhibitors with senolytic activity for a targeted therapy in a hormone-induced breast cancer senescence model.

L. Cis[1], M. Gottardi Zamperla[2], V. Barbi[3], P. Cigala Fulgosi[3], S. De Martino[1], A. Aiello[4], S. Nanni[1], C. Cencioni[4], D. Pirolli[5], P. Tabarelli De Fatis[3], G. Ivaldi[3], M. Malavolta[6], C. Steinkuhler[7], M. De Rosa[5], A. Farsetti[4], S. Atlante[4], C. Gaetano[3];

[1]Universita Cattolica del Sacro Cuore, Roma, Italy, [2]stituti Clinici Scientifici Maugeri Spa Societa Benefit, Pavia, Italy, [3]Istituti Clinici Scientifici Maugeri Spa Societa Benefit, Pavia, Italy, [4]CNR-Istituto di analisi dei sistemi ed informatica, Roma, Italy, [5]CNR-Istituto di Scienze e Tecnologie Chimiche, Roma, Italy, [6]Istituto nazionale per il ricovero e la cura dell'anziano IRCCS, Pavia, Italy, [7]Italfarmaco Group, Cinisello Balsamo, Italy

Background: The research into senescent cells, particularly their accumulation and contribution to aging and age-related diseases, has gained significant momentum in recent years. This interest is primarily driven by findings in mouse models, where the excessive buildup of senescent cells is linked to various age-related pathologies. Consequently, there has been a concerted effort in the scientific community to identify and develop senolytics. A notable development in this field is the identification of senolytics within the class of HSP90 inhibitors. These inhibitors, initially investigated for their potential in cancer therapy, have been repurposed due to their high selectivity for senescent cells. Our research has led to new compounds with mild inhibitory activity against HSP90α in response to these challenges. These compounds stand out for their lack of toxic side effects and their demonstrated senolytic activity across multiple cellular models.
Objective: The primary objective of this research is to identify and characterize innovative HSP90 inhibitors that exhibit senolytic properties, specifically in the context of hormone-driven cancers.
Methods and Results: Utilizing a structure-based virtual screening technique, we identified several compounds displaying strong affinity and predicted inhibitory activity against the target protein, HSP90α. Among these, two inhibitors designated K4 and K5, demonstrated notable senolytic activity in vitro without inducing cytotoxic effects in non-senescent cells. These compounds were tested for their efficacy in senolytic activity and displayed half-maximal inhibitory concentrations (IC50) of 155 nM and 111 nM, respectively. The experimental model for this study was the MCF7 cell line, which was treated with 4-Hydroxytamoxifen (Tam, 10uM for 96 hours) to induce a state of senescence. Subsequent growth curve analyses and beta-galactosidase assays established that Tam treatment effectively halted cell proliferation and induced a senescence state in about 40% of the cell population compared to the ethanol control. When treated with K4 and K5 (10 uM for an additional 96 hours), a significant reduction in the senescent cell population was observed, with K5 showing a particularly pronounced increase in the mortality rate of these cells (up to 2.5-fold compared to the DMSO control). Western blot analysis supported these results, suggesting the effectiveness of K5 combined with Tam in inhibiting proliferation and inducing cell death in MCF7 cells.
Conclusion: Our findings propose a novel therapeutic approach for hormone-dependent breast cancer, combining the dual roles of tamoxifen and HSP90 inhibitors to target senescent cancer cells. This strategy could reduce tumor recurrence and contribute to the advancement of cancer treatment methods.

#2978 Extracellular ATP induced senescence in human lung cancer cells.

R. A. Ward, A. Hunt, N. Anderson, X. Chen;
Ohio University, Athens, OH

In tumors, extracellular ATP (eATP) concentrations are 1,000 to 10,000 times higher than is found in normal tissues and eATP is up taken through macropinocytosis leading to a large increase in intracellular ATP levels. eATP is also linked to the TGF-β signaling pathway as exocytosis of ATP is induced that is then used in an autocrine fashion activating the P2X7 purinergic receptor[1]. Through these mechanisms, eATP has also been recently shown to induce EMT, CSC formation, and drug resistance[1]. One of the mechanisms through which these processes may be induced is a senescent cell precursor[2]. Senescence is a generally irreversible epigenetically controlled process characterized by a complete exit from the cell cycle in response to either DNA damage, stressful conditions, or aging. Recent mounting evidence has shown that senescence can be a cancer promoting mechanism by entering this state in response to stress such as during chemotherapy, but they can utilize it to enhance their malignant capabilities, including the ability to escape their senescent state with heightened stem cell characteristics, which can lead to a higher chance of relapse after treatment[2]. Senescent cells have recently been named a hallmark of cancer[3]. This study shows the time dependent induction of a senescent like state in human lung cancer A549 cells after only 2 hours of treatment with 0.5mM eATP, the concentration found in the tumor microenvironment, through analysis of transcriptional markers using total polyA RNAseq as well as chromogenic and flow cytometric assays for senescence associated beta-galactosidase activity. Additionally, inhibitors of macropinocytosis and purinergic receptors have been used to gain insight into the mechanisms of action that this pathway takes. This demonstrates a novel use of ATP within the tumor microenvironment for aiding in cancer progression and drug resistance. After EMT, CSC formation, and drug resistance, senescence is added to the long list of eATP mediated cancer promoting processes.

#2979 Pancreatic cancer cells upregulate LPAR4 in response to isolation stress to create a fibronectin-rich extracellular matrix niche and promote tumor initiation.

C. Wu, T. Rakhshandehroo, H. I. Wettersten, A. Campos, T. Schalscha, S. Jain, Z. Yu, J. Tan, E. Mose, B. G. Childers, A. M. Lowy, S. M. Weis, D. A. Cheresh; UC San Diego, San Diego, CA

Tumor initiation is an inefficient process in which tumor cells must develop cell-autonomous mechanisms to survive harsh microenvironments, establish colonies, and thereby overcome “isolation stress.” We report that pancreatic cancer cells transiently upregulate lysophosphatidic acid receptor 4 (LPAR4), a G-protein coupled receptor, in response to microenvironmental stress or chemotherapy, which promotes stress tolerance, drug resistance, and tumor initiation. Even without exogenous LPA, LPAR4 drives the expression of a subset of extracellular matrix (ECM) genes via an AKT/CREB axis, including fibronectin and versican, which are established drivers of cancer stemness. The upregulation of fibronectin is indispensable for LPAR4-induced tumor initiation in vivo and anchorage-independent growth in vitro. Furthermore, the ligation of this fibronectin-containing ECM created by LPAR4-positive cells via integrins α5β1 or αvβ3 can transfer cancer stemness and stress tolerance to LPAR4-negative cells by activating Yes-associated protein 1 (YAP). Our findings reveal that in response to isolation stress, pancreatic tumor cells that upregulate LPAR4 can autonomously generate a fibronectin-enriched ECM niche and thereby initiate tumor formation.

#2980 Exploiting the selenoproteome in uveal melanoma.

A. Sanders, C. Cunanan, E. Hartsough;
Drexel University College of Medicine, Philadelphia, PA

Uveal melanoma (UM) is a common intraocular malignancy arising from GNAQ/GNA11 mutations in uveal tract melanocytes. Although primary UM is treatable by radiation and enucleation, half of patients will develop liver metastasis. Unfortunately, patients with metastatic UM have a poor prognosis of approximately one-year - underscoring metastatic UM as one of the deadliest cancers. A strong prognostic indicator for UM liver metastases is a deletion or inactivation of the deubiquitinase BAP1, yet its specific role in disease progression is unclear. Intriguingly, upon BAP1 loss of function, the cysteine importer SLC7A11 is up regulated. Imported cysteine can be converted into glutathione serving as a cofactor for antioxidant enzymes like GPX4, a selenoprotein (SeP). SePs are a protein family characterized by having at least one selenocysteine - a selenium (Se) containing amino acid. Interestingly, the liver serves as a major hub for Se transport via Selenoprotein P (SEPP). The selenocysteine rich SEPP is secreted by hepatocytes and catabolized in recipient cells facilitating synthesis of de novo SeP. Here we hypothesize that mutant BAP1 UM utilizes the liver's Se rich microenvironment to augment selenoproteome expression to stave off oxidative stress. Using publicly available datasets, we found patients with mutant BAP1 UM have increased expression of antioxidants proteins and genes associated with SeP expression. In a panel of BAP1 expressing and deficient UM cells, we found that BAP1 deficient cells have increased expression of SePs, suggesting a predisposition to resist oxidative stress. In the presence of exogenous Se, UM cell lines upregulate SeP expression indicating the importance of selenium availability for SeP expression. In addition, a hepatocyte cell line, and an ex vivo liver slice co-culture model was used to confirm that SEPP was produced in the liver slices and was associated with increased SeP expression in UM cells. Furthermore, we found that BAP1 null UM cells were more susceptible to GPX4 inhibition compared to wild type cells, suggesting a reliance on SeP expression. Taken together, these findings suggest that the liver associated selenoproteome expression may underpin an oxidative stress-associated therapeutic vulnerability in UM liver metastases.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: microRNA- and Other Non-coding RNA-Based Translational Medicine
Poster Session

#2984 Prostate cancer associated glycosylated RNAs: Who are you and where are you hiding?.
S. McGuire, E. Jones, S. Moen, A. Esquela-Kerscher;
Eastern Virginia Medical School, Norfolk, VA

Glycosylated RNA (glycoRNA) is an emerging field. Carbohydrate modifications are vital for biomolecule (proteins and lipids) stability, transport, and localization. Glycosylation influences cell functions like differentiation, apoptosis, and immune response, potentially impacting human disease. The Bertozzi lab initially discovered that RNAs can carry sugar modifications when they metabolically labeled mammalian cultured cells using bioorthogonal chemistry methods normally employed for glycosylated protein and lipid enrichment. Our lab wanted to investigate the translational potential of glycoRNAs and determine if these modifications could be developed as novel clinical targets for aggressive prostate cancer. (PCa). As advanced forms of PCa often lead to poor prognoses, it is imperative that better screening biomarkers and therapeutic treatment options are developed to increase patient survivorship. We predicted that glycoRNA expression would correlate with malignancy, metastatic status, and hormone sensitivity in prostate cells. Our lab used the sialic acid metabolic precursor Ac4ManNAz and click chemistry to label a panel of human prostate cancer cell lines representing the spectrum of prostate disease followed by rigorous RNA isolation procedures and northern blot analysis. We found that human prostate cell lines with no (RWPE-1) or low malignancy (LNCaP) expressed higher levels of glycoRNA belonging to the small <200 nt (but not large) noncoding RNA class compared to aggressive, metastatic PCa cell lines. Our glycosidase studies and lectin northern blot analysis indicated that RNA carries both N-linked and O-linked modifications. Based on these findings, we hypothesized that glycosylated RNA plays an important role in maintaining prostate homeostasis and in cancer protection. To better profile these glycoRNAs, we aimed to: 1) Test a wider range of metabolic labeling regents to characterize the glycoRNA populations using a panel of human prostate cell lines; 2) Perform cellular fractionation studies to determine localization of glycoRNA in prostate cells; and 3) Explore glycoRNAs in a genetic animal model. These studies focused on LNCaP PCa cell lines, which express high levels of glycoRNA. We found that small glycoRNA expression was noted when LNCaP cells were metabolically labeled with Ac_4GalNAz (predominantly O-linked) and Ac_4ManNAz (predominantly N-linked), verifying glycoRNA heterogeneity. Cellular fractionation studies indicated glycoRNA localization was enriched in the membrane fraction of LNCaP cells using these metabolic labels. Furthermore, we verified that *C. elegans* grown on Ac_4GalNAz plates expressed small glycoRNA, indicating biological conservation. We are now characterizing these glycoRNAs using RNA sequencing and LC-MS/MS glycomics. Our findings will provide novel insights into cancer-associated glycoRNA, leading to improved clinical tools for PCa.

#2985 RXR agonist, 9cUAB30 impacts epigenetic regulations to achieve chemoprevention of UVB-induced Skin cancer by altering global miRNA profiling.

M. P. Kashyap, R. Sinha, C. A. Elmets, V. R. Atigadda, M. Athar;
University of Alabama at Birmingham, Birmingham, AL

Basal cell carcinoma (BCCs) and Squamous cell carcinoma (SCCs) are the most common skin neoplasms in the Caucasian population. UVB is considered as the most important etiologic factor for these cancers. The molecular mechanism regulating pathogenesis of these neoplasms is not well defined. Similar to humans Ptch$^{+/-}$/SKH-1 mice develop both BCCs and SCCs, following chronic UVB-irradiation. We used TaqMan-based Open Array platform containing 796 miRNAs (miRs) to profile miRs associated with BCCs and SCCs. Pathway enrichment analysis was performed using miRPathDB databases at https://mpd.bioinf.uni-sb.de/. 81 miRNAs were differentially expressed in BCCs, of which 54 miRs had cumulative frequency of greater than 1 (FC>1) and 78 miRs were differentially expressed in SCCs, out of which 20 miRs had FC>1. miR-721 was highly induced (123.75 fold, P<0.0430) in BCCs followed by miR-2182, miR-21, miR-451, miR-124a, and miR-685 while downmodulated miRs includes miR-1, miR-133a, miR-133b, and miR-196b. Likewise, miR-21 had maximum fold induction (45.94, P<0.007) in SCCs followed by miR-2182, miR-685, miR-1938, miR-2138, and miR-451 while miR-196b, miR196c, and miR-1 were downmodulated. Kegg pathways analysis revealed that altered miRs belong to Hepatitis B, HIF-1, FoxO, chemokine, adipocytokine, NFκB, cholinergic and TLR signaling pathways. WikiPathway database showed alterations in miRs associated with neovascularization process, Notch Signaling, Pregnane X receptor, α6β4, and BDNF-TrkB signaling. To further investigate the importance of pathways associated with tumor progression, we profiled miRs in residual BCCs and SCCs procured from UAB30 treatment groups. The chemopreventive agent UAB30 is an RXR agonist. In BCCs, UAB30 treatment significantly downmodulated UVB-upregulated miRs. These miRs includes miR-210, miR-546, miR-324-3p, miR-706 and miR-1898. However, UAB30 treatment significantly upregulates miR-380-5p which was downmodulated by UVB-alone. These miRs were involved in immune regulation, Fanconi anemia pathways, FoxO signaling, prostate cancer and p53 signaling. In SCCs, UAB30 treatment significantly reversed the expression of various miRs which were downmodulated by UVB. These miRs were miR-24, miR-26a, miR-30c, miR-328, miR-30b, miR-495 and miR-2100. The expression of miR-21a-3p was downmodulated by UAB30 in SCCs of UVB-exposed group relative to SCCs of untreated but UVB-exposed group. These miRs belong to pathways involved in cell cycle progression, p53 signaling, viral carcinogenesis, Hepatitis B, Melanoma, Prostate cancer, FoxO and PI3K-AKT signaling. In summary, this profiling of miRs in UVB-induced BCC and SCC represents the underlying epigenetic mechanisms that regulate various signaling pathways in these cancers. Our data also show the critical role of miRs responsive to UAB30 treatment in cancer chemoprevention.

#2986 Germline signatures predicting toxicity and response to CTLA4 inhibitors.

J. B. Weidhaas[1], K. McGreevy[1], N. Marco[2], N. Sundahl[3], C. R. Cabanski[4], C. Spencer[4], P. Ost[5], D. Telesca[1];
[1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]Duke University, Durham, NC, [3]AZ Groeninge, Kortrijk, Belgium, [4]Parker Institute for Cancer Immunotherapy, San Francisco, CA, [5]Ghent University, Ghent, Belgium

Background: Because germline microRNA-based variants predict toxicity risk to anti-PD-1/PDL-1 treatment, and CTLA4 inhibitors are often used in combination with them, we wanted to see if we could also predict toxicity and/or response to anti-CTLA4 therapy.
Methods: The study included 69 patients from 3 institutions treated with anti-CTLA4 therapy alone. Patients were 23-89 years old with median age of 62. “Toxicity” was defined as grade 3 or higher toxicity and “Response” as a complete response, partial response, or stable disease. A panel of previously tested variants (n=139), age, sex and cycles of anti-CTLA4 were used to predict endpoints of interest. To balance model dimensionality we pre-screened variants and included them if they were marginally associated with our outcomes of interest via Fisher’s Exact Test or Jonckheere-Terpstra Test at a p-value threshold of < 0.2. We fit Elastic Net (EN), Random Forest (RF), and Boosted Tree (BT) models with up-sampling to predict outcomes of interest. Leave-one-out cross validation (LOOCV) was used to evaluate model performance, and the model with the highest LOOCV AUC (between all EN, RF, and BT) was chosen as the final model and re-fit using all observations. We also performed a stratified gene ontology (GO) analysis to assess biological differences between variants involved in the signatures. Our GO analysis compared gene clusters across groupings with an adjusted p-value cutoff of 0.05 against a universal genomic background.
Results: 15 patients had toxicity and 21 patients had a response, with 27/139 and 25/139 variants marginally associated with these endpoints, respectively. Our toxicity model had a LOOCV AUC of 0.811 with the top variables being age, TNNT2_rs3729843, REV3L_rs465646, miR34b_c_rs4938723, and XRCC3_rs861539. Our response model had an LOOCV AUC of 0.716 with top variants being IL2RA_rs2476491, REV3L_rs465646, and IL10RB_rs2834167. Including anti-CTLA4 cycles improved the prediction accuracy for Response with an AUC 0.764. GO analysis revealed 117 pathways enriched in both the Toxicity and Response signatures, which were predominantly involved in pri-miRNA transcriptional regulation. Top GO terms in the Response signature (333 unique) were related to apoptosis and cell death. Top GO terms in the Toxicity signature (425 unique) were related to DNA replication and cellular signaling and response, including the interleukin-35-mediated signaling pathway.
Conclusion: We identified germline signatures predicting toxicity and response following anti-CTLA4 therapy. These signatures differed from each other as well as from a previously identified signature of toxicity to anti-PD1/PDL-1 therapy, and GO analysis identified plausible underlying signaling pathways. Our findings continue to validate the potential of these variants to predict meaningful endpoints in cancer therapy, and thus further research in larger and more diverse cohorts is warranted.

#2987 microRNA (miRNA) a putative biomarker to better define the molecular apocrine breast cancer (MABC) subtype.

G. Chamandi[1], A. Borgel[2], A. Kurdi[1], P. Khoueiry[1], L. Teixeira[3], M. Le Bras[2], J. Lehamnn[2], **R. Nasr**[1];
[1]American University of Beirut, Beirut, Lebanon, [2]INSERM U976, HIPI, Paris, France, [3]St. Louis Hospital Paris, Paris, France

Background: Breast cancer (BC), is a highly heterogeneous disease, divided into molecular subtypes based on gene expression and clinical outcomes. Transcriptomics profiling depicted a subtype that has luminal expression profile but lacks estrogen receptor (ER), progesterone receptor expression with an overlapping expression of HER-2; yet it overexpresses androgen receptor (AR). This subtype was referred to as MABC and constitutes 8-14% of all BC types. At present MABC is often misdiagnosed with triple negative BC (TNBC). Its improper diagnosis demands the adoption of complementary tools; miRNA, key players in BC tumorigenic processes, hold promise in defining MABC.
Methods: 539 BC microarray data were downloaded from The Cancer Genome Atlas (TCGA-BRCA) (PMID: 25691825) using TCGA biolinks R/Bioconductor package (PMID:267704973). Cases with available miRNA data were retained and classified using citbcmst R package (PMID: 21785460). Differential expression analysis identified deregulated miRNAs using DEseq2. The validation set consists of 111 ER-neg samples (68 MABC, and 43 TN samples) with an average age at diagnosis 58.51 years and a median follow-up=78.5 months. MABC tumors were characterized apart of TNBC by the molecular signature (AR, FOXA1 and AR-related genes, PMID: 25516281) on fresh tissue sections. Using miRCURY LNA™ miRNA PCR assay, miRNA profiling was done for a panel of differentially expressed miRNAs. Non tumorigenic (MCF-10A) and BC Cellular models MABC (MDA-MB-453) and TNBC (MDA-MB-231) were used to investigate the invasive potential of MABC.
Results: TCGA data analysis indicated MABC as a separate entity based on gene signature. MiRNA-seq data analysis depicted a set of 6 significantly deregulated miRNA with absolute value of log2 fold change> 1 and P-adjusted value <0.05 between MABC and TNBC. We validated, by miRNA profiling, significant upregulation of miR-2115-3p and miR-187-3p in MABC compared to TNBC. These miRNAs significantly differentiate MABC patients from TNBC patients where the combined miRNA panel of miR-2115-3p and miR-187-3p had an area under the curve of 0.904 ±0.28 (P<0.0001 and 95% CI: 0.850-0.958) and sensitivity, specificity, and a diagnostic accuracy of 90.41%, 81.1%, and 86.5% respectively. Preliminary data, showed that non-tumorigenic/non-invasive MCF-10A had a significant increase in its invasive ability upon transfection with miR-187-3p mimic (P<0.05). Similarly, the invasive cell line MDA-MB-231 showed a significant increase in invasion upon transfection with miR-187-3p mimic (P<0.05). On the other hand, only miR-187-3p inhibitor significantly decreased the invasive potential of MDA-MB-453 cells (P<0.05).
Conclusion: MABC has a unique signature of miRNA as compared to TNBC. miR-2115-3p, and miR-187-3p could be potential diagnostic biomarkers for MABC. The invasive potential of MABC could be attributed to miR-187-3p activity.

#2988 TUG1 exosomal lncRNA sponges let-7 miRNA family members and advances prostate cancer.

R. M. Marima[1], M. Mbeje[1], J. Kandhavelu[2], C. Penny[3], Z. Dlamini[1];

[1]University of Pretoria, Pretoria, South Africa, [2]Georgetown University Medical Center, Washington, WA, [3]University of the Witwatersrand, Johannesburg, South Africa

Exosomal long-non coding RNAs (lncRNAs) play an important role in cancer progression and have potential prognostic biomarker potential in several cancers including prostate cancer (PCa). Taurine-upregulated gene 1 (TUG1) is an oncogenic lncRNA overexpressed in PCa. This exosomal lncRNA has been reported to promote PCa migration, invasion and Epithelial-Mesenchymal Transition (EMT). However, TUG1 PCa prognostic mechanisms remain to be elucidated. This study aimed to profile differentially expressed lncRNAs in PCa high-grade tumor cells (PC-3) cells compared to low-grade PCa tumor cells (LNCaP). This was achieved by using a 384-well plate of PCa lncRNA gene panel. A human lncRNA database, LncSEA and other bioinformatics tools were used for annotation and enrichment analysis. RT-qPCR was used to confirm the gene array data. Up or down-regulation of ±2 and $p < 0.05$ were considered significant. Forty two (42%) percent and 14% of lncRNAs were shown to be up and downregulated, respectively. Notably, TUG1 was shown to be upregulated in PC-3 cells from PCR array and RT-qPCR results. Bioinformatics analysis revealed that TUG1 is involved in several cancer hallmarks including apoptosis evasion, migration, invasion and EMT. Furthermore, lncRNA/miRNA complexes regulate a series of oncogenic signaling pathways and this study demonstrated that TUG1 sponges the let-7 miRNA family members (a highly conserved tumor suppressor miRNA family) and promotes PCa progression. Precise mechanisms of TUG1/ let-7 axis in PCa prognosis need to be largely elucidated as this may hold potential to understanding lncRNA/miRNA-mediated PCa progression and thus be targeted for novel therapeutics.

#2989 MicroRNA profiling in human samples and cell lines uncovers eight key players in the cisplain resistance of HGSOC.

M. Rivera-Serrano[1], M. Flores[2], J. Rolon[2], V. Reyes[2], F. Valiyeva[1], P. E. Vivas-Mejia[1];
[1]UPR - Comprehensive Cancer Center, San Juan, PR, [2]UPR Medical Sciences Campus, San Juan, PR

Metastasis and drug resistance remain significant contributors to cancer-related mortality globally. In ovarian cancer, a substantial 70% of cases develop resistance to the front-line therapy, cisplatin. Despite numerous proposed mechanisms for cisplatin resistance, the complete molecular events leading to this phenomenon in ovarian cancer remain incompletely understood. Mounting evidence suggests that dysregulation of microRNAs (miRNAs) plays a pivotal role in carcinogenesis, including the development of drug resistance. While various miRNAs have been identified in ovarian cancer samples and cell lines, few studies have compared miRNA expression in human paraffin ovarian samples and cisplatin-resistant high-grade serous ovarian cancer (HGSOC), the most prevalent and malignant of gynecological malignancies. This study aimed to identify key miRNAs implicated in cisplatin resistance. We performed miRNA expression profiles in RNA isolated from human paraffin ovarian tumors and ovarian cancers cell lines. Eight miRNAs were commonly increased in paraffin samples and cisplatin resistant ovarian cancer cells. Targeting these miRNAs with inhibitors significantly reduced cell proliferation by more than 50% for miR-203a, miR-96-5p, miR-10a-5p, miR-141-3p, miR-200c-3p, and miR-182-5p, and to a lesser extent, miR-296-5p and miR-1206. Inhibitors demonstrated a reduction in cell migration for all targets except miR-200c-3p and miR-10a-5p. Analysis of online databases, literature reports, and molecular pathway construction revealed that these eight miRNAs regulate key molecular pathways associated with cell proliferation, primarily through PTEN regulation in cisplatin-resistant HGSOC cells. Interrogation of the KM plotter patient database revealed that high expression of miR-1206, miR-10a, miR-141, and miR-96 correlates with a poor prognosis in ovarian cancer patients. These findings position these eight miRNAs as potential therapeutic targets and markers for cisplatin response in ovarian cancer therapy.

#2990 Differential micro-RNA expression in circulating exosomes of pancreatic ductal adenocarcinoma patients.

R. Kaur, S. Bhoriwal, P. K. Gautam;
All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Pancreatic ductal Adenocarcinoma (PDAC) is a highly lethal solid tumor with 5-year survival rate of 5-8%. Extracellular vesicles like exosomes circulating in the blood are crucial mediators of intracellular communication, immunomodulation and tumor progression. The microRNAs being the major cargo of exosomes, are the primary carriers of intracellular information. The role of exosomal-miRNA (exoMIR's) in regulating the pathogenesis of tumors is well-established in oncology but its potential is still unexplored. To the best of our knowledge no study has yet explored the contrasting exoMIR expression in cancer patients before and after their surgery. In this study, differential exoMIR's profile of three pancreatic ductal adenocarcinoma patients at three stages: pre-surgery, post-surgery, and follow-up was established using small RNA sequencing on the Illumina platform. In blood samples taken before and after surgery total of 181, 201 and 201 microRNAs were dysregulated in circulating exosomes of three different patients viz. P_1, P_9 & P_11 (Patient identifiers) respectively. Out of the total dysregulated microRNAs in post-op samples 76 were upregulated and 105 downregulated in P_1, 95 upregulated and 106 downregulated in P_9 & 69 upregulated and 132 downregulated in P_11 as compared to their Pre surgery samples. Further, when exoMIR's of post-op samples were compared to that of follow-up samples after 6 months of surgery their expression profile changed notably such that a total of 184, 157 & 190 microRNAs dysregulated in follow-up of P_1, P_9 and P_11 respectively. Out of the total dysregulated microRNAs in follow up samples 93 were upregulated and 91 downregulated in P_1, 69 upregulated and 88 downregulated in P_9 & 96 upregulated and 94 downregulated in P_11 as compared to their post-op samples. On Venn diagram analysis 27 microRNAs were found to be commonly dysregulated in all 3 patients before surgery and 22 common micro RNAs were again dysregulated even after 6 months of surgery. Bioinformatic analysis of these
differentially expressed miRNAs and their respective protein targets revealed that their role in oncogenic molecular pathways is very prominent, thus highlighting their potential use in cancer therapeutics, diagnostics as well as prognosis.

#2991 Global analysis of miR-210 and miR-21 dysregulation and direct targeting in thyroid cancer during hypoxia.

B. H. Powell[1], W. T. Mills IV[1], A. Turchinovich[2], Y. Wang[1], M. A. Zeiger[3], C. B. Umbricht[1], M. K. Meffert[1], K. W. Witwer[1];
[1]Johns Hopkins University, Baltimore, MD, [2]SciBerg e.Kfm, Mannheim, Germany, [3]National Cancer Institute, National Institutes of Health, Bethesda, MD

Introduction: Hypoxia is frequent in solid tumors and stabilizes Hypoxia Inducible Factor-1 (HIF-1). HIF-1, in turn, activates several cellular pathways that promote tumor growth and resistance to chemotherapy. MicroRNA (miRNA) miR-210 is a direct HIF-1 target. HIF-1 binds to a Hypoxia-Response Element (HRE) in the miR-210 promoter, up-regulating its expression. miR-21 is the most widely reported oncogenic miRNA in cancer. miRNAs complexed with Argonaute-2 (AGO2) bind target mRNAs to inhibit translation. Given that a single miRNA can have hundreds of predicted mRNA targets, we sought to identify mRNA targets of miR-210 and miR-21. Identifying dysregulated target genes of miR-210 and miR-21 may highlight new therapeutic targets.
Methods: The SW1736 (anaplastic thyroid cancer) cell line was cultured at 2% (hypoxic) or atmospheric (normoxic) O_2 for 24 or 48hrs. HIF-1α accumulation relative to normoxia was analyzed by Western blot. miR-210-3p expression was measured relative to normoxia by RT-qPCR. Small and total RNA-sequencing was performed to identify additional differentially expressed miRNAs and mRNAs in hypoxia after 48hrs. To identify direct miRNA targets, SW1736 cells were cross-linked by UV irradiation after 48hrs of normoxic or hypoxic conditions. AGO2 covalently cross-linked to miRNA and target mRNAs were purified by immunoprecipitation after DNA and RNA digestion. miRNA and target mRNAs protected by AGO2 were ligated to generate chimeric miRNA:mRNA molecules followed by sequencing. miRNA:mRNA chimeras were analyzed using the SCRAP bioinformatic pipeline.
Results: miR-210-3p expression was up-regulated by ~11-fold at 24hrs and ~19-fold at 48hrs, which was consistent with increased HIF-1α protein levels assessed by Western blot. miR-210-3p and HIF-1α levels were highest after 48hr of hypoxia relative to normoxia. Small RNA-seq showed that miR-210-3p was the only miRNA significantly up-regulated (>2-fold) in hypoxia (48hr) in SW1736. Further, miRNA:mRNA chimeric sequencing results confirmed that miRNAs primarily interacted with the 3'UTRs and coding sequences of mRNA. miR-210-3p was most abundant in hypoxia and found in chimeras with HIF-1α mRNA as well as some oncogenic and tumor suppressor transcripts involved in metabolism and mRNA processing. miR-21-5p was the most abundant chimera miRNA in both normoxia and hypoxia and was primarily bound to tumor suppressor mRNAs associated with cell cycle arrest, TGFB signaling, and inhibition of tumor invasion and migration.
Conclusions: miR-210-3p and miR-21-5p elevated levels and interactions indicate hypoxia and malignancy in solid tumors including breast, thyroid, prostate, and lung. Further analysis of other miRNA:mRNA interactions and functional validation may aid in identifying novel therapies for solid tumors.

#2992 miR-200-mediated inactivation of cancer-associated fibroblasts attenuates lung cancer invasion and metastasis.

I. Cheon, S. Lee, Y.-H. Ahn;
Ewha Womans University College of Medicine, Seoul, Korea, Republic of

Cancer-associated fibroblasts (CAFs) play a crucial role in the tumor microenvironment and contribute to the development and progression of lung cancer. We aimed to elucidate whether miRNA-200 (miR-200), which is recognized for its ability to suppress EMT, prevents CAFs from promoting cancer progression. Inactivation of CAFs mediated by miR-200 suppressed lung cancer cell invasion, migration, tumorigenesis, and metastasis. Additionally, miR-200 attenuated the ability of CAFs to facilitate the aggressiveness of lung cancer cells, encourage M2 polarization of macrophages, and increase the angiogenic sprouting of vascular endothelial cells. NRP2, known as a co-receptor of VEGFR, was identified as a target of miR-200, mediating the functional activity of miR-200 in CAFs. NRP2-VEGFR signaling promoted the secretion of VEGFD and PTN from CAFs to activate cancer cell migration and invasion. Based on these findings, we suggest that miR-200 impedes cancer progression and metastasis by remodeling CAFs, and that miR-200 and NRP2 are potential therapeutic targets in the treatment of lung cancer.

#2993 TmiS: A prognostic indicator for prostate cancer survival based on total tumor cell miRNA levels.

M. Montierth[1], K. Nemeth[2], G. A. Calin[2], W. Wang[2];

[1]Baylor College of Medicine, Houston, TX, [2]University of Texas MD Anderson Cancer Center, Houston, TX

Background: MicroRNAs (miRNAs) are small noncoding RNAs that bind mRNA and inhibit translation or encourage degradation. MiRNAs play a significant regulatory role, with approximately 60% of protein-coding genes harboring miRNA binding sites. MiRNA dysregulation is associated with tumor onset, growth, and metastasis. These important regulatory RNAs have been studied as potential cancer biomarkers, yet the widespread adoption of any miRNA signature has been hindered by the variable nature of miRNA targeting, which is highly context specific. Total tumor cell mRNA content, or TmS, has been shown to have potential as a pan-cancer prognostic indicator. Here we expand the TmS framework using deconvolved miRNA expression to calculate TmiS, an estimate of total tumor-cell miRNA content and investigate the utility of TmiS as a prognostic marker in prostate cancer.

Methods: Whole exome sequencing and miRNA sequencing, along with clinical annotations were downloaded for prostate cancer patient samples from The Cancer Genome Atlas (TCGA). Sample purity and ploidy were estimated from exomes using ASACT and ABSOLUTE. Tumor miRNA proportion was estimated using our previously developed miRNA deconvolution method DeMixMir, and TmiS, the total miRNA content per haploid genome per tumor cell, was calculated for each sample. Patients were separated by Gleason category and were binarized into High-TmiS and Low-TmiS within samples with Gleason 7 and Gleason 8+ scores separately.

Results: We find Low-TmiS patients to have significantly better prognosis in both Gleason 7 ($P = 0.04$) and Gleason 8+ ($P = 0.01$) prostate cancer. We confirm that TmiS is indeed an aggregate measure of total miRNA levels, with no strong correlations observed with any one miRNA. We identify differentially expressed miRNAs and mRNAs between high and low TmiS, and find distinct enriched pathways between Gleason 7 and Gleason 8+ samples, and that several of the differentially expressed miRNAs are well-characterized cancer-related transcripts.

Conclusions: In spite of their important regulatory function, the variable and context specific nature of miRNA targeting has been a barrier to their implementation as a robust biomarker. We find TmiS to be a measure of total miRNA dysregulation, and that patients with high total miRNA content show poorer survival within prostate samples graded at Gleason 7 (as well as Gleason 8+), which has been a challenging group for further risk classification. In summary, while the consequences of miRNA dysregulation are subtype specific, we find that by measuring total tumor cell miRNA, TmiS has potential as a robust prognostic indicator independent cellular context.

#2994 MIR99AHG promotes ERα expression and ER-positive breast cancer cells proliferation via activating Hippo signaling.

Wende Wang[1], Danping Lin[1], Ziyang Lin[1], Yangyang Yan[1], Yusen Qin[1], Yuanke Liang[2], Haoyu Lin[2], De Zeng[1]

[1]Department of Breast Medical Oncology, Cancer Hospital of Shantou University Medical College, Shantou, China,[2]Department of Breast and Thyroid Surgery, The First Affiliated Hospital of Shantou University Medical College, Shantou, China

Background: Estrogen receptor (ER) positive breast cancer is the most common subtype of breast cancer. Elucidation of the regulatory network in estrogen receptor pathway is critical to develop and deliver potent targeted therapy for ER-positive breast cancer. The Mir-99a-let-7c cluster host gene MIR99AHG is a long non-coding RNA involving in a variety of tumor formation and disease progression processes. However, the biological functions of MIR99AHG in ER-positive breast cancer have not been reported.

Methods: The Western-blot, qRT-PCR, Immunofluorescence and fluorescence in-situ hybridization were used to identify potential target genes and regulatory pathway of estrogen receptor α (ERa), which is a key proliferative driver of ER-positive breast cancer cells. The cell proliferation assay, clone formation assay, xenograft tumor model and rescue assay were used to investigate the effect of differential expression of MIR99AHG on the proliferative capacity of ER-positive breast cancer cells MCF7 and T47D. In addition, correlation analysis was performed to verify the relation of the expression of MIR99AHG, LATS1, LATS2, CYR61, CTGF and ESR1 from The Cancer Genome Atlas (TCGA) and Gene Expression Omnibus (GEO) cohorts. And survival analysis was used to predict the prognostic impact of MIR99AHG in breast cancer patients.

Results: MIR99AHG expression was significantly higher in ER-positive breast cancer cells MCF7 and T47D than in ER-negative breast cancer cells SKBR3, MDA-MB-231 and BT549. The high expression of MIR99AHG predicted poor prognosis in ER-positive breast cancer patients. *In vitro* and *in vivo* assays demonstrated that MIR99AHG positively regulated the proliferation of MCF7 and T47D cells. Importantly, the Hippo signaling was identified to be down-stream mediators of MIR99AHG in modulating ERα transcription. Furthermore, XMU-MP-1, which targets the Hippo signaling upstream kinase MST1/2, was able to reverse the effect of MIR99AHG on MCF7 cell proliferation.

Conclusions: MIR99AHG up-regulates ERα expression and promotes proliferation in ER-positive breast cancer cells through activating Hippo signaling pathway. Targeting MIR99AHG/Hippo pathway is a potential strategy for the treatment of ER-positive breast cancer.

#2995 The ectopic expression of miR-380-5p interferes with the aggressive traits of diffuse malignant peritoneal mesothelima cells.

Stefano Percio, Lorenzo Di Pietro, Eisa Naghshineh, Marcello Deraco, Nadia Zaffaroni, **Marco Folini**

Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Telomerase activity (TA) and the alternative lengthening of telomere (ALT) pathway are two telomere maintenance mechanisms (TMM) yet identified in human cancers. Although the activation of either TMM seems to be equivalent in supporting tumor cell immortalization (a hallmark of cancer), the contribution of TA and ALT to tumor progression and aggressiveness may be different. Mounting evidence suggests that cancer cell aggressiveness could be associated with a TA↔ALT shift that would allow the acquisition of distinct aggressive traits. We previously showed that an ALT-like phenotype emerged in diffuse malignant peritoneal mesothelioma (DMPM) cells upon miR-380-5p-dependent inhibition of TA (*Cimino-Reale G, et al. J Hematol Oncol. 2017*). To analyze the transcriptomic changes associated with the emergence of such a phenotype, gene expression profiling was carried out. Results showed that 3331 genes were differentially expressed (FDR<0.05, adjusted for multiple hypothesis testing) in miR-380-5p- *vs.* preNeg-transfected DMPM cells, out of which 1673 genes were up-regulated and 1658 genes down-regulated. To get biological meaning about the molecular events occurring upon miR-380-5p reconstitution, Gene Set Enrichment Analysis was performed. Results showed a positive enrichment of 188 gene sets, restricted for an FDR < 0.05, out of which signatures related to DNA replication, DNA recombination and telomere maintenance via recombination were present. Conversely, only 1 gene set (GO: positive regulation of blood vessel endothelial cell migration) was negatively enriched at significant level. Notably, among the leading edge genes, *PTGS2*, which encodes for cyclooxygenase-2 (COX-2) and represents a predicted target of miR-380-5p (miRWalk), was the most significantly down-regulated gene (FDR< 0.000001; log(fold-change): -2.15). Notably, a complete abrogation of *PTGS2* expression levels and COX-2 protein amounts was observed in miR-380-5p- compared to preNeg-transfected cells upon validation by qRT-PCR and western blotting, respectively. This evidence was paralleled by reduced amounts of phospho-FAK (focal adhesion kinase) and impaired migrating/invading capabilities of cells ectopically expressing miR-380-5p. Moreover, a reduction of Vimentin and a slight increase in P-Cadherin protein levels were also observed in cells ectopically expressing miR-380-5p, likely indicating the occurrence of a reverse-EMT program. Finally, a pronounced increase in the sensitivity to Cisplatin and Doxorubicin was also appreciable in miR-380-5p- *vs.* preNeg-transfected cells, suggesting that miRNA-mediated induction of a reverse-EMT may, at least in part, contribute to improve the response of DMPM cells to chemotherapeutic drugs.

#2997 Identification of novel long non-coding RNAs in mantle cell lymphoma patients.

A. LaFerlita, S. Singh, A. Sircar, R. Baiocchi, N. Muthusamy, L. Alinari, N. Epperla, L. Sehgal;
The Ohio State University Wexner Medical Ctr., Columbus, OH

Mantle Cell Lymphoma (MCL) is a rare and incurable type of B-cell non-Hodgkin lymphoma that affects about 4,000 people per year in the United States. Despite intense research to identify novel therapeutic approaches, the median progression-free survival after first-line treatment is four years. For this reason, the discovery of novel therapeutic targets remains crucial. Over half of the human genome is actively transcribed as non-coding RNAs. Among them, the non-coding RNAs that are longer than 200 nucleotides are named long non-coding RNAs (lncRNAs). lncRNAs have been shown to play essential roles in several human diseases, including cancer, by modulating cell cycle, immune response, or stemness through their interactions with DNA, protein, and RNA. For this reason, we decided to perform an RNA sequencing (RNA-Seq) profiling to identify the dysregulated lncRNAs in MCL. In more detail, we performed RNA-Seq in a cohort of 18 MCL patients compared to normal B-cells from the peripheral blood of healthy donors (HD). Reads were first trimmed for quality filtering, and adapters were removed using Trim Galore. Trimmed reads were mapped to the human genome (HG38 assembly) using HISAT 2. All the reads mapped inside the genomic coordinates of lncRNAs, reported in the GTF annotation file of GENCODE v43, were counted by featureCounts. Differential expression analysis between MCL samples vs HD was performed by LIMMA. To validate the results obtained from our internal MCL cohort, we also downloaded publicly available RNA-Seq data of 16 MCL patients and analyzed them using the previously described pipeline. Our analyses revealed several dysregulations in lncRNA expression occurring in MCL. Precisely, we identified 385 upregulated and 387 downregulated lncRNAs ($|log2FC| > 0.58$ and adjusted p-value < 0.05) in our internal MCL cohort, and 63% of them were also confirmed in the external cohort. Notably, the lncRNA called MALAT1 showed the highest significant upregulation in both cohorts, reinforcing this lncRNA's pivotal role in cancer development. To study the potential involvement of MALAT1 in MCL, we compared the MCL samples with higher MALAT1 expression (upper quartile) against those with lower expression (lower quartile) in both cohorts. The identified differentially expressed genes were used as input for a mechanistic network-based topological pathway analysis using MITHrIL. The analysis revealed that the KEGG pathway "Cell Cycle" was among the top upregulated pathways in MCL samples with high MALAT1 expression, suggesting the relevance of this lncRNA in promoting cellular proliferation, as also reported in the literature for other tumor types. In conclusion, our is the first study to describe the novel dysregulation signature of lncRNAs in MCL in two independent cohorts.

#2998 Regulation of epidermal growth factor receptor signaling by BRCA1-microRNA 146a network.

E. Kumaraswamy[1], R. M. Koren Shimak[1], S. Gunewardena[2], K. L. Wendt[3], D. Alexander[2], S. L. Hembruff[1], R. A. Jensen[1];
[1]The University of Kansas Cancer Center, Kansas City, KS, [2]University of Kansas Medical Center, Kansas City, KS, [3]The University of Oklahoma, Norman, OK

Inherited defects in the breast cancer susceptibility gene, BRCA1 are associated with an increased risk for hereditary breast, ovarian, and other cancers. BRCA1-associated basal like breast cancers (BLBCs) are high-grade ductal carcinomas that do not express ER, PR or HER2, but frequently overexpress epidermal growth factor receptor (EGFR/ErbB1/HER1). The EGFR-driven signaling network plays a pivotal role in BLBC pathogenesis. EGFR overexpression is associated with tumor progression and metastasis, resistance to radiation and chemotherapy, and poor prognosis. Growth factor receptors are regulated by multiple miRNAs, each having many targets, coordinately controlling the complex pathways of downstream signaling. We have previously reported a post-transcriptional mechanism by which BRCA1 regulates EGFR expression through the induction of miR-146a and provided a rationale for the development of miR-146a based therapeutic strategies. In addition, we have shown that BRCA1 also exerts regulatory control over dozens of important miRNAs that appear to play a critical role in breast neoplasia. From TCGA analysis, we show that low expression of these miRNAs is associated with distinctively poor overall survival of TNBC patients. Using miR-146a loss or gain of function experiments *in vitro*, we show that BRCA1 and miR-146a regulate EGFR signaling, stemness, epithelial-to-mesenchymal transition (EMT), extracellular matrix (ECM) remodeling and chemoresistance. Using *in vivo* mouse models, we demonstrate that miR-146a overexpression delays tumor formation leading to better overall survival. BLBC unlike the other subtypes, lacks targeted therapy approaches making cytotoxic chemotherapy essentially the only option for treatment. Though EGFR inhibitors have been used to treat other cancers, clinical trials for breast cancer have so far been unsuccessful due to poor response rates. Since one miRNA can target multiple genes and regulate multiple signaling pathways, our study provides evidence to suggest that restoring miR-146a could suppress EGFR-RAS-MEK signaling and the other compensatory pathways, providing a targeted therapeutic option for BRCA1 associated BLBC.

#2999 Evaluation of microRNA expression in metastatic and non-metastatic salivary gland mucoepidermoid carcinoma.

M. E. S. Trevizani[1], K. K. Oliveira[1], F. A. Marchi[2], D. Bizinelli[2], F. V. Mariano[3], C. P. Nagano[2], F. A. Costa[1], C. A. L. Pinto[1], L. P. Kowalski[1], S. V. Lourenco[2], **C. M. Coutinho-Camillo**[1];

[1]A.C.Camargo Cancer Center, Sao Paulo, Brazil, [2]University of Sao Paulo, Sao Paulo, Brazil, [3]Unicamp, Sao Paulo, Brazil

Salivary gland tumors are a heterogeneous group of lesions, being mucoepidermoid carcinoma (MEC) the malignant neoplasm with the highest incidence, occurring mainly in the parotid gland. Characterization of its histological grade (high, intermediate, and low) is important for determining patient prognosis. Metastasis is more common high-grade tumors and can occur at regional lymph nodes or distant sites. Although the mechanisms underlying the metastatic process are largely unknown, large-scale microRNA expression profiling studies of human cancers have demonstrated that dysregulation of miRNA is frequently associated with many cancer types. The aim of this study is to validate the use of microRNA expression for the discrimination of the metastatic potential of MEC samples. Using Real Time RT-PCR (qPCR) we have analyzed the expression of 384 miRNAs and controls in 4 non-metastatic MECs, 3 MECs with lymph node metastasis, 3 MECs with distant metastasis, and 2 non-neoplastic human salivary gland samples. Comparing the expression among these groups we identified 45 differentially expressed miRNAs that may be related with the metastatic potential of these tumors. To validate the microRNA expression associated with the metastatic potential, we selected 7 out of the 45 differentially expressed microRNAs and 7 MEC samples from the different groups of samples. Considering the 7 microRNAs evaluated, we validated that the expression of miR-191 was increased in non-neoplastic samples when compared to MECs with lymph node metastasis and the expression of miR-494 was increased in non-neoplastic samples when compared to MECs with distant metastasis, suggesting that loss of these microRNAs might be involved in the development of metastasis in mucoepidermoid carcinoma. The determination of a miRNA expression profile could provide a better understanding of the molecular basis of MEC and facilitate the determination of diagnosis and prognosis of patients.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: New Insights into Tumor Suppressor Genes
Poster Session

#3003 Exon skipping for the tumor suppressor Annexin A7 promotes EGFR signaling in stem-like brain tumor initiating cells through receptor recycling.

Aran Merati, Sindhu Nair, Rajani Rajbhandari, Nicholas Johnson, Markus Bredel

Radiation Oncology, University of Alabama - Birmingham, Birmingham, AL

Background: Glioblastoma (GBM) is one of the most lethal forms of cancer. The majority of GBMs express aberrant receptor tyrosine kinase (RTK) activity, which upon activation, are canonically endocytosed and degraded. This process is disrupted in GBM to promote receptor recycling resulting in hyperactive RTK signaling. We demonstrated that the alternative splicing of the tumor suppressor Annexin A7 (ANXA7) supports the impaired endosomal trafficking of RTKs to favor recycling in GBM. Exon six of ANXA7 can be alternatively spliced to yield two distinct protein isoforms through its inclusion (I1) or exclusion (I2).
Methods: We investigated ANXA7 isoform differences for epidermal growth factor receptor (EGFR) trafficking fates first in U251 malignant glioma followed by stem-like brain tumor initiating cells (BTICs) originating from patient-derived xenografts (PDXs). U251s and primary BTICs (JX14) were transduced with lentivirus to overexpress ANXA7 and GFP for enrichment by flow cytometry. JX14 empty vector (EV; I2 only) and I1 (I2 and I1 expressing) cells were plated onto Geltrex and ligand starved overnight in serum-free media to maintain BTICs. We assessed EGFR protein levels following EGF stimulation in a time dependent manner. Immunofluorescence experiments were conducted to measure EGFR-ANXA7 colocalization (Pearson) with markers of the endocytic pathway, which included the early endosomes (EEA1), recycling endosomes (Rab4/Rab11), and lysosomes (LAMP1). EV and I1 cells were also incubated with siRNA targeting both ANXA7 isoforms to determine the impact of ANXA7 loss on endosomal EGFR trafficking.
Results: Interestingly, we found drastic differences in endosomal EGFR trafficking in I1 expressing cells. EGFR colocalized with EEA1 in both EV and I1 cells (R^2=0.01336, P>0.6275). In EV cells, EGFR was recycled via fast/slow recycling endosomes demonstrated by Rab4/Rab11 colocalization while I1 did not (Rab11: R^2=0.9267, P<0.0001). Immunoblotting revealed a significant reduction in EGFR protein in I1 cells only. Furthermore, I1 cells and not EV preferentially degraded EGFR as seen by LAMP1 colocalization (R^2=0.9398, P<0.0001). ANXA7 siRNA in EV cells did not alter EGFR trafficking, which implicates I2 as nonfunctional. On the other hand, ANXA7 KD in I1 cells impaired EGFR sorting via a 40% increase (P<0.0010) in total EGFR protein and a 40% reduction (P<0.0001) in colocalization with EEA1. Loss of I1 also shifted the degradation of EGFR back towards recycling.
Conclusion: GBMs express I2, which supports EGFR hyperactivity by favoring receptor recycling. I1 overexpression significantly reduced EGFR signaling by promoting degradation. I1-induced reduction in EGFR signaling suggests a new therapeutic vulnerability for BTICs by potentially reducing tumorigenicity or improving the efficacy of EGFR inhibition.

#3005 *Low-density lipoprotein receptor-related protein 1B* (*LRP1B*) depletion promotes tumorigenicity by modulating fibroblasts in the tumor microenvironment in esophageal squamous cell carcinoma.

K. Xu, J.-y. KO, V. Yu, M. L. LUNG;
University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong

Background: Esophageal squamous cell carcinoma (ESCC) is widespread worldwide with a poor survival rate. Tumor cells shedding from tumor tissues traveling to other organs through the blood circulatory system are called circulating tumor cells (CTCs). The CTCs in the blood of ESCC patients were enriched and then subjected to CTC mutational profiling by target sequencing. Our results suggested that CTC mutations in *low-density lipoprotein receptor-related protein 1B* (*LRP1B*) may have a potential prognostic role for ESCC. *LRP1B* belongs to the low-density receptor (LDLR) family with diverse roles in cellular functions and development, but the function of *LRP1B* in ESCC remains unclear. Therefore, this study aims to do a functional characterization of *LRP1B*.
Methods: The CRISPR cas9 system was used to functionally knock down the candidate gene in ESCC cell lines with the highest endogenous level of *LRP1B*. The *in vitro* cell proliferation rate and viability were measured by MTT assay, colony formation assay, and wound healing assay. The *in vivo* tumorigenicity assay was performed to evaluate the tumor suppressive effect by subcutaneous injection. To examine the clinical relevance of *LRP1B*, we also performed immunohistochemistry (IHC) in tumor tissue microarray (TMA).
Results: The reduction or loss of *LRP1B* mRNA was demonstrated in 60% of a panel of 15 ESCC cell lines. The depletion of *LRP1B* did not influence cell proliferation, cell clonogenic ability, or cell migration in ECSS cell lines. However, *LRP1B* depletion significantly promoted the growth of tumors in mouse xenograft models. Therefore, we hypothesize that *LRP1B* may be involved in modulating the tumor microenvironment (TME) by impacting various stromal components leading to an immuno-suppressive TME. We utilized RT-qPCR to investigate markers of various stromal components and observed that fibroblast markers (*acta2*, *pdgfrb*, and *vimentin*) had significantly higher expression levels after *LRP1B* downregulation in ESCC cell-derived mouse xenografts. The higher level of fibroblast cells was then verified by IHC staining. Further molecular mechanistic studies are underway and are expected to provide novel therapeutic insights by targeting the *LRP1B* genes. The *LRP1B* ESCC TMA data analysis is underway and statistical analysis will be presented.
Conclusions: *LRP1B* plays a tumor-suppressive role in ESCC by modulating the tumor-associated fibroblasts in the TME.

#3006 Morphogen-driven regulation of nuclear shape and its implication for colorectal cancer.

M. A. El Gendi, S. Herve, S. Gautam, Y. A. Miroshnikova;
NIH, National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), Bethesda, MD

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths worldwide despite improved rates of early detection and development of targeted treatments. Dysregulation of nuclear shape and the emergence of aberrant chromatin architecture correlate with cancer onset and progression, including CRC. Both extrinsic and intrinsic factors, most critically cytoskeletal and nucleoskeletal organization, chromatin architecture, and metabolic signaling, impact nuclear shape. Yet, what precisely determines nuclear shape in health and disease and how it is linked to cell fate and function remains a fundamental open question. In the case of over 75% of CRC cases, the first transformative genetic event is the loss of function in the tumor suppressor gene, adenomatous polyposis coli (APC). Mechanistically, perturbed APC signaling leads to aberrant activation of Wnt/beta-catenin signaling. This pathway is essential for intestinal homeostasis, as is the regulation of proper nuclear shape and function. Here, we aim to decipher the crosstalk between Wnt gradients and nuclear shape regulation in non-transformed and APC-mutated epithelial cells in vitro, as well as in WT and APC-mutant mouse colon tissues. The long-term goal of this work is to test whether a mechanistic link exists between Wnt-driven cellular transformation and the emergence of aberrant nuclear shape and function.

#3007 AZGP1 inhibits angiogenesis in prostate cancer.

R. Wen, G. Wen, Z. Qiu, E. Peterson, F. Marques, A. Bermudez, J. Pollack, H. Zhao, S. Pitteri, J. Brooks;
Stanford University, Stanford, CA

AZGP1 is involved in various biological processes, including lipid metabolism, regulation of cell proliferation, migration and invasion, and immune response. The loss of AZGP1 is associated with worse clinical outcomes, and AZGP1 has been indicated as a potential biomarker for prostate cancer. However, the underlying mechanisms of AZGP1 function in prostate cancer are unknown. This study reports AZGP1's pivotal involvement in angiogenesis within the prostate cancer tumor environment. Neither knockout nor overexpression of AZGP1 affects *in vitro* prostate cancer cell proliferation, migration, or invasion. Morphologically, AZGP1-deficient mouse prostates appear normal, but exhibit increased fibroblast growth in periglandular stroma after 6 months. The overexpression of AZGP1 does not impact the growth of PC3 and DU145 tumors; instead, these tumors significantly reduced microvessel density, suggesting AZGP1 exhibits anti-angiogenic properties. Proteomic profiling shows distinct profile of angiogenesis-related proteins between PC3-AZGP1-OV and PC3 control cells, featuring proteins like PDCD6 and MMP9. This study provides insights into the anti-angiogenic attributes of AZGP1 in prostate cancer, underscoring its potential as a therapeutic target for prostate cancer.

#3008 Loss of Rab25 accompanied by NRAS activation cooperatively mediates the tumorigenic transformation in melanoma.

S. Kandel[1], K. Rao[2];

[1]Southern Illinois University School of Medicine, Springfield, IL, [2]Simmons Cancer Institute and Southern Illinois University School of Medicine, Springfield, IL

Background: Ras oncogene activation is a common and often essential event in cancer development, including melanoma. Ras mutation is present in 20-30% of melanomas and remains an undrugged target. NRAS mutation is the most frequent Ras isoform activated in melanoma, with more than 80% cases of Q61 substitutions, and is closely associated with tumor aggressiveness. Rab25 is a ubiquitously expressed small GTPase protein with a context-dependent role in cancer pathophysiology. Its role remains undiscovered in the case of melanoma. Rab25 deep deletion can be seen in portions of melanoma in databases such as the Cancer Genome Atlas and Cbioportal. Interestingly, Rab25 has a consensus sequence homologous with the binding site of Q61 mutant Ras. We propose that the loss of Rab25 in melanocytes accompanied by Ras oncogenic activation are significant events in melanoma development, and restoration of Rab25 can potentially inhibit constitutively activated N-RAS; Rab25 serves as a tumor suppressor in melanoma genesis.

Objectives: To discover the role of Rab25 in melanoma, we studied Rab25 expression via mRNA and protein levels in different melanoma cell lines and screened biopsy-proven melanoma samples through immunohistochemistry in 61 different melanoma sections. Further, to see the tumor suppressive mechanism of Rab25 in vitro, we transduced selected cell lines Rab25.

Results: There is an 87% and 62.7% reduction in Rab25 mRNA level in NRASQ61R(SKMEL-2) and NRASQ61L type (WM1366) melanoma cell lines, respectively, also reflected in Rab25 protein level, and statistically significant at p-value <0.005, using student's T-test. Further, Rab25, prominent in adjacent normal tissues, was significantly lost in biopsy-proven melanoma tissues, with an H-score ranging from 13.28 to 91.77% and 0.00 to-11.24 % for normal skin tissue and melanoma section, respectively, and a negative correlation of -0.350, indicating a promising association of Rab25 loss with the progression of melanoma.

Conclusion: There is a loss of Rab25 in NRAS mutant melanoma with cancer progression. We saw a significant increase in Rab25 expression among the transduced sublines of NRAS mutant melanoma cell lines at the mRNA level, which will be further assessed through western blotting, cell proliferation assay, trans well migration assay, soft-agar colony formation assay to confirm NRAS mutant melanoma cell behavior. We will attempt to deliver a liposomally encapsulated six-peptide sequence to therapeutically inhibit the mutant NRAS.

#3009 ATRX loss blocks the differentiation of mesenchymal stem cells and promotes undifferentiated sarcoma development.

Y. Cai, J. Yao, D. N. Pan, Y. Jin, J. M. You, W. Yao, H. Ying;
UT MD Anderson Cancer Center, Houston, TX

Soft tissue sarcomas (STSs) are a collection of rare tumor types originated from the mesenchymal tissues. Among the over 70 histological subtypes of STS, undifferentiated sarcoma (US), which lacks any discernible morphological features of differentiated tissues, accounts for over 20% of all STSs and is correlated with high tumor grade and poor prognosis. Recent genomic profiling in US has identified p53 and ATRX among the most frequently mutated or deleted genes. ATRX is a SWI/SNF2 type of chromatin remodeling factor which functions in a histone variant H3.3-specific chaperone complex to orchestrates replication-independent nucleosome assembly at repetitive heterochromatic DNA regions including telomeres. Loss-of-function mutations occur frequently in many tumor types and is associated with the development of alternative lengthening of telomere (ALT). However, how loss of ATRX function may contribute to tumorigenesis is largely unknown. Here, we demonstrated that ATRX is required for the terminal differentiation of mouse mesenchymal stem cells (MSCs) into multiple lineages, such as adipocytes and osteocytes. Targeted deletion of Atrx in mouse MSCs, but not terminally differentiated mesenchymal lineage cells, accelerated sarcoma initiation induced by loss of p53 and significantly shortened the overall survival. Atrx-deficient tumors express high level of MSC markers such as CD44 and CD29 and exhibit pathological features highly reminiscent of human high-grade US. Transcriptomic analysis indicates that Atrx deficiency is associated with enhanced proliferation. Together, our data indicates that ATRX deficiency contributes to undifferentiated sarcoma development by inhibiting mesenchymal stem cell differentiation.

#3011 The loss of an orphan nuclear receptor NR2E3 augments Wnt/β-Catenin signaling via epigenetic dysregulation that links to the Sp1-β catenin-p300 interactions in hepatocellular carcinoma.

Y.-K. Leung[1], S.-G. Lee[2], J. Wang[3], S.-M. Ho[1], N. Rusch[1], C. Park[2], **K. Kim[1]**;

[1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]Chonnam National University, Gwangju, Korea, Republic of, [3]University of Cincinnati, Cincinnati, OH

Hepatocellular carcinoma (HCC) stands as the fourth leading cause of global cancer-related mortality due to late-stage detection, tumor heterogeneity, and drug resistance. The pivotal role of epigenetic factors in HCC development and progression necessitates the identification of critical epigenetic regulators. The orphan nuclear receptor NR2E3 (Nuclear receptor subfamily 2 group E, Member 3), primarily associated with retinal development, has emerged as a potential tumor suppressor. Earlier studies showed that the loss of NR2E3 leads to epigenetic repression of the estrogen receptor α (ER) through the involvement of Lysine Specific histone Demethylase 1 (LSD1). NR2E3 also forms a transcriptional complex with Sp1, governing the aryl hydrocarbon receptor (AHR) expression, a crucial factor in liver xenobiotic metabolism. In vivo, NR2E3 ablation results in p53 inactivation and severe liver injuries when exposed to liver toxicants, highlighting its role in activating p53. Nonetheless, the precise tumor suppressive and epigenetic role of NR2E3 in HCC remains unclear. HCC patients expressing low NR2E3 exhibit unfavorable clinical outcomes, aligning with heightened activation of the Wnt/β-catenin signaling pathway. The murine HCC models utilizing NR2E3 knockout mice show accelerated liver tumor formation and progression accompanied by enhanced activation of the Wnt/β-catenin signaling pathway and inactivation of the p53 signaling pathway. At a cellular level, losing NR2E3 increases the acquisition of aggressive cancer cell phenotype and tumorigenicity and upregulates vital genes in the Wnt/β-catenin pathway with enhanced chromatin accessibility. This event is mediated through the increased formation of active transcription complex involving Sp1, β-catenin, and p300, a histone acetyltransferase, on the promoters of target genes. Correspondingly, treatment of p300 inhibitor C646 decreased the expression of critical genes in the Wnt/β-catenin signaling pathway. These findings demonstrate that the loss of NR2E3 promotes Wnt/β-catenin signaling activation at cellular, organismal, and clinical levels. In summary, NR2E3 is a novel tumor suppressor that maintains epigenetic homeostasis, thereby preventing activation of Wnt/β-catenin signaling that promotes HCC formation.

#3012 Characterizing the functional significance of "variant of uncertain significance" of the tumour suppressor *CDH1*.

J. Wen[1], A. Singh[1], D. Nguyen[2], K. Meier-Ross[3], B. Martin[1], V. Khan[1], K. Dhami[4], J. Chao[1];

[1]University of Toronto, Toronto, ON, Canada, [2]Queen's University, Kingston, ON, Canada, [3]University of Ottawa, Ottawa, ON, Canada, [4]McMaster University, Hamilton, ON, Canada

We aim to develop a new approach to systematically characterize the functional significance of “variant of uncertain significance (VUS),” focusing on the tumor suppressor gene *CDH1*. Genetic testing is a powerful clinical tool for identifying individuals at risk of developing inherited or familial cancers. If a potential cancer-causing genetic variant (mutation) is found, clinicians can begin managing the patient’s risk early by initiating surveillance or prophylactic treatment. For an aggressive form of inherited stomach cancer called hereditary diffuse gastric cancer (HDGC), the most commonly mutated gene is *CDH1*, which encodes the tumor suppressor E-Cadherin. However, due to insufficient clinical evidence, over 50% of all publicly reported *CDH1* variants either have conflicting interpretations or cannot be classified, thus are not actionable. Consequently, almost 1 in 2 patients who undergo genetic testing for HDGC will not have a definitive test result and cannot benefit from early screening, causing strain on the healthcare system and psychological burden for the patients. To overcome this challenge, we developed a single-cell screening system to accurately classify *CDH1* variants using a combination of functional assays, machine learning, and deep learning. Our hypothesis, now supported by preliminary data, is that pathogenic variants will disrupt normal E-Cadherin’s ability to control its signaling partner beta-catenin. Thus, loss-of-function (LoF) *CDH1* variants would cause protein mislocalization and altered signaling which lead to abnormal proliferation, an early indicator for carcinogenesis. We express *CDH1* variants in human cell lines and use multiplexed high-content imaging to visualize E-Cadherin and beta-catenin. Next, our deep learning pipeline extracts single-cell phenotypic profiles, and our classifier then classifies variants as functional or LoF. Initial analysis of prioritized variants show that our pipeline can accurately separate clinically pathogenic and benign variants based on their functional status as predicted by our pipeline. The outcomes of this project will contribute to a systematic approach to reclassify VUS.

#3013 Alzheimer's-linked gene BIN1: Unraveling its unexpected role as a tumor suppressor in prostate cancer and influence on androgen receptor signaling.

C. McColl[1], D. Skapura[1], E. Ruiz Echartea[1], J. Deng[1], A. Rusin[1], J. Shin[1], A. Tyryshkin[1], C. Davis[2], E. Ehil[2], S. Kaochar[1];
[1]Baylor College of Medicine, Houston, TX, [2]Avera Institute for Human Genetics, Sioux Falls, SD

Androgen-receptor signaling inhibitors (ARSI) have been shown to significantly alter the natural history of castration-resistant PCa (CRPC). Unfortunately, resistance to ARSIs is inevitable. Unraveling the underlying mechanisms to identify potential therapeutic interventions to treat these lethal tumors has become a critical challenge in the post-ARSI era. Recent genomic sequencing has revealed a subclass of PCa harboring deletion of bridging integrator-1 (BIN1) and is associated with increased AR activity. Notably, BIN1 deletion frequently co-occurs with SPOP mutation and deletion of SPOPL, collectively suggesting BIN1 may function as tumor suppressor. To elucidate the role of BIN1 in prostate cells, we generated a prostate-specific BIN1 knockout murine model (PB-CreBIN1$^{FL/FL}$). This model revealed increased prostate mass at 6 months of age, accompanied by increased cell proliferation. We next crossed this strain to SPOP mutant (SPOP^{F133V}) model to generate a prostate specific BIN1 knockout, SPOP mutant model (PB-CreSPOP^{F133V}BIN1$^{FL/FL}$) and found increased proliferation and greater prostate mass compared to animals harboring SPOP mutation or BIN1 deletion alone. Next, we generated a doxycycline inducible BIN1 overexpressing PCa model (22Rv1BINOE) to evaluate AR signaling in vitro. We found that overexpression of BIN1 modestly reduced prostate cancer cell proliferation but profoundly suppressed androgen receptor protein level. To evaluate the transcriptional activity of AR and ARv7, we also utilized a luciferase reporter system harboring ARE consensus sequences found in the *KLK3* gene (AR-FL target) promoter or in the *EDN2* gene (ARv7 target) promoter, respectively. These reporter assays illustrated suppression of both AR-FL and AR-v7 driven gene transcriptional program upon BIN1 overexpression. Co-expression of both BIN1 and SPOPwt showed a synergistic knockdown of AR activity, while SPOPmut did not show this effect. These observations were further confirmed using global RNAseq. The RNAseq analysis also showed downregulation of several AR pathways as well as gene sets associated with cancer progression and metastasis. Interestingly, the RNAseq data showed downregulation of genes that are normally upregulated after SPOP mutation, further suggesting a synergistic role between SPOP and BIN1.

#3014 Exploring the correlation between oncogenic viruses and BRCA1/2gene mutations in Egyptian breast cancer patients.

S. Loutfy, Sr.[1], R. A. Al Najar[1], S. ElSayed[1], N. Abdel Fattah[1], A. Abdel-Samie Gaber[1], T. Hashem[1], W. S. Khalaf[2], A. F. Basyony[3], A. El-Sharif[2], S. M. Radwan[2], **M. Eltokhy**[4],

[1]National Cancer Institute, Cairo University, Cairo, Egypt, [2]Faculty of Pharmacy (Girls), Al-Azhar University, Cairo, Egypt, [3]Faculty of Pharmacy, Egyptian Russian University, Cairo, Egypt, [4]Texas Tech Health Science Center, USA, TX

Background: Recognizing the complexity of viral carcinogenesis and its perspectives, we aimed to investigate one of the key genetic factors associated with breast cancer development, BRCA1,2 mutations, and its association with the presence of some oncogenic viruses like HPV, MMTV, and EBV DNAs in both blood and tissues of breast cancer (BC) patients, hoping to provide new insights on role of oncogenic viruses in cancer development.

Patients and Methods: This study was conducted on 84 tissues and blood samples from Egyptian BC women and 50 blood samples from controls without known oncological disease. All samples were tested for the presence of viral DNAs, using real-time PCR assay. Fifty-five BC patients were investigated for the presence of mutations in exons 6 and 9 of BRCA1, and exons 11, 14, and 27 of BRCA2 using a high-resolution melting (HRM) assay. Results were correlated with the clinicopathological characteristics of BC. Results. HPV, MMTV, and EBV DNAs were detected in 30(35.7%), 19(22.6%), and 23 (27.3%) of tissues obtained from 84 BC patients, respectively, and into 16 (19%), 14 (16.7%) and 0 (0%) of blood from the same patients, respectively. On the other hand, these viruses were detected in 0 (0%), 7 (14%), and 0 (0%) of blood specimens obtained from 50 normal controls, respectively. Among 55 BC patients, mutations were detected in 37 (67%) of the tested exons of BRCA1/2 genes in the blood of BC patients, divided as 7 (12.7%) for exons 6 and 9 of BRCA1 gene, and into 11 (20%), 3 (5.5%), and 9 (16.4%) for exons 11, 14 and 27 of BRCA2 gene. Our previous investigation based on NGS showed that pathogenic mutations were (G509A:p.R170Q and c.C1471T:p.Q491X) for exons 6, 9 of BRCA1, respectively, and were (cT4001A: p.L1334X, c.7231delA: p.T2412Lfs and c.T9861A: p.C3287x) for exons 11, 14 and 27 of BRCA2, respectively. Further analysis showed that half of the patients with positive HPV DNA in tissues had mutations in the tested exons of BRCA1/2 genes. In contrast, none of the patients with MMTV DNA (15/55 (27%)) in their tissues had mutations in exons 6 and 9 of BRCA1 and only one patient had a mutation in exons 11 of BRCA2. Regarding EBV, 35% of positive patients had mutations in the tested exons of the BRCA1 gene and 21% in the tested exons of BRCA2 gene. Results were not affected by clinicopathological parameters.

Conclusion: MMTV DNA followed HPV, and then EBV DNAs were detected in more than 80% of our BC patients. HPV was the most frequent virus among BC patients showed to be associated with BRCA1/2 mutations in the tested exons. Sequencing analysis is in progress. Understanding this association will provide a relevant implication for developing novel, and personalized therapeutic options for treatment of oncogenic viruses.

#3015 HD-PTP mediates tumor suppression via modulation of anti-tumor immunity.

Chenxu Guo, Sheng Sun, Nayana Thimmiah, Agustina Maccio, Siang Koh, Leif Ellisen

Mass General Cancer Center, Boston, MA

The role of circulating extracellular vesicles in cancer biology is an area of intense research interest. Here, we reveal a tumor suppressor mechanism of HD-PTP (His Domain Protein Tyrosine Phosphatase, encoded by PTPN23), a protein associated with ESCRT (endosomal sorting complex required for transport), a complex that controls endosome sorting and exosome secretion. While loss of HD-PTP is known to be tumorigenic in mice and is frequently observed in human cancers including Triple Negative Breast Cancer (TNBC), the relevant pathways have remained obscure. We find that inhibition of HD-PTP *in vivo* promotes tumor progression selectively in a syngeneic, immune-competent TNBC model but not in a matched immune-deficient model. Through systematic profiling of the exosomal proteome in HD-PTP proficient and deficient cells, we identify PD-L1 as a key exosomal cargo selectively enriched due to loss of HD-PTP. Mechanistically, we show that inhibition of HD-PTP results in PD-L1 stabilization, its co-localization with the exosomal marker CD63, the enrichment of endosomal PD-L1 and subsequent increase in ExoPD-L1 release. Exosomes produced post HD-PTP loss inhibits antigen-dependent T cell activity *in vitro*, and HD-PTP inhibition in a syngeneic TNBC model promotes non-cell-autonomous, exosome- and PD-L1-dependent tumor progression, associated with reduced T cell infiltration and altered macrophage polarization. Consistent with these findings, low HD-PTP levels in human solid tumors are associated with decreased tumor infiltrating lymphocytes, poor response to immune checkpoint inhibition and inferior overall survival. Taken together, our studies unveil a novel tumor suppressor pathway controlling PD-L1 trafficking and ExoPD-L1 secretion, highlighting the critical roles of HD-PTP and ESCRT in anti-tumor immunity.

#3016 MCPIP1 endoribonuclease protects from liver fibrosis and regulates hepatocellular development.

K. Miekus[1], O. Kwapisz[1], P. Marona[1], J. Gorka[1], J. Kotlinowski[1], E. Pospiech[2], J. Jura[1];

[1]Jagiellonian University, Faculty of Biochemistry, Biophysics and Biotechnology, Krakow, Poland, [2]Human Genome Variation Research Group, Malopolska Centre of Biotechnology, Jagiellonian University, Krakow, Poland

Introduction: MCPIP1 (Monocyte Chemotactic Protein-1 Induced Protein), also known as Regnase-1, belongs to the CCCH zinc finger protein family, featuring a PilT N-terminus (PIN) domain-like RNase domain. Utilizing its intrinsic endonuclease activity, MCPIP1 functions as a precise modulator of cytokines, exhibiting an anti-inflammatory effect through the targeted degradation of specific mRNA transcripts. While recent studies have highlighted MCPIP1 as a potential tumor suppressor with decreased levels in breast cancer and clear cell renal cell carcinoma, its role in hepatocellular carcinoma (HCC) development remains unexplored.

Material and Methods: To investigate the role of MCPIP1 in HCC development, we used tissue-specific knockout mice with the deletion of Mcpip1 in hepatocytes. HCC was induced by administering diethylnitrosamine (DEN) to two-week-old mice. We conducted a comprehensive analysis, including the assessment of EMT and fibrosis markers, proinflammatory cytokines, and immune cell infiltration, using Western blot (WB), mass spectrometry, quantitative PCR (qPCR), and multiple immunohistochemistry (IHC) stainings. To identify differences between the wild-type (wt) and Mcpip1 knockout (KO) mice groups more effectively, hepatocytes were isolated using the perfusion method, and RNA-Seq analysis was performed.

Results and Discussion: The tissue-specific knockout of Mcpip1 in the liver has notable molecular consequences. Transcriptomic profiling revealed an upregulation of transcripts integral to tumor development, including Cxcr4, Met, Cxcl12, Hgf, and Src, alongside factors characteristically associated with cancer stem cells, Myc, Klf4, and CD133. The absence of MCPIP1 triggered immune cell activation in the liver, as evidenced by an augmented expression of markers specific to myeloid and lymphoid cell populations, indicative of an intensified immunological response. IHC examination of liver tissue from Mcpip1-deficient mice revealed significant fibrotic alterations, characterized by increased collagen deposition, and enhanced expression of alpha-smooth muscle actin (αSMA). The lack of Mcpip1 influences the increased levels of vimentin, fibronectin, and connective tissue growth factor (cTGF), indicating enhanced tissue remodeling.

Conclusions: MCPIP1, recognized for its anti-inflammatory functions, appears to function as a potential tumor suppressor in HCC development. The lack of MCPIP1 results in the upregulation of transcripts linked to tumorigenesis, immune cell activation, and notable fibrotic changes, highlighting its involvement in the complex molecular dynamics of HCC progression.

This study was supported by National Science Center grants no. 2017/26/E/NZ5/00691, 2021/41/N/NZ4/04187.

#3017 Lack of MCPIP1 enzymatic activity leads to neoplastic transformation of normal kidney cells.

P. Marona[1], I. Piasecka[1], J. Gorka[1], O. Kwapisz[1], R. Myrczek[1], E. Pospiech[2], J. Jura[1], K. Miekus[1];
[1]Jagiellonian University, Faculty of Biochemistry, Biophysics and Biotechnology, Krakow, Poland, [2]Jagiellonian University, Malopolska Center of Biotechnology, Krakow, Poland

Introduction: The MCPIP1 protein (Monocyte Chemotactic Protein-1 Induced Protein) is involved in the negative regulation of inflammation due to its RNase activity. A growing number of publications suggest that the MCPIP1 protein may influence the development of cancer by regulation of factors involved in angiogenesis, proliferation and cell death. We believe, that MCPIP1 may be a potential tumor suppressor. Our recent results show that lack of enzymatic activity of MCPIP1 leads to increased tumor growth, angiogenesis and metastasis. The main aim of our research is to study the importance of MCPIP1 for neoplastic transformation of normal, epithelial kidney cells, as well as acquirement of stemness features.
Material and Methods: To examine the effect of MCPIP1 in normal epithelial cell lines TCMK-1, RPTEC-Tert1 and HK-2 were transduced to overexpress mutated, inactive form of MCPIP1 (pLIX D141N) with proper control (pLIX PURO). We analyzed cells clonogenicity, as well as the levels of CSCs markers by western blot, NGS and qPCR. Next, cells were injected subcutaneously into NOD-SCID mice to check if mutation of MCPIP1 will induce tumor growth *in vivo*. Mice blood was analyzed for the presence of circulating tumor cells (CTCs), and secretion of cytokines by Proteome Profiler assay. Tumors were evaluated by multiple IHC stainings, as well as western blot and qPCR.
Results and Discussion: We have shown that the mutation of MCPIP1 increases the clonogenicity of kidney cells. Moreover, pLIX D141N cells were characterized by higher levels of the c-Met receptor, vimentin, Twist, CD44 and c-Myc, which are the markers of epithelial to mesenchymal transition and cancer stemness. The obtained results suggest that the loss of the MCPIP1 protein causes the acquisition of the characteristics of neoplastic cells. Next, we checked whether MCPIP1 mutation in normal cells predisposes them to proliferate when administered to mice. We found that, D141N mutation caused the growth of large tumors with higher expression of Cd44, Klf4 and Myc and number of CTCs, while the control cells injected into mice developed only local fibrosis with high expression of aSMA. pLIX D141N tumors secreted CXCL16 into mice plasma, and were characterized by increased phosphorylation of c-Met, Src kinase and c-Myc.
Conclusions: We believe that the MCPIP1 protein may be a marker of tumor initiation and play a key role in neoplastic transformation by regulating the changes in cell phenotype and levels of CSCs markers.
This study was supported by National Science Center grants no. 2022/47/B/NZ5/02724, 2022/45/B/NZ5/01973 and MNS 15/2021.

#3018 Transcriptional dysregulation in germline *TP53*-driven breast cancers.

N. Boruah, R. Moses, R. Hausler, H. Desai, A. Le, G. Kelly, A. Raghavakaimal, M. Narasimhamurthy, A. Nayak, A. J. Levine, K. N. Maxwell; University of Pennsylvania, Philadelphia, PA

Background: Pathogenic germline variants (PGVs) in *TP53* is associated with multicancer risk syndrome known as Li-Fraumeni Syndrome (LFS) and females have 80-90% risk of breast cancer at very early age compared to sporadic breast cancers. The mechanism of p53 tumor suppression relies on its function as a transcriptional activator; however, there is little data on the specific transcriptional defects in human breast tumors driven by germline mutant p53.
Methods: To investigate the specific transcriptional defects due to *TP53* PGVs in human breast, we performed bulk RNA-seq on invasive ductal carcinoma (IDC), ductal carcinoma in situ (DCIS) and surrounding and contralateral normal breast tissue in LFSBC compared to non-LFS sporadic BC. We also compared our results to breast tumors from The Cancer Genome Atlas (TCGA) with and without acquired *TP53* mutations.
Results: Our RNA-seq analysis revealed significant changes in the expression of key pathways in LFSBC compared to non-LFS breast cancer. Notably, cancer hallmark pathways such as apoptosis and reactive oxygen species were downregulated, while androgen response and cholesterol homeostasis pathways were upregulated in LFSBC compared to non-LFSBC. Expression of downstream targets of p53 such as *BAX*, tumor suppressors such as *CDKN1A* (p21) and *BTG2*, were significantly down in LFSBC suggesting impaired transcriptional activity of mutated *TP53* in LFS patients. We also observed downregulation of cell cycle regulators in LFS breast tumors compared to their surrounding and contralateral tissues. Although, there were no significant transcriptional differences as the tumor progressed from LFS DCIS to IDC, indicating that the damage caused by the mutated p53 had already occurred at the early stage. Additionally, we also investigated the immune cell composition in LFS-BC and non-LFSBC. LFSBC exhibited a higher relative proportion of CD4+ T cells, CD20+ B cells, NK cells, macrophages and monocytes compared to all sporadic non-LFSBC subtypes (TCGA) and age matched non-LFSBC. This providing novel insights into the immune landscape associated with LFS-driven breast cancer.
Conclusion: Our findings suggest that breast tissues with an inherited *TP53* mutation undergo a defective transcriptional state, shifting away from apoptosis, and experiencing dysregulation of cell cycle at an early stage as DCIS, potentially contributing to the early onset of LFS breast cancer. The preliminary analysis of immune repertoire in LFSBC opens avenues for deeper investigations into spatial transcriptomic profiles of germline *TP53*-mutated breast tumors also the immune cells. Overall, this study provides valuable insights into the *TP53* mutation driven breast cancers in humans.

#3019 Dissecting *in vivo* functions of R-Loops in *Brca1*-associated DNA replication stress and mammary tumorigenesis.

H.-C. Chiang, L. Qi, Y. Hu, R. Li;
The George Washington University, Washington, DC

Germ-line *BRCA1* mutations are associated with a significantly increased incidence of breast cancer in women. Although *BRCA1*-associated breast tumors are basal-like and estrogen receptor α negative (ERα^{-}), they originate from luminal progenitor cells. At the molecular level, BRCA1 is best known for its roles in resolution of DNA replication stress and promotion of homologous recombination (HR)-based double strand break (DSB) repair. In addition, BRCA1 is implicated in reduction of R-loops, a DNA-RNA hybrid structure and transcriptional byproduct associated with genome instability and transcriptional regulation. Our published findings suggest that BRCA1-dependent R-loop mitigation contributes to luminal cell-specific transcription and differentiation (Zhang et al, 2017, *Nature Communications*, 8:15908), which could in turn suppress *Brca1*-associated tumorigenesis. Using cell type-specific mouse genetics, we investigate a direct impact of R-loop removal on *Brca1*-associated mammary epithelial tumor formation. R-loop formation in mammary epithelial cells is efficiently reduced by over-expression of RNase H1, an R-loop-specific ribonuclease. R-loop removal does not affect mammary duct development or function. However, it drastically increases γH_2AX foci in proliferating BRCA1-deficient epithelial cells without external DNA damage. This suggests a role of R-loops in attenuating elevated DNA replication stress caused by the loss of *Brca1*. While R-loop removal does not appear to affect the overall *Brca1*-associated mammary tumor incidence, it promotes cell differentiation from ERα^{-} luminal progenitor cells to ERα^{+} mature luminal cells. Accordingly, unlike their counterparts, a significant percentage of *Brca1*-associated mammary tumors with RNase H1 overexpression tend to be ERα^{+}. Thus, our findings provide *in vivo* evidence for a previously unappreciated role of R-loop dynamics on *Brca1*-associated DNA replication stress and tumor development in mammary epithelium.

#3022 GPR109A activation limits cell growth by inducing p53 and its targets in human colon cancer cells.

M. Thangaraju[1], N. N. Thangaraju[2], L. Gilstrap[1], M. Chimenti[1], T. Patel[1], S. Sivaprakasam[3], N. Patel[1], S. Manicassamy[1], P. D. Prasad[1], V. Ganapathy[3]; [1]Augusta University, Augusta, GA, [2]Mercer University, Augusta, GA, [3]Texas Tech University Health Science Center, Lubbock, TX

Chemical carcinogens or xenobiotics present in the diet play a significant role in colon cancer (CC) formation. p53, a tumor suppressor and multi-functional protein, provides an important barrier against the initiation and maintenance of CC. p53 mutation or inactivation is observed in about 60% of CCs and about 90% of all cancers. Therefore, therapeutic avenues that will rejuvenate wild-type p53 or target mutant p53 should have a significant impact on the prevention and treatment of CC. GPR109A, a G-protein coupled receptor for the FDA-approved lipid-lowering drug Niacin (NA), bacterial metabolite Butyrate (BTR), and ketone body β-hydroxybutyrate (BHB), functions as a novel tumor suppressor in the colon by providing the molecular link between colonic bacteria and p53 function. GPR109A activation limits cAMP by inhibiting adenylate cyclase (AC), which induces RAS and its downstream growth-promoting signaling. cAMP also enhances the binding of MDM2 to p53 and induces the proteasomal degradation of p53. p53 is an NAD^{+}-dependent molecule and deficiency of NA, the precursor of NAD^{+}, impairs p53 function. We tested the role of GPR109A and its agonists (NA, BTR, and BHB) in normal immortalized colon epithelial cell lines (CCD33 and CCD81) and various CC lines such as HCT116-$p53^{+/+}$, HCT116-$p53^{-/-}$, DLD1 (p53 point mutation), VACO4A (p53 insertion mutation), and SW498 (p53 deletion) and measured cell proliferation, cell cycle, apoptosis, and analyzed the expression of GPR109A and p53 (total, phosphorylated, and acetylated), MDM2, p21, Bax, and Puma in the presence and absence of GPR109109 agonists. We found that GPR109A expression is significantly reduced in CC cell lines, especially in p53 mutant cell lines, when compared to normal immortalized colonic epithelial cell lines. Treatment of CC cell lines with GPR109A agonists-induced apoptosis in wild-type p53 expressing CC by activating p53 and its targets. However, some lesser extent in p53 mutant or p53 null cell lines. Lentiviral-mediated GPR109A expression in CC cell lines itself induced apoptosis in both wild-type and mutant p53 expressing CC cell lines and GPR109A agonists treatment induced further. Interestingly, GPR109A agonists BTR and BHB significantly increased apoptosis in p53 mutant and p53 null CC cell lines in a p53-independent manner. Overall, our results provide evidence that GPR109A activation can be used as an effective therapeutic strategy for the treatment of CC.

#3023 Master corepressor inactivation through oncogene suppressor RAI2 mediated polymerization.

N. Goradia[1], S. Werner[2], E. Mullapudi[1], G. von Amsberg[2], **K. Pantel**[2], M. Wilmanns[1];
[1]European Molecular Biology Laboratory, Hamburg, Germany, [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Imbalanced transcription of a large number of genes can be caused at various levels, ranging from alterations in individual transcription factors to dysfunctional corepressor and coactivator complexes [1]. C-terminal binding proteins (CtBPs) are ubiquitous master transcriptional coregulators associated with the Polycomb Repressive Complex 2 (PRC2), with essential functions in the development and oncogenesis of various tumor entities, including breast cancer and prostate cancer (PC) [2,3]. As CtBPs bind to short linear PxDLS-like sequence motifs (SLiMs), the presence of such motifs in tandem on the putative metastasis suppressor RAI2 [4] suggested a previously undiscovered dual interaction with CtBPs. Here, we show that RAI2 induces CtBP polymerization through well-ordered filaments of stacked tetrameric CtBP layers, as illustrated by a high-resolution single particle cryo electron microscopy structure. These filaments are mirrored by RAI2-mediated CtBP nuclear foci and relief of CtBP corepressor function in RAI2-expressing cancer cells. Analyses of a diverse PC patient cohort revealed a substantial decrease in RAI2 in the aggressive subtypes, suggesting a pivotal role of RAI2 in the transition to androgen receptor signaling-independent progression. Taken together, our data demonstrate a previously unknown mechanism of multivalent short linear sequence motif-induced polymerization. As RAI2-like SLiM motifs are found in a wide range of organisms, including pathogenic viruses, our findings serve as a paradigm for diverse functional effects through multivalent interaction-mediated polymerization by disordered proteins in healthy and diseased conditions. The specific properties of these repeated interactions open up new therapeutic opportunities.

#3024 HIF1A and HIF2A differentially contribute to early and adaptive changes following *in vivo Vhl* inactivation in the kidney.

S. Kurlekar, J. Lima, A. B. Barros, N. Masson, S. Zhai, C. W. Pugh, J. Adam, P. J. Ratcliffe;
University of Oxford, Oxford, United Kingdom

The von Hippel Lindau (VHL) tumor suppressor gene is a classical tumor suppressor whose biallelic inactivation is a truncal event in clear cell renal cell carcinoma (ccRCC) evolution. VHL is best characterized as the recognition component of an E3 ubiquitin ligase complex that targets hypoxia inducible transcription factors (HIF1A and HIF2A) for conditional oxygen-dependent degradation. HIF activation following VHL inactivation is an early event in ccRCC progression. While the functions of HIF1A and HIF2A in ccRCC biology and progression have been studied, those in VHL-null non-neoplastic cells of the renal tubular epithelium (RTE) and their contribution to tumorigenesis have not been fully explored. Here, using a combination of lineage marking and single-cell RNA sequencing (scRNA-seq), we provide the first description of HIF1A- and/or HIF2A-dependent and -independent consequences of *in vivo Vhl* inactivation in the RTE with single-cell resolution. We have previously reported on the development of a novel mouse model designed to mark and track cells that have undergone Vhl inactivation in vivo. Using this model, we have shown that Vhl inactivation has extensive, cell-type specific effects on gene expression in cells of the RTE within 3 weeks of recombination. Furthermore, we have shown that over a course of 4-8 months after Vhl inactivation, Vhl-null cells undergo specific adaptive changes in gene expression that encompass genes not regulated early after Vhl inactivation. In the work reported here, we have coupled this mouse model to a tamoxifen-inducible RTE-specific Pax8-CreERT2 and conditional alleles for Hif1a and/or Epas1 (codes for HIF2A). We have analyzed ‘marked’ recombined cells at early (1-3 weeks) or late (4-8 months) timepoints after recombination and compared these cells to time-matched Vhl-null cells using immunohistochemistry, in situ RNA hybridization and scRNA-seq. We found that though both HIF isoforms were present in Vhl-null cells at the early timepoint, expression of genes regulated early after Vhl inactivation was affected more by Hif1a inactivation than Epas1 inactivation. In contrast, expression of genes that are regulated in Vhl-null cells over time was drastically impacted by Epas1 deletion but was unaffected by Hif1a deletion. Interestingly, most of these Epas1-dependent, time-dependent changes in Vhl-null cells involved genes that have not been identified as direct transcriptional targets of HIF. Collectively, our work suggests that HIF1A and HIF2A have temporally distinct contributions to gene expression in Vhl-null cells in the RTE. We are currently analyzing the cell-type specificity of these contributions and ascertaining their relevance to the adoption of ccRCC-associated gene expression profiles.

#3025 Germline p53 R181 variants and DNA binding cooperativity in tumorigenesis.

R. Moses[1], R. Hausler[1], G. Kelly[1], A. Indeglia[2], S. Miller[3], J. Karanicolas[3], M. Murphy[2], K. Maxwell[1];
[1]University of Pennsylvania, Philadelphia, PA, [2]Wistar Institute, Philadelphia, PA, [3]Fox Chase Cancer Center, Philadelphia, PA

TP53 is the most frequently mutated gene in cancer, and its encoded protein p53 has many tumor-suppressive functions. There are several different classes of mutant p53 acquired in human cancer and inherited in cancer-prone families with Li-Fraumeni Syndrome, where individuals have an 80-90% increased risk of cancer. These include structural mutations that are generally (e.g R175H) or locally (e.g Y220C) misfolded, DNA contact mutations (e.g R273H); and oligomerization mutations (A347D). Cooperativity mutations affect binding of the p53 tetramer to DNA via disruption of a salt bridge formed by the negatively charged glutamic acid (E) 180 residue of one p53 monomer and the positively charged arginine (R) 181 residue of another. p53 “cooperativity” mutations at the R181 residue (R181H and R181C) have been increasingly identified in cancer-prone families undergoing genetic testing; however, the mechanism by which these variants disrupt p53 tumor suppression in humans is not understood. We show that the purified DNA binding domains of p53 variants R181H and R181C bind less cooperatively to the p53 binding site in the *CDKN1A* (p21) promoter, despite retaining wild-type levels of structural stability. RNA-sequencing of CRISPR knock-in colorectal and breast cancer cell lines shows reduced ability of R181H and R181C to transactivate a curated set of ~300 known p53 target genes. Upon treatment with p53 activating molecule Nutlin-3a, the R181-mutant cells fail to cell cycle arrest in the G1 phase and maintain high proliferative rates. Interestingly, we observe some residual apoptotic activity in R181H and R181C mutant cells treated with DNA-damaging agent 5-fluorouracil, despite losing the transactivation of proapoptotic p53 targets; this suggests that these mutants retain the p53 transcription-independent mechanism of apoptosis which is observed in other p53 variants such as P47S and A347D. These studies will define the pathogenicity of R181 variants and guide therapeutic intervention for patients that harbor these p53 mutations.

#3026 STK11 negatively regulates NFKB signaling in KRAS-driven lung adenocarcinoma.

David Joseph Seward[1], Sean Lenahan[2], Allison Racela[1], Israel Odekunle[1]

[1]Pathology and Laboratory Medicine, University of Vermont Medical Center, Burlington, VT,[2]Dana-Farber Cancer Institute, Boston, MA

In the US, more people die each year from lung cancer than breast, colorectal, and prostate cancers combined. Despite advances in lung cancer detection and treatment, the overall prognosis for patients remains poor. Patients whose lung tumors harbor druggable mutations often experience initial responses with targeted therapies, but acquisition of therapy resistance results in 5-year survival rates that have remained near ~20%. Immune check-point inhibitors (ICI) promise to improve outcomes in patients with lung cancer by targeting mechanisms of immune evasion. Drugs that disrupt PD-L1-mediated immune evasion, including pembrolizumab and nivolumab, have revolutionized treatment for some cancers. Unfortunately, only ~30% of lung adenocarcinomas (LUADs) respond to anti-PD-1 therapy and we cannot reliably identify this group prior to treatment. This underscores the need to discriminate which patients will respond to ICI therapies, while simultaneously highlighting the ~70% non-responder rate. To that end, recent clinical studies have linked anti-PD-1 therapy resistance with Serine/Threonine Kinase 11 (STK11) loss of function (LoF). STK11 operates in a heterotrimeric complex with the pseudo-kinase STRADα and the scaffolding protein MO25 where it regulates numerous intracellular signaling networks impacting metabolism, proliferation, transcription, and cell morphology. Why STK11 LoF correlates with anti-PD-1 resistance in the context of KRAS-driven LUAD remains unknown and represents a critical question in lung oncology. As an initial approach to understand this phenomenon, we knocked-out STK11 in multiple KRAS-driven, STK11-competent human LUAD cell lines and performed whole transcriptome analyses to identify STK11-loss-dependent differential gene expression profiles. We assert the transcriptional mediators downstream of STK11 governing the changes we report represent therapeutic targets whose antagonism may restore anti-PD-1 efficacy. Supporting this rationale, our data has identified STK11-loss-dependent activation of the NFκ-B transcriptional network. NFκB is a master transcription factor that regulates numerous cytokines, but whether and/or how STK11 directs NFκB activity remains largely unaddressed. We highlight NFκB activation as a potential mechanistic link between STK11 loss and tumor-intrinsic cytokine upregulation. We speculate that STK11 normally acts as a key player in the negative feedback loop limiting NFκB activity. When STK11 is lost, that activity continues unabated. In summary, we propose STK11 loss drives anti-PD-1 therapy resistance by generating an altered tumor immune microenvironment via constitutive activation of NFκB-mediated cytokine production. In future we intend to assess strategies for reversing anti-PD-1 therapy resistance via disruption of the NFκB transcriptional axis in KRAS-driven LUAD lacking STK11.

#3027 p53 aggregation promotes transformation from non-malignant lesions to high-grade serous ovarian carcinomas.

S. Sartini, L. Omholt, N. A. Moatamed, A. Soragni;
UCLA - University of California Los Angeles, Los Angeles, CA

High-Grade Serous Ovarian Cancer (HGSOC) is the most common and aggressive gynecological malignancy. It is typically diagnosed in late stages due to lack of diagnostic tests and current therapies available are not efficacious when the tumor is advanced. HGSOC is characterized by ubiquitous loss of functional p53 tumor suppressor protein function, largely due to point mutations that arise very early in carcinogenesis. P53 mutations are detected in pre-neoplastic cells of the fallopian tube mucosa, called p53 signature, and in early precursor lesions called serous tubal intraepithelial carcinoma (STIC). Some mutations promote the misfolding and aggregation of p53, transforming the protein into a cancer-promoting oncogene. Here, we hypothesize that the transition from folded, soluble to aggregated mutant p53 underlies the transformation from a pre-neoplastic lesion (p53 signature, STILs), to STICs and eventually HGSOC. We first set to determine the proportion of cells carrying soluble vs misfolded mutant p53 in fallopian tube tissues collected from n=10 patients undergoing salpingo-oophorectomy. We performed conformation-sensitive staining and quantification of folded and unfolded p53 cases and demonstrated that p53 misfolding, a mandatory precursor to aggregation, is present in STICs and HGSOCs, but notably absent from p53 signatures and surrounding healthy tissue. To better characterize the role of aggregated p53 in the progression of HGSOC, we took advantage of primary human fallopian tube secretory epithelial cells (FTSEC) that mimic early and more advanced stages of carcinogenesis. We utilize the FTSEC cells line FT282, immortalized by introducing hTERT and the aggregation-prone mutant $TP53^{R175H}$ that is found in p53 signature lesions and STILs, as well as the FT282-CCNE1, derived from FT282 cell line with overexpression of CCNE1, representing a more malignant phenotype.We used these models to investigate p53 aggregation, characterize the mutant p53 interactome and test the efficacy of ReACp53, a p53 aggregation-targeting peptide we developed. Our results demonstrated that p53 aggregation is more severe in the FT282-CCNE1 line, with a higher susceptibility to ReACp53 compared to the FT282 cells. Overall, our results demonstrated that aggregation of mutant p53 is a structural defect that can distinguish between pre-malignant and malignant HGSOC lesions and can potentially be targeted, offering a potential window for early intervention in halting ovarian cancer progression.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Oncogenic Transcription Factors
Poster Session

#3031 Overcoming drug resistance in cancer: A paradigm shift with FoxM1 targeting.
M. Pettersson, S. Bae, K.-k. Cho, H.-y. Yun, H.-S. Park;
Promedigen, Daejeon, Korea, Republic of

In cancer treatment, overcoming drug resistance remains a formidable challenge. The oncogenic transcription factor FoxM1 is widely recognized for its crucial role in promoting drug resistance to various chemotherapeutic and target therapies. Its involvement is attributed to pivotal pathways, encompassing cell cycle progression, angiogenesis, and metastasis. Despite its prominent role in tumor drug resistance, achieving modulation of FoxM1 using small molecule therapeutics has proven elusive. 5-fluorouracil (5-FU), a commonly used chemotherapeutic agent, is known to induce a significant upregulation of FoxM1. In this study, we demonstrate that our novel compound A3 leads to a robust dose-dependent reduction of FoxM1 driven by 5-FU in HT-29 colorectal cancer cells. Notably, exposure of 5-FU-treated HT-29 cells to A3 was shown to promote apoptosis via pro-apoptotic factors, including PUMA. The mechanism of action was further elucidated through a comprehensive analysis of cell signaling molecules. This study presents an innovative approach using small molecule modulators to control FoxM1 levels, providing profound insights for potential therapeutic interventions in cancer treatment.

#3032 Generation of a FOXC2-deficient melanoma cell line using CRISPR-Cas9 gene editing.

D. M. Clark, P. D. Conde, K. M. Hargadon;
Hampden-Sydney College, Hampden-Sydney, VA

Melanoma, a cancer derived from pigment-producing melanocytes of the skin, is a highly aggressive cancer characterized by rapid growth and metastasis. FOXC2 is a forkhead box transcription factor family member that is often dysregulated in various cancers, including melanoma, where its expression correlates with metastatic progression and drug resistance. To gain insight into the oncogenic activity of FOXC2 in melanoma, we have employed CRISPR-Cas9 gene editing technology to generate a novel FOXC2-deficient B16-F10 murine melanoma cell line. This model will be a useful tool for studying the tumor-promoting functions of FOXC2.

#3033 Oncogenic ETS transcription factors avoid repression by EZH2 and FOXO1 in prostate cancer and Ewing sarcoma .

N. F. Downing, K. M. Mills, P. C. Hollenhorst;
Indiana University Bloomington, Bloomington, IN

ETS transcription factors play roles throughout development, aiding in hematopoiesis, blood vessel formation and cell fate. The ETS family is composed of 28 members, all of which share an ETS DNA-binding domain. Chromosomal rearrangements that lead to the overexpression of specific ETS promote oncogenic transformation and tumor development. More than half of prostate tumors are driven by aberrant expression of an ETS protein. Our lab has demonstrated that oncogenic ETS form essential interactions with a ubiquitous RNA-binding protein, EWS, to promote prostate tumorigenesis. A similar mechanism exists in Ewing sarcoma (ES). ES tumors are driven by the expression EWS/ETS fusion proteins. This project focuses on the similarities and differences between oncogenic ETS in prostate cancer and EWS/ETS fusions in Ewing sarcoma.

We compared biological functions of the most common oncogenic ETS in prostate cancer, ERG, and the most common fusion in ES, EWS/FLI1. Both ERG and EWS/FLI1 promoted migration and clonogenic survival in normal prostate epithelial cell lines, RWPE1 and PNT2. These data suggest that the EWS-ERG complex and EWS/FLI1 fusion protein can function similarly in prostate cells. Knockdown of endogenous EWS/FLI1 in the ES cell line, A673, reduced anchorage-independent colony formation in soft agar. Rescue with exogenous EWS/FLI1 or EWS/ERG restored colony formation relative to control. Wildtype ERG was unable to rescue colony formation in A673. This suggests that ERG and EWS/FLI1 function differently in A673 cells. Pulldown assays from A673 lysates reveal that ERG interacts with EZH2 and FOXO1. Our lab has established that ERG acts as a transcriptional repressor through the formation of an ERG-EZH2-PRC2 complex. Others demonstrate that FOXO1 represses ERG activity by reducing its recruitment to the target sites. Both the N-terminal truncation of ERG and phosphorylation of ERG at S96 disrupted these interactions and rescued anchorage independent growth in A673 ES cells. These data suggest that EWS/ETS fusions avoid transcriptional repression in Ewing tumors due to loss of the N-terminus of the ETS protein.

#3034 Krüppel-like factors in regulation of gastric cancer progression.

S. Kakkat[1], P. Suman[1], S. Goswami[1], S. Basu[2], M. J. Heslin[1], E. A. Turbat-Herrera[1], V. Ramirez Alcantara[1], C. Sarkar[1], D. Chakroborty[1];
[1]University of South Alabama, Mobile, AL, [2]The Ohio State University, Columbus, OH

Introduction: Gastric cancer (GC) is the third leading cause of cancer-associated mortality and the fifth most frequently diagnosed cancer worldwide. The development and progression of GC is a complicated multistage process subjected to dynamic changes in gene regulation. Investigating the effects of these changes is therefore critical for improving our knowledge about GC initiation and progression. Krüppel-like factors (KLFs) are evolutionarily conserved zinc finger-containing transcription factors with altered expressions and diverse regulatory functions in GC. We previously reported that there is loss of KLF4 in GC. Here we report that KLF4 is a crucial regulator of KLF5 expression and vice versa and together they regulate GC cell behavior.
Methods: The Cancer Genome Atlas (TCGA) and pan cancer data of differential expressions of KLFs in GC was analyzed. TCGA RNAseq and clinical data for the differential expression status of KLF genes in normal and cancerous tissues and the clinicopathological association was accessed from the UALCAN web portal. The expressions of KLF4 and KLF5 in human normal stomach and GC and orthotopic xenografts were detected by immunohistochemistry (IHC). KLF4, KLF5 cross regulation was evaluated by gene manipulation of each gene individually and checking the expression of the other factor in GC cells. The effect of KLFs on GC cell proliferation, migration, and invasion was determined by Ki67 staining of tissues, PrestoBlue cell viability assay, scratch wound and transwell cell invasion assays.
Results and Conclusion: Our results indicated that not only KLF4 and KLF5 have contrasting expressions and effects in GC but also these two factors cross regulate each other. While lower expressions of KLF4 was found in human GC and orthotopic xenografts, increased expression of KLF5 was found in both human GC tissue and orthotopic xenografts. KLF4 silencing and CRISPR /Cas9 knockdown in human GC cells resulted in increased expression of KLF5 which was associated with increased GC cell proliferation and invasiveness. Interestingly, KLF5 knockdown by CRISPR / Cas9 in human GC cells on the other hand resulted in increased expression of KLF4, which was associated with decreased GC cell growth. Our data therefore suggests that the differential expressions of KLF4 and KLF5 might serve as valuable prognostic markers in GC.

#3035 Bridging the gap: Exploring the roles of ETS- coactivator interactions in promoting prostate cancer .

K. M. Mills, N. Downing, S. Metcalf, P. Hollenhorst;
Indiana University Bloomington, Bloomington, IN

The ETS family of transcription factors is comprised of 28 members that all share a common C- terminal DNA-binding domain. ETS play essential roles in developmental processes, such as stem cell maintenance, blood vessel formation, and cellular fate. While absent in the normal prostate, four members of the ETS family become expressed in prostate tumors: ETV1, ETV4, ETV5 and ERG. Our lab has previously classified these proteins as oncogenic ETS for their ability to promote cellular migration in normal prostate epithelial RWPE1 cells. Transcription factors may need to interact with additional proteins to serve oncogenic roles. My research explores the interactions between 1) ETV1 and EWS, as well as 2) ERG and p53. Our lab has established that ETV1, ETV4 and ETV5 form essential interactions with EWS, a transcriptional coactivator that promotes ETS activity. In prostate tumors, chromosomal rearrangements result in the N-terminal truncations of ETV1, ETV4 and ETV5. I hypothesize that the EWS interaction domain is retained and that these truncated ETVs will remain oncogenic. Pulldown assays using purified full-length and truncated ETV1 suggests EWS interacts with both N-terminal and C-terminal portions ETV1. I am attempting to express truncated ETV1, ETV4 and ETV5 in RWPE1 cells. Upon stable expression, I will evaluate their interactions with EWS and their ability to promote migration in vitro. To identify putative proteins that bridge EWS to ETV1, immunoprecipitation mass spectrometry will be used. Mutations in p53, a tumor suppressor protein, promote oncogenesis and occur in nearly half of all cancer cases. We hypothesize that mutant p53 interacts with ETS to promote its recruitment to new genomic sites. Previous studies demonstrate that mutant p53 binds ETS2 at a higher affinity than wildtype p53 and we have expanded this list of interacting ETS to include ERG. We seek to explore whether ERG and mutant p53 cooperate to promote oncogenic phenotypes. I successfully cloned wildtype p53, mutant p53 (R248W) and double-mutant p53 (R248W, T81A) into a retroviral backbone. I then transduced RWPE1-Vector and RWPE1-ERG expressing cells to express these constructs. Although additional replicates are needed, it appears that mutant p53 promotes colony formation in both cell types relative to wildtype p53. I plan to validate these observations and generate an appropriate negative control cell line before extending into a mouse model. Through the continuation of this work, I will provide critical insight into the molecular mechanisms by which a subset of ETS factors achieve oncogenic function. We address the contributions of DNA-binding specificity and coactivator interactions in promoting the phenotypes associated with prostate cancer.

#3036 Sensitivity of ONC201/TIC10 cancer therapeutic on neuroendocrine prostate cancer (NEPC) and neuroendocrine differentiation (NED).

E. C. Ding, M. Pinho-Schwermann, S. Zhang, C. Purcell, W. S. El-Deiry;
Legorreta Cancer Center at Brown University, Providence, RI

Although androgen deprivation therapy and androgen receptor (AR) blockade are highly effective therapies for metastatic prostate cancer (PCa), most patients develop resistance, leading to castration-resistant prostate cancer (CRPC). A subset of CRPC shows neuroendocrine prostate cancer (NEPC) features, which are associated with poor prognosis and limited therapeutic strategies. NEPC is characterized by oncogenic driver activation and epigenetic changes, partly controlled by transcription factors like BRN2 and SOX2. AR has been shown to suppress BRN2 transcription, which is required for NEPC, and BRN2-dependent regulation of the NEPC marker SOX2 (Bishop et al., 2017). Dordaviprone (ONC201/TIC10) is a first-in-class small molecule that antagonizes DRD2, induces tumor necrosis factor-related apoptosis-inducing ligand (TRAIL), and activates the integrated stress response (ISR). Neuroendocrine tumors express significant DRD2 levels, suggesting ONC201 as a potential therapeutic strategy in NEPC or when drivers for disease progression are overexpressed (OE). PCa cell lines PC3, DU145, LNCaP, and 22RV1 are ONC201 sensitive, with IC50=2.87 μM, 3.18 μM, 1.31 μM, and 1.16 μM, respectively (Ding et al., 2023). To characterize the association of BRN2/SOX2 dysregulation with ONC201 sensitivity, we transiently OE BRN2/SOX2 in PCa. We hypothesized that markers of neuroendocrine differentiation (NED), activation of the ISR, TRAIL, and ClpP and dopamine receptor expression contribute to NEPC cell death and sensitivity to ONC201. We performed CellTiter-Glo experiments to assess viability after 96 hours ± BRN2 OE. DU145 cells with BRN2 OE increased their sensitivity to ONC201 (IC50=2.75 μM) compared to empty vector (IC50=3.03 μM). Colony formation assays were conducted in PCa and analyzed 7 days after ONC201 treatment to show ONC201 effect on PCa cell lines. DU145 was treated at 0.5, 1, and 2 μM of ONC201. There were 95 ± 3.22 colonies for the control group, 83 ± 5.22 colonies with 0.5 μM, 74 ± 3.64 colonies with 1 μM, and 8 ± 2.03 colonies with 2 μM ONC201. DU145 showed a significant reduction in colony-forming ability when treated with 1 and 2 uM ONC201 compared to the control, with P values of <0.05 and <0.0001, respectively. We OE BRN2 and observed changes in NED markers and ISR pathway. In PC3, FoxO1 and ATF4 levels increased. In DU145, FoxO1, ENO2, PGP9.5, CgA, and ATF4 levels decreased. We reveal that DU145 OE at 48 hours does not result in greater expression of NEPC markers. BRN2 OE significantly increased PCa cell sensitivity to ONC201 and was evident without an increase in common phenotypical markers used for NEPC assessment (FoxO1, ENO2, PGP9.5, CgA). Expression change was not shown when PCa had an integral AR pathway. Ongoing efforts are observing ONC201 treatment effects on NED markers and the TRAIL pathway due to BRN2 OE and showing increased sensitivity of PCa to ONC201 with BRN2 OE.

#3037 Sex-specific differences in *Yap1* and *Cd276* function and expression regulate medulloblastoma progression and immune evasion.

N. Abdelfattah[1], S. Natarajan[2], H. Tran[1], J. Maldonado[1], R. McMinimy[3], H. Borland[4], S.-h. Chen[1], F. Camargo[5], J. Olson[6], J. George[7], K. Yun[1];
[1]Houston Methodist Research Institute, Houston, TX, [2]The Jackson Laboratory for Mammalian Genomics, Bar Harbor, ME, [3]Jackson Laboratory for Genomic Medicine, Bar Harbor, ME, [4]Texas A&M University, College of Liberal Arts, College Station, TX, [5]Harvard Department of Stem Cell and Regenerative Medicine, Boston, MA, [6]Fred-Hutch, University of Washington School of Medicine, Seattle, WA, [7]Jackson Laboratory for Genomic Medicine, Farmington, CT

Unveiling the molecular mechanisms underlying sex-specific differences in cancer initiation, progression and treatment outcomes will provide novel insights that will advance cancer research and clinical care. This study highlights an unexpected, sex-biased role of the oncogene *Yap1* in SHH medulloblastoma (MB). We discovered that *Yap1* deletion in *SmoM2*-driven SHH MB significantly prolongs survival in male but not female mice. Using an integrated multi-omics approach, we show that YAP1 promotes cancer stem cell maintenance through concurrent transcriptional activation of stemness genes, such as *Sox2,* and repression of differentiation genes such as *NeuroD1* and *Zic1*/2. Interestingly, while *Yap1* is essential for maintaining cancer stem cells in both sexes, it plays a more critical role in immune evasion in males. Specifically, YAP1 regulates the expression of an immune checkpoint molecule *Cd276* to suppress T cell function. Blocking CD276 or deleting *Yap1* is sufficient to significantly reverse T cell suppression in males but not females. Furthermore, YAP1 direct targets of transcriptional regulation, including CD276, predicts survival in male but not female patients across multiple human cancers, suggesting that our findings have broader implications beyond medulloblastomas and is conserved across species. This study provides compelling evidence for male-biased susceptibility to *Yap1* inhibition and uncovers the YAP1-CD276 axis as a sexually diverse pathway in T cell suppression in tumors.

#3038 PPARδ promotes gastric adenocarcinoma carcinogenesis by enhancing ZBP1-induced necroptosis and inflammation and fostering gastric tumor immunosuppressive microenvironment.

Y. Liu[1], D. Wei[1], L. Wang[1], J. C. Yao[1], I. Shureiqi[2], X. Zuo[1];

[1]University of Texas MD Anderson Cancer Center, Houston, TX, [2]University of Michigan, Ann Arbor, MI

Overexpression of peroxisome proliferator-activated receptor delta (PPARδ) in villin-positive gastric progenitor cells (VGPCs) has been demonstrated to spontaneously induce gastric adenocarcinoma (GAC) in mice. PPARδ is upregulated in human GAC tissues, and its expression level is positively associated with human GAC grades and stages. However, the potential for targeting this tumorigenic effect of PPARδ, along with the underlying molecular mechanisms, remains elusive. In this study, we investigated the impact of PPARδ genetic deletion/loss of function in VGPCs on *Helicobacter felis* (*H. felis*)-induced GAC carcinogenesis by orally exposing the mice carrying wild-type (WT) PPARδ or genetically deleted PPARδ in VGPCs to *H. felis* infection. We also examined the effect of PPARδ inhibition by its specific antagonist, GSK3787, on PPARδ-induced GAC carcinogenesis in mice. Furthermore, we conducted RNA-seq for transcriptomic profiling analysis and validated the results through quantitative reverse transcription-polymerase chain reaction (qRT-PCR) on the gastric tissues of those mice and the mice with WT PPARδ or PPARδ overexpression in VGPCs at ages 10, 25 and 55 weeks. We found that 1) PPARδ genetic deletion in VGPCs significantly inhibited *H. felis*-induced gastric chronic inflammation and GAC carcinogenesis; GSK3787 significantly suppressed PPARδ-induced GAC carcinogenesis in mice; 2) PPARδ overexpression in VGPCs significantly enhanced while PPARδ genetic deletion in VGPCs significantly inhibited ZBP1-induced necroptosis and the related inflammatory signaling pathways such as interferon-gamma signaling, IL6-JAK-STAT3 signaling, and IL2-STAT5 signaling evidenced by gene set enrichment analysis of RNA-seq data, which were further validated by qRT-PCR; and 3) PPARδ overexpression in VGPCs markedly increased the expression of CCL20 in gastric epithelial cells of the mice before (age 10 weeks) and after GAC initiation and progression (age 25 weeks-early stage GAC and age 55 weeks-late stage GAC), and gastric infiltrations of $CCR6^{+}$ myeloid-derived suppressor cells and $CCR6^{+}$ tumor-associated macrophages, thereby creating a gastric tumor immunosuppressive microenvironment. In contrast, PPARδ genetic deletion in VGPCs or the administration of GSK3787 diet significantly reversed this PPARδ-induced immune suppression in mice. In conclusion, our findings highlight the pivotal role of PPARδ in VGPCs as a key host factor in GAC carcinogenesis, especially in individuals exposed to chronic *H. pylori* infection that could lead to an upregulation of PPARδ expression. This suggests that targeting PPARδ signaling could be a novel therapeutic approach for GAC prevention and therapy.

#3039 Pan cancer therapeutic inhibition of oncogenic c-MYC by the engineered destabilized 3'UTR of c-MYC.

C. U. Awah;
UTR Therapeutics Inc, New York, NY

c-MYC is a master transcription factor that is over expressed in more than 70% of human cancers. There is no clinically approved direct inhibitor of c-MYC. Recently, we reported the development of the engineered destabilized 3'UTR of MYC constructs which is a novel mRNA overwriting technology through which we directly destabilized and degraded c-MYC. Here we report that we have extended this technology in directly targeting and degrading c-MYC in multiple ethnically diverse triple negative breast cancer cell lines, ovarian cancers, neuroendocrine prostate cancers and pancreatic cancers. The constructs are specific, titratable, and directly engaged the c-MYC target validated by RNA transcript technologies. We have performed head-to-head IC50 dose dependent titration comparison with the engineered destabilized 3'UTR of c-MYC constructs and chemotherapies (DNA damaging agents, microtubules inhibiting drugs, alkylating agents) as well as immune checkpoint inhibitor. We found evidence that suggests that the engineered destabilized 3'UTR of c-MYC is likely to be superior to these therapies in pan cancers driven by c-MYC.

#3040 Tumor-specific super-enhancer drives overexpression of *EVI1* in ovarian cancer.

Leonie Smeenk[1], Sabrina Kruse[2], Roger Mulet-Lazaro[1], Ingrid Boere[3], John Martens[3], Stefan Groschel[4], Claudia Scholl[5], Stefan Frohling[2], Ruud Delwel[1]

[1]Hematology, Erasmus MC Cancer Institute and Oncode Institute, Rotterdam, Netherlands,[2]Translational Medical Oncology, German Cancer Research Center (DKFZ), Heidelberg, Germany,[3]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands,[4]Oncology Center Worms, Worms, Germany,[5]Applied Functional Genomics, German Cancer Research Center (DKFZ), Heidelberg, Germany

Epithelial ovarian cancer (OC) is typically diagnosed at a late stage and, despite treatment with cytoreductive surgery and chemotherapy, 70-80% of patients relapse and eventually die due to the disease. Major challenges to improve patient outcomes are to overcome therapy resistance and to individually tailor therapy. Uncovering the molecular drivers of OC, especially in the most common subgroup high-grade serous (HGS), will help develop novel therapeutic strategies to meet these challenges.

Using the Cancer Genome Atlas (TCGA) data, we observed that a locus in 3q26.2, near the *EVI1* oncogene, was the most significantly amplified region in HGS OC, occurring in more than 80% of those tumors. We validated these findings in an OC dataset from the Hartwig Medical Foundation and in OC cell lines from the DepMap database. Furthermore, HGS OC had the highest mean copy number of the 3q26.2 locus co-occurring with high mean *EVI1* expression among all tumor entities in the pan-cancer TCGA dataset. These *EVI1* expression levels are significantly higher than in normal fallopian tube, from which HGS OC most likely arises. *EVI1* overexpression promotes leukemogenesis in 3q26-rearranged acute myeloid leukemia (AML), as a result of chromosomal translocations that enable hijacking of hyperactive enhancers. Here, we hypothesize that *EVI1* also plays a crucial role in OC development, but that its aberrant expression in this disease is driven by the amplification of yet undiscovered regulatory elements near *EVI1*.

We showed that EVI1-positive OC cell lines, of which the majority are HGS, are EVI1-dependent and harbor a ~200 kb amplified region near *EVI1*. This region interacts with the *EVI1* promoter (4C-Seq), is characterized by open chromatin (ATAC-Seq), and shows high levels of H3K27 acetylation (H3K27ac ChIP-Seq), suggesting the presence of an active enhancer. Furthermore, based upon H3K27ac signal, we identified within this region a super-enhancer of approximately 65 kb. In OC cell lines without detectable *EVI1* levels or cell lines from other cancer subtypes, such as breast and colon cancer, this location had no active enhancer and did not loop to the *EVI1* promoter.

Altogether, these data point to the generation of a hyperactive super-enhancer driving *EVI1* overexpression in OC. These findings emphasize the importance of epigenetic control in the regulation of *EVI1* expression, as previously shown in 3q26-rearranged AML. Since OC tumor cell lines are strongly dependent on EVI1, interference with this super-enhancer, leading to loss of *EVI1* expression, could be exploited to inhibit tumor growth. For this purpose, we generated GFP-tagged *EVI1* cell line models (e.g. SKOV3), which will be used to discover small molecules to target the activity of this super-enhancer. In conclusion, we discovered a new mechanism of enhancer-mediated overexpression of the *EVI1* oncogene as a molecular driver in ovarian cancer, with possible implications for therapy.

#3041 The small MAF transcription factor MAFG is a potent driver of melanoma.

O. Vera, M. Martinez, Z. Soto-Vargas, X. Xu, **F. Karreth**;
Moffitt Cancer Center, Tampa, FL

While common mutations in potent proto-oncogenes and tumor suppressors induce melanoma formation, no recurrent mutations associated with the late stages of melanomagenesis have been identified. Instead, non-mutational mechanisms such as the deregulation of transcriptional or epigenetic programs typically promote the malignant progression and metastasis of melanoma. We have previously identified the small MAF transcription factor MAFG as a critical target of the melanoma suppressor miRNA miR-29, prompting an in-depth evaluation of the role of MAFG in melanoma. MAFG expression is elevated in melanoma compared to melanocytes and increases with tumor stage. Ectopic expression of MAFG in human melanocytes and melanoma cells enhances proliferation in vitro and promotes melanoma growth in vivo. Moreover, MAFG overexpression in $Braf^{V600E}$; $Pten^{FL/+}$ mice accelerated melanomagenesis, significantly shortening overall survival. Despite being a critical NRF2 dimerization partner, NRF2 was dispensable for the effects of MAFG. Moreover, MAFG overexpression in melanoma cells had no effect on the activity of NRF2 transcriptional reporters, nor did it induce transcriptional programs associated with NRF2. RNA sequencing and pathway analysis revealed MAFG-mediated effects on melanoma-associated processes such hypoxia, the PI3K/AKT pathway, and pigmentation. Indeed, MAFG induced HIF1a under normoxic conditions, enhanced AKT phosphorylation, and downregulated MITF and its target genes in the pigmentation pathway in melanoma cells. Interestingly, MAFG also potently enhanced AXL expression, suggesting that MAFG may promote melanoma, at least in part, by affecting the MITF/AXL balance that is associated with melanoma phenotype switching. We next analyzed whether MAFG is required for melanoma. Interestingly, silencing MAFG in human melanoma cells robustly inhibited growth in vitro. Moreover, the CRISPR/Cas9-mediated knockout of MAFG in an aggressive $Braf^{V600E}$; $Pten^{FL/FL}$ model potently prevented melanoma formation. Given the mild phenotype of MAFG whole-body knockout mice, our results suggest targeting of MAFG or its downstream pathways as a viable therapeutic approach in melanoma. In conclusion, our study establishes MAFG as a potent driver of melanoma development and nominates it as a therapeutic target.

#3042 Unraveling the mechanism of YAP toxicity in neuroendocrine solid tumors: Insights from Merkel cell carcinoma.

F. Bahar[1], T. C. Frost[2], V. Ananthapadmanabhan[1], J. L. Schnabel[1], M. Thakuria[1], J. A. DeCaprio[1];
[1]DFCI/Harvard Medical School, Boston, MA, [2]AstraZeneca, Boston, MA

The Hippo pathway, a pivotal regulator orchestrating organ size and tissue growth, has emerged as a central player in cancer biology. The downstream transcription factor YAP within this pathway has been implicated in diverse oncogenic processes. YAP activation contributes to drug resistance, metastasis, and poor clinical outcomes in many solid tumors. Conversely, YAP exhibits growth-suppressive effects in neuroendocrine (NE) solid cancers, a paradox that remains poorly understood. Analysis of RNAseq data from the Cancer Cell Line Encyclopedia (CCLE) revealed a distinct classification of tumors into YAP1-expressing (YAP^{on}) and non-expressing (YAP^{off}) subgroups, with hematopoietic malignancies and NE solid tumors featured prominently in the latter. Merkel cell carcinoma (MCC) is a rare, high-grade, NE carcinoma of the skin with two distinct etiologies. Virus-positive MCC contains integrated Merkel cell polyomavirus that expresses the viral T antigens and virus-negative MCC caused by sunlight exposure and extensive UV damage. Bulk RNAseq performed with more than 60 MCC tumors revealed that YAP expression displayed an inverse correlation with an NE gene expression signature. To gain insight into why YAP expression is so low in MCC, we generated MCC cell lines with inducible expression of YAP. Expression of YAP led to growth arrest and cell death. We performed a genome-wide CRISPR-Cas9 screen to identify genes that when lost enable MCC cells to tolerate YAP expression. Functional enrichment analysis of the positively selected genes uncovered a variety of signaling pathways. Intriguingly, the CRISPR screen revealed a positive enrichment of non-canonical BAF complex members, including BRD9 and SMARCD1. To validate this finding, we treated MKL-1 cells with a BRD9 inhibitor, observing a substantial reduction in YAP toxicity. These findings open avenues for the development of targeted therapeutic strategies for high grade NE cancers, addressing a critical gap in our understanding of YAP biology in the context of MCC and beyond.

#3043 MYC activation and PTEN loss synergistically activate proliferation in a mouse model of lethal prostate cancer.

M. Rubenstein[1], T. Jones[1], J. Hicks[1], A. Rege[2], Q. Zheng[1], C. Gomes-Alexandre[1], G. Hubbard[1], S. Yegnasubramanian[1], C. Bieberich[2], A. DeMarzo[1]; [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland Baltimore County, Baltimore, MD

Prostate cancer kills 30,000 men per year in the U.S. Yet, of all primary prostate cancers, only a relatively small percentage are aggressive and have the potential to become life threatening. In terms of genomic copy number alterations, concurrent amplification of MYC and loss of tumor suppressor PTEN is the strongest predictor of prostate cancer specific mortality. We have previously shown, in a novel mouse model, that combined MYC overexpression and Pten loss results in the development of precursor lesions (PIN) that lead to aggressive metastatic prostatic adenocarcinoma, yet overexpression of MYC alone or Pten loss alone result only in precursor lesion development. Here, we performed genome wide transcriptome analysis using bulk RNA seq to obtain clues regarding the synergy between MYC overexpression and Pten loss. Prostates harboring PIN lesion were dissected from mice engineered to have MYC activation alone, Pten loss alone, and the combination thereof (BMPC mice), as well as invasive primary adenocarcinomas and metastatic lesions from BMPC mice. Principal Components Analysis (PCA) analysis separated the lesions into highly distinct groups. Genes contributing the most to the first principal component were related to inflammation and cell proliferation/cell cycle progression by functional annotation. The proliferation-related genes were increased somewhat by MYC overexpression alone, were not increased Pten loss, and were more consistently increased by combined MYC overexpression and Pten loss in BMPC. Strikingly, mice with combined MYC overexpression and Pten loss showed approximately 2-4 fold higher Ki67 proliferation index than mice with MYC activation alone. PIN lesions driven by MYC overexpression or PTEN loss alone were characterized by Gene Set Enrichment Analysis (GSEA). Among the pathways with the highest negative enrichment scores in PIN samples with PTEN loss were those that generally describe ribosome biogenesis and translation. PIN lesions with Pten loss showed lower hybridization signals for the 45S rRNA, which was increased by MYC alone and somewhat more in BMPC PIN lesions. Our results demonstrate that combined activation of MYC and Pten loss drive increased cell proliferation beyond that seen with either gene alteration alone. These findings suggest that a key part of the molecular mechanisms by which MYC and PTEN alterations may synergize to drive aggressive prostate cancer is related to increased tumor cell proliferation. Surprisingly, we uncovered the novel finding that Pten loss, in the absence of MYC overexpression, is associated with decreased expression of genes coding for proteins that mediate translation, as well as decreased 45S pre-rRNA. Since ribosome biogenesis is a key driver of cell proliferation, it is likely that loss of both copies of PTEN alone, in the absence of MYC overexpression, would be selected against in early lesions in prostate cancer.

#3044 Novel agents with efficacy against germline mutant RUNX1 familial platelet disorder with myeloid malignancy (FPD-MM).

C. P. Mill[1], W. C. Fiskus[1], C. D. DiNardo[1], P. K. Reville[1], J. A. Davis[1], C. E. Birdwell[1], K. Das[1], H. Hou[1], K. Takahashi[1], S. Loghavi[1], J. D. Khoury[2], K. Bhalla[1]; [1]UT MD Anderson Cancer Center, Houston, TX, [2]Univ of Nebraska, Omaha, NE

RUNX1 is a master-transcriptional regulator involved in normal and malignant hematopoiesis. Germline, mono-allelic, missense mutations in RUNX1 cause large deletions or truncations that are mostly loss-of-function mutations. They cause familial platelet disorder (RUNX1-FPD), which evolves into myeloid malignancy (FPD-MM), e.g., MDS or AML. Although curative in some patients, allogeneic stem cell transplantation from matched, un-related donors carries the risk of GVHD and relapse in FPD-MM. Thus, there is a need for novel therapies to revert FPD-MM back to FPD. LINCS1000-CMap analysis, of the RUNX1 knockdown RNA-Seq signature revealed homoharringtonine (HHT or omacetaxine) and the anthelmintic fenbendazole (analog of mebendazole (MB)) as the top expression mimickers. In our current studies, we demonstrate that treatment with HHT or MB induced significantly greater loss of viability in seven patient-derived samples of FPD-MM vs RUNX1-FPD. Analyses conducted on BMA cells harvested longitudinally from the same patient at the RUNX1-FPD versus FPD-MM stage demonstrated greater chromatin accessibility in FPD-MM cells along with increased mRNA expressions of MYB, MECOM and BCL2. Following HHT treatment, scRNA-Seq analysis demonstrated a marked reduction in the HSC population, but concomitant increase in the macrophage population in FPD-MM. This was associated with positive enrichment of apoptosis signaling and TP53 targets gene-sets, while negatively enriching those of c-Myc targets. CyTOF analysis demonstrated that HHT treatment reduced c-Myc, EVI1, MCL1, BFL1 and CDK6 expression in phenotypically characterized FPD-MM stem-progenitor cells. Utilizing an FPD-MM sample harboring Runx1 K194N, also detected in other pedigree members with FPD or FPD-MM, we established the first ever cell line (GMR-AML1) expressing germline mtRUNX1. GMR-AML1 cells exhibited high surface expression of CD117 (c-KIT), CD123 (IL-3R) and CD33. GMR-AML1 cells in which Runx1 was knocked-out by CRISPR-gRNA were outcompeted in vitro and in vivo, by cells that retained Runx1. Treatment with HHT or MB induced loss of viability in GMR-AML1 cells (LD50: 40 or 330 nM, respectively). HHT also caused concordant decline in ATAC-Seq and RNA-Seq peaks in ribosomal genes involved in protein translation. Treatment with MB inhibited cell cycle and protein translation. CyTOF analysis revealed that MB treatment also depleted CDK6, RUNX1, c-Myc and EVI1 in phenotypically defined FPD-MM stem cells. Finally, in the GMR-AML1 cell xenograft, treatment with omacetaxine or MB significantly reduced AML burden and improved overall survival of NSG mice. These preclinical findings highlight the molecular features associated with progression of RUNX1-FPD to FPD-MM and highlight HHT or MB as effective against cellular models of FPD-MM.

#3045 PPAR-α antagonist enhances immunotherapy and anti-angiogenic therapy to inhibit murine renal cancer.

M. Gillespie[1], V. Chen[2], I. Howard[1], K. Smith[1], D. Freund[2], N. Standifer[2], D. Burdette[2], T. W. Dubensky[2], S. Whiting[2], D. Panigrahy[1];
[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]Tempest Therapeutics, Brisbane, CA

Peroxisome proliferator activated receptor alpha (PPARα) is a transcription factor and master regulator of fatty acid oxidation. PPARα ligands modulate the switch between co-activator and co-repressor transcription complexes at PPARα-controlled target genes. In addition, PPARα has been shown to transrepress NF-κB signaling and inhibit angiogenesis. Renal cell carcinoma (RCC) expresses high levels of PPAR-α and is a highly angiogenic cancer. Current frontline treatments for RCC include chemotherapy, anti-angiogenics, and immunotherapy but are limited by the immune suppressive state of the tumor microenvironment. TPST-1120 is a novel PPARα antagonist for the treatment of cancer patients that binds in the ligand binding domain, positioning the AF-2 activation helix in an inactive conformation. The inactive conformation has a lower affinity for co-activator motifs and reduces activation of PPARα regulated genes. In a CHO-based reporter cell line, TPST-1120 potently competed against the PPARα-specific agonist GW7647 (IC_{50} = 36 nM at 20 nM GW7647) and an endogenous PPARα agonist oleoylethanolamide (OEA; IC_{50} = 15 nM at 30 μM OEA). Furthermore, in an enzyme fragment complementation assay, we demonstrated that TPST-1120 inhibited agonist-induced binding of PPARα to MED1 by destabilizing the co-activator complex thereby stabilizing the inactive conformation of PPAR-α. In a murine model of renal cell adenocarcinoma (RENCA), TPST-1120 treatment for 12 days (30 mg/kg qd) reduced tumor growth by 52% as a monotherapy ($p<0.0001$). Consistent with these findings, TPST-1120 inhibited tumor angiogenesis and proliferation as quantified by Ki67 levels. Combination treatment with current frontline therapeutics resulted in synergistic tumor inhibition of 74% with anti-PD1 (200 ug Q3D for 12 days) and 81% with cabozantinib (15 mg/kg QD for 15 days) ($p<.0001$). Flow cytometry-based analysis of tumors demonstrated increased CD8+ T cell infiltration in the TME as well as decreases in M2 and elevations in M1 macrophages. Importantly, we demonstrate that TPST-1120 can reverse an immunosuppressive class of immune cells to promote anti-tumor immunity and anti-angiogenesis in kidney cancer in the absence of overt toxicity. These data support advancement of TPST-1120 into RCC.

#3046 The estrogen signaling pathway reprograms prostate cancer cell metabolism and supports proliferation and disease progression.

C. Lafront, L. Germain, G. H. Campolina-Silva, C. Weidmann, L. Berthiaume, H. Hovington, H. Brisson, C. Jobin, L. Fregeau-Proulx, R. Cotau, K. Gonthier, A. Lacouture, P. Caron, C. Menard, C. Atallah, J. Riopel, E. Latulippe, A. Bergeron, P. Toren, C. Guillemette, M. Pelletier, Y. Fradet, C. Belleannee, F. Pouliot, L. Lacombe, E. Levesque, E. Audet-Walsh;
Universite Laval, Quebec, QC, Canada

Just as the androgen receptor (AR), the estrogen receptor α (ERα) is expressed in the prostate and is thought to influence prostate cancer (PCa) biology. Yet, the incomplete understanding of ERα cellular functions in PCa hinders our ability to fully comprehend its clinical relevance and restricts the repurposing of estrogen-targeted therapies for treatment of this disease. Using two human PCa tissue microarray cohorts, we first demonstrated that nuclear ERα expression was heterogeneous between patients, being only detected in half of tumors. Positive nuclear ERα levels were correlated with disease recurrence, progression to metastatic PCa, and patient survival. Using *in vitro* and *in vivo* models of the normal prostate and PCa, bulk and single cell RNA-seq analyses revealed that estrogens partially mimic the androgen transcriptional response and induce specific biological pathways linked to cellular proliferation and metabolism. Bioenergetic flux assays and metabolomics confirmed regulation of cancer metabolism by estrogens, supporting proliferation. Using cancer cell lines and patient-derived organoids, selective estrogen receptor modulators, a pure anti-estrogen, and genetic approaches impaired cancer cell proliferation and growth in an ERα-dependent manner. Overall, our study revealed that, when expressed, ERα functionally reprograms PCa metabolism, is associated with disease progression, and could be targeted for therapeutic purposes.

#3047 Interrogating TEAD protein interactions in cancer.

A. Guarnaccia, J. Lill, A. Dey;
Genentech, Inc., South San Francisco, CA

The Hippo signaling pathway is a major regulator of cellular growth and is frequently deregulated in cancer. The main effectors of the Hippo pathway are the TEAD transcription factors which function by interacting with other co-effector proteins to modulate transcriptional outputs. Notably YAP and TAZ interact with TEAD to mediate oncogenic transcriptional programs, and blocking interaction of TEAD with YAP and TAZ is a sought-after mechanism for small molecule TEAD inhibitors. However, the interaction network of TEAD extends well beyond YAP and TAZ to a variety of additional cofactors, including chromatin remodelers, epigenetic factors, and other transcriptional regulators. Thus, the impact of inhibiting TEAD could extend to unanticipated protein interactions and cellular functions. The purpose of this study is to investigate, define, and interrogate TEAD interaction networks, providing foundational knowledge for interrogating TEAD biological functions and pharmacological effects. We are employing mass spectrometry-based technologies combined with chemical and genetic tools and biochemistry to interrogate TEAD protein interaction networks. We have performed affinity purification coupled with mass spectrometry for TEAD and have identified dozens of significant interacting proteins. TEAD interactions include expected proteins, such as known Hippo pathway members, as well as unexpected protein interactions, such as DNA damage response proteins. Cellular assays probing these DNA damage protein interactions implicate TEAD as a crucial factor for efficient DNA repair mechanisms and maintaining genomic stability. These results raise questions towards a combinatorial effect for TEAD inhibitors and DNA damaging chemotherapeutic agents. Altogether, these ongoing proteomic studies are providing insights into TEAD interaction networks, leading to a deeper understanding of TEAD biology, and providing foundational knowledge that can inform the development of TEAD inhibitors as effective cancer therapies.

#3049 Similarities between ovarian cancer and endometriosis: The role of STAT3.

A. A. Kloeckner, S. R. Walker;
University of New Hampshire, Durham, NH

Endometriosis is a painful gynecological disease that affects over 190 million women worldwide. This disease is classified by the presence of endometrial-like cells growing in and around the female reproductive system. Instead of lining the uterus, these ectopic cells shed off and cluster together forming lesions that attach to different surfaces of the female reproductive system. In particular, endometriosis cells interact with and form lesions within the mesothelial cells that line the peritoneum. There is currently no cure, and many of the therapies aiming to help with pain management come with unfavorable tradeoffs. Our research on ovarian cancer led us to investigate potential overlapping characteristics with endometriosis. Growing ovarian cancer cells in 3D causes spheroids to form which mimic the physical features of tumors and are also able to better represent cell-cell and cell-environment interactions. Analysis of the endometriosis cell lines 12Z and hEM3 demonstrated that they could also form spheroids. As both ovarian cancer cells and endometriosis cells interact with mesothelial cells, we wanted to determine if endometriosis spheroids were able to clear the mesothelial layer comparable to ovarian cancer spheroids. Evaluation of 12Z and hEM3 cell lines demonstrated that endometriosis spheroids were able to undergo mesothelial clearance. While the exact cause of endometriosis is not known, different proteins have been identified as important factors in the progression of endometriosis. The Signal Transducer and Activator of Transcription 3 (STAT3) is a transcription factor involved in cell differentiation, proliferation, apoptosis resistance, angiogenesis, and metastasis. In endometriosis cell lines, STAT3 is constitutively active, which makes it a promising potential therapeutic target. To verify that STAT3 is important in endometriosis, siRNA was used to reduce the expression of STAT3 in two endometriosis cell lines, 12Z and hEM3. Both cell lines showed a decrease in cell viability. In addition, reducing the expression of STAT3 in the endometriosis cells appeared to decrease mesothelial clearance ability. Our lab previously identified statins as potential STAT3 inhibitors by using the Broad Institute's CLUE tool. After statin treatment, 12Z and hEM3 spheroids showed a decrease in cell viability and clearance ability. Taken together, these data suggest that STAT3 plays a key role in endometriosis and that the repurposing of statins may provide a benefit to patients with endometriosis.

#3050 Evaluating the role of ΔNp63α in driving growth and metastasis of pancreatic ductal adenocarcinoma.

D. H. Ryan, C.-H. Tai, X. Zhang, M. Palestino Dominguez, C. Alewine;
National Cancer Inst. - Bethesda Campus, Bethesda, MD

Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer-related deaths in the US and is rising in incidence. PDAC tumors may be either classical or basal in transcriptomic subtype, and PDAC patients with basal tumors have worse prognosis and may have increased resistance to chemotherapy. Previous studies have shown that ΔNp63α drives basal program expression. The goal of this project is to investigate whether ΔNp63α expression is sufficient to increase pancreatic cancer cell growth, metastasis and chemoresistance and whether these cells can outcompete ΔNp63α non-expressers in mixed tumors. Non-ΔNp63α expressing human PDAC cell lines AsPC1 and HPAFII were stably transduced to express either ΔNp63α or mCherry (control). For both AsPC1 and HPAFII, ΔNp63α-expressing and control cells had similar proliferation rates and susceptibility to chemotherapy agents oxaliplatin and SN38 when grown in culture. When control or ΔNp63α-expressing AsPC1 cells were implanted orthotopically into the pancreas of athymic nude mice, there was no significant difference in primary tumor mass and pathological analysis of lungs and livers did not reveal any significant difference in metastatic burden. Bulk RNA sequencing of primary tumors confirmed that tumors in mice inoculated with AsPC1-ΔNp63α had significantly upregulated expression of genes associated with the basal subtype. Collectively, these data suggest that while ΔNp63α drives the basal program in PDAC, its expression is insufficient to cause resistance to these chemotherapies or a growth or metastatic advantage in an immunodeficient setting. Further work is needed to elucidate the mechanism by which ΔNp63α contributes to more aggressive PDAC tumors.

#3051 JunAP, a peptide antagonist against the activator protein 1 transcription factor complex, demonstrates cancer cell cytotoxicity and reduced invasion in vitro and tumor regression in vivo in TNBC models.

K. Mendelson, Z. F. Mattes, S. Leong, R. Ramirez, M. Koester, C. Scuoppo, J. Diehl, E. Gallagher, J. Gonzales, F. Abbate, L. Ghamsari, G. Merutka, B. J. Kappel, A. Vainstein-Haras, J. A. Rotolo;
Sapience Therapeutics, Inc., Tarrytown, NY

The activator protein 1 (AP-1) transcription factor is a dimeric complex consisting of proteins from the JUN, FOS, MAF, and ATF families. AP-1 complexes have been identified as novel therapeutic targets in cancer due to their role in tumor growth, invasion, metastasis, angiogenesis and chemoresistance. Dimerization of components of the AP-1 complex via leucine zipper domain interactions is required for DNA binding and subsequent transcriptional activity. We designed a peptide (Jun antagonizing peptide, JunAP) targeting the basic leucine zipper motif of AP-1 to antagonize AP-1 complex formation and prevent associated activity. Fluorescence polarization and DNA ELISA assays demonstrate target binding and selectivity of JunAP towards AP-1 family members, co-immunoprecipitation experiments reveal that JunAP blocks protein-protein interactions between cJun and its key binding partners, and reporter assays confirm inhibition of AP-1 transcriptional activity in vitro. Pathway analysis of RNA sequencing data confirmed by qPCR analysis shows that JunAP disrupts key pathways required for cell survival and migration. Corresponding functional in vitro assays reveal that JunAP exhibits an inhibitory effect on invasion in Boyden chamber assays and demonstrates potent cytotoxicity in Jun-dependent cells. Further, in a BT549 triple negative breast cancer subcutaneous xenograft model, administration of JunAP results in tumor regression, demonstrating the anti-cancer potential of targeting the AP-1 complex. In summary, these data support JunAP as a potent peptide antagonist of the AP-1 transcription factor family that warrants further development as a potential therapeutic option for AP-1 driven tumors.

#3052 Investigating the role of FOXA1/2 & HNF4α in pancreatic ductal adenocarcinoma.

W. A. Orellana, K. Gillis, P. Fang, G. Fort, E. L. Snyder;
Huntsman Cancer Institute, Salt Lake City, UT

PDAC represents a formidable challenge with an alarmingly low 5-year survival rate of less than 12%. Integrated genomic, transcriptomic, and proteomic analyses have identified two distinct PDAC subtypes: classical and basal. The critical difference between these subtypes lies in the expression of endodermal lineage specifiers, with the classical subtype expressing FOXA1, FOXA2 (FOXA1/2), and HNF4α, critical for pancreatic cell-fate determination, while the basal subtype downregulates these genes, leading to the loss of endodermal identity. We reason that the transcription factors (TF), FOXA1/2 and HNF4α, that play critical roles in pancreatic development, are not only biomarkers of the classical subtype but are essential regulators of PDAC subtype differentiation state. Despite their relevance in other cancers, their specific functions in PDAC remain largely unexplored. We aim to define the functional roles of FOXA1/2 and HNF4α in the classical PDAC subtype, exploring their regulation of growth and cellular identity. Previous published work in our lab has shown that exogenous HNF4α restrains growth in a panel of human and murine PDAC cell lines. Furthermore, we have shown that HNF4α regulates the classical subtype program of PDAC. While FOXA1/2 and HNF4α cooperatively enact gene expression changes in normal tissue, the extent to which cooperative interactions between these TFs are required to activate the classical gene expression program of PDAC remains unknown. Overall, we will test the central hypothesis that FOXA1/2 and HNF4α are critical regulators of the transcriptional network governing the cellular identity of classical PDAC. To test this hypothesis, we will be reconstituting and modulating the expression of these factors in human and murine PDAC cell and organoid lines. We will assess gene expression changes through RNA-seq and genomic localization of these TFs through ChIP-seq. We have conducted bulk RNA sequencing on *Foxa1/2*-positive and negative organoids to transcriptionally identify differences brought on by *Foxa1/2* deletion and found over 2,200 differentially expressed genes. *Foxa1/2* deletion led to a significant decline in the classical PDAC signature based on gene ontology. Furthermore, we show that HNF4α can inhibit organoid growth in the absence of FOXA1/2. We discovered that HNF4α targets, such as *Lgals4,* expression levels are unaltered at the RNA level independent of FOXA1/2. By assessing the roles of FOXA1/2 and HNF4α in PDAC, we aim to determine the transcriptional network governed by these factors in the classical subtype of PDAC

#3053 PTEN as a double-edged sword regulates EGFRL858R-induced lung cancer progression.

Jan-Jong Hung

National Cheng Kung University, Tainan, Taiwan

Lung cancer is the major cause of death worldwide. Activation of oncogenes or inhibition of tumor suppressors causes cancer formation. Previous studies have indicated that Pten, as a tumor suppressor, inhibits cancer formation. In this study, we studied the role of Pten in $EGFR^{L858R}$-induced lung cancer *in vivo*. Interestingly, loss of Pten increased bronchial cell hyperplasia but decreased alveolar cell hyperplasia in $EGFR^{L858R}$*$Pten^{-/-}$-induced lung cancer. Syatematic analysis of gene expression by RNA-seq showed that a number of genes related to ciliogenesis were upregulated in $EGFR^{L858R}$*$Pten^{-/-}$-induced lung cancer and subsequently showed that bronchial ciliated cells were hyperplastic. Several critical ciliogenesis-related genes, such as mucin5a, DNAI2 and DNAI3, were found to be regulated by NR2F1. Next, NR2F1 was found to be inhibited by overexpression of Pten, indicating that Pten negatively regulates NR2F1, thereby inhibiting the expression of ciliogenesis-related genes and leading to the inhibition of bronchial cell hyperplasia during $EGFR^{L858R}$-induced lung cancer progression. In addition, we also found that Pten decreased Akt phosphorylation in A549, Kras mutant, and H1299 cells but increased Akt phosphorylation in PC9, $EGFR^{L858R}$, and $H1299^{L858R}$ cells, suggesting that Pten may function as a tumor suppressor and an oncogene in lung cancers with Kras mutation and EGFR mutation, respectively. PTEN acts as a double-edged sword that differentially regulates $EGFR^{L858R}$-induced lung cancer progression in different genomic backgrounds. Understanding the Pten in lung cancer with different genetic backgrounds will be beneficial for therapy in the future.

#3054 Investigating novel players involved in AR cistrome reprogramming.

E. J. Gardner;
University at Buffalo, Buffalo, NY

Advancements in the treatment of aggressive prostate cancer (PCa) have led to the development of second-generation AR-targeted therapeutics for advanced PCa. Unfortunately, many patients who initially respond to these treatments develop resistance and progress. Several mechanisms of resistance are being studied. We have focused on the roles of a reprogrammed AR cistrome from a canonical to a non-canonical cistrome in resistant disease. The premise of this study is based on previous studies by others and studies in our lab that suggest enrichment in non-canonical AR activity and adaptation to enzalutamide in advanced PCa cell lines and patient-derived xenografts. We aim to develop an ecosystem map of canonical and non-canonical AR activity to understand the drivers of therapeutic resistance and their vulnerabilities. We hypothesize that through combined transcriptomic/chromatin accessibility profiling at single-cell resolution and proteomics studies, we can holistically capture non-canonical AR activity. To provide invaluable information, as PCa is highly heterogeneous and not all cancer cells may be contributing to the resistance pathway that is of interest, we use castrate-resistant PCa (CRPC) and enzalutamide-resistant CRPC patient-derived xenograft (PDX) models and patient tissue samples as our disease models on our multi-omic assay platform to capture and study dynamic interplays and novel players driving a non-canonical AR cistrome and treatment resistance. Our preliminary data revealed potential transcriptional factor (TF) candidates that may modulate non-canonical AR cistrome. We verified the enrichment of these TF in PDX models of treatment-resistant PCa at the gene and protein level. Integration of our ongoing global proteomic studies will provide a holistic view of the contributions of the TF to the AR non-canonical switch.

#3055 Characterizing the role of HNF4α isoforms in human PDAC.

P. Fang[1], A. Kabir[2], G. Fort[1], E. L. Snyder[1];
[1]University of Utah, Salt Lake City, UT, [2]Huntsman Cancer Institute, Salt Lake City, UT

Pancreatic ductal adenocarcinoma (PDAC) is a deadly and recalcitrant malignancy with a 5-year survival rate of 12%. Transcriptomic studies have classified PDAC into a classical or basal-like subtype. The classical subtype has a better prognosis, response to chemotherapy, and express higher levels of endodermal lineage specifiers compared to the basal-like subtype. However, the field lacks a comprehensive understanding of the key subtype-specific regulators. Functional analysis of transcription factors associated with each subtype are needed to elucidate their roles in regulation of PDAC subtypes and to identify therapeutically targetable vulnerabilities. Previous work in our lab demonstrated that HNF4α is a key regulator of the classical subtype. Using genetically engineered mouse models, our lab showed that loss of HNF4α leads to an increase in tumor burden, a shift from glandular to poorly differentiated histology, and a decrease in the classical subtype score. However, while murine PDAC only express one set of HNF4α isoforms, human PDAC express both sets of HNF4α isoforms, suggesting murine PDAC may not fully recapitulate human disease. There are 2 subsets of HNF4α isoforms driven by expression from 2 distinct promoters, P1 and P2. P1 and P2 isoforms are differentially expressed within the gastrointestinal (GI) tract and play dichotomous roles in GI malignancies. In HNF4α-positive human PDAC, P2 isoforms are always expressed but there is variable expression of P1 isoforms. Based on the differential role of HNF4α isoforms in both normal tissue and cancer, we hypothesize that P1 isoforms will restrain tumor growth and promote greater classical/GI differentiation compared to P2 isoforms. We utilized CRISPRi to selectively inhibit transcription at the P1 or P2 promoter in HNF4α-positive, human cell lines expressing both isoforms. To test for sufficiency, we exogenously expressed P1 or P2 isoforms in HNF4α-negative, human cell lines. We then performed Incucyte, CRISPRi competition, and anchorage-independent growth assays. We performed RNA-seq and ChIP-seq on both exogenous and endogenous HNF4α isoforms. Functional assays revealed that HNF4α isoforms regulated growth in a context dependent manner. Exogenous P1 isoforms significantly inhibited growth while loss of endogenous P1 isoforms was dispensable for growth. Exogenous P2 isoforms inhibited growth to a lesser degree while loss of endogenous P2 isoforms led to a significant reduction in growth. Despite ChIP-seq analysis revealing very similar binding profiles, RNAseq analysis revealed that P1 isoforms are significantly more transcriptionally active than P2 isoforms and are stronger inducers of GI differentiation. Taken together, our data demonstrates that P2 isoforms are more compatible with growth in PDAC compared to P1 isoforms, which promote a more differentiated cell state. Mechanistically, this may be due to the increased transcriptional activity of P1 isoforms.

#3056 Copper chelation modulates YTHDF2 RNA-binding protein localization and global translation, in neuronal cancers.

J. L. Bell[1], D. K. Abruzzese[2], E. Kasiou[2], V. Vu Pham[1], J. B. Bertoldo[1], F. Michniewicz[2], O. Vittorio[2];
[1]Children's Cancer Institute, Sydney, Australia, [2]University of New South Wales, Sydney, Australia

Cancers are dependent on copper for growth, angiogenesis and metastasis and copper chelators are in clinical trials against breast cancer, however the mechanisms of this emerging cancer treatment are still largely unexplored. We previously demonstrated that copper chelation has efficacy in mouse models of neuroblastoma and glioma. Multiomics analyses in neuronal cancers suggested that RNA-binding proteins were deregulated by copper chelator treatment. We found that the “RNA Binding” gene set was the most significantly ranked molecular function list using differentially expressed RNAs after copper chelation treatment (GO:0003723, p-value 1.02e−32). We subsequently found that the copper chelator drug decreased global protein synthesis, MYC/MYCN expression, as well as the amount a key methylated (m6A) RNA-binding protein called YTHDF2 in glioma cells, by RNA-seq (-log2FC 0.3, p-value 0.005) and western blot. This downregulation was also clear in neuroblastoma and glioblastoma cell lines. Interestingly, copper chelation also shifted YTHDF2 protein location into the nucleus. YTHDF2 knock-out (DepMAP Chronos dependency score, -0.32) and knock-down studies (siRNA pool, 38% decrease in cell confluence) in neuroblastoma cell lines and others, indicated that YTHDF2 depletion is selective against neuronal cancer cell growth. YTHDF2 was found to be a MYCN transcriptional target. Moreover, as YTHDF2 protein also binds MYCN transcripts (the principal oncogene in neuroblastoma), and copper signaling mRNAs, it appears that copper signaling, YTHDF2 and MYCs operates in an oncogenic-axis. Ongoing studies are investigating novel YTHDF2 inhibitors and their neuronal cancer efficacy. Our work represents a significant breakthrough in drugging oncogenic post-transcriptional processes either directly, or indirectly via depleting copper.

#3057 The TARZN complex binds to *de novo* enhancer mutations and promotes oncogenic expression in T-ALL.

N. Zaal Anuar[1], C. Goh[1], B. Chua[1], S. Tan[1], J. R. Costa[2], M. R. Mansour[2], T. Sanda[1], D. Kappei[1];
[1]National University of Singapore, Singapore, Singapore, [2]University College London, London, United Kingdom

TAL1 is overexpressed in 40-60% of T-cell acute lymphoblastic leukaemia (T-ALL) cases and forms an oncogenic core regulatory circuit (CRC) with other transcription factors such as LMO1, LMO2 and GATA3. In 5% of T-ALL cases an insertion of a consensus GT dinucleotide is observed upstream of the *TAL1* gene, termed the “Mutation of TAL1 enhancer” (MuTE), driving *TAL1* overexpression. Using an *in vitro* reconstitution DNA pull-down assay combined with quantitative mass spectrometry, we identified nine candidate proteins that preferentially bound to the MuTE sequence compared to the WT sequence. Among the candidates, we demonstrate by reciprocal immunoprecipitation experiments coupled to quantitative mass spectrometry that the RNA methyltransferase TARBP1 and the zinc finger proteins ZBTB2, ZBTB25 and ZNF639 formed a complex that we term TARZN. Interestingly, the TARZN complex also bound to *de novo* super enhancer sites upstream of the *LMO1* and *LMO2* genes in T-ALL cells, indicating a putative common mechanism between these different non-coding driver mutations. Furthermore, knock-down of all TARZN members resulted in lower TAL1 protein expression in MuTE-positive but not in MuTE-negative T-ALL cells. Overall, these data suggest that the TARZN complex cooperatively promotes oncogenic expression in T-ALL.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Signaling Pathways That Regulate Metabolism 1
Poster Session

#3061 A positive feedback loop between GLS1 and c-Myc drives tumor aggressiveness.
J. Yang, F. Chen, F. Yang, **Y. Teng**;
Emory University, Atlanta, GA

Both GLS1 and c-Myc are upregulated in head and neck squamous cell carcinoma (HNSCC) primary tumors and further increased in metastatic tumors. However, the regulation between these two molecules remains largely unknown. GLS1 is a critical enzyme that regulates glutamate, which plays an important role in cancer metabolism that supports cancer growth and survival. Our bioinformatic analysis of the TCGA HNSCC cohort revealed a strong correlation between c-Myc and GLS1 expression. We describe the importance of c-Myc in regulating GLS1 and vice versa. c-Myc protein directly binds to the promoter of the GLS1 gene and upregulates its expression at the transcriptional level. Interestingly, blocking GLS1 signaling in HNSCC cells by lentiviral shRNA knockdown or CB-839 treatment downregulates USP1, one of the best characterized human DUBs, which in turn reduces c-Myc protein stability via the ubiquitin-proteasome pathway. The GLS1-c-Myc axis thus represents a novel positive feedback loop that is critical for driving the aggressiveness of HNSCC. As the treatment of HNSCC remains a major challenge, these novel findings provide the molecular basis for combining GLS1-specific inhibitors with c-Myc-targeted therapy for the treatment of HNSCC patients.

#3062 Unraveling the role of RCC2 in glioblastoma by mutational analysis and a murine model of glioma.

W. L. Ho, P. Or, A. M. Chan;
The Chinese University of Hong Kong, Shatin, Hong Kong

Glioblastoma (GBM) is a brain malignancy characterized by being highly aggressive, lethal, yet treatment modalities remain limited. Recent studies have implicated *R*egulator of *C*hromosome *C*ondensation *2* (RCC2), a guanine nucleotide exchange factor (GEF) for RalA, as a potential regulator in glioblastoma pathogenesis. RCC2 has been shown to play a role in promoting glucose metabolism through BACH1-dependent upregulation of hexokinase II (HK2)(1). In this study, we investigated the functional mechanism of RCC2 in gliomagenesis using two complementary approaches. First, the relevance of RCC2 structural regions on its downstream functions were examined. By superimposing the three-dimensional crystal structure of RCC2 onto RCC1 (Regulator of Chromosome Condensation 1), a related GEF, we identified several unique regions within the RCC1-like domain of RCC2. A panel of point, substitution, and deletion mutants were generated, and pulldown experiments were performed to assess their relative binding affinity with BACH1. Additional assays to assess their relative ability to modulate the expression of HK2 and other cellular parameters will be discussed. The structure-functional characterization of distinct regions within RCC2 may identify unique sequences within RCC2 that could have relevance to glucose metabolism, cell proliferation and cell motility. Additionally, we have established a murine glioma model utilizing a *Pten* heterozygous mice expressing a GFAP-Cre-recombinase transgene (*Gfap-cre;Pten*$^{fl/+}$). Glioma were induced by stereotaxically injected lentiviral constructs expressing either with HRasV12 oncogene alone or together with RCC2. Neurological symptoms were monitored over a period of 7 months, and histopathological analysis was performed to evaluate the morphological and molecular features of the tumors. We showed that co-expression of HRasV12 and RCC2 exhibited earlier emergence of neurological manifests in both male and female groups (Log-rank test, $p<0.05$) when compared to HRasV12 alone. Overall, our study provides insights into both the structural mechanism of RCC2 in gliomagenesis through mutational analysis of RCC2 and the functional relevance through a murine model of glioma.

#3063 Defining oncogene-specific metabolic vulnerabilities in a mouse model of hepatocellular carcinoma.

K. Al-Shami[1], M. Snaebjornsson[1], F. Vogel[1], L. Schlicker[1], P. Poller[1], D. Dauch[2], A. Schulze[1];
[1]German Cancer Research Center (DKFZ) and DKFZ-ZMBH Alliance, Heidelberg, Germany, [2]University Hospital, Tubingen, Germany

Despite the continued success of advanced cancer therapies, hepatocellular carcinoma (HCC) represents a substantial challenge to current treatment modalities that are not sufficiently effective for the management of advanced disease. Metabolic reprogramming is a hallmark of cancer and many oncogenic signaling pathways impact on cellular metabolism. Here, we are investigating changes in metabolism in different oncogene-driven mouse models of liver cancer to identify selective metabolic vulnerabilities associated with HCC that could be implicated in tumor initiation and progression to be exploited for cancer therapy. Transposon-based vectors coding for different combinations of oncogenes, either *Myc* and *Akt1*^{Myr} (CaMIA) or *Myc* and *Nras*^{G12V} (CaMIN), were transduced by hydrodynamic tail vein injected into C57BL/6 mice. The resulting liver tumors and control livers were subjected to a comprehensive profiling of polar metabolites (metabolomics) and lipids (lipidomics and total fatty acids) as well as changes in gene expression (transcriptomics). Despite similar overall survival, the two models display marked differences in the presentation of the tumors, with CaMIA showing larger aggressive tumors, while CaMIN livers contain numerous small tumor nodules. Both models also showed evidence for the deregulation of intermediate metabolism, indicating activation of aerobic glycolysis and deregulation of glutamine metabolism. Lipidomic analysis revealed substantial lipidome remodeling in both models. Oncogene-specific alterations included elevated levels of lysophosphatidylcholine (LPC) in CaMIN tumors, while CaMIA tumors displayed high levels of ether phospholipids compared to CaMIN and normal liver. Moreover, the fraction of polyunsaturated fatty acids (PUFAs) was enhanced in lipids from CaMIN tumors, while monounsaturated fatty acids (MUFAs) were enriched in CaMIA tumors. Furthermore, tumors from both genotypes produced higher levels of oxylipins, a class of lipid mediators involved in signaling and inflammation, compared to normal liver. Transcriptome analysis confirmed these metabolic alterations and revealed evidence for enhanced inflammatory signaling in CaMIN. In addition, analysis of tumor microenvironment composition disclosed specific differences in stromal components, indicative of immune evasion through checkpoint activation. Experiments in primary murine liver cancer cell lines confirmed oncogene-specific metabolic rearrangements and suggest elevated sensitivity towards inhibitors of lipid remodeling. Future experiments will investigate the role of altered lipid metabolism in tumor development and immune evasion in liver cancer.

#3064 Unmasking the deadly tango: PKA and lipid genes in prostate cancer's bone invasion.

P. Sanchis[1], N. Anselmino[2], E. Labanca[2], A. Sabater[1], J. Bizzotto[3], G. Pascual[3], R. Seniuk[3], S. Lage-Vickers[3], A. Mitrofanova[4], P. Valacco[3], A. Toro[3], J. Cotignola[3], N. Navone[2], E. Vazquez[3], G. Gueron[3];

[1]1- CONICET - IQUIBICEN. 2- Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC)., Buenos Aires, Argentina, [2]Department of Genitourinary Medical Oncology and The David H. Koch Center for Applied Research of Genitourinary Cancers, The University of Texas MD Anderson Cancer Center, Houston, TX, [3]CONICET - IQUIBICEN, Buenos Aires, Argentina, [4]Department of Biomedical and Health Informatics, Rutgers School of Health Professions, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

About 88% of metastatic prostate cancer (PCa) cases involve bone metastasis. When PCa cells spread to the bone, a metabolic adaptation to the new environment takes place, partly influenced by factors secreted by the homing organ. Thus, we hypothesize that metabolic reprogramming, both in the tumor and bone niche drive PCa bone metastasis. In this work, we carried out an integrative *in vitro*, *in vivo*, and bioinformatics approach to identify key regulators governing the metabolic behavior of PCa cells. We performed an indirect co-culture between PCa (PC3) and bone progenitor (MC3T3 or Raw264.7) cells. PCa cells displayed a strong transcriptional (RNA-seq) activation of lipid metabolism, including PPAR-signaling, fat digestion, and PI3K-Akt pathway. Accordingly, treatment with the conditioned media (CM) of the co-culture promoted lipid accumulation in PC3 cells (Bodipy 493/503 staining). To assess the clinical relevance of the *in vitro* model, we performed an unsupervised clustering analysis using transcriptomics data from human PCa and bone metastatic samples (GSE74685). Results showed that the metabolic genes deregulated in PC3 by the co-culture, could accurately cluster samples in primary tumor or bone metastasis. We next performed a multivariable Cox regression analysis and built a prognostic model, identifying a novel signature of 5 lipid-associated genes, *PPARA, VDR, SLC16A1, PAPSS2* and *GPX1*, associated with a 23-fold higher risk of death in PCa patients (SU2C-PCF dataset). The expression of this signature was validated in a PDX pre-clinical model (MDA PCa PDX series) when comparing MDA-PCa-183 growing intrafemorally vs. subcutaneously. In order to identify the central hubs regulating this transcriptional phenotype, we performed an Ingenuity Pathway Analysis (QIAGEN), showcasing that the lipid-related signature deregulated by the bone niche is indeed modulated by the Protein Kinase A (PKA). Accordingly, the expression of these signature was downregulated by PKA inhibition (H89; PKA inhibitor). Moreover, secretome analyses (ESI MS/MS) revealed that bone secreted type I collagen (Col1a1) and fibronectin (Fn1) regulate PKA activity in PCa cells. Further, we investigated whether PKA could modulate critical mechanisms for bone progression, focusing on osteopontin (*SPP1*), a secreted protein involved in the adhesion and invasion of PCa cells, whose regulatory mechanism in tumor cells is yet to be elucidated. Strikingly, we observed not only that the activation of PKA using Forskolin in PCa cells activated *SPP1* expression, but also that PKA inhibition led to a significant impairment of the *SPP1* induction triggered by bone soluble factors secreted during the PC3/MC3T3 co-culture. Altogether, we showcase PKA as a central hub of PCa energetic metabolism during bone progression and outline a lipid-associated gene signature that can be targeted to halt metastatic PCa.

#3065 Targeting of metabolic reprogramming in lung cancer by utilizing patient-derived organoid tissue for precision medicine.

C. Wu[1], J. D. Nguyen[1], G. Theodore[1], E. Rodriguez[2], S. Spector[3], E. Kim[1], T. Khan[4], P. Puente[5], Y. Wang[1], D. M. Nguyen[2], C.-B. Chen[1], D. Lim[1], L. G. Feun[2], N. Savaraj[1], M. Wangpaichitr[1];

[1]Univ. of Miami/VA Medical Ctr., Miami, FL, [2]Univ. of Miami, Miami, FL, [3]Nova Southeastern Univ./VA Medical Ctr., Miami, FL, [4]University of Southern California, Los Angeles, CA, [5]Univ. of Illinois Chicago, Chicago, IL

In a preliminary pilot study, we reported elevated activity of indoleamine 2,3-dioxygenase 1 (IDO1) in serum from cisplatin-resistant (CR) lung cancer patients compared to cisplatin-sensitive (CS) patients. This heightened IDO1 activity was associated with increased tryptophan (TRP) catabolism, resulting in the upregulation of kynurenine (KYN) production. The detection of KYN can now be readily achieved through immunohistochemistry (IHC). We demonstrated that this upregulation contributed to increased Treg (regulatory T cell) and MDSC (myeloid-derived suppressor cell) populations resulting in an immunosuppressive tumor microenvironment. To investigate this effect, we used dual inhibition of IDO1/TDO2 (tryptophan2,3-dioxygenase 2) in an orthotopic mouse model of CR-Lewis lung carcinoma. This resulted in a significant reduction in tumor volume compared to LLC-CS ($n=7$, $p<0.01$), confirming the role of TRP catabolism in CR tumorigenesis. To determine the relevance of the data derived from this mouse model to clinical settings, we established 50 patient-derived organoid tissues (PDOT) from patients with NSCLC. PDOT is an experimental ex vivo tissue model developed to recapitulate the intricate features of lung architecture, including the lung acinus. Upon optimizing our collection and growth protocols, each PDOT successfully developed into a spherical body within 14 days. Furthermore, through bulk RNA-seq analysis, we showed that PDOT closely mirrors the expression of key molecular markers (PD-L1 and mutations), as observed in the original tumor tissues. PDOT from patients possessing high levels of PD-L1 and KYN were exquisitely sensitive to dual inhibition with 2-3-fold greater sensitivity compared to patients with undetectable KYN expression in growth inhibition assays ($GI50=20\pm5.5\mu M$ vs. $65\pm7.5\mu M$). Increased lipid peroxidation was detected via flow cytometry by accumulation of the C11-BODIPY reporter dye in the dual inhibition treatment group. Moreover, we integrated PDOT with a novel 3D microfluidic culture that can be supplied with patient-matched peripheral blood mononuclear cells (PBMC) to assess immune response. Using CyTOF, we showed that dual inhibitors with Atezolizumab (anti-PD-L1) enhanced immune effector (CD8+, NK) and suppressed immunosuppressive (Treg, MDSC) populations. We believe that our swift progress in PDOT development may bridge the divide between cancer biomarker expression and patient trials by timely complementing conventional drug studies based on cell lines and xenografts to facilitate the design of personalized therapies. As a result, the extensive reporting that we have contributed for KYN expression profiling in CR has the potential to serve as a valuable companion diagnostic tool in the future. This can assist in applying precision oncology by finding the most appropriate patients for immunotherapies.

#3066 Lung cancer cells overcome nutrient stress by upregulating an integrin αvβ3/AMPK/OXPHOS axis.

A. Nam, S. Jain, A. Campos, R. M. Shepard, T. von Schalscha, S. M. Weis, H. I. Wettersten, D. A. Cheresh;
University of California San Diego - UCSD, La Jolla, CA

Tumor cells are exposed to various forms of stress within the tumor microenvironment, and those cells that adapt often gain stem-like properties that facilitate tumor initiation and metastasis. Here, we show that lung cancer cells exposed to nutrient stress adapt and survive by converting their metabolism from glycolytic to oxidative phosphorylation (OXPHOS). This is based on the cell's ability to upregulate expression of integrin αvβ3, a driver of tumor initiation, progression, and drug resistance. Mechanistically, integrin αvβ3 recruits and activates c-Src, promoting sustained AMPK activity leading to activation of PGC-1α, which promotes the expression of mitochondrial OXPHOS complexes. In fact, ectopic expression of integrin β3 was sufficient to drive OXPHOS-dependent metabolism even in the absence of stress. Furthermore, pharmacological targeting of this pathway not only rendered integrin αvβ3+ cells sensitive to nutrient depletion but also prevented their ability to undergo tumor initiation. These findings reveal that targeting integrin αvβ3 or its pathway can prevent cancer cell metabolic flexibility and their capacity to adapt to stress within the tumor microenvironment.

#3067 SLC7A5/LAT1 promotes the Warburg Effect for TNBC progression through Trp/QPRT/NAD+ pathway.

M. Y. W. Fedoroff, L. Zhao, L. Saeednejad Zanjani, J. He;
Thomas Jefferson University, Philadelphia, PA

SLC7A5/LAT1 is a cross-membrane transporter that functions in uptake of large neutral amino acids into cells. Many pathological studies have shown that LAT1 is highly expressed in cancer tissue from various origins such as lung, biliary tract, breast, prostate, bone, and their metastatic legions. High LAT1 expression has been recognized as a significant prognostic marker in various cancers. Our TCGA data analysis showed that the expression level of LAT1 is higher in TNBC tumors compared with normal breast tissues. The higher expression level of LAT1 is linked with poor overall and progression-free survival. Dysregulation of amino acid transporters lead to metabolic reprogramming, which changes intracellular amino acid levels, contributing to the pathogenesis of cancer. However, it remains elusive whether and how LAT1 re-wires the cellular metabolic programs to promote TNBC tumor proliferation. In this study, we showed that inhibition of SLC7A5/LAT1 significantly reduced TNBC cell proliferation, viability, migration capability while promoting apoptosis. Mechanistically, we found significant positive correlations of LAT1 with PKM2 and LDHA in breast cancer tissues, which are key enzymes in mediating glycolysis and lactate fermentation or the Warburg Effect. Knock down LAT1 via siRNA decreased the expression levels of p-PKM2 and p-LDHA in TNBC cells. Tryptophan, a major substrate amino acid transported into cytosol by LAT1, is the precursor for the de novo synthesis of nicotinamide adenine dinucleotide (NAD+). The enzyme quinolinic acid phosphoribosyltransferase (QPRT) catalyzes the conversion from quinolinate, a product of tryptophan degradation, to NAD+. We showed LAT1 inhibition reduced the expression level of QPRT, cytosolic NAD+/NADH ratio as well as lactate production. Addition of L-Tryptophan increased the levels of p-PKM2 and p-LDHA while knockdown of LAT1 reversed tryptophan-mediated increase of PKM2 and LDHA activities, suggesting that LAT1 may regulate PKM2/LDHA through Trp/QPRT/NAD+ pathway for promoting the Warburg Effect. Additionally, we found upregulations of SLC7A5/LAT1, p-PKM2 and p-LDHA in doxorubicin-resistant cells and PDX mouse model compared with their corresponding controls. Collectively, these results provide evidence that overexpression of LAT1 in TNBC drives cancer progression and drug resistance by reinforcing the Warburg Effect, suggesting LAT1 as a promising therapeutic target for addressing TNBC. Our ongoing work will evaluate whether inhibiting LAT1 genetically or pharmacologically reduces xenograft tumor growth and enhances the sensitivities of TNBC resistant cells to chemotherapy in vivo. Our investigation will elucidate the underlying mechanisms involved in these processes.

#3068 CD146mediates intimate crosstalk between adipocytes and triple-negative breast cancer cells and drives tumor metastasis through lipid metabolic reprogramming.

H. Sun[1], K. Huang[1], B. Sun[1], J. Lin[1], R. Yang[1], J. Li[1], S. Wang[1], D. Zeng[2], H. Lin[1], Y. Liang[1];

[1]First Affiliated Hospital of Shantou University Medical College, Shantou, China, [2]Cancer Hospital, Shantou University Medical College, Shantou, China

Background & Aim: In the tumor microenvironment, the adipocytes enhance the invasiveness of breast cancer (BC) by remodeling the lipid metabolism, especially in triple-negative breast cancer (TNBC). The cell adhesion molecule CD146 was highly expressed in TNBC and predicted poor distant metastasis free survival (DMFS) in patients. Meanwhile, CD146 was known to alter the obesity process by regulating the metabolic level of the body. In this study, we aimed to explore the molecular mechanism of CD146 in tumor metastasis mediating by lipid metabolic reprogramming between adipocytes and TNBC cells.
Methods: CD146 knockout (KO) or overexpression cell models were constructed by CRISPR/Cas9 or lentivirus. Cells labeled with luciferase were injected in tail vein of Balb/c-nude mice and monitored lung metastasis by IVIS Kinetic system *in vivo*. Transwell and wound healing assays were analyzed cell aggressiveness *in vitro*. We synthesized anti-CD146 nanobodies, which significantly degraded CD146 protein and inhibitd its function. RNA-seq and Lipidomics in CD146 knockout models were performed to analyze the role of CD146 in TNBC cell metabolism. Immunofluorescence was used to detect the intracellular content of Lipid Droplet (LD) and protein localization. Finally, we used oleic acid (OA) and adipocyte-conditioned medium (CM) to mimic the tumor microenvironment.
Results: CD146 was highly expressed in TNBC and predicted poor DMFS survival. Inhibition of CD146 suppressed tumor aggressiveness and lung metastasis *in vitro* and *in vivo*. According to the bioinformatics and RNA-Seq analysis, we showed that CD146 was intimately involved in the lipid metabolic pathway, particularly fatty acid metabolism, and revealed that inhibiting CD146 in TNBC elevated the intracellular triglyceride level through lipidomic assay. Meanwhile, knockout of CD146 promoted LD accumulation and decreased fatty acid oxidation (FAO) and mitochondrial ATP levels. In molecular mechanism, we found that adipocytes secrete high level of IL6 and fatty acid, which activated JAK/STAT3 signaling and FAO mediating by CD146 in TNBC cells. Blocking CD146 using its nanobody inhibited IL6/JAK/STAT3 activities and ACADM, leading to impairment of FAO and lung metastasis suppression *in vitro* and *in vivo*.
Conclusions: In this study, we demonstrate the crucial role of CD146 in the crosstalk between tumor cells and adipocytes in the tumor microenvironment. CD146 promotes the utilization of fatty acids through fatty acid oxidation and activates the downstream inflammatory pathway response with adipocyte-secreted IL-6, thereby driving BC aggressiveness. Our study has important implications for the development of TNBC therapeutics to block CD146-driven FAO process, inflammatory response and tumor metastasis.

#3069 Targeting lactic acid sensing GPR132 in ccRCC.

D. Wang;
University of Miami Miller School of Medicine, Miami, FL

Clear cell renal cell carcinoma (ccRCC) is the most common and aggressive subtype of kidney cancer, accounting for 70-80% of the cases. Despite the improvements in tumor therapeutics, patients with metastatic clear cell tumors still have a five-year survival rate lower than 10%. Most of the ccRCC tumors harbor loss of VHL tumor suppressor gene on chromosome 3, leading to constitutively stabilized HIF, activation of downstream pathways involved in glycolysis, angiogenesis and metastasis and a highly acidic, vascularized, and immunosuppressive tumor microenvironment (TME). Such molecular alterations lead to the buildup of lactic acid within the tumor microenvironment. Long has been considered as a byproduct of hypoxic tumor metabolism, but recent studies have demonstrated a pro-tumorigenic role of lactic acid. Therefore, elucidating the molecular mechanisms on how tumor cells take advantage of lactic acid can identify potential novel therapeutic options. To understand how ccRCC cells sense extracellular lactic acid, I explored the concept of a lactate sensor. The currently known lactate sensors are GPR81 and GPR132. By querying TCGA data, GPR81 is reduced in ccRCC tumors and does not predict patient outcome while GPR132 is elevated in ccRCC tumors compared to normal kidney and demonstrates a strong negative effect on survival. Therefore, GPR132 stands out as a potential lactate sensor in ccRCC with meaningful impact on patient survival. Previously, GPR132 has been shown to be involved in tumor associated macrophage M1 to M2 transition upon lactic acid exposure. However, GPR132 exerts a striking impact on ccRCC tumors. Depleting GPR132 significantly decreased the HIF2α level in multiple ccRCC cell lines, establishing a molecular connection between lactic acid, GPR132 and HIF2α. Furthermore, due to suppressed HIF2α signaling, GPR132 knockout led to decreased lactic acid uptake through MCT1. Such decreased lactic transporter MCT1 abrogated the elevated aggressive phenotype in ccRCC cells when exposed to lactic acid. Metabolically, GPR132 knockout led to decreased lipid deposition. In addition, such deprivation of lipid droplet is not replenished when cells are exposed to lactic acid. Furthermore, by conducting an isotype-tracing experiment, GPR132 knockout actively decreased lactic acid uptake by the tumors and limit their resources to regenerate TCA cycle intermediates and build up lipid droplets. More importantly, GPR132 knockout led to defective mitochondria activities and activation of apoptosis, both of which led to significantly suppressed ccRCC growth *in vitro* and *in vivo*. This suggested that GPR132 likely affects ccRCC fitness through multiple layers of signaling mechanisms. Overall, our study has revealed that lactate sensing GPR132 is a critical signaling pathway for ccRCC tumor development in a glycolytic feed-forward context. As a membrane bound receptor, GPR132 holds immense potential as a novel therapeutic target in ccRCC.

#3070 CDK12 is a novel therapeutic target in glioblastoma.

Jeong-Yeon Mun[1], Chang Shu[1], Qiuqiang Gao[1], Mike-Andrew Westhoff[2], Georg Karpel-Massler[3], Markus D. Siegelin[1]

[1]Department of Pathology & Cell Biology, Columbia University Medical Center, New York, NY, [2]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, [3]Department of Neurological Surgery, Ulm University Medical Center, Ulm, Germany

Glioblastoma (GBM), the most common primary brain tumor in adults carries a highly unfavorable prognosis of only one to two years despite treatment with the standard of care, involving surgery, temozolomide and radiation. Patient-derived xenograft (PDX) GBM cultures were assessed for their susceptibility to loss of CDK12 function, which was either mediated genetically (shRNA) or by the novel inhibitor, SR-4835. GBM metabolism was measured by utilizing extracellular flux analysis as well as LC/MS based carbon tracing analyses. In vivo efficacy was determined by orthotopic GBM models in mice. Based on Clustered Regularly Interspaced Short Palindromic Repeat (CRISPR) and shRNA library screens in multiple GBM cell cultures we identified CDK12 as essential for the growth of GBM. Consistently, loss of function of CDK12 (genetically and pharmacologically) led to a reduction of growth of GBM patient-derived xenograft (PDX) lines *in vitro*. Notably, SR-4835 reduced GBM growth in the low nanomolar range and synergistically enhanced the potency of temozolomide. Extracellular flux analysis and metabolite screening analyses, including carbon tracing (U13C-Glucose, U13C-Glutamine) suggested that loss of function of CDK12 elicited a substantial inhibition of cellular respiration, causing energy deprivation with subsequent cell death with apoptotic features. On the molecular level, loss of function of CDK12 increased ATF4 along with pro-apoptotic Noxa, whereas anti-apoptotic Mcl-1 decreased. In turn, adenoviral mediated ectopic expression of Mcl-1 inhibited cell death mediated by loss of function of CDK12 in GBM cells. In an orthotopic murine PDX model of GBM animals receiving treatment with SR-4835 had a significantly longer overall survival without induction of toxicity as compared to mice treated with vehicle. In summary, these findings suggest that CDK12 is a novel treatment target for GBM and that CDK12 is an important driver of energy metabolism in GBM to partially mediate apoptotic resistance. Moreover, SR-4835 enhanced the potency of temozolomide in GBM models. Therefore, the novel CDK12 inhibitor, SR-4835 should be tested in a clinical trial in patients suffering from GBM.

#3071 Differential susceptibility of breast cancer cells to mitochondrial dysfunction induced by Wnt inhibitors.

Y. Kam, L. Winer, G. W. Rogers, N. Romero;
Agilent Technologies, Inc., Lexington, MA

Advances in research have shown that cancer cells have distinctive bioenergetic alterations to meet their energy requirements. It has been established that certain cancers are significantly reliant on mitochondrial respiration, suggesting that modulation of mitochondrial function may have therapeutic value. The Wnt signaling pathway is a potential therapeutic target of cancer, including breast and colorectal cancers. Recent findings suggest that bi-directional crosstalk between Wnt signaling and mitochondrial function plays a crucial role in tumorigenesis, as well as differentiation and self-renewal of stem cells. In this study, 71 agents known to alter Wnt signaling were screened for effects on mitochondrial function in BT474 and Hs578T breast cancer cell lines, which have highly oxidative and highly glycolytic bioenergetic phenotypes, respectively. This screen was performed using the Agilent Seahorse XF Mito Tox assay, which enables sensitive detection and characterization of mitochondrial modulators via a standardized, quantitative parameter, the Mito Tox Index (MTI). The MTI facilitates the comparison of drug efficacy by detecting modes of mitochondrial toxicity, inhibition, and uncoupling. The MTI-based screening of the Wnt modulators identified one inhibitor and two uncouplers as potent agents inducing mitochondrial dysfunction for both BT474 and Hs578T. Despite their distinctive bioenergetic phenotypes, MTI-based dose-response assays revealed no significant differences in the efficacy of these modulators between BT474 and Hs578T cell types. In contrast, significant differential effects on ATP production rates were detected, showing cellular energy depletion induced by these agents. Using the Agilent Seahorse XF Real-Time ATP Rate assay, BT474 cells showed significant metabolic energy crisis in the presence of all 3 compounds, whereas Hs578T cells maintained stable total ATP production. This differential impact on ATP production rate corresponds directly to differences in cell viability, with BT474 showing higher susceptibility to these compounds. These results suggest that the anti-cancer efficacy of mitochondrial modulators can be different depending on the metabolic phenotype of the target cell and should be considered in therapeutic design.

#3072 BXQ-350: A novel biologic that allosterically activates glucosylcerebrosidase and demonstrates signs of activity in cancer patients.

G. H. Tapolsky, C. Cruze, R. Furnish, M. Gazda, T. Stephens, L. Stamper, N. Wilkins, R. Takigiku;
Bexion Pharmaceuticals, Inc, Covington, KY

Background: Ceramides, glucosylceramides and sphingosine-1-phosphate (S1P) are key bioactive signaling molecules. Ceramides are proapoptotic and mitigate chemoresistance while glucosylceramides and S1P promote cancer cell proliferation, activate multiple oncogenic pathways, promote chemoresistance and stimulate a pro-tumoral microenvironment. Many studies have shown a better prognosis and longer survival for patients with high ceramides levels, while high S1P and glucosylceramides levels are associated with shorter survival and worst prognosis. Levels of ceramides, glucosylceramides and S1P are controlled by enzymes involved in sphingolipid metabolism, including glucosylcerebrosidase (Gcase) and sphingosine kinase (Sphk).
Methods: BXQ-350 is a nanovesicle of Saposin C, an allosteric activator of enzymes involved in sphingolipid metabolism; preclinically, BXQ-350 was investigated in different *in vitro* and *in vivo* models. Clinically, BXQ-350 was investigated in a first-in-human Phase 1 safety dose and escalation study in cancer patients with recurrent advanced solid malignancies (NCT02859857).
Results: Preclinical results demonstrated that BXQ-350 allosterically activates Gcase *in vitro*, in cells and *in vivo* in a significant and dose-dependent manner; as expected, *in vivo*, Gcase activation results in lower levels of glucosylceramides, as much as 2/3 lower for picomolar concentrations of BXQ-350. An increase in ceramides and a decrease in S1P are also observed. By impacting glucosylceramides, ceramides and S1P, BXQ-350 rebalances the S1P/ceramide rheostat in favor of an antitumoral state and homeostasis. By lowering S1P and glucosylceramides, BXQ-350 modulates the innate and adaptive immune response and repolarizes macrophages towards the antitumoral M1 phenotype, inhibits differentiation and activity of immunosuppressor of MDSCs, and promotes the proliferation of CD4+ and CD8+ Tcells as well as their activity. Clinical results showed BXQ-350 was safe and well-tolerated (no DLT, no MTD). Also, 13 patients (~17.8% of evaluable patients) had a clinical benefit up to cycle 6 and beyond (PR, SD). Among patients with PFS > 6 months, there were 4 recurrent CRC patients: 1 patient had a PFS of ~12 months, 2 of ~18 months, and 1 is still on study after 6 years. Furthermore, there were signs that BXQ-350 may alleviate symptoms of CIPN as 4 out of 10 patients with chronic CIPN at time of enrollment experienced an improvement of their symptoms.
Conclusions: Preclinical and clinical results demonstrated that BXQ-350 activates Gcase and modulates sphingolipid metabolism leading to a novel anticancer MOA that had not been clinically tested. Additional studies are ongoing to further elucidate BXQ-350's MOA.

#3073 ACTL6a drives metabolic reprogramming and chemoresistance in head and neck squamous cell carcinoma.

Mehri Monavarian, **Andrey Finegersh**

Stanford University School of Medicine, Palo Alto, CA

Actin like protein 6A (ACTL6a), a subunit of the SWI/SNF chromatin remodeling complex, is amplified in a third of all squamous cell carcinomas including head and neck (HNSCC) cancers. Recent studies implicate ACTL6a as an oncogenic driver that potentiates SWI/SNF-related chromatin remodeling; however, the underlying mechanisms in HNSCC progression yet to be elucidated. Using the HNSCC cell lines FaDu, SCC90, and SCC2, ACTL6a knockdown (siACTL6a) led to a significant reduction in cell proliferation compared to control when measured by sulforhodamine B but not resazurin, suggesting up-regulation of oxidative phosphorylation with siACTL6a. We used RNA-seq datasets of siACTL6a in FaDu cells and found that there was a significant up-regulation of components of complex I and IV of the electron transport chain compared to control. Gene set enrichment analysis also demonstrated a significant up-regulation in glycolysis in ACTL6a amplified tumors within the HNSCC TCGA dataset. Since metabolism is a key driver of chemotherapy resistance, we studied effects of ACTL6a expression on cisplatin-mediated cytotoxicity. Compared to control, siACTL6A of the HNSCC cell lines FaDu and SCC2 had significantly decreased IC50 to cisplatin, indicating ACTL6a mediates toxicity. We also observed significantly decreased migration in a transwell migration assay in siACTL6A FaDu and SCC2 cells compared to control. We are studying the effects of shRNA directed against ACTL6a using a syngenic *in vivo* tumor model with a mouse oral cavity (MOC2) cell line that grows in C57BL/6J mice. Subcutaneous injection of MOC2 cells demonstrated significantly decreased tumor growth in shACTL6a cells compared to control. We are performing additional studies to identify specific mechanisms of ACTL6a mediated metabolic reprogramming in tumor cells. In conclusion, ACTL6A amplification is common in HNSCC and facilitates metabolic reprogramming, which drives tumor proliferation, cell migration, and drug resistance.

#3074 Regulating lactate levels in triple negative breast cancer presents a promising avenue for therapeutic intervention.

C. P. Prasad, S. M. Umar, A. D. J. R., A. Kashyap, M. Rathee;
All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Introduction: Among all subtypes of breast cancer, triple-negative breast cancer (TNBC) is associated with the most unfavorable prognosis, emphasizing the critical need to pinpoint therapeutic targets tailored to TNBCs. Lactate, produced as a by-product of aerobic glycolysis, acts as an oncometabolite and plays a substantial role in promoting tumor aggressiveness, particularly in TNBCs. In our ongoing laboratory investigations, we are actively exploring strategies to mitigate the influence of lactate on TNBCs.

Methods: The experiments utilized two triple-negative breast cancer (TNBC) cell lines, i.e., MDA-MB231 and MDA-MB468. The inhibitors employed in this study are FOXY5, XAV939, PFK15, and Quercetin. Protein expression was examined using Western blotting and Immunofluorescence assays. Trans-well and wound healing assays were employed to assess cell migration and invasion. Colony formation assays (CFU) were utilized to investigate stem cell potential and proliferation. In vivo experiments were conducted using 4T1-orthotopic Balb/c mice.

Results: Using triple-negative breast cancer (TNBC) cells, we have demonstrated the pivotal role of the WNT/β-catenin signaling pathway in promoting the generation of extracellular lactate, thus driving the progression and metastasis of TNBCs. Additionally, we have shown that inhibiting lactate production in TNBC cells, and consequently impeding cell migration and invasion, can be achieved by using recombinant WNT5A or its mimicking hexa-peptide FOXY5. Similarly, employing a β-catenin inhibitor such as XAV939 can yield comparable outcomes in relation to TNBC cells. In an alternative approach, we conducted inhibition experiments targeting PFKFB3 (6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase), a key regulator of aerobic glycolysis in cancer cells. Our findings indicate that a combined approach involving siPFKL and iPFKFB3 is more promising in suppressing lactate production in TNBCs when compared to the effects of individual iPFKFB3 treatment.

Conclusions: Our present investigations suggest that employing inhibitors targeting the WNT/β-catenin signaling pathway, PFKP, and PFKEB3 could be a promising therapeutic strategy to effectively reduce lactate levels in TNBCs.

#3075 Different roles of EPAC1 and EPAC2 in ovarian cancer: Implications for precision targeting in cancer therapy.

Z. Gao, W. Yuan, L. T. Lee;
University of Macau, Macau, China

There are two distinct functional isoforms of Exchange proteins directly activated by cAMP (EPACs), EPAC1 and EPAC2, which exhibit fundamental distinctions in structure, expression patterns, signaling specificity, and subcellular localization. This diversity suggests that EPAC1 and EPAC2 can operate independently, synergistically, or antagonistically, contributing to the wide range of reported functions and impacts in different cancers and studies. We compared the function of EPAC1 and EPAC2 in ovarian cancer using *in vitro* and *in vivo* models and further explored the underlying mechanism in the regulation of metabolism reprogramming. Selective inhibition of EPAC1 and EPAC2 markedly reduced proliferation in ovarian cancer cell lines, leading to cell death and cycle arrest. RNA-seq analysis indicated different downstream signaling pathways triggered by EPAC1 and EPAC2, with EPAC2 specifically linked to functions in energy metabolism. Treatment with an antagonist or knockdown of EPAC2 resulted in attenuation of both glycolysis and oxidative phosphorylation (OXPHOS), while EPAC1 did not induce such effects. Furthermore, inhibition of EPAC2 induced mitochondrial dysfunction, manifested by reduced ATP production, decreased mitochondrial membrane potential, and increased burden of reactive oxygen species (ROS). Our data also revealed that EPAC2 governs the MAPK pathway and mediates the mitochondrial unfolded protein response (UPRmt) in ovarian cancer cells. By delineating the distinctions between EPAC1 and EPAC2 within ovarian cancer cells, this project revised the prevailing understanding of EPACs and suggests the potential for precise targeting of EPAC isoforms as a viable strategy in cancer therapy.

#3076 Unveiling the therapeutic potential of β-catenin inhibition in triple negative breast cancers: Targeting the Warburg effect.

S. M. Umar, S. kahol, A. D. JR, A. Kashyap, S. R. Mathur, A. Gogia, S. Deo, C. P. Prasad;
All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Introduction: Triple Negative Breast Cancer (TNBC) exhibits increased glycolysis, known as the Warburg effect. Recent research, including our own Nanostring nCounter studies, identify β-catenin as an oncoprotein linked to elevated glycolysis in TNBC tumors. Our current research explores the impact of β-catenin inhibitors on glycolysis in TNBC cell lines and an *in vivo* CDX model.
Method: We employed immunohistochemistry to assess 98 TNBCs for the presence of β-catenin, PFKP, LDH-A, and MCT1 proteins, exploring their correlation with clinicopathological factors. In *in-vitro* experiments using MDA-MB-231, MDA-MB-468, and 4T1 cell lines, we investigated how β-catenin inhibitors (XAV939 & Axitinib) affected aerobic glycolysis components, and TNBC cell characteristics (proliferation, migration, invasion, and stemness). For *in-vivo* validation, 4T1 TNBC xenografts were employed to confirm our findings.
Results: Among the 98 TNBC patients, 63 (64%) displayed cytoplasmic /or nuclear β-catenin staining. Additionally, cytoplasmic accumulation of PFKP was observed in 52/98 (53%), increased cytoplasmic LDH-A expression in 57/98 (58%), and membranous MCT-1 expression in 50/98 (51%) TNBC patients. Notably, significant positive correlations were found between nuclear/cytoplasmic β-catenin and cytoplasmic PFKP ($p = 0.001$) as well as membranous MCT1 ($p = 0.014$). Furthermore, β-catenin, PFKP, LDHA, and MCT1 proteins were overexpressed in all TNBC cell lines thereby supporting their glycolytic nature. Comparative analyses between XAV939 and Axitinib revealed that Axitinib significantly reduced various TNBC cell parameters, including migration, invasion, lactate production, colony-forming ability, and expression of aerobic glycolytic pathway proteins. In the *in-vivo* studies, 30mg/kg Axitinib in a female Balb/c-4T1 xenograft model resulted in a substantial reduction in tumor volume and weight.
Conclusion: Our findings show that increased levels of β-catenin play an important role in regulating aerobic glycolysis in TNBCs. Furthermore, our findings also highlight Axitinib's potential as an effective therapeutic agent for the treatment of β-catenin-positive TNBCs.

#3077 Integrin expression during ovarian cancer progression.

N. Bano, **E. M. Schmelz**;
Virginia Tech, Blacksburg, VA

During peritoneal dissemination, ovarian cancer cells exfoliate from the primary tumor and aggregate in the peritoneal fluid. This elicits survival signals via changes in mitochondrial morphology and function. As spheroids adhere to secondary sites, mitochondrial function is restored in the form of recovery of mitochondrial morphology, increased mitochondrial membrane potential, glucose uptake and increased proliferation. These findings suggested a mitochondrial phenotypic switch from mitophagy in spheroids to upregulation of mitobiogenesis upon spheroids adhesion to secondary sites. Hence, our objective was to identify critical receptors that facilitate the adhesion of spheroids to secondary sites, focusing on integrins that facilitate cell-extracellular matrix (ECM) attachment and activate downstream signaling cascades. To investigate changes in integrin expression, we mimicked three major stages of ovarian cancer progression by developing adherent stage, spheroid stage and adherent spheroid stage using our mouse ovarian surface epithelial (MOSE) cell lines representing benign (MOSE-E) stage as well as slow-developing (MOSE-L) and fast-developing disease (MOSE-L_{TICv}) in biologically relevant conditions. Using RT qPCR and Western blotting, we determined gene and protein expression levels of integrins and adhesion related genes. Confocal microscopy was used to determine protein localization during ovarian cancer progression. RT qPCR result indicated differential up-regulated expression of integrins in both spheroid and adherent spheroid stage, suggesting the role of different integrins during the stages of ovarian cancer progression. Specifically, we observed a decrease (integrin α5, α6) or increase (α2**β**;1) of integrins after aggregation and an upregulation of **β**;1, α2, αV, α3, α5 and immunomodulatory integrins such as αE and αM in adherent spheroids, indicating their role in mediating specific steps during progression of ovarian cancer from tumorigenesis to metastatic implantation. We also observed increased expression levels of extracellular matrix proteins and their modulators, and cell-to-cell adhesion genes during ovarian cancer progression that was more pronounced in the MOSE-L_{TICv} cells which suggests their association with an aggressive cancer phenotype. Overall, this project will aid in the identification of adhesion targets to develop new anti-metastatic treatments that will reduce mortality in women with ovarian cancer.

#3078 Role of HuR in metabolic reprogramming of BRAF mutant melanoma treated with dabrafenib.

A. Loftus[1], M. Zarei[2], H. Graor[2], O. Hajihassani[2], C. Boutros[1], J. M. Winter[1], L. D. Rothermel[1];
[1]UH Cleveland Medical Center, University Heights, OH, [2]Case Western Reserve University, Cleveland, OH

Introduction: Oncogenic BRAF mutations are present in about 50% of melanoma and are clinically targetable by BRAF inhibitors such as dabrafenib. While BRAF inhibitors show high rates of clinical response, that response is transient and resistance inevitably develops. Previously we have demonstrated that BRAF inhibitors induce a metabolic shift towards the mitochondrial oxidative phosphorylation. We have shown that inhibition of wild type isocitrate dehydrogenase 1 (wtIDH1), a vital anaplerotic and anti-ROS enzyme, demonstrates synergy with dabrafenib in vitro and in vivo. IDH1 expression has been found in pancreatic cancer to be posttranscriptionally regulated by the RNA-binding and stress response protein, HuR (ELAVL1) under nutrient and chemotherapy stress. We hypothesize that HuR functions as a survival mechanism in melanoma under BRAF inhibition, regulating metabolic reprogramming including the expression of IDH1.

Methods: The human BRAF V600E mutant melanoma cell line, A375, was used for all experiments. HuR and IDH1 expression was suppressed by siRNA oilgos through lipofectamine transfection, as validated by immunoblot analysis. The bioenergetic assay was conducted using Seahorse XFp mini extracellular analyzer to measure the oxygen consumption rate (OCR) under nutrient stress, both with and without dabrafenib exposure. The impact of HuR on IDH1 expression was further explored using qPCR and Immunoblot. Ivosidenib was used for pharmacologic inhibition of wtIDH as previously described.

Results: Mitochondrial respiration (OCR) increased in parental A375 BRAF mutant melanoma cells following nutrient stress with low glucose conditions akin to the tumor microenvironment. OCR was further increased after dabrafenib exposure. Immunoblot analysis revealed that dabrafenib treated cells at 6-hour and 12-hour time points displayed HuR translocation from nucleus to cytoplasm, as detected in cytoplasmic lysates. Transient HuR silencing blocked the adaptive OCR response to both low glucose and BRAF inhibition. This suggests that HuR is involved in the metabolic response to acute BRAF inhibition in BRAF mutant melanoma. HuR cytoplasmic translocation is associated with increased IDH1 expression 24 hours after dabrafenib exposure. However, there is no increase in IDH1 levels under nutrient or treatment stress in HuR knockdown cells, indicating that IDH1 is regulated by HuR. Transient IDH1 knockdown, as well as pharmacologic IDH1 inhibition, blocks the OCR response of melanoma cells to BRAF inhibition and low glucose. This indicates that IDH1 is important in the HuR metabolic response to targeted therapy.

Conclusion: We find that BRAF mutant melanoma cells adapt to acute dabrafenib exposure via HuR mediated expression of IDH1 to upregulate mitochondrial metabolism. This demonstrates a targeted therapy induced metabolic vulnerability that can be exploited by wtIDH1 inhibition.

#3079 AMPK-HIF-1α signaling enhances glucose-derived *de novo*serine biosynthesis to promote glioblastoma growth.

H. Yun, J.-H. Lee;
Dong-A University, Busan, Korea, Republic of

Cancer cells undergo cellular adaptation through metabolic reprogrammin to sustain survival and rapid growth under various stress conditions. However, it remains unknown how brain tumors modulate their metabolic flexibility in the naturally serine/glycine (S/G)-deficient brain microenvironment. We used a range of primary/stem-like and established glioblastoma (GBM) cell models *in vitro* and *in vivo*. To identify regulatory mechanisms of S/G deprivation induced metabolic flexibility, we employed high throughput RNA-sequencing, transcriptomic analysis, metabolic flux analysis, metabolites analysis, chromatin immunoprecipitation (ChIP), luciferase reporter, nuclear fractionation, cycloheximide-chase, and glucose consumption. The clinical significances were analyzed in the genomic database (GSE4290) and in human GBM specimens. The high throughput RNA-sequencing and transcriptomic analysis demonstrate that the *de novo* serine synthesis pathway (SSP) and glycolysis are highly activated in GBM cells under S/G deprivation conditions. Mechanistically, S/G deprivation rapidly induces reactive oxygen species (ROS)-mediated AMP-activated protein kinase (AMPK) activation and AMPK dependent hypoxia-inducible factor (HIF)-1α stabilization and transactivation. Activated HIF-1α in turn promotes expression of SSP enzymes phosphoglycerate dehydrogenase (PHGDH), phosphoserine aminotransferase 1 (PSAT1), and phosphoserine phosphatase (PSPH). In addition, HIF-1α-induced expression of glycolytic genes (*GLUT1*, *GLUT3*, *HK2*, and *PFKFB2*) promotes glucose uptake, glycolysis, and glycolytic flux to fuel SSP, leading to elevated *de novo* serine and glycine biosynthesis, NADPH/$NADP^+$ ratio, and proliferation and survival of GBM cells. Analyses of human GBM specimens reveal that levels of overexpressed PHGDH, PSAT1, and PSPH are positively correlated with levels of AMPK T172 phosphorylation and HIF-1α expression and poor prognosis of GBM patients. Our findings reveal that metabolic stress-enhanced glucose-derived *de novo* serine biosynthesis is a critical metabolic feature of GBM cells and highlight the potential to target SSP for treating human GBM.

#3080 Activation of mTORC2/Akt is amplified during glutamine starvation and is mediated by GCN2.

Tatiana Hernandez[1], Nikhil Patel*[1], Jedrick Magsino[1], Jay Kavia[1], Aparna Ragupathi[1], Alysta Paneque[1], Tracy G. Anthony[2], Guy Werlen[1], Estela Jacinto[1]

[1]Biochemistry and Molecular Biology, Rutgers Univ.-Robert Wood Johnson Medical School, Piscataway, NJ,[2]Nutritional Sciences, Rutgers, The State University of New Jersey, New Brunswick, NJ

Highly proliferative cells like cancer cells depend on glucose and glutamine to augment flux through metabolic and biosynthetic pathways. The mechanistic target of rapamycin (mTOR) integrates signals from nutrients and other growth signals to maintain metabolic homeostasis. Whereas mTOR complex 1 (mTORC1) is activated by the presence of nutrients to promote anabolic metabolism, mTORC2 is activated by nutrient fluctuations, leading to increased Akt phosphorylation at Ser473. How mTORC2 signaling can be augmented by nutrient starvation remains poorly understood. Here, we found that General Control Nonderepressible kinase 2 (GCN2), an amino acid starvation-sensing kinase, conveys glutamine depletion to mTORC2. mTORC2 enhances Akt phosphorylation and Akt feeds back to mTORC2 to augment its activity during glutamine starvation. Amino acid starvation in vivo also enhances mTORC2/Akt signaling via GCN2. Our findings reveal that manipulating the GCN2/mTORC2/Akt signaling cassette could have therapeutic benefit to more effectively starve cancer cells.

#3081 Targeting lipid kinases to enhance autophagy inhibition for the treatment of pancreatic cancer.

E. G. Schechter, J. M. DeLiberty, C. A. Stalnecker, K. L. Bryant;
University of North Carolina, Chapel Hill, NC

Pancreatic ductal adenocarcinoma (PDAC) is characterized as the most KRAS-addicted cancer type, with KRAS mutations found in >95% of cases. Mutant KRAS relies on dysregulated metabolism to support growth. One dysregulated pathway upregulated in PDAC is autophagy, a lysosome-mediated process that degrades proteins and organelles to supply macromolecules for growth. Our lab and others have shown that inhibition of KRAS or the mitogen activated protein kinase (MAPK) components, MEK or ERK, further increases PDAC dependency on autophagy as a resistance mechanism. Cotreatment with ERK MAPK inhibitors and the autophagy inhibitor chloroquine (CQ) decreased autophagic flux, inhibited proliferation, and induced apoptosis in PDAC cells. CQ is the only FDA-approved autophagy inhibitor, and it demonstrates low potency *in vivo*, motivating our studies to identify strategies to improve autophagy inhibition in PDAC. We utilized a CRISPR-Cas9 loss-of-function screen to identify sensitizers to CQ in PDAC and identified 25 autophagy-related targets.

We hypothesize that targeting the autophagy pathway at multiple nodes will increase the efficacy of CQ treatment in PDAC. To validate hits identified in the CRISPR-Cas9 screen, I designed an siRNA array that contained three distinct oligos for each target. I quantified changes in proliferation in a panel of four PDAC cell lines after siRNA-mediated suppression of the target genes following 3- or 6-day time points.

I hypothesized that targets identified to be non-essential on their own would allow for potential synthetic lethality with CQ. To test this, I performed a 3-day knockdown followed by 3-day exposure to a dose response of CQ. I found that suppression of lipid kinases *PIP4K2A*, *PIP4K2C*, or *PIK3C3* shift the dose response to CQ in a panel of PDAC lines. This indicates that loss of those targets sensitizes PDAC cells to CQ treatment. Furthermore, we found that pharmacological inhibition of VPS34, the lipid kinase encoded by *PIK3C3* by the ATP-competitive inhibitor SAR-405 synergizes with CQ.

My future studies will be focused on validating other targets identified in the loss-of-function CRISPR-Cas9 screen. I will measure changes in autophagic flux and apoptosis due to the loss of validated targets. The long-term goal of this project is to enhance the translatability of autophagy inhibition for patient care through identifying combinational approaches to improve CQ response in PDAC.

#3082 The liver microenvironment promotes glycolysis in metastatic colorectal cancer by activating her3.

M. G. Rathore, K. Curry, C. Boutros, Z. Wang, J. Winter, R. Wang;
Case Western Reserve University School of Medicine, Cleveland, OH

Background: Liver metastasis occurs in ~80% of all metastatic colorectal cancer (mCRC) and the liver has a unique endothelial cell (EC)-rich microenvironment that promotes cancer cell survival. We previously reported that liver ECs secrete soluble factors to promote CRC growth via activating CRC-associated the HER3 signaling pathway. The present study reports that ECs promote mCRC growth by shifting cancer metabolism towards glycolysis and elucidates the involved signaling pathway.

Methods: We performed mass spectrometry to profile the metabolic changes in mCRC treated with/without HER3 inhibition in a syngeneic, orthotopic mCRC model. We also performed Seahorse and lactate ELISA assays to determine the effect of liver EC-secreted factors on CRC metabolism. To further determine the role of HER3 in promoting glycolysis and CRC growth in the liver, we used siRNA silencing of HER3 and pharmacological inhibition of HER3 downstream signaling proteins to identify the key mediator(s) of HER3-induced metabolic shift in CRC.

Results: We determined that HER3 inhibition leads to increased oxidative phosphorylation metabolites (OXPHOS) and decreased glycolysis metabolites in CRC liver metastases. Conditioned medium containing EC-secreted factors decreased oxygen consumption (determined by Seahorse, a readout of OXPHOS) and increased lactate secretion (determined by ELISA, a readout of glycolysis) in CRC. As HER3 inhibition reversed the metabolic shift and increased OXPHOS as an alternative survival strategy, we found that simultaneous inhibition of HER3 and OXPHOS synergistically blocked CRC cell and tumor growth. Lastly, we found that PFK2 is activated by HER3 signaling, determined by phosphorylation, and determined that the HER3-AKT-PFK2 signaling axis is the key mediator of EC-induced metabolic shifts.

Conclusions: We identified that the liver microenvironment activates HER3 and the downstream AKT-PFK2 signaling to promote glycolysis and growth in CRC liver metastases by activating AKT-PFK2-dependent glycolysis. Our findings highlighted the potential of combining HER3 and OXPHOS inhibitions as a potential strategy for treating patients with mCRC.

#3083 Unveiling the role of chemotherapy-resistant, slow-cycling cancer cells in driving cancer cachexia.

J. Cho, H.-Y. Lee;
Seoul National University, Seoul, Korea, Republic of

Cancer cachexia, a systemic disease marked by substantial, involuntary weight loss, predominantly affecting muscle and adipose tissue, manifests in patients with advanced-stage cancer. The emergence of cancer cachexia poses significant challenges to cancer treatment, diminishing the efficacy of anticancer medications, and the resultant muscle loss adversely impacts the daily lives of patients, diminishing the overall quality of life. Notably, cancer cachexia is implicated in 30-40% of cancer-related deaths, underscoring the pivotal need to comprehend its underlying principles and propose apt interventions to enhance both survival rates and the well-being of cancer patients. Based on our previous findings, cancer cells exhibiting a slow cell cycle, resistant to widely employed clinical chemotherapy agents, exhibit the formation of proinflammatory tumor microenvironment. The escalation of systemic inflammatory cytokines has long been suggested as a potential mechanism contributing to cancer cachexia. Building upon these insights, we hypothesized that slow-cycling cancer cells (SCCs) featuring resistance to chemotherapy are pivotal contributors to cancer cachexia. We investigated the impact of drug-resistant SCCs on the loss of differentiated myotubes and lipid droplets *in vitro* and muscle and fat loss in *in vivo* conditions. Interestingly, these cells induced more severe muscle and fat losses. Upon scrutinizing this cell population, we found the overexpression of a particular membrane protein, Protein A. The increase of this Protein A enhanced the release of exosomes from the cell through a novel mechanism distinct from its classical functions, consequently amplifying the release of inflammatory substances originating from cancer cells. In summary, our study elucidates that chemotherapy-resistant cancer cells, characterized by a slow cell cycle, intensify the secretion of inflammatory substances in a manner contingent upon the overexpression of a membrane protein A, which leads to the depletion of muscle and fat located in the distal peripheral regions.

#3084 Aldob regulates fructose metabolism to confer ferroptosis and immune response in colorectal cancer harboring microsatellite instability.

Y.-C. Chang[1], **C.-L. Chen**[2];

[1]Department of Biomedical Imaging and Radiological Sciences, National Yang Ming Chiao Tung University, Taipei, Taiwan, [2]Department of Pathology, Taipei Medical University and Taipei Medical University Hospital, Taipei, Taiwan

Microsatellite instability (MSI) is a genetic alteration that occurs during cancer progression, specifically in colorectal cancer. Objective evidence demonstrates that colorectal cancer patients with MSI have better survival rates than those without MSI. Moreover, patients with both dMMR and MSI respond equally well to immunotherapy. We evaluated the MSI status of colorectal cancer specimens and identified an activation of aldolase B (ALDOB), the primary regulator of fructose metabolism, in the MSI group. Our analysis of the cancer cell panel revealed that the expression level of ALDOB in MSI+ cells (HCT116 and LoVo) was significantly higher than that in the microsatellite stable (MSS) group (SW480 and HT29). We also discovered a significant negative correlation between ALDOB and numerous dMMR-related genes, such as *MLH1* and *MSH2*. We investigated how fructose concentration and pathway activation affected MSI occurrence. Our results demonstrated that abnormal fructose metabolism leaded to SLC7A11-mediated ferroptosis. SLC7A11 functioned as the active subunit and generated glutathione, GPX4, and lipid epoxides in response to transported cystine. This may explain the better clinical outcomes observed in colorectal patients with MSI. On the other hand, we also observed that ALDOB could increase certain immune ratios, such as $CD4^+$ T cells and B cells. This aligns with the implementation of immunotherapy in the MSI community, which has been proven to yield positive effects. Consistent results were still being shown. Our study revealed significant increases in various chemokines and cytokines in media conditioned with fructose. It was interesting to note that fructose resulted in more significant changes than glucose. Based on the gathered evidence, it could be posited that ALDOB plays a crucial role as a promoter of fructose metabolism, leading to the induction of ferroptosis and immune responses in MSI colorectal cancer. The findings shed new light on known consequences and provide new avenues of information.

#3085 Cholesterol sulfotransferase SULT2B1b suppresses prostate tumor growth and regulates cholesterol metabolism in prostate cancer cells.

J. Yang, D. Wusiman, T. L. Ratliff;
Purdue University, West Lafayette, IN

Prostate cancer (PrCa) ranks as the second leading cause of cancer death in males in the United States. The 5-year survival rate drops drastically from 100% in patients with early-stage confined PrCa to 30% in those with advanced metastatic PrCa. Patients with advanced PrCa face limited long-term treatment options, often developing resistance to androgen-deprivation therapy and chemotherapy. Identifying and targeting pivotal molecules or pathways in advanced PrCa can substantially enhance patient survival. Our previous findings unveiled an inverse relationship between cholesterol sulfotransferase SULT2B1b and the severity of human PrCa. The highest levels of SULT2B1b were observed in the epithelium of normal prostates, with a progressive decrease as cancer advanced. The lowest levels were found in the most advanced metastatic samples. This study aims to determine whether SULT2B1b performs any active and critical functions in PrCa progression and assess whether it regulates cholesterol metabolism in PrCa cells. We generated SULT2B1b knockout (KO) clones from mouse PrCa cell line MyC-CaP and established inducible SULT2B1b overexpression lines from androgen receptor (AR)+ LNCaP and AR- PC3 human PrCa cells. These modified mouse and human cells were implanted into syngeneic FVB mice and immunodeficient NRG mice, respectively. MyC-CaP KO cells formed significantly larger tumors compared to parental cells, accompanied by reduced survival rates. In contrast, both LNCaP and PC3 tumors with induced SULT2B1b exhibited smaller sizes compared to control tumors, leading to improved survival rates. To investigate the impact of SULT2B1b on cholesterol metabolism and the underlying mechanisms behind SULT2B1b-regulated tumor growth, we examined genes related to lipoprotein signaling and cholesterol metabolism in MyC-CaP SULT2B1b KO cells using PCR arrays and qRT-PCR. Genes responsible for cholesterol uptake and synthesis (e.g. *Ldlr*, *Cyp51*, *Sorl1, Pcsk9* and *Insig1*) were among the top upregulated genes, while genes controlling cholesterol efflux (e.g. *Abca1*) and esterification (e.g. *Soat1* and *Soat2*) were downregulated in KO cells. Consistent with these gene expression patterns, intracellular cholesterol levels significantly increased in KO cells. Interestingly, although SULT2B1b did not affect cell proliferation under normal conditions, KO cells exhibited faster growth than parental cells when cultured in lipid-depleted or charcoal-stripped media, possibly due to altered intracellular cholesterol levels. In summary, these findings align with the expression pattern of SULT2B1b in human PrCa, demonstrating that SULT2B1b inhibits tumor growth, whereas its removal promotes tumor growth. This suggests SULT2B1b may serve as a critical tumor suppressor in PrCa. Its modulation of tumor growth may occur through the regulation of cholesterol metabolism.

#3086 *NAPRT* silencing in oncometabolite-producing cancers confers therapeutic vulnerabilities to NAD$^+$ depletion.

K. J. Noronha[1], K. N. Lucas[1], **S. J. Zhao**[1], J. Edmonds[1], S. Friedman[1], M. A. Murray[1], S. Liu[1], J. Liang[2], S. Paradkar[1], H. Zeng[2], R. K. Sundaram[1], J. Spurrier[3], M. Raponi[3], D. Sajed[4], B. M. Shuch[5], J. C. Vasquez[1], R. S. Bindra[1];

[1]Yale University, New Haven, CT, [2]Sichuan University, Chengdu, China, [3]Alphina Therapeutics Inc., New Haven, CT, [4]Ronald Reagan UCLA Medical Center, Los Angeles, CA, [5]UCLA, Los Angeles, CA

Cancer associated mutations in citric acid cycle enzymes cause overproduction of 2-hydroxyglutarate (2HG), fumarate, or succinate, commonly referred to as oncometabolites. These oncometabolite-producing mutations are prevalent in 70% of gliomas, >76% of hereditary leiomyomatosis and renal cell carcinoma, and >25% of paraganglioma and pheochromocytomas, respectively and contribute to their progression. These oncometabolite-producing cancers harbor vulnerabilities in multiple cellular pathways because of their competitive inhibition of alpha ketoglutarate dependent dioxygenases, which includes the ten eleven translocation (TET) enzymes. As a result, a DNA hypermethylation phenotype is observed in oncometabolite producing cancers. Our group has found that DNA hypermethylation results in silencing of nicotinate phosphoribosyl transferase (NAPRT). NAPRT is a rate-limiting enzyme in the Preiss-Handler pathway, which is vital for NAD+ biosynthesis. We have shown that the NAPRT gene is hypermethylated in regions surrounding and within a CpG island in the promoter. Hypermethylation of the NAPRT gene also occurs in patient tumor samples. Methylation of the promoter appears to control expression of mRNA and protein. We now show that silencing of NAPRT expression occurs in patient samples of oncometabolite-producing tumors. Furthermore, oncometabolite-producing cancer models that silence NAPRT are extremely sensitive to nicotinamide phosphoribosyl transferase (NAMPT) inhibitors, which further prevents NAD+ biosynthesis via inhibition of the NAM Salvage Pathway. Furthermore, NAD+ is used to synthesize poly-ADP-ribose (PAR) chains by Poly (ADP-ribose) Polymerases (PARPs) to recruit other DNA damage response proteins, suggesting that NAMPTis and PARPis may synergize in oncometabolite-producing cancers. Ongoing studies are investigating the role of histone and DNA demethylating enzymes in NAPRT silencing and the efficacy of NAMPTis in NAPRT silenced models *in vivo*. Overall, our findings indicate that NAPRT-silencing can be therapeutically targeted in oncometabolite-producing cancers and elucidates how oncometabolite induced hypermethylation can impact diverse cellular processes from metabolism to DNA repair.

#3087 The m^{6}A methyltransferase RBM15 drives the growth of triple-negative breast cancer cells through the stimulation of serine and glycine metabolism.

S. Park[1], Y.-Y. Park[2], J.-H. Lee[1];
[1]Dong-A University, Busan, Korea, Republic of, [2]Chung-Ang University, Seoul, Korea, Republic of

N^6-adenosine methylation (m^{6}A) is critical for controlling cancer cell growth and tumorigenesis. However, the function and detailed mechanism of how m^{6}A methyltransferases modulate m^{6}A levels on specific targets remains unknown. In the current study, we identified significantly elevated levels of RBM15, an m^{6}A writer, in basal-like breast cancer (BC) patients compared to non-basal like BC and linked it to worse clinical outcome. Gene expression profiling uncovered correlations between RBM15 and serine and glycine metabolism genes including PHGDH, PSAT1, PSPH, and SHMT2. RBM15 influences overall m^{6}A levels and, specifically, m^{6}A of serine and glycine metabolism genes via direct binding to target RNA. Further RBM15 effects on cell growth were largely dependent on serine and glycine metabolism. Thus, RBM15 coordinates cancer cell growth through altered serine and glycine metabolism suggesting RBM15 as a new therapeutic target in BC.

CHEMISTRY: High-Throughput Screening and New Assay Technology
Poster Session

#3090 Development and performance of the National Cancer Institute's HTS384 NCI60 screen: A modernized platform to support drug discovery and development by the worldwide cancer research community.

N. P. Coussens[1], T. S. Dexheimer[1], E. M. Jones[1], T. Silvers[1], J. R. Britt[1], R. C. Taylor[2], M. W. Kunkel[2], J. H. Doroshow[2], B. A. Teicher[2];
[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]National Cancer Institute, Bethesda, MD

The NCI60 screen was established in the 1980s and introduced in the 1990s as a screening service for the worldwide cancer research community. The screen features 60 human tumor cell lines that represent 9 cancer types including non-small cell lung, colon, central nervous system, ovarian, renal, prostate and breast, as well as leukemia and melanoma. On a weekly basis, synthetic molecules, natural products, and biologics are screened against the 60-cell line panel to evaluate their anticancer potential. On average, more than 13,000 compounds are screened annually for investigators throughout the world. Cell growth and cytotoxicity were assessed by the sulforhodamine B (SRB) assay, performed in a 96-well format, that measures cellular protein content with an absorbance readout and enabled unprecedented throughput in the 1980s. Although the SRB assay supported a robust screening platform for three decades, its sensitivity and throughput are limited. Recently the NCI's DCTD introduced the HTS384 NCI60 as a modernized screening platform. While the same 60 cell lines are evaluated, the HTS384 NCI60 is fully automated and performed in a 384-well format to enable a higher throughput. Additionally, the 48-h test agent exposure period of the SRB assay was increased to 72 h, which may result in lower 50% growth inhibition values (GI_{50}) for some agents. A highly sensitive CellTiter-Glo luminescence readout for cell viability, based on cellular ATP content, was selected to enable comparisons of the NCI60 monolayer data to 3D cell culture models where the same assay chemistry can be applied. The HTS384 NCI60 was evaluated by screening a library of 1,003 U.S. Food and Drug Administration-approved and investigational oncology agents at five concentrations. Assay performance of the 60 cell lines was assessed from the controls of 30 - 60 microplates per cell line. The average doubling time of the 60 cell lines during the 72-h exposure period ranged between 19 h for NCI-H460 (17 - 23 h, *n* = 57) to 117 h for MDA-MB-468 (43 - 272 h, *n* = 60). The average signal-to-background ratio of all 60 cell lines was 89 (3,413 microplates) and ranged from 6 for OVCAR-5 (3 - 13, *n* = 54) to 229 for SF-539 (141 - 566, *n* = 60). The average coefficient of variation for microplate vehicle controls (*n* = 14) of all 60 cell lines (*n* = 3,413) was 5.2% and ranged from 3.2% for SK-MEL-28 (1.4 - 7.7%, *n* = 60) to 11.1% for HL-60(TB) (5.2 - 20.2%, *n* = 59). The average Z'-factor value of all 60 cell lines (*n* = 3,413) was 0.82 and ranged between 0.66 for HL-60(TB) (0.39 - 0.84, *n* = 59) to 0.89 for MALME-3M (0.79 - 0.95, *n* = 59), SF-295 (0.49 - 0.97, *n* = 59), SK-MEL-28 (0.74 - 0.95, *n* = 60), and UO-31 (0.8 - 0.94, *n* = 54). The development and performance of the HTS384 NCI60 screen will be described. This project was funded in part with federal funds from the NCI, NIH, under contract no. HHSN261201500003I.

#3091 Discovery of highly selective ligands with unique binding modes for challenging oncology targets using DNA-encoded chemical libraries.

Y. Zhang, A. Keefe, M. A. Clark;
X-Chem, Inc., Waltham, MA

DNA-encoded chemical library (DEL) technology enables the efficient screening of large collections of encoded compounds and has emerged as a powerful tool for hit identification in recent years. The technology allows for the multiplexed interrogation of target-ligand binding interactions and results in DEL hits with unusual binding modes and desirable selectivity. This screening methodology is particularly effective for oncology targets. Examples of discovery of highly selective ligands for challenging oncology targets, including kinases, protein-protein interactions, and receptors, will be presented. We will illustrate how DEL campaign strategies directly aim at novel binding modes, and provide molecular details around the uniqueness of these interactions. Furthermore, we will show how these novel binding modes lead to unique pharmacology with direct benefit to patients. Lastly, we will demonstrate how X-Chem's high-quality encoded libraries enhance the tractability and novelty of chemical equity discovered with the platform.

#3092 MICRO-TAG: A novel fluorescence-based real-time cellular target engagement platform for drug discovery.

I. Babic[1], N. Bryan[1], C. Cunningham[2], A. Sampson[2], D. Starczynowski[2], **E. Nurmemmedov[1];**
[1]Nerd Bio, San Diego, CA, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Success of drug discovery programs can be amplified by adopting emerging technologies that can interrogate drug targets within their physiological context. Cell target engagement (CTE) presents a combined biological & biophysical method, which provides quantitative evaluation of target-drug interaction within the native environment of the cell. The currently available luminescence-based CTE methods are limited to measurement of end-point signal and poor resolution, thereby limiting their mechanistic and stoichiometric insight. We have developed MICRO-TAG, a novel fluorescence-based CTE platform, which relies on complementation of split-RNAse A. It enables interrogation of target engagement without interfering with folding, localization and function of target proteins - all within the physiological milieu of the cell. Uniquely, this new platform allows for quantitation and monitoring of CTE in real- time in the cell. It enables extraction of important parameters from target-drug interaction: target thermal profile and temperature of aggregation (T_{agg}), time required to reach equilibrium (t_{eq}), apparent association rate (K_{on}) and physiologically relevant drug:target binding affinity (K_D). We provide data demonstrating potential and utility of MICRO-TAG platform on drug targets, such as KRAS, MTH1, EGFR, and UBE2N. The platform demonstrates relevance for discovery of novel drug candidates targeting challenging drug targets such as transcription factors. This highly scalable and quantitative novel method for assessing drug-target interaction within cells can enhance drug discovery programs, and offers potential to rapidly identify clinically relevant hit compounds for challenging drug targets.

#3093 Combining lab automation with data analysis automation to enable high-throughput screening of patient-derived organoids.

A. Lin[1], M. Le Compte[1], T. Gilcrest[2], E. Cardenas De La Hoz[1], G. Roeyen[3], J. Hendriks[4], F. Lardon[1], C. Deben[1];
[1]University of Antwerp, Antwerp, Belgium, [2]Orbits Oncology, San Francisco, CA, [3]University Hospital of Antwerp, Edegem, Belgium, [4]University Hospital Antwerp, Edegem, Belgium

Although patient-derived tumor organoids (PDOs) better-represent patient tumors compared to traditional in vitro cell cultures, limitations of PDO analysis remain a major hurdle for high-throughput screening (HTS) applications. In particular, current PDO analysis fall short in at least 1 of 2 major criteria: 1) accurate recapitulation of patient tumor or 2) scalability. To address this, we have developed an automation-compatible protocol to satisfy these 2 major criteria to facilitate the adoption of PDOs for HTS applications[1]. Our novel protocol leverages live-cell imaging techniques to capture the dynamic interactions and intricate complexities of PDOs, which allowed for more precise and comprehensive analysis. To further enhance the accuracy and efficiency of our approach, we developed a fully automated image and data analysis pipeline (Orbits). Using label-free detection of organoids from brightfield images, Orbits integrates growth-rate-based drug response metrics with drug synergy metrics to significantly improve the identification of synergistic drug interactions. Here, present the results of our HTS protocol on 10 distinct drug combination strategies, specifically focusing on the repurposed drug candidate Auranofin, a Thioredoxin reductase inhibitor. We screened on 10 PDOs sourced from healthy lung, non-small cell lung cancer, and pancreatic ductal adenocarcinoma. Not only were we able to distinguishing cytostatic from cytotoxic drug responses at a single-organoid level, we identified drug candidates that can synergistically enhanced the efficacy of Auranofin in a tumor selective manner. Our study presents a major step forward in the field of PDO-based drug discovery, offering a robust protocol for HTS and automated data analysis. The implementation of our method will accelerate the discovery of effective therapeutic strategies, ultimately translating to improved patient outcomes. [1] Le Compte, M., et al *JoVE* 190 (2022)

#3094 Biophysics in kinase drug discovery programs: Spectral shift technology from fragment screening to mechanism of action.

C. Legros[1], V. Porkolab[2], M. Sigoillot[2], O. Mirguet[1];
[1]Eurofins Discovery, Celle Levescault, France, [2]Eurofins Cerep, Celle Levescault, France

Using Eurofins Discovery's state-of-the art Hit-Finding platform, our experts designed an optimized screening cascade combining cutting-edge High-throughput Screening (HTS) technologies with the latest Biophysics techniques. With advanced technologies, such as the Echo® MS and RapidFire MS for HTS, and SPR, MST, TSA, nanoDSF and ITC for Biophysics, the cascade is effective for primary screening, orthogonal assays and evaluating Mechanism of Action (MoA). There are many biophysical approaches which bring value to drug discovery programs, and it is the target properties which drive the selection of the most suitable technology. In this presentation, we will highlight the novel Spectral Shift technology, one of the techniques employed by the Dianthus (well-known for the MST-TRIC). The goal was to rapidly implement an assay that monitors the ability of PIM3 to bind to ATP, as well as to compounds and fragments in solution. Using the Echo MS' acoustic-droplet ejection, nanoliter dispensing in 394-well plates, robust data by Spectral Shift were quickly generated for the fragment-based screening campaign. Hits were confirmed in Dose-response with µM-range affinity values (K_D), and TSA was used as an orthogonal assay for the identification of stabilizers among the selected PIM3 binders. For a defined set of 826 proprietary fragments, a single dose screening at 600µM using Spectral Shift was run, leading to the identification of 11% of potential binders. The 100 fragments were then confirmed in dose-response titration and 80 binders were confirmed. The top 30 binders were selected for orthogonal characterization using TSA. This led to the selection of the top 6 confirmed fragments, on which a MoA study in MST-TRIC was performed. Following this evaluation, 3 allosteric binders were identified, with K_D from 355 to 550µM (affinity of orthosteric binders from 55 to 333µM). Biophysics plays an important role in drug discovery by qualifying valuable assets and increasing the success rates of future Hit-finding programs. The fragment hits selected in this PIM3 Kinase project, which show ADP-Glo™ activities, are now ready for crystallography studies (NMR & X-ray co-crystallization).

#3095 A high-throughput phenotypic screen to identify small molecule inhibitors of Werner helicase.

C. A. Moomau, Y. Lu, X. Zhang, X. Zhai, L. Gu, Q. Sheng, F. Li, Y. Chen;
Allorion Therapeutics, Natick, MA

Werner helicase (WRN) is a RecQ DNA helicase involved in genome maintenance and DNA damage repair. It has recently been shown to be essential to cancer cells with high microsatellite instability (MSI-H). In MSI-H cancer cells, WRN depletion was shown to induce DNA damage and disrupt mitoses, resulting in a distinct phenotype of enlarged and fragmented nuclei. Here, we present a high-throughput phenotypic screen to identify compounds that selectively induce enlarged nuclei in MSI-H cancer cells. In HCT116, an MSI-H colorectal cancer cell line, approximately 40% of cells exhibited enlarged nuclei when WRN was depleted using siRNA. In contrast, fewer than 10% of control cells displayed this phenotype. In HT29, a microsatellite stable (MSS) cancer cell line, no such difference in nuclear morphology was observed, suggesting that the phenotype is specific to MSI-H cells. We used high content imaging to screen our in-house diversity library of approximately 175,000 compounds in 384-well format. 4,260 compounds induced enlarged nuclei in HCT116 cells, a 2.4% hit rate. After re-screening hits in HCT116 along with two additional MSI-H cancer cell lines, SW48 and SNU-407, and counter-screening in HT29 cells, 144 hits were confirmed to specifically enlarge nuclei in MSI-H but not MSS cells. Using the ADP-Glo Kinase Assay, two of these compounds were confirmed to inhibit WRN ATPase activity, suggesting WRN inhibition as a potential mechanism for their specific effects in MSI-H cells. This screen will also identify compounds which selectively kill MSI-H cells through mechanisms beyond direct inhibition of WRN, including interaction with WRN complex members or other members of DNA damage repair pathways. Validation studies including the assessment of cell viability and DNA damage in a panel of MSI-H and MSS cell lines will be performed. Our study proposes a phenotypic screening strategy for identifying small molecules with the potential to target WRN and uncover additional novel mechanisms for treating MSI-H cancers.

#3096 CETSA Navigate HT: A new paradigm for high-throughput screening.

H. Almqvist, **V. Brehmer**, L. Arnold, T. Friman, S. Lundgren, D. Martinez Molina;
Pelago Bioscience, Stockholm, Sweden

The CEllular Thermal Shift Assay (CETSA) technology is a powerful way to assess target engagement across various matrixes. By the introduction of the high-throughput format (CETSA Navigate HT), this technology offers a reliable high-throughput screening method in natural cellular environments that can successfully be applied in compound screening for hit identification and confirmation already during lead generation. Due to its broad applicability to native, full length protein targets in the live cellular environment, without the need for expensive and time-consuming protein and/or compound labelling efforts, CETSA Navigate HT may be regarded as a new paradigm for high-throughput screening and actives generation. As a case study to demonstrate the applicability of CETSA Navigate HT in hit identification, we have applied the technology for primary screening of a 12000 compound library for CDK4, a protein targeted in several cancers. Hits identified from this screen are privileged from the onset by binding to the target in a physiologically relevant cellular matrix and in a binding-mode agnostic way. This is in contrast to traditional screening methods targeting activity or in vitro interactions where cellular activity is addressed in later stages. Data from follow up studies using functional assays will be presented as well as mass spectrometry based CETSA selectivity profiling and comparison to commercially available de novo CDK4/6 inhibitors.

#3097 CETSA HT: Employing rapid high-throughput target engagement technology in primary screening of P53.

M. Kacal, **T. Friman**, L. Arnold, V. Brehmer, D. Martinez Molina, S. Lundgren;
Pelago Bioscience AB, Solna, Sweden

The confirmation of target engagement for candidate drugs is a fundamental requisite in drug discovery. A significant portion of projects fail to reach the clinic due to lack of efficacy or failure to show lead candidates interacting with the intended target in a more complex environment. The utility of using the CETSA® (CEllular Thermal Shift Assay) technology to measure target engagement in intact cells is increasingly exploited in high throughput screening, where examples demonstrate low false positive rates in screens of up to 500K compounds. The p53 tumor suppressor protein, a crucial guardian against cancer, functions as a transcription factor that mediates cancer suppression by regulating genes involved in a wide range of cellular processes such as DNA repair, cell cycle and apoptosis. Unfortunately, frequent mutations in the TP53 gene hinder p53's tumor suppressor role in human cancers, thus designating it as a promising target for anticancer therapy. However, attempts to restore p53 function for therapeutic purposes have not yet advanced to clinical approval, highlighting the complexities in leveraging p53 for cancer treatment. Its undruggable nature, attributed to the absence of accessible deep pockets, lack of enzymatic activity, and its intracellular location, further complicates targeted interventions with both low and high molecular weight drugs. Here, we demonstrate the analysis of a high-throughput plate based CETSA® HT screen on the challenging target p53, performed using AlphaLISA® SureFire® Ultra™ technology and our newly developed high-throughput screening platform. Hits identified from this screen are privileged from the onset by binding to the target in a physiologically relevant cellular matrix and in a binding-mode agnostic way. This is in contrast to traditional screening methods targeting activity or in vitro interaction where cellular activity is addressed in later stages. This assay cascade highlights a rapid target-to-hit lead generation strategy placing the emphasis on finding chemical matter that interacts with endogenous target in living cells first, followed by analysis of hit material activity. The ‘shortcut’ to chemical matter active in living cells represents significant potential cost savings in comparison to assay development time on recombinantly produced proteins and/or modified cell lines for traditional HTS screening approaches that still rely on target engagement assessment downstream.

#3098 CETSA for navigating your chemistry and exploring the biology of protein degraders .

V. Brehmer, S. Lundgren, T. Friman, D. Amadio, A. Chernobrovkin, D. Martinez Molina;
Pelago Bioscience, Stockholm, Sweden

Protein degradation is a non-classical modality with the potential to tackle therapeutically interesting proteins, previously deemed undruggable. In this area, CETSA is a powerful technology for identifying new binders, assessing target engagement, and investigating the mechanism of action of the degraders in the intact cell environment - without the need to modify your compound, the proteins or the cellular environment. CETSA can provide insights into the binding of the degrader to both the E3 ligase and the protein of interest (POI), as well as follow the downstream cellular and molecular effects. Here we will exemplify how CETSA can be applied in various stages of drug discovery to provide biologically relevant data to guide the design and optimization of new degraders. For example, CETSA can provide valuable information of the cell permeability and the in-cell performance of the degrader, which is important for understanding how the degrader enters cells and reaches its target proteins. By combining data from CETSA with data from degradation readout, in our case quantitative proteomics, it is possible to correlate cellular target engagement potencies with degradation efficiency and importantly, also identify any drug:protein binding that does not result in degradation By using the proteome-wide CETSA Explore format, the selectivity of the degrader and the downstream protein consequences of the elimination of the target protein could be studied.

#3099 A new HTS ELISA for monitoring NRAS activity to expedite drug discovery.

H. Park, J. Weber, M. Carlson, M. Jelinek;
Active Motif, Carlsbad, CA

Oncogenic mutations in the KRAS, HRAS, and NRAS isoforms of the RAS gene family alter GTP binding and hydrolysis leading to errant over activation of the MAPK/ERK pathway. While the total of all such RAS mutations drives some 20-25% of all human cancers, each isoform tends to favor particular mutations that are cancer specific. Many evolving treatment strategies for these cancers target these mutant isoforms to minimize off target effects. NRAS mutations are seen in about one-fifth of cutaneous melanomas and patients with NRAS mutation melanomas have a poorer prognosis due to the high aggressiveness of RAS mutant tumors, a lack of efficient targeted therapies, or rapidly emerging resistance to existing treatments. Furthermore, there is no currently authorized targeted treatment for NRAS-mutated melanoma. As a result, there is a growing need for assays which can quantify activated NRAS. Here we describe the development of a highly specific and sensitive ELISA for determining the active NRAS protein in high throughput compatible (HTS) format.

A NRAS specific recombinant antibody was developed via cloning of immunoglobulin variable regions from antigen positive B cells isolated by FACS from rabbits immunized with a NRAS peptide corresponding to a region of low homology between the RAS isoforms. Immunoblotting and a bead-based multiplex ELISA with all three RAS isoforms were used to confirm antibody specificity with recombinant HRAS, KRAS, and NRAS proteins over a wide concentration range.

The new immunoassay enables in-well lysis of cells cultivated in 96-well plate. Activated NRAS in the lysate is collected on the test plate and detected using the NRAS specific antibody via chemiluminescence. We anticipate that this assay will further the discovery of novel NRAS specific therapeutics. EGF treatment of MCF7 cells demonstrated activation in cells expressing wildtype NRAS in preliminary assay validation. Evaluation of assay performance in mutant NRAS melanoma cell lines will be presented.

#3100 Interactive analysis of drug testing data for functional precision oncology with Breeze 2.0.

Swapnil Potdar[1], Filipp Ianevski[1], Aleksandr Ianevski[1], Ziaurrehman Tanoli[1], Krister Wennerberg[2], Brinton Seashore-Ludlow[3], Olli Kallioniemi[4], Paivi Ostling[4], Tero Aittokallio[1], Jani Saarela[1]

[1]Institute for Molecular Medicine Finland (FIMM), HiLIFE, University of Helsinki, Helsinki, Finland,[2]Biotech Research & Innovation Centre (BRIC), University of Copenhagen, Copanhagen, Denmark,[3]Department of Medical Biochemistry and Biophysics, Chemical Biology Consortium Sweden (CBCS), Science for Life Laboratory, Karolinska Institutet, Stockholm, Sweden,[4]Department of Oncology-Pathology, Science for Life Laboratory, Karolinska Institutet, Stockholm, Sweden

High throughput screening (HTS) is used to screen large numbers of small molecules in cell-based assays to predicting their potential therapeutic response and when applying approved drug libraries using HTS it becomes drug repurposing. The Drug Sensitivity and Resistance Testing (DSRT) platform established at FIMM has been extensively used in testing panels of approved and investigational drugs on cells, both conventional cell lines and primary cell models derived from cancer patient samples. The results help in deepen our understanding of drug efficacy in individual patients and across specific disease to guide future patient stratification.

Breeze 2.0 is an open access, web-based platform for interactive analysis of drug screening data in real time. Breeze accepts raw data in a simple tabular format and generates detailed quality control metrics, plots, dose-response curve fits, drug response quantification in form of IC50/EC50/AUC and Drug Sensitivity Scores (DSS). Besides tabular results, Breeze generates interactive, informative, and intuitive visualizations, such as plate heatmaps, scatterplots, barplots, clustered heatmaps, circular plots, for further analysis. Based on manually-curated published datasets available through Breeze 2.0, users can instantly compare their drug response patterns with the existing DSRT profiles from patient samples, as well as cell lines. Importantly, Breeze 2.0 has integrated curated reference DSRT data tested on bone marrow samples from healthy control individuals, which plays a crucial role in understanding cancer-selective drug response by de-prioritizing generally toxic compounds. The end-users can select multiple healthy controls or relevant patient/cell line samples and choose the drugs of interest to visualize the overlaid dose responses, as well as response quantification metrics. Breeze 2.0 is built in R, PHP, MySQL and is freely accessible at https://breeze.fimm.fi/v2

#3101 Developing a drug repurposing screen for head and neck squamous cell carcinoma using a novel c-Rel bioassay.

K. A. Altwegg[1], K. E. King[2], D. Blivis[1], T. C. Voss[1], N. J. Martinez[1], W. C. Weinberg[2], M. J. Henderson[1];
[1]NIH-NCATS (National Center for Advancing Translational Sciences), Rockville, MD, [2]US Food and Drug Administration, Silver Spring, MD

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide. Approximately 890,000 new cases are diagnosed each year, while incidence continues to rise and is anticipated to increase by 30% by 2030. HNSCC occurs most often in men in their 50-60s, although the incidence among younger individuals is increasing. Current standard of care practices include surgical resection, followed by adjuvant radiation or chemoradiation. HNSCC tumors exhibit frequent mutation of CDKN2A (22% of tumors) and TP53 (72% of tumors). Additionally, two members of the TP53 gene family, TP63 and TP73, are frequently altered in HNSCC. TP63 encodes two major isoforms, ΔNp63 which lacks the main transcription activation domain and acts as a dominant-negative inhibitor of transactivation (TA), and TAp63 (contains a p53-like TA domain). ΔNp63 is overexpressed in a majority of HNSCC tumors. Our lab has reported ΔNp63α interacts with activated c-Rel (a nuclear factor-KB family member) in HNSCC, thereby promoting uncontrolled proliferation, a key alteration in the pathogenesis of cancers. Consistent with a role in growth regulation, ΔNp63α:c-Rel complexes bind a promoter motif and repress the cyclin-dependent kinase inhibitor p21WAF1 in both human HNSCCs and normal keratinocytes overexpressing ΔNp63α. The direct relationship between ΔNp63α and activated c-Rel is observed by strong nuclear co-localization in the proliferating compartment of primary head and neck SCC. Stimulation of HNSCC cells with TNFα results in the induction of the c-Rel oncoprotein that binds to ΔNp63, displacing and inactivating the tumor suppressor TAp73 from ΔNp63-TAp73 complexes. Using western blot analysis in human HNSCC cell lines, we confirmed that stimulation with TNFα enhances nuclear c-Rel localization. We then set out to design a high throughput screening bioassay for the purpose of evaluating compounds that can inhibit c-Rel accumulation in the nucleus under TNFα stimulation. By preventing activated c-Rel from interacting with ΔNp63α in the nucleus we aim to decrease uncontrolled proliferation and restore the tumor-suppressive functionality of the ΔNp63-TAp73 complex. A 384-well immunocytochemistry assay was developed using a confocal microscopy readout and an automated image analysis algorithm to quantify nuclear translocation. The optimized assay will be used to screen the NCATS collection of approved drugs and investigational oncology agents. Top candidates will undergo further investigation in vitro, ex vivo, and in vivo to explore the possibility of repurposing the small molecules for HNSCC therapeutics.

#3102 A high-throughput screening method for discovering potent P-glycoprotein modulators from the chemical library in Tohoku University.

Norihiko Sugisawa[1], Shinobu Ohnuma[1], Takayuki Doi[2], Michiaki Unno[1]

[1]Tohoku University Graduate School of Medicine, Sendai, Japan,[2]Tohoku University Graduate School of Pharmaceutical Science, Sendai, Japan

Background: Drug development is important for cancer therapy to improve patient outcomes. In most cases, drug development starts in discovering candidate compounds from a chemical library in high-throughput screening (HTS). Tohoku University Graduate School of Pharmaceutical Science owns the original chemical library consisting of thousands of original chemical compounds. P-glycoprotein (P-gp), a major drug efflux transporter mediates multi-drug resistance (MDR) in cancer cells. Therefore, P-gp modulators could revere MDR and increase chemosensitivity. The aim of this study is to reveal an adequate method of HTS for discovering potent P-gp modulators from the chemical library in Tohoku University.
Methods: The chemical library in Tohoku University had 5861 compounds in the present study, and the collection contains over 7 thousand compounds in 2023. P-gp overexpressing KB-V1, human epidermal carcinoma cell lines were obtained, and calcein AM, P-gp substrate was employed for fluorescent substrate efflux assays. A plate reader-based calcein AM efflux assay for HTS was established to select candidate compounds as P-gp modulators. After the primary HTS, structures of the candidate compounds were analyzed, then several analogous compounds were extracted from the chemical library. For the validation of the hit compounds in HTS and the analogs, a flow cytometry-based calcein AM efflux assay was conducted. In addition, reversal effects of P-gp modulators on the cytotoxicity of paclitaxel were measured in a cell proliferation assay.
Results: Of 5861 compounds in the chemical library, 53 compounds showed 2-fold or higher fluorescence intensity, and then 13 compounds showed 3-fold or higher fluorescence intensity in a plate reader-based assay for the HTS. Especially 2 candidate compounds showed over 5-fold fluorescence intensity. In the analysis for structures of the candidate compounds, 20 analogous compounds were extracted from the chemical library. To verify the result of the plate reader-based assay, a flow cytometry-based assay was conducted for 53 hits and 20 analogs. As a result, the 2 candidate compounds that selected in the plate reader-based assay showed 60-fold, the highest fluorescence intensity in a flow cytometry-based assay. The other compounds showed less fluorescence intensity than these 2 candidates. In addition, both candidates enhanced the paclitaxel-induced cytotoxicity in a cell proliferation assay.
Conclusions: A plate reader-based calcein AM efflux assay in HTS was an adequate method for discovering potent P-gp modulators from the chemical library in Tohoku University.

#3103 Alternative cell counting and viability detection using NexGreen/PI fluorescent stain on multiple low- and high-throughput image cytometry platforms.

J. Mukherjee, C. F. Nitta, M. Pierce, S. Hem, D. Browe, D. Kuksin, L. L. Chan;
Revvity Health Sciences, Inc., Lawrence, MA

In the past decade, the increase in cell and gene therapy products such as biologics, antibodies, and CAR-T has significantly increased the need for precise, robust, and consistent cell counting and viability measurements. Simplified and automated workflows benefit from assays that measure sample characteristics independent of their buffer, media, or storage conditions. Reliable and robust results are thus required to maintain quality control of downstream processes. In this work, we demonstrate a novel fluorescence-based dye, NexGreen/PI, capable of live and dead cell detection comparable to AO/PI in multiple cell buffer/media conditions. Jurkat cells of different viabilities (low, intermediate, and high) were stained in parallel with either NexGreen/PI or AO/PI for 1-2 minutes and measured on multiple image cytometer platforms including low-throughput (Cellometer K2, Auto2000, and Spectrum) and high-throughput (Cellaca MX, Cellaca PLX, and Celigo) instruments. Both NexGreen/PI and AO/PI dyes are used as equal volumes added to cell samples (ex: 20 uL cells + 20 uL dye). Additionally, we tested if difficult to analyze cells in “spent” media (typically with a lower pH) or in PBS can be stained using NexGreen/PI compared to AO/PI. Results on the high-throughput platforms show that NexGreen/PI staining can discriminate between live and dead Jurkats, analogous to AO/PI in samples of low (10-25%), intermediate (40-60%), and high (80-95%) viabilities. Measured viability of all samples using NexGreen/PI was within 5% of the paired AO/PI-stained samples. Cell concentration results with either NexGreen/PI or AO/PI also show counts with less than 6% difference. Low-throughput instrument results are similar and show that viabilities of Jurkat cells match within 5% of each other independent of sample (low, intermediate, or high viability), while cell concentrations differ up to 6% when comparing NexGreen/PI and AO/PI. Cells in “spent” media or washed and resuspended in PBS can exhibit low AO signal intensity that can be difficult to detect in a robust fashion. NexGreen/PI-stained cells, however, showed an unaltered fluorescence signal in these “tricky” cell samples. In this work, we demonstrated the capability of NexGreen/PI to measure cell counts and viability using low- and high-throughput instruments, which enables fit-for-purpose for a wide range of samples. Thus, our experiments demonstrate that NexGreen/PI is scalable and can be of significant value for use in automation and high-throughput systems where multiple samples in different mediums can be precisely measured.

#3104 A NanoBRET target engagement assay for querying domain selectivity at full-length polymerase theta in live cells.

S. Edenson[1], M. Slater[2], C. Corona[2], M. Beck[3], J. Vasta[3], K. Teske[3], A. Michaud[3], M. Robers[3];
[1]Promega, San Marcos, CA, [2]Promega, San Louis Obispo, CA, [3]Promega, Madison, WI

In HR-deficient cells, Polymerase Theta (Pol-theta) serves to repair double strand breaks and has emerged as a therapeutic target in HR-deficient cancers. Encoded by the POLQ gene, Pol-theta is a large (290 Kda) protein with two distinct functional domains (polymerase, helicase), separated by an unstructured region. Each domain of Pol-theta has proven vulnerable to small molecule inhibitors, with a number of molecules undergoing clinical evaluation. Unlike the helicase domain, target engagement at the polymerase domain requires cooperativity with DNA fragments. Here we describe a novel NanoBRET Target Engagement assay that enables domain-specific analysis of small molecule occupancy in live cells. To observe the high affinity-state of small molecule inhibitors to the polymerase domain, we have developed a cell-permeable pol domain NanoBRET probe, along with a novel work flow to introduce small DNA fragments into live cells. Together these components form a nucleoprotein complex with full length polymerase theta. This assay method can be used to quantify and rank-order engagement to the polymerase domain in live cells. To enable domain-selectivity analysis, we have developed a second NanoBRET probe directed to the helicase domain. Together these two NanoBRET probes allow for the mechanism of action studies at Pol-theta in living cells.

#3105 Computational integration with phage library to optimize clones of DEFB4A antibodies for cancer diagnostics and therapeutics.

Y. Guo[1], J. Yom[1], A. Han[1], Z. Guo[1], E. Zewdu[1], R. Gonzalez[1], T. Qu[1], B. Gilmore[1], X. Liu[1], W. Fu[1], X. Hu[2];
[1]Origene Technologies Inc, Rockville, MD, [2]OriGene Wuxi Biotechnology Co., Ltd, Wuxi, China

DEFB4A, a human beta-defensin, functions as a potential cancer biomarker, with elevated expression observed in various cancers, making it a candidate for diagnostic and prognostic applications. Additionally, its role in immune modulation suggests that DEFB4A may hold promise as a target for novel cancer treatments, particularly in the context of immunotherapy. This study aimed to develop a stable and high-affinity DEFB4A antibody for clinical and pre-clinical use. To achieve this, a combination of high-diversity phage libraries and computation-assisted analysis was employed to generate single-chain variable fragments (ScFv) clones specifically targeting DEFB4A. This research presents a robust approach for the generation of DEFB4A-targeting single-chain variable fragments (ScFv) from a phage library characterized by a high diversity of 10^9 unique clones and high titer of 10^{13} cfu/mL. Computational optimization was then applied to enhance the affinity, stability, and expression of these candidates through rational design and virtual mutagenesis programs. The binding activity of the optimized mutants was validated using biophysical methods such as surface plasmon resonance (SPR) and thermal stability assays. The process showed a remarkable 100-fold increase in affinity and stability. Additionally, the selected ScFv clone was further employed in immunohistochemistry (IHC) to detect DEFB4A in breast, prostate, and gastric cancers, showing higher expression levels compared to initial clones.

This study highlights the synergy of high-diversity phage libraries and computational methods in crafting DEFB4A antibodies with enhanced affinity, stability, and expression. The findings advance the field of antibody engineering, emphasizing the crucial integration of experimental and computational approaches. This work lays the groundwork for the development of high-performance biologics with diagnostic and prognostic applications across diverse cancer types. Furthermore, it demonstrates the possibility of integrating computational approaches in antibody development, offering the promise of expediting the process in the future.

#3106 Integrated *in vitro* and machine learning approaches for targeted drug screening in gliomas with concurrent NF1 and ATRX loss.

S. Dubey[1], S. Mohapatra[2], M. Yuan[3], C. G. Eberhart[3], F. J. Rodriguez[1];
[1]UCLA - University of California Los Angeles, Los Angeles, CA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Neurofibromatosis type 1 (NF1) frequently precipitates the development of brain and nerve tumors, with subsets of associated solid tumors demonstrating an aggressive phenotype often characterized by alpha thalassaemia mental retardation X-linked (ATRX) loss. In response, we executed an in vitro high-throughput drug screening utilizing a 10,000-compound library in an NF1-associated ATRX mutant glioblastoma cell line (JHH-NF1-GBM1) and in U251 cells with ATRX knockout, mimicking the concurrent loss of ATRX and NF1. The screening protocol aimed to pinpoint compounds selectively targeting vulnerabilities arising from the co-occurrence of ATRX and NF1 loss. To enhance the precision of our results, we employed an unsupervised-supervised machine learning approach. Unsupervised models identified distinctive chemical groups associated with heightened sensitivity in ATRX/NF1-deficient cells. Subsequently, supervised models were trained, and their uncertainty estimates were utilized to further narrow down the selection of hit compounds. We also utilized pre-trained models to predict ADME and toxicity properties, facilitating a further filtration. This multi-step in vitro screening, coupled with in silico analyses, successfully identified promising compounds, subsequently validated through biophysical characterization. The integration of machine learning in our screening pipeline enhances the identification of potential targeted therapies for aggressive tumors (gliomas) characterized by ATRX/NF1 loss, offering a comprehensive and efficient approach to drug discovery in the pursuit of more effective treatments.

#3107 SMASH: Single molecule antibody screening with high-throughput imaging system.

Jihye Jo[1], Changju Chun[2], Byeong-Kwon Sohn[2], Booyoung Yu[1], Jiyu Lee[2]

[1]Proteina Co., Seoul, Korea, Republic of,[2]Seoul National University, Seoul, Korea, Republic of

Larger, more diverse antibody libraries are being screened in recent years. Despite enabling the high-throughput screening of extensive libraries, the process for identification and characterization of antibodies remains laborious and time-intensive. Here we report a platform that not only compiles hit finding and validation processes, but also provides high-resolution binding affinity as well as rank order among the library being screened. We streamlined the library construction and affinity screening via microscale transient expression in HEK293T cells with designed antibody sequence and direct quantification of antibody-antigen binding affinity which reduced the timeline from multiple weeks to a single week. We constructed the single-chain fragment antigen binding (scFab) libraries by replacing the duplex DNA fragment in CDR of interest while preserving the human framework of Fab. We have demonstrated that the SPID technique allows to detect antibody-antigen interactions from just dozens of pg of scFabs in total. This allowed us to bypass the conventional DNA cloning or even PCR amplification to achieve the minimum amount of DNA plasmids for expressing scFabs to be analyzed such as BLI and SPR. Therefore, we assembled the DNA plasmids through in vitro ligation with high efficiency and directly introduced it to HEK293T in 96-well microplate with microscale (200 ul) for transient transfection, which only takes three days for library generation. Next, we utilized SPID to quantify the number of single molecules between free and antigen-bound fractions of scFab, resulting in occupancy at the antibody-antigen binding equilibrium. This technique facilitated the determination of binding affinity (K_D) for 200 antibody-antigen pairs within a 6-hour TAT encompassing both measurement and analysis. In total, we utilized 4,000 times less antibody for characterization while achieving enhanced sensitivity compared to both BLI and SPR methods. As a proof-of-concept, we generated a library consisting of 720 variants of Trastuzumab in scFab format to probe the landscape of CDRs affecting affinities against HER2 showing nM to low uM dynamic range of K_D. Out of 720 analyzed variants, 5% were deleterious, 38% provided substantial changes, 40% showed little/no change, 17% enhanced affinity to HER2. To validate the robustness of the platform, we extensively expanded the library screening, assessing over 2,000 antibody variants for their affinity against more than three different therapeutic targets. To conclude, we demonstrated an efficient approach for monitoring changes in affinity resulting from single mutations in scFab. This rapid screening of site-saturated libraries would lead to a combinational variant library that our platform can screen. Ultimately, our platform aims to identify potential candidates for therapeutic antibody development throughput the phases of antibody discovery, maturation, and engineering.

#3108 Antibody labeling reagents to rapidly screen for the binding and internalization of therapeutic antibodies.

R. W. Holly;
Thermo Fisher Scientific, Eugene, OR

Introduction: There is a growing need in the immunotherapy research field for tools to rapidly screen novel therapeutic antibodies, whether looking for cells expressing IgG, target binding, or tracking internalization. Thermo Fisher Scientific has developed the next generation of Invitrogen™ Zenon™ reagents to enable screening of potential therapeutic antibodies, working across a variety of sample types including primary B cells and hybridomas, while being compatible with a wide range of platforms including flow cytometry, high content imaging, and in-incubator imaging systems.

Methods: The Invitrogen™ Zenon™ Alexa Fluor™ Plus IgG Labeling Reagents to screen for antibody binding provide a fast, versatile, and reliable method to evaluate antibody binding to cell surface antigens. Zenon screening reagents are labeled with Invitrogen Alexa Fluor Plus 488, Alexa Fluor Plus 594, or Alexa Fluor Plus 647 dyes (i.e., labeling reagent). The labeling reagent is directed against the Fc portion of an intact mouse or human IgG primary antibody. The formation of the zenon-antibody complex is rapid and requires no purification steps. The Invitrogen™ Zenon™ pHrodo™ Deep Red Labeling Reagents for screening antibody internalization provides a highly sensitive method for monitoring antibody internalization. Zenon pHrodo Deep Red utilizes the same screening reagent as Zenon Alexa Fluor Plus reagents, replacing Alexa fluor dyes with the pH-sensitive dye, pHrodo Deep Red. The pHrodo Deep Red sensors have minimal fluorescence at neutral pH and only upon entry into the late endosome and lysosome do they brightly fluoresce. Zenon pHrodo Deep Red Labeling Reagents are perfectly suited for screening the endocytosis and degradation of potentially therapeutic antibodies including antibody-drug conjugates.

Results: Live cells stained with Zenon-labeled antibodies show remarkable signal to background in both flow and imaging applications, while retaining their signal following fixation. Therapeutic antibodies such as anti-Her2 labeled with Zenon pHrodo Deep Red show as bright fluorescent puncta upon lysosomal degradation in the Alexa Fluor 647 channel and co-localize with lysosomal markers such as Invitrogen™ LysoTracker Red dye. Both Zenon Alexa Fluor Plus and Zenon phrodo Deep Red are ideal reagents for screening antibody panels of up to 96 different antibodies.

Conclusions: Thermo Fisher Scientific has developed sensitive and rapid Zenon reagents to allow for high throughput therapeutic antibody screening. In addition to Zenon reagents, Thermo Fisher Scientific has developed additional tools that allow for specific monitoring of antibody and protein uptake into the lysosome for degradation. These tools not only greatly improve the workflow from our existing portfolio, but allow for increased sensitivity allowing the field to make decisive decisions when selecting candidate immunotherapies.

Acknowledgments: I would like to thank the whole team that worked to develop these new labeling reagents including: Maria Olson and Chris Langsdorf.

#3109 Development of novel mono and bivalent nanobodies against EGFR for targeted cancer therapy.

D. C. Aguilar Cortes[1], M. O. Heitrich[1], M. M. Fernandez[2], S. Werbajh[1], G. Canziani[1], V. Zylberman[1], E. L. Malchiod[2], O. L. Podhajcer[1], S. E. Vinzon[1];
[1]Fundacion Instituto Leloir (FIL), Buenos Aires, Argentina, [2]UBA-CONICET, Buenos Aires, Argentina

Introduction: The epidermal growth factor receptor (EGFR) plays a central role in the tumorigenesis of various solid tumors, rendering it a noteworthy target for cancer therapy. Nanobodies (Nbs) offer an appealing therapeutic approach due to their low immunogenicity, rapid clearance, and high targeting specificity. The aim of this study is to isolate, design, and characterize Nbs directed against EGFR.
Methods: The Nb library was constructed following llama immunization with cells overexpressing EGFR. After three rounds of panning the phage-display library (both in solid phase and solution), individual clones were screened for EGFR reactivity using ELISA against Virus-Like Particles. Positive clones were sequenced, cloned into an expression vector, and then purified by immobilized metal affinity chromatography (IMAC). The Nbs were characterized through immunofluorescence (IF), flow cytometry (FACS), and surface plasmon resonance (SPR). The most promising candidates were used to design bivalent constructs, which were subsequently characterized by SPR and in a cell proliferation assay.
Results: We successfully constructed an EGFR-targeted Nb library, which allowed the selection of multiple EGFR-specific Nbs following the optimization of the panning strategy. Two of the candidates exhibit strong binding to native EGFR in cells and outperform the gold standard anti-EGFR Nb 7D12. They demonstrate enhanced binding parameters in surface plasmon resonance (SPR) assays, with fast association and slow dissociation rates. The homo/heterodimeric bivalent constructs show improved affinity and the ability to inhibit cancer cell proliferation.
Conclusion: We were able to develop novel mono and bivalent nanobodies with enhanced binding properties which can be used for targeted cancer therapy.

#3110 An enhanced and cost-efficient method for neoantigen immunogenicity screening method: Double Barcode Neoepitope Scan™.

S. Kim, M.-H. Jung, H.-J. Hwang, S. Oh, S.-E. Hong, S. Paik, H.-S. Kim;
Theragen Bio, Sungnam-si, Korea, Republic of

Neoantigens, HLA bound peptides generated by tumor-specific mutations, have emerged as promising targets for cancer immunotherapeutic. However, the significant challenge in neoantigen-based therapies is that the neoantigens are rare and difficult to predict. Therefore, in addition to prediction algorithms, the optimization of validation methods is essential for the reliable selection of highly immunogenic neoepitopes. In this study, we have developed a cost-effective screening method to validate large scale of neoantigen candidates. The DNA library-based methods have been employed for antigen selection and T cell receptor identification. We improved the DNA library-based neoantigen screening method by adding two barcodes to each minigene transcribing multiple neoantigen candidates and pooled synthesis of minigenes. We initially designed the barcodes to allow analysis in a 10 by 10 format for screening of hundreds of neoantigens so that PCR with each barcode result in amplification of ten candidates. The second barcode allowed the deconvolution of immunogenicity results without the need for synthesis of individual peptides. In this method B cell was used as antigen-presenting cell, which were co-transfected with mRNA for a minigene pool, 41BBL, and OX40L after expansion with CD40L/IL4/IL21. The resulting B cells were co-cultured with T cells and T cell responses were evaluated using ELISpot. To validate the method the TESLA consortium reported tetramer positive neoantigens were included in minigene. In results, the neoantigens including each barcode were amplified to form a pool of ten neoantigens as a minigene and confirmed that the neoantigens were equally amplified by nested PCR. The neoantigen pools synthesized as mRNA were transfected for presentation in B cells. The result of the targeting a neoantigen pool containing tetramer-positive neoantigens of the TESLA consortium showed a positive for ELISpot. In conclusion, our optimized screening method, employing the double barcode system, offers a time- and cost-efficient approach for the selection of immunogenic neoantigens without the need for individual peptides. This method will facilitate large-scale screening to identify actual neoantigens with immunogenic potential, contributing to the development of neoantigen-targeted vaccines.

#3111 Preclinical development of a peptide-based immune-surveillance PET tracer for immuno-oncology stratification.

A. W. Sinkjaer[1], D. K. Sell[1], I. M. Dawoodi[1], B. Bakhshinejad[2], C. Stavnsbjerg[1], A. Kjaer[1];

[1]Copenhagen University Hospital - Rigshospitalet & University of Copenhagen, Copenhagen, Denmark, [2]University of Copenhagen, Copenhagen, Denmark

Introduction: Cancer immunotherapies, such as immune checkpoint inhibitors (ICIs), have become an integral part of cancer treatment. However, significant differences in their effectiveness persist among individual patients. This variability partly stems from poorly immunogenic tumors, referred to as "cold" tumors, characterized by low levels of tumor-infiltrating leukocytes (TILs). Studies indicate that lower levels of TILs, specifically CD4+ and CD8+ T-cells, lead to reduced efficacy of certain immunotherapies. Therefore, the imaging of these cell types could be invaluable in screening cancer patients to predict the effectiveness of a prescribed immunotherapeutic agent before and during treatment. CD4+ T-cells, identified by their high expression of CD4 receptors, could serve as a potential molecular imaging target for an immuno-oncology relevant PET tracer. For this purpose a peptide-based PET tracer offer several beneficial characteristics such as relatively low circulation time, cell penetration, and low development costs.

Methods: All peptides were identified through peptide phage display (PPD) and commercially synthesized (>95% purity). These peptides underwent screening for their binding affinity to recombinant human CD4 and a negative control protein using surface plasmon resonance (SPR) on a Biacore X100. Peptides exhibiting specific binding to CD4, as determined by SPR, were further selected for FITC-labeling (>95% purity). FITC-labeled peptides were applied in fluorescence-based cell assays conducted on the SUP-T1 (CRL-1942) cell line and an established SUP-T1 CD4 knockout (KO) cell line. Flow cytometry assays were performed using a Fortessa X-20, while live cell imaging was conducted on either a LSM980 or LSM900 confocal microscopy. Simultaneously, an *in silico* docking method was employed, utilizing ColabFold—an online complex predictor powered by AlphaFold2—for CD4-peptide docking analysis.

Results: Several peptides successfully identified via PPD exhibited binding to recombinant human CD4 as shown by SPR screening. The FITC-labeling and assessment against SUP-T1 and corresponding CD4 KO cell line unveiled specific CD4 binding within a subset of peptides, as observed in both flow cytometry and confocal microscopy. *In vitro* data was compared to CD4-peptide docking results to create a list of peptides for future *in vivo* studies.

Conclusions: Multiple peptides successfully identified via PPD showed robust *in vitro* CD4 binding through SPR screening. Select peptides also demonstrated specific CD4 binding in cell assays, corroborated by docking results. Future prospective for the high performing peptides include *in vivo* PET/CT Ga-68 or Cu-64 imaging in tumors with high and low CD4+ T-cell infiltration.

#3112 Colorectum metabolome map revealed etiological and survival heterogeneity in cancers of different subsites: Challenging the proximal versus distal classification.

Abhishek Jain[1], Caroline Johnson[1], Domenica Berardi[1], Sajid Khan[2], Montana Morris[2]

[1]Yale School of Public Health, new haven, CT,[2]Yale School of Medicine, new haven, CT

Objective: Colorectal cancer (CRC) is usually classified as proximal, distal and rectal cancer. clinicopathological, molecular features and risk factors do not change abruptly and variations exist even among the refined subsites, which may contribute to the failure of mechanism-targeted therapies for CRC and poor accuracy of potential CRC biomarkers. We generated a CRC metabolome map describing etiological and survival heterogeneity in cancers of different subsites of the colorectum.
Design: Utilizing 372 tumor tissues with matched normal mucosa liquid chromatography-mass spectrometry was applied to examine metabolomics profiles along 7 subsites of the colorectum: cecum (n=63), ascending colon (n=44), transverse colon (n=32), descending colon (n=28), sigmoid colon (n=75), rectosigmoid colon (n=38) and rectum (n=92). Linear regression showed distribution of metabolites along the subsites. Survival heterogeneity along subsites were statistically tested by cox regression analysis. Metabolome profiles were obtained from invitro cultures of 310 human microbial species.
Results: 40 and 76 significantly altered metabolites (including bile acids, lysoPCs and LysPEs) among tumors and normal mucosa showed metabolic heterogeneity existed among CRC subsites. Gradual changes in metabolites abundance with significantly linear trend from cecum to rectum: 23 metabolites in tumor, 30 metabolites in normal mucosa and 15 metabolites in both tumor and normal mucosa, revealed concentration gradient depends on the disease status. Exclusively significant alteration of metabolites only in one subsite showed the differences in cancers among the 7 subsites of colorectum. We identified the metabolites associated with survival were different and unique to each subsite. Integration of microbial metabolome with CRC metabolome revealed microbial metabolites contributed to etiological and survival heterogeneity among CRC subsites.
Conclusions: Gradual changes of metabolites from cecum to rectum and the association of different metabolites with CRC risk and survival in each subsite of colorectum, revealed the differences in cancers along the colorectum and challenge the simple classification of CRC in LCC, RCC and rectum. Human microbial metabolites contributed to etiological and survival heterogeneity among CRC subsites.

#3113 Development of HTS enzymatic assays for WRN helicase and exonuclease functions.

H. Pham, M. Ali, A. Ramos Martinez, R. Lowery;
BellBrook Labs, Madison, WI

WRN, a double strand break repair enzyme with ATP-dependent DNA-helicase and 3'- >5' exonuclease activities, is under intense focus as a therapeutic target because of its synthetic lethality in tumors with microsatellite instability. To accelerate discovery of WRN inhibitors, we developed and validated homogenous, fluorescence-based high throughput assays for WRN helicase and exonuclease enzymatic activities using the Transcreener HTS Assay platform, which relies on highly selective antibodies to detect nucleotides in a homogenous (mix-and-read) format with far red fluorescent readouts. We produced the WRN helicase domain (aa 500-946, N-terminal 6xHis) in BaV-infected insect cells and optimized detection of its dsDNA-dependent ATPase activity using the Transcreener ADP^2 Assay in FP, TR-FRET, and FI detection modes. Optimal reaction conditions included 50 µM ATP (approximate K_m) and saturating concentration (100 nM) of a 3' flapped duplex DNA oligomer; these conditions yielded a good signal with 250 pM WRN, a kcat of 300 min^{-1}, and a Z' of 0.85. An IC_{50} of 35 nM was determined for the probe inhibitor NSC-617145, and a 1,280 compound pilot screen (Tocris 2.0 Micro) identified multiple hits that were confirmed in dose response experiments. We produced the WRN 3'-5' exonuclease domain (aa 1-133-6xHis) in E. coli and used the Transcreener dAMP Exonuclease Assay to allow direct, FP-based detection of dAMP monomers released from a 52 bp dsDNA oligomer with a 5' overhang. With saturating DNA present (1 µM), the assay produced a good signal with 1 nM enzyme; the Z' value was 0.89. There are no published inhibitors for the WRN exonuclease, but suramin inhibited with an IC_{50} of approximately 100 nM. These assays allow sensitive, robust, quantitative detection of WRN ATPase and exonuclease activities using an extensively validated HTS platform; they should be valuable tools for screening and optimizing small molecules targeting specific WRN functions.

#3114 Development of HTS enzymatic assays for RNA helicases: DDX3, DDX5, DDX17, RIG-1 and MDA5.

M. Ali, **H. Pham**, A. Ramos Martinez, R. Lowery;
BellBrook Labs, Madison, WI

RNA helicases are a broad class of enzymes that bind and modify RNA in an ATP-dependent manner and play diverse roles in RNA metabolism, regulation of gene expression, and innate immunity. Several RNA helicases, especially in the dead box helicase (DDX) family, have been shown to be dysregulated in cancer, and there have been limited efforts to develop small molecule inhibitors. To accelerate development of selective helicase inhibitors while avoiding off target effects, especially with helicases that promote tumor immunity, we are assembling a panel of high throughput biochemical assays using the Transcreener ADP^2 assay for homogenous detection of RNA-dependent ATPase activity with a far-red fluorescence polarization (FP) readout. Here we describe development of assays for DDX3, DDX17 and DDX5, which have all been implicated in cancer, and the Rig-1-like receptor (RLR) helicases, RIG-1 and MDA5, which trigger expression of type I interferons important for tumor immunity. We produced the recombinant enzymes using BaV-infected insect cells, as full-length polypeptides, or in some cases truncated to remove disordered N-terminal domains. We determined RNA substrate and cofactor requirements and kinetic parameters with the purified enzymes and optimized the assays for initial velocity detection of RNA-dependent ATPase activity with a Z' value greater than 0.7, ensuring a sufficient signal window for inhibitor screening and dose response assays. We validated each of the helicase ATPase assays for HTS by screening a collection of bioactives (Tocris 2.0) and confirming hits in dose response mode with the enzymatic assay and with thermal shift assays to confirm target binding. These assays will enable screening and hit-to-lead/SAR for DDX helicases that drive tumorigenesis as well as selectivity profiling to avoid off target effects with RLR helicases that promote tumor immunity.

#3115 Systematic analysis of gene mutations and therapeutic efficacy via *ex vivo* hematological vitroscreen platform.

F.-J. Chou, S. Cairo, M. Gilardi, A. Andar, K. Abarca-Heidemann, M. Mancini;
Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

Acute myeloid leukemia (AML) is a common hematological malignancy found in adult patients, and FMS-like tyrosine kinase 3 gene (FLT3) mutation occurs in about 30% of patients. In 2019, a phase 3 clinical trial suggested that gilteritinib treatment resulted in significantly longer survival than salvage chemotherapy in relapsed or refractory FLT3-mutated AML patients. Targeting FLT3-mutants in AML has become one of the important therapeutic strategies in this decade. The ex vivo hematological VitroScreen platform provides a powerful tool to evaluate the performance of FLT3 inhibitors and other test articles. With Champions Oncology's primary hematological repository (https://www.championsoncology.com/hematological-vitroscreen) and proprietary LUMIN Bioinformatics platform, we classified models based on patient responses, clinical annotation, NGS data, and cell surface markers. In this Ex vivo study, we tested gilteritinib in 30 AML patients, and 8 of models were identified as FLT-3 mutants' carrier. Fold changes of cell viability after gilteritinib treatment were assessed based on quantitation of the ATP present. FLT3-mutants models showed significantly higher sensitivity to gilteritinib than FLT3-WT models (IC50, 132.56 nM vs. 234.16nM) in a 6-day assay. Only 25% of models in the FLT3-mutants group had higher IC50 than the average of all AML models (n=28, IC50 = 204.05 nM), compared to 53% in the FLT3-WT group. Our preclinical data highly match the observations in previous clinical trials, which suggest that VitroScreen is a reliable high throughput tool for drug development of drug resistant cancers.

#3116 Bioluminescent 3D tumors with immune cell co-culture for high throughput screening (HTS).

F.-J. Chou, S. Kamali, M. Gilardi, B. Walling, A. Andar, K. Abarca-Heidemann, M. Mancini;
Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

In the past decade, cancer immunotherapy has revolutionized the cancer treatment strategy. Immune-oncology (IO) drugs play an important role in treating various malignancies. Immunotherapies work by re-educating and boosting patients' immune systems to recognize and eliminate cancer cells. The immune co-culture assay provides invaluable information to understand the tumor microenvironment (TME) and observe the immune response after IO drug treatment. Recent advancements in the Champions TumorGraft3D (CTG3D) platform provides more consistent and accurate information for preclinical drug evaluation, but also efficiently simulate the tumor-Immune microenvironment (TIME) and interactions between cancer organoids and immunocyte. However, current analytic approaches in organoid-immune co-culture studies are still highly reliant on flow cytometry and high-resolution confocal imaging endpoints to provide the study outcome. There is a need for a fast and cost-effective co-culture platform to help set up experimental conditions. Easily traceable tags (e.g. bioluminescent and fluorescent) can quickly help establish reliable the effector (E) cell to tumor (T) cell conditions, thus enabling the user to test multiple immune-cell activator or engagers concentrations in a cost-effective and rapid manner. At Champions Oncology we provide stable Luc/GFP-tagged CTG3D models. We have built a reliable CTG3D-immune co-culture platform with various indications (including colon, prostate, gastric, non-small cell lung cancer, and leukemia) which can be used in co-culture with autologous TIL, allogenic TIL and NK cells, thus providing users a fast and cost-effective option to optimize the E:T ratio and monitor the drug performance.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibody-Drug Conjugates
Poster Session

#3121 Therapeutic potential of a HER3 antibody-drug conjugate for the treatment of HER3-expressing cancers .
T. O'Hare, J. Cleveland, V. M. Jansen, D. Dornan;
Elevation Oncology, Inc., Boston, MA

To address the need for targeted therapy in the treatment of HER3-positive solid tumors, the human HER3 mAb, seribantumab, was evaluated in the context of an antibody-drug conjugate (ADC). As a proof-of-concept, seribantumab was conjugated with a cleavable valine-citrulline linker and monomethyl auristatin E (MMAE) payload via the stochastic cysteine conjugation method to yield HER3-ADC1. A drug-antibody ratio of 4 was selected for preclinical assessment in HER3-expressing models. Methods: HER3-ADC1 was evaluated *in vitro* and *in vivo*, with patritumab deruxtecan (patri-DXd) as a comparator. Binding to BT474 breast carcinoma cells (HER3 high; immunohistochemical (IHC) staining intensity 3+) was measured by flow cytometry. Internalization properties were established using seribantumab and patritumab coupled to Fab-AF488 following 4 hours incubation in SK-BR-3 breast adenocarcinoma (HER3 high; IHC 3+) and HCC1569 breast carcinoma (HER3 low; IHC 0-1+) cell lines. *In vitro* cytotoxicity was evaluated for HER3-ADC1, isotype-MMAE and free MMAE payload as well as patri-DXd, isotype-DXd and free deruxtecan payload in BT474 cells, SK-BR-3 cells and NCI-H446 lung carcinoma (HER3 low; IHC 0-1+) cells. *In vivo* anti-tumor activity was assessed for HER3-ADC1, isotype-MMAE, patri-DXd and isotype-DXd in patient derived xenograft (PDX) models of pancreatic (HER3 high; IHC 3+) and breast cancer (HER3 low; IHC 0-1+). Results: HER3-ADC1 binding to cancer cells, endocytosis, MMAE release, and inhibition of proliferation were dependent on HER3 expression. In assays investigating antibody internalization, seribantumab displayed similar internalization capacity as patritumab. For both HER3 mAbs, internalization was greater in a HER3 high than a HER3 low cell line. In cytotoxicity assays, HER3-ADC1 and patri-DXd displayed HER3 expression level-dependent cell killing. HER3-ADC1 outperformed patri-DXd in HER3 high cell lines based on *in vitro* cytotoxicity. HER3-ADC1 and patri-DXd were ineffective against NCI-H466 cells with low HER3 expression. In a PDX model of pancreatic cancer (HER3 high), HER3-ADC1 induced tumor regression, while isotype-MMAE had only a moderate anti-tumor effect. Both patri-DXd and isotype-DXd had moderate anti-tumor effects, indicating a lack of HER3 target dependence. In a PDX model of breast cancer (HER3 low), HER3-ADC1 and isotype-MMAE lacked anti-tumor activity; isotype-DXd had a moderate anti-tumor effect and patri-DXd had a substantial anti-tumor effect. Conclusions: HER3-ADC1 demonstrated target-dependent *in vitro* cytotoxicity and *in vivo* anti-tumor activity in a HER3-expressing pancreatic cancer PDX model. Results from *in vitro* and *in vivo* studies highlight the promising therapeutic potential of a seribantumab-based ADC for patients with HER3-expressing cancers. Additional results on the optimization and characterization of HER3-ADC1 will be presented.

#3122 Preclinical development of a novel camptothecin-based antibody-drug conjugate targeting solid tumors expressing Claudin-6.

N. Tsang[1], N. Veillard[1], E. Horsley[1], K. Havenith[1], N. Janghra[1], K. Zaitseva[1], C. Oblette[1], I. Kirby[1], P. W. Hogg[1], F. Zammarchi[2], L. de Haan[1], P. H. van Berkel[1];

[1]ADC Therapeutics, London, United Kingdom, [2]Myricx Bio, London, United Kingdom

Claudin-6 is a member of the claudin family and consists of four transmembrane helices, two extracellular loops, and an amino- and carboxyl-terminal tail with a PDZ-binding motif in the cytoplasm. It is involved in the formation of tight junctions and is expressed in developing human epithelial structures during early-to-mid gestation while expression in iadult tissues is mostly absent. Claudin-6 expression is upregulated in ovarian cancer, testicular cancer, endometrial cancer, non-small cell lung cancer (NSCLC) and gastric cancer. Here, the generation and preclinical characterization of a novel Claudin-6 specific antibody-drug conjugate (ADC) is described, composed of a humanized IgG1 directed against human Claudin-6 site-specifically conjugated a novel payload containing a valine-alanine cleavable linker and a camptothecin warhead with a drug to antibody ratio of 6. FcγR-mediated effector function of the ADC was abrogated via mutations in the Fc portion of the antibody. The purpose of this study was to evaluate the expression of Claudin-6 in different tumour indications and characterise the *in vitro* and *in vivo* anti-tumour activity in human cancer cell lines and patient-derived xenograft (PDX) models. In addition, the tolerability of the ADC was evaluated in a repeat-dose toxicity study cynomolgus monkeys. Cell binding studies using Fabs showed high affinity binding to Claudin-6, while affinity for Claudin-9 was 16-fold lower with no binding to Claudin-3 and Claudin-4. Cross-reactivity with cynomolgus monkey and mouse Claudin-6 was also demonstrated. Fcgamma receptor binding studies confirmed the strongly reduced binding of the antibody to FcγI, FcγI,IIa, FcγIIb and FcγIIa, consistent with the introduction of mutations in the Fc domain of the antibody. *In vitro*, the Claudin-6 ADC showed potent and specific cytotoxicity against various Claudin-6-expressing solid cancer cell lines, including OVCAR3, PA-1, OV-90, FU-97, BeWo, NTERA-2 and NUGC3 in comparison to a non-binding control ADC conjugated to the same payload, and it also showed potent bystander killing. *In vivo*, a single dose intravenous (IV) of the Claudin-6 ADC demonstrated potent anti-tumour activity in multiple solid tumour xenograft models, including OVCAR3 and PA-1. Furthermore, administration of the Claudin-6 ADC to cynomolgus monkeys was well tolerated up to 40 mg/kg IV when given on Day 1 and 22. Cell membrane expression of Claudin-6 was confirmed by immunohistochemistry (IHC) in ovarian cancer (70%), testicular cancer (98%), endometrial cancer (30%), NSCLC (28%) and gastric cancer (24%), confirming expression of Claudin-6 in indications with high unmet need. In summary, this novel Claudin-6 ADC demonstrated potent, specific anti-tumour activity in Claudin-6 expressing cancer-derived models and was well tolerated in cynomolgus monkey, supporting future clinical development of this ADC.

#3123 Preclinical characterization of AMB302/GQ1011, a first-in-class FGFR3 antibody-drug conjugate (ADC) with topoisomerase 1 inhibitor against diverse FGFR3 overexpression or alteration.

Byeongkwi Min[1], Sunghyun Lee[1], Wonsik Jung[1], Lina Wang[2], Yajun Sun[2], Hyejin Kim[1], Nam-Gu Her[1], Paul H. Song[2], Gang Qin[2], **Do-Hyun Nam**[1]

[1]Aimed Bio Inc., Seoul, Korea, Republic of,[2]GeneQuantum Healthcare Suzhou Co., Ltd., Suzhou, China

Background: Molecular alterations of oncogene FGFR3 in various cancers include FGFR3 gene fusions, activating mutations, and overexpression as a driver mutation. AMB302/GQ1011 is a novel FGFR3-targeting ADC conjugated with an innovative topoisomerase I inhibitor (TopoIx) using intelligent Ligase-Dependent Conjugation (iLDC) technologies developed by GeneQuantum (GQ), providing high homogeneity, excellent druggability, and superior linker stability. Based on preclinical characterization, AMB302/GQ1011 exhibits impressive anti-tumor activities against bladder cancer (BC), head and neck squamous cell carcinoma (HNSCC), and glioblastoma (GBM) with either FGFR3 overexpression or FGFR3 alterations including gene fusions, demonstrating potential as a first-in-class FGFR3 ADC against FGFR3 relevant solid tumor indications.
Methods: For biomarker analysis, patient tissue microarrays and tissue blocks were subjected to IHC staining for FGFR3 to assess its real-world intensity. To characterize AMB302/GQ1011, in vitro assays and ex vivo plasma stability were evaluated to confirm the anti-tumor effect and linker stability. In vivo anti-tumor effects of AMB302/GQ1011 were assessed on various CDX and PDX models with FGFR3 overexpression or alterations. The potential toxicity profile of AMB302/GQ1011 was evaluated in NHP via repeated intravenous infusions.
Results: AMB302/GQ1011 conjugates a novel FGFR3-targeting antibody (Aimedbio Inc.) with TopoIx (GQ) via a cleavable linker through iLDC platform. In IHC analysis, we detected high and widespread FGFR3 expression in various tumors. In in vitro cytotoxicity assay, AMB302/GQ1011 showed excellent antitumor activity against FGFR3-expressing cells. In various CDX and PDX models with FGFR3 expression or alterations, AMB302/GQ1011 demonstrated superior efficacy compared with benchmark ADCs and FGFR pan-inhibitors. AMB302/GQ1011 dramatically prolonged survival in GBM orthotopic PDX models with F3-T3 fusion by >150% in combination with TMZ. Particularly, in combination with an immune checkpoint inhibitor (ICI), AMB302/GQ1011 exhibited an excellent synergistic antitumor effect. In a monkey toxicity study, AMB302/GQ1011 demonstrated a high tolerability up to 60 mg/kg dosing, without severe adverse effects.
Conclusion: AMB302/GQ1011 demonstrated a potent antitumor efficacy in vitro and in vivo models with FGFR3 overexpression and alterations across various solid tumors. Notably, AMB302/GQ1011 suggests the potential for combination with ICI treatment. Moreover, AMB302/GQ1011 exhibited excellent tolerability at high doses in NHP, indicating its safety profile. Our data suggest that AMB302/GQ1011 has potential to become a first-in-class FGFR3-targeting ADC for solid tumors with FGFR3 overexpression or alterations.

#3124 MRG006A, a novel glypican-3-targeting antibody-drug conjugate, demonstrated potent anti-tumor activity and good safety profile in preclinical studies.

Yanchun Wang[1], Hongfeng Li[1], Hao Shen[2], Wenchao Liu[1], Shoujia Liu[1], Kequan Yin[1], Haili Xu[1], Xueyuan Cui[1], Wei Li[1], Wei Liu[1], Xiangyu Wu[1], Liu Yang[2], Tian Ma[1], Zhongrun Zhao[1], Jun Wang[3], Feifei Cui[2], **Lei Fang**[2], Minmin Qin[3], Chaohong Hu[1]

[1]Shanghai Miracogen Inc., Shanghai, China,[2]Concept to Medicine Biotech Co., Ltd., Shanghai, China,[3]Lepu Biopharma Co., Ltd., Shanghai, China

Background: Hepatocellular carcinoma (HCC) is one of the most challenging cancers with high unmet medical need. Glypican-3 (GPC3) is an oncofetal glycoprotein anchored to the cell surface via GPI (glycosylphosphatidylinositol) and frequently over-expressed in HCC with limited expression in normal adult tissues, which makes it an appealing antibody-drug conjugate (ADC) target for HCC. MRG006A is a potentially first-in-class GPC3-targeting ADC composed of a novel humanized IgG1 antibody conjugated to a proprietary linker-payload platform utilizing a potent topoisomerase 1 inhibitor via a peptide-based cleavable linker.

Materials and Methods: As a GPC3-targeting ADC intended for clinical therapy of GPC3-expressing cancers, the mechanism of action and therapeutic potential of MRG006A were investigated in a series of preclinical studies, including (1) MRG006A and its antibody moiety binding to human GPC3 expressed on cells assessed by flow cytometry; (2) binding affinity to human and cynomolgus monkey GPC3 measured by SPR (surface plasmon resonance); (3) internalization in Huh7 cells assessed by pHAb Reactive Dye and confocal microscopy; (4) *in vitro* cytotoxicity against a panel of HCC cell lines (Huh7, HepG2, Hep3B and GPC3-negative SK-HEP-1); (5) anti-tumor activity of MRG006A evaluated in Huh7 and HepG2 cell line-derived xenograft (CDX) as well as a panel of HCC patient-derived xenograft (PDX) mouse models with a different expression level of GPC3; (6) plasma stability of MRG006A evaluated in human, cynomolgus monkey, rat and mouse plasma; and (7) an exploratory pharmacokinetic (PK) and toxicology study of MRG006A in cynomolgus monkey.

Results: The GPC3-targeting ADC, MRG006A, and its antibody moiety exhibited superior binding activity to GPC3-expressing cancer cell lines than a clinical antibody benchmark and similar nanomolar binding affinity to both human and cynomolgus monkey GPC3, which makes cynomolgus monkey suitable for toxicological studies. Rapid internalization of MRG006A antibody was observed in GPC3-expressing Huh7 cells, and MRG006A maintained comparable internalization capability to the naked antibody. More importantly, MRG006A exhibited potent GPC3-dependent cytotoxic activity in a panel of HCC cells expressing varying levels of GPC3. Administrations of MRG006A resulted in a robust and dose-dependent tumor growth inhibition of multiple CDX models and HCC PDX models. Remarkable stability of MRG006A was shown in the plasma of various species tested. MRG006A demonstrated a favorable PK and safety profile with good tolerability in the exploratory toxicology study.

Conclusion: Overall, the preclinical study results suggest that MRG006A is a feasible ADC drug candidate for treating GPC3-expressing cancers in clinical studies. MRG006A was aimed to submit IND in China and the U.S in 2024.

#3125 TCX-101, a novel antibody-drug conjugate targeting a tumor-associated carbohydrate antigen for the treatment of solid tumors.

F. G. Gomes, F. Muraca, G. M. Schmidt Garcia Moreira, K. Rosch, M. Brautigam, P. Sondermann, **M. Ocker**;
TACALYX GmbH, Berlin, Germany

Tumor-associated carbohydrate antigens (TACAs) are short oligosaccharides expressed on the surface of cancer cells and play key roles in cellular communication, immune evasion, apoptosis and metastasis. TACAs are therefore interesting targets for antibody-based therapies in cancer. We have generated an antibody (TCX-101) against a TACA structure with improved binding affinity compared to other monoclonal antibodies (mAbs) against the same target as shown by surface plasmon resonance (~ 10x superior KD), as well as high level of specificity against glycan species related to the target, as accessed by glycan array, flow cytometry, and immunocytochemistry or immunofluorescence. Immunohistochemistry studies on fresh-frozen tissue microarrays showed high expression of the target in various solid tumors (e.g. gastrointestinal, lung, and breast) and only low expression in normal tissues. *In vitro*, TCX-101 has ~ 4x higher maximum binding, ~ 2x faster binding kinetics, ~ 4x faster cellular internalization and induces ~ 2x higher antibody-dependent cellular cytotoxicity than a reference antibody. Monomethyl auristatin E (MMAE) was used in a drug-antibody ratio (DAR) of 4 to generate an antibody-drug conjugate (ADC). This ADC was effective in *in vitro* toxicity assays against murine B16 melanoma cells induced to express the target (measurable effect on WT cells), as well as human breast cancer MCF7 WT cells (~ 25x less activity on target-knockout MCF7 cells, Table 1). When tested *in vivo*, TCX-101 was highly effective in two different xenograft mouse models (B16, MCF7) with more than 95% tumor growth inhibition compared to vehicle, and no signs of toxicity (no weight loss, no histophatological findings). A fully humanized version of TCX-101 with improved binding properties (EC50 6.27 nM vs. 8.13 nM) was generated and will be evaluated in further *in vivo* experiments. In conclusion, TCX-101 is a promising ADC for the treatment of various solid tumors.

Table 1

	IC50 [nM] TCX-101-MMAE 4 DAR
B16 KI	7.64
B16 WT	no killing observed
MCF7 WT	1.97
MCF7 KO	45.97

#3126 A novel pegylated bispecific antibody-drug conjugate (P-BsADC) JY207b targeting cancers co-expressing PD-L1 and CD47.

Y. Wen, Shumin Liu, Weidong Lyu, Yang Lei, Shuangyu Tan, Zibin Wu, Shuqiang Yin, Qiudong Zhuo, Dechun Wu;
Shenzhen Enduring Biotech, Ltd., Shenzhen, China

ADCs have showed improved efficacy and target selectivity comparing to the non-specific small molecule cytotoxicity drugs. However, conventional IgG based ADC has been hindered in solid tumor therapies by the poor tumor penetration, low internalization efficiency, unexpected efflux from tumor cells, and narrow therapeutic window due to the on target/off tumor toxicity, etc. To address these issues, we have developed the pegylated bispecific ADC platform and proved the concept with JY207, which targets PD-L1 and CD47 with a 30k PEG-MMAE linker-payload. JY207 has demonstrated advantages in tumor penetration, internalization efficiency, without efflux post internalization, lacking Fc related toxicity, and better tumor inhibition than DS-8201a in a model positive for Her2, PD-L1 and CD47. In this study, we further improved the compound by site-specific conjugating the fusion protein of two scFvs that target PD-L1 and CD47, with a 40K PEG-MMAE linker-payload. As expected, the new compound JY207b retained all the advantages of JY207. Additionally, JY207b did not bind to human red blood cells at all even though an ultra-sensitive detection method was employed, while CD47 antibodies with reported low affinity bound >90% red blood cells under our ultra-sensitive detection method. Meanwhile, JY207b could still preferentially bind to CD47/PD-L1 double positive tumor cells, thus reducing the possibility of on-target toxicities. In the *in vitro* cytotoxicity assays, the compound JY207b demonstrated strong potencies in CD47/PD-L1 double positive tumor cells, with almost no killing effect to CD47 or PD-L1 single positive tumor cells. In CDX models and a PDX model of transplanted tumor tissues from lung cancer patients, the compound JY207b demonstrated strong tumor inhibition efficacies at low doses. More interestingly, although the elimination half-life (T1/2) of JY207b in mice is 59.17±3.824 hours, the elimination time of JY207b in tumors is beyond 1 week by the IVIS imaging examination, which allows for weekly dosing in PK unfavorable mouse animals for pegylated protein drugs. Moreover, preliminary repeated-dosing toxicological study has found the maximum tolerated dose of JY207 in CD47/PD-L1 double transgenic mice to be 50mg/kg. These studies suggested favorable anti-tumor effect of JY207 both in vitro and in vivo, and its mechanism of action has been well described. These findings provide evidence for the efficacy of JY207 as a clinical treatment for patients with CD47/PD-L1 double positive cancers.

#3127 Development of three-dimensional cancer cell line spheroid models for the *in vitro* functional characterization of cytotoxic antibody-drug conjugates.

Jodi Wong, Andrea Hernandez Rojas, Allysha Bissessur, Lemlem T. Degefie, Araba P. Sagoe-Wagner, Samir Das, Vincent Fung, Kevin Yin, Renee Duan, Sam Lawn, Laurence Madera, Catrina Mi Jung Kim, Alex Wu, Mark E. Petersen, Raffaele Colombo, Jamie R. Rich, Stuart D. Barnscher

Zymeworks Inc., Vancouver, BC, Canada

Background: Antibody-drug conjugates (ADCs) are an effective class of cancer therapeutics which have gained prominence for the treatment of several malignancies. A cytotoxic ADC consists of a linker-payload conjugated to a monoclonal antibody, which targets a distinct tumor-associated antigen (TAA) to enable the delivery of the cytotoxic payload to cancer cells. Presently, there is a need for *in vitro* models that better recapitulate *in vivo* tumor tissue complexity to aid in the screening and evaluation of ADCs during preclinical development. Hence, efforts have been made to develop *in vitro* three-dimensional (3D) models with improved translation to *in vivo* tumor models compared to traditional two-dimensional (2D) cancer cell line monolayer models. We aimed to generate monoculture cancer cell line spheroids in a high-throughput manner. Subsequently, we sought to evaluate the spheroid penetration capability of structurally distinct ADCs and to assess the 3D cytotoxic activity of a variety of microtubule inhibitor (MTI) and topoisomerase 1 inhibitor (TOPO1i)-bearing ADCs targeting multiple TAAs, comparing to activity in 2D models.

Methods: Monoculture cancer cell spheroids were generated by seeding cells from a variety of tumor types, using an automated liquid-handling robot, into microtiter plates treated with ultra-low attachment coating, which allows for scaffold-free self-assembly of cancer cells into a 3D arrangement. Following spheroid formation by incubation for 2-3 days under standard culturing conditions, spheroids were treated with ADCs at a range of concentrations for functional evaluation: the spheroid penetration capability of ADCs of different antibody formats was assessed using high-content confocal imaging of spheroids treated with fluorescently labeled antibodies; the cytotoxic activity of ADCs was characterized using an ATP quantification luminescent reagent, live/dead cell fluorescent stains, and confocal imaging.

Results: Monoculture spheroids of varying morphologies were successfully and reproducibly generated with a large panel of >50 cancer cell lines derived from ≥10 tumor types. Antibodies with different formats demonstrated target-mediated binding and a range of spheroid penetration depths. Additionally, MTI and TOPO1i ADCs evaluated in a panel of cancer cell spheroids demonstrated robust 3D cytotoxicity and differentiated activity when compared to the 2D monolayer assay. In a number of cases, the potency trends across multiple ADCs in 3D cytotoxicity assays were more predictive of *in vivo* efficacy compared to the 2D assay. Taken together, our high-throughput spheroid assays present important and straightforward *in vitro* tools to aid in the screening and selection of therapeutic cytotoxic ADC candidates for the treatment of solid tumors.

#3128 HRA00184-C004, preclinical characterization of a novel tissue factor-targeted antibody-drug conjugate.

H. Ying, L. You, N. He, S. Xu, P. Pu, S. Lin, J. Feng, Z. Zhang, X. Ye, M. Hu, F. He;
Shanghai Hengrui Pharmaceutical Co., Ltd., Shanghai, China

The physiological function of tissue factor (TF) is to initiate coagulation cascade by forming complex with plasma Factor VII after vascular injury. For Tisotumab vedotin (Tivdak), a TF targeting antibody-drug conjugate (ADC) approved for the treatment of cervical cancer, bleeding events were prespecified as adverse effects (AEs) of interest, besides ocular toxicity and peripheral neuropathy (known MMAE payload related AE). In order to mitigate the bleeding risk, a next generation of TF-targeting ADC is developed by Hengrui Pharmaceuticals. HRA00184-C004 is a novel ADC comprising a differentiated TF-targeted antibody (HRP07132) conjugated to a proprietary topoisomerase I inhibitor (Dxh, an exatecan derivative) via a protease-cleavable linker. In contrast to most TF-targeting antibodies, the naked HRP07132 does not interfere the interaction between TF and Factor VII or Factor X, has no impact on coagulation function in prothrombin time and thrombin generation assay, therefore reduced bleeding incidence is expected for HRA00184-C004. Meanwhile, HRA00184-C004 exhibited not only potent growth inhibition against multiple TF-expressing cancer cell lines but also bystander-killing effect *in vitro*. HRA00184-C004 also displayed robust and sustained anti-tumor activities in the PDAC HPAFII (TF high), TNBC MDA-MB-231 (TF moderate) and NSCLC H358 (TF low) TF-expressing xenograft models. Furthermore, in cynomolgus monkey, HRA00184-C004 is well-tolerated over a 6-week period with 12 mg/kg dosing every 3 weeks with acceptable PK profile. Notably, neither coagulation disorder nor skin rash was observed, which are superior to the historical NHP data reported by Tivdak. In conclusion, with the encouraging efficacy in preclinical study and promising safety profiles in NHPs, HRA00184-C004 has demonstrated the best-in-class potential and is scheduled to advance into clinical development.

#3129 BYON4413, an *in vivo* active CD123-targeting antibody-drug conjugate, combines effectively with azacitidine and venetoclax in acute myeloid leukemia cell lines.

M. M. van der Lee[1], T. van Achterberg[1], K. Hersmus[1], A. Brouwers-Vos[2], M. van der Vleuten[1], M. Pruis[2], W. Kappers[1], G. Verheijden[1], G. Huls[2], G. van Wigcheren[1], R. Ubink[1], A. Sesink[1], A. MacInnes[1], J. Schuringa[2], W. Dokter[1];

[1]Byondis B.V., Nijmegen, Netherlands, [2]University Medical Center Groningen, University of Groningen, Groningen, Netherlands

Background: CD123, the alpha chain of the interleukin-3 receptor (IL-3Rα), is overexpressed in multiple hematologic malignancies and found particularly highly expressed on the surface of acute myeloid leukemia (AML) cells. Furthermore, increased CD123 expression on leukemic stem cells relative to non-neoplastic hematopoietic stem cells makes CD123 an attractive tumor-associated target for an antibody-drug conjugate (ADC). BYON4413 is an ADC that consists of a novel humanized IgG1 anti-CD123 antibody site-specifically conjugated with Byondis' proprietary duocarmazine linker-drug technology, ByonZine® and ByonShieLD®. The efficacy of BYON4413 is studied as monotherapy and in combination with azacitidine and venetoclax (AZA/VEN), since the AZA/VEN regimen is the standard of care (SOC) for AML patients who are ineligible for intensive chemotherapy.

Method: A panel of CD123+ and CD123- hematological cell lines and AML patient-derived bone marrow mononuclear cells (BMMCs)/peripheral blood mononuclear cells (PBMCs) were utilized in *in vitro* studies to determine the cytotoxic effects of BYON4413. The induction of apoptosis and cell killing by BYON4413 in a triple combination with AZA/VEN was studied *in vitro* using the CD123+ AML cell lines MOLM-13 and MV4-11. AML patient and cell line-derived xenograft models were used to investigate the *in vivo* efficacy of BYON4413.

Results: *In vitro* studies with human AML cell lines show that BYON4413 is highly effective in eradicating CD123+ cells while having little impact on CD123- cells. These results were confirmed *ex vivo* with AML patient-derived BMMCs/PBMCs. BYON4413 effectively killed AML patient-derived blasts while largely sparing healthy hematopoietic cells. The triple combination of BYON4413 with AZA/VEN enhanced both apoptosis and cell killing of AML cell lines compared to the singular BYON4413 treatment. *In vivo* studies demonstrate that BYON4413 is remarkably efficient at reducing the tumor burden in AML patient- and cell line-derived xenograft models.

Conclusions: Preclinical studies show that BYON4413 has potential to be an effective targeted therapy against CD123+ hematological malignancies such as AML. The enhanced efficacy of BYON4413 together with AZA/VEN suggests that a clinical benefit from the triple combination may be achievable and is worth further exploration. A first-in-human dose-escalation and expansion trial with BYON4413, designed to enroll R/R AML and high-risk MDS patients, is scheduled to start in Q2 2024.

#3130 *In vitro* characterization of a novel TROP2-targeting antibody-drug conjugate OBI-992.

T.-M. Kuo, T.-Y. Chang, J.-Y. Huang, W.-C. Tang, C.-J. Lin, Y.-C. Wu, C.-H. Lu, H.-C. Weng, Y.-J. Chen, Y.-H. Tsao, C.-Y. Wei, L. Shen, W.-F. Li, M.-T. Lai; OBI Pharma, Inc, Taipei, Taiwan

BACKGROUND

TROP2, a transmembrane glycoprotein widely expressed on epithelial cancers, has emerged as an attractive target for antibody-drug conjugate (ADC) development. Sacituzumab govitecan, a TROP2 ADC conjugated to topoisomerase inhibitor (TOP1) SN-38, has been approved for patients with triple-negative breast cancer. This study aims to investigate the characteristics of a novel TROP2 antibody (R4702) and its ADC OBI-992, which is derived from the conjugation of R4702 with a TOP1 inhibitor exatecan.

METHODS

Clinical study: Prognostic roles of TROP2 and TOP1 in patients were accessed through the “Kaplan-Meier plotter” database from more than 1055 colon cancer patients.

In vitro study: An ELISA study was conducted to investigate the binding epitope of R4702. Cell binding assay and Surface Plasmon Resonance were carried out to measure non-specific binding activity and binding affinity, respectively. DNA damage activity, cytotoxicity, and immunogenic cell death (ICD) effects of three TOP1 inhibitors exatecan, deruxtecan (Dxd), and SN-38, were evaluated. Cytotoxicity of OBI-992 along with other ADC was measured in both 2D and 3D spheroids cancer cells (gastric cancer NCI-N87, pancreatic cancer Capan1, and prostate cancer DU145). TROP2 and BCRP expression as well as potential mutations in TOP1 were investigated in TROP2 ADCs-induced resistant colon cancer cells. The synergistic effects of the combination of OBI-992 with PARP inhibitors were evaluated.

RESULTS

Clinical study: Positive correlations between high mRNA expressions of both TROP2 (p=0.0075) and TOP1 (p=0.043) with poor overall survival for colon cancer patients were found.

In vitro: The R4702 antibody displayed different binding epitopes from sacituzumab and datopotamab. In addition, R4702 showed lower non-specific binding and better binding affinity to TROP2 antigen than datopotamab. The payload exatecan demonstrated excellent ICD effects. Relatively higher cytotoxicity was observed by exatecan when compared to that of Dxd and SN-38. OBI-992 exhibited excellent activities on cell growth inhibition in 2D cell cultures and 3D cell spheroids. TROP2 down-regulation and BCRP upregulation were not found in OBI-992-induced resistant cells. A mutation R364H was identified in TOP1 in the resistance study with OBI-992, which is critical for the binding to TOP1 inhibitors camptothecin analogs. Finally, a synergistic effect of OBI-992 and PARP inhibitors (talazoparib, rucaparib, niraparib, and olaparib) on the enhancement of cancer cell killing and DNA damage was observed.

CONCLUSION

High expression of both TROP2 and TOP1 is associated with poor survival in patients with colon cancer. R4702 is a novel TROP2 antibody with a unique binding epitope and low non-specific
binding. Exatecan and exatecan-conjugated ADC OBI-992 showed high cytotoxic activities. Combination of OBI-992 with PARP inhibitors have potential in TROP2-expressing malignancies.

#3131 Novel CDH17-targeting antibody-drug conjugate exhibits anti-tumor efficacy in preclinical models of gastrointestinal cancers.

P. Wong[1], L. He[2], K. Chow[1], K. Wong[1], C. O[1], D. Wong[3], J. M. Luk[3], P.-C. Lo[2], K. Wong[1];
[1]Arbele Limited, Hong Kong, Hong Kong, [2]City University of Hong Kong, Hong Kong, Hong Kong, [3]Arbele Corp, Seattle, WA

Antibody-drug conjugates (ADC) for oncology indications have been developed, however, only few of them are approved for the treatment of gastrointestinal (GI) cancers, which represent as a huge unmet medical need. As such, we developed a novel ADC of which monomethyl auristatin E (MMAE), an antimitotic agent, was conjugated to a cadherin-17 (CDH17)-targeting monoclonal antibody via protease-cleavable peptide valine-citrulline linker. CDH17 is highly restricted to the intestinal adherent junctions which is not accessible in healthy individuals. In contrast, it is overexpressed and becomes reachable in over half of the gastric and pancreatic cancer patients and in more than 95% of patients with colorectal cancer, making it a perfect target for ADC. Our ADC is designed to deliver MMAE specifically to CDH17-expressing tumors to exert the cytotoxic effect of MMAE on cancer cell, mitigating the undesired off-target cytotoxicity. LC/MS analysis revealed that MMAE was conjugated in a drug-to-antibody ratio of 4 with a yield of higher than 75%. ELISA showed that the binding of naked antibody and ADC to CDH17 was comparable (EC_{50}, 0.17 nM & 0.3 nM, respectively), indicating the conjugation process did not affect antigen binding. This ADC also bound to different CDH17-expressing cell lines, including pancreatic AsPC1 and gastric AGS (EC_{50}, 2.1 nM & 1.53 nM, respectively). By labelling the ADC with pH-sensitive fluorescent indicator, we illustrated that ADC internalization only occurred in CDH17+ but not CDH17- cells, suggesting the high specificity of the ADC. Similarly, the ADC showed selective killing on CDH17+ cells (EC_{50}, 0.02-0.5 nM), and the data together proposed a positive correlation between ADC internalization level and its cytotoxicity (R^2 = 0.4307). This supported the specificity and safety of the ADC in killing CDH17+ cancer cells only without affecting normal cells. Furthermore, a preliminary *in-vivo* study on subcutaneous AsPC1 xenograft model demonstrated that the ADC significantly suppressed tumor growth without causing any changes in body weight. Our ADC would potentially be a “First-in-class” ADC for the treatment of GI cancers with minimal adverse systemic toxicity. Further pharmacokinetics, safety, and other IND-enabling studies are underway.

#3132 A novel dual drug antibody-drug conjugate targeting hTrop2 has synergetic anti-tumor activity in solid tumor models.

J. Zhu, X. Zhao, E. Li, H. Xu, L. Nie, G. Chen, H. Wang;
BioRay Pharmaceutical Co., Ltd., San Diego, CA

Antibody-drug conjugates (ADCs) are emerging therapeutic agents for targeted cancer treatment with remarkable clinical success. However, tumor heterogeneity and microenvironment complexity are still the major factors contributing to drug resistance, recurrence, and metastasis, which cannot be resolved with a mono therapy strategy. We've developed a novel dual drug ADC (BiADC), BR113, by conjugating an anti-hTrop2 antibody with a drug linker of a Topoisomerase I inhibitor payload, and another drug linker of an immune stimulator. Our studies show that the homogeneous ADC containing two distinct payloads is a new promising drug class, with two different anti-tumor MOAs, synergistic antigen-specific cell killing potency, desirable pharmacokinetic profiles, and minimal toxicity at therapeutic doses. In the cancer cells and human PBMC co-culture assay, BR113 exerts significantly more potent killing on cancer cells than two individual single-drug ADCs and the combination of two single-drug ADCs, which suggested a synergy on anti-tumor effects of this dual-drug ADC. In the xenograft mouse model studies, BR113 exhibits greater treatment effect and survival benefit than the combo of two single-drug ADCs at various doses. This robust superior anti-tumor activity is further confirmed in a hTrop2-MC38 syngeneic model with a prolonged anti-tumor protection against the tumor re-challenge. Finally, the novel BiADC, BR113, is well tolerated in hTop2 humanized mice after repeated administration. Our findings highlight the therapeutic potential of the BiADC format for treating refractory advanced solid tumors. The outstanding anti-tumor activity across various CDX tumor models and its favorable safety profile in mice support further evaluation of the innovative BiADC, BR113.

#3133 A novel bispecific antibody-drug conjugate targeting HER2 and Trop-2 displays potent antitumor activity in a variety of tumor models with promising preclinical characteristics.

H. Zhong, Y. Xiong, H. Huang, Y. Pan, N. Wang, B. Sun, S. Liu, W. Yuan, D. Liu, J. Fang, **H. Bao**;
BiOneCure Therapeutics, Inc., Germantown, MD

Antibody-drug conjugates (ADCs) have exhibited considerable advancements in cancer therapy, though their efficacy is often confined to specific patient subsets or results in modest clinical responses due to low and heterogenous expression of drug targets in tumors. Targeting more than one tumor-associated antigens (TAAs) represents a new strategy to broaden treatment applicability and minimize on-target toxicity of ADC. Our analysis of co-expression of HER2 and Trop-2, two clinically validated ADC targets, in tumors of various histological malignancies manifests the great potential for an ADC simultaneously targeting these two antigens. We describe here a novel bispecific ADC (BIO-201) designed to co-target HER2 and Trop-2. This compound comprises a bispecific anti-HER2/Trop-2 antibody conjugated with a novel topoisomerase I inhibitor via a cleavable linker. BIO-201 demonstrates increased or comparable cell binding and internalization compared to parental antibodies. In in vitro cytotoxicity assays, BIO-201 effectively kills cancer cells with an IC50 in the sub nM range, irrespective of whether they co-express HER2 and Trop-2 or express only one antigen. Co-culture studies reveal that BIO-201 possesses a good bystander killing effect on drug target-negative tumor cells. In vivo studies further demonstrate the superior anti-tumor activity of BIO-201 in various tumor xenograft models, including those expressing different levels of HER2 and/or Trop-2, as well as models resistant to HER-2-targeting therapies. Moreover, BIO-201 exhibits favorable plasma stability, preclinical pharmacokinetics (PK), and toxicity profiles. In conclusion, these findings suggest that the anti-HER2/Trop-2 bispecific ADC, BIO-201, holds significant promise as an effective therapy for a diverse range of cancers, especially those expressing heterogenous levels of HER2 or Trop-2, and has the potential to benefit a broad patient population.

#3134 SDP03923-000-9106, a novel and optimized LIV-1 ADC with superior anti-tumor efficacy in breast cancer xenograft models.

Yanling Gong, Xing Sun, Changyong Yang, Simeng Chen, Wei Zhang, Cheng Liao

Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China

Background: LIV-1, also known as SLC39A6 or ZIP6, is a transmembrane protein belonging to the zinc transporter family. LIV-1 is a promising target for antibody-drug conjugate (ADC) therapy due to its broad expression in tumors and limited normal tissue expression. Ladiratuzumab vedotin, a LIV-1 targeting ADC with payload of MMAE, is now in phase I clinical trial stage and is the only LIV-1 ADC under clinical development worldwide. The preliminary clinical results demonstrated promising efficacy in TNBC (ORR=32%) but no response in HR+/HER2- breast cancer (ORR=0%), and typical MMAE-related adverse events were observed. Herein, we presented a novel LIV-1 directed ADC, SDP03923-000-9106, consisting of a LIV-1 mAb developed in house conjugated to a proprietary topoisomerase I inhibitor via a cleavable linker with an optimized average drug-to-antibody ratio (DAR) of 6.
Method: The *in vitro* binding affinity of SDP03923-000-9106 against LIV-1 protein was measured by Surface Plasmon Resonance (SPR) assays. The expression levels of LIV-1 in different cancer cell lines were detected by flow cytometry and IHC staining. *In vitro* activity against cancer cell lines was analyzed by CellTiter Glo assays following 10 days of treatment. The *in vivo* anti-tumor activities were investigated in both CDX and PDX models of breast cancer.
Results: SDP03923-000-9106 is a novel anti-LIV-1 ADC comprised of a humanized LIV-1 monoclonal antibody conjugated to the potent topoisomerase I inhibitor (a novel exatecan derivative designed by Hengrui with a better liposolubility and cellular permeability) by a cleavable linker. SDP03923-000-9106 had an optimal drug-to-antibody ratio (DAR) of 6 and showed strong binding affinity to LIV-1 and favorable internalization. SDP03923-000-9106 exhibited robust anti-tumor activity in cell lines across breast cancer, esophageal squamous cancer, gastric cancer, prostate cancer and non-small cell lung cancer. In the LIV-1 highly expressed breast cancer cell line of MCF-7, SDP03923-000-9106 demonstrated a strong inhibitory effect with IC_{50} of 5.36 nM. Moreover, in a LIV-1 high-expressing patient-derived xenograft model of breast cancer, SDP03923-000-9106 showed pronounced tumor regression at both doses of 3 and 10 mg/kg and showed stronger anti-tumor activity (TGI: 109%) at the same dose of 3 mg/kg versus BMK-MMAE (TGI: 75%; BMK-MMAE is synthesized by Hengrui using the published structure of Ladiratuzumab vedotin).
Conclusion: In summary, SDP03923-000-9106 is a novel LIV-1 targeted ADC with a highly permeable payload demonstrating great anti-tumor activity across multiple types of tumors in preclinical studies. The promising preclinical data support advancing SDP03923-000-9106 into clinical testing, and Investigational New Drug (IND) application to NMPA has been submitted.

#3135 BSI-730, a bispecific antibody targeting HER2 and PD-L1 for the development of a first-in-class bispecific ADC.

X. Hao[1], H. Li[1], X. F. Liu[2], J. Liu[1], W. Dai[1], Y. Pan[1], H.-H. Hu[1], J. Li[1], S. Xia[1], Q. Lyu[1], **H. M. Davis**[2], M. Chen[1], Z. Peng[1];
[1]Biosion, Inc., Nanjing, China, [2]Biosion USA, Inc., Newark, DE

Background: Antibody-drug conjugates (ADCs) have become a promising therapeutic option for patients with cancer. Bispecific ADCs targeting two tumor-associated antigens have potential differential anti-tumor advantages. HER2 and PD-L1 are co-expressed in some tumor cell types, such as breast cancer, gastric cancer, lung adenocarcinoma and urothelial carcinoma. A bispecific ADC targeting HER2 and PD-L1 should provide therapeutic benefit, particularly for patients with HER2 low cancer. Dual-target mediated cytotoxicity combined with PD-L1 mediated immunotherapy provides an innovative approach for cancer patients.

Experimental procedures: An anti-PD-L1 monoclonal antibody was identified from A/J mice immunized with PD-L1-ECD-Fc and screened by the Biosion proprietary SynTracer® High Throughput Endocytosis Platform. A “knob-in-hole” bispecific antibody, BSI-730, targeting HER2 and PD-L1 was created with trastuzumab and the humanized anti-PD-L1 scFv. Target binding specificity, binding activity, and affinity of BSI-730 were evaluated by protein-based ELISA, cell-based FACS and Biacore-based SPR, and the ligand blocking activity of PD-L1 portion was measured by competitive ELISA and cell-based FACS. The internalization activities on various cancer cell lines with different expression levels of HER2 and PD-L1 were evaluated by using the SynTracer® Platform.

Summary: BSI-730, a HER2/PD-L1 bispecific antibody, showed comparable binding affinity to HER2 as compared to trastuzumab, as well as comparable bioactivity to the parental anti-PD-L1 antibody regarding PD-L1 binding and PD-1/PD-L1 blocking. Based on a cell-based reporter assay, BSI-730 was able to reverse PD-L1 mediated T-cell suppression and exhibited comparable potency to the parental anti-PD-L1 antibody. The internalization of BSI-730 on HER2 low cancer cell lines was stronger than that of trastuzumab whereas the internalization of BSI-730 on HER2 high cancer cell lines was comparable to that of trastuzumab.

Conclusion: BSI-730 is a novel bispecific antibody for the development of a first-in-class bispecific ADC with the potential advantage of increased potency that can be further investigated to treat HER2 and PD-L1 co-expression tumors, particularly HER2 low tumors.

#3136 Towards development of a novel biparatopic trop2-ADC.

Y. Wu, B. Jiang, J. Rivera, F. Wang, J. Zhou, L. Liu, S. Hudson, W. Draper, J. Li, X. Min, H. Chen, **Z. Wang**;
RemeGen Biosciences, Inc., South San Francisco, CA

Background: Trophoblast cell surface antigen 2 (TROP-2) is a member of Tumor-associated Calcium Signal Transducer family (TACSTD2), which is a 35kDa transmembrane protein with 4 N-linked glycosylation sites. The overexpression of TROP2 in various cancers is associated with poor prognosis and increased risk of metastasis. Anti-TROP2 antibody drug conjugates (ADCs) are emerging as an innovative therapeutic intervention for cancer treatment. While these efforts were rewarded by the FDA approval of Trodelvy (Sacituzumab govitecan), a Trop2 targeted ADC, in 2020 for the TNBC patients, tumor heterogeneity could present one of the limitations for the Trop2-targeting therapy, leading to drug resistance. Here, we report our effort in developing a novel biparatopic TROP2 ADC which demonstrate superior cell killing activity compared with the monospecific TROP2 ADC, including certain resistant cell lines for the approved therapy.

Methods: Various biparatopic Abs were engineered using two different mAbs targeting the two non-overlapping epitopes of Trop2. The physical stability and biological activities were characterized. Binding competition assay was utilized for epitope binning using SPR. Cell binding affinity was determined using flow cytometry. Cellular internalization activity was measured using Incucyte system, and tumor cell killing efficacy was evaluated in multiple cancer cell lines. CDX mouse models were utilized to investigate the TROP2-ADC *in vivo* efficacy.

Results: We identified a biparatopic TROP2 mAb using two monospecific TROP2 mAbs with A recognizing the same epitope as Trodelvy, and B binding to a non-overlapping epitope vs Sacituzumab's. mAb-B demonstrates superior ability to recognize a few resistance cell lines to mAb-A. The biparatopic TROP2 mAb-A/B displays a KD of 0.81 nM protein binding compared with 6.42 nM and 0.26 nM, respectively for mAb-A and mAb-B. Importantly, the biparatopic mAb-A/B demonstrates significantly faster cellular internalization activity compared to those of the individual mAbs, signifying the biparatopic scaffold could drive receptor clustering and subsequently enhance the internalization, trafficking to the lysosome and degradation of the target. As expected, the ADC of the biparatopic mAb-A/B conjugated with a TOPi payload shows cancer cell killing efficacy in both *in vitro* and *in vivo* experiments. Furthermore, we tested mAb-A , -B and biparatopic mAb-A/B for their binding affinity to 14 missense mutations in TROP2 ECD expressed in HEK293 cells. Interestingly, mAb-A showed decreased binding in 5 mutant cell lines, while mAb-B and biparatopic mAb-A/B maintains activity.

Conclusion: We have engineered a novel TROP2 biparatopic antibody with unique biological features as well as superior in vitro and in vivo activities. Such a biparatopic ADC presents its potential to be a best-in-class ADC therapy by overcoming the limitation of the monospecific ADC therapy such as drug resistance.

#3137 Development of AT2604, a highly efficacious ADC targeting alkaline phosphatases ALPP and ALPPL2.

B. K. S. Yeung, X. Koh, W. Ling, W. Tan, Y. Wu, X. Zhang, H. Tan, S. Liu, C. Zhong, B. Zou;
Axcynsis Therapeutics, Singapore, Singapore

Placental alkaline phosphatases, ALPP and ALPPL2, are highly homologous, membrane-bound proteins involved in fetal development. Despite having limited expression in normal tissues, they are highly differentiated in tumor cells making them ideal targets for antibody drug conjugate (ADC) development.
AT2604 is an ADC that consists of a humanized IgG1 anti-ALPP/ALPPL2 antibody that displays specificity over other human alkaline phosphatases and is cross reactive to NHP ALPPL2 but not to murine ALPPL2. The anti-ALPP/ALPPL2 antibody shows high target binding affinity and internalization into ALPP and ALPPL2 positive cells. AT2604 utilizes AxcynCYS™ technology for site-specific conjugation to achieve a highly homogeneous (>97%) DAR4 ADC product. The payload is the clinically validated microtubule disrupting agent monomethyl auristatin E (MMAE) conjugated to the antibody via a protease-cleavable peptide linker approved for ADC use.
When evaluated in mouse xenograft models of gastric (NCI-N87) and pancreatic (HPAC) cancer, AT2604 displayed strong tumor growth inhibition (>90%) at 1 mg/kg (QW3x2 dosing) in both models. Furthermore, a pre-tox study in non-human primates concluded AT2604 has a HNSTD of 10 mg/kg (QW3x3 dosing) and did not exhibit any non-reversible adverse effects; implying that AT2604 possesses an improved safety profile over other vedotin-based ADCs. Taken together, the data supports the continued development of AT2604 towards evaluation in human trials.

#3138 Discovery of AT65474, a highly selective anti-CLDN6 ADC with a proprietary payload.

C. Zhong, Y. Wu, X. Zhang, Y. Cheng, Q. Wang, P. Du, S. Liu, B. Zou;
Axcynsis Therapeutics, Singapore, Singapore

CLDN6 is a membrane-bound oncofetal protein and a promising target for cancers such as ovarian and testicular cancer. CLDN6 shares high sequence homology with other CLDN family members which are expressed in normal tissues, making a high degree of selectivity required for CLDN6-targeting therapies. In particular, CLDN6 is closest to CLDN9 in sequence with a difference of only three residues in the extracellular loops, making it challenging to generate a highly selective antibody.

We report the development of a humanized anti-CLDN6 antibody with high affinity and high selectivity for targeted cells which displays > 800-fold higher binding affinity for CLDN6 over CLDN9. The antibody was refined for use as an ADC and incorporates AxcynCYS^{TM} technology for site-specific conjugation which can reproducibly achieve high DAR4 ratios of greater than 97% by HIC analysis. AT65474 is an ADC candidate that incorporates a proprietary payload derived from an FDA approved drug that was optimized in-house for increased potency and improved PK properties to limit systemic exposure. In vitro, the payload displays broad sub-nanomolar activity across a wide range of cancer cell lines including those resistant to paclitaxel, DM1, MMAE and DXd. The payload is conjugated via an enzyme-cleavable linker optimized for solubility, stability, and high drug to antibody ratios.

We provide evidence characterizing AT65474 as a highly potent ADC with high DAR4 homogeneity and strong in vivo activity at low doses. Compared with a benchmark ADC in clinical development, AT65474 shows stronger binding, higher internalization, superior in vitro cytotoxicity, and stronger bystander killing effect. When evaluated in PA-1 and OV90 xenograft models of ovarian cancer, AT65474 displays significantly higher efficacy over the benchmark ADC. Furthermore, we show that AT65474 displays an ADCC effect that contributes to tumor suppression in the OV90 model. AT65474 was shown to be well tolerated in all xenograft mouse models and a pre-tox study in non-human primates. The combined data support further development of AT65474.

#3139 BL-M11D1, a novel CD33-targeting ADC, demonstrates robust anti-tumor efficacy in preclinical evaluation.

W. Wan[1], S. Zhao[1], S. Zhuo[1], Y. Zhang[1], L. Chen[1], R. Li[1], **J. S. Khalili**[2], X. Sa[1], Y. Yan[2], X. Shen[1], Y. Zhu[2];
[1]Sichuan Baili Pharmaceutical Co., Ltd., Chengdu, China, [2]SystImmune Inc., Redmond, WA

CD33, is a transmembrane receptor expressed on cells of myeloid lineage. It is therapeutically targeted in cancer due to overexpression broadly among hematopoietic malignancies including AML. To develop a promising therapeutic anti-tumor agent, we generated BL-M11D1, a CD33-Ed-04 ADC. It is built on gemtuzumab, a specific monoclonal antibody against CD33, having a wt Fc that can mediate ADCC in vitro. BL-M11D1 is composed of gemtuzumab, a cathepsin B cleavable linker, and a novel topoisomerase I inhibitor agent (Ed-04). The novel Ed-04 is a derivative of the alkaloid camptothecin and mediates cell cycle arrest at the S phase and subsequent apoptosis. BL-M11D1 achieves a high drug-to-antibody-ratio (DAR=8) with a highly stable linker and is readily internalized and trafficked to lysosomal cellular compartments. The antitumor efficacy of BL-M11D1 was evaluated in xenograft tumor models. BL-M11D1 exhibited strong tumor inhibition capacity toward the human hematopoietic malignancies engrafted xenograft models. In summary, these studies suggest BL-M11D1, a novel CD33-targeting ADC, is potentially efficacious in the treatment of CD33-expressing disease. The clinical phase I trial is being undertaken to evaluate safety, dosing and observations of preliminary signs of efficacy.

#3140 BL-M05D1, a novel claudin 18.2-targeting ADC, demonstrates specific potent anti-tumor efficacy in preclinical evaluation.

W. Wan[1], K. Dinkel[2], A. Sanford[2], S. Zhao[1], S. Zhuo[1], Y. Zhang[1], L. Chen[1], R. Li[1], **J. S. Khalili**[2], X. Sa[1], Y. Yan[2], X. Shen[1], Y. Zhu[2];
[1]Sichuan Baili Pharmaceutical Co., Ltd., Chengdu, China, [2]SystImmune Inc., Redmond, WA

Claudin 18.2, is a member of the tight junction protein family, and an isoform of claudin18. It is therapeutically targeted in cancer due to its limited expression in normal tissue and prevalent expression in a variety of human carcinomas. To develop a promising therapeutic anti-tumor agent, we generated BL-M05D1, an anti-Claudin 18.2-Ed-04 ADC. It is comprised of a novel, specific monoclonal antibody against Claudin 18.2 (5103F3), having a wt Fc that can mediate ADCC and CDC in vitro. BL-M05D1 is composed of (5103F3), a cathepsin B cleavable linker, and a novel topoisomerase I inhibitor agent (Ed-04). The novel Ed-04 is a derivative of the alkaloid camptothecin and mediates cell cycle arrest at the S phase and subsequent apoptosis. BL-M05D1 achieves a high drug-to-antibody-ratio (DAR=8) with a highly stable linker and is readily internalized and trafficked to lysosomal cellular compartments. The antitumor efficacy of BL-M05D1 was evaluated in xenograft tumor models. BL-M05D1 exhibited strong tumor inhibition capacity toward the human gastric cancer cell MKN-45-Claudin18.2 (#C11D) xenograft model, and human pancreatic cancer cell Patu8988s-Claudin18.2 (#C7G) xenograft model. In summary, these studies suggest BL-M05D1, a novel Claudin 18.2-targeting ADC, is potentially efficacious in the treatment of Claudin 18.2-expressing carcinomas. The clinical phase I is being undertaken to evaluate safety, dosing and observations of preliminary signs of efficacy.

#3141 LCB02A an antibody drug conjugate (ADC) targeting CLDN18.2 expressing solid tumors.

E. Baek, C.-W. Chung, C. Park, T. Jang, Y. Jeong, S.-A. Lee;
LegoChem Biosciences, Yuseong-gu, Korea, Republic of

Claudin18.2 (CLDN18.2) is an isoform of CLDN18 with very limited expression in gastric epithelial cells in normal tissues, and aberrant overexpression in gastric, pancreatic, esophageal, ovarian, lung, and other solid tumors. This expression pattern presents a significant hurdle in developing an ADC targeting CLDN18.2 due to potential on-target toxicity to the gastrointestinal (GI) tract. LCB02A is an antibody-drug conjugate (ADC) that targets CLDN18.2, composed of a topoisomerase 1 inhibitor (TOPO1i) as payload (DAR4) linked to the CLDN18.2 specific binding PR301839 hClaudin18.2 (CLDN18.2) is an isoform of CLDN18 with very limited expression in gastric epithelial cells in normal tissues, and aberrant overexpression in gastric, pancreatic, esophageal, ovarian, lung, and other solid tumors. In conclusion, LCB02A is a promising ADC for the treatment of CLDN18.2 expressing solid tumors including gastric cancer (GC) and pancreatic ductal adenocarcinoma (PDAC).

#3142 NN3201, a novel c-Kit targeting ADC, exhibits robust preclinical anti-tumor efficacy in SCLC and GIST models.

C. Kim, J. Cho, T. Wi, J. Moon, H.-J. Ko, J. Lee, J. Park, Y. Lee, S. Kim, J.-O. Kim, **J. Song**, S.-H. Lee, S. Park;
Novelty Nobility, Inc., Seongnam-si, Korea, Republic of

c-Kit (CD117) is a type III receptor tyrosine kinase (RTK), which is known to be activated upon binding to its cognate ligand stem cell factor (SCF) to induce critical signaling pathways involved in cell proliferation, survival, and differentiation. Indicative of poor prognosis, overexpression and activating mutations of c-Kit have been implicated in a variety of human cancers including small cell lung cancer (SCLC), gastrointestinal stromal tumors (GIST), and acute myelogenous leukemia (AML). While imatinib, a small molecule c-Kit inhibitor, has been a beneficial treatment for GIST, resistance eventually develops to the drug, moreover, shows limited efficacy in c-Kit overexpressing tumors such as SCLC. Herein, we developed NN3201, a novel c-Kit targeting antibody-drug conjugate (ADC), comprised of fully human 2G4 antibody with a picomolar binding affinity to c-Kit and cytotoxic monomethyl auristatin E (MMAE) as the payload. NN3201 displayed potent *in vitro* cytotoxicity in various wild-type and mutant c-Kit positive SCLC and GIST cell lines with IC_{50} in the nanomolar range. In addition, NN3201 was rapidly internalized and inhibited c-Kit-mediated signaling., NN3201 treatment resulted in the increased proportions of the sub G1 and G2/M in the c-Kit positive cancer cell lines, indicating that release of MMAE induced cell cycle arrest. Moreover, bystander effect was confirmed by co-culturing c-Kit high and negative cell lines. Most importantly, in mouse xenograft models, NN3201 showed a remarkable tumor growth inhibition of several wild type, mutant c-Kit positive, and imatinib resistant SCLC and GIST cell lines. Enhanced anti-tumor activity and delayed tumor growth were observed in an SOC-treated (etoposide and carboplatin) SCLC xenograft model, by NN3201 in comparison to second line SOC (topotecan or irinotecan). In the GLP study, repeated intravenous administration of NN3201 was well tolerated at all doses (0.5, 1, 2 mg/kg Q3Wx3) without unscheduled death. Dose-dependent, yet transient, cytotoxicity of NN3201 was observed in the bone marrow. We confirmed HNSTD (Highest Non-Severely Toxic Dose) of NN3201 to be 2 mg/kg through exploratory and GLP repeat dose toxicity studies as no serious irreversible toxicity was observed. Accumulating data suggest that NN3201 is a promising therapeutic alternative for the treatment of SCLC and GIST regardless of wild-type or activating mutations in c-Kit.

#3143 The ADC payload PNU-159682 is highly active in a wide range of cancer indications by inducing DNA damage and cell death via a distinct mode of action.

M. Kaiser[1], U. Fiedler[1], D. Gerlach[2], N. Kraut[2], L. Bammert[1];

[1]NBE Therapeutics, Basel, Switzerland, [2]Boehringer Ingelheim, Vienna, Austria

During the last decade antibody-drug-conjugates (ADCs) have become an important and validated treatment modality for cancer patients. Here, we introduce a unique next generation ADC platform based on Sortase-mediated antibody conjugation (SMAC-Technology) yielding in very homogenous and stable drug conjugates with limited systemic, but powerful anti-tumor activity. The highly potent payload used is a proprietary derivative of the Anthracycline PNU-159682. Our PNU-159682-based ADCs are known to not only induce DNA damage in the target cell, but importantly also trigger immunogenic cell death and thus, stimulating anti-tumor immunity offering untapped combination potential. ADCs based on the SMAC-Technology platform currently undergo clinical development. In this work, we present functional studies that were performed to further elucidate the mode of action (MoA) of the ADC payload PNU-159682 and to investigate any potential liabilities with respect to sensitivity, which could limit treatment options for cancer patients. Flow cytometry-based readouts verified that PNU-EDA, a derivative of PNU-159682, is a highly potent inducer of DNA damage, cell cycle arrest and cell death. Interestingly, PNU-EDA arrests cells and inhibits DNA synthesis in S-phase in contrast to other Anthracyclines such as Doxorubicin, which leads to a block in the G2/M-phase. High-throughput cell line panel sensitivity screens confirmed that the activity of PNU-EDA is broad and not restricted to specific cancer indications. Notably, a correlation between lower potency and increased ABCB1 (MDR1) expression levels was observed for PNU-EDA, but not for parental PNU-159682. More detailed mechanistic insights were obtained by performing a genome-wide CRISPR-Cas9 KO screen, which revealed a partial dependency of the PNU-EDA potency on the proficiency of the TC-NER DNA damage repair mechanism. This finding further highlights a distinct MoA of PNU-159682 compared to Doxorubicin or other DNA-targeting compounds such as Cisplatin. Overall, our screens and mechanistic studies verified that PNU-159682-based ADCs efficiently kill cancer cells via a particular MoA and thereby, offer highly promising therapeutic options to a diverse and large population of cancer patients.

#3145 HRA00242-C004, a novel anti-PSMA ADC with high DAR reveals potent *in vitro* and *in vivo* anti-tumor efficacy.

G. Lin, H. Zhang, Z. Xu, L. You, Z. Xue, Y. Mao, X. Yang, B. Hu, S. Lin, J. Feng, Z. Zhang, X. Ye, M. Hu, F. He;
Shanghai Hengrui Pharmaceutical Co., Ltd., Shanghai, China

Prostate cancer (PCa) is the second most common cancer, and it is the fifth leading cause of cancer-related death among men. The incidence rates of PCa are 37.5 per 100,000 in developed countries and 11.3 per 100,000 in developing countries, while mortality rates are 8.1 per 100,000 in developed countries and 5.9 per 100,000 in developing countries[1]. As androgen receptor (AR) signaling plays an essential role in PCa initiation and disease progression, androgen deprivation therapy (ADT) has been a backbone of treatment for patients with advanced disease[2]. However, patient responses to ADT vary, and most patients eventually develop castration-resistant prostate cancer (CRPC) which remains large unmet clinical need[3]. Prostate-specific membrane antigen (PSMA), a transmembrane glycoprotein located on the cell membrane, is specifically and highly expressed in PCa with an extremely low expression level in non-prostatic tissues[4], which makes it an ideal target for the treatment of PCa[5].Here, we presented a PSMA-directed ADC, HRA00242-C004, which features a differentiated topoisomerase I inhibitor payload DXh conjugated via a cleavable linker to a humanized anti-PSMA IgG1 antibody (HRP04732). HRP04732 showed good binding affinity in both protein and cell-level assays, and a better cell internalization profile when compared with the reference antibody (AB-PG1-XG1-006, published sequences from US8114965B2). HRA00242-C004 exerted strong inhibition effect on cell lines with different PSMA expression levels. *In vivo* efficacy study, HRA00242-C004 showed potent anti-tumor activity in PSMA medium expression human prostate cancer 22RV1 xenograft model without significant weight loss during the experiments. Moreover, HRA00242-C004 demonstrated satisfactory PK profiles in SD rats and cynomolgus monkeys without any toxicity observed in PK assays. Compared with AB-PG1-XG1-006-DXh (the reference ADC), HRA00242-C004 exhibited a longer elimination half-life as well as higher serum exposure level of both the total antibody and the intact ADC. Meanwhile, as employing the same linker-payload as SHR-A1811, HRA00242-C004 has potential good plasma stability which was consistent with the results of PK study. In summary, with a highly permeable payload, high DAR, potent *in vitro* and *in vivo* anti-tumor efficacy, HRA00242-C004 demonstrated the best-in-class potential.

1.CA Cancer J. Clin. 2021, 71, 209-249.2.Nat. Rev. Urol. 2019, 16, 645-654.3.J. Clin. Oncol. 2015, 33, 1151-1156.4.World J Surg. 2006; 30: 628-36.5.Front Oncol. 2018; 8: 653-63.

#3146 HRA00130-C004, a novel anti-DLL3 ADC with bystander effect, high DAR and favorable safety profiles.

Q. Yao, C. Xue, Z. Xu, L. You, Z. Xue, Y. Mao, S. Lin, J. Feng, Z. Zhang, X. Ye, M. Hu, F. He;
Shanghai Hengrui Pharmaceutical Co., Ltd., Shanghai, China

Small Cell Lung Cancer (SCLC) is a highly aggressive neuroendocrine tumor, accounting for ~15% of all new lung cancer cases[1]. It is estimated that there are 250,000 new SCLC cases and at least 200,000 deaths globally each year[2]. SCLC exhibits high recurrence after first-line treatment, poor response to subsequent therapies, and rare survival[3]. Lacking of recommended treatments for prolonging survival remains a problem over decades[4]. DLL3 is an inhibitory ligand of the Notch receptor. It binds to its Notch receptor through a cis-interaction, thus, mediates inhibition of Notch pathway to facilitate neuroendocrine tumorigenesis[5]. DLL3 is highly upregulated and aberrantly expressed on the cell surface in SCLC and other high-grade neuroendocrine tumors with limited expression in normal tissues[6].Here we presented a DLL3-directed ADC, HRA00130-C004, which features a differentiated topoisomerase I inhibitor payload DXh conjugated via a cleavable linker to a humanized IgG1 antibody. HRA00130-C004 strongly inhibited the proliferation of cell lines with different DLL3 expression. In the bystander killing assays, HRA00130-C004 was able to kill both DMS53 cells (DLL3 over-expressed) and U-2OS (DLL3-negative) cells when they are co-cultured. The *in vivo* treatment of HRA00130-C004 resulted in a dramatic and sustained inhibition of tumor growth in H1184 (DLL3 high) and DMS53 (DLL3 low) xenograft models. No obvious weight loss was observed during the experiment. Furthermore, HRA00130-C004 demonstrated a favorable PK profile and satisfactory molecular integrity in rats with 3mg/kg dosing and cynomolgus monkeys with 10 mg/kg dosing. The exposure of total antibody and intact ADC was consistent. Moreover, HRA00130-C004 was well tolerated in rats and cynomolgus monkeys with no related adverse findings, which indicated its favorable safety profiles. In summary, taking advantage of Hengrui's DXh platform, HRA00130-C004 has demonstrated great potency and good safety profiles. These data support the future clinical development of HRA00130-C004.

#3147 DXC025, a novel anti-MUC1/EGFR bispecific antibody-tubulysin conjugate with a function linker, exhibits potent anti-tumor efficacy.

Xingyan Jiang, Junxiang Jia, Huihui Guo, Xiangfei Kong, Yongfang Xu, Sishi Ye, Yong Du, Zhicang Ye, Qikuang Cen, Lingli Zhang, Yongxiang Chen, Gaituo Chen, Lu Bai, Yunxia Zheng, Wei Zheng, Jun Zheng, Juan Wang, Wenjun Li, Yuanyuan Huang, Linyao Zhao, Yifang Xu, Mengmeng Liu, Binbin Chen, Meng Dai, Miaomiao Chen, Zhixiang Guo, Qingliang Yang, **Robert Y. Zhao**

Hangzhou DAC Biotechnology Co., Ltd., Hangzhou City, China

Antibody-drug conjugates (ADCs) have become a promised drug class in cancer therapy. Armed with three main components-an antibody, a linker molecule, and a cytotoxic agent (“payload”), plus sites of the antibody conjugation and the distribution of tumor-associate antigens, nowadays ADCs have proved the unique ability of the precision of targeted therapy, a great leap forward from traditional chemotherapeutic approaches that cause widespread effects without specificity. Both epidermal growth factor receptor (EGFR) and mucin 1 (MUC1) are tumor-associated antigens (TAA) that are co-expressed in many solid tumors, such as, colon cancer, non-small cell lung cancer (NSCLC), esophageal cancer, epidermal cancer, and pancreatic cancer. In particular, MUC1, a glycoprotein essential for the formation of the epithelial mucous barrier, is hypoglycosylated and dimerizes with EGFR, a potent oncoprotein, in transformed cells. For our anti-Muc1 ADC clinical program, for treatment of colon and pancreatic cancers, it was found out that the highly glycosylated transmembrane Muc1 had much more turning over rates on the luminal surface of epithelial cells. Here, we first designed and generated bispecific Fab/scFv antibodies targeting both MUC1 and EGFR, using the knob-into-hole technology. The addition of the affinity- and internalization-optimized anti-EGFR arm to the other single Muc1 arm was aimed to broaden tumor selectivity and to reduce on-target toxicity, for the treatment of gastrointestinal tumors in comparison to individual full IgG1-ADC, either EGFR or Muc1-ADC. Indeed, many of generated anti- MUC1/EGFR bispecific antibodies (BsAbs) showed strong binding affinity in $MUC1^{modetate}EGFR^{modetate}$ cells, in addition to both MUC1 and EGFR highly expressed cells. Internalization assays demonstrated that the BsAbs were endocytosed in tumor cells co-expressing EGFR and MUC1 more efficiently than monoclonal antibodies targeting MUC1. The selected BsAbs were subsequently conjugated with tubulysin B analogs with varieties of Tubulysin B analog payloads and function peptidyl spacer/linkers to generate bispecific ADC (DXC025) candidates. DXC025 candidates exhibited very potent cytotoxicity in vitro against epidermal cancer, lung adenocarcinoma, and pancreatic cancer cell lines with IC_{50} of single or tens digital pM. In in vivo cell-derived xenograft (CDX) models, DXC025 candidates demonstrated much superior efficacies of tumor growth inhibition in comparison with parental (monoclonal), either Muc1- or EGFR- ADC for the treatment of gastrointestinal tumors. These results indicated that the MUC1/EGFR-ADC (DXC025) would be a promising ADC candidate for targeted treatment of either Muc1- or EGFR-expressing gastrointestinal tumors.

#3148 ABBV-706 is a novel SEZ6-targeted topoisomerase 1 inhibitor ADC for SCLC and other neuroendocrine cancers.

E. J. Faivre[1], M. A. Pysz[2], E. O hAinmhire[1], L. Kreckler[1], K. Doyle[1], A. D'Souza[2], Z. Ding[2], T. Sondkar[2], D. Maji[2], F. Zhao[1], A. Phillips[1];
[1]AbbVie Inc., North Chicago, IL, [2]AbbVie Inc., South San Francisco, IL

Lung cancer has the highest rates of incidence (2.1 million cases/year) and mortality (1.8 million deaths/year) among all cancers worldwide. Approximately 15% of lung cancers are small cell lung cancer (SCLC). SCLC is typically diagnosed at late stages, with approximately 70% of patients having extensive stage disease at time of diagnosis. Unfortunately, these patients have a dismal 5-year survival rate of approximately 3%. In contrast to non-small cell lung cancer (NSCLC), there has been little advancement in the treatment of SCLC, with no biomarker directed therapies available for patients. SEZ6 is overexpressed in most SCLC's and other neuroendocrine tumor types. This overexpression and limited normal tissue expression suggest SEZ6 would be a good target for the development of an antibody drug conjugate (ADC). Validation of SEZ6 as an ADC target was supported by signs of clinical activity for ABBV-011, a SEZ6-targeting calicheamicin ADC. Preclinical and clinical data suggest an increased therapeutic index for Top1i ADCs relative to calicheamicin ADCs. Furthermore, Top1i inhibition is an effective mechanism of action in SCLC with topotecan approved in 2L, although significant toxicity limits broad utility. As such, we hypothesized that a SEZ6-Top1i ADC would enable effective Top1 inhibition in tumor cells and reduce toxicity relative to ABBV-011 or systemic chemotherapy, driving increased therapeutic benefit. ABBV-706 is an ADC comprised of the same SEZ6 targeting antibody as ABBV-011 conjugated to AbbVie's topoisomerase-1 (Top1) inhibitor. ABBV-706 is a potent anti-proliferative agent in SEZ6 positive SCLC cell lines, with sub- to low-nanomolar activity. SEZ6 dependence was demonstrated by the correlation of SEZ6 mRNA expression to ABBV-706 growth inhibition. On-target Top1i activity was confirmed in cells treated with ABBV-706 as measured by dose-dependent induction of γ-H2AX, a marker of DNA damage, and G2/M arrest. ABBV-706 possessed superior anti-tumor activity compared to ABBV-011 in a panel of SCLC cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models with a range of SEZ6 expression levels. In addition, ABBV-706 had activity in the setting of resistance to cisplatin/etoposide (1L SoC in SCLC), in combination with cisplatin, and in SEZ6-expressing neuroendocrine liver and cervical PDX models. ABBV-706 has favorable pharmacokinetics and is well-tolerated in cynomolgus monkeys with bone marrow and gastrointestinal tract toxicities common to other Top1 inhibitors. ABBV-706 shows promise as an agent for the treatment of SCLC and other difficult to treat SEZ6 expressing neuroendocrine tumors. ABBV-706 has completed dose escalation, and dose expansion is currently ongoing in a Phase 1 FIH clinical study (NCT05599984).

#3149 Development of a novel site-specific ADC glycan platform with potential for improved *in vivo* efficacy and stability of the ADC in animal studies.

T.-Y. Huang, Y.-C. Hsieh, K.-S. Fung, Y.-C. Huang, C.-S. Shia, M.-F. Chiang, N.-H. Wang, W.-F. Li, M.-T. Lai;
OBI Pharma, Inc., Taipei, Taiwan

Antibody-drug conjugates (ADCs) represent a promising modality for delivering cytotoxic drugs to targeted tumor cells while avoiding off-tumor toxicities. Despite successes in the past 20 years, development of effective ADCs with broad therapeutic window remains challenging due to the complexity of conjugation technologies and the instability of the linkers. Most platforms currently in the market as well as under clinical development may face limitations ascribed to the heterogeneity of ADCs with various drug-to-antibody ratio (DAR). This likely resulted from random conjugation and poor overall biophysical characteristics caused by linker hydrophobicity. The limitations may impact the efficacy, safety, bioavailability, and the robustness of manufacturing process of these therapeutic agents. OBI developed a unique glycan ADC platform (GlycOBI) to enable a site-specific conjugation, which is in a 'Plug and Play' format and compatible with any antibodies, linkers, and payloads in various DAR. This is an efficient and scalable process to generate homogenous ADCs. This platform overcomes the limitations of traditional ADCs, resulting in the improvement of efficacy and stability. We developed a non-genetic, engineering-free approach to generate site-specific homogenous ADCs. This was achieved by utilizing OBI proprietary enzymatic technology (EndoSymeOBI), followed by the click chemistry to conjugate the hydrophilic linker-payload via the glycan site that naturally occurs on the antibody's Fc region. The conjugation process avoids disrupting the antibody structure, ensuring the related ADC has similar biophysical characteristics compared to native antibody. Furthermore, OBI linker technology improves the conjugation efficiency of the payload, as well as reduces the aggregation propensity, and expands the half-life of the ADC products. Anti-TROP2 and anti-HER2 ADCs are developed based on OBI glycan ADC platform (GlycOBI) using a topoisomerase I inhibitor, exatecan, as the payload. Both ADCs demonstrated greater chemical stability in serum stability studies compared to competitor ADCs. Additionally, they showed broad activity against different cancer cell lines in vitro as well as in mouse xenograft models. The preclinical data presented here suggest that GlycOBI is an outstanding ADC platform to improve the performance of ADCs. Further investigations, including studies in the clinical settings, are warranted.

#3153 Regulation of ATF4-mediated stress responses by NUAK2 in ovarian cancer.

Li Chen[1], Oscar GW Wong[1], Claire LY Cheung[1], Esther SY Wong[1], Karen KL Chan[2], Hextan YS Ngan[2], **Yusanne YS Chan**[1], Annie NY Cheung[1]

[1]Department of Pathology, The University of Hong Kong, Hong Kong, China, [2]Department of Obstetrics & Gynaecology, The University of Hong Kong, Hong Kong, China

NUAK family kinase 2 (NUAK2) a member of the AMPK-related serine/threonine kinase family with crucial roles in various cancer cellular processes. The aim of this study was to elucidate the expression and functions of NUAK2 in ovarian cancer while investigating the underlying molecular mechanisms. Analysis of several publicly available databases suggested a significant increase in NUAK2 mRNA levels in ovarian cancer compared to normal tissue. The overexpression of NUAK2 in ovarian cancer was confirmed by immunohistochemistry of NUAK2 in our local collection of ovarian tumor tissues comprised of carcinomas of various histological types (N=88) as well as benign and borderline tumors (N=19). Intense nuclear NUAK2 immunoreactivity was observed in serous and clear-cell carcinomas. Furthermore, nuclear expression of NUAK2 was significantly correlated with higher tumor grade and poorer overall and disease-free survival. Knocking out NUAK2 in SKOV3 cells by CRISPR-Cas9 resulted in suppressed cell growth and migration. Transcriptome by RNA sequencing and pathway enrichment analysis of SKOV3 cells overexpressing NUAK2 revealed activation of activating transcription factor 4 (ATF4) -dependent unfolded protein response (UPR) in the cell. NUAK2 knockout exaggerated the reactive oxygen species level induced by the endoplasmic reticulum (ER) stress inducer tunicamycin treatment. NUAK2 upregulated ATF4 protein expression during ER stress, facilitating its translocation into the nucleus upon exposure to tunicamycin. SKOV3 with NUAK2 knockout grew significantly slower than its parental line in mice as demonstrated by *in vivo* imaging. Collectively, our study highlights NUAK2 as an oncogene in ovarian cancer and underscores its involvement in the UPR pathway.

#3154 The role of nuclear kinases in pancreatic carcinogenesis.

K. LaRue[1], A. Sigafoos[2], L. Flores[1], B. Tader[1], M. Fernandez-Zapico[1];
[1]Mayo Clinic Graduate School of Biomedical Sciences, Rochester, MN, [2]Mayo Clinic Department of Oncology, Rochester, MN

Pancreatic ductal adenocarcinoma (PDAC), the most common histological subtype of pancreatic cancer, is a devastating disease predicted to be the second leading cause of cancer deaths in the next 15 years. Thus, there is an urgent need to develop new treatment approaches based on a better understanding of cellular and molecular mechanisms controlling this dismal progression. PDAC development is marked by nuclear morphological changes likely resulting in changes in chromatin organization and gene expression. Oncogenic KRAS, present in more than 90% of tumors, plays a key role in disease initiation and progression and is sufficient to induce these nuclear morphology changes. Work from our lab has identified the nuclear lamina protein Emerin as a mediator of KRAS-induced nuclear morphology changes. Further, a BioID experiment identified a KRAS-induced interaction of Emerin with a group of nuclear kinases belonging to the ribosomal S6 kinase (RSK) and mitogen- and stress- activated protein kinase (MSK) families. *In silico* analysis identified candidate MSK and RSK phosphorylation sites in Emerin. Thus, we hypothesize that the nuclear kinase families RSK and MSK can act as effectors of the KRAS-Emerin axis to regulate PDAC nuclear morphology. Further studies will be done to confirm if Emerin can be phosphorylated by RSK and MSK, and to validate that this relationship is dependent on oncogenic KRAS signaling and if its nuclear morphological changes are regulated by this GTPase. Overall, this work aims to define a novel signaling axis for RSK and MSK in controlling nuclear dynamics that play a role in disease progression of PDAC, which can lead to the identification of new therapeutic targets.

#3155 Metabolic stress induces an intrinsic inflammatory CAF phenotype that regulates stromal architecture in pancreatic cancer.

Y. Zhang[1], S. Maganti[2], J. Hope[2], L. Lin[2], C. Galapate[2], F. Carrette[2], L. Bradley[1], C. Commisso[2];
[1]Sanford Burnham Prebys Med. Discovery Inst., San Diego, CA, [2]Sanford Burnham Prebys Medical Discovery Institute, San Diego, CA

Macropinocytosis is a critical amino acid supply pathway that fuels the metabolism of tumor cells and cancer-associated fibroblasts (CAFs) in pancreatic ductal adenocarcinoma (PDAC). PDAC tumors are deficient in glutamine, a critical amino acid that tumor cells and CAFs use to sustain their cellular fitness. We have previously shown that both PDAC cells and CAFs stimulate macropinocytosis as an adaptive response to glutamine depletion. How these linked metabolic mechanisms might co-operate to control stromal architecture remains elusive. In this study, we employed glutamine starvation and 5-(N-ethyl-N-isopropyl)-amiloride (EIPA), a selective inhibitor of macropinocytosis, to investigate how metabolic stress impacts the tumor microenvironment. We find that concomitant suppression of glutamine metabolism and macropinocytosis synergizes to drive an intrinsic inflammatory CAF phenotype that requires metabolic stress-induced ERK/MAPK signaling. Utilizing immunocompetent syngeneic mouse models of PDAC, we find that blocking macropinocytosis in these glutamine-depleted tumors diminishes tumor growth and reorganizes the tumor stroma by decreasing collagen deposition, increasing vasculature expansion and enhancing the infiltration of both CD8+ and CD4+ T cells. Alterations in the stromal landscape under these conditions are linked to the enhancement of CAFs that display an inflammatory signature while simultaneously suppressing more myofibroblastic identities within the tumor. Interestingly, we find that these effects on the tumor microenvironment can be harnessed to improve therapeutic responses. We determine that combining macropinocytosis inhibition with immune checkpoint blockade reduces PDAC tumor burden and significantly inhibits metastasis. We also find that macropinocytosis inhibition enhances drug delivery, thereby improving the efficacy of gemcitabine chemotherapy. Our findings demonstrate that intratumoral metabolic stress plays a critical part in preserving and modulating the tumor stroma.

#3156 Unveiling the functional role of HDGFRP3 in pediatric medulloblastoma: Implications for growth, progression, and radioresistance.

S. S. R. Nirzhor, P. Pitta Venkata, S. Abdulsahib, P. Subbarayalu, S. Timilsina, M. K. Rao;
UT Health Science Center at San Antonio, San Antonio, TX

Introduction: Medulloblastoma (MB) is the most common malignant brain cancer in children. Although long-term survival has improved in recent years, only a modest percentage of patients survive high-risk disease. The quality of life for those who survive is substantially reduced due to the high toxicity associated with the radiation and chemotherapy. Therefore, identification of safe and potent therapeutic approaches that can sensitize the therapy response in MB without inducing toxicity will lead to more efficient treatment of MB patients. We recently discovered that targeting HDGFRP3, a protein highly expressed in MB, and can block MB growth and improve the efficacy of radiation therapy. HDGFRP3 is a multifaceted protein that plays important roles in diverse cellular processes. Our investigation sheds light on the functional role of HDGFRP3 in MB, focusing on its involvement in growth, progression, and radioresistance where we report HDGFRP3 as a novel oncogenic driver of these processes.
Methods: Human MB cell lines (DAOY, D556, D425, and HDMB03) were purchased from the American Type Culture Collection and cultured in standard medium. MB cancer cells were transfected with siRNA specific to HDGFRP3. These knockdown cells were analyzed for cell viability, migration, invasion, colony formation, stemness, cell cycle, apoptosis assays for functional role assessment. Real-time qPCR and western blotting were performed to validate the downstream targets of HDGFRP3 in MB models.
Results: Our findings demonstrate that HDGFRP3 functions as an oncogene in MB, as its overexpression promotes cancer growth, while its depletion results in decreased tumor growth in MB models. Furthermore, we provide evidence that HDGFRP3 knockdown results in decreased migratory potential of MB cells as well as a reduction in stemness. Interestingly, HDGFRP3 depletion improved the efficacy of standard of care radiation in multiple MB models. At present, in vivo studies are validate the oncogenic role of HDGFRP3 in preclinical animal models of MB.
Conclusions: In conclusion, our data suggests HDGFRP3 facilitates MB growth, progression, stemness as well as resistance to radiation therapy. Our comprehensive investigation into HDGFRP3's functional role in MB presented here provides valuable insights into its potential as a therapeutic target and opens avenues for further research into novel treatment strategies for the pediatric brain tumors.

#3157 The crosstalk between STAT3 and p53/ERK signaling regulates brain metastasis.

S. L. Zeller, E. Spirollari, J. V. Wainwright, S. J. Hanft, C. D. Gandhi, **M. Jhanwar-Uniyal**;
New York Medical College/WMC, Valhalla, NY

Brain metastasis (BM) affects approximately 10% of cancer patients with metastatic disease, representing a major cause of morbidity and mortality. BM is a complex multi-step process involving various immune checkpoint proteins. Mitogen-activated protein kinase (MAPK), particularly extracellular signal-regulated kinases 1/2 (ERK1/2), and signal transducer and activator of transcription 3 (STAT3) are implicated in tumorigenesis and are critical upstream regulators of Programmed Death Ligand 1 (PD-L1) expression, a common immunotherapy target. Tumor suppressor p53 is shown to regulate STAT3 and ERK1/2 signaling, which are dysregulated in various malignancies. We hypothesize that p53 along with STAT3 and ERK1/2 play a critical role in the initiation and maintenance of BM. Twenty-six BM tumors with various primary sites of origin were used following IRB guidelines. $pSTAT3^{Tyr705}$, $pERK1/2^{Thr202/Tyr204}$, mutant p53 ($p53^{mt}$), and PD-L1 expression was determined by immunohistochemistry. Gene expression analysis of BM was performed on a cDNA microarray. Human brain metastatic breast cancer cells (MDA-MB-231) were treated with STAT3 inhibitor (NSC74859) or MAPK inhibitor (U0126) in regular or astrocytic media to determine cell proliferation and migration by MTT assay and scratch-wound, respectively. ERK1/2 signaling pathway status was determined by Western blotting. Results demonstrated: 1) $pSTAT3^{Tyr705}$ and $pERK1/2^{Thr202/Tyr204}$ were expressed profusely at tumor margins, while $p53^{mt}$ was uniformly expressed throughout. 81% of BM expressed $p53^{mt}$ while 86% and 63% expressed $pERK1/2^{Thr202/Tyr204}$ and $pSTAT3^{Tyr705}$, respectively. Venn analysis displayed significant overlap between expression, with 62% overlap between $p53^{mt}$ and $pERK1/2^{Thr202/Tyr204}$ and a 50% overlap between both $pSTAT3^{Tyr705}$ and $pERK1/2^{Thr202/Tyr204}$ with $p53^{mt}$. Expression of PD-L1 was seen in a majority of BM tumors. 2) Gene expression analysis demonstrated alterations in 32 STAT3- and MAPK-associated genes; these included upregulation of stathmin-1 and stathmin-like 3, which control microtubule dynamics in STAT3-related cell migration, and changes in cytokine-related genes, suggesting altered immune responses. 3) Cell proliferation showed augmented growth in astrocytic media ($p \leq 0.05$) and was significantly decreased following treatment with NSC74850 or U0126 ($p \leq 0.01$). While migration showed a trend towards significance in reduction following NSC74859 ($p=0.08$), migration stagnated following U0126 treatment in astrocytic media ($p \leq 0.01$). 4) $pERK1/2^{Thr202/Tyr204}$ expression was reduced following U0126 or NSC74859 treatment. These findings suggest activation of STAT3 and ERK1/2 promote BM and suppression of these pathways may lead to a reduction in cell viability and motility. Therefore, this provides compelling evidence for the use of STAT3 and ERK1/2 along with p53 as potential targets for immunotherapy in brain metastatic disease.

#3158 TUSC2 suppresses energy metabolism in lung cancer cells with opposite effects in normal bronchial epithelial cells.

J. Tonello[1], M. Berger[2], A. Shanker[1], **A. Ivanova**[1];
[1]Meharry Medical College, Nashville, TN, [2]Geneprex, Inc, Austin, TX

Introduction: TUSC2 (TUmor Suppressor Candidate 2) is a tumor suppressor gene from the human 3p21.3 chromosomal region frequently deleted in lung cancers. Independently of deletion, reduced expression of TUSC2 is observed in ~ 80% of lung cancers, mesothelioma, breast, head-and neck, osteosarcoma, glioblastoma, and other cancers, suggesting a critical anti-tumor role of TUSC2. TUSC2 resides in mitochondria and is involved mitochondrial respiration/energy metabolism, ROS production, Ca^{2+} flux to/from mitochondria, etc. Studies on tumor-bearing mice treated with TUSC2-containing plasmid encapsulated in lipid nanoparticles (quaratusugene ozeplasmid) and Phase I and II clinical trials of quar oze in lung cancer patients provides a strong rationale to further study the tumor-protective mechanisms of TUSC2 protein. Main scientific question. We asked if and how human lung cancer cells, A549 and H358, that have ~80-90% decrease in TUSC2 expression, change their energy metabolism in response to re-introduction of TUSC2 as compared to Beas2B, a normal bronchial epithelial cell line. Cancer cells rely heavily on anaerobic glycolysis, while normal epithelial cells use mitochondrial respiration as a primary way of energy production.
Methods: Transient transfection of TUSC2-expressing plasmid to 3 cell lines; qPCR to confirm TUSC2 delivery; Seahorse analysis of energy production that measures in real time Oxygen Consumption Rate (OCR) and Extracellular Acidification Rate (ECAR) in different conditions.
Results: All three cell lines demonstrated high transfection efficiency. Seahorse analysis revealed that TUSC2 re-introduction to TUSC2-deficient cancer cells consistently suppressed both glycolytic and mitochondrial ATP production, thus leaving cells without sufficient energy to support their vital functions. We found a significant decrease in basal and maximal respiration, spare respiratory capacity, ATP production, glycolysis and glycolytic capacity in cancer cell lines transfected with TUSC2-expressing plasmid. Unlike cancer cells, both glycolytic and mitochondrial metabolism of normal epithelial cells Beas2B were significantly strengthened after the introduction of TUSC2, suggesting a beneficial role of TUSC2 for the metabolic health of normal cells. The experiments were repeated four times; Student T-test was used to calculate statistical significance.
Therapeutic Significance: These experiments suggest that TUSC2 plasmid delivery to cancer patients, and thus quar oze therapeutic use, may target and disrupt the metabolism of cancer cells, triggering either senescence or apoptotic pathways, while on the other hand, supporting the metabolism of normal epithelial cells. These data have high therapeutic significance, suggesting that one of the anti-tumor mechanisms of quar oze action in patients is the suppression of cancer cell metabolism resulting in cancer cell death.

#3159 *VHL1* activation with a CRISPR-based gene activation platform causes increased *MLKL* expression and triggers necroptosis in renal cell carcinoma.

M. S. Meng, R. M. Kemper, T. J. Nelson, N. A. Hathaway, D. J. Crona;
UNC Eshelman School of Pharmacy, Chapel Hill, NC

Background: Kidney cancer is a common and deadly disease. Over 90% of all kidney cancers are classified as renal cell carcinoma (RCC), of which clear-cell RCC (ccRCC) is the most predominant subtype. *VHL* is a tumor suppressor and plays a pivotal role in ccRCC development. While >50% of ccRCC patients present with pathogenic *VHL* mutations, deep deletions and low *VHL* expression are also common. Over the past two decades, therapeutic advances have been made for metastatic ccRCC; however, none directly target *VHL*, and the five-year overall survival for metastatic ccRCC remains ~12%. Here, we used a fusion protein, consisting of a deactivated Cas9 (dCas9) linked to the histone acetyltransferase protein p300, to determine if *VHL* activation initiates programmed cell death in a preclinical model of ccRCC.

Methods: Caki-1 cells are a human ccRCC line, are wild-type *VHL* with low-moderate expression. Caki-1 cells were stably transduced with our dCas9-p300 system via lentivirus, and then transfected with either sgRNAs targeting *VHL* or a non-targeting (NT) sgRNA. Ten targeting sgRNAs were designed, with eight starting within -120 bp from the *VHL1* transcriptional start site (chr3:10141778), and two starting within +50 bp after the TSS. *VHL* gene expression changes from baseline were evaluated by RT-qPCR at 8h, 24h and 48h after sgRNA transfection. At 24-72h, Caki-1 cells were harvested and stained with Annexin V and propidium iodide; apoptosis and necrosis were then assessed by flow cytometry. Last, to determine whether *VHL* reactivation triggered necroptosis, *MLKL* gene expression changes were evaluated by RT-qPCR at 8h, 24h and 48h.

Results: Four targeting sgRNAs met internal thresholds for evaluation within our dCas9-300 system: sgRNA3 bp), sgRNA4, sgRNA9, and sgRNA10. Significant increases in *VHL* expression were observed at 8h for sgRNA3 and sgRNA10 (62.4% and 56.5%, respectively; both $P<0.0001$, n=3), at 24h for all four sgRNAs (range 91.1-236.1%; all $P<0.0001$, n=3), and again at 48h for all four sgRNAs (range 84.4-194.4%; $P<0.0001$, n=3). At 48h and 72h, sgRNA4 (6.78% and 7.35%) and sgRNA9 (6.71% and 6.76%) showed evidence of necroptosis activation. sgRNA4 demonstrated significantly increased *MLKL* expression at 24h and 48h (199.6% and 144.6%; both $P<0.0001$, n=3) as did sgRNA9 (192.7% and 235.6%; both $P<0.0001$, n=3) suggesting necrosome activation.

Conclusions: To our knowledge, this is the first study to associate *VHL* reactivation with increased *MLKL* expression and necroptosis initiation. These data support continued development of an experimental system we have pioneered (PMID: 31712774), which will leverage chemical-induced proximity to reactivate *VHL*.

#3160 PufA promotes proliferation, migration and tumorigenesis through NF-kB pathway in cholangiocarcinoma.

C.-P. Chen[1], C.-N. Yeh[2], Y.-R. Pan[2], Y.-T. Hsiao[2], C.-H. Lo[2], C.-H. Lin[2], C.-E. Wu[1];
[1]Chang Gung University, Taoyuan City, Taiwan, [2]Chang Gung Memorial Hospital-Linkou branch, Taoyuan City, Taiwan

Cholangiocarcinoma (CCA) exhibits a poor prognosis despite the recent advances in targeted therapy and immunotherapy. Therefore, exploring the novel mechanism of CCA tumorigenesis and identifying the effective targeted therapy is critical for advanced CCA to improve future treatment. A novel biogenesis factor of the 90S pre-ribosome named PufA, is higher expressed in tumors than normal tissue based on the TCGA databank implying the role of CCA tumorigenesis. Our results showed that PufA expression was significantly associated with larger tumor size, more lymph node metastasis, more tumor relapse, death, and unfavorable survivals in 205 patients with resectable CCA in Chang Gung Memorial Hospital. We demonstrated the inhibited effect of cell survival, migration ability, and the sphere-formation potential by silencing of PufA in CCA cell lines. Tumor growth is also suppressed in PufA knockdown xenograft mice. Mechanistic investigation showed that PufA was expression associated with nuclear factor kappa B p65 (RELA) activity and facilitated activity of the NF-κB transactivation. RELA, a transcription factor, is the principal regulator of the inflammatory response and is crucial for the homeostasis of the immune system and the expression of the immune checkpoint. Furthermore, decreased PufA levels also downregulated PD-L1 expression in CCA. Together, these findings suggested that the PufA-RELA axis could be a potential target for further application of targeted therapy in combination with immunotherapy.

#3161 PCTK1 driven glutamine metabolic adaptation in brain metastasis.

L. Zhang[1], F. Lowery[2], C. Zhang[1], Y.-W. Huang[1], Y.-J. Jiang[1], Y. Duan[1], D. Yu[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]NCI, Washington DC, DC

Brain metastasis (BrM) is the most common malignancy of the central nervous system and the median survival time of patients with BrM is less than 1 year. Although recent impressive advances in targeted therapy and immunotherapy enable more effective control of the systemic diseases, the incidence of BrM upon disease recurrence is steadily increasing. Unfortunately, there is no effective treatments for BrM. To surmount this challenge, we have performed an *in vivo* human kinome screening to uncover novel kinases that promote breast cancer (BC) BrMs in mice and may serve as therapeutic targets. We identified >20 different kinases enriched in BrM lesions of our mouse models and PCTK1 is one of the top “hits”. We transduced PCTK1 expression vector and the control vector into MDA-MB-231 human BC cells to generate 231.PCTK1 and 231.vector cells, respectively. Intra-carotid injection of the 231.PCTK1 cells into mice induced BrM significantly faster with shortened mouse survival than that of the control 231.vector cells, confirming PCTK1 as a BrM-promoting kinase. However, when 231.vector or 231.PCTK1 cells were injected into the mouse’ mammary glands, PCTK1 overexpression did not lead to enhanced primary tumor growth, suggesting that its pro-tumoral functions are BrM-specific. To uncover how PCTK1 promotes BrM but not primary tumor, we examined whether PCTK1 may confer growth advantage in BrM by utilizing the unique metabolic microenvironment of the brain. We analyzed the relationship between PCTK1 gene expression and gene expression of members of the glutamine metabolism pathway in TCGA database. We found that in the brain tumors, such as low-grade glioma, PCTK1 positively correlated with the expression of glutamine metabolizing genes, including glutaminase 1 and 2 (GLS and GLS2). To evaluate whether PCTK1-overexpressing cells can uptake glutamine from the media directly, we cultured 231.PCTK1 and 231.vector cells in low-nutrient BME media plus 5% d.FBS, with addition of different concentrations of glutamine. The PCTK1-overexpressing cells showed a clear growth advantage at glutamine concentrations ranging from 400 µM to 2 mM. Then, we knocked down PCTK1 in MDA-MB-231 cells by shRNAs and found that PCTK1 knocking down reduced the cell proliferation in 5% d.FBS.BME with 500 µM glutamine, a physiological glutamine level in the brain. We measured the expression of GLS, an enzyme that converts glutamine to glutamate, one of the key steps in the glutamine metabolism, and found that knockdown PCTK1 in MDA-MB-231 cells dramatically reduced the GLS expression, which indicates that PCTK1 can modulate glutamine metabolism in cancer cells. In summary, our data suggest that PCTK1 promotes BC BrM, at least partly, through increasing glutamine metabolism. Currently, we are exploring whether targeting PCTK1 or inhibiting glutamine metabolism can deter BrM progression. Our studies may reveal novel therapeutic targets for BrM inhibition.

#3162 Antagonizing beta-2 adrenergic receptor's function triggers death in glioma cells and down-regulates survivin.

O. Algranatti[1], J. Yae Lee[2], J. Angelastro[1];
[1]UC Davis School of Veterinary Medicine, Davis, CA, [2]UC Davis Graduate Studies, Davis, CA

Introduction: Epidemiological studies showed that beta-adrenergic antagonists caused a low incidence of several cancer types. Glioblastoma highly expresses beta-2-adrenergic receptors. GBM accounts for 50% of central nervous system cancers. After standard-of-care therapeutic intervention, there is a survival time of 15 months. Our goal is to develop a translational therapy that will trigger the death of GBM cells while preserving healthy cells
Methodology: Salmeterol xinafoate is a biased agonist that activates the G-protein pathway. Biased agonists activate signaling through the G-protein or the beta-arrestin pathway of G-protein coupled receptors. Dose-response experiments were performed using beta1 and beta2-adrenergic receptor antagonists and biased beta2-adrenergic receptor agonists to determine loss of glioma cell viability in GBM5, GBM12, and LN229 glioma cell lines. Western immunoblotting gauged survivin expression levels in all three lines. Epoxomicin was used to inhibit the proteasome complex. Annexin V and propidium iodide were employed to measure apoptotic or necrotic cell death.
Results: Disrupting beta2-adrenergic receptor signaling by salmeterol xinafoate led to cell death of glioma cells but spared healthy neuron-glia cells using similar doses. Salmeterol xinafoate revealed greater efficacy for killing glioma cells than beta1 and beta2-adrenergic receptor antagonists. To determine the mechanism of glioma cell death, LN229 cells were treated with escalating doses of Salmeterol xinafoate, and at 24 hours, annexin V staining showed early apoptosis, and Annexin V/propidium iodide co-staining also showed late apoptosis. Propidium iodide revealed minor necrosis in LN229 glioma cells. Western immunoblotting showed salmeterol xinafoate downregulated survivin in a dose-dependent manner. However, the epoxomicin's inhibition of the proteasome complex prevented dose-escalated downregulation of survivin for all three glioma cell lines.
Conclusion: The bitopic structure of salmeterol enables this drug to bind to the beta2-adrenergic receptors ligand binding site and an exosite site by its aryloxyalkyl tail that may contribute to the increased efficacy. Salmeterol xinafoate triggers glioma cell death by apoptosis at least in one glioma cell line. Salmeterol Xinafoate down-regulates survivin through protease degradation. Promising results show that the FDA-approved drug salmeterol xinafoate enables a favorable transition to the clinic. Repurposing this drug for GBMs may be combined with the current standard-of-care chemotherapies to enhance more significant loss of tumor volume and increase patient survival.

#3163 (Phospho)proteomic analysis reveals vulnerabilities in refractory metastatic colorectal cancer.

M. Marinucci[1], G. F. Boot[1], L. Zaidi[1], C. Esposito[1], M. Coto Llerena[1], S. Soysal[2], O. Kolmar[2], C. Ng[1], S. Piscuoglio[1];
[1]University of Basel, Basel, Switzerland, [2]St. Clara Hospital and University Hospital Basel, Basel, Switzerland

Proteomic networks are crucial for cellular homeostasis maintenance and, indeed, their aberrant regulation is implicated in cancer development and progression. Understanding alterations underlying these pathways, provides a way to design therapeutic interventions in human cancer. Improvements in mass spectrometry analysis have unlocked our potential to unveil cancer vulnerabilities. Here, we performed (phospho)proteomic analysis and ex-vivo drug testing on a cohort of refractory metastatic colorectal cancer (mCRC) tissues and matched patients-Derived Organoids (PDO) to identify new putative druggable biomarkers. The comparison between the proteome and phosphoproteome of 10 mCRCs tissues with their matched PDOs normalized to a pool of 6 colon mucosa tissues highlighted a strong overall correlation (R= 0.57 and R=0.6, respectively) suggesting a good level of similarity. Applying GSEA on our proteomic dataset, we identified up-regulation in MYC, cell cycle and MTORC1 signaling pathways in mCRC tissues and PDO, while kinase enrichment analysis highlighted an increase in Casein Kinase II (CKII) activity, an important cell cycle regulator. Our ex-vivo experiments showed that silmitasertib-mediated CKII inhibition reduced the cell viability in our PDO models, but with an overall modest effect. Analysis revealed that, even though not statistically significant, high Wnt signaling score correlated with an higher resistance to silmitasertib treatment (R=0.61; p=0.08). Previous works highlighted that MAPK activity is increased after silmitasertib treatment and responsible for resistance mechanisms to CKII inhibition. Strikingly, the combined trametinib-mediated MEK blockade and CKII blockade resulted in a synergistic interaction leading to enhanced antitumor activity, especially in PDO harboring high Wnt (R=0.74; p=0.022) and cell cycle (R=0.69; p=0.04) pathway activity. Moreover, the combined treatment strongly reduced S6 activity and RAPTOR expression, overcoming the significant effect exerted by the single agents. Surprisingly, none of them altered baseline MAPK activity, suggesting that silmitasertib and trametinib synergize their activity via inactivating the MTORC1-S6 axis in an ERK-independent manner. We are currently integrating genomic and transcriptomic data to better characterize the observed drug synergy. Taken together, our findings propose the silmitasertib and trametinib combination as a new therapeutic opportunity for refractory mCRC patients and strengthen the use of PDO as a suitable model for drug screening.

#3164 The *in vivo* Hollow Fiber model is a valuable tool in drug development of selective KRas inhibitors.

P. Metzger, C.-W. Franzke, E. Dikici, G. Sommerkamp, F. Fimm-Todt, J. E. Ehlert, C. Obodozie, **H. Weber**;
Reaction Biology Europe GmbH, Freiburg, Germany

The proto-oncogene KRas is a well-described small GTPase that functions as a molecular switch for major physiological signaling pathways involved in cell proliferation, differentiation and survival. It has been shown that activating mutations in KRas are among the most common oncogenic drivers of tumorigenesis. Missense mutations of KRas result in constitutive activation due to impaired hydrolysis of GTP which enhances tumor-promoting downstream signaling pathways. Most KRas mutations are located in exon 2 or 3 including the most frequently altered glycine 12, which is present in most pancreatic cancers as well as in colorectal cancers and lung adenocarcinomas.

A panel of cancer cell lines harboring different KRas mutations such as G12C, G12V or G12D was selected to test KRas inhibitors in several cellular assays: phosphorylation assays, 2D and 3D proliferation assays. Applying the cellular pERK AlphaLISA assay showed high selectivity of several inhibitors for specific KRas mutants, while RAF and MEK inhibitors did not show significant selectivity in the tested cancer cell lines. The KRas inhibitors were then examined in a cellular 2D and a 3D spheroid proliferation assay to determine the inhibitory effect on cell growth. These cellular assays revealed a high selectivity for a specific KRas mutant, which was even more pronounced in the 3D format than in the 2D setup.

The transferability of the cellular data obtained to in vivo was tested in the Hollow Fiber mouse model. The Hollow Fiber model allows the simultaneous study of multiple cell lines implanted in separated drug-(but not cell-) permeable fibers in a single mouse with a study duration of only 16 days. AMG510 (Sotorasib), a drug approved for tumors with a G12C Kras mutation, and MRTX1133, which is currently in clinical phase and shows activity in tumors with a G12D Kras mutation, were screened for their inhibitory effect on the pancreatic tumor cells MiaPaCa-2 (G12C Kras mutation), AsPC-1 (G12D Kras mutation) and BxPC-3 (wt Kras) in the in vivo Hollow Fiber model in female NMRI nude mice. While the growth of BxPC-3 tumor cells was not affected by either inhibitor, the growth of AsPC-1 tumor cells in particular was selectively and significantly inhibited by MRTX1133.

In summary, the in vivo Hollow Fiber model is a fast and cost-effective model that can play an prominent role in drug development as a link between in vitro and in vivo xenograft studies by providing rapid and transferable evidence for in vivo efficacy.

#3165 Targeting angiogenesis for improved survival in mantle cell lymphoma.

S. Singh[1], A. sircar[1], A. Odier[1], N. Epperla[1], N. Muthusamy[1], S. Parekh[2], L. Sehgal[1];
[1]The Ohio State University Wexner Medical Ctr., Columbus, OH, [2]Icahn School of Medicine at Mount Sinai,, New York, NY

Mantle cell lymphoma (MCL) is a subtype comprising 6% of all NHL cases and is characterized by overexpression of cyclin D1 due to chromosomal translocation t(11;14) in the nodal MCL subtype. One of the best discriminatory genes between these conventional and indolent MCL tumors is SOX11; in addition, SOX11 has been shown to promote angiogenesis in MCL. Further SOX11 protein expression in MCL patients correlated with increased microvascular density and poor outcomes. Bulk transcriptomics analysis was performed on MCL patients (n=24) and CD19-purified B cells from healthy donors (HD,n=3). To understand the role of the angiogenic process in MCL, we queried 141 genes related to angiogenesis (GO:0001525). Our analysis showed that many genes involved in angiogenesis were predominantly overexpressed in MCL compared to HD, including *FLT1* and *KDR* (p-value;0.05; FC>2). SOX11 has been shown to regulate PDGFA in MCL cell lines. Consistent with this observation, we also see upregulated PDGFA levels in MCL patients. However, PDGFA upregulation was not statistically significant in our analysis. Further expression of *VEGFR2* is overexpressed in MCL Patients (n=122) compared to naïve or activated-B cells from HD. We validated that VEGFR2 protein levels were higher in MCL primary patients than in healthy donor PBMC. Further, in two independent cohorts, high *VEGFR2* expression shows significant adverse effects on 5-year overall survival (OS). To explore the potential of targeting VEGFR, we utilized lucitanib, which potently and selectively inhibits VEGFRs. Treatment with lucitanib resulted in a dose-dependent decrease in cell viability and cellular death as determined by Annexin PI staining; further, MCL cells treated with lucitanib showed inhibition of autophosphorylation of VEGFR2 and demonstrated PARP cleavage associated with cytotoxicity *in-vitro*. To assess the role of VEGFR2 inhibitor lucitanib as a single agent in MCL growth *in-vivo*, we utilized two different murine models of MCLs. First, we used cell-line-derived xenograft (CDX) models of MCL where Jeko-1 and HS5 cells were injected together, followed by treatment (lucitanib;15mg/kg QOD; IP) and measured tumor volume until the ERC of any experimental mice was reached. Kaplan-Meier survival graphs were plotted, demonstrating that lucitanib treatment prolongs survival *in-vivo*. Further, to confirm if the lucitanib can provide an overall survival benefit in the systemic PDX MCL model, we injected the PDX cells via the tail vein in NSG mice and followed human-B2M levels for disease progression, and overall survival was the endpoint. Lucitanib treatment significantly prolonged median overall survival significantly in the systemic MCL model. Our data demonstrates that targeting angiogenesis in MCL can provide therapeutic benefits, as demonstrated in preclinical MCL models.

#3166 Lipid nanoparticles as an efficient transfection method for the delivery of elephant TP53 and retrogene9 into osteosarcoma cells.

M. Sanborn, A. Rogers, G. Mitchell, R. Kennington, M. Sharp, J. D. Schiffman, L. M. Abegglen;
University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Lipid nanoparticles (LNPs) continue to be at the forefront of nanotechnology research due to their versatile and effective ability to deliver DNA, RNA, and small molecules through the cell membrane. Since LNPs are formulated with lipids found naturally in cells, they generate a lower risk for immunogenic response and cause significantly less cell death than traditional transfection methods, such as electroporation. Our microfluidics assembled LNPs have shown transfection efficiencies over 80%, substantially higher than observed with other transfection techniques, and continues to increase over the first 72 hours. We previously reported that elephant *TP53* (*EP53*) induces apoptosis in cancer cells at higher rates than human *TP53* (*huTP53*), and elephant *TP53* RETROGENE9 (*EP53-R9*) contributes to apoptosis through transcription independent mechanisms. To further characterize the effectiveness of these genes, osteosarcoma cell lines were transfected with *huTP53, EP53, and EP53-R9* nanoplasmid and mRNA loaded LNPs. Cells treated with *EP53* and *huTP53* nanoplasmid-loaded LNPs had significantly increased caspase activity and cell death compared to those treated with the empty vector control ($P<.0001$), with over 90% of all cells treated with either type of p53 dead after 72 hours. Immunocytochemistry was performed to image cells using confocal microscopy, which showed a 36-fold increase in *TP53* signal in the nucleus of nanoplasmid LNP treated cells after 72 hours as compared to untreated osteosarcoma cells. In contrast, cells treated with the mRNA LNPs had a 7-fold increase in *TP53* signal over 72 hours, though the transfection efficiency was equivalent to the nanoplasmid treated cells. Future studies will assess the efficacy of *EP53* and *EP53-R9* LNPs *in vivo* in osteosarcoma mouse models. These results demonstrate the potential of LNP mediated delivery of *EP53* and *EP53-R9* to be developed as a new treatment approach for cancer patients.

#3167 Impact of gemcitabine modification on redox-driven responses in pancreatic cancer organoids cultured in distinct 3D microenvironments.

B. Han[1], S. Zhao[1], E. Agyare[2], X. Zhu[2], J. Trevino[3], S. Rogers[4], E. Velazquez[1], J. Brant[5], P. Eliahoo[6], J. Barajas[1], B. X. Hoang[1];
[1]Keck School of Medicine of USC, Los Angeles, CA, [2]Florida A&M University, Tallahassee, FL, [3]Virginia Commonwealth University, Richmond, VA, [4]Univeristy of Florida, Gainesville, FL, [5]University of Florida, Gainesville, FL, [6]University of Southern California, Los Angeles, CA

Pancreatic ductal adenocarcinoma (PDAC) poses a formidable challenge in oncology, characterized by its high lethality and limited treatment options. The advanced stage at diagnosis, aggressive metastasis, and the constrained efficacy of conventional therapeutic drugs collectively contribute to the grim prognosis associated with PDAC. Gemcitabine, a nucleoside analog and the longstanding standard chemotherapy for pancreatic cancer, encounters a significant hurdle in its efficacy due to the development of resistance. To establish a cancer-acquired resistance model applicable to Gem-modified drugs, it is crucial to account for the dense extracellular matrix (ECM) composition characteristic of PDAC. In this investigation, we employ three-dimensional (3D) cell culture models, specifically utilizing pancreatic cancer patient-derived organoids (PDOs) within a 3D matrix with tunable density and stiffness by incorporating variations in transglutaminase crosslinking rates. PDAC cells from different patients exhibit diverse adaptations within these altered gel matrix environments, manifesting differences in morphology, doubling time, and responses to drugs. Notably, PDAC cells display pronounced stemness characteristics in the dense matrix, featuring a more rounded and compact appearance and an increase in ABC transporters.Addressing the challenge of gemcitabine resistance, modifications such as gemcitabine conjugates with stearate (Gem-S) have shown promise in preclinical studies. Exploring the effects of both Gem and Gem-S in a viscoelastic-specific ECM model derived from PDAC patient-derived organoids, distinct responses based on matrix stiffness come to light. The physical properties of the matrix exert a significant influence on cellular function, thereby impacting the effectiveness of therapeutic agents. Intriguingly, within a stiffer environment, Gem-S demonstrates higher sensitivity compared to Gem, suggesting the potential application of Gem-S in the dense pathological PDAC environment. Further investigation reveals that Gem-S treatment induces a noteworthy increase in reactive oxygen species (ROS) and HIF-1 expression compared to Gem. Surprisingly, the role of multidrug transporters in Gem-S sensitivity is limited, while the downregulation of NRF (Nrf2) after Gem-S treatment hints at distinct mechanisms underlying the development of drug resistance. This study provides valuable insights into the intricate interplay between gemcitabine resistance and the PDAC microenvironment. Understanding the matrix-specific responses opens avenues for tailored therapeutic interventions, offering the potential for improved outcomes in PDAC patients.

#3168 Amphiphilic dendrimer-mediated siRNA delivery for precision regulation of cAMP pathway in cancer cells.

W. Yuan[1], Z. Gao[1], L. Peng[2], L. T. Lee[1];
[1]University of Macau, Macau, Macao, [2]Aix-Marseille University, Marseille, France

Exchange proteins directly activated by cAMP (EPACs) are involved in multiple cellular processes. The two EPAC isoforms (EPAC1 and EPAC2) have fundamental differences in structure, expression pattern, and signaling specificity, indicating that they may function independently. Therefore, the highly specific regulation of EPAC1 and EPAC2 could be beneficial in targeting cAMP pathway-related therapies. Small RNA molecules could theoretically target genetic components based on Watson-Crick base pairing, offering a unique and promising approach to achieve precision medicine. In this study, we successfully design small interfere (si)RNAs that specifically target EPAC1 and 2, without cross-reactivity with other isoforms. The use of the amphiphilic dendrimer (AD) efficiently delivers siRNAs, resulting in significant down-regulations of EPAC1 and 2 mRNA and protein expressions in multiple cancer cells, including ovarian, breast, colon, and pancreatic cancers. Functional analysis demonstrate that EPAC1 and EPAC2 regulate cancer progression depending on different mechanisms. siEPAC2-AD is more potent compared to siEPAC1-AD in suppressing cell proliferation by altering energy metabolism. Hence, this siEPACs-AD system not only enhances the drug specificity and reduces potential side effects, but also provides a new strategy for precision pharmaceutical control of the cAMP/PKA/EPAC signaling pathway for cancer treatment.

Keywords: EPAC1; EPAC2; siRNA; amphiphilic dendrimer; cAMP signaling; cancer

#3169 The role and mechanism of m6A methylation modification of LncRNA-ATB in regulating the invasion and metastasis of colorectal cancer.

Y. Lang#[1], **J.-L. Lin#**[1], J.-P. Kang[2], L. Yang[3], D. Zhou[4], C.-B. Fang*[5], F. Ye*[1], W.-w. Tang*[1];
[1]The First Affiliated Hospital of Xiamen University, School of Medicine, Xiamen University, The School of Clinical Medicine of Fujian, Medical University, Xiamen, China, [2]Zhangzhou Municipal Hospital, Zhangzhou Municipal Hospital Affiliated of Fujian Medical University, Zhangzhou City, China, [3]Weifang people's Hospital, Weifang Medical University, Weifang, China, Weifang City, China, [4]Application Technique Engineering Center ofNatural Cosmeceuticals, Collegeof Fuijan Province, Xiamen Medical College, Xiamen City, China, [5]Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: The epigenetic modification of LncRNA N6-methyladenosine (m6A) methylation plays a wide role in the invasion and metastasis of various malignant tumors. However, the role of LncRNA-ATB m6A methylation modification in colorectal cancer (CRC) has not been systematically elucidated.
Methods: Detect the regulatory effect of ALKBH5 on LncRNA-ATB by Luciferin reporter gene. LncRNA-ATB expression was detected by IHC and qPCR in CRC tissues and cells. Transwell and scratch tests were used to detect the effect of ALKBH5 overexpression after LncRNA-ATB knockdown and replacement on the invasion and migration ability of CRC cells. Western blotting was used to detect the expression changes of MMPs proteins.
Results: ALKBH5 could regulate the methylation level of the LncRNA-ATB 3' UTR region ($p<0.05$). ALKBH5 overexpression in CRC cells led to a significant decrease in the expression level of LncRNA-ATB ($p<0.05$). LncRNA-ATB exhibited elevated expression in CRC cells and demonstrated significantly higher levels in CRC tissues compared to paracancerous tissues ($p<0.05$), indicating the potential tumor-promoting effect of LncRNA-ATB in CRC, with the mechanism possibly regulated by ALKBH5-mediated m6A demethylation. ALKBH5 overexpression inhibited the proliferation and migration of CRC cells after LncRNA-ATB knockdown. However, this inhibitory effect was attenuated upon LncRNA-ATB rescue, accompanied by an increase in MMP9 and a decrease in TIMP1.
Conclusion: LncRNA-ATB plays a crucial role in ALKBH5-mediated m6A demethylation, regulating the invasion and metastasis of CRC. The ALKBH5-LncRNA-ATB m6A demethylation-MMPs signaling axis has been identified as a key regulatory pathway promoting CRC migration. m6A modification of lncRNA-ATB modulated by ALKBH5 provides a theoretical basis for novel therapeutic strategies for patients with metastatic CRC.
FUNDING: This study was supported by the National Natural Science Foundation of China (Grant No. 81702414), Natural Science Foundation of Fujian Province of China (Grant No. 2020J05306) and Xiamen Science and Technology Planning Project (Grant No. 3502Z20194003).

#3170 Epigenetic identification and functional characterization of a novel RING finger protein tumor suppressor in nasopharyngeal carcinoma and esophageal carcinoma.

X. Chai, F. Luo, S. Bao, L. Meng, A. T. C. Chan, B. B. Y. MA, Q. Tao, L. Li;
The Chinese University of Hong Kong, Hong Kong, Hong Kong

RING finger proteins play crucial roles in normal physiology and pathophysiology as important regulators of ubiquitin-dependent proteasomal protein degradation. Many RING finger proteins have also been implicated in tumorigenesis either as oncogenes or tumor suppressors. Through cancer CpG methylome studies, we identified RING finger protein 150 (RNF150) as a methylated target gene in nasopharyngeal carcinoma (NPC) and esophageal carcinoma (ESCC). RNF150 was found to be ubiquitously expressed in human normal tissues but frequently downregulated in NPC and ESCC cells due to its promoter methylation. Its downregulation is associated with poor survival in patients with head and neck cancer and esophageal cancer. We also found that RNF150 is a functional tumor suppressor by inhibiting tumor cell growth and inducing cell cycle arrest in NPC and ESCC cells. Furthermore, ectopic expression of RNF150 inhibited NPC and ESCC cell migration/invasion by suppressing epithelial-mesenchymal transition (EMT) through upregulation of epithelial marker E-cadherin and downregulation of mesenchymal markers (vimentin, N-cadherin, Snail, and Slug). RNF150 is located in the cytoplasm and represses several oncogenic signaling pathways including the Wnt/β-catenin and NF-kB signaling pathways. Liquid chromatography-mass spectrometry (LC-MS) was performed to elucidate RNF150 binding proteins. KEGG enrichment analysis showed that glycolysis/gluconeogenesis, pyruvate metabolism, central carbon metabolism in cancer, and AMPK signaling were the top 4 pathways with significant enrichment, suggesting potential targeting of metabolic molecules by RNF150. Thus, our results provide insights into a new ring finger protein member, RNF150, as a functional tumor suppressor for NPC and ESCC. Our study also suggests a potential epigenetic biomarker for the early dection of NPC and ESCC.

#3171 The effect of estrogen and phytoestrogens in Inflammatory breast cancer.

E. A. Peterson-Peguero[1], K. Rodriguez-Martir[1], M. Ganshert[2], D. Negron-Figueroa[1], A. N. Colon-Ortiz[1];
[1]University of Puerto Rico - Rio Piedras, San Juan, PR, [2]Loyola University Chicago, Chicago, IL

Inflammatory breast cancer is an aggressive and lethal type of breast cancer. Frequently, this cancer is diagnosed in an advanced stage with metastasis. IBC diagnosis is associated with a worse survival rate than other types of breast cancer. The presence of dermal and stromal tumor emboli blocking the lymphatic vessels under the skin is considered a hallmark of IBC and assumed to be responsible for the high metastatic behavior and aggressiveness of IBC disease. To this date, there are no effective targeted therapeutics, especially for those patients that account for approximately 20-40% of IBC cases with triple-negative breast cancer (TNBC) classification. Several studies have shown that estrogen can exert non-genomic effects in IBC and non-IBC TNBC, mediated by the expression of alternate estrogen receptors including estrogen receptor alpha-36, and GPR30. In this context, estrogen can activate non-genomic signaling pathways involved in the acquisition of oncogenic phenotypes such as increased motility and invasion in IBC cells. Phytoestrogens, naturally derived structural analogs to 17β-estradiol (E2), were evaluated as an alternative treatment option using *in vitro* IBC cell models (SUM149 and SUM190). Given the estrogenic properties of phytoestrogens, the drugs were hypothesized to interact with targets in pathways similar to E2 in non-genomic signaling. Several phytoestrogens including coumestrol (Cou) can induce a cytotoxic effect in TNBC. We hypothesize (1) that estrogen non-genomic signaling has an active role in the aggressive metastatic phenotype of IBC, and (2) that Cou has anticancer activity by inhibiting estrogen non-genomic signaling in IBC. To test these hypotheses, IBC cells were treated with E2 or Cou to determine their effects on the activation of downstream kinases by western blot and phospho-kinase array assays. In addition, transcriptional effects upon treatment with Cou were identified using RNA-seq. A dose-response curve in 2D and 3D models was generated to determine the half-maximal inhibitory concentration (IC_{50}) of Cou. Finally, treatment using the IC50 of Cou caused a decrease in cell viability in the TNBC cell line. Also, in comparison to E2, Cou decreases migration, proliferation, and tumor emboli formation in IBC cell lines. In addition, IBC cells were treated using monotherapy and combination therapy with phytoestrogens including Cou, genistein (GN), and/or 8-prenylnaringenin (8-PN). Observed reductions of cell viability in IBC cell lines treated with the different phytoestrogens and combinations make them worthy of further characterization as anti-cancer therapies in *in vitro* and *in vivo* models. In summary, IBC cells are responsive to E2 making this signaling pathway attractive for the development of innovative therapeutic strategies with phytoestrogens as potential candidates for treatment.

#3172 Significance of PELP1 signaling in liver cancer progression.

U. Pratap, K. Nassar, X. Yang, A. Baker, R. Gopalam, W. C. Arnold, T. Adeniran, M. Hernandez Fernandez, G. R. Sareddy, S. Viswanadhapalli, L. Sun, R. K. Vadlamudi;
UT Health San Antonio, San Antonio, TX

Background: Hepatocellular carcinoma (HCC) is the fastest-rising cause of cancer-related mortality in the United States. Furthermore, advanced HCC has a very poor prognosis, with a median survival time of only about ten months. Effective new targeted therapies are urgently needed for the treatment of HCC. Proline, glutamic acid-, and leucine-rich protein 1 (PELP1) is a protooncogene. PELP1 signaling has been implicated in the development of several cancers, however, its role in the progression of HCC remains unclear. The goal of this project is to investigate the significance and therapeutic potential of targeting PELP1 in HCC.
Methods: In this investigation, we have used six HCC cell lines (HUH7, HEP3B, SNU398, SNU475, SNU423, and SNU449). Using immunohistochemistry (IHC), the expression of PELP1 in HCC tissue microarrays was examined. PELP1shRNA lentiviral particles were used to create PELP1 knockdown (KD) cells. Using well-established in vitro tests for cell proliferation, colony formation, and apoptosis, the effects of PELP1 KD or PELP1 inhibitor (SMIP34) were investigated. RNA-seq, RT-qPCR, Western blotting, IHC, reporter gene assays, and signaling pathway analysis were used in mechanistic investigations. Preclinical evaluations were conducted using mice xenograft models.
Results: TNM plot analysis showed that HCC samples had increased PELP1 expression relative to normal tissue. Immunohistochemistry analysis of tissue microarray confirmed that HCC specimens overexpressed PELP1 in comparison to normal specimens. PELP1 knockdown with shRNA dramatically decreased HCC cell invasion, clonogenicity, and proliferation. Similarly, PELP1 inhibitor SMIP34 treatment significantly reduced cell viability, invasiveness, colony forming capacity, and induced apoptosis of HCC cells. RNA-seq analyses using PELP1 KD cells confirmed that PELP1 modulates the ribosome and the eukaryotic translation elongation pathways. Mechanistic studies confirmed that SMIP34 treatment contributed to the disruption of the Rix complex, which is crucial for ribosomal biogenesis. Puromycin labelling studies confirmed that PELP1 KD or SMIP34 treatment contributes to the reduction of ribosomal biogenesis and new protein synthesis. Furthermore, PELP1 KD or treatment with SMIP34 dramatically slowed the progression of HCC tumors in xenograft models. IHC analysis revealed reduced levels of the proliferation marker Ki67 in PELP1 KD/SMIP34 treated HCC xenograft tumors compared to controls.
Conclusions: Overall, the results of our study point to PELP1 as a potential therapeutic target for HCC intervention.

#3173 Impact of hypoxia on the integrated stress response activated by imipridones ONC201 and ONC206 in pediatric diffuse midline glioma cells.

T. J. Roady[1], N. Stubbs[2], J. Chen[1], Y. Xia[1], A. S. Uruchurtu[1], X. Tian[1], L. Zhou[1], W. S. El-Deiry[1];
[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]Morehouse School of Medicine, Atlanta, GA

Diffuse midline gliomas (DMGs) are highly aggressive, high-grade gliomas which typically arise in children and young adults. With currently approved treatments the median survival from time of diagnosis for pediatric DMG is 8-10 months with only 10% of children living to 2 years post diagnosis. Despite being only 15% of the cases it makes up 40% of the pediatric brain cancer deaths making it the leading cause of death for all pediatric glioma cases. Two recent clinical studies, NCT03416530 and NCT03134131, have shown the clinical efficacy of Dordaviprone (ONC201/TIC10) for the treatment of DMG; increasing median survival to 22 months in patients following radiation treatment prior to recurrence. Imipridone ONC206, a chemical derivative of ONC201, is under clinical development for treatment of pediatric and adult patients with primary brain tumors (NCT04732065 and NCT04541082). To further improve treatment, we must continue to study how the tumor microenvironment impacts the efficacy of imipridones. One crucial aspect of all brain cancers is hypoxia, so the IC50s of the SU-DIGP-25, SU-DIPG-XIII and SU-DIPGIV pediatric DMG cell lines treated with ONC201 or ONC206 were measured using the CellTiter-Glo assay under conditions of hypoxia and normoxia. Imipridones mediate apoptosis through the upregulation of the TRAIL death receptor DR5 and the activation of the integrated stress response (ISR), so western blots were used to show changes in the ISR protein expression in ONC201 treated DMG cells at multiple different degrees of hypoxia. To understand how hypoxia inducible factors (HIFs) play a role in resistance and susceptibility to ONC201 or ONC206, HIF-1a, HIF-2a, and HIF-3a were knocked down showing altered ISR protein expression after treating with the imipridones under hypoxic and normoxic conditions.

#3174 Crosstalk between protein translation and DNA replication during stress response and cancer therapy.

F. Wang;
Case Western Reserve University, Cleveland, OH

Tumor microenvironment, which includes both various types of cells (tumor cells, stromal cells, immune cells, *etc.*) and an interstitial fluid system, plays a key role in tumorigenesis, therapy response, and disease outcome. While the cell component has been heavily studied in cancer treatment, the interstitial fluid system has not. A key feature of the fluid system is constant oscillation of osmolytes such as salt, glucose, and proteins due to unstable blood supply and tumor metabolism, resulting in cycles of osmotic stress and recovery. Yet, how this osmotic stress - recovery cycle mediates tumorigenesis and cancer therapy remains poorly understood. Our unpublished results reveal sequential activation of molecular events during osmotic stress and recovery. In the stress stage, protein translation, transcription, and DNA replication are inhibited. Following recovery, protein translation resumes, gene transcription is greatly upregulated, but DNA replication is not immediately recovered. It turns out that a DNA replication checkpoint is activated during recovery; as a result, DNA replication is halted. Defects in activating protein translation inhibition during stress fail to activate the replication checkpoint during recovery, indicating a causative link from protein translation inhibition to DNA replication checkpoint activation. Many genes involved in this crosstalk are altered in a wide range of human tumors. Ovarian cancer cells that are resistant to standard of care (for instance, cisplatin) demonstrate defects in this crosstalk; however, they were also more sensitive to a combination of osmotic stress followed by the presence of replication checkpoint inhibitors during recovery than parental cancer cells. These findings highlight a unique role of the interstitial fluid system in tumor development and therapy response. They also suggest a new anticancer strategy by combining osmotic stress with checkpoint inhibitors. Key words: Tumor microenvironment; osmotic stress; protein translation control; DNA replication checkpoint; cancer therapy

#3175 Dear ABBIE, edit that colon cancer.

D. C. Aguilar, A. Gallegos;
SOHM, INC., Chino Hills, CA

Genome editing has exciting potential for gene therapy of cancers. Colorectal cancer is the third most occurring cancer in both men and women. The current treatments for colon cancers include surgery, radiofrequency ablation, chemotherapies and immunotherapies. These either involve removal of intestinal tissue that can alter the quality of life of the patient, or require doses of drugs that generally result in various side effects. ABBIE (A Binding Based Integrase Enzyme) genome editing can insert operational gene sequences into a chosen site in the genomic DNA of cells via its targetability and integrase activity. The ABBIE system offers ease of use, faster time to a readout and decreased time per genome editing experiment. SW480 and Caco-2 colon adenocarcinoma cells were used with the ABBIE system to integrate a GFP donor sequence into a safe harbor locus of the genome. Integration is to be confirmed with fluorescence microscopy and DNA sequencing. The colon cancer cell line will then be edited with the ABBIE genome editing system to include a gene cassette that overexpresses caspase genes into the genomic DNA of these cells. ABBIE-Edited colon cancer cell lines are expected to exhibit increased apoptosis as compared to non-edited controls or controls edited with DNA that do not have the caspase genes. This strategy will help lead to novel and more targetable treatments for colon cancer.

#3176 Otopetrin 3 promotes cell proliferation and regulates glycolysis via interaction with MYC in colorectal cancer.

H.-J. Jang, W. Jee, S.-M. Park, Y.-r. Park, S. Kim, J. Jung;
Kyung Hee Univ. College of Korean Medicine, Seoul, Korea, Republic of

Otopetrin 3 (OTOP3) stands out as a pivotal regulator of intracellular pH through its control over proton transportation into cells, affecting fundamental cellular processes. Previous studies have shown that OTOP3 is associated with the prognosis of colorectal cancer (CRC) patients. However, the mechanism underlying OTOP3 regulation remains unclear in cancer. Our investigation reveals OTOP3 as a potent oncogene in CRC, with higher OTOP3 levels correlating with diminished overall survival rates in CRC patients. Comparative analysis between cancerous and normal colon cells highlights a pronounced overexpression of OTOP3 in cancer cells. Suppression of OTOP3 expression significantly curtailed CRC cell proliferation, colony formation, migration, and invasion, concurrently inducing apoptosis and cell cycle arrest, ultimately leading to cancer cell death. Moreover, through CHX, FBS inactivation, and MG132 treatment experiments, it was confirmed that OTOP3 regulates c-Myc expression and stability through ubiquitination and has a critical impact on CRC cell proliferation and growth. Additionally, OTOP3's modulation of HK2, PKM2, and LDHA, underscores its role in impacting cancer cell behavior via glycolytic pathways. In summary, the overexpression of OTOP3 in CRC cells drives cell proliferation and growth through the regulation of c-Myc, impacting crucial cellular processes. Additionally, it promotes these processes by influencing glycolysis. These findings provide valuable insights into potential therapeutic targets for CRC treatment, possibly involving OTOP3 and its associated pathways.

#3177 Angiopoietin-like 4 suppress clear cell renal cell carcinoma via inhibition lysosomal acid lipase.

Z. Jin[1], U. De[1], T. Tithi[1], J. Kleberg[2], A. Nataraj[3], E. Jolley[4], B. Davies[5], W. Zhang[1], R. Kolb[1];
[1]University of Florida College of Medicine, Gainesville, FL, [2]University of Florida College of Liberal Arts and Sciences, Gainesville, FL, [3]University of Florida College of Public Health and Health Professions, Gainesville, FL, [4]Florida State University Interdisciplinary Medical Sciences Division, Tallahassee, FL, [5]University of Iowa, Iowa city, IA

Renal cell carcinomas(RCC) account for about 76,000 new cancer cases annually in the U.S. and 403,000 cases world wide. Clear cell RCC (ccRCC) is both the most common and aggressive subtype, accounting for 75-85% of cases with a 5-year survival rate of 50-69% for all cases and only 10% for metastatic disease. In our study, we report thatANGPTL4 is highly upregulated in ccRCC compared to other types of cancers and normal kidney tissues. However, we identified a cohort of patients with significantly lower expression of ANGPTL4 which had a worse prognosis compared to rest of the patients with higher expression of ANGPTL4. This subset of patients had a lower frequency of mutated VHL and were enriched for genes related to lipid metabolism. In transplant tumor models using RCC cell lines with wild-type VHL, we found that ANGPTL4 suppresses tumor growth. Moreover, loss of ANGPTL4 in ccRCC cell lines reduces colony formation in a lysosomal acid lipase (LAL) dependent manner, a phenotype that is rescued by expression of nANGPTL4. This data indicates that ANGPTL4 suppresses ccRCC tumors in a cancer cell intrinsic manner via regulation of LAL activity. This cohort of patients with low ANGPTL4 may be more dependent on lipid metabolism and less likely to respond to anti-angiogenic TKI plus immune checkpoint inhibitor therapy.

#3178 Vitamin B1 derivative, fursultiamine, prevents colon cancer growth.

S. Poludasu, C. Pompoco, K. Ramana;
Noorda College of Osteopathic Medicine, LLC, Provo, UT

Colon cancer is the second deadliest type of cancer in the United States, with surgical resection being the primary treatment modality for localized early-stage colon cancer. Still, more treatment and prevention options are needed to help improve the outcomes for colon cancer as they are currently limited to invasive procedures. One promising option is fursultiamine, a disulfide lipid-soluble vitamin B1 derivative, which has anti-oxidative and anti-inflammatory activity that could aid in preventing colon cancer. We hypothesize that supplementation of fursultiamine could be an effective chemopreventive treatment to control the growth and spread of colon carcinogenesis. Human colorectal adenocarcinoma (SW480) cell lines were incubated with complete media (CM) or human recombinant endothelial growth factor (EGF 20 ng/ml) in the absence and presence of fursultiamine. The cell viability was examined by MTT assay in a concentration- (0-150 uM) and time (24 and 48 h) - dependent manner. Our results indicate that fursultiamine prevents SW480 cell death in a dose-dependent manner. Apoptosis was detected by using Annexin-V staining and live and death cell assay. Our results suggest that fursultiamine prevents SW480 cell proliferation by inducing apoptotic cell death. The production of reactive oxygen species (ROS) and activation of caspase-3 were examined by specific assay kits. Treatment with fursultiamine resulted in the decreased production of ROS and activation of caspase-3. The expression of anti-apoptotic, pro-apoptotic, and pro-inflammatory factors was analyzed using antibody arrays. The results demonstrated that treatment with fursultiamine increased the expression of pro-apoptotic factors such as Bad, Bax, cleaved caspase 3, Fas/CD95, and FADD. Further, fursultiamine increased expression of the tumor suppressor genes p53, p27, and p21. We next planned to examine this vitamin B1 derivative's effect in preventing cancer growth in nude mice xenograft models. In conclusion, our in vitro results indicate that fursultiamine, a vitamin B1 derivative, prevents colon cancer growth through increased regulation of pro-apoptotic pathways and tumor suppressor proteins and thus has the potential for further development as a chemopreventative agent.

#3179 Spindle assembly checkpoint as a therapeutic target for *TP53*-mutated myeloid neoplasms.

A. Arsana, H. Huang, A. Al-Kali, M. Shah;
Mayo Clinic, Rochester, MN

Introduction TP53-mutated (*TP53*^{mut}) myeloid neoplasms (MN) are a distinct entity of myeloid neoplasms with no effective therapies and poor survival (Grob et al, Blood 2022). The TP53-deficient state facilitates the downstream dysfunction of the spindle assembly checkpoint (SAC), predisposing to genomic instability. Recently, a SAC protein, threonine tyrosine kinase (TTK), has emerged as an attractive therapeutic target. Upregulation of TTK has been described in various solid tumors. It is stipulated that targeting SAC proteins might result in extreme level of genomic instability that even cancer cells could not tolerate. We hypothesized that inhibition of TTK with a small molecular inhibitor—TTKi may offer a promising therapeutic strategy for *TP53*^{mut} MN.

Method We evaluated relative *TTK* mRNA expression and its association with *TP53*^{mut} and complex karyotypes (CK) in the BEAT AML cohort (Tyner et al., 2018). We used myeloid cell lines, OCI-AML-3, THP-1, and U937 cell lines that harbor-near diploid, moderately aneuploid, and highly aneuploid karyotype, respectively. The efficacy of TTKi CFI-402257 (AbMole) was tested using cell viability, apoptosis, and colony-forming unit (CFU) assays using the standard protocol. Finally, we tested the efficacy of CFI-402257 using the diagnostic bone marrow mononuclear cell (BMMC) cells from *TP53*^{mut} MN patients.

Results Among 591 AML patients in the BEAT AML cohort (41.6% diploid, 35.9% non-CK, 22.7% CK), *TTK* mRNA expression was progressively higher with increasing chromosomal abnormality burden. *TTK* expression was 1.96-fold higher in *TP53*^{mut} AML compared to *TP53*^{wt} AML (P=0.0008). Further stratified by *TP53*^{mut} VAF, there was a trend towards higher expression of *TTK* in *TP53*^{mut} VAF≥50 compared to the cases with VAF<50 (P=0.06). Next, the treatment with TTKi (CFI-402257) led to a dose-dependent reduction in cell viability across all cell lines, with *TP53*^{mut} cells (U937 and THP-1) being more sensitive than *TP53*-wildtype (*TP53*^{wt}) OCI_AML-3 cells. Similarly, TTKi inhibited the CFU potential of THP-1, U937, and OCI-AML-3 cells. Finally, TTKi induced dose-dependent apoptosis in *TP53*^{mut} MN patient BMMC but not in healthy donors, resulting in a significant reduction in colony-forming potential.

Conclusion Overexpression of TTK was strongly associated with *TP53*^{mut} and CK in AML. Inhibition of TTK-induced dose-dependent apoptosis in all myeloid cell lines tested with *TP53*^{mut} highly aneuploid cell line (U937)—traditionally the most chemorefractory phenotype—being the most sensitive. TTKi induced preferential and dose-dependent inhibition of viability and cell proliferation potential in *TP53*^{mut} MN compared to healthy donor cells, implying a therapeutic window. Further pre-clinical and clinical studies are indicated to evaluate SAC inhibition as a therapeutic strategy for *TP53*^{mut} MN.

#3180 Suppression of the CPEB3 ribozyme modulates the progression of glioblastoma.

C. Chen[1], E. Wang[1], L. Tong[1], M. Nikan[2], D. A. Bota[1], C. Benavente[1], A. Luptak[1];
[1]University of California, Irvine, Irvine, CA, [2]Ionis Pharmaceuticals, Carlsbad, CA

Glioblastoma multiforme (GBM) is the most aggressive primary malignant brain tumor in adults, with a poor prognosis that highlights a dire clinical need for innovative therapeutic interventions. Despite significant advances in diagnoses and multimodality therapies, the overall prognosis for patients with GBM remains poor, with a median survival time of 15-18 months. Therefore, there is an unmet medical need to develop alternative treatment strategies to improve clinical outcomes. Dysregulation of post-transcriptional control and translational machinery have been implicated in malignant tumor development. Cytoplasmic polyadenylation element binding proteins (CPEB1-CPEB4) are RNA-binding proteins that regulate poly(A) tail elongation of target mRNAs and subsequently contribute to phenotypic changes in cancer cells. Notably, a self-cleaving ribozyme was identified in the *CPEB3* gene, but its role in cancer is wholly unexplored. Considering the role of CPEB3 as a tumor suppressor gene and the promotion of cancer progression through the downregulation of CPEB3, our hypothesis is that the CPEB3 ribozyme regulates CPEB3 expression, and its activity contributes to the progression of tumors. Using antisense oligonucleotides (ASOs) as an approach, we demonstrated that inhibition of CPEB3 ribozyme resulted in an increase of CPEB3 mRNA and protein expression. Blocking the CPEB3 ribozyme led to a significant reduction in cell proliferation, migration, and invasion in GBM cell lines. Gene set enrichment analysis (GSEA) revealed the downregulation of epithelial-mesenchymal transition (EMT), angiogenesis, and hypoxia gene sets in GBM cells treated with ASO compared to Ctrl-ASO. We further measured VEGFA mRNA and protein expression and found that ASO-treated GBM cells secreted significantly less VEGF in conditioned media. Inhibition of the CPEB3 ribozyme also mitigated the EMT process in GBM cells. Subsequently, ASO strategies were applied to patient-derived glioma stem cells (GSCs), representing a clinically relevant model for pre-clinical therapeutic intervention. We found that treatment of CPEB3 ribozyme ASO up-regulated CPEB3 mRNA and inhibited cell proliferation in GSCs. Furthermore, the combination of ASO and temozolomide chemotherapy exhibited a more pronounced decrease in GSCs proliferation compared to individual treatment alone. Collectively, this study highlights the significance of the CPEB3 ribozyme in GBM and explores therapeutic approaches focused on targeting CPEB3 in cancer.

#3181 Immune modulatory activity of radio-sensitizing gold nanoparticle.

T. Kulkarni[1], S. Dutta[1], H. Parent[1], K. Perry[2], Y. Mackeyev[3], **S. Bhattacharya**[1];
[1]Mayo Clinic Florida, Jacksonville, FL, [2]Elizabeth City State University, Elizabeth City, NC, [3]University of Texas Houston Health Science Center, Houston, TX

Radiation therapy (RT) is frequently used in the neoadjuvant setting in borderline resectable and some resectable pancreatic ductal adenocarcinoma (PDAC) and in the definitive setting in locally advanced PDACs which is third leading cause of cancer associated death. Higher doses of RT improve overall treatment outcomes but increasing the dose significantly above 50Gy in standard 2Gy fractions risks profound gastrointestinal (GI) toxicity. Additionally, genotoxic stress such as RT, can induce CXCL12 secretion by cancer associated fibroblast (CAFs) and overexpression of CXC motif chemokine receptor 4 (CXCR4) in cancer cells. CXCL12-CXCR4 downstream signaling results in immune suppression and consequent enhanced tumor growth and metastasis and poor prognosis in PDAC. To overcome these clinical challenges, we have developed multimodal gold nanoparticle constructs (GNPs) by functionalizing the CXCR4 antagonists to (i) bind to CXCR4 and mediate GNP internalization, (ii) abolish the feedback immune inhibitory signals mediated by CXCR4 overexpression, and (iii) enhance therapeutic benefit of radiation. To achieve these multimodal activities, we have covalently attached the CXCR4 antagonist, AMD070, to thiol-terminated polyethylene glycol (PEG) to synthesize AMD-PEG which was then conjugated with GNPs to produce AMD-PEG-GNP. In our experiment AMD-PEG-GNP has successfully inhibited CXCL12-CXCR4 downstream signalling such as reduction of ERK phosphorylation in PDAC cells. To analyze the radiosensitization role of GNP nanoconjugates, PDAC cells were incubated with AMD-PEG, PEG-GNP and AMD-PEG-GNPs for 4 hours and then treated with increasing doses of radiated, from 1-4Gy. AMD-PEG-GNP demonstrated a systematic enhancement on reactive oxygen species (ROS) production and downregulation of a colony formation. Collectively, the results from in vitro study with PDAC cells confirm that the nanoconjugate with AMD070 enhances radio-cytotoxicity and impair CXCL12-CXCR4 downstream signaling. Hence AMD-PEG-GNP has strong merit to enhance radiation dose locally and simultaneously restrict RT induced immunosuppression in PDAC.

#3182 Role of Frizzled 7 in melanoma development and metastasis.

M. Nihal[1], S. A. Umar[2], A.-B. A. Chang[2], N. Ahmad[3], H. Chang[2];
[1]William S. Middleton Memorial Veterans Hosp., Madison, WI, [2]University of Wisconsin-Madison, School of Medicine and Public Health, Madison, WI, [3]University of Wisconsin-Madison, Madison, WI

The frizzled (Fzd) family of proteins are 7-transmembrane G-protein coupled receptors (GPCRs) that transduce signals mainly for Wnt ligands. There are 10 Fzds identified in mammals, and they are involved in multiple cellular and biological functions via signaling through the canonical Wnt/beta-catenin, planar cell polarity, and calcium signaling pathways. Our previous work revealed a pro-metastasis role of Fzd6 in melanoma. This project focuses on Fzd7, a homolog of Fzd6, in melanoma. We found that *FZD7* is highly expressed in multiple melanoma cell lines. siRNA knockdown of *FZD7* does not affect cell proliferation but significantly reduces cell invasion in A375, Hs294T, and SK-MEL28 cells *in vitro*. To determine the *in vivo* role of Fzd7 in melanoma, we generated Fzd7 knockout YUMM1.7 cell lines for xenograft experiments using CRISPR. All three Fzd7 knockout clones showed a significant reduction in primary tumor growth when xenografted in C57BL/6 mice. To determine the potential mechanism of Fzd7 in melanoma growth and invasion, we performed bulk RNA-Seq on the YUMM1.7 knockout cell lines and identified 215 downregulated and 31 upregulated genes (with a fold change of 2, $p<0.05$). We are in the process of confirming these transcriptional profile changes. Further functional analysis will be performed using gain- and loss-of-function approaches to determine the downstream mechanisms of Fzd7 in melanoma growth and invasion.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Cancer Immunotherapy and Drug Delivery
Poster Session

#3184 Development of an innovative bifunctional CPL976-MMAE conjugate based on a bispecific anti-PD-L1/ ant-AXL antibody with a dual mechanism of action.

K. Lacek, **A. Jablonska**, O. Abramczyk, M. Janowska, F. Mitula, A. Sowinska, A. Bojko-Matuszek, T. Kornatowski, D. Kolakowski, M. Bojko, M. Skupinska, W. Pyra, M. Gorka, J. Hucz-Kalitowska, E. Mroz, M. Choros, J. Pieczykoland, M. Wieczorek, D. Popiel;
Celon Pharma SA, Kazun Nowy, Poland

Background: Tumor immunotherapy, especially the combination of PD-1/PD-L1 inhibitors and chemotherapy, has developed rapidly. However, the systemic side effects induced by chemotherapy remain a crucial problem that needs to be addressed. Antibody-drug conjugates (ADCs) are exceptional as a target-specific prodrugs that greatly improve the therapeutic window of chemotherapy drugs. Therefore, we designed the ADC based on a bispecific anti-PD-L1/anti-AXL antibody with toxic MMAE (Monomethyl auristatin E) for precise targeting of cancer cells and reduction of the side effects.
Materials and Methods: The CPL976-MMAE conjugate was prepared with site-specific conjugation technology of Fc-glycan remodeling and click-chemistry. The binding to the extracellular domain of AXL and PD-L1 was confirmed with use of the Surface Plasmon Resonance (SPR). After the conjugation with MMAE, cytotoxicity and selectivity of the ADC were evaluated on the human cancer cell lines with different expression levels of AXL and PD-L1. The ADC's ability to force internalization of targets was shown on a panel of cell lines. The effectiveness of ADC was evaluated based on changes in the cell cycle and of treated cells. The high efficacy of the conjugates was confirmed in a mouse model of MDA-MB-231 xenografts in bi-weekly intravenous injection of 6 doses.
Results: CPL976-MMAE showed improved cellular uptake, selectivity, and anticancer activity, compared to unconjugated MMAE in the cancer cell lines with different expression of the targets AXL/PD-L1. We confirmed ADCs efficacy using cells expressing high levels of AXL and PDL-1 shown as arrest in G2-M phase of the cell cycle and dose-depended apoptosis. The in vivo experiment on a mouse xenograft model confirmed complete tumor reduction (8/8) after ADC treatment, despite the application of an 11 times lower dose in comparison to the free-MMAE control group and was well-tolerated by mice. Importantly, even after the withdrawal of 976-MMAE for 3 weeks, no tumor regrowth was observed.
Conclusions: We presented a new, ADC based on bispecific anti-PD-L1/anti-AXL antibody conjugated with MMAE, that combines the effects of cancer growth inhibition by interaction with AXL and immunotherapy by disruption of the PD-1/PD-L1 axis, with selective delivery of MMAE to cancer cells. The simultaneous action of delivering the toxin and acting on both therapeutic targets provides a potent synergistic anti-tumor effect, that can lead to complete tumor eradication and potentially overcome the primary and secondary resistance to PD-1/PD-L1 targeted therapies.

#3185 Glatiramer acetate enhances tumor retention and mitigates systemic toxicity of toll-like receptor 9 agonists as intratumoral immunotherapy.

H. Gong[1], D. J. Griffin[2], C. E. Groer[1], X. Wu[1], M. M. Abdelaziz[1], S. Wu[1], L. Xu[1], L. M. Forrest[1], C. J. Berkland[1];
[1]University of Kansas, Lawrence, KS, [2]Kinimmune, Inc., St. Louis, MO

Pathogen-associated molecular patterns (PAMP) are conserved molecular structures produced by microorganisms that are recognized as foreign by receptors of the innate immune system. Unmethylated cytosine-guanine oligodeoxynucleotides (CpG ODNs) are a storied drug class from the PAMP family that ligates Toll-like receptor 9 (TLR9). CpG ODNs have shown promising antitumor effects in preclinical studies by inducing potent pro-inflammatory immune responses. However, there are still practical challenges that have hindered clinical success, including inefficient *in vivo* delivery and severe immune-related toxicities caused by systemic exposure to CpG. We previously identified that glatiramer acetate (GA), an FDA-approved, lysine-rich polypeptide, could be applied as a cationic drug delivery vector for CpG delivery proximal to the injection site while mitigating systemic release of pro-inflammatory cytokines. To dive into the mechanism and evaluate pharmacological efficacy in more pathological models that simulate colorectal carcinoma, we validated the biodistribution of GA-CpG complexes (or R4B) and explored their safety and antitumor immunity in multiple mouse colorectal carcinoma models. In the CT26 single tumor model, intratumoral R4B treatment displayed comparable antitumoral efficacy as CpG treatment. Genome-wide transcriptome analysis showed that R4B treatment elicited much more prominent immune system response pathways in both lesions and spleens. The biodistribution study proved that R4B localized and gradually released CpG around the injection site while ‘naked’ CpG diffused away from the injection site quickly. In the CT26 dual tumor-bearing model, intratumoral administration of R4B generated systemic immune efficacy that led to an abscopal effect on distant untreated cancers, comparable to treatment with CpG alone. Notably, R4B treatment accomplished these effects with greatly mitigated systemic pro-inflammatory cytokines compared to CpG alone. These data help further elucidate the noncanonical role of glatiramer acetate to serve as a nucleic acid delivery scaffold that potentiates the safety of CpG adjuvant for cancer immunotherapy.

#3186 An Erythrocyte-αPD-1 conjugate suppresses cancers resistant to checkpoint blockade immunotherapy: A first-in-human study.

L. Yang[1], X. Nie[2], Z. Chen[1], Y. Liu[2], J. Zheng[3], X. Gao[2];
[1]Zhejiang Provincial People's Hospital, Hangzhou, China, [2]Westlake University, Hangzhou, China, [3]Westlake THerapeutics, Hangzhou, China

Background: Immune checkpoint blockade (ICB) therapy has revolutionized cancer treatment, yet resistance to this therapy can lead to immune escape and disease progression. Here, we introduce WTX-212, an erythrocyte-antibody conjugate covalently linking anti-PD-1 antibody to erythrocyte membranes. Unlike conventional antibodies, WTX-212 naturally accumulates in the spleen and remodels the splenic immune landscape in tumor-bearing mice. Pre-clinical studies have demonstrated that T cells activated by WTX-212 reduce the splenic reservoir of immunosuppressive myeloid cells, including those within tumors. This results in a systemic anti-tumor immune response and suppression of tumor growth in xenograft tumor models resistant to anti-PD-1 immunotherapies. A first-in-human (FIH) clinical trial is now investigating its potential in human cancer patients.

Methods: The FIH trial (NCT05707325) is aimed to investigate the safety, pharmacokinetics, mechanisms and preliminary efficacy of WTX-212 in cancer patients with advanced malignancies. All of patients had previously received anti-PDs therapies and developed resistance to these treatments. By November 15th, 2023, 7 patients across two cohorts had received WTX-212 monotherapy (1×10^{11}-2×10^{11} cells, Q3W IV). The tumor lesions were assessed using RECIST v1.1 criteria. Blood and tumor samples were collected for correlative analysis.

Results: 7 patients with various solid tumors, having undergone a median of 3.1 prior lines of therapy (ranging from 1-6), received WTX-212 monotherapy. No dose-limiting toxicities or treatment-related adverse events greater than Grade 3 were reported. WTX-212 was detectable in peripheral blood at the end of cycle in a dose dependent manner. Disease control, including partial remission (PR) and stable disease (SD), was observed in 5/7 patients (DCR, 71%). One patient with esophageal cancer achieved a PR with a significant 44% reduction in target lesion size after two cycles of treatment. Two patients, one with esophageal cancer (3 lines prior therapies) and another with HPV-negative cervical cancer (4 lines prior therapies), maintained disease control for over 30 weeks after WTX-212 treatment. Consistent with preclinical findings, WTX-212 systemically induced anti-tumor responses, leading to a reduction of myeloid-derived suppressor cells (MDSCs) particularly the PMN-MDSC subset in 6/7 patients (reductions ranging from 24%-82% compared to baseline), and a median 1.5-fold increase of T cells in 7/7 patients in the peripheral blood after the 1st cycle of treatment.

Conclusion: The initial promising data support further investigation and exploration of the combination therapy strategies to expand the therapeutic potential of WTX-212 in cancer patients. Erythrocyte-drug conjugation may serve as a unique strategy for targeting the peripheral immune system to treat cancers.

#3187 Enhancing STING activation by cyclic dinucleotide-manganese particles for systemic cancer immunotherapy.

X. Zhou[1], X. Sun[1], W. Gong[1], Z. Wan[1], T. Krieger-Burke[2], V. Yuzbasiyan-Gurkan[2], Y. L. Lei[1], J. Moon[1];
[1]University of Michigan, Ann Arbor, MI, [2]Michigan State University, East Lansing, MI

Background: Activating the innate immune pathway of stimulator of interferon genes (STING) can elicit potent anti-tumor immunity via the production of type-I interferons (IFN-I). However, cyclic-dinucleotide (CDN) STING agonists have undesirable pharmacological properties. Most CDNs in clinical development are administered intratumorally, thus precluding their utility against advanced cancer. Here, we report the development of a new nanoparticle system for the systemic delivery of CDN STING agonists with potent efficacy, favorable pharmaceutical properties, and acceptable safety profiles.
Methods: Various metal ions were screened for synergy with CDNs for IFN-I response from bone marrow-derived dendritic cells. Lipid nanoparticles carrying CDN and manganese ions (termed SNP) were synthesized. Mice bearing syngenetic tumors (including CT26 and B16F10) as well as genetically engineered mouse models were treated by intravenous administration of SNP, followed by tumor monitoring and immune profiling of the tumor microenvironment. White New Zealand rabbits bearing VX2 tumors as well as healthy mongrel dogs were treated with SNP and evaluated. Lastly, human tumor biopsies derived from head and neck squamous cell carcinoma (HNSCC) patients were incubated with SNP or soluble STING agonists and analyzed for immune activation.
Results: We identified that Mn^{2+} achieved strong synergy with CDN STING agonists for inducing IFN-I production. SNP carrying CDN and Mn^{2+} was dosed intravenously in mice, leading to robust IFN-I response, remodeling of the immunosuppressive tumor microenvironment, and expansion of anti-tumor $CD8^{+}$ T cells. Intravenous SNP therapy resulted in robust anti-tumor efficacy in multiple murine tumor models, including CT26, B16F10, and a genetically engineered mouse model of MMTV-PyMT triple-negative breast cancer. We have also observed robust anti-tumor efficacy of SNP against VX2 squamous carcinomas in rabbits and have demonstrated the safety of intravenous SNP therapy in healthy dogs. Mechanistically, the efficacy of SNP therapy was dependent on the host STING expression but independent of the tumor STING expression. In addition, the anti-tumor efficacy of SNP was decreased in mice lacking *Ifnar1* or *Ifngr1* expression in the B16F10 melanoma model, showing the crucial effects of IFN-I and IFN-II responses. Moreover, SNP treatment led to robust IFN-I responses from fresh human tumor biopsies derived from HNSCC patients.
Conclusions: SNP empowers highly effective systemic cancer immunotherapy via nanotechnology. It also underscores the potential of utilizing metal ions for immune-mediated disease treatment.

#3188 Chitosan-glycerol injectable gel for intratumoral retention of immunotherapeutics.

R. L. Kobrin, S. M. Mantooth, D. A. Zaharoff;
North Carolina State University, Raleigh, NC

A novel, injectable chitosan-glycerol hydrogel was developed and characterized. Upon injection with co-formulated therapeutics, the gel vastly improved molecule retention at the injection site, as compared to molecule delivery in less viscous media.

Methods. The hydrogel was formed through a centrifugation process. 70% deacetylated, medium viscosity chitosan was dissolved in 0.1M HCl. Glycerol was then added, followed by vortexing. Next, 1x PBS and 1M NaOH were added to neutralize the mixture, which induced gelation. After hydrogel centrifugation at 10,000 rpm for 5 minutes, a hydrogel was separated from precipitate. Several formulation parameters were tested, including chitosan:glycerol volume ratio, chitosan concentration, chitosan degree of deacetylation, and chitosan molecular weight. The retention of model therapeutics, formulated in hydrogel or saline vehicles, following injection in agar-based tumor phantoms was quantified via absorbance and fluorescence readings. To assess biocompatibility, a non-contact cell viability assay was performed utilizing 3T3 fibroblasts seeded in the bottom of transmembrane wells with hydrogels added to the upper chamber. After 48 hours, cells were collected and counted utilizing trypan blue.

New Data. A hydrogel for intratumoral therapeutic delivery was constructed with several desirable qualities, including biocompatibility and injectability through a 25-gauge needle. Different relative glycerol to chitosan volumes, from 5 to 95 w/v % glycerol, were tested to determine a range of gelation conditions. Glycerol volume most significantly impacted gelation conditions independent of chitosan concentration, with gelation occurring between 70-85% relative volume glycerol. Increasing chitosan solution concentration and chitosan molecular weight increased the range of chitosan:glycerol ratios resulting in gelation. The hydrogel improved load retention at the agar tumor phantom injection site for various sizes of model therapeutics compared to less viscous solutions. Cytotoxicity testing of the hydrogel showed a statistically insignificant difference between the live:dead cell ratios of the experimental and negative control groups.

Conclusion. An injectable, biocompatible hydrogel was created through the neutralization and centrifugation of a chitosan-glycerol solution. The hydrogel displays physiological pH, injectability through a 25-gauge needle, biocompatibility, and vastly improved therapeutic load retention at the injection site compared to less-viscous delivery media. Chitosan-glycerol hydrogels may be useful for intratumoral delivery and retention of immunomodulators within the tumor microenvironment.

#3189 A novel monoclonal antibody targeting TM4SF4 enhances antitumor activity through regulation of cellular levels of immune checkpoint ligands and antibody dependent cellular cytotoxicity.

Yeon-jee Kahm[1], Chang-Kyu Heo[2], Rae Kwon Kim[1], Uhee Jung[1], Byung-Chul Shin[1], Won-Yong Kim[1], Bum-Jin Kim[3], Sung-Chul Kim[3], Chun-jeih Ryu[4], Eun-Wie Cho[2], In-Gyu Kim[1]

[1]Korea Atomic Energy Research Institute, Daejeon, Korea, Republic of,[2]Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of,[3]Algok Bio. Inc., Bellevue, WA,[4]Sejong University, Seoul, Korea, Republic of

Transmembrane 4 super family member 4(TM4SF4) protein has been shown to be involved in EMT-associated stemness through autocrine of insulin-like growth factor 1(IGF1) and osteopontin(OPN) in non-small cell lung cancer(NSCLC) cells. However, its potential as a therapeutic target has not been evaluated. In this study, anti-human TM4SF4 monoclonal antibodies(anti-hTM4SF4 mAbs) were prepared in mouse as part of a strategy for developing anticancer drug using humanized antibody. A synthetic peptide(15 mer, 126-140th AA) derived from the extracellular loop(ECL) 2 of human TM4SF4 exposed on outer cell surface was used as an immunization antigen. Among the selected anti-hTM4SF4 mAbs, ECL-2B7 and ECL-12A8 showed the best affinity for the antigen(Kd), approximately 2.66 nM and 8.34 nM, as determined by surface plasmon resonance analysis. Using mouse xenograft of NSCLC cell line, it was confirmed that ECL-2B7 was superior to ECL-12A8 in producing humanized antibody. ECL-2B7 inhibited EMT-associated stemness of TM4SF4 positive cancer cells by blocking cellular signaling events such as IGF1Rβ and CD44 and their downstream signals, PI3K/AKT/GSK3β/NF-κB and JAK2/STAT3 pathways. ECL-2B7 also enhanced antitumor activity by downregulating cellular and exosomal level of PD-L1 and B7-H4, immune-checkpoint ligands that elicit immunosuppression of T cell, and by mediating antibody-dependent cellular cytotoxicity. Treatment with OPN- and IGF1-neutralizing antibodies suppressed intracellular PD-L1 and B7-H4 level. It means that the regulation of PD-L1 and B7-H4 levels by TM4SF4 is closely related to the autocrine action of OPN and IGF1 induced by TM4SF4. Using patient-derived xenograft model, it was confirmed that the ECL-2B7 has excellent antitumor activity that effectively inhibits tumor progress. These results strongly suggest that it is necessary to construct humanized antibody based on ECL-2B7 to confirm its potential as a novel anticancer drug.

#3190 Twin Fc-immune cell engager (ICE): A novel antibody platform for cancer immunotherapy with enhanced avidity for Fcγ receptors and complement.

E. S. Choi, H. Park, J. Bae, K.-J. Lee, E. Kim, S. Yoon, D. Lee, G.-H. Yang;
Centenaire Biosciences Inc., Seongnam-si, Korea, Republic of

Immunoglobulin G (IgG)-based mAbs have become a dominant class of cancer immunotherapy due to their excellent drug-like properties, long half-life, and generally safe profiles. Typical IgG-based therapeutic mAbs have strong binding to target antigens owing to the valency effect of two antigen-binding fragments (Fabs). However, the single crystallizable fragment (Fc) lacks the valency effect to engage immune effector elements. As Fcγ receptors (FcγR) such as FcγRIIa and FcγRIIIa and C1q complement component have low affinity for Fc, IgG-based mAbs require high antibody opsonization density to exhibit avidity for these low affinity Fcγ receptors and C1q. This may also account for the suboptimal efficacy of IgG-based mAbs against tumors with less abundant antigen. To enhance effector functions of IgG1 by overcoming such limitation, we devised a novel platform, Twin Fc-ICE, in which a single Fab region is attached by two Fc regions which allow for high avidity binding to Fcγ receptors and C1q. The two Fc regions of Twin Fc-ICE are arranged in parallel, not in tandem, to adopt natural topologies of multiple Fc regions presented by IgG1-opsonized targets. Supporting the avidity effect of Twin Fc-ICE for FcγR binding, we showed that CTN001, a Twin Fc-ICE with trastuzumab Fab, have markedly increased binding to FcγRs including FcγRI, FcγRIIa and FcγRIIIa compared with trastuzumab. The avid FcγR binding was further demonstrated by flow cytometry analysis of human blood which revealed significantly increased binding of CTN001 relative to trastuzumab for immune cells expressing activating FcγRs such as natural killer (NK) cells, monocytes, and dendritic cells (DCs). The monovalent antigen binding of Twin Fc-ICE requires Fab with high affinity. However, provided that high affinity is achieved, the monovalent Fab adds to the two Fc regions to maximize the Fc load on cancer cells expressing low levels of antigen. Indeed, flow cytometry analysis revealed that treatment of CTN001 alone results in higher Fc load on HER2-expressing cancer cells than combination of two anti-HER2 IgG1 mAbs, trastuzumab and pertuzumab. In consistent with increased Fc load on target cells and avid FcγR binding, CTN001 induces enhanced effector functions such as CDC, ADCC and ADCP against HER2-expressing cancer cells compared with trastuzumab, which will be presented in a separate poster. CTN001 exhibits comparable thermal stability with trastuzumab and can be readily purified to >95% purity with typical purification platforms. The serum half-life of CTN001 at 10 mg/kg intravenous dose in rats is found non-inferior to that of trastuzumab (~12 days versus ~7 days). Taken together, Twin Fc-ICE provides an optimized platform with drug-like properties, which leverages avidity effects of Fc to potentiate therapeutic efficacy of antibody.

#3191 Chk1/2 inhibition enhances response to lurbinectedin treatment in small cell lung cancer.

A. Sanchez Sevilla Uruchurtu[1], T. Roady[1], A. Anderson[2], W. S. El-Deiry[1];

[1]Brown University, Providence, RI, [2]Metropolitan Regional Career and Technical Center, Providence, RI

Small cell lung cancer (SCLC) remains a significant clinical concern, with only a 7% 5 year survival rate; therefore, there remains an unmet need for efficacious treatments. Lurbinectedin was FDA approved in 2019 to treat platinum-resistant SCLC. Preliminary experiments in SCLC cell lines indicated an increase in intracellular pChk1 when treated with lurbinectedin. Based on these data and our understanding of the role of checkpoint kinases in the DNA damage response (DDR), we hypothesize that the activity of Chk1 is indicative of upregulated DDR activity as a result of double stranded breaks and replicative stress induced by lurbinectedin. In subsequent experiments, we sought to identify the role of Chk1 and Chk2 in the tumor cell response to lurbinectedin by inhibiting their activity using prexasertib (LY2606368, Acrivon Therapeutics). Cell viability experiments indicate decreased tumor cell viability when three SCLC cell lines (H1048, H1105, H1417) are treated with prexasertib as a single agent and in combination with lurbinectedin. Western blot analysis of intracellular proteins from the same SCLC cell lines treated with both drugs demonstrate dose-dependent effects on cell death marker cPARP, DNA damage marker γH2AX, and DDR/cell cycle pathway kinases cdk1 and 2. Ongoing experiments seek to replicate results using alternative Chk1/2 inhibitors, and to explore the effect of lurbinectedin-Chk1/2 inhibitor combination treatment on antitumor immune effector function by in vitro co-culture.

#3192 A novel long acting pegylated T cell engager targeting CD3 and cd19 with effective tumor killing and no potential CRS risk in CD19+ hematologic malignancies.

S. Liu, Y. Wen, W. Lyu, S. Yin, Y. Lei, D. Wu, Z. Wu, Q. Zhuo;
Shenzhen Enduring Biotech, Ltd., Shenzhen, China

The development of bispecific T cell engagers represents a highly effective immunotherapy strategy for the treatment of hematologic malignancies. However, Blinatumomab, a bispecific T cell engager of CD3/CD19, has disadvantages in clinical setting due to the adverse pharmacokinetics (PK), which resulted in less than 2 hours of in vivo elimination half-life, neurotoxicity, and cytokine release syndrome. In this study, a bispecific antibody JY108 was developed to target CD19 and CD3e with much reduced affinities towards both targets (revealed by Biacore assay results). JY108 was prepared by a patented pegylation bispecific linker technology, which could address the limitations of current therapeutic approaches. *In vitro* cytotoxicity assay results demonstrated that the EC50s of the drug specific cytotoxicity of T cells mediated by JY108 are in the concentrations of ng/ml, while blinatumomab mediated cytotoxicity to the same CD19+ cells are in the concentrations of pg/ml. Despite the weaker in vitro cytotoxicity than Blinatumomab, JY108 presents comparable tumor inhibition effects with Blinatumomab in different i*n vivo* studies, which include the PBMC reconstructed models with established MEC-1 or Farage tumors, the delayed drug administration on human PBMCs/tumor co-transplanted model of Raji. In addition, JY108 prolonged the survival of animals with Nalm6 brain metastasis more significantly than Blinatumomab at the same dosage. Furthermore, the PK study revealed that at the different dosages, the circulation $T_{1/2s}$ of JY108 in mice are above 20 hours, which is expected to result in more significant efficacious benefits in clinical setting. Meanwhile, the completed package of GLP-toxicity study did not observe any drug related tox to the model animals (including no cytokine release in vivo, no neurotoxicity, no respiratory toxicity, etc.), and JY108 did not induce significant cytokine release than the blank control to the whole blood or PBMCs from healthy donor in vitro. In the efficacious concentrations of exerting cytotoxicity to CD19+ tumor cells in the presence of PBMC, JY108 did not induce significant cytokine release than the blank control, while blinatumomab always induced significant cytokine release. We postulated that the lower CD3 affinity of JY108 most probably resulted in the decoupling of the signaling for activating the gene expression of cytokines from the secretion of the polarized lytic granules by T cells, which resulted in a much milder T cell activation by JY108. Currently, JY108 is a phase I trial candidate and awaits further evaluations.

#3193 Utilizing a pH sensitive peptide (pHLIP) for antigen-directed T cell therapy.

A. M. Yurkevicz, Y. Liu, P. M. Glazer;
Yale University, New Haven, CT

Many targeted therapies, such as antibody drug conjugates (ADCs) and chimeric antigen receptor (CAR) T cell therapies, rely on the identification of an optimal antigen as the cell marker for targeting cancer cells. However, there is a paucity of antigen candidates that are sufficiently specific to epithelial cancers. Therefore, technologies that can mark tumor cells for immune recognition could prove beneficial in the treatment of these solid cancers. pH low insertion peptides (pHLIPs) act as a unique delivery platform that can specifically target the acidic microenvironment of tumors, sparing healthy tissue in the process. We developed a pHLIP-peptide conjugate (pHLIP-SIINFEKL) to deliver the SIINFEKL peptide, an immunogenic fragment of ovalbumin, to investigate antigen delivery and recognition to tumors *in vivo*. When processed intracellularly, SIINFEKL is presented for immune recognition through the major histocompatibility complex (MHC) class I pathway. We observed selective delivery of pHLIP-SIINFEKL both *in vitro* and *in vivo* using fluorescently labeled constructs. *In vitro*, treatment of melanoma tumor cells with pHLIP-SIINFEKL resulted in recognition by SIINFEKL-specific T cells (OT1), leading to T cell activation and effector function. Mechanistically, we show that this recognition by OT1 cells was abrogated by siRNA knockdown of the β2 microglobulin (β2m) component of MHC class I in the target tumor cells, indicating that an intact antigen processing pathway in the cancer cells is necessary to mediate the effect of pHLIP-directed SIINFEKL delivery. *In vivo*, pHLIP-SIINFEKL treatment of tumor-bearing mice resulted in recruitment of OT1 T cells and suppression of tumor growth in two syngeneic tumor models in immunocompetent mice, with no effect when mutating either the pHLIP or SIINFEKL components of the conjugate. These results suggest that pHLIP-mediated peptide delivery can provide a novel approach to decorate solid tumors with engineered antigens for enhanced immune recognition and anti-tumor efficacy.

#3194 Discovery of T cell receptor mimic antibody against MAGE-A4 with single B-cell cloning platform.

H. Cheng, Y. Wu, T. Shi, Y. Yu, M. Wang, C. Jia, W. Xin, **H. Liu**, T. Yang, D. Yao;
ChemPartner Biologics Co., Ltd, Shanghai, China

Antibody therapeutics has been proven clinically against various cancer types and have achieved great success. Majority of the therapeutic antibodies target cell surface or extracellular proteins. Most of the tumor-specific antigens that control cell growth, proliferation, and death are intracellular, and traditional antibody therapies fail to recognize intracellular antigen targets. Such tumor specific intracellular targets consist of overexpressed self antigens, oncofetal protein, cancer testis antigens, viral protein and neo-antigens of mutant proteins. Recently, an emerging approach to target these neo-epitopes has been developed called T-cell receptor-like/TCR-mimic antibodies as they recognize similar epitopes to those of T cell receptors which target specific peptide-MHC complexes(pMHC). TCR mimic antibodies open a new avenue for targeting intracellular antigens yet there are lots of challenges for generating highly selective and potent TCR mimic antibodies. MAGE-A4, melanoma-associated antigen A4, is a member of the MAGE protein family of cancer-testis antigen (CTA). In healthy adult, MAGE-A4 expression is restricted to immune-privileged sites. But MAGE-A4 is widely expressed on many cancers such as lung cancer, head and neck squamous cell cancer, synovial sarcoma(SS), ovarian cancer, urothelial cancer and melanoma. The decapeptide GVYDGREHTV(amino acids 230-239) derived from MAGE-A4, can be presented by HLA-A*02:01 molecule, elicits specific cytotoxicity T cell response. Afami-cel, a genetically modified autologous T cell therapy against this pMHC complex, showed promising potency for patients with metastatic SS. So MAGE-A4/ HLA-A*02:01 may be a good target for TCR mimic antibodies and cancer immunotherapy. In the present study, we utilized a newly established single cell cloning platform LyTARS to generate TCR mimic antibodies against HLA restricted MAGE-A4 peptide. Recombinant HLA-A*02:01 MAGE-A4 protein was used to immunize mice and plasma B cells from immunized mice were sorted and loaded onto LyTARS system. Clones that showed reactivity to recombinant HLA-A*02:01 MAGE-A4 but not to irrelevant pMHC (WT-1) were exported and sequenced. Purified antibodies were extensively characterized by the specificity, affinity, and potency by ADCC. Results demonstrated that the TCR mimic antibodies identified have sub-nano molar affinity by protein based ELISA, bind to peptide pulsed T2 cells that endogenously expressing HLA with nano-Molar apparent affinity. TCR mimic antibodies also demonstrated antibody dependent cell killing with the potency of sub-nanomolar. In summary, we have generated and extensively characterized a panel of high affinity and selective TCR mimic antibodies against HLA-A*02:01 MAGE-A4 using a newly established single cell cloning platform.

#3195 SHR-4602, next generation of HER2-targeting ADC with potent anti-tumor efficacy overcoming the resistance of HER2 ADC with Topo I inhibitor payload in xenograft models.

Y. Tian, X. Sun, C. Yang, C. Liao;
Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China

Background: Current clinical HER2-targeting ADCs (i.e. DS-8201) have shown promising clinical efficacy in HER2 expressing or mutant cancer patients. However, most of them will ultimately experience disease progression due to different mechanisms. Herein, we presented a novel HER2 ADC, SHR-4602, which demonstrated good *in vitro* and *in vivo* anti-tumor activities and could overcome the resistance caused by HER2 ADC including DS-8201 analogue (synthesized using DS-8201 structure) and SHR-A1811 (composed of trastuzumab, a cleavable linker, and a Topo I inhibitor payload, in phase III clinical trials) in xenograft models.

Method: We used a stable enzyme-cleavable linker technology to conjugate the HER2 ADC using the amino acid sequence of pertuzumab and ER300 (eribulin derivative). The *in vitro* biological and anti-tumor activities were assessed by a series of assays. The *in vivo* anti-tumor efficacies were evaluated in the JIMT-1 (HER2 low expressing) as well as the SHR-A1811 and DS-8201 analogue induced JIMT-1 resistance (caused by treating with SHR-A1811 followed by DS-8201 analogue for a long-term) xenograft models in BALB/c nude mice.

Results: Through the SPR assay, SHR-4602 exerted single nanomolar binding affinity to human and rhesus monkey HER2, but no binding activity against rat HER2. It demonstrated varying inhibitory activity on the proliferation of cancer cell lines with various HER2 expression levels, with the IC_{50} at the range of 0.007 nM to 8.21 nM. SHR-4602 showed highly efficient internalization in NCI-N87 HER2 expressing cells and could be translocated to the lysosome followed by releasing ER300. The cytotoxic activity of SHR-4602 was predominantly mediated by released ER300 through microtubule dynamics inhibition, G_2/M arrest and apoptosis induction. Furthermore, SHR-4602 showed a strong *in vitro* bystander effect in the co-culture of HER2 positive/negative cells. SHR-4602 showed significant anti-tumor efficacy in JIMT-1, SHR-A1811 and DS-8201 analogue both-resistant JIMT-1 xenograft models. In SHR-A1811 and DS-8201 analogue both-resistant xenograft models, treatment with 10 mg/kg SHR-A1811 or DS-8201 analogue exerted negligible anti-tumor activity (TGI% < 17%), whereas SHR-4602 at 2.5, 5 and 10 mg/kg significantly inhibited the tumor growth ($p < 0.001$, vs. vehicle), with TGI% of 84.96%, 101.64% and 113.11% on Day 42, respectively, which indicated a superior anti-tumor efficacy against SHR-A1811 and DS-8201 analogue both-resistant xenograft models.

Conclusion: SHR-4602 represents a new generation HER2-targeting ADC to deliver a potent cytotoxin to HER2 expressing tumor cells and may be more efficacious to the tumors in which current anti-HER2 therapies are ineffective. SHR-4602 is now in the phase I clinical development stage for advanced malignant solid tumors (NCT05819684).

#3196 Overcoming lung cancer drug resistance: Enhanced cellular delivery using lipid-extracted nanoliposomes.

M. Alqaryan, R. Allahyani, D. Lee, R. Campbell;
MCPHS University, Worcester, MA

Background: Lung cancer causes substantial cancer deaths in the U.S. Drug resistance remains a major issue. Nanoliposomes demonstrate enhanced drug targeting and resistance-overcoming potential. Incorporating lipid extracts derived from target cells shows improved delivery over conventional nanoliposomes. This study examined the effects of lung cancer cell lipid extract nanoliposomes against target and non-target cell populations from different environments.
Method: Cellular Membrane Lipid-Extracted Nanoliposomes (CLENs) were fabricated with DOPC, DOTAP, ChaGo-K-1 lipid extract, cholesterol, PEG5000, and rhodamine fluorescent label was incorporated for uptake studies. The liposome size was reduced by probe sonication. Particle size and polydispersity index (PDI) were measured by dynamic light scattering. Zeta potential was quantified by laser Doppler micro-electrophoresis. Four cell lines were utilized: ChaGo-K-1 NSCLC target, A549 pulmonary microenvironment control, 4T1 extra-pulmonary control, and normal lung fibroblasts off-target control. All cell lines were cultured in 48-well plates at a seeding density of 10,000 cells/mL and incubated for 24 hours. Freshly prepared CLENs were added to all cell lines and incubated for an additional 24 hours. Cells were washed with PBS, and fluorescence intensity was then quantified and qualified by a microplate reader to measure the cellular uptake of the CLENs.
Results: The mean particle size and PDI of the ChaGo-K-1 CLENs were 117 ± 0.7 nm and 0.216 ±0.009, compared to 126 ± 0.5 nm and 0.195 ± 0.008 for the control, respectively. Both formulations were within the optimal size range for drug delivery and tumor cell penetration. The zeta potential of the ChaGo-K-1 CLENs was -1.75 ± 1.81 mV compared to -1.74 ± 6 mV for the control. Quantification and qualification of cellular uptake using fluorescence intensity measurements revealed a 3.2-fold increase in ChaGo-K-1 CLENs compared to conventional liposomes without ChaGo-K-1 lipid extracts. This demonstrates that the inclusion of the lipid extracts in the CLEN significantly enhanced selectivity and delivery to target cancer cell populations.
Conclusion: Higher uptake occurred with target cells using CLENs with lipid extracts versus standard liposomes. NSCLC-derived CLENs show potential to improve selective delivery and overcome drug resistance. Further, in vivo studies evaluating selective NSCLC tumor accumulation and efficacy enhancement are warranted.

#3197 Addressing drug metabolism and pharmacokinetics (DMPK) challenges of small molecule-drug conjugates (SMDCs).

A.-S. Rebstock[1], H.-G. Lerchen[1], H. Wong[2], B. Stelte-Ludwig[1], M. Wiedmann[1], A. J. Johnson[2], R. Izumi[2], A. Hamdy[2];
[1]Vincerx Pharma, Monheim, Germany, [2]Vincerx Pharma, Palo Alto, CA

Background: SMDCs are gaining momentum with potential advantages over antibody-drug conjugates (ADCs), eg, better tumor penetration and lack of immunogenicity. We have developed a novel platform technology with tailored solutions for ADCs and SMDCs with intracellular and extracellular cleavage options. Key features of the SMDC technology comprise of a small molecule ligand such as an αvβ3 integrin binder showing efficient tumor homing and a linker extracellularly cleaved by neutrophil elastase (NE) in the tumor microenvironment allowing for seamless release of different payload classes.[1] Our lead SMDC VIP236[2] is currently in a Phase 1 clinical trial for the treatment of advanced solid tumors (NCT05712889). SMDCs often have a shorter half-life compared with ADCs, which may result in more frequent dosing schedules. Here we show significant reduction of clearance and drastic prolongation of half-life of SMDCs achieved by adding a second binding moiety.

Methods: Payloads such as kinesin spindle protein inhibitors (KSPi), cyclin-dependent kinase 9 inhibitors (CDK9i), and monomethyl auristatin E (MMAE) have been linked via elastase-cleavable linkers to one or, via a branched linker, to two αvβ3 integrin binding moieties. Cytotoxicity of SMDCs was measured in cell lines with or without NE. Monovalent and bivalent SMDCs were investigated in DMPK studies in rats while monitoring the conjugate and the released payload.

Results: Payloads were coupled to the NE-cleavable peptides via different linkages. MMAE was conjugated via sterically hindered ester bonds, CDK9i was conjugated via sulfoximide bonds, and KSPi payloads were coupled via amide bonds. Each of these SMDCs was highly stable in plasma and buffer. Without NE, in vitro cytotoxicity of SMDCs in each cell line was poor with IC50 in the micromolar range. In contrast, in the presence of NE, potency increased, and cytotoxicity (IC50) was in the low nanomolar to picomolar range depending on the cell line and payload. In each case, the SMDCs reached similar potency as the free payload indicating efficient cleavage of the SMDC by NE. In DMPK studies of SMDCs in rat, none or trace levels of free payload (<0.1% as compared to the respective conjugates) was measured. With each of the SMDCs and independent of the conjugated payloads, a remarkable impact on exposure was observed when attaching a second binding ligand. The SMDCs with two ligands showed a 37- to 81-fold reduced plasma clearance as compared with the respective monovalent SMDCs, which parallels a 12- to 57-fold increase in half-life (eg, 2.1 h and 28 h for mono and bivalent MMAE SMDCs respectively). Initial in vivo studies in a cell line-derived xenograft model showed efficacy of bivalent SMDCs with once weekly dosing.

Conclusion: Our technology platform comprises NE-cleavable SMDCs with promising options to tune the DMPK profile for a longer half-life.

#3198 An analysis of breast cancer membrane lipid-modified nanoliposomes for enhanced targeting of triple-negative breast cancer.

C. Ayertey, P. Amid, M. H. S. Almozain, R. B. Campbell;
McPhs University, Worcester, MA

Background: Every breast cancer diagnosis is unique in its own way. Triple-negative breast cancer (TNBC), has a highly aggressive phenotype characterized by a rapid growth rate profile, increased risk of metastasis and recurrence. TNBC is devoid of epidermal growth factor receptor 2, estrogen, and progesterone receptors. All three are commonly present in other forms of breast cancer disease. The aim of this study was to develop a cell membrane lipid-extracted nanoliposomes (CLENs) for selective targeting compared to conventional nanoliposomal varieties. An additional objective was to investigate the role of microenvironment on targeting using cell model of TNBC, and representations of non-target tissue environments for comparison.
Method: Lipid extracts (LE) obtained from 4T1, a murine mammary carcinoma cell line from a BALB/cfC3H mouse was used to formulate the CLENs (cell membrane lipid-extracted nanoliposomes) with different ratios of 1,2-dioleoyl-sn-glycero-3-phosphocholine (DOPC), a phospholipid used in most conventional drug delivery liposomes. Different lipid compositions and ratios were employed to evaluate cellular uptake in target, non-target and off-target cells. The target cell line, 4T1, off-target and non-target cell populations included CRL-2089, normal breast fibroblasts, SKBR3 a (human breast cancer), and A549 a (lung cancer) cell lines. Other studies involved determination of molecular charge and zeta potential of various nanoliposomal preparations and corresponding fluorescence studies in vitro.
Results: The physicochemical properties of CLENs such as particle size and surface charge characteristics were vital when assessing benefit of the lipid-based preparations. The size of the CLENs typically ranged between 130 - 165 nm and zeta potential values were negatively-charged. The inclusion of 70 mol% of LE in preparation of 4T1-CLENs demonstrated increased cellular uptake and binding by the 4T1 target cells compared to the control DOPC (100%). The highest degree of selectivity was observed in early cell binding events, and with studies involving more extended incubation time points under different experimental conditions. Off-target cells demonstrated reduced uptake by comparison. Overall, 4T1-CLENs was most efficient when applied against intended target 4T1 cells, when compared to relevant control cell populations. In conclusion, studies performed to date suggest the notion that lipid extracts derived from TNBC improves targeting.

#3199 Nano gelasomes: Novel lamellar metal-protein suprastructures for nucleic acid delivery.

A. Suresh Babu, **D. Suresh**, Z. Li, A. Upendran, R. Kannan;
University of Missouri, Columbia, MO

There is considerable interest in the development of self-assembled charged nanocarriers that form organized, predictable structures to enhance stable packaging and delivery of nucleic acid materials *in vivo*. However, the synthesis of stably-charged, organized nanostructures is highly challenging, requiring a controlled balance of nanomaterial components, stabilizers, and hydrophobic forces. Herein, we report a significant step forward in the controlled lamellar assembly of a charged complex between ultra-small 2 nm gold nanoparticles and a lipidoid within an organic matrix to form Gelasomes. These spherical suprastructures feature an intricate 3D concentric arrangement with a constant interlayer distance (4nm). The cationic lipidoid within this arrangement aids in the highly efficient packaging of nucleic acid materials in the nanoparticle. To demonstrate the potential biomedical applications of Gelasomes, we have loaded siRNA (AXL or YAP), mRNA (EGFP), or CRISPR components (Cas9 mRNA and guide RNA) and validated their functionality by *in vitro* or *in vivo* studies. Gelasomes with AXL siRNA (~20 bp) demonstrated rapid uptake (<2 hrs), successful endosomal escape, remarkable transfection efficiency (99.87 ± 0.04 %), gene downregulation (97 ± 2.8 %), and disassembly within the cell (<24 hrs). *In vivo* downregulation studies in Lung Cancer PDX (Gelasomes with AXL siRNA) and CDX (Gelasomes with YAP siRNA) models confirm the gene-silencing capability (91% or 38 % respectively) of Gelasomes underscoring their potential in advancing nanomedicine. Similarly, Gelasome loaded with EGFP mRNA (1 kb) showed 47 ± 8.54 % expression efficiency within 48 h of treatment *in vitro*. We also show the packaging of larger nucleic acids such as CRISPR Cas9 mRNA (5 kb) along with the guide RNA (100 bp) *in vitro* for generating knockouts, that achieved an editing efficiency of ~6%. Together, the results from this study pave the way for the development of adaptable, biodegradable, and functionally versatile supraparticles for medical applications.

#3200 Assessing the utility of cell membrane lipid-extracted nanoliposomes (CLENs) as a targeted drug delivery system for pancreatic cancer.

K. Alshammari, S. Verdery, S. George, R. Campbell;
Massachusetts College of Pharmacy and Health Sciences, Worcester, MA

Background: Pancreatic cancer is a challenging type of cancer to treat as evidenced by a 9% 5-year survival and a dismal rate of mortality. Nanoparticles represent a revolutionary treatment method, primarily due to characteristics including cellular absorption, boosting therapeutic effectiveness, and mitigating side effects through localized actions. For nanomedicine, optimizing liposome formulations is crucial for achieving the highest level of specificity in drug targeting. This study aims to evaluate cellular interaction of pancreatic cancer lipid-extract modified nanoliposomes when compared to unmodified varieties *in vitro*.
Method: Cell membrane lipid-extracted nanoliposomes (CLENs) were prepared via the thin film evaporation technique. The composition included various compositions and ratios of DOPC, DOTAP, Cholesterol, DPPE-PEG-$_{5000}$, and lipid extracts derived from MS1-VEGF target cells. MS1-VEGF was the cellular model of pancreatic cancer used for this study. Cellular binding studies were performed using cellular suspension and adherent cell populations. Studies were performed in 48-well plates under different experimental conditions including alterations in time of incubation, and periods of cellular exposure to dual humidified and oscillation environments in the presence of lipid-extracted (LE) nanoliposomal preparations and conventional controls.
Results: The particle size for nanoliposomes employed for this study was approximately 115 ± 0.7 nm for control and 128 ± 2.7 nm for experimental (lipid extract-modified) nanoliposomes. Following cellular exposure to different lipid extract concentrations (typically 0 to 100 nmoles per ml of growth medium), the fluorescence values demonstrated increased cellular uptake with greater LE content for floating and adhered MS1-VEGF cell populations. With the floating cells, LE-modified nanoliposomes demonstrated significantly higher fluorescence intensity values compared to conventional nanoliposomes. Similarly, with MS1-VEGF adherent cells, LE-modified nanoliposomes targeted cells to a greater extent compared to unmodified controls.
Conclusions: The increased cellular uptake of CLENs designed for targeting pancreatic tumor cells (both floating and adherent cells) demonstrated an improvement over the use of conventional nanoliposomes under similar experimental conditions. Further research is needed to fully explore the potential use of CLENs for targeting and treatment of pancreatic cancer.

#3201 Preclinical development of a novel Romidepsin nanoparticle for the treatment of T-Cell lymphoid malignancies.

I. Pal, A. Illendula, A. Joyner, T. M. Deddens, D. P. Damera, T. E. Fox, M. E. Dunlap-Brown, K. D. Jayappa, T. P. Loughran, Jr., D. J. Feith, **O. A. O'Connor**; University of Virginia, Charlottesville, VA

The histone deacetylase inhibitors (HDACi) have long been regarded as an important class of drugs for treating T-cell lymphoid malignancies (TCL). Romidepsin (Romi), a bicyclic peptide, was approved for patients with relapsed or refractory cutaneous (CTCL) and peripheral T-cell lymphomas (PTCL). Unfortunately, the approval of Romi for relapsed/refractory PTCL was withdrawn due to a negative Phase 4 post-marketing requirement. Given its potent activity against Class I HDACs, Romi is considered one of the most effective HDAC inhibitors studied and used in patients with TCL. Herein, we report on a first-in-class nanoparticle of Romi (NanoRomi) with a superior safety and efficacy profile compared to the free drug in preclinical models of PTCL and large granular lymphocyte leukemia (LGLL). We developed a first-in-class NanoRomi using our proprietary amphiphilic di-block copolymer-based nanochemistry platform. NanoRomi was characterized in cell viability, flow cytometry, and western blotting (WB) assays to determine the concentration-effect relationships with regard to the induction of apoptosis and histone acetylation in cell lines representative of TCL and LGLL, as well as primary LGLL patient PBMC samples. In addition, we performed extensive *in vivo* modeling using murine xenografts of CTCL, including repeated dose toxicity, biodistribution, efficacy, and survival studies. Cytotoxicity assays demonstrated superior/comparable activity of NanoRomi (IC50: 1.1-2.3 nM) compared to free Romi (IC50: 4.8-10.6 nM) across all PTCL and LGLL cell lines studied, while in primary LGLL samples, NanoRomi exhibited superior cytotoxicity (2-fold) compared to Romi. WB analysis showed that NanoRomi induced apoptosis and increased acetylation of histone H3 and H4 in a time and concentration-dependent manner in cell lines representing CTCL, ALK+-ALCL, and LGLL. Repeat dose toxicity studies in CTCL xenografts confirmed that the overall tolerability of NanoRomi was substantially better than Romi. Tracking studies with a fluorescent dye (DiO) in the NanoRomi demonstrated preferential localization of NanoRomi in tumors of mice compared to the normal organs after 6 hours of drug administration. NanoRomi exhibited superior efficacy in the murine CTCL xenograft models, including a significant improvement in overall survival compared to Romi. Collectively, these data show that NanoRomi exhibits markedly superior pharmacokinetics, tolerability, and efficacy in models of TCL. We anticipate that the improved activity and tolerability of NanoRomi relate to the altered pharmacologic profile and superior bioavailability of the drug, which optimizes the effects of the drug for its influence on epigenetic biology. This unique platform offers the prospect of improving the tolerability and efficacy of epigenetic treatment strategies in these challenging diseases.

#3202 Investigating the induction of ferroptosis by nano drug delivery system.

E. M. Jacob[1], S. Y. Kim[2], P. Sirohi[3], M.-E. Wang[1], M. L. Davis[1], A. R. Bawcom[1], A. Chilkoti[3], M. R. Wiesner[3], J. Huang[1], M. Chen[1];
[1]Duke University School of Medicine, Durham, NC, [2]Washington and Lee University, Lexington, VA, [3]Duke University, Durham, NC

Prostate cancer is the second leading cause of cancer-related death in U.S. men. Genomic and clinical associations have identified loss of RB function as a dominant mechanism driving prostate cancer lethality. We recently demonstrated that ferroptosis induction *in vivo* by ferroptosis inducers blocks *RB1*-deficient prostate tumor growth and metastasis and leads to improved survival of the mice. As all ferroptosis inducers are newly discovered, there is a great need to improve their therapeutic potential through different avenues, including innovative drug delivery systems. Poly Lactic-co-glycolic acid (PLGA) is an FDA-approved biodegradable polymer. Due to their strong biocompatibility and consistent release, PLGA-based nanotherapeutics are an attractive carrier for small molecule drugs. This study aims to further improve the efficacy of ferroptosis induction against lethal *RB1*-deficient prostate cancer through PLGA-based ferroptosis-induced nanoparticles (NPs). The PLGA NPs encapsulating JKE-1674 were synthesized using the solvent evaporation method. The NPs were characterized using dynamic light scattering (DLS) and scanning electron microscopy (SEM) to assess the physicochemical properties of the NPs. The cell-killing efficacy of free-form or PLGA NP encapsulated JKE-1674 was then evaluated in vitro. Our analyses showed that the particle size and polydispersity index (PDI) of JKE-1674 PLGA NPs were 160.8 nm and 0.049, respectively. SEM images of JKE-1674 PLGA NPs further validated the DLS data. These findings suggest that encapsulation of JKE-1674 within the PLGA NPs results in a stable and biocompatible formation. Critically, JKE-1674 encapsulated by PLGA NPs is as potent as JKE-1674 in its free form to induce ferroptosis and associated lipid peroxidation in various human prostate cancer cell lines. This study presents the first effort to develop and validate PLGA-based ferroptosis-induced nanotherapeutics. Based on our *in vitro* data, we will test the *in vivo* efficacy of JKE-1674 PLGA NPs against lethal *RB1* deficient prostate cancer.

#3203 Extravasation and metastasis dynamics are cytoplasmically controlled by the epitranscriptome.

O. R. Grafinger[1], G. Thillainadesan[1], B. Su[1], Y. Mo[2], X. Xu[2], S. Mar[1], M. Sheng[1], S. Al Islam[1], J. Geddes-McAllister[3], M. G. Coppolino[3], H. H. He[2], G. Zheng[2], K. J. Jerzak[1], H. S. Leong[1];

[1]Sunnybrook Research Institute, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]University of Guelph, Guelph, ON, Canada

Non-coding RNA (ncRNA) and RNA binding proteins (RBPs) primarily reside in the nucleus to regulate splicing, transcription, and transcript stability. However, their role(s) in the cytoplasm were unclear until now. Evidence now suggests that ncRNAs within the cytoplasm play an important role in cancer invasion. In concert with MT1-MMP, a protease involved in invadopodia formation, long non-coding RNAs (lncRNAs) and RBPs form cytoplasmic complexes with MT1-MMP, which we termed “R-bodies” and are abundant in invasive breast cancer cells. RNA immunoprecipitation sequencing (RIP-seq) of only the cytoplasm identified the RNA at the core of these complexes to be metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), a lncRNA which has been previously described as playing a fundamental role in cancer but only within the nucleus. Further investigation revealed that R-body-associated-MALAT1 was m6A-epigenetically marked. Depletion of any component of R-bodies and inhibition of m6A epigenetic marking of MALAT1 halted R-body formation and subsequent cell invasion. Importantly, we demonstrate that this cytoplasmic complex can be functionally targeted using RNA therapy against m6A-MALAT1 as well as drugs which inhibit the methyltransferase responsible for the m6A methylation of MALAT1. The identification of R-bodies has far-reaching implications and links the roles of cytoplasmic ncRNA and RBPs to the progression of disease.

#3204 Antitumor activity of a coencapsulated liposomal formulation of ceramides and doxorubicin in neuroblastoma models.

V. Bensa[1], M. Biscaia-Caleiras[2], M. Ponzoni[1], J. N. Moreira[3], C. Brignole[1], **F. Pastorino[1]**;
[1]IRCCS Istituto Giannina Gaslini, Genoa, Italy, [2]Bluepharma- Industria Farmaceutica, S.A, Coimbra, Portugal, [3]University of Coimbra, CIBB, Faculty of Pharmacy, Coimbra, Portugal

***Background*:** Neuroblastoma (NB) represents the most frequent and aggressive form of extracranial solid tumor of infants. Targeted therapies are severely limited by the lack of specific receptors, thus chemotherapy and radiotherapy remain the main treatment choices, which expose NB patients to systemic toxicity. Recently, we have demonstrated that cell surface Nucleolin (NCL) represents a novel cellular target for NB therapy.
***Methods*:** The cytotoxic potential of pH-sensitive nanocarriers (NC), decorated with the NCL-recognizing F3 peptide and incorporating a combination of the PI3K/Akt signaling inhibitors, C6-Ceramide (C6-Cer) or C18-ceramide (C18-Cer), and the topoisomerase II inhibitor doxorubicin (DXR) (F3-NC[C6-Cer/DXR] and F3-NC[C18-Cer/DXR], respectively), was tested *in vitro* on a panel of NB cell lines. Cytotoxicity was evaluated in monolayer and in multicellular tumor spheroid models, by MTS proliferation and Cell Titer Glo 3D cell viability assays, respectively. Apoptotic/necrotic cell death was investigated by Real Time-Glo Annexin VApoptosis and Necrosis assay.
***Results*:** F3-NC[C6-Cer/DXR] and F3-NC[C18-Cer/DXR] resulted significantly more effective, in term of reduction of NB cell viability, compared to the corresponding “drugs”-loaded untargeted NC formulations. Both formulations triggered apoptotic cell death, even if in a different kinetic profile. In particular, NB cells treated with F3-NC[C6-Cer/DXR] underwent apoptotic cell death earlier with respect to those treated with F3-NC[C18-Cer/DXR]. Interestingly, F3-NC[C6-Cer/DXR] exerted a significant superior cell killing effect when compared both to F3-NC[C18-Cer/DXR] and to F3-NC encapsulating only DXR, suggesting the importance of the combination treatment to enhance the antitumor effect against NB cells.
***Conclusion*:** Our preliminary findings demonstrate that the co-encapsulation and delivery of C6-Ceramide and DXR by NCL-recognizing nanoparticles exert potent antitumor effects against NB models *in vitro*. Ongoing *in vivo* experiments on clinically relevant mouse NB models (i.e. recapitulating primary tumor growth, metastases, and minimal residual disease) will allow us to define the possible use of F3-NC[C6-Cer/DXR] as an innovative therapeutic strategy for relapsed/refractory NB.

#3205 MicroRNA-peptide polyelectrolyte complex nanoparticle-hydrogel composite attenuates mesothelioma growth.

A. Singh[1], A. Caleb[2], J. P. Schneider[2], C. D. Hoang[1];
[1]National Institutes of Health, Bethesda, MD, [2]National Institutes of Health, Frederick, MD

Diffuse pleural mesothelioma (DPM) is a biologically unusual, aggressive asbestos-associated cancer affecting the entire pleura surface. DPM defies current standard multimodal therapies due to intrinsic chemoresistance and inability to achieve negative-margin resection of complex surface anatomy. Hence, current non-specific drug regimens ultimately fail because the biology of this tumor is poorly understood and even if surgically resected, tumor inevitably recurs from residual microscopic tumor foci. These various clinical challenges led us to develop a therapeutic platform delivering microRNA (miRNA), a novel anti-cancer agent therapeutic regimen, with the goal of eradicating residual microscopic tumor foci thereby improving the efficacy of multimodal therapy. We engineered a peptide-based biodegradable hydrogel that can be injected or sprayed directly to coat anatomic surfaces (surface-fill hydrogel; SFH), functioning as a therapeutic depot. Properties of SFH allow us to specify critical composition parameters such as biopersistence time, therapeutic payload, cell-specific targeting etc. In the first step of SFH formulation, miRNA complexed with different amphiphilic cationic peptides varying in length (19-26 amino acids) and amines (9-17), to form stable nanoparticles. Flash nanocomplexation (FNC) were used to produce highly scalable and kinetically controlled assembly of miRNA-peptide polyelectrolyte complex (PEC) nanoparticles (NPs), which utilizes a confined impinging jet (CIJ) mixer to achieve turbulent micromixing of the NPs components, yielding highly uniform and stable NPs. Next, NPs were encapsulated into another peptide hydrogel, formed via self-assembly of amphiphilic cationic peptide HLT2, thus forming a surface-fill hydrogel NPs composite. The SFH-NPs composite was not toxic to DPM cells and demonstrated efficient release of miRNA-peptide NPs from the SFH matrix in-vitro. The uptake of FAM-labeled miRNA-peptide NPs was confirmed by flowcytometry. Biodistribution analysis of NPs in mice bearing luciferase-positive DPM xenografts treated locally with Cy3-miRNA-SFH composite showed that Cy3-miRNA was concentrated in tumor cells but not in other organs. Furthermore, miR-215 exhibiting potent anti-tumor activity in DPM was used to study the therapeutic efficacy of SFH miRNA-nanoparticle composites. Subcutaneous DPM xenografts treated locally with miR-215 SFH composite shrank tumor significantly. Thus, delivery of specific miRNA-peptide PEC nanoparticles via SFH therapeutic platform in preclinical models of DPM displayed potent anti-cancer effects. Together, this new generation microRNA-peptide polyelectrolyte complex nanoparticles-SFH composite is a very promising delivery platform that could be extended for a diverse array of locoregional therapies.

#3206 Tumor-targeted nanoparticles for cancer therapy.

H. Kang[1], B. Upton[2], J. Nagy[2], T. Triche[1];
[1]Children's Hospital Los Angeles, Los Angeles, CA, [2]NanoValent, Bozeman, MT

Introduction: Untargeted cancer therapy is often toxic, limiting the maximum tolerated dose (MTD) and thus potential cure. Targeted therapy with antibody-drug conjugates (ADCs) has demonstrated greater efficacy, as with those directed at HER2 for triple negative breast cancer and other HER2 expressing tumors. However, ADC drug-antibody ratio (DAR) is limited, typically 3 to 1. In contrast, antibody-targeted nanoparticles deliver thousands of drug molecules per nanoparticle, with potentially greater anti-tumor effect.

Experimental Procedures: Antibody targeted nanoparticles (TNP) were created that preferentially deliver cytotoxic molecules to tumor cells. TNPs were created with various antibodies and payloads and evaluated for their efficacy against 12 different adult and pediatric malignancies (see below), using tumor xenografts in NOG-SCID mice. Survival of control, free drug, and TNP treated animals was compared. MED was also determined. Non-tumor bearing animals treated at the same dose and schedule were evaluated for evidence of toxicity. PK/PD metrics were obtained and drug delivery to normal and tumor tissue was evaluated microscopically and by mass spectroscopy.

Data: Plasma TNP drug levels persist for 48 hours, compared to free drug which is undetectable by 2 hours. Microscopically, nanoparticles accumulate in tumor tumor tissue but not normal tissue. Drug levels are typically 15 times higher in tumor tissue than normal tissue by quantitative mass spectroscopy. The minimum effective dose (MED) is reduced 25-fold for Ewing sarcoma, from 50 mg/kg to 2 mg/kg. TNPs also cross the blood-brain barrier (BBB), and were used to treat orthotopic GBM PDX xenografts, prolonging animal survival 3-fold over control or free drug treated animals. Ewing sarcoma, osteosarcoma, triple negative breast cancer, GBM, hepatoma, and adult ALL, bearing animals all showed complete tumor ablation and 100% survival when treated biweekly at 10mg/kg. Pancreatic, prostate, and ovarian Ca showed 100% survival in TNP treated mice after all control animals had died but remained tumor bearing with slow but progressive tumor growth when treated identically. Lung and colorectal Ca and melanoma bearing animals treated similarly with TNPs showed 50-80% survival at the time of control animal death. No animal in any study showed evidence of off-target toxicity.

Conclusions: Tumor antigen targeted, cytotoxic molecule containing nanoparticles have been created that show broad utility in the treatment of at least a dozen different adult and pediatric cancers. Six of 12 types showed complete tumor ablation when treated at 10mg/kg biweekly injections, and the remainder showed enhanced anti-tumor effect and survival compared to free drug treatment. We conclude that use of tumor antigen targeted, small molecule cytotoxic containing nanoparticles results in dramatically enhanced tumor response and in many case, complete tumor ablation where the same free drug fails to do so.

#3207 Chemical fabrication and characterization of a novel nanoparticle of the histone deacetylase (HDACi) romidepsin.

Samir Zuberi[1], Deepthi P. Damera[1], Ipsita Pal[1], Susan Walker[2], Ramesh Katla[1], Colin Haws[3], Akhil Gajjala[1], Andrea Joyner[1], Kallesh D. Jayappa[1], David J. Feith[1], Todd E. Fox[2], Thomas P. Loughran[1], Owen A. O'Connor[1], **Anuradha Illendula**[1]

[1]Department of Medicine, Division of Hematology/Oncology, University of Virginia, Charlottesville, VA,[2]Department of Pharmacology, University of Virginia, Charlottesville, VA,[3]National Resilience, Boston, VA

Introduction: Histone Deacetylase inhibitors (HDACi) are important drugs for the treatment of patients with PTCL (peripheral T-cell lymphoma). Romidepsin (R), a potent Class I HDACi, is given intravenously, weekly for three to four consecutive weeks. R has a half-life of three hours and is extensively protein bound. The indication for R in PTCL was recently withdrawn due to a failed Phase 4 study. Given the need for new drugs in PTCL, and the importance of epigenetically targeted drugs for the disease, we developed a first-in-class nanoparticle of R (NR) deploying a proprietary nanochemistry platform.
Methods: We modified the bulk nanoprecipitation method with FDA approved and Generally Recognized as Safe (GRAS) materials, specifically including PEGylated amphiphilic diblock copolymers, to develop NR combinatorially. By combining a drug and polymer solution with an anti-solvent, we produced core-shell structured NR particles with “stealth” properties. To achieve high R loading, stability, purity, scalability, and reproducibility, we devised a multi-pronged optimization system by modulating parameter sets in tandem. We determined the optimal parameters for the "lockdown" formulation. We purified NR by using centrifugal filters and determined stability by storing at 4°C. We used Cryo-electron microscopy (cryo-EM), Dynamic Light Scattering (DLS), and Liquid Chromatography-Mass Spectrometry (LC-MS) to determine the morphology, size, PDI, and drug concentration of NR. We developed fluorescent-NR with DiO dye to test bioavailability. We tested NR in T-cell lymphoma cell lines for histone acetylation and apoptosis induction. Furthermore, we investigated the *in vivo* pharmacokinetics and toxicity of NR in PTCL xenograft mouse model and quantified the drug by LC-MS.
Results: The physiochemical analysis of NR demonstrated that the particles were spherical, with a hydrodynamic diameter of 46 ±5 nm and PDI of 0.15 - 0.2. NR had a negative zeta potential and an exceptional drug encapsulation efficiency of over 50% (>500 µg/mL). NR exhibited high stability with respect to size, PDI and drug concentration for over two years. Flow cytometry and western blot analyses indicate NR induces apoptosis and histone acetylation in a time and dose-dependent manner, equivalent to or better than that observed for R. NR’s AUC increased 25-fold when administered intravenously. NR had superior tolerability, and DiO-NR confirmed superior biodistribution in tumor in a PTCL xenograft mouse model.
Conclusion: We developed a cutting-edge approach with minimum excipients, which enabled NR scale up with batch-to-batch reproducibility and high quality co-packaging of fluorescent dye and drug. NR improved R’s pharmacokinetic profile and efficacy in pre-clinical xenograft mice models. Our versatile technology enables Chemistry Materials and Controls products, an essential step in clinical product development.

#3208 A nano sized system for the treatment of gastrointestinal cancers.

D. Vaskovich[1], R. Acurcio[2], R. Kleiner[1], B. Carreira[2], A. Matos[2], H. Florindo[2], R. Satchi-Fainaro[1];
[1]Tel Aviv University, Tel Aviv, Israel, [2]University of Lisbon, Lisbon, Portugal

Despite the recent progress in cancer immunotherapies, most patients do not benefit from the currently available immune checkpoint blockers, and many develop severe immune-related adverse events. Therefore, it is urgent to develop alternative, effective immunotherapeutic approaches. An example of non-responsive cancers are gastrointestinal (GI) cancers, which account for 26% of the global cancer incidence and 35% of all cancer-related deaths. In many GI cancers, the failure of immunotherapies to yield clinical response is partially attributed to the inefficient antigen presentation by DC, which results in insufficient T cell stimulation despite their expression of tumor-associated antigens (TAA). To overcome these hurdles, we designed novel polymeric-based nanoparticles (NP) to deliver a combination of GI cancers antigens of CEACAM5 protein and toll-like receptor ligands to DC. We chose to encapsulate CEACAM5 antigens because it is overexpressed in GI cancers, such as gastric cancer, colorectal cancer, and pancreatic cancer. With this approach, we aim to modulate the tumor milieu-immune cell interactions to an anti-cancer phenotype in order to control tumor growth and improve overall survival. Our NP present an average diameter below 200 nm, narrow polydispersity index, slightly negative surface charge, spherical morphology, and high antigens and immune potentiators loading. Cy5-labeled NPs were found to be extensively internalized by DC, which triggered their activation *in vivo*, shown by the increasing expression of DC-related co-stimulatory molecules such as CD80, CD86, and CD40. Furthermore, we assessed the immunotherapeutic effect of our NP on mouse models and on a human 3D multi-cellular spheroid *ex-vivo* model, composing the patient's tumor cells and peripheral blood mononuclear cells (PBMC). We found that the NP successfully induced a potent immune-mediated anti-tumor response against CEACAM5-positive GI tumors, sensitizing the tumor microenvironment to other therapies and decreasing tumor volume, ultimately leading to prolonged survival. Taken together, the developed NP induced a strong antigen-specific immune response and overall sensitized CEACAM5-expressing GI cancers to the clinically relevant treatments *in vivo*, that so far have shown limited clinical outcomes in addition to a specific T cell anti-tumor activity that was shown on our patient-derived *ex vivo* model.

#3209 Antibody mediated targeted drug delivery approach for pancreatic cancer.

N. Dan[1], S. Setua[2], P. Shaji[3], S. Kumari[4], M. M. Yallapu[3], **S. S. Khan**[3], S. Chauhan[3];
[1]University of connecticut, Connecticut, NY, [2]University of Maryland, Baltimore, MD, [3]University of Texas Rio Grande Valley, Edinburg, TX, [4]National Institutes of Health, Bethesda, MD

Pancreatic ductal adenocarcinomas, originating from the epithelial cell lining of ducts, account for approximately 95% of tumors in this category, showcasing a survival rate of less than 5-7%. Unfortunately, little progress has been seen in the outcomes of patients with PDAC as tumor develops high desmoplasia and chemo-resistance to chemotherapeutic drugs, such as gemcitabine (Gem). The therapies are unable to penetrate to the fibrotic tumors leading to insufficient availability of the therapeutic drugs at the tumor site. We and others have shown that MUC13 is aberrantly expressed in pancreatic tumors but not in normal pancreas, which makes MUC13 as an excellent protein for specifically targeting pancreatic tumors. Herein, we demonstrate a unique ability of our in-house generated mouse and humanized monoclonal antibody of MUC13 to penetrate and target pancreatic cancer. These antibodies have been conjugated with our recently developed novel patented superparamagnetic iron oxide nanoparticles (SPIONS) to deliver therapeutics specifically to pancreatic tumors. In this study, we are using curcumin that depletes tumor microenvironment and gemcitabine to investigate the efficacy of the MUC13 conjugated SPION in delivery of therapeutic drugs. Our results demonstrate that enhanced uptake of MUC13-SPION formulation in MUC13 positive (MUC13+) PanCa cells, compared with MUC13 null (MUC13-) cells as demonstrated by immunofluorescence, Prussian blue staining and flow cytometry experiments. Interestingly, the formulation resulted in sustained delivery of curcumin (CUR), enhanced inhibition of cell proliferation, migration and invasion in MUC13+ cells as compared with MUC13- cells, which suggests the targeting efficacy of the formulation. In PanCa orthotopic mice model, MUC13-SPION efficiently targeted pancreatic tumors resulting in significant tumor accumulation. We observed inhibition of tumor volume, metastasis, gem resistance and improved survival in mice treated with the formulation. Additionally, the tumor tissues from treated mice showed extensive downregulation of PCNA and expression of key proteins in SHH pathway, such as SHH, Gli-1, Gli-2, Patched 1, SMO, which has been associated with cancer progression and drug resistance. In conclusion, the results indicate high therapeutic significance of MUC13-SPIONS for achieving pancreatic tumor specific delivery of drugs.

#3210 Raptamer-drug conjugates as molecularly targeted cancer therapeutics.

S. P. Vega[1], N. E. Ward[1], U. Saini[1], L. Castan-Chibas[1], G. Kaushik[2], D. Ciznadija[2], D. Chatterjee[1], M. J. Heffernan[1], A. Varadhachary[1], M. Ritchie[2]; [1]Fannin, Houston, TX, [2]Champions Oncology, Rockville, MD

The use of aptamers as a therapeutic targeting moiety holds the promise of building on the success of antibody-drug conjugates (ADCs). While ADCs are an attractive modality, they face limitations, including limited penetration into solid tumors and a complicated production process for large-scale manufacturing. Aptamers have several potential advantages over antibodies as a targeting moiety including: (i) a smaller size that enables better tumor penetration; (ii) chemical synthesis which allows rapid scale-up and ease of incorporating modifications; (iii) a superior safety profile from lack of immunogenicity and (iv) room temperature stability. Therefore, the use of aptamers in conjunction with drugs (similar to ADCs) holds promise for development of targeted therapeutics. We have identified a novel therapeutic target for certain cancers (COF-01) using proteomics data and immunohistochemistry from patient-derived tumors. Both the COF-01 protein and related mRNA expression was shown to be significantly increased in non-small cell lung cancer, head and neck cancer and pancreatic cancer. Here, we present a new therapeutic approach that targets COF-01-positive cancer cells using next generation aptamer conjugates. We performed a cell- and protein-based selection using our proprietary bead-based combinatorial libraries to generate next-generation base-modified ssDNA aptamers (Raptamers) against COF-01. Binding affinities of the COF-01 Raptamer candidates were determined by concentration curves using biolayer interferometry. The dissociation constants for the COF-01 Raptamers ranged from 80 nM - 200 nM. COF-01-specific Raptamer-drug conjugates (Rap-DCs) were developed by conjugating the Raptamers to monomethyl auristatin E via a cleavable linker. *In vitro* efficacy data showed the COF-01 Rap-DC can selectively induce cytotoxicity in different types of COF-01-positive human cancer cells (A431, CAL 27, BxPC-3). There was a significant decrease in cell viability of COF-01-positive cells when compared to COF-01-negative control cells (IC_{50} values ranged from 5.19 nM - 14.11 nM). *In vivo* efficacy testing in a COF-01-postive cell-derived xenograft mouse model showed a significant decrease in tumor volume in animals treated with the COF-01 Rap-DC when compared to saline- and erlotinib-treated controls. This provides proof-of concept for the use of high-affinity Raptamers against novel molecular targets, such as COF-01. This platform can be used to develop Rap-DCs against emergent neo-antigens on cancer cells that have escaped chemotherapy.

#3211 Development of first in class zip code drug conjugate in pancreatic ductal adenocarcinoma.

M. Cinar[1], P. Ganji[1], A. Pisarev[2], L. Martinez-Medina[3], D. S. R. Bandi[4], P. K. Puvvula[3], S. Chang[5], D. Maneval[3], B. El-Rayes[6], **L. Bernal-Mizrachi[1]**;
[1]Emory University School of Medicine, Atlanta, GA, [2]Kodikaz Therapeutic Solutions,LLC, New York, NY, [3]Kodikaz Therapeutic Solutions, LLC, New York, NY, [4]University of Alabama, Birminghan, AL, [5]Kodikaz Therapeutic Solutions, LLD, New York, NY, [6]University of Alabama, Birmingham, AL

Pancreatic ductal adenocarcinoma (PC) is the fourth most common cancer-related cause of death in Western countries. It is projected that PC will become the second most prevalent cause of cancer-related mortality by the year 2030. Although chemotherapy may offer certain advantages to those who have been diagnosed with pancreatic cancer, its effectiveness is notably constrained by the emergence of chemoresistance and excessive toxicity. In recent studies, it has been established that circulating tumor DNA (ctDNA) serves as a mechanism for cell-specific genetic transfer. We discovered that transposon sequences (known as Zip Codes, ZC) were responsible for ctDNA cell targeting. Therefore, we investigated the possibility of hijacking these ZC to deliver drugs specifically. We began by determining whether PDCA ZC synthesized chemically could target PDCA cells selectively. To achieve this, ZC sequences were labeled with CY5 for high-throughput microscopy. Results show that numerous PDCA-ZC were specific and efficient at targeting PC cell lines while sparing other cancer cell lines. The AluSc8 (PCZC) sequence was chosen for further investigation. The specificity of PCZC for targeting cells was validated using pancreatic islet cells. Based on these findings, we developed a technique for conjugating PCZC with SN38 via a CL2A linker. The results indicated that PCZC-SN38 was a very effective agent at killing PC cells (IC50: 1
µg), but not other cancer cell lines. The therapeutic efficacy of PCZC-N38 was evaluated in vivo using PDX (patient-derived xenografts, Garcia et al Plos One 2013). Maximum tolerated dose testing (MTD) (dosing from 1 to 21 mg of PCZC-SN38/Kg) failed to reach an MTD. Subsequently, we evaluated the efficacy signal of PCZC-SN38 by administering PCZC-SN38 to animals three times per week for three weeks at concentrations of 3 and 30 mg/kg of DNA (equivalent to 0.05 and 0.5 SN38 mg/kg). We used animals treated with vehicle, PCZC alone, and irinotecan (either once per week (50 mg/kg) or three times per week (0.5 mg/Kg) as a comparison. PCZC-SN38 decreased tumor growth by 41% and 70%, respectively, when compared to the vehicle or PCZC alone. The observed efficacy did not result in a change in body weight. In contrast, every animal administered irinotecan at a dosage of 50 mg/kg died within a week. On the contrary, animals that were given irinotecan at a dosage of 0.5 mg/kg demonstrated a growth inhibition of 60% and exhibited remarkable tolerability. Currently, research is being undertaken to determine the therapeutic efficacy of PCZC-SN38 at higher doses. The results outlined in this study illustrate the preliminary application of PC targeted drug delivery using a PC zip code drug conjugate. The results of our study demonstrate an innovative methodology for targeting PC cells specifically with therapeutic cargo material and supports further preclinical development of PCZC-SN38 for PC.

#3212 Development of a Trop2/CD3 bispecific antibody with modulated Trop2 binding affinity as a novel immunotherapy for advanced gastrointestinal cancer treatment.

C. O[1], **P. Wong**[1], K. Chow[1], K. Wong[1], D. Wong[2], J. M. Luk[2], K. Wong[1];
[1]Arbele Limited, Hong Kong, Hong Kong, [2]Arbele Corp, Seattle, WA

Trophoblast cell surface antigen 2 (Trop2) is considered as a potential therapeutic target because its over-expression in tumors is found to be associated with poor prognosis of patients with different cancers. Trop2-directed antibody-drug conjugates have been approved for the treatment of solid tumors, however, the expression of Trop2 in a broad range of epithelial tissues, even in low expression, would limit their clinical benefits. The present work generated a novel Trop2/CD3 bispecific antibody with its binding affinity towards Trop2 being well-modulated to mitigate the chance of on-target off-tumor effect. By linking a humanized anti-Trop2 monoclonal antibody with a CD3-binding scFv, a Trop2/CD3 bispecific antibody was produced. In order to adjust the bispecific antibody's affinity to the tumor target, ProABC-2 was used for in-silico paratope prediction (Ambrosetti F et al., 2020). A complementarity-determining residue (CDR) variant was produced and its binding to Trop2 antigen was analyzed using biolayer interferometry. The binding of both wild type (WT) and variant antibodies to Trop2-positive cancer cells, the activation of T cells upon target engagement and the redirection of T cell-mediated killing on cancer cells expressing high level of Trop2 were examined. The binding affinity of CDR variant to Trop2-expressing tumor cells was significantly reduced, which led to a slower induction of cytokines and T-cell proliferation, less acute T-cell activation, and a milder cytotoxic effect. This allowed the bispecific antibody to have a higher level of safety by restricting the cytotoxicity only to cancer cells that expressed high level of Trop2. Our novel Trop2/CD3 bispecific antibody not only showed potent anti-tumor activity, but also demonstrated a lower risk of on-target off-tumor toxicity. Monkey toxicity and other IND-enabling studies are beginning to further bring the drug candidate into clinical trial.

Table showing EC50 values of Trop2/CD3 bispecific WT and CDR variant antibodies in different assays

		WT	**CDR variant**
Binding affinity (M)	Trop2	4.62E-11	2.14E-10
Cytotoxicity (M)	AsPC1 (low Trop2 level)	1.24E-11	No killing effect
	SW480 (medium Trop2 level)	1.25E-12	2.25E-11
	NCI-H596 (high Trop2 level)	5.65E-12	5.89E-10
Receptor occupancy (%)	Trop2	0.65	2.75
	CD3	0.08	5.83
Cytokine induction (M)	IL-2	4.82E-11	5.42E-11
	IFNγ	6.46E-13	2.59E-11
T cell activation (M)	CD25+ marker	2.02E-12	2.39E-10
	CD69+ marker	3.81E-13	7.40E-11
T cell proliferation (M)	Ki-67 marker	3.54E-12	8.80E-11

#3213 A novel CDH17/PD-1 bispecific antibody for treatment of advanced gastrointestinal cancers.

K. Wong[1], **P. Wong**[1], K. Chow[1], C. O[1], D. Wong[2], J. M. Luk[2], K. Wong[1];
[1]Arbele Limited, Hong Kong, Hong Kong, [2]Arbele Corp, Seattle, WA

Targeting immune checkpoints like programmed death receptor 1 (PD-1) with monoclonal antibodies has achieved durable responses in a range of cancers, however, immune-related adverse events may occur in a subset of patients. As such, we developed a bispecific antibody targeting cadherin-17 (CDH17) and PD-1 with a hope to rejuvenate specifically the exhausted T cells within tumor microenvironment. In healthy individuals, CDH17 is expressed at a restricted level in intestinal epithelial junction that is not accessible to biologics, however, in gastrointestinal cancers, CDH17 is overexpressed and can be targeted by antibodies. Our new CDH17/PD-1 bispecific antibody would reactivate anti-tumor immunity with reduced risk of on-target off-tumor toxicity. Different bispecific antibody formats were designed, cloned, and expressed. Strong binders were first identified using CDH17 and PD-1 ELISA. The binding affinities to CDH17 and PD-1 of the selected candidate were examined using biolayer interferometry. The effect of these bispecific antibodies on blocking PD-1/PD-L1 axis in T cells was demonstrated in a cell-based reporter assay. T-cell mediated killing on CDH17-positive GI cancer cells and induction of T cell activation markers upon antibody treatment were also studied. A total of 7 CDH17/PD-1 bispecific antibodies of different formats were screened. Of these candidates, one, named ARB204, was selected because of its potent binding to both antigens in ELISA (i.e., EC_{50} values: CDH17, 1.6nM; PD-1, 0.4nM) and biolayer interferometry (i.e., K_D values: CDH17, 2.4E-09M; PD-1, 6.02E-11M). ARB204 blocked PD-1/PD-L1 axis in the reporter assay with EC_{50} value 4.4nM. Notably, ARB204 redirected T cells to eradicate CDH17-positive pancreatic AsPC1 cells with an EC_{50} value of 3.5nM. No cytotoxicity against CDH17-negative cancer cells were seen. ARB204 effectively bound CDH17 on GI cancer cells and PD-1 on T cells. This bispecific design allowed selective T-cell mediated killing on cancer cells expressing CDH17, mitigating the risk of off-tumor toxicity. ARB204 warrants further studies on its immune checkpoint inhibition in animal models.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Epigenetic Targets
Poster Session

#3217 Discovery of novel inhibitors of the epigenetic regulator Kat6a histone acetyl transferase and characterization of their anti-tumor activity.

L. J. Holsinger[1], R. Rai[1], R. R. Nagawade[2], B. K. Pal[2], S. G. Pawar[2], K. A. Putta[2], S. S.C.[2], M. Jaleel[2], J. Wang[1], A. L. Hannah[1];
[1]ISOSTERIX, INC., San Carlos, CA, [2]Sai Life Sciences Limited, Medchal-Malkajgiri, India

KAT6A and its paralog KAT6B are histone acetyltransferases (HATs) which direct chromatin structural rearrangement and subsequent changes in gene transcription through acetylation of histones, primarily specific lysine residues on histone H3. KAT6A is modified in cancer, including genomic amplification, overexpression, mutation, as well as genetic rearrangement, resulting in the production of fusion proteins. Dysregulation of this MYST family member and its acetyl transferase activity is known to drive gene expression and tumorigenic progression in cancers. An inhibitor of KAT6A and KAT6B entered phase 1 clinical trials (NCT04606446). With continuous daily dosing, durable partial responses were seen in estrogen-receptor positive (ER+) breast cancer patients who had progressed on a prior endocrine therapy and CDK4/6 inhibitor. In that study, evidence of dose dependent pharmacodynamics (H3K23Ac inhibition) was observed in peripheral blood mononuclear cells and paired tumor biopsies (Sommerhalder, ASCO2023). Isosterix has developed a series of structurally diverse small molecule KAT6A-selective inhibitors which engage at the active site in the acetyl CoA substrate binding pocket. Lead compounds are selective for KAT6A and have significant potency and cellular activity in a variety of assays; they inhibit KAT6A-mediated histone acetylation in a biochemical assay as well as pharmacodynamic dose-dependent inhibition of histone acetylation in the breast cancer tumor cell line ZR-75-1. These compounds reduce cell viability of ZR-75-1 in 10 days with continuous compound administration, confirming the dependence of this cell line on KAT6A acetyl transferase activity for proliferation and cell cycle progression. Lead inhibitors are orally bioavailable with excellent pharmacokinetic properties in rodents. They demonstrate dose-dependent anti-tumor efficacy with minimal weight loss with continuous daily dosing in mouse xenograft tumor models. Inhibitors against this novel epigenetic target demonstrate the potential for efficacy in not only ER+ breast cancer but also other tumor indications which exhibit transcriptional induction dependent on KAT6A-directed chromatin remodeling. Selection of a lead candidate is planned for early 2024 with IND enabling studies to follow.

#3218 Combination drug screen identifies novel epigenetic therapies to enhance menin inhibitor efficacy in KMT2A rearranged and NPM1 mutant AML.

T. M. Totiger, S. Chaudhry, S. Montoya, M. Affer, A. K. Sondhi, A. Chirino, C.-H. Volmar, S. Brothers, J. Watts, J. Taylor;
University of Miami, Miami, FL

Background: Acute myeloid leukemia (AML) with KMT2A-rearrangements have a poor prognosis and so there is an urgent need for novel therapies. Menin inhibitors have shown promising anti-leukemic effects in KMT2A-rearranged and NPM1-mutated AML. However, the efficacy of menin inhibitors as single agents may be limited by the development of resistance mutations. Combining menin inhibitors with other epigenetic drugs may present a strategy to enhance their therapeutic potential. In this study, we performed a combination drug screen using an epigenetic drug library in KMT2A-rearranged (MV4;11) and NPM1-mutant (OCI-AML3) AML cell lines to identify synergistic therapies that can be used in conjunction with menin inhibitors.
Methods: During assay optimization, MV4;11 and OCI-AML3 cells were treated with the menin inhibitor DSP-5336, and their viability was assessed. Quality control metrics were applied with Z' values consistently greater than 0.5 for all assay plates and then the cells were subjected to a small molecule compound library screen containing a set of 932 epigenetic drugs. The screening process included a systematic evaluation of each drug's effect on cell viability in combination with the DSP-5336.
Results: The combination drug screen demonstrated robust performance in both MV4;11 and OCI-AML3 cell lines, with reliable quality control metrics. Among the epigenetic drugs tested, five compounds were identified as potential hits that synergistically enhanced the efficacy of DSP-5336 across both cell lines.The five identified compounds exhibited enhanced anti-leukemic effects when combined with the menin inhibitor in either one of the cell lines. The targets of these drugs varied, including histone deacetylases, histone acetyltransferases and BRD4 inhibition, suggesting many alternate mechanisms of action involving epigenetic modulation. Remarkably, one of the 5 hits C301-3161, a KAT2A inhibitor, showed limited activity in either cell line alone but increased cell killing with DSP-5336 in both cell lines, highlighting its potential as a specific therapeutic for combining with DSP-5336 in AML patients.
Conclusions: Our findings suggest combining menin inhibitors with other epigenetic drugs may improve AML treatment outcomes. The combination drug screen successfully identified four novel compounds that synergistically enhance menin inhibitor efficacy in both KMT2A-rearranged and NPM1-mutant AML cell lines. These compounds hold significant promise as potential therapeutic candidates for further investigation. Future studies should focus on elucidating the underlying mechanisms of action for each hit and evaluating their effects in preclinical animal models. Ultimately, this research may pave the way for the development of innovative combination therapeutic strategies for AML patients with KMT2A-rearragned and NPM1-mutant AML.

#3219 STAT3 inhibition synergizes with epigenetic therapy to suppress glutamine metabolism and clonogenic potential in non-small cell lung cancer.

J. An, Y.-Y. Chen, J. Park, S. Baylin, M. Topper;
Johns Hopkins University, Baltimore, MD

Non-small cell lung cancer (NSCLC) remains one of the deadliest cancers with metastatic disease being the primary driver of mortality. Therefore, there is a critical need for therapies that prevent disease dissemination in both early and late-stage disease presentations. Among the recent novel therapeutic combinations that have transformed the treatment landscape of NSCLC is an approach developed in our lab and others utilizing DNA methyltransferase inhibition (DNMTi) paired with histone deacetylase inhibition (HDACi) to sensitize patients to immunotherapy. However, most patients do not benefit durably from epigenetic therapy alone or in combination with other therapies.

In this study, we identified STAT3 as an actionable target in tumor cells that synergizes with epigenetic therapy (DNMTi+HDACi). We and others have previously shown that STAT3 signaling is augmented after epigenetic therapy. To interrogate the importance of this finding, we treated a panel of 12 human NSCLC cell lines with STAT3i+epigenetic therapy and identified five cell lines demonstrating a synergistic reduction of cell viability. These *in vitro* monolayer observations were recapitulated in an intermediate complexity 3D model, thus providing orthogonal validation of response applicability in a more treatment-resistant setting. In addition to phenotypic characterization, we deployed RNA sequencing to define the whole transcriptome consequences of our novel therapeutic paradigm. These transcriptional data showed that STAT3i+epigenetic therapy suppressed cell cycle and activated apoptotic pathways, which were validated by immunoblotting and flow cytometry-based approaches. We further demonstrated a significant and durable reduction in colony formation after treatment with STAT3i+epigenetic therapy. Additionally, we observed significant perturbation of a subset of genes involved in both epithelial-to-mesenchymal transition and suppression of glutamine and fatty acid metabolism.

Reliance on glutamine is considered a hallmark of cancer metabolism. Furthermore, glutamine metabolism has been implicated in the plasticity between epithelial and mesenchymal cancer cell states, which is required for metastatic success. Additionally, survival of metastatic cells requires upregulation of pathways that promote anchorage-independent growth and anoikis resistance, which are suppressed in our phenotypic and transcriptional data, respectively. Taken together, our results suggest **1.** STAT3i+epigenetic therapy diminishes the ability of NSCLC cells to survive and return to a colony-forming state and **2.** This phenotype is associated with metabolic dysfunction. Our studies therefore provide a basis for the development of novel strategies to intercept metastatic recolonization by impairing circulating tumor cells from seeding distant sites.

#3220 Osimertinib-induced epigenetic and transcriptional reprogramming drives a BRD4-POUF-PDGFRB-YAP-EMT axis of resistance in NSCLC.

A.-V. Hartley, C. Weston, S. Baldacci, W. Feng, M. Al-Dulaimi, C. Gentile, M. Booker, M. Tolstorokuv, C. Kadoch, P. Janne;
DFCI/Harvard Medical School, Boston, MA

Acquired resistance to Osimertinib continues to pose a major limitation to achieving durable therapeutic responses in EGFR mutant non-small cell lung cancer (NSCLC). While multiple actionable genetic mutations have been identified as the underlying molecular basis of resistance, a genomic mechanism cannot be identified in >50% of Osimertinib resistant tumors and thus an effective combinatorial treatment strategy cannot be deployed for these patients. Recently, we identified YAP/TEAD activation and ERK1/2 reactivation as two major non-mutational counter-regulatory pathways that diminish the efficacy of Osimertinib, promoting establishment of the drug tolerant persister (DTP) and resistant states. Moreover, it is well known that cancer cells escape tyrosine kinase inhibitor (TKI) therapy by developing dependence on alternate, non-mutated receptor tyrosine kinases (RTKs) through a treatment-induced “RTK switch” phenomenon. The link however between alternate RTK signaling and YAP/TEAD/ERK1/2 has never been explored in the context of Osimertinib resistance. In this study, we systemically uncover transcriptional de-repression of, and critical dependence on PDGFRβ as part of a novel “RTK switch” mechanism deployed by cells to evade Osimertinib-induced death. Genetic or pharmacologic co-inhibition of PDGFRβ renders NSCLC cells more sensitive to Osimertinib during drug naïve, DTP and resistant phases of treatment through suppression of ERK1/2 reactivation, YAP activity/nuclear translocation and YAP-mediated induction of EMT factors, SLUG and Zeb2. Importantly, compared to Osimertinib alone, co-targeting EGFR and PDGFRβ robustly suppresses tumor regrowth following treatment cessation both *in vitro* and *in vivo* which is consistent with a reduction in the DTP cell population. These data auspiciously demonstrate a two-fold utility of concomitant PDGFRβ inhibition: to enhance the initial efficacy of Osimertinib and to eliminate the DTP and resistant cells following chronic Osimertinib treatment. Further mechanistic studies from integration of ATAC-seq, CUT&RUN and RNA-seq reveal that Osimertinib induces the dynamic cooperativity of chromatin modulator BRD4 with pluripotent POU-domain transcription factors Oct-4, Pit-1 and Brn-3 at putative proximal enhancer elements, facilitating upregulation of PDGFRβ. Collectively, we demonstrate a novel treatment-induced BRD4/POUF epigenetic/transcriptional mediated “RTK switch” that involves co-opting PDGFRβ signaling to activate YAP/TEAD and ERK1/2 as a means of driving adaptive resistance to Osimertinib. These data provide compelling rationale for combined anti-EGFR and PDGFRβ targeted therapy to improve patient outcomes.

#3221 Targeting ARID1A-mutated gastric cancer cells with synthetic lethal approaches.

Menghan Fang[1], Youfen Lin[2], Chaorong Xue[2], Kaiqin Sheng[2], Zegeng Guo[2], Yuting Han[2], Hanbin Lin[2], Yuecheng Wu[2], Stephen B. Howell[3], Xu Lin[2], **Xinjian Lin**[2]

[1]Department of Pathology, Fujian Medical University Cancer Hosptial, Fuzhou, China,[2]Key Laboratory of Gastrointestinal Cancer (Fujian Medical University), Ministry of Education, Fujian Medical University, Fuzhou, China,[3]Department of Medicine and the Moores Cancer Center, University of California, San Diego, San Diego, CA

AT-rich interaction domain 1A (ARID1A) functions as a tumor suppressor gene, and its loss or inactivation is a common occurrence in various human malignancies, including around 30% of gastric cancers (GC). This study aimed to identify potential therapeutic targets for GC cells with ARID1A deficiency. After robust screening from a chemical library consisting of 551 diverse protein kinase inhibitors, we identified the AKT inhibitor AZD5363 as being the most potent lead compound in inhibiting viability of ARID1A$^{-/-}$ cells. A synthetic lethality between loss of ARID1A expression and AKT inhibition by AZD5363 was validated in both GC cell model system and xenograft model. Mechanistically, AZD5363 treatment induced pyroptotic cell death in ARID1A-deficient GC cells through activation of the caspase-3/GSDME pathway. Furthermore, ARID1A occupied the AKT gene promoter and regulated its transcription negatively, thus the GC cells deficient in ARID1A showed increased expression and phosphorylation of AKT. Our study demonstrates a novel synthetic lethality interaction and unique mechanism between ARID1A loss and AKT inhibition, which may provide a therapeutic and mechanistic rationale for targeted therapy on patients with ARID1A-defective GC who are most likely to be beneficial to AZD5363 treatment.

#3222 Acute and long-term responses to treatment with the HDAC inhibitor quisinostat in preclinical models of glioblastoma.

K. Orndorff, J. McNamara, M. Stavnichuk, C. Lo Cascio, C. White, E. Luna Melendez, G. Uzunalli, N. Sanai, S. Mehta;
Barrow Neurological Institute, Phoenix, AZ

Introduction: High expression of histone deacetylases (HDACs), particularly HDAC1, is strongly associated with poor prognosis for glioblastoma (GBM) patients. Quisinostat is a second-generation, class I-II selective HDAC inhibitor with high specificity for HDAC1 and potent anti-tumor activity. Here, we evaluated GBM PDX tissues and glioma stem cells (GSCs) for cellular, transcriptomic and phenotypic changes after acute and long-term treatment with quisinostat.

Methods: Multiple GBM PDX models and PDX-derived GSCs were treated with quisinostat, radiation, or a combination of quisinostat and radiation. Tissue and cells were processed for RNA-seq, qRT-PCR, and immunofluorescence assays to examine alterations in neuronal signaling, cell fate, DNA damage, and markers of stemness and differentiation.

Results: Bulk RNA sequencing of tumor tissue revealed that chronic co-treatment with quisinostat and radiation led to increased cellular expression of neuronal signaling and neuronal development pathways compared to the untreated control group. Increase in expression of neuronal signaling genes was also observed upon *in vitro* treatment of GSCs with quisinostat. Immunocytochemistry and immunofluorescence staining confirmed changes in neuronal signaling and neuronal cell fate proteins after quisinostat treatment.

Conclusions: Quisinostat treatment induces a shift in tumor cells towards a neuronal-like cell fate. Considering that GSCs have been shown to establish synaptic junctions with healthy neurons to evoke enhanced excitatory currents within glioma cells and contribute to treatment resistance, further investigation of this shift upon HDAC inhibition is crucial. Ongoing studies are aimed at evaluating the significance of these cellular and molecular changes resulting from quisinostat treatment and whether the quisinostat-induced cell fate changes can be exploited for future combination therapy for GBM.

#3223 Embryonic ectoderm development (EED) inhibitor APG-5918 (EEDi-5273) and MDM2 inhibitor alrizomadlin (APG-115) synergistically inhibit tumor growth in preclinical models of prostate cancer (PCa).

Y. Yin[1], Y. Yang[1], E. Liang[2], B. Li[1], H. Wang[1], D. Yang[1], Y. Zhai[1];

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China, [2]Ascentage Pharma Group Inc., Rockville, MD

Advanced PCa, especially castration-resistant PCa, represents an urgent unmet treatment need. Dysregulation of the polycomb repressive complex 2 (PRC2), which mediates trimethylation of histone H3 at lysine 27 (H3K27me3) and leads to gene silencing, is common in PCa and correlates with poor prognosis. EED, a core PRC2 component, is crucial for histone methyltransferase activity. MDM2, a negative regulator of p53, is often amplified or overexpressed in PCa and associated with metastasis and poor clinical outcomes. We evaluated antitumor activity and molecular mechanisms of EED inhibitor APG-5918/EEDi-5273 and MDM2 selective inhibitor alrizomadlin in preclinical PCa models. Human castration-resistant (22Rv1) and androgen-dependent (LNCaP) PCa cell lines were used in antiproliferation assays. Cell viability was determined by CellTiter-Glo luminescent assays. Western blotting was used to explore mechanisms of action. Subcutaneous 22Rv1 and LNCaP cell line-derived xenograft (CDX) models were established to evaluate antitumor effects of APG-5918 and alrizomadlin *in vivo*. Single-agent APG-5918 or alrizomadlin had limited inhibition on PCa cell growth; combined, they demonstrated synergistic antitumor activity. In the 22Rv1 CDX model, single-agent alrizomadlin (100 mg/kg) or APG-5918 (100 mg/kg) administered for 26 days exerted no/limited antitumor activity, with treatment-to-control (T/C) values of 93.39% and 49.89%, respectively. In contrast, the doublet enhanced antitumor activity (T/C value, 33.22%), with a synergistic index of 1.40. In the LNCaP CDX model, APG-5918 (100 mg/kg) administered for 28 days exhibited minimal antitumor effects (T/C value on last day of dosing, 80.32%). Alrizomadlin (100 or 50 mg/kg) showed limited antitumor activity (T/C value, 47.61%). Combined treatment significantly enhanced antitumor activity (T/C value, 15.69%), with a synergistic index of 2.44. Regarding putative mechanisms, western blot analyses showed that APG-5918 downregulated oncogenic drivers and DNA methylation factors (UHRF1, DNMT1) and on-target-related pharmacodynamic markers (H3K27me3, EED, EZH2). Alrizomadlin markedly downregulated UHRF1 and DNMT1, and upregulated p53 and p21 expression. Combined treatment further enhanced downregulation of DNMT1, UHRF1, cell cycle pathway proteins (pRb, CDK6), antiapoptotic protein MCL-1, and synergistically increased cleavage of PARP-1, a marker of apoptosis. In summary, we show that targeting EED and MDM2 synergistically enhances antitumor activity in PCa cell lines and CDX models. Mechanistically, this combination likely modulated pathways related to DNA methylation, cell cycle, and apoptosis. The findings provide a scientific rationale for future clinical development of APG-5918 and alrizomadlin for PCa patients.

#3224 Identifying the molecular mechanisms underlying progesterone receptor downregulation in endometrial cancer.

X. Meng, L. Lamont, S. Yang;
Carver College of Medicine, University of Iowa, Iowa City, IA

Background: Endometrial cancer (EC) is the most common gynecologic cancer. Cancer survival has improved over the past four decades for all the most common cancers except cervical and EC, calling for significant treatment advancements. Progesterone receptor (PR) is a favorable prognostic marker for EC and other solid tumors. However, PR expression has been shown to be reduced or lost in these malignant tumors, which correlates with worse patient survival and limits the effectiveness of progestin therapy. Thus, restoring functional PR expression is vital to sensitizing tumor cells to progestin therapy, enhancing EC clinical interventions, and improving patient outcomes. In this project, we aim to restore functional PR expression.

Methods: To visualize PR expression in real-time, we constructed an innovative endogenous PR reporter gene transfected EC cells. This system facilitated screening potential small molecular PR inducers from the FDA-approved oncology drug library. Sixteen drugs were identified to increase PR expression; topoisomerase II inhibitors (Top IIi), mitoxantrone and idarubicin were the top hits. Drug effect of Top IIi, as well as HDAC inhibitor romidepsin, dual PI3k/HDAC inhibitor CUDC-907, and PHB2 inhibitors, fluorizoline (FLZ) and rocaglamide (RocA), were evaluated as single drug or in combination. Potential PR repressors, including G9a, HDAC2, PHB2, and Top2A, were knocked down using siRNA, shRNA, or CRISPR-Cas9 in EC cells and PR expression was analyzed. A chromatin immunoprecipitation (ChIP) assay was also conducted to validate bona fide PR repressors.

Results: Mitoxantrone and idarubicin were validated to be effective PR inducers. G9a, HDAC2, PHB2, and Top2A were confirmed PR repressors. Single treatment with mitoxantrone, idarubicin, romidepsin , CUDC-907 , FLZ , and RocA achieved effective inhibition of EC cell proliferation and enhanced PR expression except FLZ and RocA. Combined romidepsin with Topi or PHB2i demonstrated additive or synergistic effects. More importantly, dual treatment of CUDC-907 with mitoxantrone enhanced PR expression compared to a single treatment or no treatment control. Our mass spectrometry and ChIP assay by specific antibodies against HDAC2 and PHB2 revealed that potential mechanisms include PHB2 forming a complex with HDAC2 that binds on the PR promoter, thus inhibiting PR transcription.

Conclusion: Co-treatment of CUDC-907 with Top2Ai increased PR expression and enhanced cell death in EC cell lines, indicating a potential treatment strategy. *In vivo* studies utilizing our EC-PDX models will further validate the efficacy of restoring PR expression and suppressing EC tumor growth. Further studies of the molecular mechanisms behind this strategy will be conducted.

#3225 Profiling the DNA regulome to discover direct inhibitors of the brachyury transcription factor.

Alexander Joel Federation, Yang Gao, Brian McEllin, Tonibelle Gatbonton-Schwager, Andrea Gutierrez, Julia Robbins, Bodhi Hueffmeier, Erin Broderick, Daniele Canzani, William Fondrie, Lindsay Pino

Talus Bioscience, Inc., Seattle, WA

Background: The human genome encodes more than 1,600 transcription factors (TFs), along with additional cofactors, chromatin regulators, and structural proteins that collectively execute the regulatory instructions encoded within the nuclear DNA. Dysfunctions of these proteins, collectively known as the Regulome, are known to drive multiple conditions such as cancer, autoimmune conditions, and fibrosis. Despite their importance, many of these proteins are considered undruggable due to challenges in modeling their activity in vitro.
Methods: We have addressed these shortcomings by implementing a live-cell Regulome profiling approach that quantifies the global activity of TFs without the need for cell manipulation or genome engineering, called TF-Scan. The technology coupled rapid, automated purification of the DNA-bound proteome coupled to scalable Data Independent Acquisition (DIA) quantitative mass spectrometry proteomics and machine learning.
Results: We completed a screen of covalent compounds across 8 tissue types to discover hotspot sites on TFs that control their DNA-binding activity. A chordoma cell line was included in this screen. The screen identified compounds capable of binding to and disrupting the activity of several previously undruggable transcription factors, including brachyury. Hit validation and hit-to-lead medicinal chemistry resulted in a covalent chemical probe for brachyury, with activity in cell line models of chordoma.
Conclusion: Phenotypic drug discovery in live, unmodified human cells with systematic regulome profiling enables the discovery of compounds that disrupt previously undruggable targets by multiple mechanisms of action.

#3226 PRMT1 is a critical dependency in clear cell renal cell carcinoma with roles in post- transcriptional regulation and DNA damage response.

J. Walton[1], K. Arevalo[2], A. Ng[2], J. Meens[1], C. Karamboulas[1], P. Prinos[3], B. Raught[1], E. Chen[1], C. Arrowsmith[1], L. Ailles[1];
[1]University Health Network, Toronto, ON, Canada, [2]The University of Toronto, Toronto, ON, Canada, [3]The Structural Genomics Consortium, Toronto, ON, Canada

The majority of sporadic renal cell carcinoma (RCC) cases present as the clear cell subtype (ccRCC) and are associated with the biallelic inactivation of the von Hippel-Lindau (*VHL*) gene, leading to constitutive activation of the cellular hypoxia response and deleterious alterations to gene expression, metabolism, and growth. Despite the near ubiquity of VHL loss, evidence suggests that it alone is insufficient to drive tumor establishment. Additional loss of function (LOF) mutations in epigenetic regulatory proteins including *PBRM1*, *SETD2* and *BAP1* have been identified as tumor drivers. The frequency and penetrance of these mutations in epigenetic regulators implicates a vulnerability in ccRCC that may be exploited to develop new therapies. To explore this vulnerability, the Ailles lab completed a screen of the Structural Genomics Consortium's (SGC) epiprobe library - a panel of inhibitors targeting an array of epigenetic regulators in patient derived ccRCC models. Among the several promising targets identified, a particularly favorable inhibition profile was noted for MS023, an inhibitor of the type I protein arginine methyltransferase family (PRMT1/3/4/6 and 8). PRMTs transfer methyl groups to nuclear histones and cytoplasmic targets, influencing gene expression, mRNA processing and viability. This growth inhibition was corroborated using an additional type I PRMT compound, GSK3368715. CRISPR-mediated deletion of type I PRMT targets indicated that PRMT1 is the main enzyme responsible for growth inhibition in our ccRCC models. Furthermore, genetic depletion of PRMT1 *via* shRNA phenocopied pharmacological inhibition and proliferative growth was restored in the presence of MS023 by overexpressing PRMT1. Finally, MS023 treatment of mice bearing ccRCC cell line and patient derived xenografts led to significant inhibition of tumor growth *in vivo*. Transcriptomic profiling of chemical treatment and PRMT1 genetic depletion demonstrated that PRMT1 inhibition triggers a significant down regulation of genes related to cell cycle progression and DNA damage. ccRCC cells treated with MS023 accumulated significant levels of DNA damage before undergoing cell death, with several DDR-related proteins being down-regulated. Proximity ligation and proteomic analysis (Bio-ID) revealed that PRMT1's interactors skew heavily towards RNA metabolism regulators and widespread alterations in mRNA processing were noted with MS023 treatment. Evidence continues to mount that PRMT1 is implicated in the biology of cancer, but to our knowledge, no thorough investigations have been performed in the context of ccRCC. Our data suggests that inhibition of PRMT1 inhibits processing of mRNA transcripts, compromises DDR mechanisms, leading to an accumulation of double stranded breaks, cytostasis and cell death. Thus PRMT1 represents a viable therapeutic target in ccRCC.

#3227 Developing brain-penetrating MAT2A inhibitors for *MTAP*-deleted brain metastatic cancer and GBM.

S. Ki, J. Kim, J. Na, I. Koh, H. Cho, H. Lee, H. Jung, G. Cho, M. Moon, Y. Shin, S.-K. Park;
SK Biopharmaceuticals Co., Ltd., Seongnam, Korea, Republic of

Background: Homozygous deletion of *MTAP* is one of the most frequent genetic alterations in various solid tumors including glioblastoma (GBM), mesothelioma, pancreatic cancer and lung cancer. While *MTAP*-deleted cancers are associated with a poor prognosis, there are no approved drugs for the treatment of patients with *MTAP* deficiency. MAT2A has emerged as a potential target for selective anticancer effects in *MTAP*-deleted cancers. However, development of brain-penetrating MAT2A inhibitors are yet to be reported in preclinical or clinical stages despite of high *MTAP* deletion fraction in GBM and brain metastatic cancers. Here, we present highly potent and selective MAT2A inhibitors capable of brain penetration for *MTAP* deleted cancer therapy.
Methods: A MAT2A biochemical enzyme assay was performed with phosphonate colorimetric kit. To evaluate *in vitro* and *in vivo* activities of compounds, S-adenosylmethionine (SAM) and symmetrical dimethyl arginine (SDMA) levels were measured using LC-MS/MS and high-content screening systems. Cell growth inhibition assay was evaluated to confirm the selectivity in isogenic pairs of HCT116 WT and *MTAP*-deleted cells. *In vivo* efficacy was conducted using the *MTAP*-deleted HCT116 xenograft.
Results: To develop novel brain penetrating scaffolds, we focused on interaction of hydrogen bond acceptor in the scaffolds with arginine residue Arg313 in MAT2A protein and the improvement of physicochemical properties, including logP and logBB. A series of MAT2A inhibitors significantly inhibited MAT2A enzymatic activity, resulting in the reduction of intracellular SAM level, the direct product of MAT2A. These compounds showed highly potent inhibition of SDMA and cell proliferation in *MTAP*-deleted cells, while displaying minimal effect on *MTAP*-WT cells, showing >100-fold selectivity towards *MTAP*-deletion over *MTAP*-WT. Furthermore, anti-proliferative activity of MAT2A inhibitors were observed in *MTAP*-deleted cancer cells across various cancer types, including GBM, breast cancer, and non-small cell lung cancer. Remarkably, mouse pharmacokinetic study revealed high level of plasma and brain exposure with outstanding brain-to-plasma ratio (> 0.75). Robust tumor growth inhibition as well as reduction in tumor SAM levels were observed as monotherapy in an *MTAP*-deleted HCT116 xenograft model.
Conclusion: We have identified novel brain-penetrating MAT2A inhibitors displaying encouraging *in vitro* and *in vivo* pharmacological profiles, indicating the potential use of these compounds as therapeutic agents for *MTAP* deleted brain metastatic cancer and GBM.

#3229 IACS-16559, a CBP/P300 bromodomain inhibitor for the treatment of specific AML subsets.

Ciro Zanca, Michael Soth, Guang Gao, Jason Gay, Ningping Feng, Christopher Bristow, Kang Le, Quanyun Xu, Phuong Nguyen, Yongying Jiang, Teresa Perry, Faika Mseeh, Paul Leonard, Jason Cross, Virginia Giuliani, Joe Marszalek, Philip Jones, Tim Heffernan

The University of Texas MD Anderson Cancer Center, Houston, TX

Block in differentiation and accumulation of undifferentiated blasts are hallmarks of Acute Myeloid Leukemia (AML) and epigenetic processes have been shown to play a critical role in hematological malignancies. Paralogs CREBBP and EP300, in association with co-factors, are hijacked during leukemogenesis by aberrant transcriptional factors, thus driving blast proliferation and maintaining the undifferentiated phenotype. Here, we introduce IACS-16559, a bromodomain inhibitor targeting CREBBP/EP300. IACS-16559 is highly selective for the bromodomains of CBP and EP300 versus BRD4, showing a dose-dependent inhibition of H3K27 acetylation residue *in vivo* and *in vitro*. In addition, IACS-16559 pharmacokinetic properties show low clearances, high oral exposures and predicted QD dosing in human. We screened AML cell lines *in vitro* for their response to IACS-16559 and identified specific subtypes of AML that exhibit heightened sensitivity to CBP/EP300 inhibition, specifically AML with AML1-ETO and MLL-AF9 rearrangements, and AML featuring mutations in the nucleophosmin (NPM1c) gene. IACS-16559 inhibited proliferation of AML responder cell lines *in vitro*, halted cell cycle progression, with an accumulation of cells in G1 and a decrease of cells in S phase. IACS-16559 did not induce apoptosis across a panel of AML cell lines, indicating that induction of apoptosis is not a major mechanism of action of CBP/EP300 inhibition. To augment the anti-tumor effects of IACS-16559, we prioritized the pharmacological combination of CBP/EP300 and MLL-Menin inhibitors. This combination synergistically impeded cell proliferation and potently triggered apoptosis *in vitro* and *in vivo*, whereas none of the individual agents alone had this effect. The changes in gene and surface marker expression produced by these treatments, as single agents and in combination with synergistic effects, were in line with an induced myeloid differentiation phenotype. Collectively, our findings provide a compelling basis for further exploring the use of a CBP/EP300 bromodomain inhibitor in conjunction with an inhibitor of the MLL-Menin interaction in a subset of AML patients with MLL rearrangements or NPM1 mutations.

#3230 Discovery of selective BRM (SMARCA2) ATPase inhibitors for the treatment of BRG1 (SMARCA4) mutant cancers.

J. Y. Lee[1], N. Brooks[2], B. Antonakos[1], B. Perria[2], C. Langan[2], B. D. Jones[2], R. S. Flack[2], Z. Li[1], D. Terry[1], R. Wallace[3], R. Bondi[3], G. Sis[3], R. Baracani[3], M. McVean[3], G. Kolakowski[3], D. Osimboni[1], K. Wilson[1];

[1]Foghorn Therapeutics, Cambridge, MA, [2]Loxo@Lilly, Indianapolis, IN, [3]Loxo@Lilly, Louisville, CO

BRM (SMARCA2) and BRG1 (SMARCA4) are highly homologous ATPases that are members of the BAF (also known as the mSWI/SNF) chromatin remodeling complex. BRM and BRG1 are mutually exclusive enzymatic subunits of BAF complexes, and functional genomic screens have shown a synthetic lethal relationship between the two genes. BRG1 is frequently mutated in cancer, including in approximately 10% of non-small cell lung carcinomas. Selective inhibition of BRM is a mechanism by which BRG1-mutated cancer cell growth would be affected by losing BRM function, while normal tissues should be spared as they still express functional BRG1. Given that the ATPase domains of BRM and BRG1 are 92% identical, the identification of selective enzymatic inhibitors of BRM has been challenging. Here, we report the discovery of novel, highly potent compounds that selectively inhibit BRM over BRG1 as seen in cell-based transcription and proliferation assays, that also possess excellent oral pharmacokinetics. Our lead compounds inhibit BRM in a cell-based reporter assay with an unbound IC_{50} of 1 nM and are greater than 20-fold selective over BRG1. They are also selective against other helicases and do not show any significant activity in off-target screening panels. Dosing of mice carrying BRG1-mutant xenografts causes target gene modulation that is correlated with compound exposure. Treatment of A549 and RERF-LC-AI xenografts with lead compounds led to tumor growth inhibition of 87% and 96%, respectively, at well-tolerated doses, and significant tumor growth inhibition was also achieved in multiple other BRG1-mutant models. The results suggest that our compounds have first-in-class potential as potent and selective BRM ATPase inhibitors for the treatment of BRG1-mutated cancers, and we are planning to file an IND in 2024.

#3231 Pharmacological inhibition of the m^{6}A RNA reader, YTHDC1, as a novel approach to targeting biomolecular condensates in cancer.

R. C. Centore[1], M. Charles[2], M. Arora[1], Y. Chen[1], M. Watson[2], C. Kelley[1], M. Czekalska[2], M. Rebmann[2], M. Ghandi[1], J. Cattin[2], N. Bharatham[2], P. Radhakrishnan[1], A. Howarth[2], G. Rudlaff[1], W. E. Arter[2], S. Qamar[2], K. Saar[2], D. Williamson[2], A. Seeber[1], T. Knowles[2], **S. Arora[1]**;
[1]Transition Bio, Watertown, MA, [2]Transition Bio, Cambridge, United Kingdom

Epigenetic dysregulation is a hallmark of cancer, and tumors have evolved complex mechanisms to fine-tune oncogenic gene expression. In acute myeloid leukemia (AML), one such regulatory mechanism involves post transcriptional modification of RNAs. The most abundant post transcriptional modification is methylation of adenosine at the N6 position (m^{6}A). This modification is catalyzed by the m^{6}A “writer”, METTL3 and METTL14 complex, and is removed by “erasers” such as FTO and ALKBH5. m^{6}A RNAs can regulate a variety of cellular processes which can impact tumor phenotypes, including RNA stability, splicing, and nuclear export; and METTL3 catalytic inhibitors are currently in clinical development for AML and other cancers (NCT05584111).The m^{6}A “reader”, YTHDC1, has been recognized as a critical contributor to the proliferation and survival of AML cells. As the primary nuclear m^{6}A reader, YTHDC1 localizes with m^{6}A marked RNAs in phase-separated assemblies, termed biomolecular condensates, helping to maintain the stability of oncogenic transcripts such as *MYC*. Here, we have employed our proprietary microfluidics based screening platform (termed PhaseScan^{TM}) to identify modulators of YTHDC1 biomolecular condensates. Evaluation of early screening hits helped identify that disruption of the interaction between YTHDC1 and m^{6}A RNA is a functionally relevant mechanism of action (MoA) that results in dissolution of YTHDC1 condensates. Using computational and knowledge based approaches, we have identified other structurally distinct inhibitors that occupy the RNA binding pocket of YTHDC1 and disrupt its interaction with m^{6}A RNA at nanomolar potencies. These compounds disrupt cellular YTHDC1 condensates, suppress oncogenic gene expression, and result in anti proliferative and pro-differentiation phenotypes in AML cell lines. Compounds are selective for YTHDC1 over other YTH family members and are also selective in dissolving YTHDC1 condensates over other nuclear and cytosolic condensate systems. Our optimized chemical matter has suitable ADME properties to support *in vivo* studies. Thus, targeting YTHDC1 biomolecular condensates represents a novel approach to the treatment of AML.

#3232 LSD1 inhibition transcriptionally reprograms neuroendocrine prostate cancer exposing unique therapeutic vulnerabilities.

S. M. Jasmine[1], A. Mandl[1], S. L. Dalrymple[1], S. Kim[1], J. Dias[2], M. Kleppe[2], C. Celatka[2], A. Tapper[2], I. Coleman[3], P. Nelson[3], H. Rienhoff[2], S. R. Denmeade[1], W. Brennen[1];

[1]Johns Hopkins University, Baltimore, MD, [2]Merck, Boston, MA, [3]Fred Hutchinson Cancer Center, Seattle, WA

Therapeutics have been developed to target castration-resistant prostate cancer (CRPC) classified as adenocarcinoma (CRPC-Adeno). However, an increasing frequency of CRPC-Adeno tumors progress to the highly aggressive and lethal neuroendocrine prostate cancer (NEPC) by acquiring a neuroendocrine (NE) phenotype as a mechanism of therapeutic resistance. This transformation from CRPC-Adeno to NEPC requires distinct epigenetic reprogramming by lysine-specific demethylase 1 (LSD1), which can be exploited for development of novel therapies to target NEPC. LSD1 is upregulated in NEPC and promotes a stem-like transition state through lineage plasticity which enables the cancer cell to undergo NE differentiation. We have shown that LSD1 inhibition reduces the NE program, driving NEPC towards a non-neuroendocrine state through ASCL1 suppression and YAP1 re-expression. This less aggressive non-neuroendocrine state exposes unique vulnerabilities for the development of novel combination therapies to treat this lethal disease.

#3233 EP102: Pharmacological Inhibition of METTL3 causes tumor growth inhibition and prolongs survival in preclinical models of NSCLC, ovarian and squamous cell carcinoma.

G. Fraser, C. Sorlet, N. Parmentier, E. Brunel, C. Coremans, S. Rorive, A.-F. Hartiel, K. Oukoloff, G. Dutheuil;
EPICS Therapeutics, Gosselies, Belgium

METTL3 is the RNA methyltransferase predominantly responsible for the addition of N-6-methyladenosine (m6A), the most abundant epigenetic modification to mRNA. The prevalence of m6A and the activity and expression of METTL3 have been linked to the appearance and progression of numerous hematological and solid tumor cancers. EPICS has discovered and optimized small molecule inhibitors of METTL3 ("M3i"). The aim of the current study is to evaluate the efficacy of M3i in various CDX mouse tumor models. M3i compound potency was evaluated in vitro by measuring enzymatic inhibition of METTL3/14 by scintillation proximity assay (IC_{50} = 2 nM). The anti-proliferative effects of M3i were measured in cell viability assays following a 72h treatment of A549 (NSCLC, IC_{50} = 190 nM), SKOV3 (ovarian, IC_{50} = 9 nM) and FaDu (hypopharyngeal squamous cell carcinoma, IC_{50} = 24 nM) cells. Complementary data in all three cell lines demonstrates a clear concentration-response for a target engagement biomarker (m6A; IC_{50} = 2-8 nM, across cell lines) as well as M3i-induced changes in biomarkers of oncogenic drivers. M3i (30 mg/kg, IP, QD) was tested in vivo in mouse models using FaDu (subcutaneous implant) in addition to A549 and SKOV3 (both orthotopic implants); all animal models were performed by LabCorp (MI, USA). Daily M3i treatment significantly prolonged survival in all three disease models consistent with efficacy on tumor growth inhibition as measured by imaging (A549, SKOV3) or direct measurement of tumor volume in the case of subcutaneous implant (FaDu). M3i has previously been shown to be effective in mouse CDX and PDX models of AML. The current results extend the application of METTL3 inhibitors to include the treatment of various types of solid tumors. The efficacy of M3i as a single-agent on tumor growth inhibition and survival advances the validation of METTL3 as a cancer target and provides additional evidence for the applicability of mRNA epigenetic mechanisms to the treatment of solid tumors.

#3234 A new vulnerability to BET inhibition due to enhanced autophagy in *BRCA2*-deficient pancreatic cancer.

S. Archasappawat[1], E. Lee[1], K. Ji[1], J. Pena[2], V. F. Vega[2], R. Gangaraju[1], N. S. Beesabathuni[1], M. J. Kim[1], Q. Tian[1], P. Shah[1], L. Scampavia[2], T. Spicer[2], C.-I. Hwang[1];

[1]University of California, Davis, Davis, CA, [2]The Herbert Wertheim UF Scripps Institute for Biomedical Innovation & Technology, Jupiter, FL

Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer-related deaths in the United States, with the lowest five-year survival rate of all cancers. Around 10% of pancreatic cancer diagnoses are thought to be familial pancreatic cancer (FPC). *BRCA2* pathogenic variants have been identified to be closely associated with FPC. Personalized medicine approaches that are tailored to FPC patients based on their mutation profiles could improve patient outcomes and minimize adverse effects. This study aims to identify novel potential drug candidates for *BRCA2*-deficient PDAC and dissect its underlying molecular mechanisms. To discover new vulnerabilities for *BRCA2*-deficient pancreatic cancer, we performed high-throughput drug screening (HTS) using isogenic murine *Brca2* knockout (KO) and control PDAC cells. The HTS assay revealed that JQ1, a small molecule inhibitor of the bromodomain and extra-terminal domain protein (BET) family, selectively induced cytotoxicity in *Brca2* KO cells. JQ1 significantly decreased the cell viability of *Brca2* KO cells in vitro and suppressed the growth of *Brca2* KO tumors in vivo compared to the controls. The transcriptomic analyses showed that JQ1 treatment resulted in upregulation of the gene sets associated with macroautophagy. Multi-orthogonal autophagy assays, including live cell imaging of fluorescence-based autophagy reporter, also supported that *Brca2* KO cells had a constitutively higher basal level of autophagic activities compared to the controls, and JQ1 further induced autophagic flux in *Brca2* KO cells. Moreover, blocking the autophagy process by pharmacological inhibition or knocking down essential autophagy genes rescued JQ1-induced cell death in *Brca2* KO cells, indicating that the increased autophagy is responsible for JQ1-mediated cell death in *Brca2* KO cells. In conclusion, we found that BRCA2 deficiency elevated autophagic flux, and extensive autophagy was further activated by BET inhibition, culminating in autophagy-dependent cell death in *Brca2*-deficient pancreatic cancer cells. Our findings suggest that BET inhibition could be a promising therapeutic strategy for treating *BRCA2*-deficient pancreatic cancer.

#3236 Discovery of hydrazide-based HDAC8 selective PROTACs.

Y. Xiao[1], Y. Liu[1], N. Awasthee[1], C. Meng[1], M. He[2], S. Hale[1], R. Karki[3], Z. Lin[3], R. Kridel[2], D. Liao[1], G. Zheng[1];
[1]University of Florida, Gainesville, FL, [2]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [3]Washington University in St. Louis, St. Louis, MO

HDAC8 plays crucial roles in biological processes and is a highly desirable target for therapeutic interventions. However, due to the conserved catalytic domain among HDACs, developing specific inhibitors for these isozymes has proven challenging. HDAC8 also has deacetylase-independent activity which cannot be blocked by an inhibitor. Previously we reported the discoveries of a potent HDAC3 degrader XZ9002 and an HDAC3/8 dual degrader YX968. In this study, we carried out further optimizations based on the warhead of YX968 through rational design, which led to the discovery of YX862 and YL246, novel hydrazide-based HDAC8 selective PROTAC degraders with single-digit nanomolar DC50 and excellent selectivity. We demonstrated that the degradation of HDAC8 affects its non-histone substrates; however, it does not trigger profound histone hyper-acetylation and gene expression alteration, highlighting the unique role of HDAC8. The PROTACs developed in this study are well-characterized HDAC8 degraders without triggering pan-HDAC inhibition which represent valuable tool compounds for exploring the biological and therapeutic potential of HDAC8 in cancers and beyond.

#3237 KDM1A/LSD1 inhibition enhances chemotherapy response in ovarian cancer.

J. D. Johnson[1], Y. Chen[2], S. Jayamohan[1], Y. He[2], D. Jamwal[1], N. Pandey[1], E. Kost[1], R. K. Vadlamudi[1], G. R. Sareddy[1];
[1]UT Health Science Center at San Antonio, San Antonio, TX, [2]Central South University, Changsha, China

Background: Ovarian cancer (OCa) is the deadliest of all gynecological cancers. The standard treatment for OCa is platinum-based chemotherapy, such as carboplatin or cisplatin in combination with paclitaxel. Most patients are initially responsive to these treatments; however, nearly 90% will develop recurrence and inevitably succumb to chemotherapy-resistant disease. Recent studies have revealed that the epigenetic modifier lysine-specific histone demethylase (KDM1A/LSD1) is highly overexpressed in OCa. However, whether KDM1A plays a role in chemoresistance and whether its inhibition enhances chemotherapy response in OCa is unknown. In this study, we explored the hypothesis that KDM1A inhibition will sensitize OCa cells to standard-of-care chemotherapy.
Methods: Transduction of KDM1A-specific shRNA was used to generate KDM1A knockdown (KD) cells. Cell viability, colony formation, and apoptosis assays were used to determine the impact of KDM1A KD on sensitization of SKOV3, OVCAR8, and OVCAR5 OCa cells to cisplatin, carboplatin, and paclitaxel. The combination effect of KDM1A inhibitors (NCD38 and SP2509) and chemotherapy drugs was further determined. Mechanistic studies were conducted using RNA-sequencing, RT-qPCR, and Western blotting. *In vivo* efficacy ofKDM1A knockdown with or without chemotherapy was determined using OCa orthotopic xenograft models.
Results: Analysis of TCGA datasets revealed that KDM1A expression is negatively correlated with OCa survival, and its expression is high in patients who do not respond to chemotherapy. Further, Western blotting results show that treatment with chemotherapy drugs cisplatin, carboplatin, and paclitaxel increased KDM1A expression in OCa cells. KDM1A-KD or KDM1A inhibition sensitized OCa cells to chemotherapy drugs in reducing cell viability, survival, and enhancing apoptosis. Moreover, knockdown of KDM1A sensitized carboplatin-resistantA2780-CP70 cells to carboplatin treatment. RNA-seq studies revealed that KDM1A-KD and cisplatin-regulated genes showed negative correction with epithelial-mesenchymal transition (EMT) and positive correlation with apoptosis-related pathways. Importantly, KDM1A KD in combination with cisplatin significantly reduced the tumor growth in the orthotopic OCa xenograft model.
Conclusion: These results suggest that the combination of KDM1A inhibitors with chemotherapy is a viable therapeutic approach for the treatment of OCa

#3238 Therapeutic targeting of the genome guardian sirtuins in metastatic prostate cancer.

S. Giri;
Medical College of Wisconsin, Wauwatosa, WI

Introduction: The effective treatment paradigm for the lethal form of metastatic prostate cancer (mPCa) remains challenging. Almost all mPCas eventually develops therapy resistance against androgen receptor (AR) inhibitors (e.g., Enzalutamide, Abiraterone) or to poly (adenosine diphosphate-ribose) polymerase (PARP) inhibitors (Olaparib, Niraparib, Talazoparib) (HRRd) when used as monotherapy. Although the patients in the ARSi+PARPi combination produced significantly longer radiologic progression-free survival (rPFS), a substantial number had attained therapy resistance by the end of the study tenure. So, a newer therapy is urgently needed. In recent years, a new targetable therapeutics development domain has been unfolding with an expanding understanding of the role of SIRTuins in prostate cancer cell survival, invasion, and progression to an aggressive metastatic state. Here, we will investigate the therapeutic efficacy of SIRT1/7 inhibitor (SIRT1/7i) and determine synergy with DNA-damaging PARP inhibitor combinations through a battery of cell and molecular assays using various prostate cancer cellular models.

Methods: We have treated the mPCa cell lines 22Rv1, LAPC4, PC3 and LnCAP as well as prostate epithelial cell line RWPE1 with SIRT1 inhibitor SIRT1-IN-2 (MedChemExpress, HY-146689), SIRT7 inhibitor 97491 (MedChemExpress, HY-135899) and AR inhibitor Enzalutamide individually as well as in combination of PARP inhibitor Olaparib. The treatment of the SIRT1 and SIRT7 monotherapy arm was 72 hours long, and combination therapy continued for 7 days. The cell viability was assessed with CellTiter-Glo® 2.0 Cell Viability Assay (Promega). The cell cycle progression and proliferation analysis were done using flow cytometry through Propidium iodide staining and AnnexinV-FITC apoptosis detection chemistry. Cell survival was orthogonally assessed using colony counting assays. We adopt RAD51 foci counting assays and COMET assays for evaluating treatment-induced genome instability.

Results: The preliminary result suggested that the SIRT1i+Olaparib and SIRT7i+Olaparib combination significantly sensitized the mPCa cell lines 22Rv1, PC3, and LnCAP for cell death compared to the prostate epithelial cell RWPE1. Upon the combination treatment, the mPCa cell lines showed elevated apoptotic cell death, reconfirmed through colony counting assay.

Conclusion: Therapeutic combination treatment of SIRT1 and SIRT7 inhibition with Olaparib could be an effective treatment option for aggressive metastatic prostate cancer.

#3239 Targeting the GAS41 YEATS domain in non-small cell lung cancer with novel small molecules.

A. Winkler, D. Listunov, B. Linhares, J. Ray, S. Weaver, S. Zolov, V. Keshamouni, J. Grembecka, T. Cierpicki;
University of Michigan, Ann Arbor, MI

Background: Glioma amplified sequence 41 (GAS41) belongs to the Yaf9, ENL, AF9, Taf14, and Sas5 (YEATS) domain family of epigenetic reader proteins. This domain preferentially recognizes acetylated lysine residues on chromatin to facilitate gene expression by recruiting chromatin remodeling and transcription activating complexes. The *YEATS4* gene encoding for GAS41 protein is frequently amplified in NSCLC patient samples relative to normal lung tissue, and GAS41 protein is overexpressed in NSCLC cells. In knockdown experiments using NSCLC xenograft mouse models, GAS41 has been shown to be essential for NSCLC tumor growth. In mutagenesis studies, the YEATS domain residues responsible for acetylation reader activity were found to be essential for NSCLC cellular proliferation and tumor progression. Thus, the YEATS domain of GAS41 represents an attractive target for the development of small-molecule inhibitors as potential therapeutics for NSCLC.

Results: We developed the first-in-class small-molecule inhibitors for the GAS41 YEATS domain. Using an NMR-based fragment screen, we identified a hit with low millimolar binding affinity. Structure-based drug design followed by extensive medicinal chemistry optimization yielded the potent and selective inhibitor DLG-369 with sub-micromolar inhibition of the GAS41 YEATS domain interaction with acylated histones. Using the NanoBRET platform, we showed that DLG-369 selectively disrupts the association of GAS41 YEATS with chromatin in mammalian cells. Furthermore, DLG-369 inhibits proliferation of NSCLC cell lines without affecting normal lung fibroblasts. In transcriptomic experiments, DLG-369 treatment regulates expression of multiple genes in NSCLC cells, including upregulation of the critical tumor suppressor genes *CDKN1A* and *CYR61* and downregulation of chemokine genes *CXCL5* and *CXCR4* associated with NSCLC progression.

Conclusions: We developed DLG-369, a potent inhibitor of the GAS41 YEATS domain with activity in NSCLC cellular models. DLG-369 potently binds to the YEATS domain acetylation reader pocket and disrupts GAS41 recognition of acetylation in cells. DLG-369 potently reduces proliferation and drives differential expression of key genes associated with NSCLC. DLG-369 can serve as a chemical probe to further interrogate the biological role of the GAS41 YEATS domain in NSCLC and other cancers for potential therapeutic implications.

#3240 Synthetic lethal strategy of an EZH1/2 dual inhibitor, HM97662, for the treatment of ARID1A-mutated solid cancers.

Y.-Y. Kim, S. Jung, S. Han, J. Byun, G. Lee, M. Lee, J. Park, T. Kong, H. Han, S. Lee, Y. Ahn;
Hanmi Pharmaceutical Co., Ltd., Hwaseong-si, Korea, Republic of

Enhancer of zeste homolog 2 (EZH2), an enzymatic subunit of polycomb repressive complex 2 (PRC2), is known to catalyze tri-methylation of histone H3 at lysine 27 (H3K27me3), leading to repression of the transcription of its target genes involved in cell cycle regulation, cell proliferation, cell differentiation, and tumor suppression. It has been proposed that epigenetic regulators could serve as novel drug targets, and EZH2 is one of the targets with considerable therapeutic potential. Meanwhile, synthetic lethality is a phenomenon whereby individual genes in a pair can be knocked-out without affecting cell viability, while disruptions of both genes concurrently cause cell death. It has been shown that loss-of-function (LOF) mutations of component proteins in SWI-SNF chromatin remodeling complex, including PBRM1, ARID1A, SMARCA4, and so on, are synthetic lethal with inhibition of the histone methyltransferase EZH2. Especially, ARID1A-mutated solid tumors are vulnerable to EZH2 inhibition. Given that ARID1A is mutated in approximately 10% of all tumor types, inhibiting EZH2 activity could be a promising therapeutic strategy for cancer patients with this mutation. Although the methyltransferase activity of PRC2 is mainly contributed by EZH2, EZH1 also plays a compensatory role in maintaining tri-methylation of H3K27 and directly binds to chromatin, modulating its condensation. These emphasize that blocking both EZH1 and EZH2 might have greater anti-tumor effect than EZH2 alone. Herein, we introduce a novel EZH1/2 dual inhibitor, HM97662, which concurrently suppressed the methyltransferase activity not only wild-type EZH1, but also wild-type and gain-of-function (GOF) mutant EZH2 at nanomolar concentrations. HM97662 potently repressed tri-methylation of H3K27me3 in TOV-21G (ovarian cancer) and HT-1376 (bladder cancer) cell lines with ARID1A LOF mutation. HM97662 also showed a wide and strong growth inhibitory effect in various solid cancer cell lines harboring ARID1A mutation. HM97662 exhibited potent antitumor activities in xenograft mouse models with various ARID1A-mutated cancer cells including ovarian, bladder, small cell lung cancer, prostate, and gastric cancers (e.g. TOV-21G, HT-1197, NCI-H128, LNCap, and MKN-45, respectively). Once-daily oral dosing of HM97662 greatly inhibited tumor growth in a dose-dependent manner without significant clinical signs compared to known EZH2 selective or EZH1/2 dual inhibitors. HM97662 also exhibited a synergistic effect in combination with second-line standard of care in small cell lung cancer. In conclusion, these preclinical studies demonstrated that HM97662 as an EZH1/2 dual inhibitor, holds promising therapeutic potential for ARID1A-mutated solid cancers. It is crucial to evaluate the effectiveness of HM97662 in subsequent clinical trials.

#3241 Elevated H3K27 trimethylation mediates adaptation to DNA demethylation in BRAF^{V600E}-mutated colorectal cancer.

H. Lee[1], A. Saw[1], V. K. Morris[1], A. K. Singh[1], S. Napolitano[2], A. Sorokin[1], P. Kanikarla Marie[1], O. Coker[1], O. E. Villarreal[1], N. Esmaeili Anvar[1], K. Rai[1], S. Kopetz[1];

[1]University of Texas MD Anderson Cancer Center, Houston, TX, [2]Universita degli Studi della Campania "Luigi Vanvitelli", Napoli, Italy

Background: BRAFV600E in colorectal cancer (CRC) defines a unique subgroup of patients with poor prognosis and scarcely benefit from BRAF inhibitor-based treatment. Interestingly, BRAFV600E tumors demonstrated profound CpG island methylator phenotype (CIMP), suggesting extensive epigenetic dysregulation. Thus, we investigated epigenomic regulations in this subset of tumors with treatment-induced DNA demethylation.

Methods: We treated six cell lines and two patient-derived xenograft (PDX) models of BRAFV600E CRC with vehicle, 5-azacitidine (DNMTi), vemurafenib (BRAFi), and combination treatment. PDX tumors treated with either vehicle or 5-azacitidine were collected on day 21 and sequenced for DNA methylation (Infinium HumanMethylation 450k BeadChip array), histone marks (ChIP-seq), chromatin accessibility (ATAC-seq), and gene expression (RNA-seq). Comprehensive post-translational modifications (PTMs) in histones with DNMTi or BRAFi treatment were assessed by mass spectrometry (MS). The combinational effect of 5-azacitidine with EZH2 or RNF2 inhibitors (Polycomb repressive complex activity (PRC) inhibition) was assessed through cell viability assays and colony formation assays in BRAFV600E CRC cell lines.

Results: Analysis of TCGA COAD/READ tumors demonstrated a higher DNA methylation profile in BRAFV600E tumors than wild-type tumors even among the CIMP population (FDR < 1e-4). The combination of DNMTi with BRAFi showed selective additivity in vitro; however, did not improve efficacies in PDXs. The 5-azacitidine treatment induced profound demethylation in PDXs compared to control samples, predominantly attributed to promoter regions (48%). However, DNA demethylation failed to reactivate classic CIMP markers or tumor suppressor genes in CRC (e.g., CDKN2A, MGMT). Interestingly, demethylated genomic regions gained H3K27 trimethylation, repressive histone mark, in azacitidine-treated samples compared to control (9,431 vs 5,147 peaks respectively). We validated the elevation of H3K27 trimethylation as well as additional histone PTMs following DNMTi in MS-based histone analysis. Finally, combining a demethylating agent with EZH2i or RNF2i, which either deplete H3K27 trimethylation or block the PRC activity respectively, has demonstrated additive growth inhibitory effects in BRAFV600E CRC cell lines ($p < 0.05$).

Conclusions: This study unveiled intriguing aspects of demethylation agent treatment, which led to the compensatory engagement of other epigenomic markers, particularly repressive histone marks, resulting in limited efficacies to azacitidine treatment in preclinical BRAFV600E CRC models. This finding suggests the existence of adaptive interactions between epigenetic modifiers and potential clinical strategies in combinational epigenetic therapeutics.

#3242 TNG917 is a clinical-grade, potent and selective inhibitor of EHMT1/2 for the treatment of immune cold tumors.

CRISPR-based functional genomics screening can be designed to identify novel cancer cell intrinsic targets that increase tumor immunogenicity. Using a FACS-based CRISPR sorting screen for PD-L1 expression, we identified Euchromatic histone-lysine-*N*-methyltransferase 1 and 2 (EHMT1/2) as negative modulators of the interferon signaling pathways. EHMT1 and EHMT2 are histone methyltransferases that mono- and di-methylate lysine 9 of histone H3 to repress gene transcription of defined target genes. Gene knockout or pharmacological inhibition of EHMT1/2 in cancer cells resulted in de-repression of gene promoters, upregulation of interferon-stimulated genes (ISGs), and secretion of pro-inflammatory cytokines. Here, we present the preclinical characterization of TNG917 - an oral and highly selective EHMT1/2 inhibitor with low nanomolar cellular potency, and favorable pharmacodynamic and pharmacokinetic properties. In humanized and syngeneic mouse models, treatment with TNG917 in combination with anti-PD1 promoted a T-cell-infiltrated tumor microenvironment, led to significant anti-tumor activity, and resulted in survival benefit. In summary, our in vitro and in vivo studies provide a rationale for the clinical development path of TNG917, in combination with checkpoint inhibition, in patients with immune cold tumors.

#3244 EWS-FLI1-driven upregulation of UGT3A2 unlocks drug sensitivity pathway in Ewing sarcoma.

O. Olaoye[1], C. Harrington[2], K. Ross[1], B. A. Seong[1], L. de Waal[2], J. Qi[1], J. Roth[2], K. Stegmaier[1];
[1]DFCI/Harvard Medical School, Boston, MA, [2]Broad Institute, Cambridge, MA

Ewing sarcoma (ES), an aggressive pediatric bone tumor, presents a clinical challenge, particularly for metastatic or relapsed disease. The hallmark genetic alteration involves the fusion of the FET RNA-binding protein, EWSR1, with an ETS transcription factor, typically FLI1, resulting in the EWS-FLI1 fusion oncoprotein. EWS-FLI1 orchestrates a unique epigenetic program, leading to the aberrant expression of genes crucial for cell-cycle regulation, DNA damage response, and cell migration.

Targeting the EWS-FLI1 fusion oncoprotein is a daunting task, which has prompted us to pursue other strategies in parallel. Here, we present an innovative approach harnessing the power of phenotypic drug screens to uncover amenable pathways for targeted medicines in ES. Leveraging data from the Broad Institute's repurposing dataset encompassing 4,518 drug molecules screened across 578 adherent cancer cell lines using the high-throughput multiplexed screening platform known as PRISM, we identified compounds with selective efficacy against ES.

The top-ranking compound identified for selective ES toxicity in the screen was R112, an ATP-competitive inhibitor of Spleen Tyrosine Kinase (SYK). In low-throughput evaluation, R112 induced selective ES cell death when compared to other sarcomas. However, the reported target of R112, SYK, is a dependency in ES based on the Cancer Dependency Map (DepMap) resource.

Subsequent validation of compounds identified in the PRISM screen as selectively toxic in ES revealed that while majority of them induced selective ES cell death, their reported targets were diverse and not linked to known dependencies in ES. Notably, one of the emerging compounds, luteolin, a natural compound known for its antioxidative properties, stood out and was selected for further studies alongside R112.

Comprehensive genome-wide CRISPR-rescue screens identified *UGT3A2*, encoding a UDP glycosyltransferase, along with its solute carrier, *SLC35B4*, as pivotal genes that when deleted rescued both R112 and luteolin-induced cytotoxicity in ES cells. UGT3A2, a direct target gene of EWS-FLI1, demonstrated hyperexpression in EWS-FLI1-positive ES cells and no expression in most cancer and normal cells. While ES cells do not depend on UGT3A2 for survival, this abnormal elevation of *UGT3A2* expression emerged as a key determinant driving their hypersensitivity to a subset of additional small molecules identified from the PRISM screen. Despite divergent mechanisms and direct targets, these drugs shared a common phenoxy motif, which UGT3A2 glycosylated.

This specific EWS-FLI1-induced UGT3A2 upregulation, thus, unveils a novel biomarker for drug sensitivity,paving the way for precision medicine strategies tailored for Ewing sarcoma.

Beyond Ewing sarcoma, this work holds promise in reshaping therapeutic paradigms and offering new avenues for discovering safe and enhanced treatments across a spectrum of cancers.

#3245 Use of hypomethylating agents to reprogram the epigenome in large granular lymphocyte leukemia.

A. Sabzevari, I. Pal, T. Deddens, T. Fox, A. Ratan, D. J. Feith, T. P. Loughran, Jr.;
University of Virginia, Charlottesville, VA

Large granular lymphocyte (LGL) leukemia is a rare heterogeneous blood cancer that is characterized by the clonal lymphoproliferation of CD8+ T cells (T-LGL leukemia) or, less frequently, natural killer cells (NK-LGL leukemia). These cells evade activation induced cell death, allowing them to accumulate as highly cytotoxic lymphocytes that contribute to autoimmune attacks, neutropenia, and anemia. Frontline treatments are limited to repurposed, nonspecific immunosuppressive agents with limited efficacy and incomplete response rates. As there are no FDA-approved antineoplastic agents for LGL leukemia, our research explores novel therapeutic avenues for this orphan disease. Somatic activating mutations in the transcription factor *STAT3* are the most common molecular alteration found in >50% of patients, and STAT3 signaling is dysregulated in almost all LGL leukemia patients. In the largest molecularly profiled LGL leukemia patient cohort to date, we found that *STAT3* mutations frequently co-occur with mutations in chromatin and epigenetic modifying genes, suggesting crosstalk and cooperativity between STAT3 activation and epigenetic dysregulation. Moreover, *TET2*, which promotes DNA demethylation, is frequently inactivated in LGL leukemia via loss-of-function mutations and promoter hypermethylation. As DNA hypermethylation is an emerging hallmark of LGL leukemia, we evaluated the therapeutic potential of two epigenetic agents, azacitidine (AZA) and cladribine (CLAD), that directly and indirectly inhibit DNA hypermethylation, respectively. We hypothesize that AZA and CLAD will 1) exhibit cell intrinsic efficacy, 2) reprogram the epigenome of LGL leukemia through DNA hypomethylation to normalize aberrant gene expression, and 3) induce cytokine-mediated immune responses. AZA and CLAD cytotoxicity was assessed by the Cell Titer Glo viability assay in human LGL leukemia cell lines. Each exhibited potent anti-leukemic effects with IC50 values in the low micromolar and nanomolar ranges. Western blotting analysis demonstrated the decrease in protein expression of DNA methyltransferases and phosphorylated STAT3 levels with treatment in a time- and dose-dependent manner. We also explored the immunomodulatory effects of these hypomethylating agents since LGL leukemia is a pro-inflammatory malignancy with cytotoxic lymphocytes. Preliminary findings using the Isoplexis platform suggest that AZA and CLAD induce production of anti-inflammatory cytokines in LGL leukemia cells. Ongoing studies will identify differential methylation, chromatin accessibility, and gene expression using RRBS, ATAC-seq, and RNA-seq of AZA or CLAD treated samples to define the mechanisms and consequences of DNA demethylation. Uncovering the reprogramming capabilities of AZA and CLAD could allow for the potential repurposing of these inhibitors for treatment of LGL leukemia patients.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Immune Modulators and Antisense Molecules

#3248 Metabolic rewiring shifts engineered TCR T cell bioenergetics to enhance cytotoxicity.

R. Pillai[1], X. Zhang[2], Y. Abassi[2],
[1]Rashmi Pillai (Individual), San Diego, CA, [2]Agilent Technologies, San Diego, CA

Background: Adoptive T cell-based transfer has shown tremendous success in hematological cancers. However, an important obstacle to using cell and gene therapy for solid tumors is the aggressive tumor microenvironment (TME). To significantly improve prognosis of subjects undergoing immunotherapy, it is essential to incorporate unique methods to drive T cell energy production and metabolism towards empowering T cells to dismantle the suppressive TME. This can promote anti-tumor effects and persistence of the transfused engineered T cells. In the present study we present a simple metabolic preconditioning process that improves T cell performance and bioenergetics.
Methods: Using the Agilent xCELLigence RTCA eSight, and Seahorse XF Analyzer we assessed the killing efficiency, and bioenergetics of engineered T-cells after pretreating with Arginine. Briefly, engineered TCR T-cells against MART-1 were generated by transducing $CD3^+$ T-cells (Hemacare, Seattle, WA) with retrovirus SAMEN-DMF5 with a CD34 marker gene, against MART-1. The TCR T cells were pre-conditioned in 6mM Arginine for 7 days, followed by a killing assay using MART-1 expressing melanoma cell line as target cells (624.38) at the E:T ratio of 5:1. Target melanoma cells, 624.38 cells, were engineered to express a red-fluorescent nuclear protein. The comparison was made with transduced T-cells grown in RPMI (no added amino acid supplementation, and non-transduced T cells. The cytotoxicity assay was assessed using real-time impedance and live cell imaging data collected on xCELLigence RTCA eSight. Concurrently, the metabolic profiling of the engineered T-cells was examined by the XF96 Analyzer.
Results: Supplementing the growth medium with 6 mM Arginine significantly increased the potency of MART-1 engineered T cells (up to 6-fold) and bioenergetic studies revealed increased spare respiratory capacity, basal respiration, and ATP production via mitochondrial respiration.
Conclusions: Arginine pre-conditioning improved TCR T cell potency through metabolic rewiring favoring mitochondrial respiration. For Research Use Only. Not for use in diagnostic procedures RA45236.3483333333

#3249 Simple, rapid, and robust bioluminescent cell-based assay for detecting neutralizing antibodies against AAV in serum.

Morten Seirup, Kirsten Wingate, Jeff Nelson, Kara Machleidt, Vanessa Ott, Trish Hoang, Marjeta Urh

Promega Corporation, Madison, WI

Adeno-associated viruses (AAV) are prevalent gene therapy vectors, delivering therapeutic transgenes to treat various diseases including cancer and rare monogenic diseases. Individuals with pre-existing immunity to AAVs are less likely to benefit from AAV-based therapies due to both, a reduction in cellular AAV uptake and activation of a cytotoxic T-cell response to transduced cells, decreasing efficacy or changing the safety profile. Measurement of serum neutralizing antibodies (NAbs) against AAV is essential to determine treatment eligibility and to identify clinical trial candidates. Here we introduce a cell-based assay using NanoLuc® luciferase to detect NAbs in serum samples. The superior brightness of NanoLuc® luciferase in our AAV reporter system results in the need of low concentrations of AAV and a short 24h assay time. The minimal AAV concentration in our assay aids in detecting low NAb titers in serum samples, reducing false negatives and enhancing decision-making accuracy. Testing 60 human serum samples against a range of AAV serotypes, we found that a large fraction of the population had pre-existing NAbs to at least one serotype, and of the pre-exposed individuals a majority displayed NAbs against multiple AAV serotypes. Interestingly, fewer samples were seropositive for AAV-DJ than for either parental serotype (AAV2, AAV8 or AAV9), highlighting the assays utility in the development of engineered capsids. Furthermore, the broad dynamic range of our assay facilitates serum sample categorization into four NAb tiers: negative, low, medium, and high using a single serum dilution. Neutralizing titers (ND_{50}) which was determined by serial dilution of the serum samples strongly agreed with the assigned NAb tiers. Our study with 40 naïve mice further validated the assay's robustness, showing a clear correlation between NAb levels and injected AAV viral loads. Taken together, this rapid, highly sensitive, and reliable assay enabled by NanoLuc® AAV reporter technology precisely measures NAbs against AAVs in both human and animal serum. Further validation of the assay is required for future use in a clinical setting.

#3250 LNA gapmer to gastrin inhibits growth and metastases of human pancreatic cancer in mice.

G. Chekuri[1], W. Chen[1], N. Shivapurkar[1], H. Cao[1], R. N. Kularatne[2], S. Stern[2], J. P. Smith[1];
[1]Georgetown University, Washington, DC, [2]National Cancer Institute, Frederick, MD

Background: Pancreatic cancer has a poor prognosis and novel strategies are needed to improve the survival. Gastrin stimulates growth of pancreatic cancer by an autocrine mechanism and RNAi techniques that decrease gastrin expression have been shown to inhibit growth of this malignancy in vitro. Locked nucleic acid (LNA) Gapmers are antisense oligonucleotides (ASO) that have long half-life and stability in vivo, hence represent a potential method to deliver RNAi for cancer therapeutics. We developed an LNA Gapmer that selectively downregulates gastrin expression in pancreatic cancer cells in culture. The goal of this project was to test this anti-gastrin Gapmer in vivo as a novel therapy for pancreatic cancer.
Methods: The anti-gastrin LNA Gapmer was modified using thiol-click chemistry to conjugate a peptide to the 5' end and render the Gapmer target-specific with the ability to bind selectively to the cholecystokinin-B receptor that is over-expressed in pancreatic cancer. Forty athymic nude mice with established AsPC-1 human pancreatic orthotopic tumors were divided into four groups of equal tumor size. Mice (N=10 per group) were treated with PBS (controls), an untargeted LNA-Gapmer, the CCK-BR targeted Gapmer (60nM), and the CCK-BR targeted Gapmer (120nM) intraperitoneally twice a week for 4 weeks. Growth was monitored by luciferase IVIS imaging. At necropsy, tumors were excised, and metastases counted.
Results: Mean tumor mass was 43% smaller in mice treated with the targeted Gapmer-120nM (P=0.0007). Untargeted and targeted Gapmer 60nM slightly decreased tumor mass but this difference was not significant. Compared to PBS control-treated mice, metastases were significantly less in mice treated with the untargeted Gapmer by -39% (p=0.01); in the targeted Gapmer-60nM by -44% (p=0.003), and with the targeted Gapmer-120nM by -72% (p<0.0001). Gastrin mRNA analysis of the tumors by qRT-PCR confirmed downregulation of gastrin.
Conclusion: Novel LNA Gapmers that downregulate gastrin mRNA expression decrease growth and metastases of pancreatic cancer in a dose-related fashion.

#3251 QTOLIMOD: A specific TLR9 agonist nanomedicine with high anti-solid tumor activity.

F. Su[1], J. Bai[1], C. Li[1], Y. Wu[1], J. Li[1], X. Zhao[2], Y. Yang[2], **R. J. Lee**[2];
[1]Zhejiang Haichang Biotechnology Co., Ltd., Hangzhou, China, [2]The Whiteoak Group, Inc., Rockville, MD

Background Toll-like receptor 9 (TLR9) agonists are extensively studied for cancer treatment, but face challenges in delivery, clearance, and side effects. Our study showed that QTOLIMOD, a 26nt CpG-ODN delivered via QTsome™ lipid nanoparticle, significantly inhibited tumor growth in MC38-bearing mice (TGI%=99.06%, $p<0.001$). Here, we report QTOLIMOD's potential for complete tumor rejection, prevention of recurrence, and advantages in safety and immune-cell induction.

Methods C57BL/6 mice were subcutaneously inoculated with 1×10^6 MC38 cells. To assess drug tissue distribution, Cy5-labeled naked CpG-ODN or QTOLIMOD were intratumorally injected and in vivo imaging was conducted. ELISA was utilized to determine the levels of cytokines in serum and tumor samples. Once the tumor volume reached an average size of 80-100 mm^3, mice were grouped and intratumorally injected with saline, vehicle, or QTOLIMOD. Tumor volume was calculated using the formula: length × $width^2$ × 1/2.

Results Following intratumoral injection of QTOLIMOD or naked CpG-ODN, free CpG-ODN were significantly reduced within 24 hours, while QTOLIMOD exhibited extended duration of action up to 7 days. Anatomical examination revealed that a dose of 5 mg/kg naked CpG-ODN caused liver and spleen enlargement in mice, whereas QTOLIMOD at the same dose did not cause the adverse events. Immunohistochemical assay indicated a significant increase in the infiltration of macrophages, dendritic cells, and CD8+ T cells at the tumor site after dosing. IL-10, IFN-γ, and IL-12 were significantly upregulated in the tumor samples, but not in the serum. In a dose escalation experiment, tumor suppression were observed with intratumoral injection of 0.5, 1, 1.5, or 2 mg/kg (every 3 days, 5 doses), resulting in tumor growth inhibition rates ranging from 92.5% to 98.8%. In the QTOLIMOD treated groups, complete tumor rejection was achieved in 4 out of 6 animals in the 0.5 mg/kg group and in all animals in the 1-2 mg/kg groups within 56 days. To investigate the effect of QTOLIMOD on tumor recurrence, cured mice were re-inoculated with MC38 tumor cells at a distant site. All cured mice rejected newly inoculated tumors without additional injection, resulting in 100% survival for up to 60 days. In a dosing frequency experiment, mice were administered with QTOLIMOD at 1 mg/kg once every 3, 5, 7, or 14 days for a total of 5 doses. The results suggested that fortnightly dosing of QTOLIMOD is more effective than more frequent dosing.

Conclusions QTOLIMOD exhibits a high intratumoral retention rate, resulting in increased safety, while effectively promoting the expansion and infiltration of immune cells associated with tumors. Moreover, QTOLIMOD demonstrates potent efficacy in inhibiting tumor growth, potentially leading to complete eradication. Furthermore, treatment with QTOLIMOD effectively prevents tumor from recurrence, offering promising long-term effect.

#3252 Anti-tumor effect of the combination of a lipid nanoparticle suspension of an AKT-1 antisense oligonucleotide (WGI-0301) with tyrosine kinase inhibitors in an orthotopic murine tumor model.

F. Xie[1], T. Lin[1], C. Wang[2], J. Wei[2], R. J. Lee[2], B. Zhao[1], Y. A. Men[2];

[1]Zhejiang Haichang Biotech Co., Ltd., Hangzhou, China, [2]The WhiteOak Group, Inc., Rockville, MD

Background: Archexin is a fully phosphorothioated 20-mer antisense oligonucleotide, complementary to AKT-1 mRNA, which leads to the inhibition of translation and the downstream pathway activities of AKT-1 mRNA. WGI-0301 is a proprietary lipid nanoparticle formulation (QTsomeTM) of Archexin designed to enhance delivery. A phase I clinical study of WGI-0301 as monotherapy in patients with advanced solid tumors is currently ongoing in the U.S. Given the limited efficacy of TKIs compared to immunotherapy and growing incidence resistance, WGI-0301 combined with TKIs may augment the therapeutic response to TKIs by enhancing angiogenic blockade, inhibiting AKT-1, and overcome resistance. Methods: The anti-tumor effect of combining WGI-0301 with Lenvatinib/Sorafenib/Cabozantinib was assessed using a Hep3B-Luciferase orthotopic mouse tumor model. We divided sixty-four female Balb/c nude mice into groups (8 mice per group), including vehicle control, WGI-0301 (8 mg/kg), Lenvatinib (10 mg/kg), Sorafenib (20 mg/kg), Cabozantinib (20 mg/kg), WGI-0301+Lenvatinib (8+10 mg/kg), WGI-0301+Sorafenib (8+20 mg/kg), and WGI-0301+Cabozantinib (8+20 mg/kg). We administered treatments via tail vein injection (vehicle/WGI-0301, QW4 weeks) or oral administration (Lenvatinib/Sorafenib/Cabozantinib, QD28 days). We monitored body weight twice weekly and measured tumor burden using bioluminescence with an IVIS (Lumina III) imaging system twice weekly as well. Treatment was suspended between Day 29 and Day 70 for survival observation.

Results: The tumor growth inhibition (TGI) rates of the combination of WGI-0301 with Lenvatinib/Sorafenib/Cabozantinib were 66.05%, 86.81%, and 75.89%, respectively. These values were higher than those of the Lenvatinib/Sorafenib/Cabozantinib single drug group with TGI rate of 50.84%, 55.68%, and 47.84%. The tumor bioluminescence signal intensities of the two drugs combination (56.74*108, 22.28*108, and 40.40*108 photon/s) were slightly lower than that of the Lenvatinib/Sorafenib/Cabozantinib single drug group (81.97*108, 73.95*108, and 86.96*108 photon/s). The median survival time was 35.0, 46.0, 55.5, and 51.5 days in the vehicle, WGI-0301+Lenvatinib, WGI-0301+Sorafenib and WGI-0301+Cabozantinib, respectively. The median survival time of Sorafenib, the two-drug combinations were 55.5, 55.5, 58.0, and 53.5 days, which was significantly prolonged compared to the vehicle in the mice bearing the Hep3B-luc orthotopic tumor model. No severe adverse effects were observed in the drug combination groups.

Conclusion: The combination of WGI-0301 with TKIs demonstrated superior anti-tumor efficacy over TKI monotherapy in the absence of substantial increase in toxicity. This finding warrants further robust clinical investigation in patients with advanced HCC.

#3253 Novel gene & protein-carrying vector BC-PIV expressing immunomodulatory molecules potently stimulates anti-tumor immunity against solid tumors in mice.

M. Fukumura[1], J. Ohtsuka[1], T. Ohtsuka[1], H. Nakajima[2], T. Nosaka[3];
[1]BioComo Inc., Mie-Gun, Japan, [2]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [3]Mie University Graduate School of Medicine, Tsu, Japan
