AACR Annual Meeting 2024 Regular Abstracts

This PDF contains all regular abstracts (submitted for the November 16, 2023 deadline) that were scheduled for presentation as of Monday, April 1, 2024, with the exception of abstracts that are embargoed as part of the AACR Annual Meeting Press Program.

Abstracts are sorted in presentation number order. Session categories and titles are included.

Sunday, April 7, 2024

IMMUNOLOGY: Adoptive Cell Therapies 1: Tumor Antigen-Specific T-cells and TCR-T
Poster Session

#0001 Biomarkers of response and acquired resistance to TIL-ACT in solid tumors.

W. Robinson[1], A. Castro[1], M. Al-Bakir[1], J. J. Gartner[2], C. A. Chamberlain[1], A. H. Kverneland[3], T. H. Borch[3], I. Svane[3], M. Donia[3], P. Robbins[2], K. Litchfield[1]; [1]University College London, London, United Kingdom, [2]National Institutes of Health, Rockville, MD, [3]National Center for Cancer Immune Therapy (CCIT-DK), Copenhagen, Denmark

Background: Cancer immunotherapy has revolutionized cancer treatment in the last decade. However, most patients either do not respond to immunotherapy or eventually relapse so there is a need to identify biomarkers of response and understand mechanisms of resistance. Most biomarker studies have analyzed patients treated with immune checkpoint inhibitors (CPI) therapy while the few studies of adoptive cell transfer of tumor infiltrating lymphocytes (TIL-ACT) have analyzed relatively small patient cohorts.
Methods: To systematically identify biomarkers of response and resistance to TIL-ACT, we collected published and unpublished whole-exome and transcriptomic data for tumors from 400 patients treated with TIL-ACT from five tumor types across four institutions and processed these datasets using a standardized bioinformatic pipeline.
Results: To identify biomarkers of response in pre-treatment tumors, we analyzed previously reported biomarkers and performed biomarker discovery in our cohorts. For the subset of 200 patients with T cell reactivities identified from the infusion products and fresh tumor, we refined our biomarkers to include neo-antigen reactivities in addition to identifying both mutational processes and transcriptional signatures associated with neo-antigens reactivity. To identify mechanisms of acquired resistance to TIL-ACT, we analyzed 15 patients with paired pre- and post-treatment tumors and found multiple mechanisms of immune evasion specific to infused reactive T cells including loss of heterozygosity of the HLA allele presenting the neo-antigen, genomic loss of the neo-antigen and inactivation of interferon-gamma signaling pathway.
Conclusions: In summary, we will present the biomarkers landscape of TIL-ACT therapy including differences between histology and across treatment modalities to improve our understanding of the mechanisms of treatment response.

#0002 T cells selected from lymph node acquisition for adoptive cell therapyin NSCLC.

Tatiana Delgado Cruz[1], Yanping Yang[2], Rachel Honigsberg[3], Geoffrey Markowitz[4], Nasser K Altorki[5], Vivek Mittal[4], Moonsoo M. Jin[6], Jonathan Villena-Vargas[4]

[1]Weill Cornell Medicine/Sandra and Edward Meyer Cancer Center, New York, NY,[2]Radiology, Houston Methodist, Houston, TX,[3]Meinig School of Biomedical Engineering, Weill Cornell, ithaca, NY,[4]Cardiothoracic Surgery, Weill Cornell Medicine/Sandra and Edward Meyer Cancer Center, New York, NY,[5]Cardiothoracic surgery, Weill Cornell Medicine/Sandra and Edward Meyer Cancer Center, New York, NY,[6]Radiology, Houston Methodist Research Institute, New York, NY

Background: A primary limitation of PD-1 inhibitors in non-small cell lung cancer (NSCLC) arises from their inability to act on 'cold' tumors without tumor-reactive T cells, necessitating alternative approaches. Adoptive cell therapy (ACT) using (CAR)-engineered cells, strives to enhance antitumor immunity but faces several challenges such as identifying safe antigens, tumor heterogeneity, antigen escape, cell trafficking, and T cell persistence. To address these issues, we explored a new source of T cells from the benign tumor draining lymph nodes (tdLNs) of NSCLC patients. Our initial results have shown that tdLNs is a reservoir for of tumor-relevant 'stem-like' T cells. We posit that employing these pluripotent T cells for ACT could achieve significant tumor rejection in NSCLC.
Methods: Resected tumors, tdLN, non-draining (ndLN), and blood from NSCLC patients, as well as a syngeneic murine lung cancer model (344SQ), underwent analysis. T cells were profiled using flow cytometry, cytotoxicity and proliferation assays. TCR and single cell (sc)RNA sequencing assessed clonal expansion, diversity, and transcriptional profiles of tumor-relevant T cells. T cells were then transduced with an ICAM-1 targeting CAR, in vivo efficacy was evaluated in an A549 murine lung cancer model.
Results: T cell subsets with stem-cell memory characteristics, as indicated by PD-1+, TCF1hi, CXCR5+, and CD8+ expression, which were not significantly found in the tumor or PB. These T cells exhibited progenitor-like transcriptional signatures, enhanced SELL and TCF-1 expression, fewer exhaustion markers, and superior in vitro proliferation compared to TILs from both a murine lung cancer model and patient-derived tissues. scRNA sequencing, coupled with TCR "tumor matching" (TM) techniques, exposed a rich clonal diversity of tumor-relevant clones within tdLNs, which showcased a broader transcriptional memory profile and distinct CD4+ and CD8+ phenotypes. Upon analyzing the top 100 expanded (n>3) TM clones, 47 featured the presence of tdLN-derived T cells, covering progenitor, stem cell-like, and central memory clusters. T cell subsets were then transduced with a CAR targeting ICAM-1—a cell surface protein frequently overexpressed in NSCLC tumors. Manufacturing protocol yielded high transduction efficiency and T cell expansion within two weeks in 6/6 patients, consistent with PB-derived CAR T cells and on par with the optimal dosing requirements of an ICAM-1 CAR Phase I trial (NCT04420754). tdLN-CAR T cells showed potent antitumor efficacy compared to the control in an aggressive NSCLC murine model (Median survival 103d vs 66d; respectively; p=0.006).
Conclusions: This represents the first reported use of T cells from tdLN for genetically engineered ACT. The data indicate that modifying antigen-experienced, stem-like T cells from tdLN with CAR is a promising and efficient method in a NSCLC murine model, warranting further research.

#0003 Multiomics analyses reveal functional DNA, methylation pattern changes in clinical transgenic T-cell receptor cell therapy products.

G. Protti, C. Peters, M. Kawakami, C. Kidd, V. Subramanyam, A. Lechien, A. Dinh, A. Ribas, M. Pellegrini, **T. S. Nowicki**;
UCLA - University of California Los Angeles, Los Angeles, CA

Background: Transgenic T-cell receptor T-cells (TCR-T) directed against tumor-specific antigens are associated with robust initial clinical responses. However, these responses are often not durable, and patients relapse frequently. Therefore, there is a significant need to understand how these cells change at the epigenomic level over time following infusion into the patient.
Methods: We analyzed MART-1 TCR-T products from 8 patients treated under a clinical trial at UCLA (NCT00910650). Samples from the baseline infusion product and samples from day +30 recovered from peripheral circulation were sorted for TCR+ cells via flow cytometry, and were then subjected to whole genome bisulfite sequencing (WGBS), ATACseq, and RNAseq in parallel. Differential chromatin accessibility and gene expression by the ATACseq and RNAseq datasets, respectively, were analyzed via DESeq2, with P adjusted less than 0.1. WGBS datasets were analyzed via Metilene, and differentially methylated regions (DMRs) were defined as those regions with CpG loci containing a methylation difference >= 10% and a P adjusted < 0.05. Functional DMRs were defined as those repressed over time (increased DNA methylation with decreased chromatin accessibility/gene expression relative to infusion product), or activated over time (decreased DNA methylation with increased chromatin accessibility/gene expression relative to infusion product). Functional DMRs were then analyzed via EnrichR to evaluate gene ontology and pathways significantly enriched in gene lists.
Results: We collectively identified three genes with repressed DMR activity and 49 genes with activated DMR activity compared to baseline infusion products. Our findings revealed that genes associated with repressed DMRs included IL2RA, FBLN7, and ZNRF1. These genes were collectively associated with a decrease in T-cell activation, cytokine signaling, and migration activity, potentially impacting the functional capabilities of T-cells in the post-infusion environment. Conversely, genes associated with activated DMRs included PDCD1 (PD1), FGR, KIR3DL1, KIR2DL4, and KLF3, with pathway enrichment analysis indicating a significant shift in the T-cell landscape towards reduced anti-tumor activity, decreased T-cell proliferation, T-cell aging, and the promotion of immune escape tumor phenotypes.
Conclusions: This comprehensive multi-omics approach showcases an atlas of genes in clinical TCR-T cell therapeutics which are subject to functional changes in DNA methylation over time *in vivo.* These findings shed light on the complex interplay between DNA methylation, chromatin accessibility, and gene expression in the context of TCR-T cell therapy, with implications for the development of more effective immunotherapeutic strategies.

#0004 Identifying novel patient-derived T cell receptors targeting TP53 public neoantigens.

Michael V. Gormally, Smita S. Chandran, Inaki Etxebarria, Christopher Klebanoff

Memorial Sloan Kettering Cancer Center, New York, NY

Adoptive cell transfer (ACT) is a promising immunotherapeutic strategy to bolster reactivity against immunologically cold tumors through infusion of T cells that can recognize and eliminate cancer cells bearing mutation-derived neoantigens (NeoAgs). T cell receptors (TCRs) that confer recognition of public NeoAgs--an elite subset of Human leukocyte antigen (HLA)-restricted epitopes arising from recurrent hotspot mutations in driver genes that enhance cancer cell fitness and are clonally conserved--are highly desirable and would be effective against many tumors sharing the common hotspot mutation. Tumor suppressor *TP53* is a supreme target for this approach: it is the most frequently mutated gene in cancer yet remains untargetable with FDA-approved therapies. The most common *TP53* alteration (R175H) generates a public NeoAg in the context of *HLA-A*02*, an allele expressed by ~40% of the North American and Western European populations. Earlier work established the immunogenicity of this public NeoAg by isolating a *TP53*(R175H)-specific clone from a colorectal cancer patient. ACT of this TCR in a single patient produced an objective anti-tumor response, but also resulted in multisystem organ failure indicating this receptor might possess off-target reactivity to unrelated proteins in healthy tissue. To discover safe and effective *TP53*(R175H)-specific TCRs, we assembled a unique biorepository of peripheral blood mononuclear cells (PBMCs) from *n=26* cancer patients with diverse tumors that co-express *HLA-A*02*/*TP53*(R175H) and applied a novel high-throughput screening technique to retrieve candidate TCRs. These efforts resulted in a panel of *n=9* genetically distinct and functionally validated receptors, each with NeoAg-specific anti-tumor activity against a panel of cancer cell lines. To define the cross-reactivity profile of these novel TCRs and the benchmark TCR that caused toxicity, we performed amino acid scanning mutagenesis (X-Scan) to identify potential off-targets. Importantly, we identified significant off-target reactivity to normal human proteins for the benchmark TCR, which may explain the lung and kidney toxicities observed in the trial patient. By contrast, a subset of the novel TCRs exhibited exquisite specificity for the *TP53* public NeoAg with no predicted off-targets. Finally, we performed ACT of all TCRs in a mouse xenograft model and identified several novel TCRs that potently eliminated *TP53*(R175H)$^{+}$/*HLA*A02*$^{+}$ tumors in vivo. Based on these data, we are now proceeding with the clinical development of a best-in-class TCR. This work is poised to bring an important new class of precision immunotherapeutics to patients with *TP53*-mutant tumors that presently lack effective molecularly targeted agents.

#0005 Cytosine base editor ameliorates the safety profile of TCR edited T cells for the adoptive cell therapy of gastrointestinal tumors.

M. Spiga[1], A. Potenza[1], S. Beretta[2], A. Airaghi[1], C. Iozzi[1], M. Fiumara[2], S. Ferrari[2], N. Mohammadi[1], O. Botrugno[1], M. Reichert[3], M. Protti[1], S. Crippa[4], M. Falconi[4], L. Naldini[2], E. Ruggiero[1], C. Bonini[1];

[1]Universita Vita-Salute San Raffaele, Milan, Italy, [2]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milan, Italy, [3]Technical University of Munich, Munich, Germany, [4]Ospedale San Raffaele, Milan, Italy

Among gastrointestinal tumors, colorectal cancer (CRC) and pancreatic ductal adenocarcinoma (PDAC) are major unmet medical needs, with a high mortality rate mainly related to the onset of metastases, hindering the therapeutic efficacy of conventional treatments. Adoptive Cell Therapy (ACT) with TCR-edited T cells is a promising therapeutic strategy for patients with late-stage tumors, but its applicability is limited by the paucity of TCRs targeting relevant tumor antigens and the presence of an immunosuppressive tumor microenvironment. Moreover, the safety of the therapeutic cellular products, generated by genome editing tools, is fundamental for an effective and rapid clinical translation. With the aim of improving the safety profile of T-cell based therapeutic products manufactured by genome editing, we evaluated the efficacy and safety of cytosine base editor (CBE). We disrupted the endogenous TCR to redirect T cells specificity toward tumor cells, and TIGIT, a major inhibitory molecule in gastrointestinal tumors to enhancing T cell ability to counteract immunosuppression. Beyond the high efficiency of CBE in simultaneously disrupting the target genes, we observed only marginal sgRNA-dependent and -independent off-target events as measured by targeted sequencing of the top predicted off-target loci and by ultra-deep whole exome sequencing, respectively. In addition, unlike CRISPR/Cas9-treated cells, we could not detect translocations in CBE edited T cells. To select the antigens to target by engineered T cells, we investigated published datasets and identified 19 relevant tumor-associated antigens. By clonal tracking of the TCR repertoire of T cells stimulated with autologous APCs loaded with the selected antigens, we isolated 5 different TCRs specificities, including mesothelin. Importantly, these antigens are expressed in our cohort of primary and metastatic PDAC and CRC patients. TCR-edited T cells displayed anti-tumor activity against PDAC cell lines, CRC and PDAC patient-derived organoids while sparing HLA-unrelated and antigen-negative controls. To boost the efficacy of anti-tumor T cells, we coupled TIGIT disruption with TCR editing. By challenging TCR-edited $TIGIT_{KO}$ T cells *in vitro* and in an orthotopic model of CRC liver metastases, we observed that TIGIT disruption can ameliorate the ability of tumor-specific T cells to control tumor growth. Our findings suggest that base editors can generate cellular products with a better safety profile and a promising therapeutic efficacy in gastrointestinal tumors.

#0006 Defining and therapeutically targeting a fusion-derived public neoantigen in desmoplastic small round cell tumor using T cell receptor gene therapy.

L. Banks[1], H. Arkin[1], S. Chandran[1], E. Slotkin[1], M. Espinosa-Cotton[1], N. Shukla[1], L. Morris[1], M. Ladanyi[1], A. Kung[1], M. Klatt[2], C. Klebanoff[1];
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Charité University Medicine, Berlin, Germany

Sarcomas are a heterogenous group of mesenchymal cell malignancies that are difficult to treat and often respond poorly to current immunotherapies. Approximately 30% of sarcomas are associated with oncogenic driver fusion proteins. Desmoplastic small round cell tumor (DSRCT) is a prototypical fusion-driven sarcoma defined by a pathognomonic *EWSR1-WT1* fusion event. The resultant EWSR1-WT1 fusion protein contains a shared junctional amino acid sequence that is clonally conserved and significantly divergent from normal human proteins. Consequently, the EWSR1-WT1 fusion might yield a highly immunogenic shared, or public, neoantigen (NeoAg) that may serve as a target for novel immunotherapeutic approaches.Using a functional HLA-immunoprecipitation/mass spectrometry (HLA-IP/MS) screen, we identified a 9-amino acid peptide sequence derived from the junction of the most common EWSR1-WT1 fusion protein that is presented in the context of the prevalent HLA-A*03 and -A*11 alleles. We confirmed that HLA-A*03$^+$ DSRCT cells physiologically present the same peptide sequence. Using fluorophore-conjugated HLA-multimers loaded with the HLA-IP/MS-derived fusion NeoAg, we identified a rare population of circulating NeoAg-specific CD8$^+$ T cells in HLA$^+$ DSRCT patients. Through antigen-directed clonal expansion, we discovered n=3 HLA-A*03-restricted and n=1 HLA-A*11-restricted fusion NeoAg-specific T cell clones and retrieved the paired TCRαβ gene sequences of their T cell receptors (TCRs) using 10x single-cell sequencing. Polyclonal CD8+ T cells transduced with candidate TCRαβ gene sequences robustly upregulated TNFα after coculture with HLA$^+$/Fusion$^+$ target cells but not HLA$^-$/Fusion$^+$ or HLA$^+$/Fusion$^-$ control cells. Further, T cells expressing candidate TCRs, but not viral-protein-specific TCRs, lysed HLA$^+$ DSRCT cells *in vitro* and controlled established DSRCT tumors *in vivo*. Finally, we discovered that one TCR was capable of cross HLA allele fusion NeoAg recognition and could lyse both HLA-A*03$^+$ and -A*11$^+$ DSRCT cells. These findings imply that a single TCR therapeutic could cover >36% of North American DSRCT patients.Collectively, our data establish for the first time that DSRCT cells present a junction-spanning fusion-derived neoantigen in the context of two prevalent HLA alleles that may be therapeutically targeted using TCR gene therapy. These data lay the foundation for first-in-human clinical translation of a T-cell based therapy targeting EWSR1-WT1. More broadly, these findings establish proof-of-principle that recurrent fusion proteins are an actionable source of immunogenic public NeoAgs, providing a framework for developing targeted immunotherapies for other fusion-driven malignancies.

#0007 Ginsenoside Rb1 delays the senescence of $CD8^+$ T cells to expand T cells with superior antitumor immunity.

C. Ma, X. Sheng, C. Li;
Shandong University, Jinan, China

Background and Objective: Immunosenescence represents a distinct state of T cell dysfunction in the TME, and plays crucial role in many age-related diseases including tumor. Senescent cell removal by senolytic agents or therapies that inhibit the SASP have demonstrated benefit in both preclinical and clinical models of geriatric decline and chronic diseases. Here, we aimed to screen anti-aging compounds to delay T-cell senescence in TME, and explore novel strategies of reversing tumor induced T-cell senescence to restore antitumor immunity.
Methods and Results: Using in vitro senescence inducing system, we screened ginsenoside Rb1 from 22 anti-aging compounds as the compound that had the most effective activity to reduce CD8+ T cell senescence, displayed as decreased β-gal, p16, and p21. Further analysis showed that ginsenoside Rb1 promoted anti-CD3/CD28-induced TCR signaling and the secretion of effector cytokines IFN-γ, TNF-α and IL -2 in OTI T cells. Intriguingly, ginsenoside Rb1 treatment significantly increased TCF-1 in $CD8^+$ T cells, and ginsenoside Rb1 treated OT-I T cells significantly inhibited tumor growth. Moreover, ginsenoside Rb1 greatly enhanced the efficiency of CD19-CART cells to kill Namalwa tumor cells.
Conclusion: Ginsenoside Rb1 delays T cell senescence and enhances T cell antitumor activity. This data provides a new insight into T cell based antitumor therapy.

#0008 Deep Immunomics pipeline for discovery and validation of novel cancer-specific T cell receptors.

H. Fields[1], J. Velez Lujan[1], K. Wu[2], N. Epstein[1], N. Beevi[1], F. Chioh[2], N. Tan[2], N. Kulkarni[2], N. Mukobo[2], S. R[2], Y. Purwanti[2], E. Newell[3], A. Nardin[2], M. Fehlings[1], K. Fink[2], D. MacLeod[1];

[1]ImmunoScape, San Diego, CA, [2]ImmunoScape, Singapore, Singapore, [3]Fred Hutchinson Cancer Center, Seattle, WA

Background: T cell receptor-engineered T cell (TCR-T) therapy has been studied as a high potential approach for cancer treatment. Beyond cell-surface tumor antigens, TCR-Ts can recognize HLA-presented intracellular epitopes which allows them to address a wide range of cancer-specific targets. Existing TCR-T therapies focus on a limited number of epitopes, many of which are restricted to HLA allele HLA-A*02:01. Identification of novel anti-tumor TCRs covering a broad range of HLA alleles is necessary to address unmet clinical needs. Natural T cells undergo thymic selection and present a favorable safety profile for mining such anti-tumor TCRs for therapeutic development. However, discovery of natural anti-tumor TCRs has been challenging due to i) the absence of high-throughput methods for identifying tumor-reactive TCRs in limited quantity human samples and ii) lack of sensitivity in detecting low frequency, naturally occurring tumor-reactive T cells.

Methods: We developed TargetScape® as a part of our Deep Immunomics platform for efficient discovery of natural tumor-specific TCRs in healthy donors and cancer patients. Cells from blood and tissue samples were stained with metal-barcoded peptide-MHC tetramers, containing 500+ tumor-specific antigens, alongside metal-conjugated antibodies, allowing rapid identification and high dimensional phenotypic analysis of CD8+ T cells at the millions of cells scale. Single-cell sequencing revealed paired TCR sequences. Selected TCRs were introduced into luminescent Jurkat reporter cells for validation screening with peptide-pulsed targets and the relevant HLA restriction. TCRs of interest were further integrated into primary T cells and evaluated for their effector function.

Results: We utilize our sensitive, high-throughput TargetScape® platform to detect and characterize putative cancer-specific TCRs from blood and tissue samples in frequencies as low as ~0.003% of total CD8+ cells. We have functionally validated over 100 TargetScape® derived TCRs with luminescent Jurkat reporters. Validated TCRs cover high prevalence HLA alleles and target a broad range of cancer antigen classes, including tumor associated antigens (TAA), Human endogenous retroviruses (HERVs), shared splice variants, and frameshift mutations. Several natural TCRs demonstrate recognition of low concentrations of peptide, indicating high functional avidity. Further evaluations of specificity and activity of TCRs of interest transduced into primary T cells are currently in progress.

Conclusions: Our Deep Immunomics platform allows us to identify and confirm activity of novel, naturally-derived TCR candidates against therapeutically relevant cancer antigens presented on six common HLA alleles. These findings validate our discovery workflow leading to a portfolio of potential clinically relevant candidates that are currently under preclinical development.

#0009 AFNT-212: A *TRAC*-knocked-in KRAS^{G12D}-specific TCR-T cell product enhanced with CD8αβ and a chimeric cytokine receptor for treatment of solid cancers.

A. Drain[1], N. Rouillard[1], N. Swanson[1], M. Canestraro[1], S. Narayan[1], T. Warner[1], N. Danek[1], K. Gareau[1], J. Liang[1], L. Shen[1], T. Tetrault[1], I. Priyata[1], S. Vidyasagar[1], T. Riggins-Walker[1], H.-W. Liu[1], K. Pechhold[1], L. Brown[1], J. Francis[1], X. He[1], P. Browne[2], R. Lamothe[2], M. Storlie[2], G. Cost[2], T. M. Schmitt[3], P. D. Greenberg[3], S. S. Chandran[4], C. A. Klebanoff[4], H. Lam[1], A. Gupta[1], D. Hallet[1], G. Shapiro[1], K. Nguyen[1], **L. Vincent**[1];
[1]Affini-T Therapeutics, Inc., Watertown, MA, [2]Metagenomi, Emeryville, CA, [3]Fred Hutchinson Cancer Research Center, Seattle, WA, [4]Memorial Sloan Kettering Cancer Center (MSKCC), New York, NY

The KRAS^{G12D} mutation is an ideal target for anti-cancer therapies as its expression is typically clonal, restricted to cancer tissue, and is among the most common oncogenic drivers in solid tumors. TCR-T cell therapies have demonstrated clinical activity in some solid cancers but have been limited by heterogeneous antigen expression and unfavorable tumor microenvironments. By targeting the KRAS^{G12D} mutation for which the cancer has established genetic dependency, AFNT-212 is designed to selectively target all cancer cells while avoiding on-target/off-tumor toxicities. AFNT-212 is non-virally engineered to knock-in a 5-transgene cassette expressing a high-avidity TCR specific for the KRAS^{G12D} mutation, a CD8α/β coreceptor, and a chimeric cytokine receptor. Transgene insertion at the *TRAC* locus disrupts expression of the endogenous TCRα, further enhancing the expression/activity of the transgenic KRAS^{G12D} TCR.

Primary human CD8$^+$ and CD4$^+$ T cells were genetically engineered by a novel CRISPR-Cas nuclease system to integrate AFNT-212 transgenes within the *TRAC* locus. A cGMP compatible scale-up process for non-viral knock-in was established to support AFNT-212 clinical manufacturing. The activity of AFNT-212 was assessed against a panel of human KRAS^{G12D} tumor cell lines *in vitro* and established mouse xenograft models *in vivo*. The preclinical safety profile of AFNT-212 was evaluated by X-scan and crossreactivity assessment, alloreactivity studies, and cytokine independent growth studies. The specificity of gene-editing (GE) was assessed by an unbiased oligo-capture method followed by targeted sequencing.

AFNT-212 TCR-T cells demonstrated potent *in vitro* anti-tumor activity against endogenously expressing HLA-A*11:01 KRAS^{G12D} tumor cells, including during chronic exposure to viable tumor cells. AFNT-212 TCR-T cells showed robust antitumor activity in established xenograft mouse models *in vivo*. No cross-reactivity was identified for the KRAS^{G12D} TCR against potential self-peptides even at supraphysiological levels, demonstrating high specificity of the TCR. No alloreactivity or cytokine-independent proliferation was observed. GE safety evaluations did not reveal any off-target activity using high sensitivity (~0.1%) NGS-based analyses or any GE-associated chromosomal rearrangements. The manufacturing of AFNT-212 consistently delivered >50-fold expansion of engineered TCR-T cells to meet expected clinical dose levels and exhibit memory/stemness phenotypes and negligible markers of immunologic exhaustion.

AFNT-212, a novel TCR T cell therapy targeting KRAS^{G12D} mutant tumors, demonstrates robust activity against KRAS^{G12D} mutant tumors *in vitro* and *in vivo*. The robust manufacturing process developed using non-viral gene editing in the *TRAC* locus will support future clinical development of AFNT-212.

#0010 Non-viral engineered T cell therapy specific for the hotspot mutation p53 R175H that integrates signal 1 (TCR), signal 2 (co-stimulation) and signal 3 (cytokine) and co-opts FasL-dependent apoptosis to achieve a coordinated antitumor CD4/8 T cell response.

S. Narayan[1], K. Gareau[1], A. Gupta[1], J. Ferrell[1], N. Rouillard[1], T. Warner[1], J. Liang[1], L. Shen[1], T. Tetrault[1], J. Francis[1], X. He[1], P. J. Browne[2], R. Lamothe[2], M. D. Storlie[2], G. J. Cost[2], T. M. Schmitt[3], P. D. Greenberg[3], S. S. Chandran[4], D. Hallet[1], M. Gormally[4], C. A. Klebanoff[4], **G. Shapiro**[1], K. Nguyen[1], L. Vincent[1]; [1]Affini-T Therapeutics, Inc., Watertown, MA, [2]Metagenomi, Inc., Emeryville, CA, [3]Fred Hutchinson Cancer Research Center, Seattle, WA, [4]Memorial Sloan Kettering Cancer Center, New York, NY

Adoptive T cell therapy (ACT) has demonstrated antitumor efficacy in patients with solid cancers but requires further optimization to become a reproducibly effective treatment. T cell receptor (TCR)-engineered T cells recognize peptides derived from intracellular and surface proteins presented in the context of MHC class I. Targeting mutated oncogenic drivers addresses many of the major obstacles of this modality, in that the antigenic epitope is: 1) tumor-specific, 2) essential for tumor survival, and 3) derived from a stably expressed protein. However, the immune-suppressive tumor microenvironment makes further optimization of engineered T cells necessary to bring long-term clinical benefit to patients. For an optimal anti-tumor response, T cells require three signals: TCR, co-stimulation, and cytokine signaling. The tumor suppressor *TP53* is the most frequently mutated gene across human cancers, with a highly recurrent arginine to histidine hotspot alteration in codon 175 leading to novel tumor-dependent functions. Here we report the use of a novel CRISPR-Cas nuclease system to knock-in a six-parameter multi-cistronic cassette into the *TRAC* locus with high efficiency. We employed several strategies to maximize the potency and durability of a TCR-T cell product targeting the p53 R175H oncogenic driver, including: 1) A high-affinity TCR (α and β chains) specific for the p53 R175H mutation presented by HLA-A*02:01 permits the recognition of tumor cells expressing even low levels of the epitope (Signal 1), 2) Inclusion of the CD8αβ co-receptor drives stimulation of CD4+ T cells with the MHC class I restricted TCR, allowing for a physiologic coordinated immune response required for maximal efficacy, 3) A FAS-41BB switch receptor acts as a dominant negative to the FASL-inducing apoptotic signal in the tumor microenvironment and drives stimulation and persistence of the T cell product via 41BB co-stimulatory signaling (Signal 2), 4) A chimeric cytokine receptor (constitutive Interleukin Receptor) promotes expansion and survival while avoiding immunologic exhaustion (Signal 3). Together, these strategies deliver the three signals required for maximal T cell function: antigen-driven activation, co-stimulation, and growth/survival-promoting cytokine signaling. The non-viral *TRAC*-knocked-in T cells demonstrate robust and specific cytotoxicity against endogenously expressing HLA-A*02:01 and p53 R175H cell lines *in vitro* and effective anti-tumor activity *in vivo* while maintaining a favorable preclinical safety profile. These data support the planned clinical development of a novel non-viral *TRAC*-knocked-in T cell therapy for the treatment of p53 R175H-mutant solid tumors.

#0011 Development of innovative off-the-shelf cancer immunotherapies with iPSC-derived CD8-positive T-cells.

R. Tawo[1], M. Mirenda[2], O. Cypris[1], P. Hublitz[1], N. Wagner[1], M. Epstein[3], M. Esquerre[2], A. Holtzinger[1], M. Braun[1], **M. Dangl**[1], R. Grandy[3], D. Sommermeyer[1];
[1]Evotec International GmbH, Goettingen, Germany, [2]Evotec France SAS, Toulouse, France, [3]Evotec (UK) Ltd., Abingdon, United Kingdom

Chimeric antigen receptor (CAR) based T-cell immunotherapies have transformed the oncology landscape and evolved as part of the standard of care for several hematological malignancies. To generate CAR-T-cell products, autologous patient-derived αβT-cells are engineered with a CAR for tumor cell targeting. However, generating autologous T-cell products fails in a significant number of cases due to the poor quality and quantity of blood-derived T-cells and is associated with manufacturing and logistical complexity as well as high product costs. Therefore, it is crucial to develop strategies for off-the-shelf T-cell products as otherwise many patients are left without this treatment option. Manufacturing allogeneic T-cells from induced pluripotent stem cells (iPSCs) has a great potential to generate cell products with consistently high quality and scalable quantities. In addition, high fidelity gene-editing can be performed in iPSCs to address tumor resistance mechanisms and to prevent exhaustion of the T-cells. We have established a feeder-free differentiation protocol that enables robust production of iPSC-derived αβT-cells (iαβT). Flow cytometry and single cell transcriptome analysis ensure stringent monitoring of all process stages. To demonstrate functional activity of iαβT, cytotoxicity and cytokine release assays were performed. We compared the differentiation potential of iPSC lines derived from T-cells (t-iPSCs) to a hematopoietic stem cell-derived iPSC line with an αβTCR knock-in. Hematopoietic progenitor cells were induced from the different iPSC lines and differentiated into iαβT. During the differentiation process, surface markers CD45, CD5 and CD7 were displayed, and cells started to express αβTCRs. Importantly, iαβT derived from the different iPSC lines expressed CD8α and CD8β which is crucial for the function of cytotoxic T-cells. The CD4/CD8 double positive stage is an important step in T-cell development and was observed only when T-cells were generated from t-iPSC, but not from the TCR knock-in cells. Functional analysis of iαβT-cells confirmed their cytotoxic activity and potential to release cytokines after activation. Our scalable process for iαβT differentiation generates CD8-positive T-cells that secrete cytokines and show cytotoxic activity against tumor cells, demonstrating their potential as a promising cell source for TCR-T or CAR-T cancer immunotherapies.

#0012 TCR-gated control of costimulatory switch protein (CSP) activation in rTCR-T cells expressing PD1-41BB.

M. Buerdek, P. U. Prinz, K. Mutze, **A. Coluccio**, S. Tippmer, M. Bosch, G. Longinotti, M. Catarinella, K. Davari, C. Geiger, B. Loesch, K. Crame, D. J. Schendel; Medigene Immunotherapies GmbH, a subsidiary of Medigene AG, Planegg-Martinsried, Germany

Chimeric antigen receptor (CAR-)/T cell receptor (TCR-)T-based immunotherapies have shown promising results in the treatment of patients suffering from hematological malignancies. However, targeting solid cancer patients with CAR-T/TCR-T cells represents a more challenging approach, due to various factors present within the hostile tumor micro-environment (TME), inhibiting T cell functionality and leading to T cell exhaustion. Programmed cell death ligand-1 (PD-L1) is expressed on tumor cells as well as various cell types within the TME and binds to programmed cell death protein 1 (PD-1) expressed on the surface of activated T cells, thereby inducing T cell exhaustion and mediating tumor immune escape. To impair this inhibitory mechanism and improve TCR-T cell efficacy for the treatment of solid tumors, we use the chimeric costimulatory switch protein (CSP) PD1-41BB that turns the inhibitory signal mediated via the PD-1-PD-L1 axis into a costimulatory one. The CSP-mediated costimulatory signal is TCR-gated, whereby costimulation can only occur if a specific peptide-HLA complex present on a target cell interacts with a recombinant TCR expressed in T cells. *In vitro* co-cultures of rTCR-T cells expressing the CSP (CSP rTCR-T cells) and antigen-negative or -positive cell lines carrying or lacking PD-L1 demonstrated that CSP rTCR-T cells display functionality only if the respective target antigen is expressed in target cells, but not in the absence of target antigen. PD-L1-positive, antigen-negative tumor cells are not lysed by CSP rTCR-T cells, not even in the presence of antigen-positive tumor cells, showing gated functionality and a favorable safety profile of CSP-armored TCR-T cells. CSP rTCR-T cells displayed enhanced cytokine release and killing after encounter of PD-L1-positive tumor cell lines, compared to tumor cells lacking PD-L1, and showed the capacity to recognize and lyse a large panel of tumor cell lines expressing various levels of HLA-A*02, target antigen and PD-L1 *in vitro*. 3D spheroids derived from PD-L1-positive, target antigen-positive tumor cell lines mimicking cell-cell interactions within a solid tumor mass efficiently triggered CSP rTCR-T cells, leading to specific IFN-γ release and lysis of tumor spheroids. Furthermore, CSP rTCR-T cells showed enhanced proliferative capacity and expansion in co-cultures with PD-L1-positive tumor cells, compared to tumor cells lacking PD-L1 expression. Importantly, various target antigen-negative healthy cell types expressing or lacking PD-L1 and representing different vital organs were not cross-recognized by CSP rTCR-T cells *in vitro*. Our preclinical *in vitro* assessments of CSP rTCR-T cell functionality and safety proved their superior and gated functionality as well as favorable safety profile, showing the great potential for the treatment of cancer patients suffering from advanced solid tumor malignancies.

#0013 Discovery and development of T cell receptors targeting MAGE family antigens for adoptive T cell therapy against solid tumors.

J. Velez Lujan[1], H. Fields[1], K. Wu[2], Y. Purwanti[2], E. Xin Zi Tang[1], M. Cordeau[1], K. Mendez[1], M. Wirawan[2], M. Fehlings[1], K. Fink[2], Z. Liu[1], D. MacLeod[1]; [1]ImmunoScape, San Diego, CA, [2]ImmunoScape, Singapore, Singapore

Background: T cell receptors (TCRs) recognize epitopes from intracellular and cell surface antigens, enabling targeting of diverse tumor antigen classes including overexpressed, differentiation, cancer-testis antigens, as well as those from driver mutations, frameshift mutations, splice variants, and human endogenous retroviral elements (HERV). Melanoma-associated antigens (MAGE) are highly expressed in various solid tumor types, including melanoma, non-small cell lung cancers (NSCLC), bladder, and head and neck cancers, representing promising targets for TCR-T therapy. However, discovering robust and specific MAGE-reactive TCRs remains challenging due to limited throughput of TCR screening methodologies, and the inherently low frequency of tumor-reactive T cells in tumor samples and peripheral blood.

Methods: We employ a proprietary mass-cytometry-based multiplexed tetramer staining approach, TargetScape®, to screen and characterize CD8+ T cells in healthy donors and patients' samples. Our screening panels contain multiple peptides for MAGE family antigens including A1, C2, and A10. Subsequent single cell sequencing or single cell PCR (scPCR) of identified tumor antigen-specific T cells with high sensitivity enables comprehensive analysis of T cell phenotype, transcriptome, TCR specificity, and paired TCR sequence. TCRs identified through this method are transduced for expression in Jurkat reporter cell lines and their reactivity to corresponding peptides is assessed. Selected TCR candidates are then transduced into primary T cells and evaluated for activation and effector function using a variety of cancer cell lines expressing the corresponding endogenous antigens. Specificity assessment is performed through alanine scans and identification of potential off-target peptides and screening for reactivity.

Results: We utilized this approach to discover natural TCRs that target several MAGE family antigens. Through Jurkat reporter screening, we observed specific activation of multiple TCRs in the presence of antigen presenting cells and the peptide initially employed to identify the TCRs. Primary T-cells expressing promising TCR candidates exhibited killing activities and cytokine release when confronted with multiple solid tumor cell lines expressing endogenous levels of the MAGE antigen. Specificity assessment is currently in progress, with preliminary data indicating overall favorable specificity profiles for selected TCRs.

Conclusions: Our Deep Immunomics platform enables us to detect, characterize, and validate TCR candidates against highly clinically relevant shared cancer antigens. Leveraging this platform, we identified various natural tumor specific TCRs exhibiting activities against a range of solid tumor cell lines expressing MAGE antigens. Promising candidates are currently undergoing in vivo efficacy studies.

#0014 Identification of tumor-reactive T cell receptors through functional single cell interaction analyses for personalized T cell therapy.

T. R. Wagner[1], N. Kehl[1], S. Steiger[1], M. Kilian[1], B. Schonfelder[1], T. Boschert[1], K. Lindner[1], P. Schmidt[2], K. Rippe[1], H. Goldschmidt[3], M.-S. Raab[3], M. Platten[1], M. Friedrich[4], S. B. Eichmuller[1];

[1]DKFZ German Cancer Research Center, Heidelberg, Germany, [2]National Center for Tumor Diseases (NCT), Heidelberg, Germany, [3]University Hospital Heidelberg, Heidelberg, Germany, [4]Broad Institute of MIT and Harvard, Boston, Germany

Innovative immunotherapy approaches such as adoptive transfer of chimeric antigen receptor (CAR) T cells or tumor infiltrating lymphocytes (TILs) have shown great success in the treatment of solid tumors and hematological malignancies. Although treatment of multiple myeloma with CAR T cells can induce deep responses, relapses frequently occur due to antigen escape and limited CAR T cell persistence. TCR-engineered T cells may show prolonged persistence *in vivo* and could mediate sustained antitumor effects. A further benefit of TCR transgenic T cells is the ability to target intracellular antigens that are inaccessible to CAR T cells, expanding the range of potential targets for immunotherapy. In our project, we propose to identify T cell receptors (TCRs) specifically targeting autologous myeloma cells. Tumor-reactive T cells were identified using the Bruker Cellular Analysis Lightning® platform, allowing simultaneous functional analysis of up to 1500 individual T cell/target cell interactions on a chip. Reactive T cells were identified upon detection of secreted cytokines (IFNγ, TNFα, IL2) and measurement of 4-1BB (CD137) surface expression. Tumor-reactive T cells showing various cytokine secretion patterns and 4-1BB expression profiles were detected in each myeloma patient (on average 11.9 T cells out of 1243 cells tested per assay run). Individual tumor-reactive T cells have been isolated and their TCRs were sequenced. TCR sequences of tumor-reactive T cells were mapped to single-cell RNA sequencing data of T cells from the same patiens to reveal a gene expression signature of myeloma-reactive T cells. TCR genes of reactive T cells were cloned and overexpressed in autologous T cells for functional validation and analysis of tumor derived neoepitope specificity. In summary, we present a pipeline allowing identification of myeloma-recognizing T cells and recovery of *bona fide* tumor-reactive TCRs eligible for patient-individualized T cell therapy.

#0015 Massively parallel base-editing screens to map variant effects on anti-tumor hallmarks of primary human T cells and improve cell-based cancer immunotherapies.

Z. H. Walsh, P. Shah, N. Kothapalli, G. Nikolenyi, S. Shah, G. Leuzzi, N. Vasan, M. AlQuarishi, A. Ciccia, J. Melms, B. Izar;
Columbia University Irving Medical Center, New York, NY

Base editing enables precise generation of single nucleotide variants, but large-scale screening in primary human T cells has been limited by low editing efficiency. Here, we developed a high-throughput approach for highly efficient, massively parallel adenine and cytosine base-editor screening in primary human T cells. We performed multiple large-scale pooled screens editing 108 genes with central functions in T cells and whole-gene tiling mutagenesis of selected genes. All screens were functionally read out to capture the effect of variants on hallmarks of T cell anti-tumor immunity, including activation, proliferation, long-term persistence, and cytokine production. We discovered a broad landscape of gain-of-function and loss-of-function mutations and characterized their impact across multiple axes of T cell functions. Among others, we identified gain-of-function mutations in *PIK3CD* and its regulatory subunit *PIK3R1, LCK, AKT1,* and loss-of-function mutants of *CTLA-4,* driving increased T cell polyfunctionality. We validated several of these mutations by probing downstream signaling and functional outputs. To demonstrate the feasibility of using such screen results for improving cell-based cancer immunotherapies, we used human T cells with engineered T cell receptors recognizing specific epitopes in melanoma models. We base-edited these T cells with mutations identified in our screens and demonstrate that these mutations indeed significantly enhance cytotoxic cytokine production and tumor-lytic capacity with minimal off-target activity. Lastly, we also provide proof-of-feasibility for high-efficiency combinatorial base-editing in T cells. This study presents a framework for large-scale base editing screens with multi-dimensional functional readouts in cells that are typically difficult to molecularly engineer in a precise manner. This work also has important therapeutic implications: T cells are the substrate for clinically active cell-based therapies, such as adoptive transfer of tumor-infiltrating lymphocytes (TILs) or chimeric-receptor antigen T (CAR-T) cells. Our screen-informed base editing to achieve an improved T cell product against melanoma exemplifies the therapeutic power of generating synthetic protein variants that improve a wide range of existing and future T cell-based cancer immunotherapies.

#0016 CD4+ and CD8+ TCRαβ-deficient bioluminescent reporter T cells for screening and characterization of neoantigen-specific TCRs.

M. Cong, J. Grailer, M. Slater, P. Stecha, J. Hartnett;
Promega, Madison, WI

Adoptive antigen-specific T cell therapy is currently comprised of chimeric antigen receptor (CAR) and T cell receptor (TCR) engineered T cells. Clinical results from CAR-T cells have demonstrated promising results in treating leukemias, while TCR-engineered T cells, which have the advantage of recognizing intracellular tumor antigens, is still in early development. Here, we report the development of CD4+ or CD8+ TCRαβ-KO reporter T cell lines for the screening and characterization of transgenic TCRs. A TCRαβ-KO reporter T cell line was first developed by knocking out the endogenous TCR α and β chains in the reporter T cell line using CRISPR/Cas9. Successful knockout was confirmed by phenotypic assays and TCR v chain locus sequencing. We demonstrated that re-introduction of influenza hemagglutinin (HA) peptide-specific TCR (HA1.7) α and β chains into TCRαβ-KO reporter T cell lines results in HA peptide-dependent TCR activation and luciferase reporter expression when HA peptide is presented by a MHCII+ cell line. Similarly, re-introduction of MART-1-specific TCR (DMF5) resulted in MART-1-dependent activation in the presence of MHCI+ cells. The select expression of CD4- or CD8-expressing variants of the TCRαβ-KO reporter T cell line enables the development of transgenic TCRs for both MHCI- and MHCII-restricted tumor antigen targets. Further development of CD4/CD8 double-positive and double-negative cell lines enables screening of low and high affinity TCRs without MHC bias. Together, this TCRαβ-KO platform represents a powerful tool for the screening and characterization of neoantigen-specific TCRs.

#0017 Metabolic screening of T cells guides the enrichment of stem cell memory phenotype.

A. Lauer, N. Karassina, K. Sylvester, J. Vidugiriene;
Promega Corporation, Madison, WI

The efficacy of T cell-mediated immunotherapy is improved by the proliferation of T cells with a stem cell memory phenotype (Tscm). These cells are capable of long-term persistence, self-renewal, multipotency, and robust engagement with cancer cells. This study focuses on refining T cell activation protocols to bolster the presence of Tscm within the therapeutic arsenal against cancer. Through a series of cell health and metabolic assays, we traced the activation-induced metabolic reprogramming that results from Tscm enrichment. *Ex vivo* activation was characterized by a rapid 2.5-3 fold increase in ATP production and a 2 fold shift in intracellular reducing potential, paralleling the metabolic demands of Tscm in the cancer microenvironment. Progression of activation intensified the metabolic flux through catabolic and anabolic pathways, with significant fluctuations in metabolites such as glucose, lactate, glutamine, glutamate, branched chain amino acids, and pyruvate. These metabolic alterations were accompanied by a 2 fold increase in the prevalence of Tscm cells, and demonstrated a dependency on media composition. Our findings reveal that metabolic profiling during T cell activation provides early and actionable insights into the enrichment of Tscm, and may serve as a strategic guideline for the enhancement of cancer immunotherapies.

#0018 The polyamine-hypusine axis is a promising avenue to improve T-cell metabolism and persistence for adoptive cell therapy.

M. Kehinde-Ige, O. Okoko, G. Zhou, H. Shi;
Augusta University, Augusta, GA

There are significant barriers to the application of Adoptive Cell Therapy (ACT) to many cancer types. One of these barriers is a result of poor metabolic fitness of T cells, leading to poor proliferation, persistence, and dampened anti-tumor function. Leveraging T-cell metabolism to improve their function is becoming increasingly important to make significant strides in immunotherapy. Stat5a has been shown to be a master regulator of energy and metabolism in T cells, highlighting it as a promising avenue to improve T-cell metabolism for ACT. We have established that the expression of Constitutively Active Signal Transducer and Activator of Transcription 5A (CASTAT5) on tumor-specific $CD4^+$ T cells improves their persistence, polyfunctionality, and anti-tumor effects in a mouse model. This study further examines Stat5a and its downstream metabolic targets in the context of ACT. We carried out scRNAseq analysis and found that Stat5a directly interacts with genes involved in polyamine metabolism. More specifically, Stat5a activation increases the expression of ornithine decarboxylase (Odc1), spermidine synthase (Srm), deoxyhypusine synthase (Dhps), and deoxyhypusine hydroxylase (Dohh) in a subset of $CD4^+$ T cells expressing CASTAT5. Cleavage Under Targets and Tagmentation (Cut&Tag) analysis of histone H3K27ac also demonstrated increased H3K27ac at promoter and enhancer regions of polyamine pathway genes in CASTAT5 compared to control $CD4^+$ T cells. To further examine the function of Stat5a, the murine pro-B cell line, Ba/F3, is being used as a model to study Stat5a-mediated signaling. We have found that upon withdrawal of IL-3 from Ba/F3 cells, Stat5a activation is significantly downregulated. Our scRNA-seq-based metabolic flux estimation showed a significant reduction in metabolic fluxes and related genes, including polyamines, following IL-3 withdrawal. Correspondingly, Stat5a ChIP-Seq and Cut&Tag analyses of H3K27ac revealed Stat5a binding to active enhancer regions in the presence of IL-3 that are lost following its withdrawal. Untargeted metabolomics confirmed the marked Stat5a-mediated reduction in metabolite abundance after IL-3 deprivation, in a time-dependent manner. The polyamine-hypusine axis revealed in our studies is a promising avenue to improve T-cell function. This axis has been shown to regulate T-cell function, and potentially modulate mitochondrial respiration and T-cell activation. Hence, our studies have identified polyamine supplementation and gene modulation as promising strategies to improve the metabolism of Adoptive T cells in a Stat5a-mediated manner. Further studies will evaluate the effectiveness of this avenue in improving T-cell function, improving their efficacy for ACT, and improving patient outcomes.

#0019 Patient derived tumor-on-a-chip platform potentiates adaptive immune response against primary tumor cells.

C. R. Schaaf[1], T. Liu[1], D. Hutchins[1], M. Kooshki[1], **C. Wagner**[1], N. Edenhoffer[1], S. Forsythe[2], R. Greissinger[1], L. Miller[1], P. Triozzi[1], E. Levine[1], S. Soker[1], A. R. Hall[1], K. I. Votanopoulos[1];

[1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]National Institute of Health, Bethesda, MD

Background: Adoptive cellular therapy (ACT) is a promising antitumor immunotherapy showing success in select trials/patients. However, major challenges limit ACT in all tumors including insufficient cell numbers and failure to target heterogeneous tumors. To improve ACT, we developed a novel biomimetic device where patient-derived tumor organoids, enriched with antigen presenting cells, are cocultured with autologous peripheral blood mononuclear cells (PBMCs) in a microfluidic tumor-on-a-chip system (TOC). As PBMCs circulate through the device, they are exposed to dispersed tumor polyclonal neoantigens, leading to formation of patient- and tumor-specific organoid interacting lymphocytes (OILs).

Objectives: Demonstrate that a 3D tumor-on-a-chip (TOC) platform generates organoid interacting lymphocytes (OILs) with enhanced antitumor reactivity.

Methods: Specimens were collected from 15 surgical patients: melanoma (2), mesothelioma (6), and metastatic appendiceal adenocarcinoma (9). Tumor cells were combined with autologous antigen presenting cells (healthy spleen/lymph node) in a 3D matrix to generate immune-enhanced tumor organoids in the TOC system. Autologous PBMCs circulated through the system to produce OILs (7 days). Uncirculated PBMCs and tumor infiltrating lymphocytes (TILs) were cultured as controls. Resultant CD8+ controls and OILs were examined by single cell proteomics to compare cytokine secretion polyfunctionality. To assess anti-tumor reactivity, OILs and controls were reintroduced to tumor cells via coculture. Secreted bulk cytokine profiles were compared by Isoplexis CodePlex and confirmed by ELISA. NanoString Geomx spatial proteomic analysis of coculture PTOs identified key lymphocyte activity and phenotypes during anti-tumor reactivity. Coculture cytotoxic lymphocyte activation and tumor cell death was confirmed by flow cytometry. Data were analyzed using student *t*-test and differential expression from linear mixed-effect model.

Results: Compared to controls, CD8+ OILs showed increased polyfunctionality within single cells immediately after training, particularly in effector T-cell associated cytokine profiles (INF-γ, Granzyme B, Perforin). Upon re-introduction to PTOs, OILs excreted significantly increased inflammatory-associated proteins IFN-γ, MCP-1, and Granzyme A ($p<0.05$). Furthermore, OIL re-exposure to tumor led to cytotoxic lymphocyte activation (CD8+CD69+) and significantly increased tumor cell death compared to control ($p<0.05$).

Conclusion: Compared to controls, OILs produced in the TOC system show enhanced cytotoxic lymphocyte polyfunctionality and induce tumor cytotoxicity, independent of tumor type. With further validation of the OILs' increased tumor-targeting efficacy, we propose a new potential ACT modality to target a broad array of tumors previously untreatable by current therapies.

#0020 KSQ-001EX: An engineered TIL therapy manufactured from a clinical-scale, feeder-free process for the treatment of solid tumor indications.

S. Lin[1], G. Martinez[1], M.-A. Forget[2], K. Adlerz[2], M. Ghose[1], L. Williams[1], P. Dunbar[1], F. Thompson[1], F. Sharp[1], H. Gannon[1], C. Calnan[1], A. Yeri[1], D. Sangurdekar[1], D. Sakellariou-Thompson[2], S. Fix[1], T. Griffith[2], E. Jafari[2], J. Zulovich[2], P. Balasubramanian[2], E. Willert[2], M. Benson[1], C. Bernatchez[2], **K. K. Wong**[1];

[1]KSQ Therapeutics, Lexington, MA, [2]CTMC, Houston, TX

Tumor Infiltrating Lymphocyte (TIL) therapy is an autologous adoptive cell therapy involving the isolation, ex vivo expansion and infusion of tumor infiltrating lymphocytes (TIL) into late-stage cancer patients for therapeutic benefit. While clinical responses to TIL therapy have been observed in metastatic melanoma, efficacy in other tumor types including non-small cell lung cancer (NSCLC), and head and neck squamous cell carcinoma (HNSCC) [SM1] is limited by the intrinsic functionality and persistence of transferred T cells and the immunosuppressive tumor microenvironment. To improve the clinical outcome of TIL therapy, we have developed KSQ-001EX, an engineered TIL therapy using CRISPR/Cas9 technology to knockout the SOCS1 gene, for the treatment of solid tumors. SOCS1 is a negative regulator of cytokine signaling in T cells that we previously identified as a top target restraining T cell anti-tumor function and persistence using genome-wide in vivo CRISPR screens. To streamline and shorten TIL manufacture, we established a next-generation manufacturing process with resected tumors or core biopsies as starting materials that eliminates the use of feeder cells and REP, shortening the length of manufacture to 22 days. We demonstrated robust manufacture of cryopreserved KSQ-001EX at clinical scale from NSCLC, HNSCC, checkpoint refractory melanoma, and heavily pre-treated colorectal carcinoma (CRC). KSQ-001EX manufactured from clinical-scale runs were highly viable (>90%) following cryopreservation and thaw, with > 90% SOCS1 on-target editing and complete knockdown of SOCS1 at the protein level. Importantly, KSQ-001EX across all indications assessed showed high frequency of CD8 (median ~80%), an attribute associated with TIL clinical responses. KSQ-001EX also retained high diversity of TCR repertoire. Consistent with the biology of SOCS1 editing, KSQ-001EX exhibited greater cytotoxicity and higher IFNγ production against tumor spheroids in comparison to TIL and enhanced induction of pSTAT4 upon IL-12 stimulation, demonstrating heightened sensitivity of KSQ-001EX to cytokines. In conclusion, KSQ-001EX, an engineered TIL therapy with CRISPR/Cas9 mediated inactivation of SOCS1, can be manufactured at clinical doses from surgical resections or core biopsies within 22 days using a simplified feeder-free manufacturing process from multiple indications. KSQ-001EX exhibits heightened anti-tumor activity in preclinical models, with therapeutic benefit to be evaluated in a planned clinical trial in patients with treatment-refractory melanoma, NSCLC, and HNSCC. [SM1]Spell out these at first instance?

#0021 Discovery of ALK-specific TCR clonotypes for the development of TCR-T cell therapies against ALK-positive cancers.

C. Mecca[1], A. Azambuja[1], L. Alessandri[1], E. Bergaggio[1], S. Piane[1], M. Simoes-Costa[1], E. L. Reinherz[2], R. Blasco-Patino[1], R. Chiarle[1];
[1]Boston Children's Hospital, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA

Introduction: Anaplastic Lymphoma Kinase (ALK) tyrosine kinase inhibitors (TKIs) have extended the survival of patients with ALK-rearranged cancers, including non-small cell lung cancer (NSCLC). Unfortunately, acquired resistance develops within 2-3 years, highlighting the urgent need for novel and effective therapeutic strategies for these patients. Here, we aimed to identify T cell receptor (TCR) clonotypes against two human ALK immunogenic peptides we previously identified by mass spectrometry in biopsies from patients with ALK-rearranged NSCLC (PMID:37430060) and to develop TCR-T cell therapies for ALK-positive NSCLCs.
Methods: BALB/c mice were vaccinated with the murine ALK peptide PGPGRVAKI and transgenic mice expressing human HLA-B*07:02 were vaccinated with human ALK peptides RPRPSQPSSL and IVRCIGVSL. All mice received two priming injections (days 1 and 14) followed by two boosters, and activated $CD8^+$ T cells were sorted and subjected to single-cell sequencing.
Results: As proof of concept, we first vaccinated BALB/c mice with the ALK peptide PGPGRVAKI and identified 381 unique ALK-specific clonotypes. Among these, we cloned the most expanded 5 clonotypes and confirmed that these clonotypes were functional as evidenced by the release of significant amounts of IFN-γ and IL2, and potent *in vitro* killing activity following co-culture with murine ALK-positive lung cancer cells. To identify TCR clonotypes for the development of TCR-T therapy in patients with ALK-positive cancers, we next vaccinated transgenic mice expressing human HLA-B*07:02 with human ALK peptides RPRPSQPSSL and IVRCIGVSL. We again identified multiple unique ALK-specific TCR clonotypes among $CD8^+/CD137^+$ cells from these transgenic mice vaccinated with RPRPSQPSSL peptide (N=353 TCR clonotypes) and IVRCIGVSL peptide (N=742 TCR clonotypes). Single-cell RNA sequencing of the expanded clonotypes (TCR clonotype frequency ≥4) versus non-expanded clonotypes (TCR clonotype frequency <4) revealed significant upregulation of *Ccl3, Ccl4, Ccl1, Ifng, Xcl1, and Il13* across mice vaccinated with RPRPSQPSSL and IVRCIGVSL ($p < 0.05$). Gene set enrichment analysis (GSEA) confirmed significant upregulation of multiple pathways of adaptive immune response, including T cell activation, IFN-γ signaling and production, cytokine release, and T cell proliferation (adjusted $p < 0.05$), suggesting functional activity of these TCR clonotypes against ALK.
Conclusion: Here, we first demonstrated the feasibility of isolating ALK-specific TCR clonotypes by mice vaccination that exerted anti-tumor activity. Additionally, we identified ALK-specific TCR clonotypes from transgenic mice expressing human HLA-B*07:02 vaccinated with two human ALK peptides. This discovery lays the basis for the successful development of TCR-T cell therapies for ALK-positive NSCLCs, and possibly other ALK-positive cancers.

#0022 Development and characterization of human tumor specific cytotoxic lymphocytes for preclinical drug development.

I. Rohleff, L. Grone, K. Lashuk, **J. B. Schueler**;
Charles River Laboratories, Inc., Freiburg, Germany

Heterogeneity within a tumor allows it to better adapt to changing conditions and can have therefore a negative impact on a patient's prognosis, response to treatment and overall health. Breast cancer is a highly heterogeneous disease caused by distinct genetic mutations in mammary epithelial cells, resulting in significantly different forms of the disease and a need for highly personalized treatment schemes for patients. Hence, it is important to develop and improve (immuno)therapies for breast cancer patients. Adoptive T-cell therapy with autologous CD8+ cytotoxic T cell lymphocytes (CTL) is a promising method that has already shown promising effects in melanoma patients. Unfortunately, there is almost no information about the use in breast cancer patients. We developed an in vitro protocol to generate tumor-specific CTLs by priming on HER2+ breast cancer cell lines JIMT-1 and SKBR-3. Subsequently, these primed CTLs were tested in 2D and 3D immune cell killing assays in a life cell imaging device in combination with an endpoint viability assay. The activity was compared with unspecific CD8+T cells activated by phytohemagglutinin (PHA) or αCD2/αCD3/αCD28, HER2-peptide specific T cells and HER2-CAR T cells serving as a positive control. We investigated the feasibility to freeze CTLs for use in subsequent studies and validated the relevance of HER2 as the main druggable target in the tumor lines using an siRNA approach. The CTLs were most effective on JIMT-1 in a 3D setting, whereas the SKBR-3 CTLs displayed similar activity in 2D and in 3D. The respective CTLs were tumor line specific, as SKBR-3 CTLs did not kill efficiently the JIMT-1 cells and vice versa. The same CTLs displayed the same efficacy pattern after thawing but less pronounced. Thus, within one experimental set-up it is recommended to use either one. The Her2 knockdown in the target cells reduced the killing activity of the CTLs slightly. However, this effect was not statistically significant proving the importance of CTLs as treatment option as well as neoantigens as targets in drug development. In summary, the CTLs proved to capture the respective tumor heterogeneity showing high killing rates in both SK-BR3 and JIMT-1 being more active than HER2-peptide specific T cells. The availability of CTLs in a preclinical setting facilitates screening approaches for combinational studies. Beyond that they can serve as starting material to develop cancer vaccines and identify highly immunogenic neoantigens.

#0023 The use of baboon envelope pseudotyped lentiviral (BaLV) vector allows high-efficiency transduction of CD8+ T cells.

I. Kaplan, M. Sheffer, Y. Abdulhamid, E. Bobilev, R. Romee;
Dana-Farber Cancer Institute, Boston, MA

CAR-T (chimeric antigen receptors T) cell therapy has been proven to be effective in treating various types of cancers. To prevent graft vs. host disease, CAR-T cells are mostly produced from the patient's own T-cells and transduced using pseudotyped vesicular stomatitis virus glycoprotein (VSV-G) lentivirus system. Typically, CD8+ effector T cells have relatively low transduction rates, compared with CD4+ T cells, and yet it is the CD8+ T cells that are the dominant effector immune cells in a CAR product. To achieve high efficacy of the CAR-positive effector T cells, a higher number of the patient's CD8+ T cells are needed for transduction. However, cancer patients may not have enough T cells by the time they are eligible for CAR-T therapy due to multiple treatment cycles. One potential way to overcome this problem is to achieve a much higher transduction rate of the CD8+ T cells.

Recently, our lab published the use of pseudotyping CAR lentivirus with baboon endogenous retroviral envelope (BaEV) for the generation of CAR transduced natural killer (NK) cells, exhibiting high transduction rates of above 50%. BaEV lentivirus targets the amino acid transporter, SLC1A5 (ASCT2), to enter the cell. SLC1A5 is highly expressed on activated NK and T cells. Therefore, we hypothesized that CAR-T transduced with BaEV lentivirus will have increased transduction rates compared with VSV-G.

To assess transduction, we used anti-mesothelin (MSLN) CAR construct which consists of the mesothelin single chain variable fragment (scFv), CD8α hinge and transmembrane domain, 4-1BB costimulatory domain, and a CD3ζ activation domain, followed with GFP linked by self-cleavage P2A. The concentrated virus was titrated in Jurkat cells, resulting in 90% transduction efficiency with VSV-G and 50% with BaEV, for the same amount of virus.

Primary CD8+ T cells were isolated from the peripheral blood of 3 healthy donors and activated with CD3/CD28 beads for three days prior to transduction. Then, the cells were transduced with either VSV-G or BaEV meso-CAR pseudotyped lentiviruses. Transduction rates were measured by flow cytometry, 3 days post-transduction. In addition, the CAR-T cells were expanded *in vitro* to evaluate their cytotoxicity against the mesothelin-positive cell line OVCAR-8, for 24 hours. VSV-G led to 10-20% transduction rates, while BaEV exhibited much higher transduction rates (55-70%), leading to improved cytotoxicity against the tumor cells.

The successful increase of transduction rates for CD8+ CAR-T using our BaEV lentiviral system can be utilized in the clinic to treat patients that previously didn't qualify for adoptive therapy, due to low lymphocyte counts. In addition, higher numbers of CD8+ CAR-T cells may result in better tumor control in both blood and solid tumor settings, compared with the traditional approach for CAR-T production.

#0024 Utilizing T cell receptor-based therapy to treat anaplastic thyroid cancer.

S.-H. Hung, Y. C. Henderson, P. Ke, Y. Chiu, S. Singh, Y. Chen, S. Y. Lai, C. Yee;
UT MD Anderson Cancer Ctr., Houston, TX

Anaplastic thyroid cancer (ATC) is one of the most aggressive solid tumor in thyroid tissue, with a 6-month medium overall survival. The effectiveness of conventional treatments in extending the survival of patients is limited. Therefore, there is an urgent need to develop novel systemic therapeutic interventions. Adoptive cell therapy has revolutionized cancer immunotherapy by successfully treating B-cell malignancies through chimeric antigen receptor-based approaches. For solid tumors, there is a need to identify a broader spectrum of tumor target antigens, and the field has now shifted towards leveraging T cell receptors (TCRs) which can recognize both intracellular and extracellular antigen-derived epitopes. Our team has established an immunogenic epitope discovery pipeline, followed by a specialized protocol for empiric validation of candidate epitopes. We characterized immunogenic epitopes by coupling tandem mass spectrometry of MHC-eluted peptides with tumor proteome and MHC-peptide binding prediction databases. By integrating multi-omics data (genomics, transcriptomics, and immunopeptidomics) from both in-house and publicly available ATC databases, we find that ATC exhibits significant upregulation of pathways associated with microtubule-based movement, chromosome segregation, and kinetochore complex components. We have identified several HLA-A2- and A24-restricted immunogenic peptides representing these pathway-associated proteins that covered more than 60% of the patient population. These immunogenic peptides were subsequently utilized to isolate antigen-specific T cells from peripheral blood and identify cognate TCR. These peptide-specific T lymphocytes elicit cytotoxicity toward multiple HLA-matched ATC cell lines and tumor samples *in vitro* and *in vivo*. In conclusion, our studies contribute to the development of a new treatment paradigm for treating ATC.

#0025 Multimodal single-cell analysis of lifileucel tumor-infiltrating lymphocyte (TIL) product identifies additional high-resolution potential features.

J. Dean, J. Yglesias, H. Yin, R. Qi;
Iovance Biotherapeutics, San Carlos, CA

Introduction: Autologous TIL cell therapies such as lifileucel have demonstrated durable responses in patients (pts) with various solid tumors including melanoma and lung cancer. The TIL drug product (DP) phenotype was previously assessed and extensively characterized based on the bulk population. The current research further characterizes the TIL DP at a single-cell level using high-dimension multimodal sequencing and explores features that have a potential to inform future development of TIL therapies.

Methods: Manufactured lifileucel TIL DP from 20 pts (best overall response [BOR]: 6 complete response [CR], 4 partial response, 5 stable disease, 5 progressive disease [PD]) from the registrational melanoma C144-1 trial were analyzed using single-cell RNA and T-cell receptor (TCR) sequencing, resulting in 153K single-cell transcriptomes. To aid with cell-type annotation, 130 surface proteins on TIL DP samples from a subset of 4 pts (BOR: 2 CR, 2 PD) were detected via Cellular Indexing of Transcriptomes and Epitopes by sequencing. Multimodal weighted nearest-neighbor analysis combined with manual cluster annotation (via known marker genes and proteins), cell-type-specific gene signatures, and automated annotation were used to develop a single-cell TIL (scTIL) reference map, resulting in high-resolution subsets of cells. TCR clonotypes from lifileucel TIL DP were compared to those from respective pretreatment tumors previously identified by bulk TCR sequencing.

Results: Mapping of the full dataset to the novel scTIL reference revealed a $CD8^+$ TIL-dominant composition of responder TIL DP. TIL from pts with BOR PD exhibited reduced $CD8^+$ effector memory (Tem)-like and resident memory (Trm)-like T cells. Differential expression analysis showed that responder $CD8^+$ TIL had increased expression of TCR signaling genes while responder $CD4^+$ TIL exhibited gene expression consistent with a more cytotoxic-like phenotype. Relative to responders, $CD8^+$ TIL of pts with BOR PD had lower expression of the $CD39^-CD69^-$ (stem-like) gene signature and higher expression of the $CD39^+CD69^+$ (terminal differentiation) gene signature. Pseudotime trajectory analysis found that both $CD8^+$ and $CD4^+$ TIL of pts with BOR PD were more terminally differentiated. Single-cell TCR sequencing revealed that $CD8^+$ T-cell clusters had greater clonal overlap than $CD4^+$ T-cell clusters. Expanded clonotypes in pretreatment tumor tissues were more prevalent in TIL TCR repertoires of responders and were more likely to be expressed by $CD8^+$ (specifically $CD8^+$ Tem- and Trm-like TIL) than $CD4^+$ T cells.

Conclusions: Collectively, these results shed additional light on the cellular and molecular characteristics of ex vivo expanded lifileucel TIL DP and signal additional features with a potential to guide future TIL product development.

#0026 An HLA-class II restricted HPV18 E7 specific TCR cloned from a long-term surviving cervical cancer patient.

J. Long[1], X. Chen[2], S. Ou[2], M. Ma[2], J. Chu[2], **Y. Han**[2];
[1]Department of Oncology, Cancer Center, the First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China, [2]HRYZ BIOTECH Co., Ltd., Shanghai, China

T cell receptor (TCR)-engineered T cell therapy is a promising approach for the treatment of solid malignancy, with multiple clinical trials reporting impressive responses using affinity-matured TCRs. However, artificially mutated TCRs can increase the risk of off-target toxicities due to unexpected cross-reactions, which limits the overall safety of this approach. To tackle this challenge, we have developed a novel strategy for cloning tumor-specific endogenous therapeutic TCRs from long-term surviving patients who have responded to immunotherapy. Specifically, we have identified a TCR (10F04) that is specific to human papillomavirus type 18 (HPV18) $E7_{84-98}$ and restricted to human leukocyte antigen (HLA) class II molecular DRA/DRB1*09:01 from the peripheral blood of a patient with HPV-positive metastatic cervical cancer who received multiple antigens stimulating cellular therapy (MASCT) and exhibited sustained T-cell immunological responses. Upon transduction into human T cells, the 10F04 TCR demonstrated robust antitumor activity in both *in vitro* and *in vivo* models. Notably, the TCR effectively redirected both CD4 and CD8 T cells to specifically recognize tumor cells and induced multiple cytokine secretion along with durable antitumor activity. Importantly, no cross-reactivity was detected in toxicity studies. As a result, this TCR is currently being investigated in a phase I clinical trial for treating HPV18-positive cancers (NCT05787535). The first-in-human infusion had been just completed. No severe adverse event had been observed, while an early proliferation of TCR-T was detected several days after infusion. Our approach of cloning tumor-specific and safe endogenous therapeutic TCRs from long-term surviving patients offers a promising strategy for developing safe and effective TCR-engineered T-cell therapies for solid tumors. These findings provide important insights into the potential of HLA class II-restricted TCR-T therapy as a novel cancer treatment modality.

#0027 A single amino acid mutated AFP specific T cell receptor uniting synergistic functionalities of CD4 and CD8 T Cells with no cross-activity.

Chen-Song Huang[1], shudan Ou[2], Jun Li[2], Junjun Chu[2], **Yanyan Han**[2]

[1]Department of Pancreato-Biliary Surgery, the First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[2]HRYZ BIOTECH Co., Ltd., Shanghai, China

Background: Genetically engineered T cells with T cell receptor (TCR-T) cell therapy have shown great potential for cancer treatment by targeting tumor-associated antigens. Despite its success in treating various tumor types, such as synovial sarcoma, head and neck tumors, and cervical cancer, its application in liver cancer is limited. Alpha-fetoprotein (AFP), a highly expressed tumor-associated antigen in liver cancer, is an ideal target for TCR-T cell therapy. Although early human trials have confirmed the safety of AFP-targeting TCR-T products, their efficacy is still modest, highlighting the need for further research and development.

Methods: We developed a robust strategy combining ex vivo stimulation and single-cell paired TCR sequencing to identify AFP-recognizing TCRs in liver cancer patients. To optimize TCR expression and minimize mispairing, we employed codon optimization and replaced the constant regions with murine counterparts. Furthermore, structural analysis guided the affinity optimization of the CDR3 region to enhance the antitumor function of the selected TCR. The anti-tumor efficacy of TCR-T cells was rigorously evaluated through in vitro cytotoxicity assays using the Real-Time Cell Analyzer (RTCA) system and in vivo antitumor assessment in immunodeficient mouse xenograft models. Antigen specificity, HLA restriction, and other potential toxicity were carefully evaluated in both *in vitro* and *in vivo* models.

Results: We successfully cloned a highly effective TCR that recognizes the $AFP_{158-166}$ epitope presented by HLA-A*0203. After sequence optimization, we further changed a single amino acid on the TCR vβ chain based on AI prediction. The expression and functionality of this TCR was significantly improved. When introduced into human T cells, the single amino acid mutated TCR demonstrated robust and specific anti-tumor activity in various models, including cultured tumor cells, patient-derived organoids, and mouse xenografts models. Notably, this TCR also redirected CD4 T cells to recognize tumor cells, induced the secretion of multiple cytokines, and maintained long-lasting anti-tumor effects. Our rigorous screening assays confirmed that the TCR showed no cross-reactivity with the human proteome or major HLA subtypes. Additionally, extensive preclinical safety assessments in tumor-bearing animals treated with ST08A01-AM14 TCR-T cells showed no significant safety concerns.

Conclusion: In this study, we have developed an HLA-A*0203 restrict $AFP_{158-166}$ specific TCR-T therapy, which exhibits exceptional anti-tumor effects while ensuring a favorable safety profile. The promising results support the further investigation against AFP-positive solid tumors in clinic.

#0028 A CRISPR/Cas9 screening platform ImmuT Finder® enables in vivo T cell functional screening and identification of potent immunoregulatory targets for next-generation T cell therapy.

J. Sun, J. Jin, J. Wang, Y. Sheng, F. Li, L. Chen, Y. Tan, Z. Xu, Y. Liu, K. Liu, Y. Liu;
Grit Biotechnology, Shanghai, China

Insufficient tumor infiltration and the presence of various immunosuppressive mechanisms in tumor microenvironment (TME) are two major challenges compromising the anti-tumor efficacy of T cell therapy post infusion. PD-1/PD-L1 blockade has been proven to benefit a portion of late-stage solid tumor patients, however KO of PD-1 may impact the long-term persistence of CAR-T cells, indicating target selection strategies for gene editing of cell therapy products may differ from antibody drugs. To discover potent and/or novel immunoregulatory targets that could maximize the function of T cell therapy, we established an *in vivo* CRISPR/Cas9 screening platform, ImmuT Finder®, to identify functional gene targets in primary mouse T cells. Notably, T cells carrying sgRNA library have been collected at different harvest time points post transfer based on different screening purposes; library size has been rationally designed to ensure good coverage of the whole library in harvest samples. We selected top targets from *in vivo* screening and quickly validated their function in primary human T cells in a 96-well array. Then, the top targets that showed significant enhancement in proliferation and function of human T cells were further selected, and their combinational effects on human peripheral T cells and TIL were tested both *in vitro* and *in vivo*. Finally, GT307 stands out as the most potent KO combination, which significantly improves serial tumor killing of TCR-T and CAR-T as well as autologous tumor cytotoxicity of TIL *in vitro*. Furthermore, GT307 KO TCR-T and TIL demonstrated significantly improved tumor control in mouse models than their unedited counterparts and promoted long-term persistence with low support of IL-2. In summary, these data demonstrated that our ImmuT Finder® platform enables discovery of potent and/or novel targets for the development of T cell product and supports the clinical assessment of GT307 as a next-generation T cell therapy.

#0029 A genetically modified tumor-infiltrating lymphocytes product (GT216) enhanced anti-tumor efficacy against solid tumor by fine-tuning multiple negative immune regulators.

J. Sun, Y. Tan, J. Jin, J. Wang, L. Chen, F. Guo, Y. Tan, Z. Xu, Y. Liu;
Grit Biotechnology, Shanghai, China

Adoptive cell therapy by tumor-infiltrating lymphocytes (TILs) has demonstrated promising clinical benefits for patients with solid tumors. However, the large-scale expansion during manufacture may drive hypofunction or exhaustion status of the final TIL product, leading to impaired anti-tumor efficacy and persistence post infusion. Grit Biotechnology designed a genetically engineered TIL product (GT216) to overexpress an intracellular protein that is induced by antigen-specific T cell response and mediates the degradation of multiple immunoregulatory molecules, which releases the therapeutic potential of TIL with enhanced cytotoxicity as well as persistence *in vitro* and *in vivo*. Multiple vector construct designs of GT216 were compared and the best design was selected based on stable and efficient expression of surrogate marker in TILs. GT216 could be successfully manufactured by Grit's StemTexp® and StaViral® platforms with good memory phenotype and no signs of overactivation or exhaustion. In vitro functional analysis showed that GT216 demonstrated significantly increased cytotoxicity and cytokine production when cocultured with tumor cells and better tumor control ability during a serial killing assay than conventional TILs. Notably, GT216 TILs eradicated tumor growth with low IL-2 support in NOG mice inoculated with HLA-matched tumor cells while conventional TILs showed limited tumor control with high IL-2, corelated with their better infiltration and persistence in tumor and periphery. In summary, GT216 demonstrated enhanced anti-tumor efficacy and persistence as well as reduced IL-2 dependency *in vitro* and *in vivo*, supporting the clinical evaluation of GT216 as a next-generation TIL therapy in treatment of refractory solid tumors.

#0033 Revitalizing CAR-T cells for TNBC: Targeting phosphorylation of TCF7 to overcome T cell exhaustion.

Z. Jiang[1], Y.-Y. Chu[1], H.-H. Lee[1], M.-C. Hung[2], L. Yang[1], C. Lin[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]China Medical University, Tai Chung, Taiwan

Breast cancer stands as the second leading cause of cancer-related deaths among women in the United States, with triple-negative breast cancer (TNBC) representing the most aggressive subtype. Although immune checkpoint inhibitors (ICI) demonstrated durable response in some TNBC patients, the added benefit of current FDA-approved ICI in combination with chemotherapy is estimated to be only around 10%. Fortunately, TNBC displays the highest number of tumor-infiltrating lymphocytes (TILs), compared to other BC subtypes, indicating an optimal context for the survival of T cells. Therefore, CAR-T therapy emerges as a promising therapeutic option for TNBC patients. Expanding the application of CAR-T therapies to solid tumors, including breast cancer, remains challenging. One of the key hurdles lies in the immunosuppressive tumor microenvironment, where the T cell receptor experiences long-term exposure to tumor antigens, leading to T cell exhaustion. This state impedes the T cells' capacity to efficiently target and eliminate cancer cells. Identifying key regulatory mechanisms downstream of the T cell receptor holds the potential to revolutionize existing immunotherapeutic strategies.

In our study, we discovered that the presence of the master transcriptional factor of T cell stemness, TCF1, in $CD8^+$ T cells, is essential for controlling TNBC tumors. TCF1 undergoes phosphorylation by LCK, a crucial component of initiating T cell receptor signaling, upon T cell activation. We found this phosphorylation site is indispensable for TCF1's transcriptional activities, inhibiting the downstream program of T-cell persistence and causing T-cell exhaustion. Reversing this process, either through LCK inhibition or introducing a non-phosphorylated form of TCF1, results in a more sustained CAR-T cell-mediated anti-tumor response. Our findings reveal the significance of TCF1 post-translational modification in the development and longevity of stem-like $CD8^+$ T cells, bridging the gap between TCR signaling and transcriptional and epigenetic programs of stem-like CD8+ T cells. This insight contributes to a potential cure for TNBC by maintaining T cell persistence.

#0034 Improving CAR T cell efficacy in pancreatic cancer using an *in vivo* CRISPR Cas9 screen.

T. Kienka[1], F. Korell[1], N. Knudsen[2], K. Yates[2], A. Cheng[2], D. Sen[1], M. Maus[1], R. Manguso[2];
[1]Massachusetts General Hospital, Boston, MA, [2]Broad Institute of MIT and Harvard, Cambridge, MA

Introduction

Chimeric antigen receptor (CAR) T cell therapy has demonstrated remarkable success in the treatment of certain hematologic malignancies. However, efficacy against solid tumors has remained limited and is associated with relatively low T cell persistence. Here, we perform an *in vivo* CAR T cell CRISPR screen in pancreatic adenocarcinoma using a curated guide library to identify genes that enhance CAR T cell persistence *in vivo*.

Material and Methods

The Mario library consists of 1180 total guide RNAs targeting 135 genes that have been shown to modulate T cell functions in other models. To generate Mario-CART cells, primary human T cells were transduced with two lentiviral vectors, the first encoding an anti-mesothelin CAR and the second containing a fixed guide targeting the TCR alpha gene constant region (TRAC) as well as the Mario library. Mario-CART cells were transduced at low MOI, expanded in vitro and selected for loss of CD3 expression using magnetic selection, to enrich for cells that had a successful gene-edited event. Purified Mario-CART cells were intravenously injected into NSG mice bearing subcutaneous pancreatic adenocarcinoma (ASPC1). Tumor and spleen were harvested 2 or 4 weeks after Mario-CART injection, and engrafted T cells were isolated by CD45 positive selection. Genomic DNA was prepared from retrieved cells and illumina sequencing was used to evaluate guide abundance to identify gene knockouts that had been enriched after tumor exposure *in vivo*.

Results

The transcription factor, GATA3, was consistently identified as the most enriched hit across two donor T cells when Mario-CART was recovered at the 2-week timepoint. When compared to control or a depleted hit, GATA3 KO CAR showed early improvements in tumor clearance *in vivo.* However, relapse occurred at similar timepoints across groups. At the 4-week timepoint, the most enriched guides comprised a different set, including genes involved in transforming growth factor beta and JAK-STAT signaling pathways as well as T cell trafficking. In vivo anti-tumor control data are being collected.

Conclusions

Our findings highlight the dynamic nature of CART-tumor interactions. Gene knockouts that confer enhancements may change over time with varying context (such as in vitro vs in vivo conditions). It may be difficult to identify single gene knockouts that enhance CAR-T cell functions across different conditions and over time, but rather it may be necessary to exert more dynamic functional control of CAR T cells to enhance their function in different settings.

#0035 *In situ* CAR T cell engineering using lipid nanoparticles for B cell lymphoma therapy.

N. Zhang, E. Robinson, A. Rivera-Rodriguez, J. Wang, Y. Guo, B. Wu, S. K. Tumbale, M. Raie, M. Inayathullah, D. K. Czerwinski, R. Levy, K. W. Ferrara; Stanford University School of Medicine, Palo Alto, CA

Chimeric antigen receptor (CAR)-T cell therapy represents a breakthrough in immunotherapy, offering promising outcomes in the management of hematological malignancies. Current CAR-T cell *in vitro* manufacturing routes involve T cell isolation, purification, activation, gene transduction and cell expansion. The process duration and the costs present significant barriers. Therefore, there is a need for innovative strategies to address these concerns. Herein, we developed lipid nanoparticles (LNPs) to deliver CAR-mRNA efficiently and safely to T cells *in vivo*, thereby enabling *in situ* CAR-T cell engineering. By optimizing their composition and introducing anti-CD5 as the targeting ligand, we were able to enhance mRNA delivery and T cell transfection efficiency while maintaining T cell function. Furthermore, to augment T cell responsiveness to exogenous genetic elements, we investigated the pretreatment of T cells with interleukin (IL-7), thereby modulating T cell homeostasis by enhancing survival and proliferation, and rendering the cells more receptive to exogenous genetic modifications. We tracked firefly luciferase (FLuc) in naïve Balb/c mice using *in vivo* and *ex vivo* bioluminescence imaging after intravenous injection of anti-CD5 FLuc-mRNA LNPs. We observed positive mRNA expression in lymphoid organs, particularly in the spleen. Additionally, we harvested the lymphoid organs, and performed immunophenotyping analysis using flow cytometry after the administration of anti-CD5 LNPs encapsulating mRNA encoded CD19-CAR with a flag tag. We showed enhanced LNP binding in 65.2% of T cells and CAR expression in 11.64% of T cells as compared with non-treated controls, anti-CD5 FLuc-mRNA LNPs, or IgG CAR-mRNA LNPs. In a $CD19^+$ A20 tumor-bearing mouse model, treatment with CAR-LNPs resulted in a significant increase in chemoattractants (CCL2, CCL4, CCL5, CCL7 and CXCL10) and pro-inflammatory cytokines (TNF-α, IFN-γ, IL6, IL8 and IL15) in blood, and infiltration of T cells and other immune cells in tumors, compared to the non-treated control group over 48 hours post treatment. *In vivo* engineering allows simultaneous CAR T cell engineering and delivery, reducing the time between manufacturing and treatment, minimizing contamination risks, eliminating complex *ex vivo* processes, and reducing the need for high-dose preconditioning chemotherapy. In conclusion, the adoption of *in situ* CAR-T cell production holds promise for improving this therapeutic approach.

#0036 The discovery of a novel CD19xCD22 dual-targeting CAR for the development of an IPSC-derived cell therapy.

J. M. Carton, **J. Wheeler**, C. Dower, L. Campion, H. J. Millar, M. Beqiri, B. Morse, B. Gurung, R. Genovese, S. DeLuca, C. Dominick, M. Naso, H. Levitsky; Century Therapeutics LLC, Philadelphia, PA

Dual-targeting cell therapies to address CD19 antigen loss in heme malignancies are being explored by Century Therapeutics and others for unmet clinical need in hematological malignancies. CD22 chimeric antigen receptor (CAR) T-cell therapies have shown promising efficacy in relapsed or refractory B-lineage acute lymphoblastic leukemia (B-ALL) alone and in combination with CD19 CAR-T cell therapies (1,2). CD22 is a multi-domain glycoprotein expressed on B-cells. Natural splice variants of CD22 can exclude domains near the N-terminus, allowing for therapeutic resistance when these domains are targeted. We identified novel single domain antibodies (VHH) to CD22 that bind to multiple epitopes on different domains of CD22, including membrane proximal binders. The VHHs were affinity matured to enhance cell-based binding and formatted as CARs in monovalent and tandem, bivalent formats. Our data demonstrates the best efficacy against CD22+ tumor cells with a biparatopic, tandem VHH CAR format. Through additional engineering, bispecific CARs that combined three CD22-binding VHH and the anti-CD19 scFv, FMC63, in a loop CAR configuration were designed and tested. This CD19xCD22 bispecific, CD22 biparatopic CAR was engineered into primary T-cells and demonstrated cytotoxicity activity against CD19 and CD22 positive tumor cells as well as CD19 knockout and CD22 knockout cell lines. CD19xCD22 bispecific primary CAR-T cells were efficacious in controlling tumors in mouse xenograft models. This novel CAR is being tested in IPSC-derived iT and iNK cells for off-the-shelf allogeneic cell therapy to expand patient access beyond CD19 CAR-T cell therapies. Ref: 1. Nat Med. 2018;24(1):20-28. doi: 10.1038/nm.4441. 2. Blood. 2018;132(suppl 1). Abstract 27

#0037 IL-4 drives CART cell exhaustion in a CD4 independent manner.

C. M. Stewart[1], E. L. Siegler[1], T. N. Huynh[1], R. Sakemura[1], B. Kimball[1], L. Mai[1], K. Yun[1], J. H. Girsch[1], J. Feigin[1], O. Gutierrez Ruiz[1], M. Rodriguez[1], E. Ogbodo[1], I. Can[1], C. Manriquez Roman[1], O. Sirpilla[1], H. Xia[1], J. Kim[2], J. Budka[2], M. Mattie[2], N. Scholler[2], S. Filosto[2], S. S. Kenderian[1];
[1]Mayo Clinic, Rochester, MN, [2]Gilead Sciences Inc., Foster City, CA

While chimeric antigen receptor T (CART) cell therapy has shown remarkable success, the development of exhaustion limits durable response. We identified a role for interleukin (IL)-4 in the development of CART cell exhaustion through three independent approaches including: 1) a genome-wide CRISPR knockout screen using healthy donor CART cells in an *in vitro* model for exhaustion, 2) RNA and ATAC sequencing on freshly produced and chronically stimulated healthy donor CART cells, and 3) RNA and ATAC sequencing on pre-infusion CART cell products from responders and non-responders in the Zuma-1 clinical trial that led to the FDA approval of axi-cel. Further, *in vitro* validation studies revealed that CD19 directed CART (CART19) cells chronically stimulated in the presence of human recombinant IL-4 (hrIL-4) displayed signs of exhaustion such as 1) decreased proliferation ($p = 0.01$), 2) increased coexpression of inhibitory receptors ($p = 0.01$), and 3) decreased production of IL-2 and interferon (IFN)-γ ($p= 0.02$, $p = 0.002$). Encouragingly, CART19 cells combined with an IL-4 monoclonal antibody improved antitumor activity ($p = 0.045$) and expansion ($p = 0.01$) while also decreasing the co-expression of inhibitory receptors ($p = 0.02$) in a mantle cell lymphoma xenograft mouse model. Building on these results, we asked if IL-4 driven exhaustion results from a direct impact of IL-4 on CART cells. To test this, we used a tumor-free assay where CART19 cells were chronically stimulated with CD19 beads in the presence of hrIL-4 or diluent. CART cells treated with hrIL-4 displayed an exhausted phenotype characterized by increased co-expression of inhibitory receptors ($p = 0.04$) and decreased production of IL-2 ($p = 0.01$). Next, we asked if IL-4 driven CART cell exhaustion is dependent on the costimulatory domain. We tested the impact of IL-4 on both CD28ζ and 41BBζ costimulated CART19 cells. Similar to our previous studies with CART19-28ζ cells, chronic stimulation of CART19-BBζ cells in the presence of hrIL-4 enhanced the exhausted phenotype as seen by increased co-expression of inhibitory receptors ($p = 0.04$) and decreased production of IL-2 and IFN-γ ($p = 0.08$ and $p = 0.007$). Finally, we asked if IL-4 induces exhaustion independently of its classic role in Th2 polarization of CD4 CART cells. Following CART production, we isolated CD8 cells and chronically stimulated them in the presence of hrIL-4 or diluent. CD8 CART cells treated with hrIL-4 displayed an enhanced exhausted profile as seen by 1) decreased proliferative ability ($p < 0.0001$), 2) increased co-expression of inhibitory receptors ($p = 0.01$), and 3) decreased production of IL-2 and IFN-γ ($p < 0.0001$, $p = 0.004$). Together, our data indicates a novel role for IL-4 in the development of CART cell exhaustion that is independent of tumor cells, costimulatory domain, and CD4 cells. As such, we believe IL-4 neutralization may be a widely applicable and actionable approach to improve the durable response to CART cell therapy.

#0038 AB-2100, a PSMA-inducible CA9-specific CAR T cell product for the treatment of ccRCC provides long-term tumor responses in preclinical mouse model.

S. Mohanty, J. Chen, A. Gomez, A. Boroughs, I. Scarfo, L. Lim, K. Dang, M. Chew, R. Sudhakah, M. Nguyen, T. J. Gardner, B. Millare, J. Zhang, D. Moskowitz, S. Zhou, N. H. Xie, N. Attanasio, A. Fearon, I. Chan, V. Sail, V. Thomas, J. Smith, J. McDevitt, L. Gray-Rupp, **A. Gonzalez**, C. Murriel, W. Haining;
Arsenal Biosciences, South San Francisco, CA

Common challenges of CAR-T cell therapies in solid tumors, such as clear cell renal cell carcinoma (ccRCC), include insufficient therapeutic potency and lack of tumor specificity. We have developed AB-2100, an autologous integrated circuit T (ICT) cell product, generated via CRISPR-mediated knock-in of a single transgene into a safe-harbor locus. AB-2100 encodes a transcriptionally regulated sequential AND gate that comprises a priming receptor (PrimeR) specific for PSMA and an inducible CAR targeting CA9 antigen, which is widely expressed on local and metastatic lesions. AB-2100's sequential AND logic-gate confers tumor-specific activity by priming off of PSMA-expressing tumor vasculature to induce CA9 CAR expression. This unique feature of the logic gate is intended to increase the safety profile of AB-2100 given that PSMA and CA9 are predicted to have limited co-expression in normal tissues. Additional functionality includes short-hairpin RNAs (shRNA) against Fas and TGFBR designed to prevent tumor-mediated resistance, and a synthetic pathway activator (SPA) that drives constitutive STAT3 signaling and enhanced T cell cytotoxicity and expansion. Mechanism of action studies demonstrate that AB-2100 can prime off of PSMA-expressing endothelial cells and induce tumor-specific killing of CA9 tumor cells, leading to the eradication of ccRCC targets in vitro. AB-2100 also exhibited selective killing of dual antigen expressing tumors in vivo using a dual-flank subcutaneous xenograft model. Preclinical xenograft studies also demonstrated that TGFBR shRNA and SPA modules enhanced antitumor activity of ICTs. When AB-2100 potency was evaluated in the subcutaneous A498 xenograft model, treatment with AB-2100 resulted in complete and durable anti-tumor responses. In summary, preclinical data demonstrate that AB-2100 selectively targets tumors co-expressing PSMA and CA9, and can overcome multiple suppressive mechanisms in the tumor microenvironment. These results support the evaluation of AB-2100 in the clinic for the treatment of advanced or metastatic ccRCC.

#0039 Preclinical *in vitro* and *in vivo* evaluation of CD8αβ+ CD19 CAR iPSCs T cells generated in a TCR signal-independent manner using DLL4/VCAM-coupled microbeads.

M. S. Belew[1], R. Carpenedo[1], A. Pallaoro[1], H. Hoi[1], A. Deyati[2], D. C. Kirouac[2], S. Chandrasekaran[2], V. Wall[2], L. Abraham[2], S. Apelu[2], M. H. Cadell[2], A. AuYeung[1], O. Subedar[1], E. Martinez[1], S. Joshi[1], E. Csaszar[1], S. Woodside[1], E. Titus[1], C. Bond[2];
[1]Notch Therapeutics, Inc., Toronto, ON, Canada, [2]Notch Therapeutics, Inc., Seattle, WA

The use of clonally-derived, induced pluripotent stem cells (iPSCs) as starting material for therapeutic T cell manufacturing would overcome many limitations of autologous Chimeric Antigen Receptor T cell (CAR-T) therapies. Complex, multi-stage genome engineering, large batch production and rigorous lot testing could provide a consistent source of off-the-shelf, functionally enhanced T cell products. However, this vision cannot be realized using existing T cell differentiation platforms, which fail to present Notch ligands with the precision and intensity required to control T cell differentiation in scalable, suspension culture.

We have previously shown that VCAM1 synergizes with DLL4 to enhance Notch signaling and progenitor T cell differentiation. We have extended the utility of this discovery through the creation of DLL4/VCAM1-coated magnetic microbeads, enabling precise and temporal control of Notch signaling in suspension culture. iPSC-derived CD34+ cells cultured with DLL4/VCAM1 beads demonstrate dose-responsive activation of Notch gene expression (e.g., Notch1, DTX1, TCF7), resultant T lineage commitment (e.g. CD5, CD7 expression) and maturation to CD4-CD8+ (single positive) cells in a TCR signal-independent manner. Removal of the endogenous TCR is necessary to prevent graft-versus-host-disease. Therefore, differentiation and maturation in a TCR-independent process presents substantial advantage in the development of safe, off the shelf iPSC T cell products.

Using a clonal iPSC line with a CD19 CAR knocked in at the *TRAC* locus, we apply this approach to generate CAR-expressing, CD8αβ+ functional T cells, capable of multiple rounds of *in vitro* tumor cell lysis and sustained tumor growth inhibition *in vivo* comparable to primary T cells. This advancement demonstrates proof-of-concept for generation of highly efficacious, off-the-shelf CAR-T cells using novel, small-footprint manufacturing in order to broaden the applicability and accessibility of T cell therapies for cancer patients.

#0040 Persistence but not antitumor efficacy of CAR-engineered lymphocytes is governed by a FAS/FAS ligand auto-regulatory circuit.

Fei Yi[1], Tal Cohen[1], Paul Zumbo[2], Razan Eltilib[1], Hannah Arkin[1], Michael Gormally[3], Christopher S. Hackett[4], Korbinian Kropp[1], Smita Chandran[1], Jae H. Park[5], Doron Betel[2], Christopher A. Klebanoff[1]

[1]Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Applied Bioinformatics Core, Weill Cornell Medicine, New York, NY,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]Weill Cornell Medical College, New York, NY,[5]Cell Therapy Service, Memorial Sloan Kettering Cancer Center, New York, NY

Adoptive cell transfer of chimeric antigen receptor (CAR) engineered T and NK cells has revolutionized the treatment of many B-lymphoid malignancies; however, limited persistence of infused lymphocytes can restrain the full potential of this approach. Apoptosis induction through the FAS ligand/FAS pathway is a key negative regulator of lymphocyte survival. To define which cellular subsets express *FASLG*, the gene encoding FAS ligand, we generated a single-cell transcriptomic atlas from 37 patients with diverse cancer types. We discovered that *FASLG* expression is highly constrained and limited primarily to T and NK cells while stromal and tumor cells express minimal to no *FASLG*. Multiplex RNA *in situ* hybridization of clinical samples from patients treated with anti-CD19 CAR-T cells confirmed these results and revealed significantly higher *FASLG* content in CAR-expressing compared with non-CAR expressing T cells. Based on these findings, we hypothesized that FAS ligand expression by CAR^+ T and NK cells will engage FAS^+CAR^+ cells to induce apoptosis and limit cellular persistence. To test this hypothesis, we performed competitive fitness assays using two phenotypically discernable populations of human CAR-T and CAK-NK cells that are either responsive or unresponsive to FAS-signaling through expression of a FAS dominant negative receptor (ΔFAS). ΔFAS^+ and ΔFAS^- CAR-expressing cells were co-infused 1:1 into tumor bearing hosts and persistence of each population was quantified. For both CAR-T and CAR-NK, we measured significant enrichment in ΔFAS-expressing cells across multiple tissues, demonstrating that FAS-signaling regulates CAR^+ cell survival in a cell-intrinsic manner. Knock out (KO) of *FASLG* using CRISPR/Cas9 prevented population skewing while KO of the *AAVS1* control locus had no effect, indicating that CAR-derived *FASLG* is sufficient to restrain the persistence of transferred cells. By contrast, we discovered that *FASLG* was dispensable for CAR-T and CAR-NK mediated tumor killing both *in vitro* and *in vivo*. Finally, using two different tumor models, we found that adoptive transfer of CAR-T or CAR-NK cells that co-express ΔFAS resulted in superior antitumor efficacy compared with control cells that express the CAR alone. Taken together, these findings reveal that CAR-engineered lymphocyte persistence is governed by a FAS/FAS ligand auto-regulatory circuit. Further, they indicate that the therapeutic benefit of a FAS-dominant negative receptor is broadly applicable and agnostic of whether *FASLG* is expressed by cells in the tumor microenvironment.

#0041 Mitigating on-target off-tumor toxicity of mesothelin-targeting CAR T cells by affinity-tuning.

Y. Yang[1], Y. Vedvyas[1], Y. Alcaina[2], J. Y. Son[2], N. Salehi[2], I. M. Min[1], M. M. Jin[1];
[1]Houston Methodist Research Institute, Houston, TX, [2]Weill Cornell Medicine, New York, NY

Purpose: Mesothelin (MSLN) is a surface antigen associated with tumor invasion and is overexpressed in mesothelioma and lung, pancreatic, ovarian, and other cancers. Chimeric antigen receptor (CAR) T cells targeting MSLN have been tested in patients with MSLN-positive solid tumors. Despite reported patient fatalities in trials sponsored by PENN, Memorial Sloan Kettering/Atara Bio, and MD Anderson/TCR[2], the design approach for MSLN CAR remains constructing high affinity CARs to maximize target cell killing. In this study, we designed MSLN CARs with two different antibodies: one targeting human MSLN specifically and another binding both human and mouse MLSN with comparable affinities. The objectives are to 1) elucidate the risk of fatal on-target off-tumor toxicity associated with high affinity MSLN CAR, and 2) demonstrate how optimizing the affinity of CARs can render CAR T cells to spare normal tissues while retaining cytotoxicity against tumors.
Methods: To asses on-target off-tumor toxicity in animal models, we developed a CAR using a nanobody isolated from an immune alpaca library with nanomolar affinity for both human and mouse MSLN (labeled as hmMSLN CAR). For comparison, we constructed a CAR using a scFv specific only to human MSLN, designated hMSLN CAR. Each CAR is designed to co-express somatostatin receptor 2 to enable PET/CT imaging of CAR T cells with ^{18}F-NOTA-Octreotide. Anti-tumor activities and toxicities were assessed in NSG mice using MSTO-211H cell line expressing human MSLN.
Results: In NSG mice bearing subcutaneous MSTO-211H tumors, hMSLN CAR T cells eliminated tumors rapidly without inducing any overt toxicity. In contrast, hmMSLN CAR T cells not only failed to control tumor growth but also caused severe toxicity, resulting in significant body weight loss and necessitating euthanasia. PET/CT imaging revealed while hMSLN CAR T cells expanded exclusively within the tumor and subsequently contracted after tumor elimination, hmMSLN CAR T cells exhibited extensive infiltration and expansion in the lungs, liver, and bone marrow, indicating off-tumor, normal tissue-driven proliferation of CAR T cells. To test if affinity-tuned hmMSLN CAR T cells can selectively target tumors, we used a yeast display system to screen for affinity variants of the hmMSLN CAR. We identified one micromolar affinity CAR that binds approximately 1,000 times weaker to MSLN than the parental CAR. In stark contrast to the onset of severe toxicity soon after the administration of the parental hmMSLN CAR T cells, animals treated with micromolar affinity hmMSLN CAR T cells exhibited tumor regression without overt toxicity.
Conclusions: Our findings underscore the risks of using high affinity CAR against MSLN, which may cause unpredictable on-target, off-tumor toxicities. Fine tuning the affinity of MSLN CAR offers a promising strategy for developing a potent and safe CAR for the treatment of MSLN-expressing solid tumors.

#0042 Tunneling CARs: Gene modifications to enhance CAR-T infiltration into solid tumors.

S. N. Van Pelt[1], B. Omer[1], L. Talbot[2], C. Rooney[1], R. Fernandes[3], C. Tat[4], M. White[1];
[1]Baylor College of Medicine, Houston, TX, [2]St. Jude, Memphis, TN, [3]The George Washington University, Washignton, DC, [4]Texas Childrens Hospital, Houston, TX

Background: CAR-T therapy has been largely ineffective in solid tumors because the dense, rigid, extracellular matrices (ECMs) and basement membranes (BMs) that encapsulate these tumors exclude T cells. Tumor-specific ECMs and BMs, made of type I and type IV collagen respectively, are heavily cross-linked and characterized by small pores. T cell infiltration into tumors relies upon the enzymatic degradation of these matrix fibers, and adhesion molecule-mediated movement. Gene expression analysis of tumor infiltrating leukocytes from patient samples showed that MMP-7, an enzyme that degrades type IV collagen, and osteopontin (OPN), a molecule that interacts with adhesion molecules to mediate movement, were highly upregulated in infiltrating cells compared to those that were tumor adjacent, suggesting they may be important in navigating tumor-specific environments. *We hypothesized that overexpressing MMP-7 and/or OPN in CAR-T cells will enhance their infiltration into solid tumors.*
Methods: We overexpressed MMP-7 and OPN in second-generation CAR-Ts (GD2-28Z and HER2-28Z) and evaluated their infiltration *in vitro* using Halo invasion assays. T cell movement out of type IV collagen and into tumor droplets, composed of tumor targets polymerized in type I collagen, was visualized over time to characterize T cell movement through the tumor-specific BM and ECM, respectively. The expansion, phenotype, and cytotoxicity of OPN and MMP-7-modified GD2-28Z CAR-Ts was compared to unmodified GD2 CAR-Ts by counting, flow cytometry and chromium release, respectively. We then used a xenograft model of neuroblastoma to determine if increases in GD2 CAR-T infiltration led to reduced tumor burden.
Results: *In vitro*, MMP-7 overexpression increased GD2-28Z (2.05-fold, $p<0.0001$) and HER2-28Z (3.16-fold, $p<0.0001$) CAR-T infiltration, and OPN overexpression increased GD2-28Z (1.20-fold, $p=0.0496$) and HER2-28Z (1.49-fold, $p=0.002$) CAR-T infiltration. *In vivo*, 52 days after CAR-T infusions, mice treated with OPN-modified GD2-28Z CAR-Ts had reduced tumor burden (0.206 cm, ±0.21) compared to GD2-28Z CAR-Ts (0.903 cm, ±0.33, $p=0.0449$).
Conclusions: The overexpression of MMP-7 or OPN in second-generation CAR-Ts enhances CAR-T infiltration *in vitro*, and the expression of these genes does not impair CAR-T expansion, phenotype or cytotoxicity. The overexpression of OPN in GD2-28Z CAR-T enhances tumor clearance in a xenograft model of neuroblastoma, and may increase overall survival.

#0043 Targeting trogocytosis through cathepsin B inhibition enhances CAR T cell persistence.

K. A. Dietze[1], M. L. Olson[2], E. Gebru[1], D. Atanackovic[1], A. P. Rapoport[1], T. Luetkens[1];
[1]University of Maryland, Baltimore, Baltimore, MD, [2]Dana Farber Cancer Institute, Boston, MA

Chimeric Antigen Receptor (CAR) T cell therapy is an effective treatment for cancer patients. While CAR T cells have shown remarkable efficacy, most patients receiving CAR T cell therapy eventually relapse. CAR-mediated trogocytosis (CMT) is a potential tumor escape mechanism involving the transfer of cell surface proteins from tumor cells to CAR T cells. CMT results in antigen-negative tumor cells and correlates with reduced CAR T cell persistence, possibly due to increased CAR T cell fratricide or exhaustion. To date it has not been conclusively demonstrated that antigens transferred by CMT are the cause of fratricide or exhaustion. To answer this question, we developed a system to rapidly degrade trogocytosed protein in CAR T cells. Using this system, we show that the transfer of CD19 to CAR T cells directly causes CAR T cell fratricide and exhaustion. We hypothesize that reducing CMT will increase CAR T cell persistence. To identify molecular mechanisms driving CMT as potential therapeutic targets, we inhibited various proteins essential for cell adhesion, endocytosis, actin polymerization, or antigen processing using small molecule inhibitors. We found that inhibition of the cysteine protease Cathepsin B (CTSB), with a membrane-permeable (Ca-074) or membrane-impermeable (Ca-074-Me) inhibitor, significantly reduced CMT without affecting CAR T cell cytotoxicity. We hypothesize that CTSB inhibition could be a potential therapeutic approach to limit CMT.CTSB activity is regulated by the protein Cystatin A (CSTA). Both Ca-074-Me and CSTA sterically block access to the active site cysteine of CTSB. We found that overexpression of CSTA in CAR T cells significantly reduced CTSB activity and reduced antigen transfer. CSTA overexpression minimized antigen loss on tumor cells, indicating that CTSB inhibition blocks CMT early during the trogocytic process. CSTA overexpression reduced CAR T cell exhaustion but did not alter their expansion, tumor cell killing, or phenotype, indicating that this approach selectively inhibits CMT. Next, we assessed the effect of CSTA overexpression on CAR T cell persistence in vivo. NALM6 tumor-bearing NSG mice were injected with conventional or CSTA-overexpressing CD19 CAR T cells. Four weeks after CAR T cell injection, we observed substantially increased CAR T cell numbers in the blood (10.6x, p=0.0317), bone marrow (7.3x, p=0.0159), and spleens (5.6x, p=0.0556) of mice treated with CSTA-overexpressing CAR T cells. Taken together, we provide the first experimental evidence that CMT directly causes fratricide and exhaustion, reducing CAR T cell persistence. We demonstrate that CMT can be targeted efficiently by overexpressing the CTSB inhibitor CSTA in CAR T cells, resulting in substantially increased CAR T cell persistence. This represents a promising approach to improve CAR T cell efficacy and limit the occurrence of relapse in patients receiving CAR T cell therapy.

#0044 A novel, codon-based method to modulate off-tumor toxicity of chimeric antigen receptor (CAR) T cells.

R. A. Vedia, S. Lu, A. V. Philips, A. Sergeeva, L. S. St John, K. Clise-Dwyer, G. Alatrash, J. J. Molldrem;
UT MD Anderson Cancer Center, Houston, TX

Chimeric antigen receptor (CAR) T cell therapies for hematologic malignancies, while promising and efficacious, can also result in a variety of adverse effects. Of note, on-target, off-tumor toxicity is one adverse effect that continues to limit the safety and efficacy of CAR-T cells and has even led to life-threatening or fatal outcomes in patients (Morgan et al. 2010.). To address this, we have developed a unique, codon-based approach by replacing strategically selected codons within CAR non-antigen binding domains with their rare synonymous isoforms. Hoekema et al. (1987) reported the ability of synonymous rare codons to alter gene and protein expression in other model systems. In CAR-T cells, we aim to use this novel, codon-based approach to fine tune and modulate CAR-T cell expression and function to elicit full on-tumor activity while lessening off-tumor toxicity.

In our approach, we replaced specific endogenous codons within the non-antigen binding domains of Hu8F4-CAR, a TCR-like 2nd generation CAR developed by our group which targets the leukemia-associated antigen PR1/HLA-A2 (Ma et al. 2016.). Briefly, we created variants of Hu8F4-CAR containing rare codon substitutions in two subtypes: intracellular-based (type 1) and combined extracellular- and intracellular-based (type 2). Each variant subtype (type 1 or 2) had either between 6 and 30 or 27 and 57 rare codons introduced, respectively. Expression profiling and functional assessment of the Hu8F4-CAR variants was assessed in the Jurkat mutant cell line (J.RT3-T3.5) or human primary healthy peripheral blood mononuclear cells (PBMCs) that were enriched for T cells, respectively. Expression profiling results show that surface expression is reduced in J.RT3-T3.5 cells when assessed by flow cytometry by 1-1.5-fold compared to unmodified Hu8F4-CAR. When evaluated by immunoblotting, novel lower molecular weight bands emerge only in rare codon-modified variants, suggesting that rare codons may have altered translational or post-translational processing leading to truncated CAR protein isoforms (30, 45, or 60kDa vs 73kDa for unmodified Hu8F4-CAR), which may contribute to reduced cell surface CAR expression. Furthermore, we have conducted *in vitro* functional testing of the rare codon-modified variants and show reduced activity against non-malignant off-tumor targets that express PR1 and/or HLA-A2 including healthy donor PBMCs, mobilized hematopoietic cells, and bone marrow. Importantly, in addition to reduced off-tumor activity against healthy myeloid cells, rare codon-modified variants preserve their activity against on-tumor target cells, including the U937-A2+ cell line and primary acute myeloid leukemia. Altogether, these results suggest that our approach can modulate CAR expression and functionality creating a novel methodology to reduce the likelihood of off-tumor adverse effects typically associated with CAR therapies.

#0045 Driving AMPK signaling in CD4+ CART cells enhances metabolic capacity, memory formation, and anti-leukemia activity.

E. Braverman[1], H. Schuler[1], M. Qin[2], C. Byersdorfer[1];
[1]University of Pittsburgh, Pittsburgh, PA, [2]Tsinghua University, Beijing, China

Background: While Chimeric Antigen Receptor (CAR)T cell therapy has seen great success in pediatric and young adult acute lymphoblastic leukemia, up to 50% of patients will relapse following treatment. Increased memory formation and mitochondrial capacity, particularly in the CD4+ subset, have been linked to improved CART cell function and enhanced *in vivo* persistence, leading to long-term relapse-free survival. AMP-activated protein kinase (AMPK) is a cellular energy sensor responsible for promoting metabolic efficiency and T cell memory formation. We have previously demonstrated AMPK activity can be increased in human T cells via overexpression of the AMPKγ2 domain. We hypothesized that overexpression of AMPKγ2 in CART cells would enhance their metabolic capacity and improve their anti-leukemia function.

Methods: Human CART cells bearing a CD19-CAR utilizing a 41BB costimulatory domain were generated from healthy human donors via lentiviral transduction and co-transduced with AMPKγ2 (AMPK) or an empty vector (EV) control. Flow sorting for the co-transduced populations yielded >95% CD4+ CART cells. CARTs were expanded in IL-2 for approximately 2 weeks, followed by overnight stimulation and subsequent metabolic analysis using the Seahorse Metabolic Analyzer. Memory status was assessed by CD62L and CCR7 co-expression. *In vitro* CART function was assessed using Zs-green+ NALM6 targets, with loss of green fluorescence over time measured on the Incucyte analyzer. Where indicated, tumor conditioned media was harvested from 72-hour NALM6 cultures. For *in vivo* experiments, immunodeficient NOD-scid IL2Rγ^{null} (NSG) mice were injected with luciferase+ NALM6 targets, followed one week later by AMPK- or EV-CARTs. Leukemia burden, via IVIS imaging, and survival were followed over time.

Results: CD4+ CARTs co-transduced with AMPKγ2 (AMPK-CARTs) increased oxygen consumption, maximal respiration, and spare respiratory capacity following overnight stimulation by ~20% compared to CARTs co-transduced with the EV (EV-CARTs) ($p<0.05$). Following expansion, CD62L+CCR7+ central memory cells were 4.5-fold more abundant in the AMPK-CART group (2.4-6.2-fold, $p<0.01$). *In vitro*, while AMPK-CARTs demonstrated similar cytotoxicity against NALM6 targets as EV-CARTs in standard media, they mediated faster killing of NALM6 targets when challenged in tumor conditioned media ($p<0.001$). *In vivo*, recipients of AMPK-CARTs showed a consistent decrease in tumor burden as measured by median radiance values, translating to a significant survival advantage ($p<0.05$).

Conclusions: Increasing AMPK signaling in CD4+ CARTs via overexpression of AMPKγ2 improved metabolic profile, increased memory generation, and enhanced toxicity against leukemia targets both *in vitro* and *in vivo*. Together, these features make elevating AMPK signaling an attractive method to increase the efficacy of CART therapy.

#0046 Mechanisms and impact of bystander killing by CAR T cells.

J. Chorazeczewski, L. Xie, X. Chen, S. Wang, J. Kline;
University of Chicago, Chicago, IL

While CD19-directed chimeric antigen receptor (CAR) T cell therapy has improved outcomes of patients with relapsed/refractory diffuse large B cell lymphoma (r/r DLBCL), a majority will suffer disease relapse following CAR T cell infusion. Therefore, understanding mechanisms of CAR T cell killing is critical to enhance therapeutic efficacy. Cytolysis of CAR T cell targets presumably involves recognition of CD19 antigen by the CAR followed by activation of the granzyme/perforin axis. However, bystander elimination of CD19-negative lymphoma cells by CAR T cells has been reported, indicating that an alternative pathway may be required for optimal killing. Through in-depth phenotyping of a large panel of human DLBCLs and *in vitro* killing assays, we observed that CD19 expression levels on DLBCL cells and vulnerability to CAR T cell killing were weakly correlated. Conversely, cell surface expression of the death receptor, FAS, on DLBCL cells was strongly associated with susceptibility to CAR T cell killing. Although FAS expression across DLBCL cell lines varied, it could be broadly enhanced following exposure to IFNγ. Potent CAR T cell-mediated cytolysis of CD19-negative, Fas-positive murine DLBCL cells required the presence of CD19-positive lymphoma cells in the culture. CRISPR/Cas9 targeting was employed to delete *FAS* and/or *CD19* in isogenic human DLBCL cells to generate $CD19^{+}FAS^{+}$, $CD19^{+}FAS^{-}$, $CD19^{-}FAS^{+}$, and $CD19^{-}FAS^{-}$ subsets, which enabled us to define the extent to which CD19 engagement by the CAR was required to affect killing via FAS. When CAR T cells were co-cultured with equal numbers of the four gene-modified DLBCL cells described above, $CD19^{+}FAS^{+}$ DLBCL cells were killed most effectively, followed by $CD19^{+}FAS^{-}$ DLBCL cells, and $CD19^{-}FAS^{+}$ DLBCL cells. Double-negative DLBCL cells were poorly killed. This result suggested that CD19 engagement by the CAR was required for optimal DLBCL cell killing via FAS, and that CD19 and FAS need not necessarily be engaged on the same target cell. Future studies will determine if Fas/FasL interactions can be exploited by overexpression of FasL in CAR T cells and examination of DLBCL killing *in vitro* and *in vivo*.

#0047 Stabilization of long CAR T cells is crucial for in vivo antitumor efficacy.

H. Paavilainen[1], J. Koski[2], V. Nikoskelainen[1], M. Elmadani[2], E. Elbasani[1], C. Hekim[1], E.-L. Ihantola[1], V. Kergourlay[1], P. Vehmaan-kreula[1], M. Nyman[1], K. Kalke[1], M. Nurmi[1], H. Monzo[3], P. Ojala[3], A. Autio[1], M. Korhonen[2], **A. Thotakura**[1];

[1]Orion Corporation, Turku, Finland, [2]R&D, Finnish Red Cross Blood Service, Helsinki, Finland, Helsinki, Finland, [3]Translational Cancer Medicine Research Program, University of Helsinki, Helsinki, Finland

Introduction: Genetically engineered T cells expressing chimeric antigen receptors (CARs) have shown substantial anti-tumor efficacy in hematological malignancies during recent years. As the field evolves to novel target epitopes, longer CAR structures are needed to reach membrane proximal epitopes for improved efficacy. Our approach to reach such epitopes is to have (non-functional) SIRPalpha based extracellular extension, spacer, to our CAR structure. We have shown, in this proof-of-concept study, that stability of the extracellular spacer of a CAR plays a pivotal role to improve in vivo anti-tumor efficacy. Various SIRPalpha-based CARs, FiCARs, targeting CD19 was studied for their function. Protein stability of the CD19 CAR structures were characterized and subsequently the killing efficacy of target cells and cytokine release in in vitro as well as in vivo anti-tumor efficacy was evaluated.

Methods & Results: In vitro co-culture assays with primary CD19 CAR T and CD19 positive cancer cells had shown no significant differences between the different spacer containing FiCAR structures. A dose dependent killing efficacy was observed in all the tested structures with up to >90% killing of NALM6 and Raji cells. Comparable results for IL-2, IFN-gamma, TNF-alpha, IL-4, IL-13 and granzyme B response were seen in co-cultured assay. In the protein stability studies, modifications in the extracellular part of the CAR structure led to an increase in thermal stability (over 2 °C) and reduced/halted multimer formation. To study the FiCAR T cell function in an in vivo tumor model, NSG mice were injected i.v with Raji cells and few days later mice were injected i.v with FiCAR T cells. Anti-tumor efficacy and overall survival were studied at the end of the study (60 days), the enhanced stability of FiCAR T structure translated into improved anti-tumor efficacy and survival. Interestingly, none of the mice survived in the least stable structure, 40% survival with intermediate stability structures and over 70% survival was observed in most stable structures.

Conclusion: A stabilized SIRPalpha-based CD19 FiCARs dramatically enhance anti-tumor efficacy and survival in Raji tumor model. The stabilization is critical for improved efficacy, especially in the in vivo setting. This data suggests that, in addition to the length of the CARs stability of the CAR structure appear to play a crucial role in the efficacy of the CAR T cells. The modifications presented here enhanced CD19-targeting CAR T cell efficacy. This approach requires further investigation to improve the efficacy of currently approved CAR T cells, especially CD19-CAR T cells.

#0048 T cell-specific *in vivo* transduction with preclinical candidate KLN-1010 generates BCMA directed CAR T cells with potent anti-multiple myeloma activity.

E. T. Beura, H. J. Latimer, D. Wong, J. Obrigewitch, A. J. Warr, S. Dong, M. Ariel, J. Figueroa, J. Figueroa, C. S. Dobson, S. K. Janaka, **A. J. Najibi**, M. Lau, S. Contrastano, K. Friedman;
Kelonia Therapeutics, Inc., Boston, MA

Introduction: Multiple Myeloma (MM) is the second most diagnosed hematologic malignancy and remains an incurable disease. KLN-1010 is a novel treatment for MM currently in preclinical development that uses our iGPS^{TM} platform, an envelope-modified lentiviral vector particle engineered for specific and efficient in vivo gene delivery, to transduce T cells. T cells modified in vivo by KLN-1010 express a fully human anti-BCMA CAR following a single IV injection without the need for additional treatments or conditioning chemotherapy.
Results: Human T cells exposed to KLN-1010 in vitro resulted in transduction and expansion of anti-BCMA CAR T cells in a concentration dependent manner. The resulting CAR T cells were highly avid and specific to BCMA-expressing cell lines. KLN-1010 treatment of preclinical mouse models resulted in T cell-specific CAR expression with no evidence of off-target modification including in the lung and liver, except phagocytes. A varied CAR T cell lineage composition was observed that included effector and memory CD4 and CD8 T cells. A single dose of KLN-1010 caused potent anti-tumor efficacy and complete tumor regression in a stringent model that requires high dose levels of ex vivo-cultured CAR T cells similar to those commercially available. When the anti-BCMA CAR molecules used in KLN-1010 are compared in preclinical models to other clinically relevant CARs, we observed superior tumor control by the KLN-1010 anti-BCMA CAR molecules. Clinical application of iGPS technology was modeled in non-human primates (NHP) using an NHP T cell-targeting particle that expresses an anti-CD20 CAR. CAR T cell activity, assessed by B cell depletion, and tolerability were evaluated without prior lymphodepleting chemotherapy across a 10x dose range. Rapid clearance of the iGPS particles from the blood was observed at all dose levels. Even at a low dose of 1.3e8 IU/kg, potent and durable CAR T cell activity was observed as evidenced by complete B cell depletion lasting over two months. Multiple CAR T cell expansions and contractions were observed during this period. The treatment at all dose levels was highly tolerable with no observed toxicities, cytokine release syndrome, or neurotoxicity.
Conclusions: These data demonstrate that KLN-1010 is safe and efficacious in preclinical models and may offer greater accessibility than other therapeutic modalities to address an unmet medical need in MM. Without requirements of ex vivo manufacturing, lymphodepletion and inpatient treatment that restrict patient access to therapy, the iGPS technology is well poised to provide significant clinical benefit for a multitude of indications as an off-the-shelf, single dose treatment.

#0049 LYL119, an investigational ROR1-targeted CAR T-cell product incorporating four novel reprogramming technologies designed for effective cell therapy for solid tumors.

V. C. Lam[1], A. Li[1], M. Galindo Casas[2], J. Barragan[1], **C. Cheung**[1], J. Briones[1], E. Afreen[2], G. Vavra[2], J. Lu[1], P. Sundar[1], R. Martinez[1], C. Sims[1], S. Potluri[1], O. Ali[1], A. S. Cheung[1], R. C. Lynn[1];

[1]Lyell Immunopharma, Inc., South San Francisco, CA, [2]Lyell Immunopharma, Inc., Seattle, WA

Effective solid tumor cell therapy requires new strategies to improve T-cell activation, persistence, and durable function. We developed four complementary T-cell reprogramming technologies to enhance chimeric antigen receptor (CAR) T-cell therapy in solid tumors: 1) overexpression of the activator protein 1 (AP-1) family transcription factor c-Jun to delay T-cell exhaustion and improve antitumor activity; 2) nuclear receptor subfamily 4A member 3 (NR4A3) gene knockout (KO) to further delay exhaustion and enhance functionality; 3) Epi-R^{TM} manufacturing protocols to preserve stem-like characteristics; and 4) Stim-R^{TM} technology, a novel activating reagent to improve product potency compared with standard reagents. LYL119 is an investigational ROR1-targeted CAR T-cell product that combines these technologies to create potent and durable CAR T cells. Healthy or NSCLC patient donor T cells were manufactured with the Epi-R protocols, activated with Stim-R or a standard reagent, and transduced with a vector encoding a ROR1 CAR and c-Jun. The *NR4A3* gene or a control gene was edited using SpyFi^{TM} Cas9 nuclease (Aldevron®). Cytotoxicity, cytokine production, phenotype, and single-cell transcriptomic and epigenetic profiles were evaluated in vitro after antigen restimulation assays designed to promote exhaustion. CAR T cell activity was evaluated in vivo using a ROR1^{+} NSCLC xenograft mouse model. Research and clinical scale LYL119 products achieved ~90% genome editing efficiency at the *NR4A3* target gene resulting in a 13-fold protein reduction compared to non-edited CAR T cells. LYL119 exhibited superior cytotoxicity and cytokine production upon antigen restimulation across 7 different ROR1^{+} solid tumor cell lines compared to CAR T cells that lacked one or more reprogramming technologies. After repeated rounds of tumor cell killing, LYL119 displayed reduced surface expression of exhaustion-related receptors (e.g. TIM-3) and higher expression of stemness-related markers (e.g. CD127) compared to non-edited CAR T cells. Furthermore, transcriptomic analysis revealed global downregulation of exhaustion-related gene signatures and retention of unique cell subsets characterized by upregulation of memory and effector-associated gene signatures. LYL119 exhibited robust antitumor efficacy in vivo across a 10-fold dose range, including a very low dose of $1x10^5$ CAR T cells. Lastly, LYL119 derived from NSCLC patient donor T cells also demonstrated enhanced cytotoxicity in vitro compared to control CAR T cells. These nonclinical data suggest LYL119, which combines c-Jun overexpression, *NR4A3* KO, Epi-R protocols, and Stim-R technology, can limit exhaustion, maintain stem-like features, and has the potential to provide effective and durable CAR T-cell antitumor activity in patients with ROR1^{+} solid tumors.

#0050 ALK inhibitors increase ALK expression and sensitize neuroblastoma cells to ALK.CAR-T cells.

E. Bergaggio[1], W.-T. Tai[1], A. Aroldi[2], C. Mecca[1], E. Landoni[3], M. Nuesch[1], I. Mota[1], J. Metovic[4], L. Molinaro[4], L. Ma[5], D. Alvarado[6], C. Ambrogio[4], C. Voena[4], R. B. Blasco[1], T. Li[7], D. Klein[7], D. J. Irvine[5], M. Papotti[4], B. Savolodo[3], G. Dotti[3], R. Chiarle[1];

[1]Boston Children's Hospital, Boston, MA, [2]University of Milano-Bicocca, Monza, Italy, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of Torino, Torino, Italy, [5]Koch Institute and MIT, Cambridge, MA, [6]Celldex Therapeutics, New Haven, CT, [7]Yale University School of Medicine, New Haven, CT

Neuroblastoma is the most common extracranial solid tumor of childhood, with limited success in treating refractory or relapsed cases using current therapies. Chimeric antigen receptor (CAR) T cell therapy targeting GD2 has shown promise in neuroblastoma treatment, but relapses are associated with loss of antigen expression. The selection of the best tumor antigen is critical for the therapeutic success of CAR-T cells in hematologic malignancies and solid tumors. The Anaplastic Lymphoma Kinase (ALK) receptor is expressed by most neuroblastomas while virtually absent in most normal tissues. ALK is an oncogenic driver in neuroblastoma and ALK inhibitors show promising clinical activity. All these features make ALK an attractive target for CAR-T cell therapy. We developed ALK.CAR-T cells that show potent efficacy in monotherapy against neuroblastoma with high ALK expression without toxicity. For neuroblastoma with low ALK expression, combination with ALK inhibitors specifically potentiates ALK.CAR-T cells but not GD2.CAR-T cells. In neuroblastoma cell lines and in a patient-derived xenograft (PDX), the combination of ALK inhibitors and ALK.CAR-T cells significantly reduced tumor growth and extended mice survival. Mechanistically, ALK inhibitors impair tumor growth and upregulate the expression of ALK, thereby facilitating the activity of ALK.CAR-T cells against neuroblastoma. Thus, while neither ALK inhibitors nor ALK.CAR-T cells will likely be sufficient as monotherapy in neuroblastoma with low ALK density, their combination specifically enhances therapeutic efficacy. These findings provide insights into the potential of ALK.CAR-T cells as a novel therapeutic strategy for neuroblastoma. A Phase I clinical trial to test ALK.CAR-T cells in combination with ALK TKIs in children with refractory/relapsed neuroblastoma is being implemented based on these results.

#0051 OPB-101: An optimized mesothelin-specific CAR T cell product expressing CD8-targeted IL-2/15 and engineered to resist T cell exhaustion.

R. Amin, H. Moffett, K. Haworth, J. Chen, J. Yokoyama, A. Wang, L. Tait, M. Steele, J. Crowl, T. Davenport, J. DeSautelle, J. Hammer, W. Obenza, V. Montoya, R. Kirkpatrick, L. Baker, T. Tan, K. Shirley, B. Hammerson, R. Langan, D. Clausen, P. Sample, B. Weitzner, S. Yuan, M. Lajoie, S. Boyken, A. Foster; Outpace Bio, Inc., Seattle, WA

T cell therapies have had modest efficacy in solid tumors due to their failure to proliferate following infusion. We have designed a mesothelin (MSLN) CAR T product (OPB-101) which includes a novel promoter (OP1), an optimized CAR, a safety switch, and a CD8α-targeted IL-2/15 designed cytokine to promote T cell expansion and improve efficacy in solid tumors. Human anti-MSLN binders were optimized for the target using our OUTSPACER^{TM} library. CAR evaluation was conducted using *in vitro* coculture assays and validated NSG tumor xenograft models. OUTSMART^{TM} IL-2/15 was designed to avoid regulatory T cell activation by ablating IL-2Rα binding and re-targeted to CD8α to enhance CD8^{+} T cell and NK stimulation. EGFRopt^{TM} was engineered for improved sensitivity to EGFR-targeted immunotherapies. Using 2A polypeptides, all transgenes were expressed with an antigen-dependent, inducible “stim-on” promoter (OP1) to regulate CAR expression, cytokine production, and resistance to exhaustion. The efficacy of the OPB-101 construct was tested in stringent exhaustion assays. *In vivo* efficacy was assessed with mice engrafted with s.c. H1650 tumors that were treated by i.v. injection of mock, CAR only or OPB-101 T cells at doses ranging from 0.25 x 10^6 to 2 x 10^6 cells. Tumor volume and weight were measured for 80 days. T cell levels and phenotype were measured by peripheral blood (PB) draws and intratumoral analysis (IT; day 14). OPB-101 efficiently killed MSLN^{+} tumor cell lines in repeat challenge and spheroid assays, and inducibly produced the IL-2/15 cytokine. IL-2/15 expression did not result in antigen-independent CAR T cell proliferation but extended survival in conditions without exogenous cytokine support. *In vivo* efficacy studies showed tumor control at 2 x 10^6 cells in the CAR only condition and modest anti-tumor efficacy at the 1 x 10^6 dose. In contrast, OPB-101 demonstrated complete and durable tumor elimination at the lowest dose of 0.25 x 10^6 cells (OPB-101 versus CAR only at 1 x 10^6 cells, $p < 0.0001$ and $p < 0.0005$ for donor 1 and 2, respectively). OPB-101 efficacy was associated with robust expansion in the PB (>100-fold) within IT (>5-fold) compared to the CAR only condition. OPB-101 PB and IT T cells showed reduced levels of PD-1, TIGIT and CD39 compared to CAR only suggesting resistance to exhaustion. Finally, studies conducted in tumor-free mice showed that OPB-101 expansion *in vivo* was dependent on the presence of tumor. In summary, OPB-101 using a regulated promoter (OP1) to dynamically express an optimized MSLN CAR, EGFRopt^{TM}, and a CD8-targeted IL-2/15 cytokine enhances anti-tumor efficacy against solid tumors by promoting CAR expansion and persistence while limiting T cell exhaustion. These technologies allow for complete elimination of solid tumors at a low treatment dose (i.e., <250K cells) and may pave the way to more effective CAR T cell therapies for solid tumors.

#0052 CRISPR-mediated knock-out of A20 lowers the activation threshold and induces metabolic rewiring of CAR-T cells.

N. J. Chu[1], C. Nava-Barbero[2], A. Merlino[1], P.-H. Lee[1], D. Baker[2], B. Taylor[2], G. Moody[1], L. Giardino[2];
[1]AstraZeneca US, Gaithersburg, MD, [2]AstraZeneca, Cambridge, United Kingdom

Background: Common failures of chimeric antigen receptor (CAR)-T cell therapy regimens stem from immune escape of target antigen low tumors. Strategies to improve CAR-T cell therapy efficacy include enhancing intrinsic effector function while preventing T cell exhaustion. The ubiquitin-modifying enzyme A20, is a key negative regulator of the NF-kB pathway downstream of T cell receptor activation in T cells. Dysfunctional CD8 T cells in tumors have high expression of A20, and deletion of A20 enhances antitumor activity of CD8 T cells in murine tumor models. We tested whether CRISPR-mediated knock-out (KO) of tumor necrosis factor α-induced protein 3 (TNFAIP3), the gene for A20, increases the effector function and alters the metabolic state of CAR-T cells.
Results: A20 deletion led to upregulation of NF-κB target genes and resulted in higher levels of activation marker expression and effector cytokine secretion compared to unarmored CAR-T upon incubation with target cells. In addition, A20 KO CAR-T cells maintained prolonged expression of activation markers upon antigen clearance in the absence of enhanced differentiation, and were more resistant to dysfunction in a repeat challenge serial kill assay. *In vivo*, A20 deficient CAR-T exhibited increased anti-tumor efficacy against low, medium, and high target expressing tumor models. Consistent with NF-κB upregulation, A20 KO cells significantly upregulated key glycolytic intermediates suggesting that amino acid anabolism was fueled by glycolysis and the pentose phosphate pathway. Moreover, the preferential increase of glycolysis over oxidative phosphorylation confirmed that A20 KO CAR-T cells were skewed towards an effector-like phenotype. Notably, glutathione and its cysteine-glycine bi-products were upregulated upon activation to a higher level in A20 KO CAR-T suggesting enhanced resistance to oxidative stress, in line with their prolonged persistence.
Conclusions: CRISPR-mediated knock-out of A20 lowers the activation threshold of CAR-T cells producing enhanced *in vitro* and *in vivo* anti-tumor efficacy particularly against tumors with very low levels of target expression. A20 KO induces metabolic rewiring of CAR-T cells by promoting glycolysis and amino acid anabolism to sustain their superior effector functions. This intrinsic armoring strategy can be applied to any CAR-T in any indication to increase tumor control and reduce immune escape.

#0053 T-cell receptor repertoire changes associated with clinical response in patients with B-cell non-Hodgkin's lymphoma receiving CD19 CAR-T therapy.

A. J. Faruqi[1], P. Wang[2], R. Bansal[2], A. De Menezes Silva Corraes[2], H. Zhang[2], Z. Shao[2], K. Regan[2], E. Moreno Cortes[2], A. Khurana[2], N. Bennani[2], Y. Wang[2], P. Hampel[2], J. Paludo[2], P. Johnston[2], H. Murthy[2], M. Iqbal[2], S. Ansell[2], J. Munoz[2], A. Rosenthal[2], M. Kharfan Dabaja[2], J. E. Castro[2], S. Kenderian[2], H. Dong[2], Y. Li[2], Y. Lin[2];

[1]Mayo Clinic College of Medicine and Science, Rochester, MN, [2]Mayo Clinic, Rochester, MN

Background: Although CAR T-cell therapy has achieved remarkable response rates in adult patients (pts) with relapsed and refractory B-cell non-Hodgkin's lymphoma (NHL), 20-30% of pts still have primary refractory disease, and 30-40% of pts relapse, often within 6 months of therapy. Given that durable clinical response can be achieved without CAR T cell persistence, we hypothesized that durable remission is correlated with the expansion of tumor-reactive T-cell receptor (TCR) clones following CAR T-cell infusion. To assess this, we examined the TCR repertoire of adult pts with B-NHL who received CD19 CAR T-cell (axi-cel) therapy to identify correlates of clinical response.

Methods: Single-cell (sc) RNA sequencing (seq) and scTCR-seq were performed on peripheral blood mononuclear cells from B-NHL pts before lymphodepletion chemotherapy (pre), at peak CAR-T expansion (peak), and one month following CAR-T (M1). scRNAseq and scTCR-seq data were processed using CellRanger v7.0.1, which were then analyzed using Immunarch (v0.9.0) for TCR clonality and sample diversity. Diversity was assessed using the Gini coefficient to indicate clone size inequality (0 = maximum diversity). TCR diversity and phenotype of expanded and emerged TCR clones post CAR-T were compared across clinical response categories: CR (complete remission for at least 6 months), PD1 (primary refractory), and PD2 (relapsed after partial or complete response).

Results: We analyzed 107,035 T cells from 77 serial samples of 32 pts (16 CR, 4 PD1, 12 PD2) and 5 healthy controls. Compared to pts with PD1 and PD2, pts with CR had a larger Gini coefficient for TCR clones at M1 relative to Pre and Peak. The Gini coefficient was the largest for tumor recirculating CD8 T effector memory (Tem) and activated CD8 peripheral memory (Tpm) cells at M1 for pts with CR. Examining the repertoire of emerged and expanded TCR clones at Peak and M1 from Pre, pts with PD2, compared to pts with CR, had a higher percentage of activated CD8 T peripheral memory (Tpm) and T regulatory cells (Treg) among the emerged clones and activated CD8 Tpm among the expanded clones. Patients with PD1, relative to patients with CR, had more proliferating and non-activated CD8 Tpm among the expanded and emerged clones.

Conclusion: NHL pts with CR after CAR-T had more robust clonal expansion of T cells, particularly tumor recirculating CD8 Tem and activated CD8 Tpm, compared to pts with relapsed or refractory disease. In contrast, pts with relapsed or refractory disease had an expansion of TCR clones with a larger proportion of CD8 Tpm and Tregs. Endogenous tumor-reactive TCR expansion may help predict favorable clinical response following CAR T-cell therapy.

#0054 Engineering chimeric antigen receptor (CAR) T cells using autoantigen binding domains for treatment of B cell malignancies with increased specificity.

Abiagil Cheever, Hunter Lindsay, MacKenzie Hansen, Chloe Kang, K. Scott Weber, Kim O'Neill

Microbiology and Molecular Biology, Brigham Young University, Provo, UT

Introduction: Chronic inflammation often leads to cancer, and many autoimmune diseases lead to a significantly increased risk of developing cancer. Though many autoimmune diseases, like Graves' Disease (GD), don't have treatments that address this risk. Chimeric antigen receptor (CAR) T cells are an effective treatment for hematological cancers by eliminating all B cells, but a more targeted form of CAR T cells could eliminate specific B cell populations in B cell malignancies, including GD.
Methods: To allow our CAR T cells to target specific B cell populations that cause GD, we engineered chimeric autoantigen receptors (CAAR) with epitopes of thyroid stimulating hormone receptor (TSHR) as the binding domain. This acts as bait for the anti-TSHR B cells. Jurkat T cells were lentivirally transduced with these CAAR plasmids. Anti-TSHR B cell lines were engineered by transducing Nalm6 cells with lentivirus for anti-TSHR B cell receptors. Cytotoxicity assays were performed on primary human TSHR CAAR T cells incubated with the anti-TSHR B cell lines. Cytokine production, proliferation, and cytotoxicity assays were performed on these coincubated cells to determine the efficacy of our TSHR CAAR T cells.
Results: Two of the three Jurkat TSHR CAAR T cells showed significant binding to anti-TSHR antibodies (TRAbs). They also showed significant activation, measured by CD69 expression, when incubated with plate bound TRAbs, but not soluble TRAbs. The B cell lines were validated by binding to TSHR. The primary TSHR CAAR T cells showed significantly increased proliferation and production of TNF, IFN-γ, and IL-2, when compared with controls. The TSHR CAAR T cells also had significant cytotoxic action against the anti-TSHR B cell lines, but not Nalm6 B cells. The cytotoxic function was comparable to our CD19 CAR T cell with the same activation domains, though it demonstrated specificity to only anti-TSHR B cells.
Conclusion: TSHR CAAR T cells are a potentially curative treatment for GD that will stop chronic inflammation and could reduce GD patient's risk of developing thyroid cancer. This is also an important development in CAR T cell therapies that allows for specific targeting of certain B cell populations.

#0055 CD70-specific CAR-T cell therapy for the treatment of glioblastoma.

Alexandros Kourtesakis[1], Hiu Nam Hannah Chow[1], Dennis Alexander Agardy[2], Eileen Bailey[1], Sandra Horschitz[3], Ammar Jabali[3], Rainer Will[4], Denise Reibold[1], Sonja Pusch[1], Christoph Schifflers[5], Manuel Fischer[6], Ling Hai[1], Dirk C. Hoffmann[1], Yu-Chan Chih[2], Robin Wagener[7], Leon Kaulen[7], Philipp Koch[3], Michael Breckwoldt[2], Michael Schmitt[8], Wolfgang Wick[7], Tim Sauer[8], Tobias Kessler[7]

[1]Clinical Cooperation Unit Neurooncology, German Cancer Research Center, Heidelberg, Germany,[2]Clinical Cooperation Unit Neuroimmunology and Brain Tumor Immunology, German Cancer Research Center, Heidelberg, Germany,[3]Hector Institute for Translational Brain Research, Mannheim, Germany,[4]Core Facility Cellular Tools, German Cancer Research Center, Heidelberg, Germany,[5]Department of Immunotherapy and Immunoprevention, German Cancer Research Center, Heidelberg, Germany,[6]Department of Neuroradiology, University Hospital Heidelberg, Heidelberg, Germany,[7]Department of Neurology, University Hospital Heidelberg, Heidelberg, Germany,[8]Department of Hematology, Oncology and Rheumatology, University Hospital Heidelberg, Heidelberg, Germany

Despite the remarkable success of chimeric antigen receptor (CAR)-T cell treatment for patients with hematologic malignancies, this method has yet failed to confer meaningful survival benefits to patients suffering from glioblastoma (GB), the most lethal type of brain tumor. This highlights the need to develop novel CAR-T cell approaches for this disease. CD70 is a member of the tumor necrosis factor receptor (TNFR) superfamily. Although absent on normal brain tissue, it is ectopically expressed in a substantial fraction of GB patients, indicating its suitability as a CAR-T cell therapy candidate. In this study, we generated CD70-targeting CAR-T cells and tested their cytotoxicity *in vitro* and *in vivo*. First, we detected CD70 in a panel of primary GB cell lines and to investigate its role, it was overexpressed in human and murine GB cells. In a syngeneic glioma model, C57BL/6J mice injected with CD70-overexpressing GL261 cells developed significantly larger tumors compared to the control counterparts. Additionally, RNA-sequencing revealed that CD70-overexpression in the same cells led to higher expression levels of immunosuppressive marker *CD200* and lower levels of tumor inhibition genes *Prkg2* and *Sh3bgrl2*, suggesting a tumor-promoting role in GB. For our immunotherapeutic intervention, we designed CD70-targeting CAR-T cell constructs featuring different co-stimulatory domains (CD27, CD28 or 4-1BB) and successfully transduced primary T-Cells from healthy donors. In an *in vitro* co-culture, all CAR-T cells recognized and eliminated primary cancer cells in a target-dependent and donor-independent manner, while secreting high levels of Granzyme B. The killing capacity of these cells was further highlighted in a 3D system in which *in vitro*-generated cortical organoids were treated with CAR-T cells after being infiltrated by CD70-expressing or control cells. Immunofluorescence (IF) staining and enzyme-linked immunosorbent assay (ELISA) revealed increased levels of Granzyme B and IFN-γ in all treated organoids previously infiltrated by $CD70^+$ tumor cells. Importantly, generated CAR-T cells showed high specificity and efficiency in killing $CD70^+$ tumors *in vivo* in the brains of immunodeficient mice. Namely, 80% of NSG mice orthotopically implanted with $CD70^+$ GB cells and subsequently treated by CARs but not mock-transduced T-Cells showed complete tumor remission by the end of the experimental endpoint, determined by bioluminescence imaging (BLI). IF analysis of these brains showed high levels of apoptotic marker cleaved caspase-3, enhanced effector cell presence and significantly lower tumor cell occupancy compared to control-treated animals. In conclusion, we provide evidence in favor of utilization of CAR-T cells against CD70-expressing gliomas. Based on these findings, a phase-I clinical trial to assess the safety and efficacy of autologous CD70-specific CAR-T cells for relapsed $CD70^+$ GB is being planned.

#0056 Preclinical *in vivo* characterization underpinning LGR5-targeting CAR-T cells as a cancer immunotherapy.

J. Foeng[1], T. Tyllis[1], C. Abbott[1], D. McPeake[1], E. Thompson[2], V. Bandara[1], B. Gundsambuu[1], S. Napoli[1], C. Bonder[1], I. Comerford[1], T. Sadlon[1], S. Barry[1], S. McColl[1];

[1]University of Adelaide, Adelaide, Australia, [2]Centre for Cancer Biology, Adelaide, Australia

Incidences of early-onset colorectal cancer (CRC) have been accelerating worldwide. To begin to address the lack of therapeutic options for CRC, we have developed a CAR-T cell therapy specific for leucine-rich repeat-containing G-protein coupled receptor 5 (LGR5). LGR5 is known to potentiate Wnt/B-catenin signaling and mark cells-of-origin in intestinal cancers. Extensive screening has demonstrated elevated expression of LGR5 in CRC, which is correlated with reduced patient survival. In CRC, LGR5 has been intimately linked with metastasis, cell survival and perturbation of chemotherapeutic interventions. We have developed a 9-day preclinical manufacturing method to generate LGR5-targeting CAR-T cells with a minimally differentiated T cell phenotype, which was concomitant with significant cytotoxic and activation marker expression. In human CRC xenograft mouse models, LGR5-targeting CAR-T cells eradicated tumors at doses as low as 800,000 CAR^+ cells, and were capable of significantly inhibiting advanced tumor growth following delayed administration. Robust CAR-T cell-mediated immunological protection was observed in rechallenge experiments, in which secondary tumor growth was undetectable in mice which had tumors rejected following previous CAR-T cell administration. LGR5 protein and mRNA expression was also detected in a diverse range of cancer families, including ovarian, brain, liver and stomach, expanding upon the clinical indications with which LGR5-targeting CAR-T cells may be harnessed. These results contribute to a preclinical body of work that culminated in a Phase I/IIa clinical trial in metastatic colorectal cancer patients, which was approved for initiation by the FDA and commenced in 2023 (NCT05759728).

#0057 Ibrutinib improves chimeric antigen receptor T cell control of leukemia by inhibiting myeloid-derived suppressor cells.

B. F. Frost[1], O. Shestova[2], F. Shen[2], C. Sharpe[3], J. C. Byrd[3], S. I. Gill[2];
[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]Department of Medicine, University of Pennsylvania, Philadelphia, PA, [3]Department of Medicine, University of Cincinnati, Cincinnati, OH

Background: In patients with chronic lymphocytic leukemia (CLL), we and others have shown that the addition of the BTK inhibitor ibrutinib to CART cells increases the rates of durable complete responses. The mechanism for this remains unknown. Lymphodepletion (LD) is considered critical for CART cell therapy success, yet emergency myelopoiesis during recovery from LD may induce a surge of myeloid-derived suppressor cells (MDSC), particularly in patients with advanced cancer. BTK inhibition has been shown to inhibit MDSC function in vitro. We therefore hypothesized that administration of ibrutinib during and following LD could reduce MDSC-mediated suppression of CART cells and thereby improve CART cell outcomes.
Methods: To explore the effects of ibrutinib on human MDSCs, we engineered suppressive monocytes through *in vitro* culture of CD14+ cells in the presence of IL-6 and GM-CSF. We added ibrutinib to the culture on Days 0-4 and compared the ability of the monocytes to inhibit proliferation of human CAR-T cells. To model CLL treatment with CART in immunocompetent mice, we used the Em-*TCL1* adaptive transfer model of CLL. Mice were treated with ibrutinib (I), cyclophosphamide and fludarabine (FC), or ibrutinib + FC (FC+I). MDSCs were isolated from these mice for *in vitro* function studies. In subsequent experiments mice were also treated with syngeneic CART19 with or without FC or FC+I.
Results: *In vitro* generated human MDSC suppressed CART19 function, and this was prevented by pre-treatment of MDSC with ibrutinib. Myeloid cells from the spleens of CLL-bearing mice inhibited syngeneic CART19 function *ex vivo* regardless of treatment with FC or I alone, but myeloid cells harvested from CLL-bearing mice treated with FC+I lost suppressive function. Finally, mice treated with CART19 after a LD regimen resembling that in our recently reported clinical trial (FC+I) showed a survival advantage over all other groups.
Conclusions: BTK inhibition with ibrutinib prevents myeloid cell suppression of CART cells *in vitro* in human and murine systems. When combined with lymphodepleting chemotherapy (FC), ibrutinib enhances CART cell control of CLL *in vivo*, possibly by preventing MDSC-mediated suppression of CART cells.

#0058 Immunocytokines with specificity for invariant region of CAR molecules enhance effector function of multiple CAR T cell therapies.

J. T. Keane, O. K. Dagher, F. Liu, **A. D. Posey, Jr.**;
University of Pennsylvania, Philadelphia, PA

The effector functions of CAR T cells can be enhanced through delivery of immunostimulatory cytokines, such as IL-12, IL-18, or IL-23. However, systemic delivery of recombinant cytokines or paracrine secretion by CAR T cells can elicit toxicities due to non-specific targeting of the cytokines. Here, we designed immunocytokines with antibodies specific for the invariant linker peptides that join variable domains in the CAR scFv and immunostimulatory cytokines. The immunocytokines were capable of targeting CAR molecules agnostic of target antigen, demonstrating broad applicability without the need for further genetic engineering of CAR therapies, such as co-expression of a surrogate molecule (tEGFR, etc.). The addition of immunocytokines enhanced CAR T cell cytolytic activity and secretion of type I cytokines, even at low concentrations of immunocytokine. In a stringent Nalm6 xenograft model, the addition of immunocytokines delivering IL-12 enhanced the anti-tumor activity of anti-CD19 CAR T cells and overall survival compared to controls of antibody alone or PBS. This technological development presents the opportunity to specifically enhance the activity of multiple CAR T cell therapies in the absence of non-specific toxicities.

#0059 Triple negative breast cancer (TNBC) targeting CAR-T cell constructs with phage display-derived peptides.

M. G. Khodary[1], A. W. Yirsaw[1], Y. A. Elsobky[2], R. Gurung[1], J. Jaynes[1], T. Samuel[1], M. Sandey[3], D. Bedi[1];
[1]Tuskegee University, Tuskegee, AL, [2]University of Sadat City, Sadat City, Egypt, [3]Auburn University, Auburn, AL

Introduction: Triple Negative Breast Cancer (TNBC) poses treatment challenges due to the absence of effective targeted therapies. CAR-T cell therapy, successful in hematological cancers, is now being investigated for solid tumors. Finding new CAR-T targets is vital to overcome TNBC's therapeutic constraints.
Methods: In this study, a Biopanning phage display strategy employing a library of random peptides was utilized to identify potential targets for CAR-T cell therapy against TNBC. Through this approach, Heat Shock Protein 60 (HSP60) emerged as a promising candidate due to its binding affinity to the selected phage clones. Subsequent validation of HSP60 surface expression on TNBC cell lines in comparison to normal cells was conducted using flow cytometry. Concurrently, patient survival data were gathered and analyzed to evaluate the clinical significance of HSP60 expression in TNBC. The identified peptides demonstrating high specificity and affinity for HSP60 on the surface of TNBC cells were chosen for the development of a third-generation CAR-T model, incorporating various optimizations and innovations.
Results: The Biopanning strategy successfully identified HSP60 as a prominent target for CAR-T cell therapy in TNBC. Flow cytometry analysis confirmed significantly elevated surface expression of HSP60 on TNBC cell lines compared to their normal counterparts, substantiating its potential as an accessible antigen for targeted therapy. Patient survival analysis linked elevated HSP60 levels with poorer prognosis in TNBC, highlighting the protein's clinical relevance. Peptides showing high specificity and binding to TNBC's HSP60 were integrated into a meticulously engineered third-gen CAR-T cell model. This design aimed to boost the CAR-T's precision in targeting and eliminating HSP60-expressing TNBC cells. Iterative optimizations ensured the construct's accuracy, laying the groundwork for a potent, tailored TNBC immunotherapy.
Discussion: The discovery of HSP60 as a prime target for CAR-T cell therapy in TNBC is a pivotal advancement. Its distinct presence on TNBC cell surfaces, confirmed via flow cytometry, highlights its suitability for targeted immunotherapy. The correlation between elevated HSP60 levels and poorer prognosis in TNBC patients underscores its value as both a biomarker and a therapeutic focus. The peptides' exceptional specificity and strong binding to HSP60 validate their use in crafting a third-generation CAR-T cell model. Their integration and careful refinements in CAR-T design aim to optimize efficacy while reducing off-target effects, laying a robust foundation for tailored TNBC immunotherapy. Preclinical evaluations are imperative to thoroughly assess the safety and effectiveness of this innovative CAR-T approach.

#0060 Functional mapping of glioblastoma recurrence reveals targetable dependencies in an axonal guidance pathway in highly invasive brain cancers.

S. K. Singh[1], C. Chokshi[1], V. Shaikh[1], B. Brakel[1], A. Anand[1], C. Venugopal[1], T. Kislinger[2], K. Henry[3], M. Rossotti[3], K. Brown[4], J. Lazo[5], J. Moffat[4]; [1]Centre for Discovery in Cancer Research, McMaster University, Hamilton, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]NRC, Ottawa, ON, Canada, [4]Hospital for Sick Children Research Institute, Toronto, ON, Canada, [5]University of Virginia, Charlottesville, VA

Resistance to genotoxic therapies and tumor recurrence are hallmarks of glioblastoma (GBM), an aggressive brain tumor. Here, we explore the functional drivers of post-treatment recurrent GBM. By conducting genome-wide CRISPR-Cas9 screens in patient-derived GBM models, we uncover distinct genetic dependencies in recurrent tumor cells that were absent in their patient-matched primary predecessors, accompanied by increased mutational burden and differential transcript and protein expression. These analyses map a multilayered genetic response to drive tumor recurrence, identifying protein tyrosine phosphatase 4A2 (*PTP4A2)* as a novel modulator of self-renewal, proliferation and tumorigenicity at GBM recurrence. Genetic perturbation or small molecule inhibition of PTP4A2 represses axon guidance activity through a dephosphorylation axis with roundabout guidance receptor 1 (ROBO1), exploiting a functional dependency on ROBO signaling. Importantly, engineered anti-ROBO1 single-domain antibodies also mimic effects of PTP4A2 inhibition. Since a pan-PTP4A inhibitor was limited by poor penetrance across the blood brain barrier (BBB) *in vivo*, a second-generation chimeric antigen receptor (CAR)-T cell therapy was engineered against ROBO1 that elicits specific and potent anti-tumor responses *in vivo*. A single dose of anti-ROBO1 CAR-T cells doubles median survival in patient-derived xenograft (PDX) models of recurrent glioblastoma, and also eradicates tumors in around 50% of mice engrafted with PDX models of lung-to-brain metastases and pediatric relapsed medulloblastoma. We conclude that functional reprogramming drives tumorigenicity and dependence on a multi-targetable PTP4A-ROBO1 signaling axis at GBM recurrence, with potential in other malignant brain tumors.

#0061 A novel immunotherapy for metastatic prostate cancer: A monoclonal antibody that can bind both STEAP1 and STEAP2.

M. Sheng[1], G. Thillainadesan[2], A. Sparkes[2], B. Su[1], E. Matus[1], J. Wright[1], S. Liu[2], J. Gariepy[2], H. S. Leong[2];
[1]University of Toronto, Toronto, ON, Canada, [2]Sunnybrook Research Institute, Toronto, ON, Canada

Prostate cancer (PCa) is the second most prevalent cancer among males, and the 5-year survival rate for patients with metastatic PCa (mPCa) is ~30%. Although significant progress has been made in improving survival in mPCa patients, many of these patients experience relapse or systemic toxicities. Protein expression of prostate-specific membrane antigen (PSMA), a common PCa antigen often targeted in PCa therapy, is unfortunately lost in the later stages of mPCa. In contrast, six transmembrane epithelial antigen of the prostate 1 and 2 (STEAP1 and STEAP2) are both overexpressed in most PCa compared to normal and vital organs and has emerged as a next-generation target in mPCa.
We hypothesize that an antibody that binds to both STEAP1 and STEAP2 via their second extracellular domain (60% homology) could be useful therapeutically. Using an immunogen of this second extracellular domain, we raised several antibody clones that appear to have an affinity towards both STEAP1 and STEAP2 (STEAP1/2). The specificity and affinity of these antibody clones were successfully determined by immunofluorescence, flow cytometry and ELISA. Immunofluorescence results in PCa cell lines and those that overexpress STEAP1 and STEAP2 demonstrate the potential specificity of one clone for human STEAP1 and STEAP2. In addition, ELISA data revealed that the binding affinity of this clone to STEAP1 and STEAP2 is in the low nanomolar and low micromolar range, respectively. This monoclonal STEAP1/2 antibody has been sequenced and will become the basis for future development of immunotherapies thus expanding the therapeutic armamentarium for mPCa.

#0062 Intra-tumor persistence of activated anti-mesothelin hYP218 CAR T cells is associated with increased efficacy in gastric and colorectal cancers.

S. A. Mir, A. Venugopalan, J. Zhang, M. Khanal, C. Stathopoulou, M. Sengupta, Q. Jiang, R. Hassan;
National Institutes of Health (NIH), Bethesda, MD

Purpose: Patients with gastric and colorectal cancers that have progressed after standard therapies have poor prognosis. Given the high expression of mesothelin in these tumor types, we examined the potential utility of the anti-mesothelin hYP218 CAR T cells to treat these cancers.
Experimental Design: Cell surface mesothelin expression in a panel of gastric and colorectal cancer cell-lines was analyzed using flow cytometry. *In vitro* efficacy of hYP218 CAR T cells against these cell lines was evaluated using cytotoxicity and cytokine release assays. *In vivo* efficacy of hYP218 CAR T cells was studied using gastric (HGC27) and colorectal (SW48) tumor xenografts in NSG mice. NSG mice were injected with 1×10^6 cancer cells and the tumors were allowed to grow until they reached a volume of 80-100mm³, after which the mice were treated with either 5×10^6 hYP218 CAR T cells, 5×10^6 untransduced T cells, or saline and monitored over time. Persistence of CAR T cells in the tumor was evaluated over time and expression of activation and exhaustion markers were studied.
Results: hYP218 CAR T cells demonstrated strong cytotoxic activity against mesothelin positive gastric and colorectal cancer cell lines and exhibited increased pro-inflammatory cytokine production. In both the HGC27 and SW48 tumor models hYP218 CAR T cells demonstrated significant reduction in tumor volume and overall survival compared to mice treated with untransduced T cells or saline. CAR T cells isolated from tumors of both the xenograft models, at day 40 after treatment, displayed higher expression levels of activation markers CD39 and CD69 when compared to the infused product. Furthermore, a concomitant elevation in the levels of effector cytokines, TNF-α and IFN-γ, was detected in the blood of treated mice demonstrating the functional capacity of the CAR T cells to not only persist but also to maintain an activated state.
Conclusions: hYP218 CAR T cells show anti-tumor efficacy against gastric and colorectal tumor xenografts due to increased accumulation of activated CAR T cells in the tumor and warrants further investigation for treatment of patients with these cancers.

IMMUNOLOGY: Biomarkers, Immune Monitoring, and Immune Assays

#0065 Differential impacts of PD-L1 expression in tumor vs. stroma on survival in esophageal squamous cell carcinoma.

Tomohiro Murakami[1], Satoru Furuhashi[1], Yuuki Sakai[1], Kenichi Sekimori[1], Ryoma Haneda[1], Eisuke Booka[1], Tomohiro Matsumoto[1], Hirotoshi Kikuchi[1], Yoshihiro Hiramatsu[2], Hiroya Takeuchi[1]

[1]Department of Surgery, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan,[2]Department of Surgery, Perioperative Functioning Care & Support, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan

Background: Esophageal squamous cell carcinoma (ESCC) has high incidence and recurrence rates, particularly in advanced stages. While the combined positive score (CPS) and tumor proportional score (TPS) are standard benchmarks for PD-L1 assessment in ESCCs, they face challenges such as reliance on subjective human interpretation and the uncertain clinical significance of strong staining intensities. Our study utilizes H-scores for PD-L1 expression and separates analysis of tumor and stroma, providing additional layers of information that complement current methods and contribute to a more comprehensive understanding of the role of PD-L1 in ESCC.
Methods: This retrospective single-center cohort analysis involved 194 cases of ESCC who underwent surgical resection. We performed a comprehensive evaluation of PD-L1 expression within the tumor and stroma using whole slide images (WSI). QuPath image analysis software was used to classify regions as tumor or stroma and quantify the PD-L1 expression H-score.
Results: Using optimal H-score cutoffs determined from the minimum P-value method, the Kaplan-Meier survival analysis showed that higher PD-L1 expression was significantly linked with better post-operative survival across all compartments. This correlation was most pronounced in the stroma ($P<0.001$). However, in multivariate Cox regression analysis, only high tumoral PD-L1 expression emerged as an independent predictor of favorable prognosis (HR=0.47, 95% CI: 0.27-0.81, $P=0.007$). The non-significant contribution of stromal PD-L1 in this model could be attributed to its association with advanced pT and pN stages, and the presence of lymphatic and venous invasion ($P<0.001$, respectively). Interestingly, stromal PD-L1 expression was associated with a longer duration of cytotoxic chemotherapy (cutoff 8 months, Median H-score 98.28 vs 55.24, $P=0.026$), but no significant correlation was observed with the duration of immune checkpoint inhibitor treatment.
Conclusions: The study underscores the complex role of PD-L1 in ESCC, with tumoral PD-L1 expression emerging as an independent prognostic factor, and stromal PD-L1 expression found to be related with tumor progression and the duration of cytotoxic chemotherapy response.

#0066 A new mechanism of tumor immune escape: TCF19 promotes the development of novel terminally exhausted T cells through E2F and MYC transcription family.

F. Wang, N. Dong, C. Zhang;
The Seventh Affiliated Hospital of Sun Yat-sen University, Shen Zhen, China

Introduction: ICB (immune checkpoint blocking) has been a promising therapy in cancer treatment, but there are still some patients do not response to this therapy. And it is well known that the majority cells reactivated to ICB are TCF1+ precursor exhausted T cells. Thus, studying the formation and heterogeneity of exhausted T cells are very necessary for improving the efficacy of ICB therapy. In this research, we identified a new population as TCF19+PD1+TIM3+ exhausted CD8+ T cells, which blocked the responds to ICB therapy.
Methods: We collected single cell sequencing data, including colorectal cancer, gastric cancer, melanoma, and lung cancer, and drew tumor immune cells map through cluster analysis. Then using bioinformatics tools CytoTRACE. T and CCAT. A to calculate the differentiation of exhausted T cell populations, which discovered a new subset of highly proliferative and poorly differentiated terminal exhausted T cells. Subsequently, the existence of this group of cells was verified through in vitro experiments, and their formation mechanism and correlation with immunotherapy were further studied.
Results: We utilized CytoTRACE.T and CCAT.A to predict differentiation states of terminally exhausted T cells. Then GEO and KEGG pathway gene set enrichment analysis were used. After analyzing, we found out that there was a subset of cells in terminally exhausted T cells defined as TCF19+PD1+TIM3+ Tex cells, which presented low differentiated and high proliferative potential.Then we performed multiple immunofluorescence staining and flow cytometry to verified the existence of TCF19+PD1+TIM3+ Tex cells in vitro. Clarifing the generation of these cell subset through regulating the expression of E2F and MYC transcription factor families.By collecting pathological sections of patients with immunotherapy information, we found that the amount of TCF19+PD1+TIM3+ Tex cells was inversely proportional to the efficacy of ICB, through immunofluorescence staining and immunohistochemical analysis as well as organoid models cocultured with T cells.
Conclusion: In this research, we found a new subpopulation of terminal Tex cells, which showed high proliferation and low differentiation. For cells, TCF19 mediated the generation of stemness terminal Tex cells may through regulating the expression of E2F and MYC. Finally, we discovered that the existence of TCF19+PD1+TIM3+ Tex cells can predict the efficacy of ICB, that the more TCF19+PD1+TIM3+ Tex cells contained, the less efficacy of ICB in patients.This finding may provide a new research direction for immunotherapy. Thus, more attention should be paid to this new cell subset.

#0067 Predicting colorectal patient prognoses by functional characterisation of heterogeneous cell types and their spatial interaction using a new technique: Whole slide imaging mass cytometry.

R. M. Costello[1], S. Fenton[1], H. McGuire[2], L. Lim[3], D. Howell[3], Q. Raza[3], J. Chwee[4], R. Kemp[1];
[1]University of Otago, Dunedin, New Zealand, [2]University of Sydney, Sydney, Australia, [3]Standard BioTools Canada Inc., Toronto, ON, Canada, [4]Standard Biotools Canada Inc., Markham, ON, Canada

Immunotherapies stimulate T cell function in the tumor microenvironment (TME). CD3+ and CD8+ T cell infiltration can predict disease recurrence in colorectal cancer (CRC) patients and has been validated as Immunoscore® (IS). The TME comprises multiple heterogeneous populations of immune cells, including T cells and cancer-associated fibroblasts (CAFs); CRC tumors are also morphologically diverse. Standard BioTools™ (SBI) has developed a novel whole slide Imaging Mass Cytometry™ technique that allows complete analysis of cell population heterogeneity in the TME using >40 markers.
We hypothesised there are multiple heterogeneous subtypes of CAFs within CRC tumors and that they modulate T cell infiltration and patient outcome. In collaboration with SBI, we studied a cohort of CRC patients stratified based on T cell infiltrate and disease recurrence. We identified multiple CAF populations that interact with tumor-infiltrating T cell populations.
Slides from 10 CRC patients with high or low CD3+CD8+ T cell infiltrate (IS) were stained with a panel encompassing markers for CAF and T cell heterogeneity, function, and metabolism. Slides were imaged using the Hyperion XTi™ Imaging System at SBI. Using a scan mode called Preview Mode, the whole slide was imaged in minutes to identify CAF and T cell phenotypic regions of interest. Next, the same slide was imaged at 1 µm resolution using Cell Mode (CM). Finally, for each sample, an additional serial section was imaged using a slightly lower resolution called Tissue Mode (TM). TM allowed us to image the samples in several hours instead of days while capturing the full heterogeneity of the entire tissue sample. We used clustering to identify phenotype clusters and neighbourhood analysis to study spatial enrichment. We also compared results between CM and TM.
We report: Identification of heterogeneous CAF subtypes in CRC patients with high or low IS; determination of CAF populations that spatially interact with T cells in patients with high or low IS; and examination of consistent spatial interactions between CAF and T cells in CRC, and whether these interactions differ in patients with high or low IS. TM revealed several heterogeneous cellular populations that differed between patients with high or low IS; importantly, low IS tumors had more podoplanin+αSMA+ CAF populations and fewer podoplanin+αSMA- cell populations compared with high IS tumors. High IS tumors had more PD-1+CD8+ T cells compared with low IS tumors; these PD-1+CD8+ T cells spatially interacted with podoplanin+αSMA- CAF populations in high IS tumors. CAF-PD-1+CD8+ T cell interactions were absent from low IS tumors. Thus, CAF-PD-1+CD8+ T cell interactions are important in CRC patients with high IS, and these cellular interactions require further investigation.

#0068 Imaging Endothelial PD-L1 expression with ultrasound molecular imaging to stratify immune checkpoint inhibitor responders.

A. Natarajan, F. Tabesh, M. Bataghva, R. Paulmurugan, A. N. El Kaffas;
Stanford University School of Medicine, Palo Alto, CA

Immune checkpoint blockade therapies (ICTs) have revolutionized oncology through substantial and lasting treatment outcomes, but only in 15-20% of patients. Non-invasive diagnostic tools to select patients that are most likely to respond to ICT and guide treatment regimens, and thus minimize toxicities to non-responder patients, are in high demand. Program death-1 ligand (PD-L1) marker evaluation in the tumor vasculature and tumor microenvironment is an essential criterion for identifying a suitable patient for PD-L1 based ICT, and it also serves as a prognostic marker in tumor response evaluation. Ultrasound molecular imaging (USMI) is an up-and-coming non-invasive imaging modality that enables longitudinal characterization of endothelial-specific markers. We are developing USMI methods to image immune markers expressed specifically on endothelial cells (EC) of tumors as a decision-support tool for guiding ICT strategies. In this work, we demonstrate for the first time the potential of imaging EC-specific immunosuppressive markers such as PD-L1 and investigate whether it can act as a marker for predicting ICT response. Target-ready microbubble (MB) was used (Trust Bio-sonics, Taiwan) to generate PD-L1 antibody (Ab) linked MBs (TMBs). DSPE-PEG was functionalized to anti-PD-L1 Ab or isotype-Ab (control) to generate stable TMBs (~5×10^7 MBs/mL) to target PD-L1 expressing ECs *in vivo*. We studied the treatment effect of anti-PD-L1-Ab and isotype-Ab using a syngeneic CT-26 tumor in mice and demonstrated the targeting potency of TMB or iso-Ab-MB (NMB). US imaging was performed using Vevo 2100 high-frequency US system with M250 transducer to evaluate and quantify the differentially targeted enhancement parameter (dTE). We observed that TMBs bound PD-L1 expressing ECs in vivo, with high and low enhancement for TMB and NMB, respectively, in tumors validated by dTE quantification through characterization of the slower washout kinetics. Furthermore, TMBs exhibited increased tumor retention and prolonged binding with average differential targeted enhancement values (dTE) (+/- SD) of 5.2 ± 7.4 for TMBs compared to 2.4 ± 3.9 for NMBs (p=0.14). Preliminary results of USMI (dTE values of TMBs) indicate that PD-L1-treated mice showed a higher response (4.5 ± 5.2; n=9) to the treatment group than control mice that did not receive Ab (1.4 ± 0.8; n=4). The tumor growth rate for the treated mice group was 5.4 -fold retarded compared to the control group which correlated with USMI dTE values. The USMI signals correlated with IHC performed on tumor tissue ex vivo from the respective mouse used for US imaging. Overall, our pre-clinical study suggests that USMI using TMBs may contribute to non-invasive assessment of IC expression on tumor ECs, and that it may serve as a predictive biomarker of ICT response. This novel TMB agent could be a game changer for CE USMI-based cancer prognosis in ICB therapy.

#0069 Versican proteolysis signature as a potential immune infiltration biomarker for colorectal cancer.

D. Buckalew, S. Kraus, K. Johnson, C. A. Pasch, D. A. Deming;
University of Wisconsin - Madison, Madison, WI

Background: A subset of patients with mismatch repair proficient colorectal cancers (CRCs) benefit from immunotherapies, though currently no markers predict which cancers are likely to respond. Our group demonstrated that versican (VCAN), an immunoregulatory tumor matrix proteoglycan, when proteolyzed to an immunostimulatory fragment called versikine (Vkine) results in enhanced CD8+ T cell infiltration across multiple cancers. Here we evaluate if a RNA expression signature of VCAN proteolysis can identify CRCs with an immune cell infiltrated phenotype.
Methods: The TCGA PanCancer Atlas colorectal adenocarcinoma dataset (594 patients (pts)) was divided into cohorts based on RNA expression Z-scores for VCAN, TIMP3, and ADAMTS4. The VCAN proteolytic predominant (VPP) cohort (Z-score VCAN >0, TIMP3 <0.5, ADAMST4 >0) was compared to the VCAN proteolytic weak (VPW) cohort (Z-score VCAN >0, TIMP3 >0.5, ADAMST4 >0). Differences in clinical characteristics, mutation profile, differential gene expression, and gene set enrichment analysis (GSEA) were evaluated.
Results: The VPP group consisted of 42 pts (20:22 female: male, median age: 68.5 years old). The VPW group consisted of 29 pts (12:17 female: male, median age: 64 years old). The two groups had no significant difference between stages of disease. There was a significant increase in the mutation count in the VPP cohort (VPP median=115.5, VPW median=91, p=0.045). The MSI MANTIS scores were not different between the cohorts (VPP median=0.35, VPW median=0.37, p=0.325). The VPP cohort was enriched for gene sets associated with immune cell infiltration (interferon gamma response (FDR q<0.001), inflammatory response (FDR q<0.001), complement (FDR q<0.001), TNFA signaling via NKFB (FDR q<0.001), IL2 STAT5 signaling (FDR q<0.001), and IL6 JAK STAT3 signaling (FDR q<0.001). The VPW cohort was enriched for gene sets involving cell proliferation (WNT beta catenin signaling (FDR q<0.214), hedgehog signaling (FDR q<0.190), and KRAS signaling DN (q<0.159). Specifically, the VPP group demonstrated enhanced expression of CD274 (PD-L1; log2FC=1.41, p<0.001), LAG3(log2FC=1.41, p<0.001), PDF1(log2FC=1.34, p<0.001), CD8A(log2FC=1.25, p<0.001), CXCL9(log2FC=1.19, p=0.001), CXCL10(log2FC=1.44, p=0.001), IL6(log2FC=2.23, p<0.001), and CD19(log2FC=1.26, p<0.001).
Conclusion: VPP expression signature correlates with immune infiltration based on RNA expression and deserves further investigation to predict response to immunotherapies in CRC as well as other cancer types.

#0070 Unlocking the potential of the T-cell receptor in prostate cancer.

E. N. Glud[1], J. H. Fredsoe[1], I. K. Nordentoft[1], A. Kjar[1], M. Rusan[1], B. E. Laursen[2], B. G. Pedersen[1], N. J. Birkbark[1], L. Dyrskjot[1], M. Borre[1], K. D. Sorensen[1]; [1]Aarhus University Hospital, Aarhus, Denmark, [2]Aarhus University, Aarhus, Denmark

Introduction: Prostate cancer (PC) is the most commonly diagnosed cancer among western men, with its diagnosis and subsequent monitoring still heavily dependent on the prostate specific antigen (PSA) test. However, the prognostic accuracy remains poor, leading to overtreatment of patients with non-aggressive cancer and undertreatment of those with aggressive cancer in need of intervention. Malignant cells are subject to constant monitoring and elimination by T-cell lymphocytes recognizing cancer-specific antigens through the T-cell receptor (TCR). Consequently, to establish itself and progress, cancer must evade or modulate the surveillance mechanisms of the immune system. As cancer growth accelerates, immune evasion becomes more difficult, resulting in a more pronounced impact on the immune system. Recently, our research group documented the clinical value of tumor-infiltrating T-cells as markers of aggressive PC. Here, we hypothesize that this signal can also be found in circulating T-cells isolated from the blood and used as proxy for the antitumoral immune response in tissue.

Methods: This study utilizes a diverse and well-characterized cohort, encompassing 220 castration resistant PC patients (CRPC) with blood samples taken at the time of CRPC diagnosis, 30 newly diagnosed hormone-naïve PC patients, and 30 healthy male donors. For a deeper understanding of the mechanisms underlying the antitumoral immune response and its impact on disease progression, a subset of CRPC patients (n = 25) are TCR sequenced throughout their disease course and uniquely, the TCR repertoire of their metastatic biopsies is characterized.

Results: In an initial comparison of 8 CRPC patients and 8 age-matched healthy males, we observed that cancer patients had a higher proportion of hyper-expanded T-cell clones (P = 0.003; Fisher's exact test) and a less diverse TCR repertoire in blood. Furthermore, 86.5 % of hyper-expanded clones found in peripheral blood samples could also be found in malignant prostate tissue from matched CRPC patients, while overlap between patients was virtually non-existent

Conclusion: Our pilot study detected differences in the TCR repertoire between cancer patients and matched controls. The clones contributing most to this difference were concurrently found in malignant tissue indicating that the antitumoral immune response can indeed be detected in the periphery. Given these promising results, we are currently running the larger study described above to obtain a better understanding of the TCR repertoire and establish its prognostic potential in PC. While the findings showcased in this abstract exclusively stem from the pilot study, results for the full cohort will be presented at the conference.

#0071 Differential infiltration of key immune cell populations across malignancies varying by immunogenic potential and likelihood of response to immunotherapy.

A. A. Tarhini[1], I. Eljilany[1], S. Coleman[2], D. J. Hedges[3], M. McCarter[4], J. Carpten[5], H. Colman[2], A. Naqash[6], I. Puzanov[7], S. Arnold[8], M. Churchman[3], P. Hwu[1], W. S. Dalton[3], G. J. Weiner[9], A. Tan[2], J. R. Conejo-Garcia[10], P. C. Rodriguez[1];

[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]Huntsman Cancer Institute, Salt Lake City, UT, [3]Aster Insights, Tampa, FL, [4]University of Colorado Cancer Center, Denver, CO, [5]USC Norris Comprehensive Cancer Center, Los Angeles, CA, [6]Stephenson Cancer Center, Oklahoma City, OK, [7]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [8]Markey Cancer Center, Lexington, KY, [9]University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA, [10]Duke Cancer Institute, Durham, NC

Background: Emerging literature has identified key immune cell populations that appear to significantly impact immune activation or suppression in patients with cancer. We investigated candidate populations and their differential infiltration within tumors as estimated from mRNA co-expression levels of corresponding cellular markers.

Methods: We utilized clinical and transcriptomic data from patients with melanoma, urothelial, ovarian, and pancreatic carcinomas enrolled in the Total Cancer Care Protocol (NCT03977402) to which patients provided a written informed consent. We analyzed mRNA co-expression levels of biomarkers defining stem-like tumor-infiltrating lymphocytes (TILs) (TCF7, IL7R, CXCR5, CD28, and CD27), tissue-resident memory (TRM) T cells (CD69 and CD103), early dysfunctional T cells (PD1+, CCR5+, TCF7+, TIM3-), late dysfunctional T cells (PD1+, CD38+, CD39+, CD101+, TIM3+), activated-potentially anti-tumor (APA) T cells (PD1+, CD27+, CD28+, CD137+, GITR+), and Butyrophilin 3 A (BTN3A) isoforms (BTN3A1, BTN3A2, BTN3A3). Mann-Whitney U or Kruskal-Wallis H tests were used to compare median gene expression signature scores between immunotherapy (IO) responders (> 2 years survival) and non-responders (< 2 years survival). Cox regression was used to assess 2-year survival outcomes following immunotherapy.

Results: We found a significant difference in the estimated infiltration of APA T-cells in melanoma ($P = 4.67 \times 10^{-12}$ and $P = 5.80 \times 10^{-12}$) and in urothelial carcinoma ($P = 1.86 \times 10^{-09}$ and $P = 1.38 \times 10^{-09}$) as compared to ovarian and pancreatic tumors, respectively. There was less TRM T-cell infiltration in ovarian compared to melanoma ($P = 2.23 \times 10^{-8}$), urothelial ($P = 3.86 \times 10^{-28}$) and pancreatic ($P = 7.85 \times 10^{-9}$). A similar trend was seen with stem-like T-cells, early dysfunctional T cells, and late dysfunctional T cells. Differences in the expression of BTN3A isoforms were less apparent between the different tumors, with a trend towards higher expression in melanoma. In melanoma, a higher density of stem-like TIL, TRM, early dysfunctional T cells, late dysfunctional T cells, activated-potentially anti-tumor T cells, and BTN3A isoforms were associated with improved survival ($P = 0.0075$, 0.00059, 0.013, 0.005, 0.0016 and 0.041, respectively). A higher density of stem-like TIL was associated with improved survival in the urothelial cohort ($P = 0.028$). TRM gene signature had the best AUCROC as a moderate predictor of survival in our melanoma cohort (AUROC = 0.65); Examining the 6 signatures in public datasets of IO treated melanoma patients, they were similarly predictive of survival (AUROC of 0.61 - 0.64).

Conclusions: Our results support a higher infiltration of key cellular elements related to immune activation within immunogenic versus non-immunogenic tumors supporting a central role in anti-tumor immune response.

#0072 A spatial interactomics approach reveals interplay between the tumor microenvironment and T cell activation.

D. Eden, J. Vennberg, T. Busgen, **D. Raykova**, A. Zieba-Wicher;
Navinci Diagnostics AB, Uppsala, Sweden

Background: T cells play a fundamental role in immune response to tumors. However, the tumor microenvironment (TME) - a complex network of cells, signaling molecules, and extracellular matrix components - employs various strategies to evade immune surveillance and suppress T cell activity. Among the many molecular interactions taking place in the TME, the role of CD8/MHC I, LAG3/MHC II and PD1/PDL1 is pivotal in modulating anti-cancer response and the escape routes that cancer in turn uses to withstand immune defense. LAG3/MHC II and PD1/PDL1 interactions are inhibitory, causing T cell dysfunction and exhaustion, while the CD8/MHC I interaction is essential for initiating an effective anti-tumor response. Here, we used a cutting-edge *in situ* proximity ligation strategy combined with immunofluorescence (IF) to reveal these key interactions and TME biomarkers in hepatocellular carcinoma and Hodgkin lymphoma. Since the method does not compromise the structural integrity of tissues, communication between proteins can be studied in their native milieu.
Method: Protein-protein interactions (PPIs) were detected with the NaveniFlex Tissue Atto647N kit in human FFPE tissues according to the manufacturer's protocol. This technique can detect proteins located within interaction range (<40 nm) via oligonucleotide-antibody conjugates that create amplified fluorescent signal. Parallel IF co-staining for α-fetoprotein, Ki67, CD30 and CD3 was performed during the Naveni® detection step. Slides were mounted and imaged on the Olympus V200 automated scanner.
Results: Tumor cells were identified by α-fetoprotein/Ki67 (hepatocellular carcinoma) or CD30 (Reed-Sternberg in Hodgkin lymphoma) IF staining, and tumor-infiltrating lymphocytes were visualized by CD3 staining. With the help of the Naveni® assay, we observed abundant interaction between CD8/ MHC I in hepatocellular carcinoma and Hodgkin lymphoma. Suppressive immune checkpoint interactions such as LAG3/MHC II and PD1/PDL1 were also detected. In the case of Hodgkin lymphoma, the CD8/MHC I, LAG3/MHC II and PD1/PDL1 interactions were largely seen in the same areas, and specifically between T cells and Reed-Sternberg cells, indicating a crosstalk between the TME and the immune landscape in the cancer tissues.
Conclusion: The interactomics approach, employing *in situ* proximity ligation for observing protein function as opposed to mere expression, allows the detection of key PPIs in the TME. Understanding the intricate crosstalk between them is crucial in developing effective immunotherapies. Targeting these pathways simultaneously or in combination, such as using immune checkpoint inhibitors against PD1/PDL1 while exploring strategies to modulate LAG3/MHC II and CD8/MHC I interactions, holds promise in reinvigorating T cell responses against cancer and improving the efficacy of immunotherapies within the complex landscape of the TME.

#0074 Exploring the expression of cancer-intrinsic PD1 in osteosarcoma cells: A comprehensive proteomic analysis of its functional landscape.

K. J. Dziubek[1], J. Faktor[1], T. Hupp[2], M. Parys[2], S. Kote[1];
[1]University of Gdansk, Gdansk, Poland, [2]University of Edinburgh, Edinburgh, United Kingdom

Cancer treatment was revolutionized by immune checkpoint inhibitors (ICIs) targeting the PD1/PDL1 axis - a brake to the immune system. Despite remarkable success, some patients do not respond to therapy or rapidly deteriorate due to an unclear mechanism. As reported for several types of tumors, PD1 receptor is not solely expressed on immune cells but also on cancer cells. Depending on the tumor type, it may act either as a suppressor or a tumor promoter. The limited response to ICIs was also reported in osteosarcoma (OSA), the most common type of bone cancer, mostly affecting children and young adults. With no significant improvement in therapy over the past 30 years, there is an urgent need for therapeutic advancement. This study aimed to determine if PD1 protein is expressed in OSA and whether it has a functional role, potentially affecting the response to ICIs. Strikingly, our results revealed both surface and intracellular PD1 expression in U2OS osteosarcoma cells, confirmed by Western Blot, flow cytometry and immunofluorescence analyses. siRNA-mediated *PDCD1* gene silencing significantly increased cell migration and viability in scratch and viability assays. LC-MS-based global proteomics showed that *PDCD1* knockdown markedly affects U2OS cells' proteomic landscape compared to the control. To dissect PD1 receptor downstream signaling effects, we subjected the identified proteins to GO and GSEA large-scale data interpretation tools. The results strongly suggested that *PDCD1* silencing leads to the enrichment of proteins involved in cell growth, migration and motility, corresponding to the cellular effects we initially observed. Importantly, the analysis clearly indicated positive regulation of MAPK cascade in cells with perturbed PD1 expression, aligning with PD1 mediated MAPK regulation in T cells. To reveal the mechanism underlying PD1 signaling, we focused on proteins with significantly changed expression in response to the knockdown. Using the STRING database, we created their interacting network, revealing that numerous proteins are closely related, and the majority of them are phosphoproteins, indicating significance in cellular signaling. Remarkably, many of the STRING-analyzed proteins belong to intersecting pathways, such as AKT1S1 and LAMTOR proteins, the critical components for mTORC1 signaling, or selected members of the Src family kinases along with their negative regulator CSK. In summary, we report previously undiscovered functional expression of PD1 in OSA cells, providing insights into the landscape of PD1 downstream signaling. Our studies indicate the role of PD1 in regulating cell growth, proliferation, and motility, suggesting osteosarcoma-expressed PD1 as a tumor suppressor. Further studies are urgently needed to investigate its therapeutic significance and explore if we could make ICIs more effective to treat osteosarcoma.

#0075 Luciferase reporter cell lines allow simultaneous incorporation of tumor cells, innate immune cells, and adaptive immune cells for in-depth immune checkpoint studies.

H. Chang, A. C. Walker, J. G. Foulke, L. Chen, F. Tian, Z. Gu;
American Type Culture Collection (ATCC), Manassas, VA

Despite the considerable success of immune checkpoint therapies targeting T cells, a sizable proportion of patients experience resistance or relapse due to the immunosuppressive nature of the tumor microenvironment. Myeloid cells, a major component that suppresses effector lymphocytes, have emerged as an alternative and promising therapeutic target. However, there is a deep lack of widely accessible immunological models capable of representing the intricate three-way interaction between tumor cells, T cells, and myeloid cells. To address this need, we conducted a comprehensive protein profiling of human tumor and immune cell lines available at ATCC for various established and novel immune checkpoint molecules. Cell lines with high endogenous expression of the immune checkpoint proteins, such as programmed death-ligand 1 and 2 (PD-L1 and PD-L2), cluster of differentiation 155 (CD155), B7 homolog 3 (B7-H3), sialic acid-binding Ig-like lectin 10 (Siglec-10), or signal-regulatory protein alpha (SIRPα), were selected and constructed into luciferase reporter cell lines. For tumor reporter cell lines, a gamma interferon activation site (GAS) response element was placed upstream of the luciferase gene in the lentiviral vector, enabling the activation of the JAK-STAT signaling pathway within tumor cells to induce luciferase expression. In myeloid reporter cell lines, a nuclear factor kappa B (NF-κB) response element replaced GAS to monitor the activation of the NF-κB signaling pathway. In the presence of corresponding immune checkpoint inhibitors that enhance T cell-mediated anti-tumor activity, these reporter cell lines produce a bioluminescent signal based on luciferase expression. This signal can be easily detected and quantified to assess the efficacy of the inhibitor. Our data revealed that bioluminescence intensity in the tumor and myeloid reporter cell lines increased by >100-fold in a dose-dependent manner in response to interferon gamma (IFN-γ) and tumor necrosis factor alpha (TNF-α) stimulation, respectively, and by >50-fold in response to the conditioned media collected from activated primary T cells. Furthermore, in co-culture assays involving various combinations of immune cell and tumor cell types with corresponding immune checkpoint inhibitors, these reporter cell lines demonstrated a significant increase in bioluminescence intensity. In conclusion, these newly established luciferase reporter cell lines offer an excellent ex vivo model for cancer immunotherapy. These cell lines naturally express immune checkpoint proteins, enabling the sensitive and reproducible monitoring of combinatorial responses from various immune cell types.

#0076 Correlated multi-scale 3D optical microscopy of tumor tissues.

J. Zheng, S.-Y. Lee;
University of Illinois at Chicago, Chicago, IL

Three-dimensional (3D) optical microscopy in combination with advanced tissue clearing methods permits the interrogation of intact large-sized tumor tissues. There are many optical microscopy methods (e.g. light-sheet and confocal microscopy) offering 3D tumor images at varying levels of spatial resolution (e.g. organ, tissue, cell, and molecule level). However, it is a challenge to correlatively integrate various resolution 3D images obtained by different optical microscopy of tumor tissue. In this project, we developed a correlated multi-scale 3D optical microscopy method that enables the acquisition of macroscopic to microscopic spatial information from a single tumor tissue in 3D. Firstly, we used light sheet microscopy to image a whole large-sized, cleared tumor tissue and analyzed the results to identify regions of interests (ROIs). After defining ROIs in the 3D whole tumor image, we added a UV-activatable visible dye, spiropyran, in the agarose gel surrounding the cleared tumor and exposed the sample to a UV light sheet horizontally at the height (z-axis) of the tumor where the ROIs present. The activated dye showed ‘purple’ colored lines in the agarose gel and we physically marked the gel along the visible colored lines. We further sectioned the tumor at the ROI positions using a vibratome after reversing tissue clearing process. After immunofluorescence staining and aqueous-based tissue clearing, confocal microscopy allowed the localization of various cell types in the ROIs of tumor macrosections. To validate the method for multi-scale evaluation of cancer immunotherapy, we tested it with control and DMXAA-treated mouse mammary tumor tissues. We successfully acquired the 3D images of whole tumors by capturing autofluorescence signals with a 633 nm excitation laser and its matched emission filter. Based on the autofluorescence tumor images, we defined two ROIs for each control and treated tumor and performed optical marking and physical sectioning of the tumors as described above. Next, we stained the macrosections (400 µm thick) with DAPI, CK8-DL488, CD45-DL550, and ER-TR7-DL680 to visualize cancer, immune, and stromal cells in the ROIs at cellular resolution. We quantitatively analyzed the correlated multi-scale 3D image data for assessment of the effects of DMXAA treatment on the tumor microenvironment including eradiation of cancer cells, immune infiltration, and remodeling of tumor stroma. In summary, this new microscopy method will provide comprehensive spatial information of tumor tissues and benefit a broad cancer research field such as the discovery of new tumor biomarkers and the development of effective cancer therapies.

#0077 Real-time multiparametric assessment of immune cell-mediated cytotoxicity.

G. Yang, Y. Lu, T. Wang, P. Ye, **X. Zhang**;
Agilent Technologies, Inc., San Diego, CA

A hallmark of effective immunotherapy is the reliance on the cytotoxic effects of immune cells, such as T-cells and natural killer (NK) cells, on tumor lesions. Cell cluster formation is an important sign of activation, and proliferation, as well as an indication of the killing capability of immune cells. Understanding and modulating the mechanisms underlying the activation, proliferation, and clustering of immune cells is essential for the development of innovative approaches to promote immune cell-induced cytotoxicity and address tumor progression. Here, we report a novel kinetic immuno-oncology assay using the Agilent xCELLigence RTCA eSight, which can simultaneously and quantitatively assess effector/immune cell clustering and proliferation through brightfield live cell time-lapse imaging and immune cell-mediated cytotoxicity of target/cancer cells through real-time monitoring cancer cell viability over a chronic treatment. In this study, we validated the assay using 2 cell models, including CD19 CAR T-cells against Raji cells and NK-92 cells against A549 cells, in a 96-well plate format. The activation, clustering, and proliferation of CD19 CAR T-cells and NK-92 at different Effector: Target (E: T) ratios, as well as the sequential killing of the target cancer cells, were plotted using imaging and cellular-impedance-based readouts throughout the entire assay, respectively. Our results showed 1) the clustering and proliferation of the effector cells could be accurately assessed by brightfield without the facilitation of fluorescent label using the image analysis module of the system; 2) the killing efficacy of the effector cells quantified by the impedance readout highly correlated to their clustering and proliferation assessed by the live-cell imaging; 3) cellular impedance provided a sensitive readout CAR-T killing of immobilized Raji cell count, independent of fluorescent labeling; 4) the kinetics of cluster formation/proliferation and killing efficacy of CD19 CAR T-cells were different from NK cells. The capability of multiparametric assessment of immune cell-medicated cytotoxicity from both effector and target cell perspectives of the assay provides a simple and real-time workflow to understand the correlation and interaction between effector and target cells, which could be an addition of immense value to the development of innovative immunotherapies.

#0078 Superior resolution of intracellular markers with CyTOF reveals greater functional diversity of human T cells.

E. L. Smith-Mahoney[1], M. J. Cohen[2], A. C. Belkina[1], T. Selvanantham[2], D. King[2], C. Loh[2], A. J. Cappione III[2], J. E. Snyder-Cappione[1];
[1]Boston University Chobanian and Avedisian School of Medicine, Boston, MA, [2]Standard Biotools, Markham, ON, Canada

Measuring functional signatures of immune cells in a comprehensive manner, spanning the inflammatory (Th1/Th17) and immunosuppressive (Th2/Treg) lineages, would provide key insights into several facets of cancer research and therapy. Determining mechanisms underlying success/failure of checkpoint blockade, defining immunosuppressive activity of the tumor-resident cell subsets, and identifying immunological biomarkers that predict clinical outcomes, could all be achievable if detection of cytokines spanning many lineages among individual cells was in reach. To achieve this goal, powerful cytometric research tools are required. Cell phenotyping panels are expanding and often now include measurement of intracellular markers of functional potential, such as cytokines, phosphorylation events, and transcription factors. Many of these readouts, including cytokines of the Th2/Treg lineages (IL-5, IL-10, and IL-13), have been notoriously difficult to detect in human cells using fluorescence-based cytometry. Large panels with multiplex intracellular markers are subject to challenges with autofluorescence and spillover spread, thus limiting fluorochrome capacity and reducing resolving power for rare subsets even with full spectrum flow cytometers. For such applications, mass cytometry may overcome such limitations and enable better signal resolution. To address this, we evaluated three small (13-plex) panels using a full spectrum flow cytometer and the CyTOF XT™ mass cytometer. Each panel was comprised of surface and intracellular analytes (cytokines, phospho-epitopes, or transcription factors) and designed to minimize potential impact of spectral overlap on the resolution of spectral flow data. PBMCs were stimulated, split, and stained with either fluorochrome- (Cytek® Aurora) or metal-conjugated antibodies (CyTOF XT). Data sets were analyzed by PhenoGraph clustering and visualized with opt-SNE to determine cellular functional diversity. Overall, data collected on the CyTOF XT demonstrated superior resolution for many intracellular readouts, including cytokines IL-5, IL-10, and IL-13. Also, when better signal/noise enabled accurate clustering, a higher number of immune cell clusters possessing distinct functional signatures resulted from mass cytometry datasets as compared with fluorescent counterparts. In summary, the CyTOF XT mass cytometry platform offers superior signal resolution compared to spectral flow for a range of intracellular targets. Use of mass cytometry translates to the identification of more diverse functional subsets and thus a clearer understanding of the immune signatures present in a sample in the context of unbiased analysis. Our findings indicate that the CyTOF XT platform could serve as a catalyst for seminal discoveries in immune profiling to drive therapeutic design and advanced disease monitoring in cancer.

#0079 Enabling fast and convenient immune profiling of fresh and long-term stabilized human whole blood samples with CyTOF.

M. Cohen, S. Hasan, S. Li, C. Loh;
Standard BioTools, Markham, ON, Canada

Accurate phenotyping of immune cells in whole blood (WB) from patients with cancer is critical for making disease prognoses and monitoring clinical efficacy of immunotherapies. Fresh WB must be analyzed within 24 hours of collection to minimize changes in cellular composition. However, WB collection and cytometric analysis are often performed at different sites, which can result in sample processing delays. Several WB preservation reagents have been developed to address this challenge, including PROT1 (Smart Tube Inc.) and Cytodelics Whole Blood Cell Stabilizer (Cytodelics). However, not all antibody panels are compatible with these reagents. A CyTOF® panel was developed to be compatible with these commercial WB stabilizers and for use in pharmaceutical and clinical research. CyTOF flow cytometry uses metal-tagged antibodies to identify cellular and functional phenotypes. Advantages and features of CyTOF technology enable rapid design and application of 50-plus-marker panels and convenient workflows in which samples can be stained and acquired in a single tube. Compensation is not required since CyTOF flow cytometry has low signal spillover and no autofluorescence. Moreover, antibody cocktails and stained samples can be frozen for later use and acquisition. Thus, CyTOF technology overcomes major hurdles of fluorescence-based cytometry and provides a streamlined and flexible workflow in clinical research. The CyTOF panel contains 20 antibodies to identify over 30 immune cell populations. For easy customization, there are more than 30 additional open channels to analyze markers of interest. The panel works with fresh and stabilized WB samples and is amenable to different staining and acquisition workflows. To show the flexibility of sample staining and stabilization, WB from three healthy donors was assessed using two stabilization workflows. First, fresh WB samples were stained with the antibody panel, followed by PROT1 or Cytodelics stabilization and storage at -80 °C. The second workflow involved immediate stabilization/fixation of WB with PROT1 or Cytodelics and storage at -80 °C. Subsequently, the samples for the second workflow were thawed, surface stained, and acquired. To reduce technical variability from staining, the antibodies were pooled together and frozen at -80 °C as single-use aliquots. Furthermore, all samples were barcoded and acquired as a single tube to reduce variability from sample acquisition. The CyTOF panel developed for broad immune profiling is compatible with WB stabilizers, which overcomes traditional and logistical challenges with WB processing and acquisition. Furthermore, freezing antibody cocktails is a unique feature of CyTOF flow cytometry, ensuring batch-to-batch consistency in clinical research. Thus, CyTOF workflows enable swift and convenient analysis of WB samples. For Research Use Only. Not for use in diagnostic procedures.

#0080 Toward best practices for B-cell receptor repertoire profiling.

W. Xiao, BCR-SEQC consortium;
Food & Drug Administration, Silver Spring, MD

FDA anticipates that immune cell receptor profiling will become crucial to the Agency's evaluation of the efficacy and safety of emerging cancer immunotherapies and immunomodulatory drugs by advancing precision medicine and providing orthogonal, functional evidence. High-throughput sequencing of B-cell receptor sequencing (BCR) gene rearrangements and downstream analysis empowers researchers to define the B-cell clonal landscape, as well as identify biomarkers for minimal residual disease (MRD). Although this field has made vast strides over the last decade, it lacks standardized assay controls, adequate sensitivity and specificity in gene mapping/alignment, and appropriately qualified reference data sets, materials, and validation methods. Moreover, detailed comparisons of wet-bench analytical methods or bioinformatic procedures have not appeared. The FDA led B-cell receptor sequencing quality control (BCR-SEQC) consortium is establishing protocols for the development of reference materials and data sets for the evaluation of NGS-based BCR repertoire reconstruction. The consortium is also developing materials for performance bench-marking studies. To this end, we performed whole-genome sequencing, RNAseq, and BCR-seq on 50 B-cell lines to determine the clonotype, full-length transcripts, and expression abundance of BCR genes in each cell line. Two batches of reference materials (DNA, RNA, and cells) were generated from each of nine cell lines that were determined unambiguously to be monoclonal in BCR expression of both heavy and light chains. These materials were distributed to ten companies to test up to 15 BCR-seq products. Our benchmarking studies include six widely-used sequencing technologies. The overarching objectives of this research were to elucidate current capabilities and limitations, address fundamental technical needs, provide reference materials and data sets, and establish actionable best practices for reconstructing B cell receptor repertoires from NGS data.

#0081 High-resolution monitoring of B cell isotype switching for biomarker analysis of adenosine pathway inhibition immunotherapy.

R. Prathapam[1], K. Champion[1], A. Burkhardt[2], C. L. Smith[2], R. Singh[2], **T. J. Looney**[3];
[1]Quest Diagnostics, Lewisville, TX, [2]Quest Diagnostics, Chantilly, VA, [3]Quest Diagnostics, Austin, TX

Background B cell isotype switching gives rise to IgG-, IgA-, and IgE-expressing B cells and is an essential step in generating effective humoral responses to antigen challenge. Within the tumor microenvironment, extracellular adenosine may contribute to cancer immune evasion by inhibiting isotype switching through interaction with A2aR, a possibility that has driven investigation of adenosine pathway inhibition as an immunotherapeutic modality. In this context, methods to quantify isotype switching may provide insight into the pharmacodynamics of candidate agent activity and serve as a source of predictive biomarkers of response. We recently clinically validated the Oncomine IGH-LR assay for the measurement of CLL somatic hypermutation (SHM). Given that this assay also detects isotype switching events, we retrospectively analyzed our validation dataset to determine the suitability of the assay as a potential tool for biomarker analysis of adenosine pathway inhibition immunotherapy.
Methods The Oncomine IGH-LR assay determines B cell SHM and isotype through targeted next-generation sequencing of IGH chains from RNA. The assay software organizes detected IGH chains into B cell clonal lineages, of which a subset may comprise multi-isotype lineages indicative of isotype switching events. The software further reports secondary repertoire features such as clonality/evenness. Total RNA was extracted from peripheral blood mononuclear cells or bone marrow aspirates from patients identified as having >10% monoclonal B-cell population by flow cytometry. Intra-assay precision was evaluated by processing RNA from 7 samples in triplicate and sequencing in the same run. Inter-assay precision was evaluated by having different operators process 10 samples on different days with different sequencing barcodes. Dominant clone isotype and clonal lineage assignment, total isotype abundance, and repertoire clonality were evaluated across replicates.
Results Overall, 100% concordance was achieved for dominant clone isotype and clonal lineage calls for both intra- and inter-assay studies. Intra-assay and inter-assay median coefficient of variation (CV) for reported isotype frequencies ranged from 0.10-0.16 and 0.15-0.28, respectively. Intra-assay and inter-assay median CV for clonality (1 - Normalized Shannon Entropy) was 0.06 and 0.04, respectively.
Conclusions We observe high reproducibility and repeatability of the IGH-LR assay for B cell isotyping, clonal lineage analysis, and clonality assessment. Multi-isotype clonal lineages are automatically reported by the software and provide a means to directly monitor isotype switching events in the context of antigen challenge or immunomodulation. Taken together, we anticipate this assay to be a useful tool for biomarker analysis of adenosine pathway inhibition immunotherapy.

#0082 Single-cell cytokine secretion kinetics probed by Time-lapse flow (TM) cytometry.

M. Fahlberg[1], S. Forward[1], E. Assita[1], T. Brown[1], P. Chattopadhyay[2], S. Kwok[1];
[1]LASE Innovation, Woburn, MA, [2]Talon Biomarkers, Whippany, NJ

Cytokine secretion from immune cells is a central element of the immune response and a major determinant of immunotherapy efficacy. Several methods, including bulk in-solution assays and flow cytometry, have been used to measure cytokine secretion. Population-level analyses have shown that different cytokines can have different rates of secretion, depending upon their differentiation state or the stimulus itself. However, no current method can interrogate cytokine secretion from individual cells over time.

Here, we describe a novel flow cytometry-based assay for measuring single-cell cytokine secretion kinetics. Our approach, called "Time-lapse flow TM" uses semiconductor probes called laser particles (LPs) to optically barcode individual cells, providing a means to track single cells across a series of measurements over time. We applied this approach to measure T-cell cytokine secretion kinetics using stimulated primary human T cells.

Isolated T cells from cryopreserved human PBMCs were barcoded with LPs and stained with a bispecific antibody that binds to the cell surface on one end and "catches" secreted cytokines (IFNy and IL-2) on the other end. This permits analysis of cytokines from live cells. Next, T cells underwent three sequential stimulations over the course of 3 hours with PMA/Ionomycin. After the first stimulation, cells were stained with a surface marker panel that defined T cell memory phenotypes (CD3, CD4, CD8, CD45RA, CCR7, CD57, CD27, and CD95) and "detection" antibodies that recognized IFNy and IL-2 bound to the cell surface. The detection antibodies were re-added after each stimulation to quantify the accumulating cytokine on the cell surface. In total, kinetic profiles from over 100,000 CD3+ cells were measured.

We discovered massive heterogeneity of responding cells, identifying at least three distinct groups of cells defined by their initial time of cytokine secretion (early, middle, and late responders) and varying intensities of cytokine accumulation over time. Cells peaking in cytokine expression at the middle time points were mainly memory types with higher intensity, while later responders skewered towards naïve cells with less cytokine. However, IFNy variation wasn't solely due to these markers, as diverse kinetics occurred across all subsets. For IL-2, we found that most responses initiated later than those of IFNy, and there was a reduced heterogeneity of both intensity and kinetics at these time points. These results were consistent across multiple donors and replicates (n=3).

Laser particle barcoding enables measurement of single-cell function over time. This novel time-lapse data allows interrogation of functional heterogeneity of immune cells at scale, enabling discovery of new relationships between T cell responses, diseases, and immunotherapies.

#0083 NK cell ADCC assays: Leveraging flow cytometry and reporter cell lines for enhanced biological relevance and throughput.

D. W. Draper, Y. Xing, S. Wise;
Labcorp, Ann Arbor, MI

Amid the growing arsenal of cancer treatments, antibody-dependent cellular cytotoxicity (ADCC) assays have emerged as a significant contributor to the quest for more effective therapies. The ADCC-based antibody therapy often exploits Natural Killer (NK) cells as effectors. This immunotherapeutic approach harnesses the innate cytotoxic potential of NK cells, offering a promising solution for the precision targeting of malignant cells. In this study, we employed two methods that can be used to measure ADCC potency and specificity during preclinical drug discovery. The first was a flow cytometry-based approach that focused on enhancing biological relevance by utilizing primary human peripheral blood mononuclear cells (PBMCs) as a source for NK effector cells. To this end, target cells were fluorescently labeled with CFSE and cultured with freshly isolated PBMCs at 3 effector to target (E:T) ratios, in the presence of ADCC antibody. After 16h incubation, a viability dye was added, and percent cytotoxicity was measured in CFSE+ targets cells by flow cytometry. The second method offered a high-throughput plate reader-based approach (ADCC Reporter Bioassay; Promega), that utilized an ADCC reporter effector cell line harboring a luciferase cassette driven by an NFAT promoter, which is activated when effector and targets cells are bridged by a therapeutic antibody. Cytotoxicity was read out by measuring light output on a Cytation 3 plate imaging reader (Agilent Technologies) after a 6h cell culture incubation using the recommended 6:1 E:T ratio. Preclinical application for both assays was demonstrated using an anti-HER2 therapeutic antibody (trastuzumab) against BT-474, which is a HER2 positive cell line. To demonstrate specificity, an anti-VEGF antibody (bevacizumab) and Hs 578T cells (HER2 low) were used as controls. Our results revealed trastuzumab induced a strong dose-dependent increase in cytotoxicity in the BT-474 cells but not the Hs 578T cell line (range: 40-70%) while bevacizumab failed to induce any cytotoxicity above background levels at any concentration. Furthermore, the flow cytometry and plate reader methodologies produced similar trends. In summary, both applications can be used to produce reliable ADCC drug screening assessments. Additional considerations include investigational needs surrounding high throughput capability versus biological relevance. Unlike traditional models using immortalized cell lines, primary human PBMCs more faithfully recapitulate the physiological interactions between effector cells and target cells. On the other hand, the more streamlined reporter cell line approach not only accelerates assay throughput but also ensures consistent and reliable results in an attractive option for large-scale screening and drug development efforts.

#0084 StarBright Dyes: Fluorophores with superior performance for multiplexing in flow cytometry and Western blotting.

S. Sanderson, **O. Rosenwasser**, M. Blundell;
Bio-Rad Laboratories, Kidlington, United Kingdom

New StarBright^{TM} Dyes from Bio-Rad are bright fluorescent fluorophores ideal for many antibody-based applications, for example, western blotting and flow cytometry. Traditional fluorophores can be dim, have high cross laser excitation, or don't work with all protocols, leading to poor data. StarBright Dyes have been designed to address these pain points.

Western blotting secondary antibodies are available conjugated to StarBright Blue 700 and StarBright Blue 520 Dyes. Their brightness, the short exposure time required, and low background make them ideal for detection of a single target, or as shown here for multiplex detection of several proteins in combination with other common fluorophores.

For flow cytometry, we have a full range of 32 StarBright Dyes excited by the most common laser lines: 355 nm, 405 nm, 488 nm, 561 nm, or 640 nm. They are available conjugated to highly cited clones against common immunophenotyping targets. Data shown here on the ZE5 Cell Analyser demonstrates how the features of StarBright Dyes can improve multiplexing immunophenotyping data. They have narrow excitation and emission spectral profiles, which reduce compensation and spread. This, combined with their exceptional brightness, enables high resolution of cell populations. They work in all buffers and fixatives, so including them in existing panels does not require a change in protocol. They can also be premixed in a master mix for over six months with no loss in performance. Premixes are ideal when using the same panel over an extended period, such as in clinical and longitudinal studies, to ensure reproducible results, also saving time and money.

StarBright Dyes are ideal for multiplexing assays in both western blotting and flow cytometry.

#0085 Immunomics of immune-deficient mouse models before and after CD34 humanization.

H. Luche, L. Hadjem, M. Mello, P. Canavese, F. Angelis, A. Joachim, S. Bouilly, F. Guinut, F. Fiore, B. Malissen, A. Zarubica, E. Corcuff;
Janvier Group, Le Genest Saint Isle, France

Preclinical tumor oncology research relies historically on the analysis of mouse or human tumor cell lines implanted onto severely immune-deficient mouse models carrying nude, SCID or Rag mutations on different genetical background (C57Bl/6N, BalbC, NMRI, CB17 or NOD). These lines harbor defects in several leukocyte lineages among which Tc, Bc and NKc might be affected. Humanized mice are emerging models that have been transplanted with human cells or tissues (and/or equipped with human transgenes). Currently, the most advanced strains are the nonobese diabetic, severe combined immunodeficiency (NOD-SCID) mouse with complete disruptions in the interleukin-2 (IL-2) common γ-chain (IL2R γ null) receptor (NSG) and BALB/c $Rag2^{-/-}$ IL2R γ null $Sirpa^{NOD}$ mice (BRGS).[1] Neonate or juvenile chimera are reconstituted in NSG, BRGS or B6 RGS with CD34+ hematopoietic progenitor cell (HPCs) from human cord blood yielding robust engraftment of a human immune system (HIS).. We genetically modified the mouse genome introducing mutations involved in Tc, Bc and NKc development. We then immuno-phenotyped over 23 lines of mouse mutants produced from the same animal house to minimize the impact of microbiota on innate immune cell populations. High content cytometry analysis of several organs was performed in a standardized manner before and after humanization. The resource obtained of these immunotypes was used to highlight similarities and differences among these lines across several genetical background and will help in selecting the most appropriate model to use for tumor implantation and CD34 or PBMC humanization.

#0086 Deep immuno-profiling of syngeneic tumor mouse models for preclinical studies.

A. Joachim, E. Maturin, M. Mello, L. Hadjem, M. Grange, O. Deas, A. Zarubica, B. Malissen, H. Luche, F. Romagne, S. Blanchin;
Janvier Group, Le Genest Saint Isle, France

The identification of the major cellular players involved in the progression of a type of cancer is a key step for the success of new immunotherapies for personalized medicine. Immune cells play critical functions in cancer, and mice with intact immune systems are vital to understanding tumor immunology. It is however a daunting challenge as complex relationships interplay between tumor cells and the immune system. Each component of innate immunity or adaptive immunity, such as T lymphocytes, macrophages or neutrophils, may be directed to a pro- or anti-tumor function. In order to cope with the complexity of the tumor microenvironment, it is necessary to use an experimental approach capable of characterizing the heterogeneity of the cell types present in the tumor, the evolution of their relative proportion and their fine-tuned functional specificity. This approach leads to the identification of new cellular biomarkers of different stages of tumor progression in order to identify new targets for therapeutic time-window of and improve cancer diagnosis
To decipher the impact of immunotherapy treatments involved in the anti-tumor response, cellular phenotyping of leukocytes infiltrating a tumor but also those present in peripheral organs is necessary. Essentially based on extracellular labeling, this primary screen aims to quantify the different cell populations present in a syngenic tumor models on B6/N or BalbC genetical backgrounds. In order to increase our understanding in the precise mode of action of anti-PD1 treatment at the cellular level in sensitive and unsensitive models, we investigated immunophenotypes and responses to immune checkpoint inhibitor (ICI) of several hallmark syngeneic tumor models (MC38, CT26, B16F10, B16-OVA, RENCA, EMT6) in immunocompetent mouse models by flow and mass cytometry. We compared growth kinetics and profiled the immune cell composition of tumor microenvironment (TME), draining lymph node (dLN) and blood in order to establish immune-phenotypic cell signatures that correlates with treatment efficacy. Supervised, unsupervised and integrative data analysis as well as visualization tools are used to identify significant changes across different experimental settings. Our results indicate that each model possesses a unique tumor-immune infiltrate profile that can be modulated with immunotherapies.
Overall, these studies provide an important resource of highly-characterized syngeneic tumor model and highlight the importance of tumor immune landscape variance across models that will drive selecting the most appropriate model to test novel immunotherapeutic agents and enhance our translation of knowledge from syngeneic models to human tumors.

#0087 Integrated pipeline for immuno-oncology drug testing: from patient-derived organoid assays with reconstituted TME to fresh ex vivo patient tissue cultures.

E. Kaya Aksoy, S. Chavez Abiega, T. Stessuk, S. De Man, **M. Putker**, S. Basten, N. Meesters, E. Spanjaard, L. S. Price, G. Goverse, N. Beztsinna;
Crown Bioscience Netherlands B.V., Leiden, Netherlands

Introduction: Successful pre-clinical evaluation of immuno-oncology drugs requires complex models to accurately represent all components of the human tumor microenvironment (TME). Patient-derived organoids (PDO) are known to reflect genetic and morphological profiles of the original patient's tumors. In our immuno-oncology in vitro assays, PDOs can be combined with immune cells and fibroblasts to re-constitute the TME and study drug efficacy and mechanism of action. Alternatively, we have developed assays with fresh tumor material containing native TME in the 3D Ex Vivo Patient Tissue (EVPT) platform. Both types of assays have advantages and limitations. Here, we will present a case study displaying both capabilities and benchmarking the technologies against each other.
Methods: Patient tumor tissues were obtained from tissue providers and processed within 24 hours to preserve the TME. Freshly isolated ex vivo tumor clusters were embedded in a protein-rich hydrogel and exposed to drug panels in a 384-well format for 5-7 days. Phenotypic effects of therapies on morphological features were measured using our proprietary automated high content imaging (HCI) analysis platform. IHC, FACS, or sequencing, were used for in-depth sample characterization. In parallel, PDOs were generated, biobanked and characterized from same ex vivo samples. Allogenic or autologous PBMCs were isolated from blood. PDOs and PBMCs were then co-cultured together in presence of immuno-oncology drugs, and drug effects were analyzed by the same automated HCI analysis platform.
Results: Samples from ovarian, head and neck, breast, prostate, lung cancer, and melanoma were used in the pipeline. Fresh ex vivo culture of a melanoma sample presented here has shown mild responses (tumoroid size reduction) to immunomodulatory treatments (SEA and Pembrolizumab) and strong responses to targeted therapy treatment (Dabrafenib and Trametinib). Genetic characterization of the sample identified heterozygous BRAF V600E mutation and IHC analysis showed a large proportion of immune cells (CD3, CD4, CD8, CD80 and CD68 positive cells) present, confirming the observed ex vivo drug responses. Part of the melanoma sample was allocated for PDO generation and biobanking. Established PDOs were used in co-culture with allogeneic and autologous PBMCs and treatment responses to SEA stimulation and CD3/CD28 beads as well as increased PBMC infiltration rates were observed.
Conclusion: Choice of the pre-clinical model for immuno-oncology studies relies on multiple factors such as biological relevance, replicability, TME representation, and scalability. Here we present a spectrum of assays ranging from complex ex vivo systems (EVPT) for 'close to the clinic' scenarios to more scalable PDOs co-cultured with allogeneic and/or autologous PBMCs for high-throughput mechanistic drug screenings.

#0088 Novel cell-based bioassays enable preclinical animal studies during immuno-oncology drug development.

J. Wang, D. Garvin, A. Paguio, E. Perrin, J. Hartnett, M. Cong, J. Grailer;
Promega, Fitchburg, WI

Translation of immuno-oncology research into novel therapies relies on animal models to advise target selection and portray mechanism of action (MoA) and pharmacokinetics of lead candidates. Mouse, monkey, and more recently, canine models of human cancers are being utilized to this end. However, one major challenge in developing and utilizing these models is the lack of technology to characterize non-human analogs of therapeutic antibodies. Herein, we report the development of novel cell-based bioassays for mouse, monkey, and canine targets to enable immuno-oncology preclinical studies. Antibody-dependent cellular cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP) are important MoAs for antibody-based cancer immunotherapies. We have developed a suite of cell-based bioassays, each expressing a corresponding animal Fcγ receptor (FcγR) and a luciferase reporter that responds to FcγR activation. These assays exhibit sensitive and quantitative luciferase readouts of FcγR activation. Animal models are further used to provide insight into the potential efficacy of immune checkpoint (IC) inhibitors. Programmed cell death protein 1 (PD-1) is an IC receptor that negatively regulates T cell function. Blockade of PD-1 has demonstrated clinical efficacy, but there remains a significant fraction of patients unresponsive to this therapy. Combination of PD-1 inhibitors with other interventions has been a significant focus for many programs. However, tools for functional validation of non-human PD-1 inhibitors are lacking. We report here the development of two new bioassays for functional characterization of PD-1/PD-L1 inhibitors for mouse and canine targets. Each of these assays consists of two engineered cell lines: a T effector cell line that express a luciferase reporter driven by specific promoter/response elements responding to the intracellular signals mediated by the T cell receptor (TCR), with modulation from PD-1, and an artificial antigen presenting cell line (aAPC). The bioassays are sensitive, quantitative, and have demonstrated characteristics required for potency assays for validation of antibodies in preclinical combination studies.

#0089 Comprehensive cell based bioassay approaches for characterization, and clinical development of therapeutic agonistic antibodies for cancer immunotherapy and autoimmune diseases.

V. Chari, J. Lin-Jones, L. Yang, J. E. Lamerdin, **G. Agrawal**;
Eurofins DiscoverX, Fremont, CA

Agonistic antibodies are emerging as promising therapeutics for targeting immune checkpoints, particularly those within the TNF Receptor Superfamily, as they play a crucial role in regulating immune cell function, especially in the context of cancer treatment. In addition, there is also a growing focus on the potential of agonistic antibodies to selectively activate co-inhibitory checkpoint receptors. This offers a promising avenue for suppressing inflammation in autoimmune diseases and restoring tolerance in graft-vs-host disease (GvHD) while avoiding the complications of global immunosuppression.
While a substantial number of clinical trials are currently underway for oncology and autoimmune indications, there is a notable scarcity of commercially available assays to support the clinical development of this class of therapeutics, impacting their time-to-clinic. Existing assays frequently fail to accurately assess the agonistic activity of antibodies as they are unable to replicate the necessary physiologically relevant conditions.
In this context, we present several case studies that highlight the pivotal role of cell-based bioassay approaches developed by Eurofins DiscoverX in driving the characterization and clinical development of agonistic antibody therapeutics targeting various checkpoint receptors. Additionally, we discuss our data demonstrating the indispensable role of FcyR-mediated antibody clustering in establishing the otherwise elusive agonistic activity of antibodies.

#0090 *In vitro* functional evaluation of immuno-oncology drug candidates in customized bioassays.

Martijn Vlaming, Emmanuelle Sidot, Jezabel Lefevre, Ellen Boelen, Sofie Pattyn

ImmunXperts SA, a Q2 Solutions Company, Charleroi, Belgium

Increased understanding of the complex tumor microenvironment and its interactors has boosted therapeutic interest and highlighted the importance of the development of innovative *in vitro* bioassays to represent all the players of the cancer immune response and thereby potentially provide pivotal information on the functional dynamics of candidate therapeutics. Regulatory T cells play an important role by downregulating the anti-tumor response. Their regulation mechanisms constitute an important target for new therapeutics. To study these mechanisms in a human model, suppressive Treg bioassays, mimicking the suppressive action of these cells, were developed and optimized. We further highlight the study of neutrophil function *in vitro* using flow-cytometry or the Incucyte® live imaging system to monitor neutrophil functions such as antibody-dependent cell-mediated cytotoxicity (ADCC), Neutrophil Extracellular Traps (NETs) formation and the release of Reactive Oxygen Species (ROS). Additionally, multiplex cytokine and peroxidase enzyme analysis after activation and stimulation of neutrophils can be evaluated using ELISA or Luminex technology. Moreover, to refine/reduce non-human primate (NHP) usage, we aimed to develop cost-effective NHP *in vitro* assays with predictive value for *in vivo* studies. We isolated Cynomolgus Macaque monocytes and successfully differentiated/polarized them into M0- and M2-like macrophages with a cell surface phenotype comparable to that of their human counterparts. We further developed a Cynomolgus Macaque PBMC x human dendritic cell (DC) mixed lymphocyte reaction (MLR) assay for functional evaluation of test compounds, effectively generated Cynomolgus Macaque immature DCs and implemented Cynomolgus Macaque cytokine release assays.Using high quality primary human immune cells from our own biobank, *in vitro* bioassays have been developed with superior robustness and reproducibility to screen candidate Immuno-Oncology therapeutics.

#0091 Comprehensive 27-marker standard panel for immune monitoring of pre-clinical tumor mouse models using spectral analyzer technology.

J. F. Hummel, **P. Metzger**, R. Sonntag, D. Borrero-Wolff, C. Obodozie, H. Weber;
Reaction Biology Europe GmbH, Freiburg, Germany

Within the last decade, major technological advances in flow cytometry and (single cell) RNA-sequencing have deepened our understanding of complex anti-tumoral immune responses. This allows a comprehensive immune monitoring of novel therapies in pre-clinical models.
Conventional flow cytometry is reaching its technical limitation. The emitted fluorescence signal of the target population stained with antibodies is evaluated with simple bandpass filters, which leads to spectral overlap and thus the number of parameters that can be analyzed simultaneously is limited. The spectral analyzer technology combines both methods, providing great flexibility in evaluating different immune cell populations. This provides the opportunity to obtain target information by measuring the entire fluorescence spectrum measuring each wavelength individually and thus evaluating the true signal of each fluorochrome unaffected by autofluorescence or spillover.
Our standard all-in-one flow cytometry panel uses the full capacity of a conventional BD Fortessa flow cytometer and enables the differentiation of important immune cell populations in tumors, such as T cells (CD4+, CD8+, regulatory T cells), B and NK cells as well as macrophages (M1/M2), MDSCs (granulocytes and monocytes) and dendritic cells. However, it would be of great advantage to gain further insights into activation and effector functions of the immune cells using markers like CD44 & CD62L, CD69, PD-1, Lag-3, Tim-3 and PDL-1, CD80, CD86, CD40 and Ki-67. The Sony ID7000 spectral analyzer enables the simultaneous assessment of 27 markers to evaluate immune phenotypes, with the ability to include up to 4 individual target antibodies.
Flow cytometry data from various tumor models are presented, demonstrating the enormous utility and potential of the spectral analyzer, especially with limited and precious tumor sample material, by evaluating different immune cell populations simultaneously without reaching its technical limits. The spectral analyzer technology enables us to mechanistically investigate differences in tumor therapies such as PD-1 treatment or other immune cell modulators not only phenotypically but also with regard to activation and differentiation of immune cell populations.

#0092 Assessment of an in vitro potency assay for evaluation of immune cell-mediated cytotoxicity using the Omni Pro 12 automated imaging platform.

D. Sullivan[1], L. Stemkens[2], I. Thijssen,[2], **S. Meiler**[2], D. Califano[1], S. Chvatal[1], D. Millard[1];
[1]Axion BioSystems, Atlanta, GA, [2]Axion BioSystems, Eindhoven, Netherlands

The development of immunotherapies relies on the use of *in vitro* potency assays—which are key for understanding complex interactions between immune cells and cancer cells. Immune effector T-cells are a promising cancer therapy due to their innate cytotoxicity. In particular, CAR T-cell therapy uses genetically engineered T-cells that express a chimeric antigen receptor that binds to a specific antigen on tumor cells. Assessing the efficacy and potency of CAR T-cell therapies *in vitro* and at high throughputs is vital for the preclinical development of these promising therapies. Here, we describe an *in vitro* potency assay that uses an automated imaging platform to quantify immune cell-mediated cytotoxicity of cancer target cells by immune effector cells. A GFP fluorescent and HER-2 expressing lung cancer cell line, A549, was seeded into a 96-well cell culture plate. Then, HER-2 CAR T-cells were added at 24 hours post target cell seeding at various E:T ratios (1:10, 1:5, 1:2, 1:1, and 5:1). Fluorescent images of the target cells were captured every 6 hours by the Omni Pro 12, an automated, high-throughput, live-cell analysis platform designed for continuous multi-well imaging inside an incubator. Automated image analysis was performed using the Confluency Module in the Axion Portal to view attachment and proliferation and quantify cytolysis of fluorescent A549 target cells. Percent cytolysis of the target cells was calculated by comparing the green fluorescent confluency of treated wells to no treatment control wells. A549-GFP cells showed a dose-dependent decrease in confluency over time that correlated with increasing amounts of CAR T-cells. At 92 hours post HER-2 CAR T-cell addition, the 5:1 ET group demonstrated approximately 91.8% +/- 2.0% cytolysis of A549-GFP cells, while the 1:10 group demonstrated approximately 69.2% +/- 3.0% cytolysis. Future work will evaluate differences in CAR T-cell potency when co-cultured with target cells that express different levels of HER-2. Overall, the Omni Pro 12 platform enables continuous quantification of the potency and kinetics of immune cell-mediated cytolysis.

#0093 Validation of an impedance-based *in vitro* potency assay for repeatability and precision.

D. Califano[1], J. Jiang[2], D. Windgassen[2], C. De La Flor[2], S. Chvatal[1], D. Sullivan[1], D. Millard[1];
[1]Axion BioSystems, Atlanta, GA, [2]Miltenyi Biotec, Inc, San Jose, CA

Cell-based immunotherapies, such as CAR T cells, are emerging as a promising approach to therapeutic intervention against cancer. Developing cell and gene therapy products requires reliable and reproducible methods of quantifying critical quality attributes, such as potency, to ensure product strength and consistency. A variety of assays can be used to assess potency; however, it is crucial that these tests are qualified for assay performance to ensure intra- and inter-assay precision. Although inherently variable, biological assays are often the best methods to investigate a product's mechanism of action and predict clinical outcomes. Previous work has shown that impedance-based potency assays provide a non-invasive, real-time measure of effector cell-mediated cytotoxicity, thus reducing cell manipulation that impacts data reliability. Here, we describe an *in vitro* potency assay that demonstrates low variability and high precision across replicates, analysts, and days. Effector cell-mediated cytotoxicity was performed using a CD19-positive liquid tumor cell line (Raji) tethered to the well surface using an anti-CD40 antibody. CD19-specific CAR T effector cells were added 24 hours after the target cells and co-cultured with the target cells across a range of E: T ratios, and cytolysis was monitored for three days. Real-time measurement of cell-mediated cytotoxicity also allowed for the calculation of kill time 50 (KT50), defined as the time required for 50% cytolysis of the target cells. Repeatability was calculated across three replicates per E:T ratio. The co-culture experiment was performed in duplicate by a second analyst and on two subsequent days for a comparison of f three plates as well as two operators to evaluate inter-assay precision. In addition to this, CAR T-mediated cell killing in a multiplate impedance system was also investigated for plate-to-plate variability. The percent coefficient of variation (% CV), a statistical measure that describes the precision and repeatability of an assay, was calculated to assess variability between assay replicates, operators, and plate replicates. In all conditions tested, the percent CV for all E:T ratios was below 20%, illustrating the repeatability and precision of the assay. These data support the use of an impedance-based potency assay for evaluating and characterizing immunotherapy products.

#0094 Interrogation of STING induced cytokines in the tumor microenvironment using an Integrated MultiOmyx-RNAscope panel for spatial and quantitative profiling.

S. Lam, **C. Todorov**, J. Fei, H. Nunns, E. Leones, M. Thio, F. Sahafi, E. Parnell, Q. Au;
NeoGenomics, Aliso Viejo, CA

The STING (Stimulator of Interferon Genes) pathway is a pivotal player in the innate immune response, responsible for detecting cytosolic accumulation of endogenous DNA and initiating a cascade of events leading to the production of pro-inflammatory type I interferons, which promote an antitumor environment through activation of T cells, dendritic cells, and natural killer cells. Therefore, STING agonists are currently being explored as a potential therapeutic for cancer treatment, often in combination with immune checkpoint inhibitors. While the STING pathway can be stimulated in multiple cell types, activation in antigen presenting cells, such as dendritic cells (DC), is crucial for antitumor activity in the tumor microenvironment (TME). Additionally, the type 1 interferon family consists of multiple subtypes, including IFNb and IFNa, which can produce differential biological responses. Although the STING pathway is known to induce expression of multiple cytokines, combined spatial characterization of STING and type I interferons in the TME has not been performed. To characterize STING-interferon expression in the TME, we use the Integrated MultiOmyx-RNAscope platform. MultiOmyx^{TM} (NeoGenomics Laboratories, Inc) is a proprietary multiplex immunofluorescence (mIF) platform for the visualization and characterization of up to 60 protein biomarkers in a single formalin-fixed paraffin-embedded (FFPE) section and offers high-resolution spatial and quantitative analysis of protein expression in tissue samples. RNAscope^{TM} (Bio-Techne) Multiplex is a highly sensitive fluorescent in-situ hybridization (ISH) assay that can detect up to 3 RNA markers in a single FFPE section. The Integrated MultiOmyx-RNAscope assay allows for simultaneous detection of both protein and RNA markers in a single sample. Herein we report the design and use of a novel panel of commercially-available antibodies and ISH probes broad enough to characterize various immune subpopulations and cytokine expressing cells, including DCs and interferons, in the TME of a variety of tumor indications including melanoma and head and neck squamous cell carcinoma. Quantification and analysis will be performed using NeoLYTX^{TM}, the proprietary MultiOmyx Analytics pipeline, to examine the spatial distribution and expression levels of key STING pathway induced cytokines to elucidate the dynamic communication of signaling molecules and their localization within specific cell populations. Understanding of the variety and phenotype of STING/cytokine expressing cells in the TME is crucial to define the populations being targeted by therapies for cancer treatment.

IMMUNOLOGY: Tumor-Induced Immune Suppression 1: Extrinsic Factors
Poster Session

#0097 A E2F6 ceRNA network suppresses dendritic cell function, via PBX1/IL-10 signaling, in ovarian cancer.

M. W. Chan[1], Y.-C. Chen[1], C.-W. Lin[1], F. Cheng[1], C.-C. Yan[2], C.-P. Hsu[2], Y.-M. Chuang[1], J.-T. Low[1], X. Ma[3], Y.-T. Huang[1], C.-B. Chang[1], C. Li[1], H.-C. Lai[4], S.-F. Wu[1], S.-H. Hung[5], J.-C. Tsai[5];

[1]National Chung Cheng University, Chia Yi, Taiwan, [2]Academia Sinica, Taipei, Taiwan, [3]Weill Medical College of Cornell University, New York, NY, [4]Taipei Medical University, Taipei, Taiwan, [5]National Tsing Hua University, Hsinchu, Taiwan

It is reported that long-term use of estrogen could increase the risk of ovarian cancer. However, the role of estrogen in immunoevasion is not fully explored. We have previously demonstrated that estrogen-mediated upregulation of E2F6, and, c-Kit, by epigenetic silencing of miR-193a, and a competing endogenous (ceRNA) mechanism. In this study, we found that PBX1, a transcriptional activator of the immunosuppressive cytokine, IL-10, is also a target of miR-193a. Importantly, overexpression of the E2F6 3'UTR upregulates both E2F6 and, PBX1, as well as IL10 in ovarian cancer cell lines, suggesting that ceRNA mechanism exists between E2F6 and PBX1. These phenomena are further supported by our stochastic simulation of the estrogen-mediated E2F6 ceRNA network on the distribution of E2F6 and PBX1 mRNA in cancer cells, which is consistent with the TCGA ovarian cancer RNA-Seq dataset. Importantly, monocyte-derived dendritic cell activation of T-cell function was inhibited by pretreatment of conditioned media derived from ovarian cancer cells overexpressing E2F6 3'UTR; such inhibition was rescueable by an anti-IL-10 antibody. Clinically, IL10 level was higher in ovarian cancer patients with higher E2F6 and PBX1, and in ovarian cancer cell lines overexpressed with E2F6 3'UTR. Taken together, these results showed that E2F6 could suppress anti-tumor immune response of dendritic cell, E2F6 ceRNA network. Epigenetic intervention in restoring the expression of miR-193a may be able to enhance anti-tumor immune response against ovarian cancer.

#0098 SETDB1 promotes tumorigenesis in endometrial cancer through suppressing anti-tumor immune response and increasing proliferation.

K. Salari[1], J. Hao[1], M. Wells[2], E. Johnson[1], R. Jilek[1], J. Gilbert[1], R. Mclerran[1], D. Meyerholz[1], M. Yates[3], B. Li[1], S. Yang[1];
[1]University of Iowa, Iowa City, IA, [2]Rosalind Franklin University, North Chicago, IL, [3]University of North Carolina, Chapel Hill, NC

Background: An H3K9 methyltransferase and cancer driver gene, SETDB1, promotes tumorigenesis in many cancer types, such as melanoma, and breast cancer. SETDB1 is often overexpressed and correlates with worse survival. Multiple mechanisms have been reported for its oncogenesis from promoting tumorigenesis and regulating immune evasion. The roles of SETDB1 in driving endometrial cancer (EC) progression is not well-studied.
Methods: EC cell lines were used for knockout SETDB1 using CRISPR-Cas9 system, RNA-seq was conducted to discover SETDB1 regulated genes. ChIP-qPCR was performed to identify SETDB1 direct targets. Immunocompromised NSG and immunocompetent C57BL/6 mice were utilized to investigate SETDB1 promoted tumor growth, immune evasion, and mice survival. IHC and flow cytometry was conducted to evaluate macrophage infiltration. Cytokines were screened by qPCR for potential macrophage chemoattractant.
Results: *In vitro*, knockout SETDB1 decreased cell proliferation and enhanced G1/S cell cycle arrest. RNA-seq data revealed that in SETDB1$^{-/-}$ clones, many important oncogenes such as POLR2A, MUC5AC, and MKI67 were downregulated, while tumor suppressors such as PGR, RERG, and ZNF582 were upregulated. ChIP assay discovered that SETDB1 directly binds and represses ZNF582, ZNF266, ZNF841 expression via depositing H3K9me^3 at promoter region. *In vivo*, SETDB1$^{-/-}$ significantly reduced tumor growth and prolonged NSG mice survival up to 100 days. SETDB1 promoted tumor growth via 1. Intrinsic: increasing mitotic figure, pH3-S10 and Ki67 level, 2. Extrinsic: blocking macrophage infiltration and chemokine secretion. Our *in vitro* functionality assay confirmed that bone-marrow derived M1-polarized macrophages promoted greater killing for SETDB1$^{-/-}$ cells. We surveyed 17 cytokines and found CCL5, CXCL9, and IL6 mRNA expression were enhanced in SETDB1$^{-/-}$ tumors suggesting active immune response. Consistent with the elevated CCL5 mRNA expression, CCL5 protein level was also upregulated in macrophages and cancer cells in SETDB1$^{-/-}$ tumors. To prove SETDB1 directly regulates CCL5 expression, we re-expressed SETDB1 in SETDB1$^{-/-}$ cells, and indeed, the SETDB1 re-expression did suppress CCL5 expression. Using immunocompetent C57BL/6 mice, we further confirmed that SETDB1 promotes tumor growth of MSH2-369 mice cells and blocks macrophage infiltration. To understand SETDB1 regulated pathways in EC patients' samples, using EC-TCGA data, we discovered that high SETDB1 expression correlated with higher level of active transcription genes and reduced immune response genes. Our findings provide the mechanisms behind these observations.
Conclusion: SETDB1 drives EC tumorigenesis by both intrinsically upregulating cell proliferation genes and promoting immune escape extrinsically. Our novel findings suggest SETDB1 is a promising anticancer target for EC patients.

#0099 Versican regulates T cell abundance within the colorectal cancer microenvironment.

S. Kraus, P. Emmerich, M. Hayes, K. Matkowskyj, W. Zhang, C. Pasch, F. Asimakopoulos, D. A. Deming;
University of Wisconsin-Madison, Madison, WI

Background: Clinical benefit from immunotherapy is seen in a minority of patients with metastatic colorectal cancer (CRC). Identifying how the tumor microenvironment (TME) influences immune infiltration and treatment response is an unmet need. Versican (VCAN), a chondroitin sulfate proteoglycan, common in the CRC TME has immunoregulatory properties and can be cleaved releasing an immunostimulatory product, versikine (Vkine). Here we evaluate the impact of the abundance of VCAN and Vkine on CD8+ T cell infiltration in CRC.
Methods: Samples include 306 primary colon tumors, an additional 176 primary CRCs with matched liver metastases (175 samples), and 328 normal samples (238 colon and 90 liver). Samples were stained via immunohistochemistry (IHC) for VCAN, Vkine, and CD8. CD8+ tumor infiltrating lymphocytes (TILs) were counted per high powered field (HPF, 400X magnification) and presented as averages. Intensity of VCAN and Vkine expression were scored from 0-3+. Samples designated a 0/1 were considered low accumulation and samples scored as a 2/3+ were designated high. Samples scored low for VCAN but high for Vkine were designated VCAN proteolytic predominant (VPP) and all other combinations considered VCAN proteolytic weak (VPW). To create an *in vitro* model, the mouse MC38 cell line was CRISPR engineered to over-express VCAN. Conditioned media was then concentrated and added to a collagen matrix in a transwell with activated T cells. The number of cells and their subtype that migrated through the matrix were evaluated with flow cytometry.
Results: VCAN accumulation was highest in cancerous stroma with 58% of cancers being VCAN high and only 14% of adjacent normal tissues ($p<0.001$). Vkine accumulation was similar between groups, with 67% of tumors and 54% of adjacent normal samples scored as Vkine high. The VPP phenotype was least common in tumor tissues with only 27% of tumor samples designated VPP versus 43% of adjacent normal samples ($p<0.001$). VCAN high tumors had significantly fewer TILs with 4 TILs/HPF vs 13 in the VCAN low tumors ($p<0.001$). High levels of Vkine correlated with greater TIL abundance (Vkine high: 10 TILs/HPF, Vkine low: 5 TILs/HPF; $p=0.02$). Versican proteolysis had the strongest correlation with TIL abundance in cancers (VPP: 18 TILs/HPF, VPW: 5 TILS/HPF; $p<0.001$). In vitro, the addition of VCAN containing media into transwell matrices reduced both CD4+ and CD8+ T cell migration through the matrix (Control: 4277 CD8+ T cells, VCAN: 2603 CD8+ T cells; $p<0.001$ and Control: 7770 CD4+ T cells, VCAN: 5340 CD4+ T cells; $p=0.007$).
Conclusions: VCAN accumulation in human CRCs is common and correlates with reduced TIL abundance, whereas VCAN proteolysis correlates with increased TILs. *In vitro,* VCAN demonstrated the ability to reduce T cell migration. Future studies will explore the mechanism by which VCAN abundance leads to decreased T cell infiltration and the importance of this as an immunotherapy biomarker.

#0100 Blockade of CCL5 and CXCL10 signaling as a novel immunotherapy for epithelial ovarian cancer.

A. C. Lin, J. Moscarelli, **Z. Lin**, E. S. Ratner;
Yale University School of Medicine, New Haven, CT

Background: Cancer immune evasion remains a major barrier in developing enduring therapies for epithelial ovarian cancer (EOC). Expression of programmed death-ligand 1 (PD-L1) is known for its immunosuppressive role in cancer, thus interferences to PD-L1 have shown marked efficacy against many advanced cancers. However, the mechanisms by which PD-L1-negative cancers evade immune response remain unelucidated. We have found chemokine (C-C motif) ligand 5 (CCL5) and (C-X-C motif) ligand 10 (CXCL10) to up-regulate in PD-L1-negative EOC. Therefore, the present study aims to investigate blockade of CCL5/CXCL10 signaling to overcome immune evasion of EOC.
Methods: Isogenic BRCA2-mutated PEO1 and BRCA2-wild type PEO4 EOC cells were treated with IFNγ, olaparib, or both in combination for western blot and flow cytometric analyses of PD-L1 expression. The conditioned medium of PEO1 and PEO4 cells was analyzed for immune array analysis to determine and compare the levels of 36 cytokines. PEO1 and PEO4 cells were co-cultured with CD3/CD28 antibodies-activated human peripheral blood mononuclear cells (PBMCs). Then, PBMCs were stained with anti-CD8 or CD4 and CD25 antibodies for flow cytometric analyses of cytotoxic or helper T cells, respectively. PEO1 and PEO4 cells were co-cultured with activated PBMCs in the presence and absence of TAK-779 or AMG-487. Thereafter, PBMCs were stained with anti-CD4, CD25, and FOXP3 antibodies for flow cytometric analyses of regulatory T cells (Tregs). PEO1 and PEO4 cells were transfected with CCL5- or CXCL10-siRNA and subsequently co-cultured with activated SUPT1 cells or PBMCs. The conditioned medium was collected and analyzed for the levels of IFNγ by ELISA.
Results: PEO1 cells exhibited an up-regulation of basal and IFNγ-induced PD-L1 compared with PEO4 cells. PEO4 cells displayed a pronounced increase in the CCL5 and IFNγ-induced CXCL10 compared with PEO1 cells. Co-culture of PBMCs with PEO1 and PEO4 cells led to a significant decrease in activated CD8+ effector T and CD4+ helper T cells. However, co-culture of PBMCs with PEO4 cells caused a significant increase in activated CD4+ helper T cells. Co-culture of PBMCs with PEO4 cells caused a significant increase in FOXP3+CD4+CD25+ Tregs. This increase in Tregs was significantly reduced by the treatment with the CCL5/CCR5 antagonist TAK-779 or the CXCL10/CXCR3 antagonist AMG-487. Silencing of CCL5 or CXCL10 in PEO4 cells by siRNA significantly increased IFNγ production by SUPT1 cells and PBMCs.
Conclusions: PEO4 cells secrete CCL5 and IFNγ-induced CXCL10 to activate Tregs, enabling tumor cells to evade host immune response by dysregulating their microenvironment. PEO4 cells-induced Tregs are reduced by CCL5/CXCL10 signaling blockade with TAG-779 or AMG-487. Furthermore, silencing of CCL5 or CXCL10 in PEO4 cells with siRNA abolishes Treg-mediated immunosuppression and restores the antitumor activity of effector T cells.

#0101 A novel humanized mouse model recapitulates the unique TME found in patients with HIV-associated NSCLC.

M. Juric[1], G. Kaufmann[1], L. Zhu[1], K. Ranjan[1], K. Agrawal[1], B. Rajendran[1], J. K. Rajashekar[1], H. Zhao[2], Y. Kluger[1], B. Emu[1], K. A. Schalper[1], P. Kumar[1], R. A. Flavell[1], **M. Chiorazzi**[1];

[1]Yale School of Medicine, New Haven, CT, [2]Yale School of Public Health, New Haven, CT

Among people with HIV (PWH), non-small cell lung cancer (NSCLC) is increasing in incidence, presents with more advanced disease, and portends a worse prognosis compared to the general NSCLC population. Despite effective control of viral replication with antiretroviral therapy (ART), PWH have evidence of immune dysfunction, and it is unknown whether these immune perturbations impact the tumor microenvironment (TME) to influence disease disparities.Here we preclinically model HIV-associated NSCLC using MISTRG6-A2, a humanized mouse system that is highly optimized for development of functional innate and adaptive immune cells. We compare tumor growth and immune features of HIV-infected, ART-suppressed MISTRG6-A2 hosts to uninfected hosts, with parameters informed by parallel analyses of human tissue samples obtained from PWH with NSCLC, and non-HIV controls.MISTRG6-A2 mice were engrafted with human CD34+ HSPCs from HLA-A*02-expressing donors on post-natal day 2 and intravenously infected with HIV-1 at 6 weeks of age. When HIV viral titers were $>10^6$ copies of viral RNA/ml plasma and hCD4 T cells were depleted, ART was initiated (RAL/FTC/TDF). When plasma viral RNA was undetectable and CD4 T cells recovered, NSCLC PDX tissue from HLA-A*02-expressing tumor was implanted into these HIV-infected, ART-suppressed MISTRG6-A2 mice as well as non-infected littermate controls which had received HSPCs from the same donor. HIV-infected mice displayed enhanced growth of PDX tissue (mean tumor size 206.7 mm^3 vs 110.2 mm^3; $p < 0.05$).Quantitative immunofluorescence of the TME from these hosts revealed significantly increased infiltration of CD4 and CD8 T cells in tumors of HIV-NSCLC mice ($p<0.01$ and 0.05, respectively); of note, enhanced T cell infiltration was restricted to tumors, with similar frequency of CD4 and CD8 T cells detected in spleen, lung and liver tissues of HIV-infected vs uninfected hosts. Staining of tumor epitopes revealed increased expression of B2M and EGFR in tumors from HIV-NSCLC mice (mean qIF scores in NSCLC vs HIV-NSCLC $3.8x10^6$ vs $1.2x10^7$ for B2M, $p<0.001$; 440 vs 1,971 for EGFR, $p<0.01$), consistent with our findings in samples from HIV-NSCLC tumor tissues vs NSCLC tumor tissues. Of note, elevated EGFR staining was only present in tumor tissue, not found in stromal cells or other tissues. Single cell transcriptomic analyses of the TME revealed prominent interferon and antigen presentation signatures in HIV-NSCLC tumors, as well as differential expression of immunoregulatory molecules.These results demonstrate the fidelity of the HIV-NSCLC MISTRG6-A2 system as a model for HIV-associated NSCLC and suggest EGFR-directed therapies as potentially relevant in this neglected disease.

#0102 LMP1-mediated recruitment of ALIX directs exosomal PD-L1 sorting and contributes to immunosuppression in EBV$^+$ nasopharyngeal carcinoma.

F. He, Y. Gong, Y. Zhou, C. Xie;
Wuhan University, Wuhan, China

Epstein-Barr virus (EBV) is known to cause multiple cancers and plays a pivotal role in tumor immune evasion. Latent membrane protein 1 (LMP1) is a key viral oncoprotein expressed in most EBV-associated cancers and contributes to tumor microenvironment remodeling. However, the exact role of LMP1 in modulating tumor immunity remains unclear. In this study, we elucidate how LMP1 interacts with PD-L1 and ALIX to form a trimolecular complex, facilitating the selective sorting of PD-L1 into exosomes and consequently impairing $CD8^+$ T cell function in nasopharyngeal carcinoma (NPC). Specifically, the transmembrane domain of LMP1 interacts with and stabilizes PD-L1, while the intracellular domain of LMP1 binds to ALIX, thus enabling access to the exosomal secretory pathway. This interaction leads to the formation of a trimolecular complex comprising LMP1, PD-L1, and ALIX, which is indispensable for the exosomal trafficking of PD-L1. Importantly, disrupting ALIX significantly diminishes LMP1-induced exosomal PD-L1 secretion, thereby restoring $CD8^+$ T cell functionality. Furthermore, we found that elevated levels of LMP1/ALIX expression are positively associated with immunosuppressive characteristics and poorer outcomes in human NPC. Our findings highlight the crucial role of the LMP1/ALIX axis in exosomal PD-L1 sorting and EBV-mediated immune evasion, presenting a novel and promising target for cancer immunotherapy.

#0103 Prostate cancer bone metastasis: Therapeutic targeting of tumor associated macrophages.

H. Zhang, S. Mei, N. E. Jeffries, D. M. Dahl, C.-L. Wu, P. J. Saylor, **D. B. Sykes**;
Massachusetts General Hospital, Boston, MA

Introduction: Castration-resistant bone metastatic prostate cancer is a morbid and deadly disease with an exceedingly low response rates to available immunotherapies. Understanding the mechanisms behind immune evasion and tumor progression is critical to improving therapy. Historically, bone metastases have been challenging to model in the laboratory. Our foundational work was built upon fresh patient samples taken directly from the operating room for analysis across multiple platforms: IHC, single cell expression profiling, and spatial transcriptomics. We compared tumors from patients with bone metastatic disease to tumors from patients with disease localized to the prostate. Our work (*Cancer Cell*, 2021 and *Nature Communications*, 2023) has consistently pointed towards dysregulated myeloid populations within the tumor microenvironment, particularly TREM2+ tumor associated macrophages (TAMs), as key drivers of disease progression.
Methods: Our patient samples and murine pre-clinical models of prostate cancer highlighted several specifically upregulated molecules and pathways in TAMs. Here we focus on TAMs *in vitro* and *in vivo* using a new and genetically tractable myeloid model to interrogate the mechanistic role of key pathways, and how they may contribute to T-cell immune suppression. The ER-Hoxb8 system of conditional myeloid differentiation permitted the generation of isogenic cell lines to interrogate the roles of key molecules TREM2, MSR1, APOE, and MERTK through overexpression or CRISPR/Cas9 knockout.
Results: Using a system of co-culture *in vitro*, we quantified the role of these proteins in suppressing T-cell proliferation and cytokine production, as well as their role in TAM differentiation and function. *In vivo*, these lines were co-injected subcutaneously with syngeneic RM1-BM3 tumor cells to quantify their effect on tumor growth and T-cell suppression *in vivo*. In addition to localized subcutaneous tumors, bone metastatic disease was established by intracardiac injection. Furthermore, established tumors were treated with TAM-directed small molecule therapy (e.g., MERTK inhibition) as well as immune checkpoint inhibition (anti-PD1) alone, and in combination.
Conclusions: TAMs are immune suppressive myeloid cells that are not found in normal tissues. They are specifically recruited to tumors and highly enriched in bone metastatic disease. Transcriptomic analyses highlighted signaling pathways potentially amenable to productive therapeutic targeting. The ER-Hoxb8 system was highly effective in generating a genetically tractable model of TAM for study *in vitro* and *in vivo*. Our work supports the hypothesis that the specific targeting of TAMs, by focusing on critical signaling pathways, can be effective in the treatment of pre-clinical models of prostate cancer. This new approach merits further study as a potential strategy for the treatment of patients with bone metastases.

#0104 Profiling peripheral blood to predict response to targeted androgen receptor axis therapy in mice.

Marco A. De Velasco, Yurie Kura, Kazuko Sakai, Yoshitaka Saito, Takafumi Minami, Kazuhiro Yoshimura, Kazutoshi Fujita, Kazuto Nishio, Hirotsugu Uemura

Kindai University Faculty of Medicine, Osaka-Sayama, Japan

Background: Targeting the androgen receptor (AR) signaling axis (ARAT) continues to be the mainstay treatment for advanced-stage prostate cancer. Using second-generation antiandrogens like abiraterone acetate (Abi) and apalutamide (Apa) has contributed to the survival of prostate cancer patients. However, resistance to these therapies remains a problem and most of these patients progress to castration-resistant prostate cancer (CRPC). Myeloid-derived suppressor cells (MDSCs) have been shown to drive CRPC. We previously showed that unfavorable responses to androgen deprivation therapy (ADT) or ADT plus Apa were associated with polymorphonuclear MDSCs (PMN-MDSCs) cells enriched in prostate tumors from conditional *Pten/Trp53*-double knockout (DKO) mice. Here, we explore the association between pre-treatment immune cell subsets blood and antitumor to ARAT therapy DKO mice.
Methods: Twenty-eight-week-old DKO mice were surgically castrated and after four weeks were randomized to treatments with vehicle, Apa or Abi for an additional four weeks (*n*=20). Individual treatment responses were assessed and classified according to tumor burden as follows: high tumor burden (HTB), ≥20% of median; moderate tumor burden (MTB), -20% to 20% of median; or low tumor burden (LTB), ≤-20% of median. Peripheral blood was collected both before and after treatment and analyzed by multi-color flow cytometry panels for lymphoid and myeloid subsets. Blood samples from healthy wildtype and untreated DKO mice with castration-naïve prostate tumors were collected as reference samples. Subsets of PMN-MDSCs and monocytic-MDCSs (m-MDSCs) were represented as % of total abundance and 5 of parental population. revealed a signature that was correlated with treatment responses. Profiles were constructed and the data was used to train supervised learning models to predict treatment responses. Shapely additive explanations (ShAP) were used to determine feature importance. The model was tested and validated on an independent cohort of 20 DKO mice treated with ADT and ADT plus Abi.
Results: Moderate prediction from baseline blood could be identified for tumor burden following ARAT using a Naïve Bayes classifier. Model evaluation, using an independent cohort, yielded favorable performance with area under the curve (AUC) mean, 0.707; HTB, 0.627; MTB, 0.750; and LTB, 0.745. The most important features for prediction were identified.
Conclusion: Our study revealed that MDSC subsets present in blood were associated with treatment responses to ARAT.

#0105 Understanding the role of β2-adrenergic receptor signaling on type II innate lymphoid cells in cancer.

J. Choi, C. R. MacDonald, S. Daneshmandi, J. Wang, N. T. Roberts, C. M. James, P. L. McCarthy, H. Mohammadpour, E. A. Repasky;
Roswell Park Comprehensive Cancer Center, Buffalo, NY

Increased norepinephrine (NE) due to chronic stress can activate adrenergic receptors, specifically β2-adrenergic receptors (β2AR), to produce an immunosuppressive tumor microenvironment (TME). Previous work by our lab demonstrated that tumor burden can be reduced by blocking β2AR signaling. Immune cells express β2AR and we have shown that the increased β2AR signaling leads to increased T cell exhaustion and increased inhibitory activity of myeloid-derived suppressor cells (MDSCs). In general, the resulting immunosuppression leads to a modest but significant reduction in tumor growth. However, the lack of a dramatic reduction in tumor growth reveals the complex nature of adrenergic signaling dependent regulation of the cancer immune response. Recent literature revealed that innate lymphoid cells (ILCs), especially type II ILCs (ILC2s), express high levels of β2AR. Therefore, we evaluated whether β2AR regulates ILC2s within the TME and how that affects tumor prognosis. We generated a genetic conditional knockout murine model where β2AR expression in ILC2s was deleted by crossing $IL5^{cre}$ expressing mice to $\beta2AR^{flox/flox}$ mice ($IL5^{cre}\beta2AR^{f/f}$). AT3 breast cancer cell line was injected into the 4^{th} mammary fat pad and tumor volume was measured every 2-3 days. Tumor infiltrating ILC2s ($CD45^{+}Lineage^{-}CD90.2^{+}CD127^{+}ST2^{+}$) were analyzed by flow cytometry at D36 post-tumor implantation. Notably, $IL5^{cre}\beta2AR^{f/f}$ mice had increased AT3 breast cancer tumor growth compared to control mice. Flow cytometric analysis of the tumor revealed an increased frequency of $GATA3^{+}$ ILC2s within the TME. These $GATA3^{+}$ ILC2s lacking β2AR expressed higher levels of the IL33 receptor, ST2, and a higher percentage of $IL13^{+}$ cells compared to WT $GATA3^{+}$ ILC2 cells. We also observe a trend toward increased MDSC population within the TME of mice lacking β2AR in ILC2s. These results reveal an anti-tumor function of β2AR signaling through the suppression of ILC2 activity within the TME that warrants further investigation. This work has been in part supported by NIH Grants F30 CA284763 (to J.C.), K99 HL155792 (to H.M.), and RO1 CA205246 (to E.R.)

#0106 Selective elimination of CD169^{+} macrophages in lymph nodes invaded by breast cancers.

Y. Maeshima[1], T. R. Kataoka[2], A. Vandenbon[3], M. Hirata[3], Y. Takeuchi[3], Y. Suzuki[4], Y. Fukui[1], Y. Ibi[5], H. Haga[3], S. Morita[5], M. Toi[1], S. Kawaoka[6], K. Kawaguchi[1];

[1]Kyoto University Hospital, Graduate School of Medicine, Kyoto, Japan, [2]Iwate Medical University, Iwate, Japan, [3]Kyoto University, Kyoto, Japan, [4]The University of Tokyo, Tokyo, Japan, [5]Kyoto University Graduate School of Medicine, Kyoto, Japan, [6]Tohoku University, Sendai, Japan

Background: Lymph node metastasis is known as one of the strongest prognostic factors in breast cancer. The invasion mechanism of metastasized cancer cells in such immune cell-rich organs remains clear. Here, we aimed to elucidate the impact of metastasized cancer cells on the lymph node immune cell landscape.

Methods: Multiscale transcriptomic analyses were performed on both metastatic and nonmetastatic lymph node samples from breast cancer patients with lymph node metastasis. As cancer cells interact with lymphocytes in lymph nodes in direct, proximal, and distant manners, we tried to capture the direct and proximal impact on immune cells in invaded lymph nodes by comparing paired metastatic and non-metastatic lymph node samples. Laser-micro-dissected sections were obtained from 17 lymph nodes across six breast cancer patients at stages II–III, with each patient contributing both types of lymph nodes for direct comparison. We performed bulk transcriptome, spatial transcriptome, and imaging mass cytometry to analyze the obtained lymph nodes. Furthermore, we conducted immunohistochemistry analyses against a larger patient cohort (574 lymph nodes from 58 patients).

Results: Comparing the transcriptomes of paired lymph nodes with and without metastasis from the same patients revealed selective downregulation of CD169+ macrophage-related genes in metastatic lymph nodes. The spatial transcriptome indicated a potential depletion of CD169+macrophages, initiators of anticancer immunity, from their residence in metastatic lymph nodes, while other principal immune cell types were unaltered. Mass cytometry imaging revealed that the numbers of CD169+ macrophages were smaller in the metastatic lymph nodes than in the nonmetastatic lymph nodes. Conversely, the number of B cells, CD4+ T cells, CD8+T cells, Treg cells, and CD11c+ cells remained comparable in both lymph node types. Additional immunohistochemistry analysis of 315 nonmetastatic lymph nodes and 159 metastatic lymph nodes from 58 patients with breast cancer showed that a reduced CD169+ macrophage population was prevalent in all breast cancer subtypes. CD169+ macrophages gradually decreased in correlation with pathological lymph node metastasis status, while no correlation was identified with pathological tumor size classification or metastasized cancer volume in invaded lymph nodes.

Discussion: CD169+ macrophages are a unique type of resident macrophages in the lymphoid organs that present cancer-derived antigens to CD8+ T cells. The antigen-presenting role of CD169+ macrophages to T cells is a pivotal step in adaptive immunity. The elimination of CD169+ macrophage implies the disruption of the first step of the initial immune response. This study uncovered CD169+ macrophage suppression as a pronounced pathological phenotype in lymph nodes with breast cancer metastasis, thereby establishing it as a critical future therapeutic target.

#0107 Application of MSD on the lung cancer associated idiopathic pulmonary fibrosis.

Wei Bao, Ying-Ji Li, Jin-Fan Gu, Cong-Lin Yang, Yi-Da Wang, Tie-Jun Bing, **Wen-Jen Yu**

ICE Bioscience, Inc., Beijing, China

Idiopathic pulmonary fibrosis (IPF) is a progressive and irreversible chronic disease that kill ten thousand of people in China every year. The risk of IPF is highly correlated with smoke, air pollution, dust, virus infection and aging. Average survival period of patients diagnosed as IPF is around 2.8 years which is less than several types of cancers, therefore, IPF is also thought to be a lung cancer-like disease. In the past few decades, many animal models were created to mimic human IPF, however, induction materials, animal species and strain differences, sex, physiology structure and progress of disease make the choice of IPF animal models selection more difficult. In addition, lack of strong evidence of cytokines biomarker detection hampered the discovery of anti-IPF drugs. Meso Scale Discovery (MSD) instrument is an efficient tool to high throughput analyze the lowest level of several cytokines and other biomarkers in the same time and was used to detect the bleomycin (BLM) induced mouse lung fibrosis. Meanwhile, animal sex and dose effects of BLM were also tested to define the proper mouse model for anti-IPF drugs development. Our results indicated that 0.6-0.8 mg/kg of intratracheal injection of single dose BLM is sufficient to create the IPF model without sex differences by examining the lung weight, lung ratio, soluble hydroxyproline, HE staining and mason staining. However, male mice were more resistant to the lethal effect of BLM due to the larger size or bodyweight. Using MSD detection, several mouse cytokines were measured simultaneously and showed that IFN-γ, IL-5, TNF-α, and IL-10 were increased in the IPF mouse model and were recovered after pirfenidone treatment at day 14 which mimics the cytokines profile in IPF patients. In summary, the MSD detection and pathological evaluation prove that male mouse treated with 0.8 mg/kg BLM through intratracheal injection is a suitable mouse model for the development of anti-IPF dugs.

#0108 Tumor-derived complement C3 is overexpressed in STK11 mutant non-small cell lung cancer and contributes to an immunosuppressive tumor microenvironment in a syngeneic mouse model.

S. Suzuki, C. Ting, B. Kandar, T.-A. Chen, A. Khan, T. Giridharan, B. Segal, **E. H. Yau**;
Roswell Park Comprehensive Cancer Center, Buffalo, NY

Mutations in *STK11* that lead to loss of its protein LKB1 occur in 15-20% of non-squamous non-small cell lung cancer (NSCLC) and are frequently co-mutated with oncogenic *KRAS* mutations. *KRAS* and *STK11* co-mutant NSCLC is associated with poor prognosis, low PD-L1 expression, low T-cell infiltration, and poor response to immune-checkpoint inhibitors (ICI). Loss of LKB1 leads to altered transcriptional programs with the activation of CREB-dependent gene transcription and changes in the tumor microenvironment including recruitment of suppressive myeloid cells. We used the syngeneic *Kras* mutant murine CMT167 tumor cell line that is wild-type for *Tp53* and *Stk11* and sensitive to ICI and generated isogeneic *Stk11* knockout cell lines (CMT167-Stk11-KO) by CRISPR/Cas-9 deletion. Loss of *Stk11* recapitulated LKB1-loss transcriptional signatures and rendered CMT167 tumors resistant to ICI. Single-cell RNA sequencing (10x) of implanted tumors demonstrated significantly less CD8 T-cells and increased neutrophils (PMN) in *Stk11*-KO versus *Stk11*-WT tumors. Analysis of differentially expressed genes in the tumor compartment identified increased expression of complement pathway genes including the central mediator *C3* in CMT-167-Stk11-KO tumors. Examination of a well characterized clinical cohort of human *KRAS*-mutant NSCLC patient samples with and without *STK11* mutation confirmed the increased expression of complement *C3* in *STK11*-mutant tumors. Analysis of a human NSCLC cell line panel demonstrated that *C3* expression was modulated by LKB1. Knockout of *C3* in CMT167-Stk11-KO tumor resulted in dramatic inhibition of tumor growth and re-sensitized CMT167-Stk11-KO tumors to ICI treatment in WT mice. Using *C3*-/- knockout mice, this effect was determined to be reliant on tumor-derived *C3* and dependent on adaptive immunity as no difference in growth of CMT167-Stk11-KO tumors occurred in nude mice or in WT mice after CD8 T-cell depletion. We then compared the transcriptome of Stk11-KO tumor cells with and without *C3* deletion, and observed that *C3* upregulates the expression of *Cxcl1*, *Cxcl2* and *Cxcl3* which mediate PMN recruitment and activation. Since these chemokines ligate Cxcr2, we asked whether Cxcr2 mediated tumor growth and ICI resistance in Stk11-KO tumors. While treatment with single-agent Cxcr2 inhibitor and anti-PD-1 therapy had no effect on tumor growth, the combination resulted in significant suppression of tumor growth *in vivo*. These results support a role for tumor-derived *C3* suppressing CD8 T-cell immunity, potentially indirectly through recruitment of PMN or inducing PMN suppressor function. Our results also provide rationale for targeting tumor-derived complement and inhibiting Cxcr2 to enhance ICI efficacy as novel therapeutic approaches in patients with *STK11*-mutant NSCLC.

#0109 Identification of tumor-intrinsic and extrinsic mechanisms of T cell exclusion in estrogen receptor-positive (ER+) breast cancer through integration of bulk and single-cell transcriptome and spatial analysis.

K. Shimada[1], Y. X. Cui[2], D. Michaud[2], K. F. Zheng[3], J. Goldberg[2], R. Pastorello[4], L. Kania[3], S. S. McAllister[5], S. M. Tolaney[2], A. Waks[2], R. Jeselsohn[2], P. K. Sorger[1], J. Agudo[2], J. L. Guerriero[1], E. A. Mittendorf[1];

[1]Harvard Medical School, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Hospital Sirio Libanes, Sao Paulo, Brazil, [5]Brigham and Women's Hospital, Boston, MA

T cells are generally present in low numbers in estrogen receptor-positive (ER+) breast cancer (BC) potentially due to limited antigens or impaired antigen presentation, however defined mechanisms are not fully understood. This study explores the interplay between estrogen receptor signaling (ERS), antigen presentation machinery (APM), and T cell signaling (TC) using diverse datasets, including BC cell lines, TCGA, METABRIC, and clinical trial bulk transcriptomes, single-cell RNA-sequencing of ER+ primary BC, and single-cell spatial multi-plex cyclic immunofluorescence (CyCIF) of primary BC patients. Co-expression analysis of both computationally and manually curated genes in TCGA and METABRIC data unveiled distinct 29-gene ERS and 225-gene combined APM/TC modules with strong inverse correlations in ER+ BC. This inverse correlation was confirmed in independent cohorts. ERS and APM/TC modules were down- and up-regulated, respectively, in response to aromatase inhibitor therapy in ER+ BC patients from the ACOSOG Z1301B trial who demonstrated clinical benefit. Analysis of published single-cell RNA-sequencing data of 20 primary ER+ BC was performed to elucidate cell types that express individual genes in the modules. It confirmed that high ERS activity is associated with reduced T cells, and identified distinct cell types contributing to each module, showing higher ERS activity in tumor cells and higher APM/TC activity in stromal and immune cells. At the cell type level, we found distinct contributions and precise insights of individual genes. The prevalence of ERS activity in tumor cells prompted investigation to determine if the ERS and APM/TC modules were preserved as tumor-intrinsic signaling. Analysis of 54 BC cell lines indicated partially preserved module correlations in cancer cell lines and revealed that the APM/TC module is a contribution of both tumor-intrinsic (e.g., complement and type-I IFN-response), and tumor-extrinsic (e.g., lymphocyte activation) factors. CyCIF analysis of 29 ER+ BC samples was performed to bridge gene signatures with spatial biology and validated that higher ERS activity correlates with lower T cell infiltration. The spatial pattern of T cells varied from immune desert to stromally bound to fully inflamed tumors. Neighborhood analysis revealed increased frequency of CD8 T cells around a tumor cell is associated with elevated MHC I and II in broad immune cells and macrophage subsets, respectively. pTBK1+ macrophages inversely correlated with CD8 T cell frequency and MHC expression in neighboring cells, suggesting an immunosuppressive role. This study uncovers robust and tightly regulated ERS and APM/TC signaling in ER+ patients, unraveling molecular intricacies and offering potential insights for targeted therapeutic interventions.

#0110 Adoptive transfer of tumor antigen-specific T cells alters the renal tumor microenvironment in the presence and absence of immunotherapy.
H. Stephens, E. Elkins, F. Dempsey, Z. Swalley, J. Li, J. Zhang, R. Kirkman, B.-R. Chen, Z. Roberts, S. Sudarshan, B. Sleckman, H. Tse, D. L. Smith, Jr., L. A. Norian;
University Of Alabama At Birmingham, Birmingham, AL

Immunotherapies are the standard of care for patients with renal cancer, yet their effects on renal tumor antigen-specific CD8 T cell responses and their subsequent ability to modulate the renal tumor microenvironment remain difficult to evaluate. In order to address this gap in the field, we developed a novel murine model to examine tumor-antigen specific CD8 T cell immune responses in orthotopic renal cancer utilizing a new cell line, Renca-tERK-LUC. Parental Renca cells were transduced with a lentivirus expressing the naturally-occurring, mutated tERK peptide found in CMS5 fibrosarcoma cells to create Renca-tERK-LUC tumor cells. The tERK mutation consists of a one base pair change that creates an Sfc1 site, so it can be detected by RT-PCR followed by restriction enzyme digestion. Our data show that Renca-tERK-LUC cells express tERK at high levels and grow progressively in control BALB/c mice, but are rejected in DUC Thy1.1 mice, which contain endogenous TCR transgenic CD8+ T cells specific for tERK peptide / MHC I complexes. We then performed adoptive transfers of 5×10^5 DUC Thy1.1 T cells into mice with established, orthotopic Renca-tERK-LUC tumors to evaluate: 1) the effects of immunotherapy on tumor-antigen-specific T cell responses; and 2) the effects of tumor-antigen-specific T cells on the broader renal tumor microenvironment. Our data indicate that the transfer of relatively low numbers of tumor antigen-specific CD8+ T cells induces transcriptomic and cellular changes in the tumor microenvironment in both the presence and absence of immunotherapy. Defining the parameters surrounding tumor-antigen-specific T cell responses and their ability to modulate the renal tumor microenvironment under the influence of clinically relevant immunotherapeutic intervention has the potential to increase the understanding of immunity to renal tumors, which could ultimately prove beneficial for renal cancer patients.

#0111 Establishing orthotopic renal cell carcinoma xenograft in PBMC-humanized immunodeficient NSG-MHC I/II double knock-out mice.

W. Kang[1], Y. Wang[2], Y. N. Laimon[3], O. Pham[1], B. Matran[1], L. Bottoms[1], S. Khang[1], H.-C. Yuan[2], N. Murugan[2], A. B. Sheshdeh[3], L.-c. Yao[1], J. Yang[1], M. Cheng[1], S. Signoretti[3], W. A. Marasco[2], J. G. Keck[1];

[1]The Jackson Laboratory, Sacramento, CA, [2]Dana Farber Cancer Institute, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA

Clear cell renal cell carcinoma (ccRCC), the predominant histological subtype of RCC, is highly correlated with immune cells, an association that is linked to a worse prognosis. Our study aimed to establish an orthotopic ccRCC mouse model reconstituted with human peripheral blood mononuclear cells (PBMCs) and implanted with human ccRCC SKRC-59 cells under the kidney capsule in immunodeficient NSG-MHC I/II double knock-out (DKO) mice. The study was conducted using two experimental designs to optimize humanization and tumor formation. In the first experimental design, the mice were engrafted with SKRC-59 cells under the left kidney capsule 24 hours post-irradiation on study day 0. The PBMCs were then injected intravenously on study day 9. The second experimental design involved irradiating mice on study day -1, followed by engraftment with PBMCs either perfectly (6/6) or partially (3/6) matched human leukocyte antigens (HLA) with the tumors. Subsequently, SKRC-59 cells were placed under the kidney capsule on study day 0. Daily post-operative observations were conducted for six days following surgery to ensure the well-being of the mice. Tumor burden was assessed twice weekly using an *in vivo* imaging system, along with monitoring body weights and clinical signs. The humanization rates were evaluated 7, 14, and 21 days post-PBMC engraftment, as well as at the end of the study, using peripheral blood. Approximately 5 to 6 weeks post-tumor implantation, the mice were euthanized, and both left and right kidneys were collected and weighed for further analysis. The humanization rates were significantly higher when the PBMCs were engrafted on the same day as irradiation compared to 10 days post-irradiation. The PBMC humanization, and HLA-type PBMC donors did not affect tumor burden. Additionally, we found that distant metastasis in the lungs developed in several mice. Using flow cytometry and immunohistochemistry (IHC) to analyze tumor infiltrating leukocytes (TILs), a predominant number of CD3+ T cells were found in human CD45+ TILs, indicating that this model could be useful for evaluating T cell-mediated immunotherapies. Moreover, lympho-myeloid aggression (LMA) was observed in this peripheral blood leukocytes (PBL) mouse model, showing early stage tertiary lymphoid structures (TLS), which potentially provides a powerful tool to recapitulate TLS formation and study associated mechanisms and therapies. Our study demonstrated the growth of ccRCC SKRC-59 tumors under the renal capsule and observed TILs and metastatic patterns in PBMC humanized DKO mice. This PBMC-humanized orthotopic ccRCC xenograft model can recapitulate tumor microenvironment (TME), and be potentially used to assess the safety and efficacy of various immunotherapeutics.

#0112 The NSG-Flt3KO; Tg(hFLT3LG); hIL15 mouse strain improves engraftment of innate immune cells post-CD34+ humanization.

S. Boreddy, S. Hu, B. Soper;
The Jackson Laboratory-West, Sacramento, CA

Human immune system mouse models play critical roles in numerous preclinical drug development pipelines, including immunology, infectious diseases, and immuno-oncology. These models are constantly evolving, with addition of human cytokines to sustain engraftment of human immune cells. To date, most humanized models have primarily focused on T lymphocyte cell biology, leaving room for improvement in developing models that effectively represent NK cells and the myeloid lineage. Previously, we demonstrated that the introduction of human IL-15 (NSG-IL-15) or FLT3L (NSG-FLT3L) to NOD-scid IL2rγ^{null} (NSG) mice enhanced engraftment of innate immune cells, including human CD56^{+} NK cells, CD141^{+} and CD1c^{+} DC subsets, CD123^{+} pDCs, and CD14^{+} monocytes. In this study, we describe a new NSG mouse variant (NSG-Flt3KO; Tg(hFLT3LG); hIL15) that expresses physiological levels of both human IL-15 and FLT3L and detail the immune cell diversity following HSC engraftment. NSG-Flt3KO; Tg(hFLT3LG); hIL15 mice, along with control strains NSG, NSG-IL15, and NSG-FLT3L, were engrafted with human umbilical cord blood derived CD34^{+} hematopoietic stem cells from three different donors, and blood samples were collected until Week 20 post-transplantation. Blood samples were analyzed via flow cytometry to assess the engraftment of innate and adaptive immune cells. Spleen and bone marrow samples were collected at Week 12 post-transplantation and analyzed for lymphoid and myeloid immune cell populations via flow cytometry. To compare the differences among the strains in terms of immune cell sub-populations across weeks, a Two-Way ANOVA (mixed-model) was conducted, with $p<0.05$ considered statistically significant. Overall, the results demonstrate that NSG-Flt3KO; Tg(hFLT3LG); hIL15 mice have enhanced CD56$^{+/dim}$ CD16^{+} NK cells compared to NSG-FTL3L strain (20.5±12.8% vs 7.0±3.5% at Week 12), but comparable to NSG-IL15. Furthermore, myeloid sub-lineage cells in NSG-IL15-FLT3L mice, such as monocytes, macrophages (M1), granulocytes, dendritic cells, and neutrophils, were greater than in NSG or NSG-IL15 strains, but comparable to NSG-FLT3L mice. Overall levels of hCD45+ and T cell sub-populations (CD3^{+} or CD4^{+} or CD8^{+}) were comparable across all strains tested. In sum, our NSG-Flt3KO; Tg(hFLT3LG); hIL15 engraftment data suggest an improved model that supports drug development targeting human myeloid and NK cell populations.

#0113 Generation and validation of a novel humanized IL-31/IL-31RA/OSM/OSMR mouse model.

L. Wang[1], L. Zhao[1], M. Zhang[1], Z. Zhang[1], Z. Chen[1], **M. Kuraguchi**[2], J. Lian[1], J. Zhang[1];
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China, [2]Biocytogen Boston Corp, Waltham, MA

Oncostatin M (OSM) and interleukin-31 (IL-31) are two pleiotropic cytokines that share a common signaling receptor subunit, the OSM receptor beta (OSMR). Both cytokines are released by monocytes, macrophages, dendritic cells and T lymphocytes in inflammatory situations, and upon binding to their respective receptors, induce the production of inflammatory cytokines (such as IL-6), chemokines, and other cellular growth factors during tissue repair, mainly via the JAK/STAT signal pathway. As OSM and IL-31 are reported to be involved in a variety of physiological and pathological processes, targeting IL-31 or OSM signaling is of therapeutic interest. To provide a novel preclinical platform for testing novel modulators of these signaling axes, a humanized IL-31/IL-31RA/OSM/OSMR mouse model was generated. First, single gene knock-in mice were constructed by gene editing technology; multigenic knock-in mice were then obtained by breeding, yielding a quadruple humanized model in which the murine cytokine sequences were replaced by full-length human cytokine sequences *in situ*, while the murine receptor sequences were replaced by chimeric sequences comprised of the human extracellular region and murine intracellular regions *in situ*. mRNA expression confirmed expression of IL-31, IL-31RA, and OSMR in this model, while ELISA confirmed expression of human OSM protein in the model without evidence of murine OSM expression. Next, the signaling capacity of the humanized OSMR receptor was confirmed: mouse embryonic fibroblasts (MEFs) isolated from humanized B-hOSM/hOSMR mice were capable of responding to human OSM to release IL-6, while wild-type MEFs could only respond to murine OSM. Subsequently, the ability of IL-31RA antibodies to alleviate scratching was tested in a chemically induced model of atopic dermatitis. Compared to mice receiving control antibodies, scratching frequency in humanized B-hIL31/hIL31RA/hOSMR mice treated with nemolizumab was attenuated (analog antibody was generated in-house). Finally, blood counts and flow cytometric profiling indicates that the humanized mice have a normal frequency of leukocytes and lymphocytes. Taken together, this quadruple humanized IL-31/IL-31RA/OSM/OSMR mouse model is a promising preclinical tool that can be used to evaluate novel modulators of this signaling pathway prior to clinical development.

#0114 Identification of the actionable target, LILRB4, through genetic linkage analysis of Diversity Outbred (DO) F1 mice expressing HER2(neu).

J. B. Jacob[1], W.-Z. Wei[1], B. L. Kidder[1], T. Adeyelu[2], A. Elliott[2], G. Bepler[1], J. D. Reyes[1];
[1]Wayne State University School of Medicine, Detroit, MI, [2]Caris Life Sciences, Irving, TX

Our goal is to identify, *in situ*, the regulatory genes that dictate the onset age and growth rate of spontaneously arising tumors to implement new intervention strategies. For genetic linkage analysis, we crossed HER2(neu) Tg mice with Diversity Outbred (DO) mice, an outbred population comprised of 8 founding strains (A/J, C57BL/6J, 129S1/SvlmJ, NOD/ShiLtJ, NZO/HILtJ, CAST/EiJ, PWK/PhJ, WSB/EiJ) maintained by non-sibling crossing to ensure each mouse is genetically unique. Using R/QTL package, we linked Quantitative Trait Loci (QTL) in Chr 1 and X with tumor onset age, and a Chr 10 QTL with tumor growth rate. The Chr1 (=human Chr2) QTL was linked to human breast cancer diagnosis in 11 Genome-Wide Association Studies (GWAS; the human GWAS catalog, https://www.ebi.ac.uk/gwas/). Because human GWAS data is deficient in Chr X mapping and also does not assess tumor growth rate as a trait, the QTL loci identified in mouse Chr X and 10 were discoveries beyond the capacity of human GWAS. In total, we identified 26 candidate genes across the 3 QTL. For clinical validation, the genes were analyzed with CodeAI (Caris LS) which associated cancer patient clinical data with candidate gene expression. We found 21/26 genes significantly associated with the survival of patients with primary (n=3,533) and/or metastatic (n=4,870) breast cancers and 17/26 were associated with lung cancer (n=11,334) survival, with 13 overlapping genes between lung and breast cancer, indicating broad applicability of these candidate genes.
We interrogated the immune status in BALB NeuT and (BALBxPWK)F1 NeuT mice because the F1 mice developed tumors around 9 wk, much earlier than the 14 wk observed in BALB NeuT mice. Surprisingly, (BALBxPWK)F1 mice responded to cancer vaccines more vigorously. Single cell RNA (scRNA) libraries from (BALBxPWK)F1 NeuT tumors showed an expanded lymphocyte cluster (12%), compared with BALB NeuT (2%) and an enrichment of T cell activation genes. These findings may reflect a deficiency in tumor cell recognition by the activated anti-tumor effectors and a window of opportunity for correction.
Of the 21 candidate genes, LILRB4, a myeloid cell checkpoint molecule, was of particular interest. Expression of LILRB4 is predictive of patient survival in both breast and lung cancer. Using scRNA
sequencing, we found this transmembrane receptor expressed primarily by tumor infiltrating myeloid cells. In a reported scRNA sequencing dataset (GSE161529), LILRB4 was expressed by infiltrating macrophages in human breast cancers, and is also correlated with reduced survival. In a PAN Cancer ATACseq dataset (Corces et al., 2018), promoter accessibility of LILRB4 was associated with reduced survival. Taken together, there are multiple immune regulatory mechanisms of tumor progression and LILRB4 is an important new actionable target. CA76340 (WZW), KCI TBM program (JBJ) and CCSG P30 CA022453 (GB).

#0115 Developing uPAR CAR T Cells for High-Grade Serous Ovarian Cancer.

Zeda Zhang[1], Xin Fang[1], Yu-jui Ho[1], Sascha Haubner[1], Friederike Kogel[1], Clemens Hinterleitner[1], Stella Paffenholz[1], Kevin Chen[1], Wei Luan[1], Amanda Kulick[1], Gertrude Gunset[1], Andreina Garcia Angus[1], Jing Zhang[1], Zijian Xu[1], Adam Wang[2], Qingwen Jiang[1], Elisa de Stanchina[1], Britta Weigelt[1], Dmitriy Zamarin[3], Aveline Filliol[1], Judith Feucht[1], Jorge Mansilla-Soto[4], Corina Amor[1], Michel Sadelain[1], Scott Lowe[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Rockefeller University, New York, NY,[3]Icahn School of Medicine at Mount Sinai, New York, NY,[4]Moffitt Cancer Center, Tampa, FL

Chimeric Antigen Receptor (CAR) T cells are a modality of immunotherapy that act to eliminate cancer cells by redirecting the cytolytic activity through targeting a protein overexpressed on the surface of the cancer cell. In contrast to move conventional cancer therapies, their anti-cancer activity does not depend on a cancer-specific molecular vulnerability but rather the differential expression of the target antigen on tumor cells compared to normal tissues. We have developed CAR T cells targeting the urokinase plasminogen activator receptor (uPAR), which is overexpressed on senescent cells but not expressed highly in vital organs, to selectively target senescent cells in a range of tissue damage pathologies where they are known to be pathogenic. uPAR is also highly overexpressed in a wide range of cancer types, including pancreatic, kidney, bladder, brain and ovarian carcinomas, respectively, raising the possibility that CAR T cells targeting uPAR may also be effective against cancer. Indeed, leveraging an electroporation-based genetically-engineered mouse model of ovarian cancer, we demonstrate the robust anti-tumor efficacy of murine uPAR CAR T cells in immunocompetent syngeneic mice. Moreover, through an exhaustive functional screening of 37 distinct human uPAR single-chain fragment variants (scFVs), we have successfully identified lead scFVs exhibiting subnanomolar affinity to membrane-anchored uPAR. Significantly, these human uPAR CAR T cells exhibit the capability to eliminate both orthotopic and metastatic human HGSOC xenograft tumors without inducing severe adverse effects. Ongoing efforts encompass the assessment of the long-term safety and toxicity profiles of uPAR CAR T cells utilizing a humanized mouse model platform. Our results provide a strong rationale for developing uPAR CAR T cells as an anticancer strategy relevant to a broad range of tumor types, and provide an avenue for safety profiling of uPAR CAR T cells prior to clinical testing in non-cancer patients harboring senescence-related pathologies.

#0116 Generation of humanized PD-1/PD-L1/CD94/NKG2A mice for evaluating novel combination therapies.

F. He[1], J. Yuan[1], Y. Shan[1], H. Bahetiyaer[1], Q. Xu[1], **J. Frame**[2], Q. Lin[2], X. Zhou[1], C. Shang[1];
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China, [2]Biocytogen Boston Corp, Waltham, MA

NKG2A and its co-receptor, CD94, are expressed on the surface of NK cells, and function to send inhibitory signals to NK cells upon recognition of the HLA-E complex on adjacent cells. Blockade of the NKG2A/CD94 complex is a promising strategy for cancer immunotherapy, due to the potential to trigger NK-mediated tumor killing. Previously, we generated humanized NKG2A/CD94 mice for testing novel therapeutics targeting human NKG2A/CD94. To explore the potential that this complex could be targeted as part of a novel combination therapy, we crossed humanized NKG2A/CD94 mice with humanized PD-1/PD-L1 mice, which were previously engineered to express the extracellular regions of human PD-1/PD-L1. Flow cytometric data from splenocytes isolated from the quadruple humanized mice confirmed expression of human NKG2A and CD94 in NK cells and activated CD8 T cells, as well as PD-1/PD-L1 on the surface of T cells. To test the efficacy of antibodies targeting these checkpoints *in vivo*, B-hHLA-E plus/hPD-L1 MC38 colon cancer cells were subcutaneously implanted into the quadruple humanized mice and treated with antibodies targeting human NKG2A, human PD-L1, or both antibodies. Results indicate that the combination therapy significantly reduced tumor growth when compared to NKG2A single antibody treatment. Together, these data suggest that humanized PD-1/PD-L1/CD94/NKG2A mice are a validated model for further evaluation of novel combination therapies.

#0117 Improved PBMC humanized mouse models for immuno-oncology drugs evaluation.

B. Xie, X. Hou, P. Yang, Y. Zhou, **D. Wen**;
Shanghai LIDE Biotech Co., Ltd., Shanghai, China

It has been demonstrated that anti-PD(L)1 therapy could significantly improve survival outcomes for patients with metastatic solid cancers, such as melanoma, non-small cell lung cancer and MSI-H colorectal cancer. However, more than half of these patients (NCT02563002, NCT02142738, NCT02563002) do not respond to immune checkpoint blockade (ICB) therapy, and 90% of colorectal cancer patients have MSS/pMMR characteristics and almost no response at all, which drives scientists to design novel drug candidates urgently and integrate tumor and tumor microenvironment (TME) signals systemically to rejuvenate exhausted immune system and overcome ICB resistance. LIDE has developed both traditional PBMC humanized mice model, and human immune cells and cancer co-inoculated model for IO drugs functional evaluation in the last 5-years by using unique PBMC donor selection and standard cancer biobank (PDX patient-derived xenografts, CDX cell derived xenograft) establishment. Cancer biopsies with MDM2 amplification or DNMT3A alternation have been shown resistant to PD1-Ab therapy but sensitive to chemical combo-therapy, and pMMR cancer PDX models seem responsible well to EGFR targeted, CD39-CD73-Adenosine targeted therapy. Human IL15 transgenic mice are used as one useful tool to investigate in vivo function of NK cells, NK engagers/modulators as well as drugs with ADCC (Antibody dependent cell-mediated cytotoxicity) effect. The activated immune cells and cancer co-transfer model, can significantly delay the graft-versus-host-reaction for another month compared with traditional PBMC humanized model, and archives maximal therapeutic effect of the testing drugs by pre-activating T cells with specific tumor antigens. Dendritic cells or macrophages could be successfully introduced into this co-inoculated system to work together with T cells, mimic human tumor tissue complexity, to help determine the overall effect induced by integrated signals. It seems CD40 agonist or CD47 antagonist could well synergies with anti-PD(L)1 to control melanoma and triple negative breast cancer development, respectively. This optimized PBMC humanized cancer-bearing mice models have been tested for various cancer targets, e.g. PD(L)1, Tim3, Lag3, Tigit, PVRIG, TGFβ1, CD73/CD39, CD47/Sirpa, DLL3/CD3, Claudin18.2/4-1BB, B7-H3, GITR, to better understand the interaction between cancer cells and immune cells.

#0118 Development of a novel murine model, NCG-M/hIL15, for enhanced post-HSC transplantation immunoreconstruction.

H. Wang, J. Xing, J. Fan, Y. Fan, J. Zhao, X. Gao, C. Ju;
Gempharmatech Co., Ltd., Nanjing, China

Advances in the field of immunology and hematopoietic stem cell (HSC) transplantation have prompted the development of murine models that faithfully recapitulate human immune responses. We present the NCG-M/hIL15 model, an innovative advancement in the realm of preclinical research, addressing two key challenges associated with existing models: the limited capacity for human natural killer (NK) cell regeneration in NCG-M and the suboptimal reconstitution of T cells, myeloid lineage cells in NCG-hIL15 mice.

Compared to the conventional NCG-M model, the NCG-M/hIL15 model demonstrates a significant improvement in its ability to regenerate human NK cells post-HSC transplantation. This advancement offers a valuable tool for studying NK cell biology, immune surveillance, and antitumor responses.

Furthermore, when compared to the NCG-hIL15 model, the NCG-M/hIL15 model outperforms in the reconstitution of human T cells and myeloid lineage cells, contributing to a more comprehensive simulation of human immune responses. The overall survival of mice in this model is notably stable, further enhancing its utility for long-term immunological studies.

The NCG-M/hIL15 model not only advances our understanding of human immune responses but also has significant implications for the development of novel immunotherapies and the preclinical evaluation of HSC transplantation strategies. This novel murine model offers a more accurate representation of the human immune system, with the potential to expedite the development of innovative therapeutic interventions. We present this model as a valuable addition to the preclinical research toolkit, promising a deeper understanding of immunology and a brighter future for clinical applications.

#0119 A non-surgical method for developing a pre-clinical orthotopic mouse model for colorectal cancer.

N. Singh[1], S. Sharma[1], K. Jeught[2], Z. Zhou[1], X. Zhang[1], X. Lu[1];
[1]Indiana University School of Medicine, Indianapolis, IN, [2]University of Miami Miller School of Medicine, Miami, FL

Recapitulating physiologically relevant tumor microenvironment is important yet a significant challenge in modeling colorectal cancer (CRC) for basic and translational studies. Among the different methods, using the cecal-wall injection technique is the most common way to create animal models of colorectal cancer (CRC). However, this approach requires complex surgery, and its unnatural placement creates a significant obstacle for developing treatments. Here, we report a non-surgical procedure for establishing orthotopic CRC mouse models, reflecting the appropriate tumor microenvironment to better model the disease development and facilitate translational studies including drug identification and validation. In this procedure, anesthesia is induced in overnight fasted study immunocompetent or immunodeficient mice while placed on a thermostat-controlled heating blanket. A specialized catheter is inserted and distended into the mouse colon to gently block the colon and ensure the localization for tumor development. Hereafter, the colonic epithelium is treated with proteases and mechanical abrasion to cause mild disruption. Following the local gut inflammation, the targeted colon region is incubated with tumor cells, leading to the adhesion of tumor cells to the colonic epithelium. Based on the animal background and the cell line used, the tumor developed within 3-4 weeks. The stages of tumor development at different time points were successfully confirmed using hematoxylin and eosin stain. Tumor microenvironment data revealed a significant increase in the immune cell infiltration specifically $CD4^+$ T-cells and tumor-associated macrophages in the non-surgical procedure as compared to the cecal-wall injection. Furthermore, a significant increase in the PD-1 expression of the $CD8^+$ T-cells in the cecal-wall injection as compared to the non-surgical procedure, suggests that the precise location of the tumor site may exert a substantial influence on pre-clinical therapeutic outcomes of immune-checkpoint inhibitors, thereby potentially hampering the clinical efficacy of drug treatments. Additional adaptations of this procedure may include: i) tumor development in different mouse strains, ii) local delivery of adeno-Cre in transgenic mice for CRC, and iii) delivering tumor organoids and patient-derived xenografts in immuno-deficient mice. Overall, our non-surgical procedure overcomes the technical difficulties of surgery and offers several advantages like ease of handling, cost-effectiveness, pain-free with nearly no procedure-associated mortality and adaptability to several strains. In conclusion, this procedure provides novel and promising alternative to conventional surgical orthotopic CRC mouse models for therapeutic interventions.

#0120 A closer Look at colorectal cancer risk: Insights from the complex relationship of HIV, helminths, and immune responses.

B. P. Damane[1], T. V. Mulaudzi[2], S. S. Kader[1], R. E. Ogunsakin[2], P. Naidoo[1], Z. Dlamini[2], Z. L. Mkhize-Kwitshana[1];
[1]University of KwaZulu-Natal-Natal, Durban, South Africa, [2]University of Pretoria, Pretoria, South Africa

The advent of antiretroviral therapy has markedly increased the survival rates of individuals with human immunodeficiency virus (HIV). However, this demographic, particularly in low-middle-income countries (LMICs) where HIV-helminth co-infections are prevalent, remains susceptible to infections. The intricate interplay between helminth infections and HIV susceptibility, often inducing immunological phenotypes that heighten vulnerability, remains poorly understood. Studies have shown the association between HIV-helminth co-infections and elevated susceptibility to colorectal cancer (CRC), introducing an additional layer of health concerns for this already vulnerable population.

This retrospective observational study delves into the profound effects of HIV-helminth co-infections on immune responses, with a specific focus on type 2 T helper (Th2) cell immunomodulation and susceptibility to CRC. Utilizing samples from a master project (n=414), 80 systematically randomized individuals were categorized into uninfected control, HIV-infected only, helminth-infected only, and HIV-helminth co-infected groups. Parasite detection employed the Kato-Katz technique, and serum testing was conducted for helminth-specific antibodies. Serological HIV testing, viral load categorization, white blood cell counts, and differential analyses were performed. Human ProcartaPlex Panel 1 was used for cytokine profiling of immune stimulatory and inhibitory soluble proteins.

A significant reduction in B and T lymphocyte attenuator (BTLA) (p=0.049) in helminth infections compared to the control. The association of BTLA with its ligand, herpesvirus entry
mediator (HVEM), establishes a direct link between the CD28 and tumor necrosis factor receptor (TNFR) families, triggering wide-ranging and robust immune responses. Subsequently, a notable reduction in CD28 was observed in HIV-infected subjects (p=0.003), followed by helminth-infected and HIV-helminth co-infected individuals (p=0.03) compared to the control. Furthermore, programmed death ligand-2 (PD-L2) expression, a major contributor to alternatively activated macrophage polarization during helminth infections, was significantly increased in the HIV-helminth co-infected group (p = 0.05), favoring a shift towards Th2 immune responses.

These observed alterations underscore the complexity of the immunological interplay in co-infected individuals, emphasizing an additional risk factor for colorectal cancer development. This necessitates a comprehensive understanding, providing valuable insights for the development of therapeutic strategies in LMICs and similar settings, addressing the heightened risk of CRC within this population.

#0121 Gut microbiome association with dietary habits and abemaciclib-induced diarrhea:A multicenter, prospective study.

Y. Fujimoto[1], K. Kawaguchi[2], Y. Maeshima[1], H. Ishiguro[3], K. Yamagami[4], S. Takahara[5], H. Suwa[6], M. Torii[7], S. Nagai[8], Y. Sagara[9], W. Tsuji[10], H. Yamashiro[11], T. Kotake[11], S. Fukuda[12], K. Saito[13], Y. Yamamoto[13], M. Kataoka[2], Y. Himoto[7], A. Yonezawa[2], Y. Fukui[1], Y. Nakamura[1], W. Li[1], S. Tanaka[2], M. Takada[1], S. Morita[1], M. Toi[1];

[1]Kyoto University Graduate School of Medicine, Kyoto, Japan, [2]Kyoto University Hospital, Kyoto, Japan, [3]Saitama Medical University International Medical Center, Hidaka, Japan, [4]Shinko Hospital, Kobe, Japan, [5]Kitano Hospital, Tazuke Kofukai Medical Research Institute, Osaka, Japan, [6]Hyogo Prefectural Amagasaki General Medical CenterKyoto University Graduate School of Medicine, Amagasaki, Japan, [7]Japanese Red Cross Wakayama Medical Center, Wakayama, Japan, [8]Saitama Prefectural Cancer Center, Kitaadachi, Japan, [9]Sagara Hospital, Kagoshima, Japan, [10]Shiga General Hospital, Moriyama, Japan, [11]Tenri Hospital, Tenri, Japan, [12]Keio University, Tsuruoka, Japan, [13]Fujita Health University, Toyoake, Japan

Background: Abemaciclib, a leading treatment used for HR-positive, HER2-negative metastatic and primary breast cancer patients, often causes diarrhea. Understanding the reasons machinery behind this adverse event leads to reduce the toxicity and improve the quality of life. This study explores a hypothesis that specific gut microbiota profiles are engaged in gastrointestinal toxicities caused by abemaciclib and may be influenced by patients' dietary habits. We assessed it using the Brief Diet History Questionnaire (BDHQ).

Materials and Methods: Our research involved collecting blood and stool samples, as well as dietary data through the BDHQ from 39 patients diagnosed with HR-positive, HER2-negative metastatic breast cancer. These were obtained prior to the start of abemaciclib treatment, at the first imaging evaluation, and at either disease progression or treatment discontinuation due to adverse effects. Incidence and severity of diarrhea were evaluated by the Bristol stool scale at baseline, from day 1 to day 14, and at day 90 of treatment. Stool samples were collected at baseline and at day 90 after the start of abemaciclib treatment. We conducted 16S metagenomic sequencing for gut microbiome analysis and used mass cytometry along with RNA-sequencing to profile immune cells.

Results: Our findings indicate a significant association between the gut microbiota composition and abemaciclib-induced diarrhea, which also appears to be modulated by dietary patterns. An increase in Dorea was observed with higher Bristol Stool Scale scores, while Bifidobacterium and Sellimonas abundances were inversely related to changes in stool characteristics. The presence of Dorea was also positively associated with the consumption of specific food items such as tea, root vegetables, and dietary minerals. In contrast, Collinsella abundance decreased as the frequency of diarrhea increased and it was associated with the consumption of fried foods and certain fats.

Conclusion: The prevalence of diarrhea as a side effect of abemaciclib treatment highlights the need for better management strategies. Our study indicates that gut microbiota, altered by dietary habits, is linked to this adverse effect. The data suggest a possibility of using specific gut bacteria as probiotics to alleviate this condition, pointing towards personalized dietary interventions as a potential avenue for improving treatment tolerance.

#0122 *Fusobacterium nucleatum* in saliva of oral cancer patients induces tumor stemness defense phenotype in cancer stem cells.

Partha Jyoti Saikia[1], Bidisha Pal[2], Lekhika Pathak[3], Shirsajit Mitra[4], Tutumoni Baishya[5], Rupam Das[5], Bikul Das[1]

[1]Department of Cancer and Stem Cell Biology,Department of Stem Cell and Infectious Diseases, KaviKrishna Laboratory, Guwahati, India,[2]Department of Experimental Therapeutics, Thoreau Laboratory for Global Health, M2D2 University of Massachusetts, Lowell, MA,[3]Department of Cancer and Stem Cell Biology, Department of Stem Cell and Infectious Diseases, KaviKrishna Laboratory, Guwahati, India,[4]Department of Cancer and Stem Cell Biology, KaviKrishna Laboratory, Guwahati, India,[5]KaviKrishna Telemedicine Care, Sualkuchi, Assam, India

Background: Oral squamous cell carcinoma (OSCC) is a highly aggressive cancer. Cancer Stem Cells (CSCs) having cell surface markers CD44, ALDH, and EpCAM+ have been identified in OSCC. However, the host pathogen interaction between CSCs and oral microbiome has not yet been studied. A number of studies have recently demonstrated the presence of specific oral bacteria populations and their lipopolysaccharides (LPS) in the tumor microenvironment (1). We previously reported pathogenic bacterial internalization in the CSCs (2). Based on the findings, we have developed an in-vitro model to investigate how oral microbiota may integrate into the tumor microenvironment's CSC population and control its activity. Here, we investigated the host/pathogen interaction between CSCs and FN.
Methods: Oral bacteria FN was selectively isolated using FEA agar plates from oral saliva of oral cancer patients (n=10) at stage 3 or 4. The isolated bacteria was co cultured with SCC 25 cells at MOI of 1:50. After co culturing the stemness genes such as SOX 2, OCT 4, Nanog ,LPS and ABCG2+ cancer stem cell markers were analysed. ABCG2+ CSCs and ABCG2- cells were immunomagnetically sorted and lysed followed by RNA extraction and RT QPCR was performed to observe if FN has selectively internalised in the CSCs. Also ABCG2+ and ABCG 2- cells were used to perform clonogenic assay.
Results: Coculture of FN with SCC 25 cell line induced high expression of stemness genes SOX, OCT 4 and Nanog along with CSC markers ABCG2+. Moreover high expression of LPS was observed indicating the presence of FN in the coculture. Importantly live bacteria was found internalized in ABCG2+ cells but not in ABCG2- cells. High clonogenicity was observed in ABCG2+ CSCs compared to ABCG2- cells. Notably, we found that live bacteria and their LPS, mostly *Fusobacterium nucleatum* isolated (FN) from clinical subjects, were capable of invading CSCs in the in-vitro setting. Post the host-pathogen interaction; it enabled the activation of a niche modulatory tumor stemness defense (TSD) phenotype in the CSCs. These aggressive CSCs with the TSD phenotype have been found to have a critical role in the progression and relapse of oral cancer.
Conclusion: Expression of stemness genes infers the niche defence mechanism of the CSCs of the tumour microenvironment due to infection of FN. Importantly presence of live bacteria in ABCG2+ CSCs indicates that FN selectively infects ABCG2+ CSCs but not ABCG2- cells. High clonogenicity of ABCG2+ CSCs confirms the TSD phenotypic attributes of the CSCs .

#0123 Establishment of humanized CD3EDG/4-1BB mice for testing novel T cell engagers.

C. Shang[1], C. Li[1], L. Zhao[1], Q. Xu[1], **J. Jin**[2], M. Ren[1];
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China, [2]Biocytogen Boston Corp, Waltham, MA

Agonism of the 4-1BB receptor is an attractive therapeutic strategy for tumor cell therapy, due to the ability of this receptor to stimulate activity of T and NK cells for tumor cell killing. Many classes of biologics targeting 4-1BB have been generated to date, including bispecific or multispecific engagers designed to stimulate 4-1BB and CD3 activity on the T cell surface. To provide a preclinical platform to test such therapies, Biocytogen generated a humanized B-hCD3EDG/h4-1BB mouse model. This was achieved by crossing humanized mice expressing chimeric CD3E, CD3D and CD3G with mice expressing the human extracellular region of 4-1BB. Previously, we showed that these humanized CD3EDG mice and humanized 4-1BB mice can be used for validating efficacy of anti-human CD3 and 4-1BB antibody-based therapies, respectively. Here, we confirmed expression of human CD3 and 4-1BB on splenocytes in homozygous humanized B-hCD3EDG/h4-1BB mice by flow cytometry, which also demonstrated lack of murine CD3 and 4-1BB expression. Assessment of leukocyte subpopulations in the spleen and peripheral blood confirmed that humanization of the mice did not significantly alter the development or frequency of blood cell populations. Further evaluation of lymphocyte frequency was also performed, which demonstrates no significant alterations in the CD4/CD8 T cell ratio in spleen, lymph node, or peripheral blood of the animals. Presence of T_{reg} and NK cells was also confirmed. Taken together, these data indicate that the humanized B-hCD3EDG/h4-1BB model is a novel, robust tool for testing novel T cell engagers.

#0124 Validation of humanized TL1A mice for advancing preclinical research.

C. Li[1], S. Zhang[1], Z. Zhang[1], J. Feng[1], **J. Jin**[2], Y. Du[1];
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China, [2]Biocytogen Boston Corp, Waltham, MA

TL1A, or Tumor Necrosis Factor-Like Ligand 1A, plays a pivotal role in regulating the immune system and has garnered considerable attention in the field of cancer research. Studies have shown that TL1A can impact the tumor microenvironment via inflammatory signaling, immunosuppression, and tumor growth and survival. Targeting TL1A or its downstream effects could offer new avenues for cancer treatment and immunotherapy. To this end, we generated a human *TL1A* knock-in (B-hTL1A) mouse model. Human *TL1A* gene expression in B-hTL1A mice was confirmed by RT-PCR. TL1A protein expression was not altered following TL1A humanization in B-hTL1A mice as shown by flow cytometry. Lastly, soluble human TL1A was detected in B-hTL1A mice by ELISA. Due to the purported role of TL1A in mucosal immunity, efforts to induce inflammatory bowel disease in this humanized model are currently underway. Taken together, we established a preclinical B-hTL1A mouse model for the evaluation of TL1A-targeted immunotherapy.

#0125 Development of humanized VEGFA models to assess preclinical efficacy of novel therapeutics *in vivo*.

S. Zhang[1], C. Liu[1], J. Guo[1], Z. Shen[1], **J. Jin**[2], B. Huwatibieke[1], Y. Shen[1];
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Bejing, China, [2]Biocytogen Boston Corp, Waltham, MA

VEGFA is an essential growth factor required for angiogenesis in the context of normal wound healing as well as malignant tissue growth, ultimately facilitating the delivery of oxygen and nutrients to fuel cellular survival, expansion, and repair. VEGFA signaling has also been reported to exert effects on cancer cells and immune cells directly, with evidence suggesting that the pathway can both support tumor growth and inhibit immune surveillance. Thus, targeting VEGFA has been intensely explored as a therapeutic strategy for several cancer indications. Here, we generated a novel humanized VEGFA model (B-hVEGFA mice) to explore the ability of novel VEGFA-targeting therapeutics to curb cancer cell growth and angiogenesis *in vivo*. This was achieved by replacing the murine *Vegfa* gene with the corresponding human *VEGFA* coding region. We confirmed exclusive expression of human VEGF in lung homogenates of the humanized model at levels comparable to murine VEGF quantified in wild-type C57BL/6 mice. Immunohistochemical analysis at 8 weeks of age demonstrates no significant difference in the CD31+ area in several organs of the humanized mice when compared to wild-type C57BL/6 mice, including kidney, heart, liver, and eye. To assess the functional utility of this model in evaluating VEGFA modulators, tumor studies were conducted: murine colon cancer MC38 cells that were also engineered to express VEGFA in a similar manner (B-hVEGFA MC38 cells) were subcutaneously implanted into homozygous B-hVEGFA mice. Treatment with bevacizumab analog essentially abolished tumor growth in the humanized mice, while control tumors continued to expand over the 3 week study. To further evaluate the role of novel combination therapies or bispecific antibodies targeting VEGFA and PD-1, we also generated a triple humanized model expressing human VEGF, PD-1, and PD-L1 (B-hPD-1/hPD-L1/hVEGFA mice) by crossing B-hVEGFA mice with our B-hPD-1/hPD-L1 mice model, which expresses the extracellular domains of human PD-1 and PD-L1. Flow cytometric analysis of this model is currently underway to validate the model for further efficacy testing. Together, these humanized VEGF models provide robust *in vivo* platforms to evaluate novel VEGFA therapeutic candidates.

#0126 Effect of active cytomegalovirus infection on symptoms of fatigue, cancer-related cognitive impairment, and peripheral neuropathy in ovarian cancer survivors.

X. Li, K. Brown, K. Honeyfield, D. Hunter-Schlichting, M. Gruner, D. Teoh, M. Geller, H. Nelson, R. I. Vogel;
University of Minnesota, Minneapolis, MN

Background: Fatigue, cancer-related cognitive impairment (CRCI) and neuropathy are among the most common and distressing side effects reported by individuals treated with chemotherapy for ovarian cancer. Cytomegalovirus (CMV) is a highly prevalent herpes virus infection worldwide, affects inflammation and immune function, and can reactivate with treatment for cancer. This study aimed to explore the associations between active CMV infection and patient-reported symptoms among ovarian cancer survivors who have completed front-line chemotherapy.
Methods: We conducted a cross-sectional study among individuals with a history of a diagnosis of ovarian cancer, primary peritoneal cancer, or fallopian tube cancer from academic and community cancer clinics in Minnesota at any time point after completion of front-line chemotherapy. Participants completed a one-time survey and provided a blood sample. The exposure of interest was plasma CMV DNA level measured using digital PCR, with ≥100 copies/mL of plasma considered active infection (CMV+). We measured symptoms of fatigue (Fatigue Symptom Inventory), CRCI (PROMIS Cognitive Function 8a) and peripheral neuropathy (Functional Assessment of Cancer Therapy/Gynecologic Oncology Group - Neurotoxicity) using validated self-reported measures. Data were analyzed using descriptive statistics and compared by active CMV infection status (CMV+ vs. CMV-) in the full group and by treatment status (receipt of chemotherapy within 30 days prior to data collection) using t-tests.
Results: A total of 160 participants were analyzed. Participants were median of 64.0 years old and 2.3 years from initial diagnosis. Most (75.2%) had advanced stage disease, 43.8% had experienced at least one recurrence, and 40.0% received chemotherapy within 30 days prior to participation. Overall, 40.0% were CMV+, with 40.6% CMV+ among those who received chemotherapy within 30 days and 39.6% CMV+ among those who had not. Participants who were CMV+, compared to those who were CMV-, had overall worse symptoms, with greater symptoms of neuropathy in the full group (11.9±9.2 vs. 9.1±7.8, p=0.04) and particularly greater symptoms of CRCI among those who had recently received chemotherapy (29.2±7.4 vs. 33.2±6.7, p=0.03).
Conclusion: We identified that active CMV infection is common in this survivor population and found that worse symptoms of neuropathy and CRCI are associated with CMV+ status. These results are consistent with studies among other immune-compromised populations, and with further validation, provide a potential therapeutic path for reducing these symptoms.

TUMOR BIOLOGY: Developmental Origins and Drivers of Pediatric Cancer
Poster Session

#0129 Understanding the molecular drivers that regulate Ewing sarcoma cell fate.
D. Truong, D. McCall, C. Agyemang, S. Krishnan, A. Lazar, J. Ludwig;
UT MD Anderson Cancer Center, Houston, TX

Like other translocation-positive sarcomas, Ewing sarcoma (ES) harbors a pathognomonic fusion protein (FP) capable of widespread epigenetic reprogramming that can lead cells to acquire a high-grade, undifferentiated phenotypic state. To better understand how this might occur, we employed a CRISPR knockout (CRISPR-KO) model of A673, targeting exon 4 of the N-terminus EWSR1 portion of the FP and generated a clonal pool (EWSR1 CRISPR KO). We used single-cell RNA and ATAC sequencing (scMultiome) to identify the transcriptional and chromatin changes after the FP knockout (FP KO). We identified several clusters of ES cell heterogeneity. Since the EWSR1-KO is a pooled population, we used known FP-regulated genes to delineate cells bearing the FP KO from wild-type (FP WT) cells. We observed robust expression of FP-activated genes, *PRKCB,* and *LIPI,* in many clusters suggesting regular FP function (FP WT). Conversely, FP-repressed genes, *LOX,* and *IGFBP3* were elevated in a single cluster containing only EWSR1-KO cells. This suggests the FP was successfully knocked out in this cluster (FP KO). That FP KO cluster also lost transcriptional resemblance to ES. A granular identification with cell lines confirmed that all clusters except FP KO were identified as A673 cells. However, the FP KO resembled cell lines with a fibroblastic phenotype. We analyzed enriched motifs and observed no significant difference between the FP KO and FP WT for EWSR1::FLI1. However, the FP KO cells were enriched for motifs in the Fos/Jun family and Smad2/3, which have roles in EMT and mesenchymal differentiation. The FP-KO cells significantly expressed the Fos/Jun family of proteins. Next, we identified peak-gene associations within a ± 500 kb window around the TSS. When we analyzed peaks linked to genes expressed in FP-WT, we found enrichment of the Fos/Jun protein family ($p < 1e-34$), Ets family, and GGAA-microsatellites. However, the FP-KO were strongly enriched for Fos/Jun protein family ($p < 1e-540$) with no change in Ets family motif. Knocking out the FP in the A673 cell line significantly shifted the ES lineage. We observed peaks linked to genes positively associated or regulated by the FP were enriched for Fos/Jun family, Ets family, and GGAA-microsatellites. There may be a cooperative interaction between these TFs that affects the genes linked to the FP. The fact that FP loss enriched the Fos/Jun family motifs, but not Ets family or GGAA-microsatellites, suggests that FP loss activates FP-repressed genes and enables chromatin remodeling to open previously inaccessible DNA binding sites.

#0130 Multi-omic analysis of desmoplastic small sound cell tumors reveal distinct epithelial and neuroendocrine lineages.

D. Truong[1], E. Arslan[1], V. Kochat[1], S. Krishnan[1], C. Agyemang[1], M. Divenko[1], D. Ingram[1], R. Lascano[1], A. Basi[1], J. Gomez[1], H. Beird[1], C.-C. Wu[1], J. Burks[1], P. Futreal[1], A. Lazar[1], R. Ratan[1], N. Daw[1], A. Hayes[2], K. Rai[1], J. Ludwig[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Howard University, Washington, DC

Desmoplastic small round cell tumor (DSRCT) is a rare and aggressive sarcoma subtype that is usually uncurable. All malignant cells harbor a pathognomonic EWSR1::WT1 fusion protein (FP), but FP-targeted agents are nonexistent, and less than 20% of patients survive beyond five years. Lacking the availability of FP-targeted drugs, we seek to understand how the FP regulates tumor cells to promote the characteristic multilineage phenotypes of epithelial and neuroendocrine (NE) cell fates to discover a therapeutic opportunity. Herein, we share the results of gene expression and chromatin accessibility analyses to explore fundamental mechanisms explaining epithelial and NE biology in DSRCT. We profiled 85,640 nuclei from fresh-frozen tissue of nine DSRCT patients post-chemotherapy using single-nucleus RNA-sequencing (snRNA-seq) and ATAC-sequencing (snATAC-seq). A subset of DSRCT patients with low or negative expression of AR expressed partial NE reprogramming, akin to NE prostate cancer (NEPC), exhibiting NE markers (SYP, ENO2, CHG, FOXA2, ASCL1, and SOX2). Another patient subset expressed epithelial markers (MUC1, MUC6, KRT18, KRT23, CDH1). One specimen appeared to exhibit both markers - implying a hybrid or a poorly differentiated phenotype. This suggests that DSRCT could be classified into three subtypes: 1) Epithelial/AR-positive, 2) NE-positive, and 3) hybrid AR/NE. We used CytoTRACE to predict differentiation states. As expected, normal cells (i.e., fibroblasts and immune cells) were the most differentiated. Neoplastic cells, identified by EWSR1::WT1 gene targets and copy number variations, had lower differentiation scores, indicative of a less differentiated phenotype. The NE subtype had the lowest differentiation score indicative of open chromatin and greater plastic capacity, previously implicated in NEPC. SnATAC-seq revealed that the WT1 motif was enriched in malignant cells. Epithelial/AR-positive subtypes were enriched in DNA-response elements for nuclear receptors (ARE, GRE, and PGR) and the forkhead box family of transcription factors (FOXA1, a known pioneer factor for AR). The NE subtype lacked the ARE, GRE, and PGR motifs but was enriched with FOXA1 and neural-specific motifs, including NEUROD1, ATOH1, OLIG2, and NANOG.We show significant heterogeneity in DSRCT phenotypes, where we observe both epithelial and NE lineages. Initially, we detected the Epithelial/AR-positive and NE-positive lineages by gene expression, but the snATAC-seq data also supports this. Although the emergence of the NE subtype in prostate cancer is generally in response to therapy, how it emerges in DSRCT is yet unknown. The CytoTRACE analysis suggests that NE dedifferentiated from the more differentiated Epithelial/AR-positive subtype, but this remains an active area of investigation. Finally, we are working to understand the Epithelial/AR and NE in DSRCT dimorphic states.

#0131 Utilizing human induced pluripotent stem cells (hiPSCs) as a model to study the genetic drivers of rhabdomyosarcoma.

Celeste Romero, Yanbin Zheng, Lin Xu, Stephen Skapek

UT Southwestern Medical Center, Dallas, TX

Rhabdomyosarcoma (RMS) is a childhood soft tissue sarcoma composed of skeletal myoblast-like cells that lack the capacity to differentiate despite their high expression of terminal differentiation markers like myogenin. There are two main types of RMS: fusion-positive RMS (FP-RMS), which is associated with a chromosomal translocation resulting in an oncogenic fusion protein (PAX3-FOXO1), and the more common form, fusion-negative RMS (FN-RMS) which lacks this translocation and is instead thought to be driven by numerous other oncogenes. Our lab used a Bayesian-based computational algorithm to analyze NGS sequencing data from 290 RMS samples and identified 25 potential genetic drivers of RMS. We aim to use induced pluripotent stem cells as a new model to study how these drivers, including the PAX3-FOXO1 fusion gene, influence RMS formation and progression. To this aim, we have successfully made a doxycycline inducible lentiviral vector containing the full-length sequence of human PAX3-FOXO1 which we used to ectopically express PAX3-FOXO1 in two well-characterized iPSC lines. We subcutaneously injected these iPSCs into NOD/SCID mice and treated them with doxycycline to form teratomas, non-malignant tumors containing tissue from all three germ layers. We hypothesized that PAX3-FOXO1 induction in these differentiating teratomas, may have transforming capabilities and may deregulate transcriptional programs to form FP-RMS-like tumors. We have found that PAX3-FOXO1 overexpressing teratomas grew faster and histologically look more “immature” than their control counterparts but do not seem to give rise to rhabdo-like tumors. We want to further understand what other critical factors are necessary to drive RMS formation by focusing on one of our drivers of interest EZH2, a histone methyltransferase implicated as either an oncogene or a tumor suppressor in certain forms of cancer. We have data suggesting that EZH2-dependent histone methylation activity may act as a proto-oncogene with PAX3-FOXO1 to silence the expression of key tumor suppressor genes CDKN2A and CDKN2B in RMS. To this aim, we reasoned that iPSCs differentiated into myogenic progenitors, one of the potential cells of origin of RMS, will be a novel way to study the role of oncogenes like PAX3-FOXO1 and EZH2 in RMS. We have derived myogenic progenitors from iPSCs (iPSC-MPCs) that express key myogenic factors like PAX7 and MYOD and differentiate and fuse to form mature myofibers. We plan to next explore how ectopic expression of EZH2 and/or PAX3-FOXO1 alters gene expression and histone methylation and whether these alterations can drive RMS formation in these iPSC-MPCs. Using this model system of iPSC-MPCs to drive expression of these oncogenes has the potential to offer new and exciting ways to identify the most important genes in driving cancer formation hopefully providing insight into better targets for treatment of RMS.

#0132 DNA-PK inhibition to enhance etoposide therapy in neuroblastoma.

M. Norouzi, B. Zhu, T. Izumi, E. J. Rellinger, B. Evers, P. G. Rychahou;
University of Kentucky, Lexington, KY

Introduction. Neuroblastoma is the most common extracranial solid tumor in children and accounts for ~15% of all pediatric cancer deaths. DNA-PK, a key regulator of repair responses to double-strand DNA breakages induced by radiation or induction chemotherapy is used in the treatment of high-risk neuroblastomas. Here, we have demonstrated that high DNA-PK expression is associated with poor overall survival in a patient population, DNA-PK is highly activated in neuroblastoma cell lines, and inhibition of DNA-PK enhances therapeutic effects of DNA damaging therapies.
Methods. DNA double-strand break damage was induced with etoposide, a topoisomerase II inhibitor. DNA-PK activity was inhibited with peposertib or DNA-PK siRNA. DNA-PK Ser2056 phosphorylation was analyzed in *MYCN* amplified (SK-NDZ, BE(2)-C, LAN-1) and *MYCN* non-amplified (SK-N-AS, SK-N-SH) cell lines. Clonogenic and proliferation assays were used to evaluate the efficacy of peposertib in combination with etoposide in BE-2-C and SK-N-DZ neuroblastoma cell lines. DSB-induced DNA repair was visualized with confocal laser scanning microscopy using γ-H2AX immunofluorescence. Western blot was used to confirm inhibition of DNA-PKcs (pDNA-PKcs S2056) and analyze cleaved PARP expression in combination groups.
Results. DNA-PK inhibition resulted in enhancement of etoposide cytotoxic therapy (BE-2-C IC50 ET = 2.77 ± 0.2, ET+Pep 0.76 ± 0.04; SK-N-DZ IC50 ET = 0.55 ± 0.06, IC50 ET+Pep = 0.11 ± 0.02) in both BE-2-C and SK-N-DZ cell lines. Immunofluorescence analysis detected γH2AX foci increase in the etoposide and peposertib combination group. DNA-PK inhibition in combination with etoposide treatment significantly increased PARP cleavage in BE-2-C and SK-N-DZ cell lines. The effect of DNA-PK knockdown on neuroblastoma cell survival was even more pronounced compared to DNA-PK inhibition with peposertib. DNA-PK knockdown by siRNA alone increased PARP cleavage to the levels comparable to 2 μM etoposide treatment. The combination of etoposide and DNA-PK knockdown enhanced PARP cleavage even further in neuroblastoma cells.
Conclusions. High DNA repair activity is commonly associated with cancer drug resistance. We have shown that DNA-PK activation is continuously supported in both *MYCN* amplified and *MYCN* non-amplified neuroblastoma cell lines. The importance of DNA-PK activity in neuroblastoma cell lines is confirmed with DNA-PK knockdown that leads to apoptosis in MYCN amplifiedneuroblastoma cell lines. In addition, the combination of DNA-PK inhibition or DNA-PK knockdown with DNA-damaging therapies stalled DNA damage response and enhanced neuroblastoma cell apoptosis. These findings demonstrate the significance of high DNA-PK activity in neuroblastoma cells and provide a potent therapeutic strategy to enhance neuroblastoma cell apoptosis with selective DNA-PK inhibition.

#0133 GMDS is a key driver of *MYCN*-amplified neuroblastoma core fucosylation and tumorigenesis.

B. Zhu[1], M. Pitts[1], M. Buoncristiani[1], L. Bryant[1], O. Lopez-Nunez[2], J. Gurria[2], C. Shedlock[3], R. Ribas[3], S. Keohane[3], J. Liu[1], C. Wang[1], M. Gentry[3], N. Shelman[1], D. Allison[1], B. Evers[1], R. Sun[3], **E. J. Rellinger**[1];

[1]University of Kentucky, Lexington, KY, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]University of Florida, Gainesville, FL

Introduction: *MYCN*-amplification (*MYCN*-amp) is a genetic hallmark of ~40% of high-risk neuroblastomas (NBs). N-MYC is an oncogenic transcription factor and master regulator of metabolism. Glycosylation is a major post-translational modification that is critical for cancer progression, spread, and immune evasion. How genetic signatures such as *MYCN*-amp alter glycosylation profiles is unknown. Herein, we utilized matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI) to define the N-linked glycome of *MYCN*-amp NBs *in situ* identifying enrichment of core fucosylated glycans. GDP-mannose 4,6-dehydratase (*GMDS*) is the first enzyme responsible for *de novo* GDP-fucose synthesis. We hypothesized that GMDS is a key mediator of NB core fucosylation and tumorigenesis.

Methods: MALDI-MSI was performed on five *MYCN*-amp primary NBs and six *MYCN* non-amplified primary NBs using a timsTOF fleX mass spectrometry imager. Significance analysis of metabolites (SAM) was performed with a q-value <0.05 used to define significance. Kaplan-Meier analysis was performed to determine whether *GMDS* expression correlated with overall survival using the R2 Platform. GMDS blockade was performed using genetic knockdown and chemical inhibition with 2-fluorofucose (2-FF). Core fucosylated glycan abundance was measured by western blotting, ELISA, and flow cytometry using *Aleuria aurantia* lectin. *MYCN* tet-inducible NB cells were used to investigate the interplay of N-MYC and *GMDS* expression. Chromatin immunoprecipitation (ChIP) and luciferase promoter assay were performed to investigate the direct interplay of N-MYC and the *GMDS* promoter. Subcutaneous tumor formation was our measure of *in vivo* tumorigenesis.

Results: MALDI-MSI revealed increased expression of eleven N-linked glycans within *MYCN*-amp NBs, and six of these glycans feature core fucosylation. High *GMDS* expression is associated with poor overall patient survival ($p=3.5x10^{-22}$) and correlates with *MYCN*-amp in human NB tumors ($p=7.4x10^{-27}$). Genetic and chemical inhibition of GMDS blocks core fucosylated glycan abundance and secretion, while impeding NB cell growth and adhesion *in vitro*. Induction and blockade of N-MYC directly correlates with GMDS expression. ChIP and promoter luciferase reporter assay demonstrates direct binding and activation of the *GMDS* promoter by N-MYC. Importantly, GMDS knockdown blocks NB tumor formation ($p<0.01$), and 2-FF impedes established tumor progression ($p<0.05$).

Conclusions: This multi-institutional study utilized MALDI-MSI to reveal that core fucosylated glycans are enriched in *MYCN*-amp NBs. GMDS is a key regulator of NB core fucosylation that is driven by N-MYC. GMDS blockade impairs NB growth *in vitro* and *in vivo*. These critical findings identify *de novo* GDP-fucose production as a metabolic vulnerability that may be exploited in designing novel treatment paradigms for high-risk NBs.

#0134 ZEB2 as a therapeutic target in fusion-positive rhabdomyosarcoma.

A. Fahs, A. Munshi, L. Barbar, S. Zimmerman, C. Counter, C. Linardic;
Duke University, Durham, NC

Rhabdomyosarcoma (RMS) is a highly aggressive childhood soft tissue cancer with skeletal muscle histogenesis. It is classified at the molecular level into fusion-negative (FN) and fusion-positive (FP) subtypes, with FP subtypes being defined by their signature oncofusions between the transcription factors PAX3 (or PAX7) and a variety of 3' partners. Patients with FP-RMS have a five-year survival of &lt30%, and current treatments remain ineffective against the driving oncofusions. To address this challenge, we are interested in identifying proteins that interact with the oncofusions as alternate therapeutic targets, and conducted an unbiased proximity labeling screen for seven of the known RMS oncofusions. This approach revealed that ZEB2 is a common member of the interactome for all seven FP-RMS subtypes. ZEB2 is a DNA-binding transcriptional repressor that interacts with SMAD proteins and is known to be important for coordinating muscle and nerve development during embryogenesis. ZEB2 has been identified as an oncogene in various cancer types such as leukemia, glioblastoma, lung, and breast cancers. Further analysis of ZEB2's expression in FP-RMS cell lines, compared to skeletal muscle and other cancer cell lines, showed significantly higher levels of expression. In silico analyses of genomic CRISPR and RNAi screens in DepMap suggested a strong dependency of FP-RMS on ZEB2, with ZEB2 being one of the top four differential CRISPR dependencies in RMS cell lines compared to all other cancer cell lines. To investigate the functional consequences of ZEB2 suppression, we employed a loss-of-function approach using RNAi (siRNA and shRNA) in human FP-RMS cells. Our experiments confirmed the knockdown of ZEB2 through qRT-PCR and immunoblotting. Interestingly, the extent of ZEB2 knockdown determined whether FP-RMS cells underwent apoptosis or differentiation, potentially towards a neurodifferentiation pathway. We hypothesize that ZEB2 holds potential as a therapeutic target for FP-RMS patients. We aim to elucidate ZEB2's phenotypic role and mechanism of action in FP-RMS tumorigenesis, and assess its value as a therapeutic target *in vivo*. Our long-term goals for this project are to contribute to the development of innovative therapies that can mitigate the oncogenic activity driven by oncofusions in FP-RMS.

#0135 Resolving the tumorigenesis continuum of DICER1 syndrome with novel lineage-trackable genetically engineered mouse model.

J. Zhang[1], S. Chen[1], Y. Moscovitz[1], B. Lynch[1], M. Douglas[1], J. Senz[1], W. Scott[2], M. Underhill[3], Y. Wang[1], D. Huntsman[1];
[1]BC Cancer Research Centre, Vancouver, BC, Canada, [2]Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [3]University of British Columbia, Vancouver, BC, Canada

Background: DICER1 syndrome is a rare cancer predisposition syndrome associated with germline *DICER1* mutations, which develops pulmonary or extra-pulmonary manifestations mostly in pediatric patients. Unlike classic tumor suppressors, the 2nd hit in *DICER1* gene is a missense mutation that renders the RNase IIIb domain defective; therefore, this mutant form of DICER1 is the only protein expressed in these cancer cells, leading to a biased 5p-miRNA production deficiency. Many DICER1 cancers are sarcomas; we therefore postulate the cell of origin is mesenchymal. We recently developed a RNase IIIb-mutant mouse strain and embryonic activation of this mutant along with silencing of the other Dicer1 allele in Mullerian mesenchymal progenitor cells led to the development of tumors resembling sarcomas in human patients. To expand the model and enable lineage tracking, we developed a tamoxifen inducible, tdTomato-trackable, Hypermethylated in Cancer 1 (HIC1)-creERT2 driven transgenic mouse strain. Hic1 marks mesenchymal progenitors. With this strain, we created a model that histologically recapitulates the 3 renal tumors in DICER1 syndrome: cystic nephromas, Wilms tumors, and anaplastic sarcomas. **Objective:** to identify oncogenic events underlying *Dicer1* mutation-driven murine kidney tumor development with single cell RNA-sequencing (scRNA-seq).
Method: To build the tumorigenesis continuum, we harvested kidneys from *Dicer1*$^{+/fl\text{-}D1693N}$ and *Dicer1*$^{fl/fl\text{-}D1693N}$ mice at 1, 3, 6, months post tamoxifen injection, sorted out tdTomato+/CD45-/Epcam- cells, and performed scRNA-seq. Five endpoint tumors were included for analyses. Single cell transcriptomic profiles were integrated and clustered using Seurat to identify cell populations that emerge and expand along the tumor development continuum. Differential gene expression, pathway analysis were conducted to identify genes/oncogenic pathways that are activated along the course of tumor development. Cell differentiation trajectory analysis will be performed using Monocle.
Results: Integration of 5 tumors revealed diverse cell populations: epithelial, mesenchymal, endothelial cells, lymphocytes, and macrophages. We further clustered the mesenchymal population and identified sub-populations such as highly proliferative cells, muscle satellite cells, and terminally differentiated muscle cells. These mesenchymal cells show high expression of blastema markers (Ncam1, Sox11) - a histological component in Wilms tumors. Temporal trajectory of tumorigenesis with time point samples is currently being analyzed.
Conclusion: With scRNA-seq, we begin to unravel heterogeneity of these murine tumors and will identify critical oncogenic events driving the development of DICER1 syndrome-associated cancer, enabling us to utilize this model to develop therapeutic approaches to improve patient management.

#0136 Determining the genomic basis of PAX3-FOXO1 mediated transformation in rhabdomyosarcoma.

B. T. Stevens, Y. Zhang, R. K. Larsen IV, G. E. Adkins, J. D. Hopkins, D. W. Kimbrough, M. R. Garcia, B. J. Abraham, M. E. Hatley;
St. Jude Children's Research Hospital, Memphis, TN

Rhabdomyosarcoma (RMS) is the most common pediatric soft tissue sarcoma. Despite rigorous scientific advances and clinical trials, the survival rate for high-risk RMS has not increased above 20% in the last three decades. A deeper understanding of the basic biology driving RMS tumorigenesis is needed to discover novel therapeutic targets. RMS can be divided into two major histologic subtypes: embryonal RMS (ERMS) and alveolar RMS (ARMS). ARMS accounts for 20% of pediatric cases and has poorer survival. The majority of ARMS tumors harbor t(2;13)(q35;q14) or t(1;13)(p36;q14) chromosomal translocations resulting in the PAX3-FOXO1 (P3F) and PAX7-FOXO1 (P7F) fusion oncoproteins, respectively. ARMS tumors that lack oncofusions more closely resemble ERMS. Classifying on fusion status more accurately describes the disease and highlights the significance of P3/7F. ARMS tumor genomes only contain an average of 6.4 somatic mutations suggesting the oncofusion protein is the key oncogenic driver and a potential candidate for therapeutic intervention. RMS is commonly thought to arise from skeletal muscle progenitor cells that fail to terminally differentiate. However, RMS occurs throughout the body in sites devoid of skeletal muscle, underscoring the potential for alternative cells of origin. Our lab established that endothelial progenitors are indeed a cell of origin for ARMS by generating a genetically engineered mouse model with endothelial cell specific P3F expression coupled with *Cdkn2a* loss. We further generated a human model system derived from *TP53*-null human induced pluripotent stem cells (iPSCs), in which we direct differentiation to endothelial cell fate and then force P3F expression. P3F expression during endothelial cell directed differentiation blocked endothelial maturation and instead reprogrammed cells shifting cell fate to skeletal muscle-like cells that form ARMS tumors in mice. Generation of iPSC-derived ARMS (iARMS) occurs over 15 days and provides a unique model to determine the kinetics and specific genomic contributions facilitated by P3F during RMS transformation. To investigate the genomic changes occurring during iARMS transformation I utilized CUT&RUN for P3F and H3K27ac to assess P3F occupancy and enhancer landscape, ATAC-seq to assess chromatin accessibility, and RNA-seq to assess gene expression changes at timepoints throughout the transformation event. These results define the fundamental genomic changes needed for transformation into FP-RMS by P3F and uncovers the key determinants of ARMS cell identity. The iARMS system provides a unique platform to uncover how P3F establishes and maintains RMS cell state and to dissect the specific dependencies required to maintain the ARMS cell state. Understanding the fundamental mechanism of P3F-driven tumorigenesis could provide greater resolution into the key disease determinants to focus pre-clinical efforts on pivotal targets.

#0137 Increased activity of protein kinase A is sufficient to cause fibrolamellar carcinoma.

M. Shirani, M. Tomasini, S. Levin, s. heissel, H. Molina, Y. De Jong, c. Rice, P. Coffino, B. Lyons, S. Simon;
The Rockefeller University, New York, NY

Tumor cells of almost all patients with fibrolamellar carcinoma (FLC) have a somatic mutation, a ~400 kB deletion on one copy of chromosome 19 that results in a fusion transcript of DNAJB1 to PRKACA, the catalytic subunit of protein kinase A. The resulting fusion oncoprotein, DNAJB1::PRKACA, has kinase activity, and is required and sufficient for transformation. To understand the oncogenesis of this tumor and to help identify potential therapeutic targets, we explored the pathways of pathogenesis mediated by the aberrant kinase. We explored three mechanisms that might explain transformation by the oncogenic kinase:

- A difference in the substrate specificity of DNAJB1::PRKACA kinase versus native PRKACA kinase.
- A difference in the interactome of DNAJB1::PRKACA kinase versus native PRKACA kinase.
- An increase of total catalytic kinase activity (DNAJB1::PRKACA + PRKACA) versus the native PRKACA condition.

We found, comparing cytosolic extracts of tumor and normal liver cells, that there are differences in the substrate specificity of the DNAJB1::PRKACA kinase. Additionally, such comparisons revealed differences in the interactions between the catalytic subunit of the kinase and cytosolic components. We also demonstrated a consistent increase in total PRKACA catalytic subunit in the FLC tumor, relative to the adjacent nontransformed tissue. Further, there is an increase in free, unregulated catalytic activity in the tumor cells and a change in the localization of the catalytic subunit in the tumor cells. Additionally, we have found that this increase in free catalytic activity is sufficient to account for the changes in the transcriptome in tumor cells of FLC patients. Importantly, enhanced expression in hepatocytes of either DNAJB1::PRKACA kinase or native PRKACA kinase caused very similar changes in the transcriptome, and the resultant transcriptomes closely resembled that of tumor cells from FLC patients. This suggests that the DNAJB1 domain is dispensable and not critical for transformation. In our investigation of patient tumors we found two rare and different subclasses of FLC that are indistinguishable from “classic” FLC, based on their transcriptome and based on their drug response profiles. Importantly, both subclasses are associated with changes of PRKACA, but neither involves the DNAJB1 domain. Thus, the DNAJB1 domain is not a critical component of transformation, and the significant driver is an increase of the cellular catalytic activity.

#0138 UCHL5 and PAX3-FOXO1 resolve replication stress in rhabdomyosarcoma.

A. J. Sabnis, P. K. Sahu, Y. Pan;
UCSF - University of California San Francisco, San Francisco, CA

PAX3-FOXO1 positive rhabdomyosarcoma (RMS) is an aggressive pediatric sarcoma with a terrible prognosis. The resultant fusion acts as a chimeric transcription factor, in part remodeling chromatin to inhibit terminal differentiation and maintain cancer cell proliferation. As this oncoprotein is not directly druggable, we have used genetic screens to identify dependencies downstream of *PAX3-FOXO1* to improve our understanding of pathogenesis and develop new therapeutic targets. We performed pooled CRISPRi screening in an isogenic system of a patient-derived RMS cell line with or without knockdown of *PAX3-FOXO1.* Loss of the ubiquitin hydroxylase *UCHL5* led to selective depletion of *PAX3-FOXO1* positive Rh30 cells compared to *PAX3-FOXO1* knockdown cells, suggesting that the fusion creates *UCHL5* dependence. We validated this finding in competition growth assays in additional fusion positive (FP) and fusion negative (FN) RMS cell lines, and observed *UCHL5* dependency only in the former. By contrast, *UCHL5* was dispensable for cell growth and survival in FN RMS cell lines. These data were recapitulated in the large DepMap dataset, which also identified the top genetic co-dependencies of *UCHL5* as INO80-complex (INO80c) members. We therefore investigated whether the fusion selective effects of *UCHL5* were mediated by the INO80c, of which UCHL5 is an N-terminal member. We observed that knockdown of another N-terminal component of INO80c, *NFRKB*, phenocopies the fusion-selective effects of UCHL5 loss. Conversely, the catalytic ATPase *INO80* was pan-essential, suggesting that only N-terminal subunits of INO80c regulate PAX3-FOXO1 specific functions. INO80c plays an essential role in mitigating DNA replication stress. Indeed, loss of *UCHL5* led to DNA damage as measured by γH2AX and slowing of replication forks as measured by fiber assays in FP, but not FN RMS. Unexpectedly, acute degradation of *PAX3-FOXO1* also slowed DNA replication fork speed, suggesting a genetic model in which *UCHL5* and *PAX3-FOXO1* cooperate to resolve replication stress in FP RMS. Finally, *in vivo* experiments using cell line xenografts confirms that loss of *UCHL5* slows the growth of FP RMS, but not FN RMS. These findings suggest that loss of UCHL5 induces replication stress in a fusion-specific manner, and offers both an opportunity to study the mechanisms by which the PAX3-FOXO1 oncoprotein mitigates replication stress, and to develop UCHL5 inhibitors as precision therapies for FP RMS patients.

#0139 Modeling and genomic profiling of osteosarcoma development in murine chondrocyte-origin models.

X. Zhou, H. Beird, Y. Yi, Z. Xu, Z. Zhang, H. Singh, W. Zhang, Y. Wang, S. Jusu, M. Roth, J. Gill, R. Gorlick;
The University of Texas MD Anderson Cancer Center, Houston, TX

Osteosarcoma (OS) manifests during puberty, coinciding with rapid bone growth, a feature requiring exploration. We selectively deleted *p53* or both *p53* and *Rb1* alleles in growth-dependent chondrocyte-origin models, utilizing Col10a1-Cre or Agc-CreERT2, incorporating with ROSA-Tomato for tracing and isolating the mutant cell collection.

Col10p53^{flfl}(tm) and Col10p53^{flfl}Rb^{fl+}(tm) mutants exhibited 100% penetrance in osteoblastic OS, with the latter displaying shortened latencies (mean: 335 vs 265 days) and increased metastases. Tamoxifen-induced AgcCreERT2 models highlighted growth stage-dependent OS development, correlating penetrance inversely and latencies positively with mouse age at tamoxifen treatment. Tumors exclusively occurred in endochondral bones, near growth plates.

Whole-genome profiling of tm$^+$ tumor cells revealed genetic variations, including SNPs, Indels, CNVs, and SVs. CNVs involved genes altered in human OS, emphasizing losses in *Dmd* and gains in *Myc*, *Vegfa*, *Foxm1*, *Akt1*, *Aurkb*, and *Ccen1*. A common CNV (losses, Chr. 10: 34,158,531-34,443,999, Log ratio <-0.05) occurred in all sequenced primary and metastatic samples, with male specimens sharing a loss in the Y chr. p region (approximately 725,200-799,409).

Orthotopic transplantation of tm$^+$ p53$^-$ stromal cells from 4-month-old Col10p53^{flfl}tm mice gave rise to bone tumors and lung migration in wild-type recipients, explicitly establishing the transplanted cells as the direct origin of the cancer precursors within early tm$^+$ p53$^-$ stromal populations. Whole-genome sequencing unveiled a discernible progression of genomic alterations from 1 to 4-month-old tm$^+$ p53$^-$ stromal cells, culminating in donor-derived tumors. Notably, only these specific donor-derived tumors, and not the early tm$^+$ p53$^-$ stromal cells, exhibited the Chr. 10 CNV observed in autochthonous malignancies.

Micro-metastases, identified by fluorescence imaging, were prevalent, alongside macro-metastases (~10% in Col10p53^{flfl}Rb^{fl+}tm and ~25% in AgcCreERT2p53^{flfl}Rb^{fl+}tm cohorts). Notably, amputation of primary OS sites in mice surviving longer revealed larger and more abundant tm+ cell clusters. Some micro-metastases not only expressed signature genes typical of macro-lung metastases but also shared genomic variations with corresponding primaries, including the prevalent loss in Chr. 10. Enhanced immune cell infiltration was evident in lungs hosting micro-metastases, suggesting a potential immune response triggered by pre-tumor early seeding cells.

Murine OS models faithfully replicate human OS features, underscoring chondrocytes as significant contributors to OS cell sources. The inclusion of a tomato reporter enables precise tracking, rendering these models invaluable for studying OS etiology, particularly in unraveling pre-tumor molecular events in both primary and metastatic settings.

#0140 Distinct pathways regulated by activated β-Catenin and YAP in hepatoblastoma pathogenesis.

W. Liao[1], X. Chen[2];
[1]West China Hospital of Sichuan University, Chengdu, China, [2]Hawaii University Cancer Center, Honolulu, HI

Hepatoblastoma (HB) is a rare, yet the most common primary malignant hepatic liver in children. A significantly portion of children with HB have tumors that are not resected at diagnosis, leading to the dismal prognosis in these patients. Concomitant YAP and β-catenin activation could be seen 80% of HB. The signaling pathways regulated by YAP and β-catenin in HB pathogenesis remain unclear. Here, we engineered a inducible HB murine model using hydrodynamic injection to deliver transposon plasmids encoding constitutive YAP and doxycycline (Dox) inducible ΔN90-β-Catenin (*Yap/TRE-β-Catenin*). When fed with Dox, HB formed rapidly in the mice. Upon Dox withdraw, HB regressed over the long term. We analyzed gene expression patterns in mouse HB lesions upon short term Dox withdrawal, i.e, tumors still existed yet ΔN90-β-Catenin was turned off. This approach assisted to identify genes regulated by the activated β-Catenin in HB tumors. We compared these genes with the previously identified YAP regulated genes and found the distinct gene expression programs regulated by YAP and β-Catenin in HB. Specifically, YAP off down-regulated Hippo pathway and up-regulated metabolism-related pathways, whereas β-Catenin off down-regulated protein export, DNA replication pathway and up-regulated immune-related pathways. Finally, we identified ONECUT1 as a gene down-regulated by activated β-Catenin in HB. ONECUT1 expression was down-regulated in human HBs, and co-expression of ONECUT1 strongly suppressed Yap/β-Catenin HB formation in mice. Mechanically, ONECUT1 could regulate proliferation-related downstream signaling. Altogether our studies demonstrated that suppression of activated *CTNNB1* mutations could repress HB progression *in vivo*, and we identified distinct pathways regulated by activated β-catenin and YAP in HB. Suppression of ONECUT1 expression by β-catenin is a key genetic event leading to HB formation.

#0141 A human induced pluripotent stem cell model of KMT2A rearranged leukemia.

E. Guest, M. Vacek, J. Nemechek, I. Pushel, B. T. Thornton, M. Leyda, M. S. Farooqi, J. M. Perry, J. L. Vivian;
Children's Mercy Kansas City, Kansas City, MO

Acute lymphoblastic leukemia in infants (iALL) is a high-risk subtype of childhood leukemia with poor survival outcomes despite intensive therapies. Rearrangement of *KMT2A* (*KMT2A*-r) occurs in 70% of cases and is associated with refractoriness to therapy, early relapse, and rapid leukemia progression. *KMT2A*-r generates a driver fusion oncogene, most commonly *KMT2A::AFF1* in iALL, which leads to epigenetic dysregulation of target gene transcription. iALL with *KMT2A::AFF1* is an unusual cancer in that other somatic mutations are uncommon, there are no known genetic risk factors, and phenotypic switch from lymphoid to myeloid, mixed, or undifferentiated phenotype is common during treatment and particularly resistant to therapies. The cell of origin is thought to be a very early hematopoietic precursor, with transcriptomic studies of iALL blasts showing similarities to hematopoietic stem and progenitor cells (HSPCs), multipotent progenitors and early lymphoid progenitors (ELPs). Unfortunately, research into this rare but devastating disease has been hindered by a lack of appropriate, representative models. Interestingly, *KMT2A*-r originates in HSPCs *in utero* and the age of onset of iALL is a strong prognostic factor, with age younger than six months associated with the highest risk of relapse. However, little is known regarding how *KMT2A*-r subverts early hematopoiesis or drives the severe disease phenotype. In an effort to understand the role of the developmental state of the cell of origin in iALL, we have created a highly controlled induced pluripotent stem (iPS) cell model system of *KMT2A::AFF1* leukemia. Specifically, we engineered human iPS cell lines with doxycycline regulatable expression of *KMT2A::AFF1* fusion and we are employing CRISPR gene editing technology to introduce clinically identified variants of interest. Utilizing directed differentiation, we have produced functional HSPCs from iPS cells. Notably, this model recapitulates hematopoietic ontogeny, with the ability to control iALL induction at specific developmental stages. Following doxycycline treatment, we demonstrate that the cells express *KMT2A::AFF1* fusion transcripts. We are utilizing single cell genomics to investigate transcriptomic changes during hematopoietic differentiation of our *KMT2A::AFF1* iPS cells. We will compare these results to published data sets of single cell RNA sequencing data from healthy fetal HSPCs and to our existing iALL and pediatric *KMT2A*-r ALL single cell sequencing data sets. Our iPS cell based iALL model system provides the opportunity to investigate a range of critical and outstanding questions of iALL disease initiation, progression, and treatment.

#0142 HDAC3 is required for pathognomonic features of Langerhans cell histiocytes.

P. Dimitrion[1], J. Toor[1], J. Ge[1], Q. Wang[1], C. Allen[2], L. Zhou[1], Q.-S. Mi[1];
[1]Henry Ford Health System, Detroit, MI, [2]Baylor College of Medicine, Houston, TX

Langerhans cell histiocytosis (LCH) is an inflammatory myeloid neoplasm that develops due to dysregulated dendritic cell (DC) development and most commonly affects the children with an incidence of 2.6 to 8.9 cases per million individuals per year. $BRAF^{V600E}$, the most common disease-driving mutation, activates the mitogen-activated protein kinase (MAPK) pathway causing pathognomonic features that lead to the accumulation of LCH cells and formation of granulomatous lesions. These features include enhanced myelopoiesis, reduced tissue-egress and acquisition of an oncogene induced senescence-associated secretory phenotype (SASP) (marked by increased expression of anti-apoptotic proteins and inflammatory cytokines). Accumulation of LCH cells can occur in any organ causing a wide range of clinical sequelae, which is directly related to the originating cell bearing the oncogenic mutation. Frontline therapy for LCH involves combination chemotherapy and steroidal anti-inflammatories, or MAPK inhibitors, which have significant toxicity and fail to eliminate disease causing precursors. We have found that HDAC3 is required for epidermal LC homeostasis and hypothesized that LCH cells rely on similar epigenetic factors to LCs. *$CD11c^{Cre}$ LSL-BRAFV600E* (*$BRAFV600E^{CD11c}$*) mice develop severe multifocal LCH with pronounced lesion development in their livers and lungs, hepatosplenomegaly, and a reduced lifespan due to the accumulation of LCH cells. To test our hypothesis, we generated *$BRAFV600E^{CD11c}$ $HDAC3^{fl/fl}$* (*$BRAFV600E^{HD3KO}$*) mice, which produce LCH cells that harbor a conditional deletion in the deacetylase domain of HDAC3. Compared to *$BRAFV600E^{CD11c}$* mice, *$BRAFV600E^{HD3KO}$* mice exhibited significantly less hepatosplenomegaly, reduced lesional burden, and improved survival indicating reduced LCH disease burden. Compared to *$BRAFV600E^{CD11c}$*, flow cytometry showed *$BRAFV600E^{HD3KO}$* had reduced numbers of LCH cells in lungs and livers, which were more apoptotic. We also found decreased frequencies of circulating LCH cells and LCH precursors, indicating that a lack of HDAC3 activity prevents the development of LCH cells. Bone-marrow derived LCH-like cells provide a valuable drug screening tool. We treated Bone-marrow derived LCH-like cells with RGFP966, an HDAC3-specific inhibitor, increased apoptosis indicated by annexin-V and DAPI staining, reduced expression of Bcl-2, increased CCR7 expression, and decreased S6 phosphorylation (an indication of a loss of the SASP), thus inhibition of HDAC3 may prove therapeutically efficacious by abrogating pathognomonic features of LCH cells. Together, our findings identify HDAC3 as a critical epigenetic regulator LCH cell pathophysiology and HDAC3 blockade would address a great need in treatment of patients with LCH. Furthermore, our results indicate that LCH cells rely on similar epigenetic regulators as epidermal LCs despite coming from a different myeloid lineage.

#0143 Molecular profiling of tumor-initiation events in rhabdomyosarcoma uncovers mitochondrial vulnerabilities.

B. Kalita[1], G. Martinez-Cebrian[2], J. McEvoy[3], B. Gordon[3], K. Blankenship[3], A. Karlstorm[3], E. Stewart[3], M. Dyer[3], B. Dynlacht[1];
[1]NYU Langone Health Perlmutter Cancer Ctr., New York, NY, [2]Josep Carreras Leukaemia Research Institute, Barcelona, Spain, [3]St. Jude Children's Research Hospital, Memphis, TN

Background: Alveolar Rhabdomyosarcoma (ARMS) is a very aggressive soft tissue tumor affecting children and adolescents. It is found that pediatric patients with RMS harboring chimeric PAX fusion transcription factors (TFs) exhibit a greater incidence of tumor relapse, metastasis, and poor survival outcome, thereby underscoring the urgent need to develop effective therapies to treat this subtype of childhood cancer.
Methods: We generated a novel ARMS model by stable transduction of myogenic progenitor cells with a cassette encoding the exact PAX3/7-FOXO1 fusion protein found in ARMS tumors. We analyzed genome-wide expression levels with RNA-seq and utilized Cut&Run to map the binding sites of PAX3/7-FOXO1, active histone marks, enhancers, and super-enhancers in our novel model. Hi-C and promoter capture HiC (pCHiC) were also performed to generate 3D chromatin conformation maps in cells expressing the oncogenic TFs. We compared these data with analogous datasets from orthotopic patient-derived xenografts (O-PDXs) of PAX3/7-FOXO1 fusion-positive ARMS tumors from St. Jude and established ARMS cell lines to validate whether our model system recapitulates ARMS tumors. CRISPRi was performed to silence key targets in two representative ARMS cell lines and proliferation was scored after silencing. Next, we found that ARMS tumors displayed anomalies in mitochondrial mass and numbers, metabolic parameters, and membrane potential by performing TEM, Seahorse assays, and FACS-based TMRM and mitotracker Red dye uptake in a panel of ARMS cells and PDX samples. We performed cell viability and colony forming assays in ARMS cells treated with single drugs and combinations of drugs targeting FGFR4 and mitochondrial metabolism.
Results: Our data provide evidence to support muscle progenitors as potential cells-of-origin for ARMS. We showed that rewiring of chromatin architecture mediated by PAX3/7-FOXO1 TFs is evident across established cell lines, primary tumors as well as O-PDXs. By integrating PAX3/7-FOXO1 binding, RNA-seq, and pCHiC data, we identified key promoter-enhancer (P-En) interactions that are erased or established de novo at multiple loci of master TFs like *MYOD*, *MYOG* and *MYCN*. We also identified key regulators of proliferation, including FGFR4, and mitochondrial function that are essential for tumor growth and invasiveness. Our data indicated aberrant and enhanced mitochondrial metabolism in ARMS as well as selective sensitivity to mitochondrial inhibitors in RMS cells. Administration of these inhibitors preferentially inhibited cell viability and clonogenicity in ARMS, and prompted a pre-clinical phase II study to test these inhibitors at St. Jude Research Hospital.
Conclusion: We present a novel treatment strategy leveraging the mitochondrial dependencies of fusion positive PAX-driven tumors which can be exploited for precision therapy in high-risk ARMS.

#0144 Sex bias in neuroblastoma: Worse outcomes for female patients are associated with dysregulation of *DLK1* and *H19*.

Mariya Raleigh[1], Vishwa Patel[1], Lorraine R. Benhamou[2], Xin Shen[1], Dennis A. Sheeter[2], Erika C. Espinosa[2], Niharika Reddy Badi[2], Chase Calvert[2], Garrett Bourne[2], John T. Powers[2]

[1]Division of Pharmacology and Toxicology, College of Pharmacy, University of Texas at Austin, Austin, TX, [2]Department of Pediatrics, Dell Medical School at the University of Texas at Austin, Austin, TX

Neuroblastoma (NB) is a devastating neural crest-derived tumor primarily affects children under five. Forty percent of NB patients are classified as high-risk (HR), and less than half of them survive. HR disease is split into two equally sized groups: one exhibiting genetic amplification of the *MYCN* proto-oncogene (*MA*), and another where *MYCN* is non-amplified (*MNon*). Overall survival (OS) studies are often either poorly annotated or focused on outcomes across the entire patient group, which may mask differential outcomes or biases among NB subgroups. Here we report our assessment of OS among several genetic, histopathological, and sex-based subgroups in three different well annotated NB patient datasets. Our analysis reveals a previously unseen sex-bias in HR *MNon* patients, where female patients have significantly worse OS than males. This disparity carries into stage 4s NB, defined by high survival in infants despite the presence of broadly disseminated disease. In stage 4s patients across two studies, we observe no deaths among males (n=66) and 6 among females (n=48), again marking significantly worse OS in females. Expression analysis comparing male and female HR *MNon* patients identifies *DLK1* and *H19*, two imprinted genes implicated in multiple malignancies, as frequently overexpressed in females. A similar pattern is seen in RNA seq analysis of human *MA* (n=4) and *MNon* (n=4) cell lines. In addition, both *DLK1* and *H19* are associated with worse prognosis in female but not male patients. We also report that depletion of either gene results in reduced growth *in vitro*. Moreover, the NB-related *ATRX* tumor suppressor has been shown to inhibit *H19* via insertion of histone variant *H3.3*. We observe an inverse correlation between *H3.3B* and *H19* expression in female HR *MNon* patients. Further, *H19* levels increase upon *ATRX* depletion in human NB cells, suggesting that *ATRX* indeed regulates *H19* in NB. These findings provide the first evidence of female-biased outcomes in NB and suggest functional involvement of *DLK1*, *H19* and *ATRX*.

#0145 Unraveling SMARCB1 depletion in hiPSC-derived neural crest cells: Implications for ATRT cell of origin.

C. Wang, F. Furnari;
University of California San Diego - UCSD, La Jolla, CA

Atypical teratoid rhabdoid tumors (ATRTs) are highly aggressive pediatric brain cancers that lack standardized treatment regimens and are associated with poor prognoses. Despite being driven by biallelic inactivation of a single gene, *SMARCB1*, ATRTs exhibit three epigenetic subgroups (SHH, TYR, and MYC), each with different clinical outcomes. Like many pediatric brain tumors, ATRTs share the fundamental underlying mechanism of stalled differentiation, suggesting that it may arise from neural progenitor cells that fail to terminally differentiate. However, unlike other brain tumors, ATRTs share molecular similarities with malignancies found outside of the CNS, especially in the kidney and soft tissues. This unique feature implies a putative cell of origin that is not restricted to the CNS: neural crest cells, a transient embryonic cell population that emerges from the neuroectoderm but then migrates throughout the embryo during development. To study SMARCB1 loss in a genetically defined neural progenitor cellular context with isogenic controls, the Furnari lab engineered a doxycycline inducible *SMARCB1* knockdown system into human induced pluripotent stem cells (hiPSCs). After simultaneous *SMARCB1* knockdown with directed neural differentiation, the resulting SMARCB1-depleted neural progenitor cells exhibited transcriptomic profiles that were similar to ATRTs, particularly to the SHH subgroup. Building upon these findings, the engineered hiPSCs were differentiated into neural crest cells using a modified version of a published protocol. Via RT-qPCR, these hiPSC-derived neural crest cells were confirmed to express typical neural crest marker genes and lose expression of *SMARCB1* in the presence of doxycycline. Remarkably, ATP assays demonstrated that neural crest cells that were differentiated without SMARCB1 acquired enhanced proliferation in comparison to those differentiated with SMARCB1 intact. Further work aims to tease apart this proliferative phenotype in the neural crest cellular context via RNAseq, evaluate the impact of cell identity upon subgroup status, and to determine whether SMARCB1 depletion post-differentiation also enhances proliferation. Together, these findings feature the utility of hiPSC-derived models for investigating mechanisms underlying ATRTs to hopefully identify novel subgroup-specific targets.

#0146 Development of a novel pediatric patient-derived xenograft model with THPO and NDUFB3 mutations.

J. Shilyansky, C. J. Chan, K. L. Coleman, M. Leidinger, S. Bhagavathi, A. Sharathkumar, P. Ear;
University of Iowa, Iowa City, IA

Familial myeloproliferative neoplasms (MPN) of childhood are extremely rare and have propensity towards malignant transformation such as leukemia and lymphoma. Due to the rarity of these cases, few cellular and mouse models are available for understanding the tumor biology. Therefore, the molecular mechanisms of malignant transformation remain poorly understood limiting the therapeutic progress to treat these conditions. Here, we report the development of a novel pediatric patient-derived xenograft (PDX) mouse model harboring mutations in the THPO and mitochondrial subunit NDUFB3 genes and characterization of their functions . THPO is a regulator of hematopoiesis and induces trilineage hematopoiesis through HSPC proliferation while NDUFB3 is a subunit of the mitochondrial complex 1. We isolated malignant cells from an enlarged spleen sample and blood sample from a pediatric patient with TPO mediated MPN and established a PDX model (PDX-2333) that recapitulates the patient's disease. Short tandem repeat analyses confirmed an exact match between the PDX-2333 tumors and patient samples. Exome and Sanger sequencing analyses were performed to identify mutations. Immunohistochemistry staining was used for tumor characterization. Wildtype (WT) and mutant forms of NDUFB3 genes were cloned into expression plasmids with a puromycin selection marker and stably transfected in HEK-293 cells. Stable clones of HEK-293 overexpressing WT and NDUFB3 mutants were tested for growth and sensitivity to anti-cancer therapies. We established a novel PDX model of lymphomagenesis harboring unique mutations in *THPO* and *NDUFB3* genes. The *THPO (c.-52C>T)* mutation in upstream open reading frame causes loss of inhibition of THPO mRNA expression. The NDUFB3 (c.23 A>G) mutation results in a change of amino acid from glutamine 8 (E8) to glycine 8 (G8) (Ndufb3_E8) and is highly conserved in many vertebrate species. HEK-293 cell lines stably overexpressing WT or NDUFB3 mutants were tested for growth and their sensitivity to ruxolitinib, a Jak2 inhibitor and doxorubicin, an FDA-approved treatment for leukemia and lymphoma. Our data showed that cells overexpressing Ndufb3_E8 have increased proliferation and are highly resistant to ruxolitinib and doxorubicin in comparison to the WT NDUFB3. Developing a novel pediatric PDX model and exome sequencing allow us to identify novel genes involved in malignant transformation leading to lymphoma development. Our data demonstrated that mutations in the THPO (c.-52C>T) and NDUFB3 (c.23 A>G) genes play a key role in the pathogenesis of a lymphoma and in regulating drug sensitivity.

#0147 Identification of cell sub-populations in Neuroblastoma cell lines with single-cell-sequencing analysis.

Michele Tomanelli[1], Davide Ceresa[1], Adriana Bajetto[2], Paola Modesto[3], Paolo Malatesta[1], Tullio Florio[2], Aldo Pagano[1]

[1]Department of Experimental Medicine, University of Genoa, Italy, Genova, Italy,[2]Department of Internal Medicine, University of Genoa, Italy, Genova, Italy,[3]Istituto Zooprofilattico Sperimentale del Piemonte, Liguria E Valle D'aosta, Turin, Italy

Neuroblastoma is the most frequent extracranial tumor in neonatal patients. Engineering SKNBE2 Myc-N amplified Neuroblastoma cell lines we generated individual clones expressing NDM29 non-coding-RNA at different levels. Using these cell models we documented a specific role of NDM29 in tumor cell differentiation leading to the identification of novel genes to be pharmacologically targeted for an efficient control of tumor malignancy (CA9 and MCM2 genes). Further studies taking advantage of the same models suggested the possible co-existence of different cell sub-populations in the apparently homogeneous cell culture with possible different roles in tumor maintenance and growth. Here we test this hypothesis by performing single-cell sequencing analysis and identified different sub-populations on the base of their gene expression patterns. The characterization of their specific profiles of membrane markers allowed an efficient separation of the individual populations by FACS analysis. Our preliminary results show the co-existance of cells with a marked neural phenotype with other two populations one VEGF secreting and the other VEGF recipient/responder. These preliminary findings suggest further detailed investigations of possible paracrine loops that might be at the base of tumor cell nodule growth and maintenance.

#0148 Multiomic sequencing reveals diversity in clonal landscape and genomic alterations in a lung metastatic PDX osteosarcoma model.

S. Jusu, W. Zhang, Z. Zhang, X. Zhaohui, S. Kannan, Y. Wang, Z. Xin, Y. Yanhua, M. Roth, J. Gill, R. Gorlick;
The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Osteosarcoma is a primary malignant bone tumor characterized by the production of spindle cells resulting in immature bone formation. The lung is the most frequent site of metastatic disease and relapse occurs in more than 30 % of patients. Recent results show that relapse is due to a subset of cells with different phenotypic and genetic signatures conferring advantage to drive progression and drug resistance within the intra-tumorally heterogeneous population. Thus, developing a defined in vivo model that can identify the rare genetic subpopulation and recapitulate clonal evolution is crucial. In this study, we used whole exome, barcode and RNA sequencing to characterize the landscape of genomic alterations and also track and identify the clonal subpopulations, clonal and genetic drivers of lungs metastasis.
Methods: We injected barcoded PDX (OS17) cells intravenously in ten SCID mice to track the clonal subpopulation of cells that metastasize to the lungs. Metastasized lung nodules were collected following death or euthanasia. All samples collected were snap frozen in liquid nitrogen and stored at -80^{0}C. DNA and RNA was extracted and analyzed by PCR, NGS, WES and RNA sequencing to map clonality, mutational and evolutionary profiles.
Results: Four (40%) of the mice developed lung metastases with three mice having multiple metastatic lung nodules. Surgery to remove the metastatic nodules was performed 216 ± 55.5 days following tumor cell injection. Nine metastatic lung nodules from three mice were used for sequencing and analysis. A Shannon-Weaver and Jaccard similarity index show a diversity in clonal architecture between the lung nodules. A total of 15,394 somatic variants was identified including 12,547 single nucleotide variants (SNV), 4054 synonymous, 2662 missense, 28 nonsense mutations and 1639 somatic indels. The SNVs accounted for 81% of all variants followed by CNV 11 % and indels 8% respectively. Synonymous and missense mutations were the most frequently observed in all samples. Copy number loss was two-fold compared to copy number gain across all tumors. Furthermore, the deletions span longer genomic distances compared to amplifications. The mutational spectrum showed that the highest substitutions were C>T/G>A followed by T>C/A>G; the least substitutions were T>A/A>T. Also, we identified a large set of genes with genomic aberrations. These include amplifications in VEGF, RB1, RUNX, PARP4, ICAM3, EGFR, BRCA2, COLA6A1, COLA6A2, CCND3, CDKN2D etc.
Conclusions: In the current model, we identified multiple tumorigenic seeding clones and the diverse set of genes mutated in osteosarcoma. Further analysis of the mutational signature resulted in the identification of potential genes that act as drivers in the lung metastatic process. Acknowledgments: Swim Across America, the Foster Foundation and the Barbara Epstein Foundation.

#0149 Modeling patient-specific *CHEK2* genetic variants associated with high-risk neuroblastoma.

X. Xiong[1], S. Cohen-Gogo[2], A. Villani[2], A. Shlien[2], M. S. Irwin[2], M. Hayes[2];
[1]University of Toronto, Toronto, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada

Background: Neuroblastoma (NB) is the most common extra-cranial solid tumor in children and accounts for approximately 10% of childhood cancer deaths. Recently, next-generation sequencing of patients enrolled in the SickKids Cancer Sequencing (KiCS) program revealed somatic and germline alterations in genes involved in the DNA damage response (DDR). Multiple germline and somatic pathogenic variants in *CHEK2* were detected in patients with NB.
Aims and Methods: To better understand potential roles for *CHEK2* in NB pathogenesis, we are modeling patient-derived *CHEK2* variants in an established transgenic zebrafish model of MYCN-driven NB. Using a CRISPR/Cas9 “knock-in” approach, we have generated stable zebrafish lines that are homozygous and heterozygous for variants of interest with either null, heterozygous, or wild-type *tp53* functional status. We aim to assess tumor incidence, growth, and metastasis using direct visualization of disseminated EGFP+ tumor cells, as compared to MYCN over-expression only control fish. Given potential drug sensitivities, we also plan to assess the efficacy of various DDR pathway inhibitors in combination with frontline chemotherapies, which are effective in the treatment of DDR-deficient adult cancers.
Results: Targeting *chek2* in a *tp53* null background had no significant effect on tumor incidence and growth compared to *tp53* mutant control animals ($p=0.1570$ log-rank test). This contrasts with other patient-specific DDR models including gene targeting *brca2* ($p=0.0235$, log-rank test), *atm* ($p<0.001$, log-rank test), and *bard1* ($p<0.001$, log-rank test), potentially highlighting Tp53-dependent roles for Chek2 in NB formation *in vivo*. Through functional characterization of patient-specific *CHEK2* variants in NB progression, our work will provide important preclinical information that will inform future diagnostics and therapeutic strategies for patients with high-risk NB.

#0150 Transcriptional rewiring of BET inhibitor treated Ewing sarcoma cells augments their dependency on focal adhesion kinase.

S. S. Ganapathi[1], E. Wrenn[1], N. Garcia[1], N. Katiyar[1], A. Miyaki[1], Y. Kang[2], M. Chan[2], T. S. Gujral[2], E. R. Lawlor[1];
[1]Seattle Children's Research Institute, Seattle, WA, [2]Fred Hutchinson Cancer Center, Seattle, WA

Outcomes for patients with recurrent and metastatic Ewing sarcoma (EwS) are dismal and novel therapies are needed. As EwS are initiated and maintained by the EWS::FLI1 transcription factor, agents that target aberrant gene transcription are of interest and bromodomain inhibitors (BETi) have shown promise in preclinical models. Nevertheless, despite initial efficacy, BETi tolerance emerges across tumor types, often via transcriptional rewiring. We reasoned that the therapeutic potential of BETi in EwS could be augmented by identifying and targeting mechanisms of drug resistance. To investigate this, we performed transcriptional and phenotypic profiling of BETi-naïve, responsive, and drug-tolerant (DT) EwS cells and used these data to nominate biologically-informed drug combinations. EwS cells (A673, CHLA10, TC32) were exposed for 72 hrs or 20 days to BMS-986158, a clinical grade BETi being tested in a phase I pediatric clinical trial (NCT0393465). A profound cytostatic effect was observed at 72 hrs but in all cell lines proliferation was restored by 20 days. RNA-seq confirmed reversion of the EWS::FLI1-dependent gene signature at 72 hrs and this was maintained at 20 days, demonstrating continued on-target effects despite restored growth of DT cells. Interrogation of differentially expressed genes between drug naïve, cytostatic, and DT cells indicated that that DT cells had been transcriptionally rewired to more mesenchymal states, with notable upregulation of genes involved in integrin signaling. In support of this, DT populations displayed more fibroblastic morphologies, increased F-actin filaments, and enhanced invasion in collagen-rich 3D culture. In parallel, an unbiased kinase inhibitor screen that exploits mathematical modeling revealed that, while BETi-treated cells were overall more resistant than parent cells to kinase inhibitors, their viability depended on focal adhesion kinase (FAK) activity. Western blot confirmed increased phospho-FAK in DT cells. We next tested BMS-986158 and the FAK-inhibitor Defactinib singly or in combination *in vitro* and *in vivo*. Defactinib induced cell death in 2D cultures and blocked invasion of 3D spheroids in collagen. Conversely, BMS-986158 enhanced invasive potential in 3D. The combination of Defactinib and BMS-986158 in naïve and DT populations was highly synergistic in 2D assays. In 3D collagen assays, viability and invasion of DT tumor spheroids were significantly reduced by the combination. Finally, ongoing studies show that the combination of FAK and BET inhibition prolongs survival of mice with EwS tumor xenografts. Thus, our studies reveal that exposure of EwS cells to BETi induces transcriptional rewiring that activates integrin and FAK signaling, restoring proliferation. This work supports further investigation of FAKi as agents that could prevent or reverse the BETi tolerant state in EwS.

#0151 BMP signaling determines neuroblastoma cell fate and sensitivity to retinoic acid.

M. Pan, Y. Zhang, W. C. Wright, H.-M. Lee, R. H. Chapple, X. Liu, J. Low, D. Currier, A. J. Loughran, D. A. Dyer, S. M. Pruett, B. Freeman, T. Chen, B. J. Abraham, E. Stewart, J. Easton, P. Geeleher;
St. Jude Children's Research Hospital, Memphis, TN

While retinoic acid (RA) has been successfully used for leukemia treatment for decades, the attempt to treat solid tumors with RA remains challenging, with less than 10% of neuroblastoma (NB) patients achieving complete remission when treated with RA alone. It has been believed the anti-cancer activity of retinoids is due to retinoid-induced terminal differentiation, however, what determines cell response or whether differentiation is the main effect of RA has never been fully understood. To better understand RA's activity, we conducted genome-wide CRISPR modifier screens in RA-treated hyper-sensitive NB cell lines. Surprisingly, we found that, in these cells, RA primarily decreased cell viability via apoptosis or senescence, rather than differentiation—activities in which the CRISPR screens strongly implicated bone morphogenetic protein (BMP) signaling. BMP activation promoted apoptosis/senescence and sensitized cells to RA. Conversely, BMP inhibitors and *SMAD9* (a critical transcription factor of the BMP pathway) knockout enhanced RA's ability to induce differentiation but reduced cell sensitivity to RA. Our ChIP-seq and RNA-seq data showed these behaviors were mediated by the coordinated gene regulatory actions of *RARA* and BMP-family SMAD transcription factors. Furthermore, in a panel of 19 cell lines we screened with RA, we assessed the correlations between RA IC50 and the expression of all (~20,000) genes (publicly available data from the GDSC and Depmap). Remarkably, *SMAD9* was the number 1 and number 10 most correlated gene, respectively, with RA IC50 (ranked by Pearson correlation coefficient; GDSC R = -0.92, $P = 4.2 \times 10^{-6}$; Depmap R = -0.81, $P = 4.8 \times 10^{-4}$). We also performed comprehensive large-scale drug screens in these cell lines with combinations of RA and a BMP activator FK506. RA exhibited a synergistic effect with FK506 in all the NB cell lines, very strikingly in some cell lines. All these data suggest BMP signaling is generally required for RA sensitivity and BMP activators are promising candidates in combination with RA to treat NB. Using published bulk and single cell RNA-seq data from NB patient samples, we found BMP signaling activity is relatively low in primary tumors, but well maintained in disseminated NB cells derived from bone marrow. This explains why RA is clinically used as a maintenance therapy and can only successfully treat the minimal residual disease and suggests that tumor microenvironment is a critical factor in determining cell response to RA. Overall, our study revealed that BMP controls NB cell fate and sensitivity in RA treatment. Notably, interactions between BMP signaling and RA are well established in developmental biology, where BMP signaling can tip cell fate decisions between differentiation, apoptosis, and senescence upon exposure to endogenous RA. Our data suggest that this developmental process can be maintained in NB cells, unveiling a novel mode of anti-neoplastic action.

#0152 Exploring the impact of heat shock protein 90 on the antitumor efficacy and stemness in medulloblastoma cells.

S.-M. Chen[1], H.-Y. Huang[1], C.-K. Wang[1], Y.-Y. Yang[1], S.-J. Leu[1], Y.-Y. Li[2];
[1]Taipei Medical University, Taipei, Taiwan, [2]Department of Veterans Affairs, Miami VA Healthcare System, Floria, United States, Miami, FL

Background: Medulloblastoma (MB) is the most common children's malignant brain tumor. Although MB can be treated with conventional chemotherapies, chemoresistance has been frequently developed and thereby hampers their therapeutic effectiveness. The preliminary reports of our research showed that some heat shock proteins have higher levels in MB cells. Among these heat shock proteins, HSP70 and HSP90 expressions are particularly high in MB CD133+ cancer stem cells (CSCs), which arouses our attention and interest. Numerous studies demonstrated that heat shock proteins are prominent in some chemotherapy-resistant cancer cells and CSCs. As known HSP90 and its client proteins are required for the maintenance of self-renewal/stemness and regulation of cell cycle, synergistic killing of cancer cells by simultaneous inhibition of HSP90 expression and activity may be a considerable good therapeutic strategy for treating MB. The purpose of this study is to verify the regulatory function of HSP90 in chemoresistance and stemness of MB.
Materials and Methods: The levels of HSP90, its client proteins (P13K/pAKT, Erk, NFκB, and c-Myc), and stemness makers were detected using immunoblotting and immunoprecipitation after the treatment of HSP90 inhibitor (17-AAG) or knockdown of HSP90 by siRNA in MB and MB CSCs. The antitumor effects of HSPs inhibitors or knockdown of HSPs on these cells were evaluated by MTT assay, Annexin V/PI analysis and cell cycle analysis.
Results: Our findings revealed elevated expression of HSP90 and its target client proteins in MB cells compared to normal astrocytes. Silencing or inhibiting HSP90 expression induced cell cycle arrest in MB cells. Notably, CD133+ MB CSCs exhibited higher HSP90 levels than parental MB cells. Inhibition of HSP90 led to reduced sphere formation and expression of stemness markers in CD133+ MB CSCs. Treatment with 17-AAG demonstrated antitumor activity in CD133+ MB CSCs, and a synergistic effect was observed when combining conventional chemotherapeutic agents with 17-AAG in MB cells
Conclusion: These results illustrated that inhibition of HSP90 could eliminate CSCs, and thereby overcome resistance to chemotherapeutic agents in MB. Chemotherapies in combination with HSP90 blockade may be an emerging MB therapy in the future.

#0153 Noncoding elements of *MYCN* mRNA are powerful drivers on oncogenicity in neuroblastoma.

V. Patel[1], L. Benhamou[2], D. T. Powers[2];
[1]The University of Texas At Austin, Austin, TX, [2]Dell Medical School at The University of Texas at Austin, Austin, TX

Precision in genetic modeling of oncogene-driven cancer is crucial for comprehending disease pathology. Traditionally, models focused on protein expression through open-reading-frame (ORF) transgenes. This approach overlooks post-transcriptional regulation in endogenous mRNAs, which include noncoding elements like 5' and 3' UTRs and introns. All patient oncogene mRNAs encompass these elements, and grasping the collective impact of noncoding and protein coding components may revolutionize our comprehension of cancer origins.Neuroblastoma (NB) is the most common extracranial solid tumor in children. Genetic amplification of *MYCN* (*MA*) in NB results in very high mRNA levels and drives poor prognosis. *MYCN* mRNA is targeted by multiple microRNAs, including *let-7*. We previously demonstrated that in *MA* disease the 3' UTR of *MYCN* can sequester *let-7*, inhibiting its function. *MYCN* mRNA thus also influences genetic patterning in NB by relieving the selective pressure to lose chromosome arms harboring *let-7* loci, an event frequent in *MYCN* non-amplified NB but exceedingly rare in *MA* disease. This work established for the first time that noncoding mRNA elements within an oncogenic mRNA can itself contribute to disease pathology. To further understand the roles of noncoding elements within *MYCN* mRNA, we generated BALB/c 3T3 fibroblasts and murine Neuro-2a cells that express the following transgenes:
1.*MYCN*-ORF: expresses only *MYCN* open reading frame sequence.2.*MYCN*-GL: intact genetic locus of *MYCN*, expresses full length *MYCN* mRNA.3.*M/GFP*-GL: variant of #2 where *MYCN* protein coding sequences are replaced by *EGFP*.
All three constructs demonstrated significantly enhanced *in vitro* proliferation compared to GFP control cells. Notably, cells expressing *MYCN*-GL exhibited best growth in both cell types, despite possessing an intact 3'UTR. Unexpectedly, *M/GFP*-GL cells demonstrated comparable growth to *MYCN*-ORF in 3T3s and significantly outperformed *MYCN*-ORF in Neuro-2a cells. This observation not only validates our prior research on the oncogenic role of the *MYCN* 3' UTR but also extends it by revealing direct contributions to growth advantages, occasionally surpassing even MYCN protein. Syngeneic animal studies mirrored these trends, with *MYCN*-GL and *M/GFP*-GL inducing nearly 100% tumor incidence, surpassing the 57% incidence associated with *MYCN*-ORF. Tumors induced by *MYCN*-GL and *M/GFP*-GL were more than twice the size of those induced by *MYCN*-ORF. These observations underscore that full-length *MYCN* mRNA, encompassing all noncoding elements, serves as a more potent driver of cellular growth and oncogenicity than only MYCN protein expression. These findings have exciting implications for understating neuroblastoma pathology and genetic patterns, with broader implications for other oncogene-driven cancers. We are currently generating transgenic mouse models based on the above three constructs.

#0154 Diffuse midline glioma invasion and metastasis rely on cell-autonomous signaling through a phenotypic switch controlled by BMP7.

M. Bruschi[1], L. Midjek[1], Y. Ajlil[1], S. Vairy[1], M. Lancien[1], S. Ghermaoui[1], T. Kergrohen[1], M. Verreault[2], A. Idbaih[2], C. de Biagi, Jr.[3], I. Liu[3], M. G. Filbin[3], K. Beccaria[4], T. Blauwblomme[4], S. Puget[4], A. Tauziede-Espariat[5], P. Varlet[5], V. Dangouloff-Ros[4], N. Boddaert[6], G. Le Teuff[7], J. Grill[1], G. Montagnac[8], N. Elkathib[8], M.-A. Debily[1], **D. Castel**[1];

[1]Inserm U981, Gustave Roussy, Villejuif, France, [2]Institut du Cerveau, ICM, Paris, France, [3]Dana-Farber Cancer Institute, Boston, MA, [4]Necker Enfants Malades Hospital, Paris, France, [5]GHU Paris Psychiatrie & Neurosciences, Paris, France, [6]Necker Enfants Malades Hospital, Villejuif, France, [7]Gustave Roussy, Villejuif, France, [8]Inserm U1279, Gustave Roussy, Villejuif, France

Diffuse midline gliomas (DMG) are pediatric tumors with negligible two-year survival after diagnosis characterized by their ability to infiltrate the central nervous system. In the hope of controlling the local growth and slowing the disease all patients receive radiotherapy. However, distant progression occurs frequently in DMG patients. Current clues as to what causes tumor infiltration circle mainly around the tumor microenvironment, but there are currently no known determinants to predict the degree of invasiveness. We use patient-derived glioma stem cells (GSCs) to create patient-specific 3D avatars to model interindividual invasion and elucidate the cellular supporting mechanisms. We show that 3D models mirror the invasive behavior of the parental tumors, thus proving the ability of DMG to infiltrate as an autonomous characteristic of tumor cells. Furthermore, we distinguished two modes of migration, mesenchymal and amoeboid-like, and associated the amoeboid-like modality with GSCs derived from the most invasive tumors. Using transcriptomics of both organoids and primary tumors, we further characterized the invasive amoeboid-like tumors as oligodendrocyte progenitor-like, with highly contractile cytoskeleton and reduced adhesion ability. Moreover, we identified the cell-autonomous BMP7-related signaling as a major regulator of DMG motility and invasion, controlling a switch between two migration modalities. Finally, we deciphered MEK, ERK and Rho/ROCK kinases activated downstream of the BMP7 stimulation as actionable targets controlling tumor cell motility. Our findings identify two new therapeutic avenues. First, patient-derived GSCs represent a predictive tool for stratification of patient with increased risk of metastatic progression in order to adapt their irradiation strategies within weeks after diagnosis. Second, autocrine and short-range BMP7-related signaling becomes a druggable target to prevent DMG spread and metastasis.

#0155 Clinico-radiological and histomolecular analyses identify of a new subtype of diffuse midline glioma, H3 K27 and BRAF/FGFR1 co-altered.

L. Auffret[1], Y. Ajlil[1], A. Tauziede-Espariat[2], T. Kergrohen[1], C. Puiseux[3], L. Riffaud[4], P. Blouin[5], A.-I. Bertozzi[6], P. Leblond[7], K. Blomgren[8], S. Froelich[9], A. Picca[10], M. Touat[10], M. Sanson[10], K. Beccaria[11], T. Blauwblomme[11], V. Dangouloff-Ros[11], N. Boddaert[11], P. Varlet[2], M.-A. Debily[1], J. Grill[1], **D. Castel**[1];
[1]INSERM U981, Gustave Roussy, Villejuif, France, [2]GHU Paris psychiatrie & neurosciences, Paris, France, [3]Rennes University Hospital, Rennes, France, [4]Rennes University Hospital, Villejuif, France, [5]CHRU de Tours, Tours, France, [6]Hopital des Enfants, Toulouse, Toulouse, France, [7]Centre Leon Berard, Lyon, France, [8]Karolinska University Hospital, Stockholm, Sweden, [9]Hopital Lariboisiere AP-HP, Paris, France, [10]Institut du Cerveau, ICM, Paris, France, [11]Necker Enfants Malades Hospital, Paris, France

Diffuse midline gliomas (DMG) H3 K27-altered are incurable grade 4 gliomas and represent a major challenge in neuro-oncology. This tumor type is now classified in four subtypes by the 2021 edition of the WHO Classification of the Central Nervous System (CNS) tumors. However, the H3.3-K27M subgroup still appears clinically and molecularly heterogenous. Recent publications reported that rare patients presenting a co-occurrence of H3.3K27M with *BRAF* or *FGFR1* alterations tended to have a better prognosis. To better study the role of these co-driver alterations, we assembled a large pediatric and adult cohort of 29 tumors H3K27-altered with co-occurring activating mutation in *BRAF* or *FGFR1* as well as 31 previous cases from the literature. We performed a comprehensive histological, radiological, genomic, transcriptomic and DNA methylation analysis. Interestingly, unsupervised t-distributed Stochastic Neighbor Embedding (tSNE) analysis of DNA methylation profiles regrouped $BRAF^{V600E}$ and all but one $FGFR1^{MUT}$ DMG in a unique methylation cluster, distinct from the other DMG subgroups and also from ganglioglioma (GG) or high-grade astrocytoma with piloid features (HGAP). This new DMG subtype harbors atypical radiological and histopathological profiles with calcification and/or a solid tumor component both for $BRAF^{V600E}$ and $FGFR1^{MUT}$ cases. Contrary to other DMG, these tumors occur more frequently in the thalamus (70% for $BRAF^{V600E}$ and 58% for $FGFR1^{MUT}$) and patients have a longer overall survival with a median above three years. The analyses of a H3.3-K27M $BRAF^{V600E}$ tumor at diagnosis and corresponding *in vitro* cellular model showed that mutation in *H3-3A* was the first event in the oncogenesis, indicating a distinct oncogenesis from classical DMG despite an identical founder H3K27 alteration, and possible subclonal evolution.In conclusion, *DMG, H3 K27 and BRAF/FGFR1 co-altered* represent a new subtype of DMG with distinct genotype-phenotype characteristics, which deserve further attention with respect to trial interpretation and patient management. Our work also lays the foundations for therapeutic development highly-needed against this deadly disease.

TUMOR BIOLOGY: Macrophages, Neutrophils, and NK Cells in Cancer

#0159 LYVE-1-expressing macrophages modulate the hyaluronan-containing extracellular matrix in the mammary stroma and contribute to mammary tumor growth.

A. K. Elfstrum, A. H. Rumahorbo, B. M. McCluskey, K. L. Schwertfeger;
University of Minnesota, Minneapolis, MN

Macrophages represent a heterogeneous myeloid population with diverse functions in normal tissues and tumors. While macrophages expressing the cell surface marker lymphatic vessel endothelial hyaluronan receptor 1 (LYVE-1) have been identified in stromal regions of the normal mammary gland and in the peri-tumoral stroma, their functions within these regions are not well-understood. Using a genetic LYVE-1^+ macrophage deletion mouse model, we demonstrate that loss of LYVE-1^+ macrophages is associated with altered extracellular matrix remodeling in the normal mammary gland and reduced mammary tumor growth in vivo. In further studies focused on investigating the functions of LYVE-1^+ macrophages in the tumor microenvironment, we demonstrate that LYVE-1 expression correlates with an increased ability of macrophages to bind, internalize, and degrade hyaluronan. Consistent with this, we show that deletion of LYVE-1^+ macrophages correlates with increased hyaluronan accumulation in both the normal mammary gland and in mammary tumors. Analysis of single cell RNA sequencing of macrophages isolated from these tumors reveals that deletion of LYVE-1^+ macrophages in tumors drives a shift in the majority of the remaining macrophages towards a pro-inflammatory phenotype, as well as an increase in $CD8^+$ T cell infiltration. Together, these findings demonstrate that LYVE-1^+ macrophages represent a tumor-promoting anti-inflammatory subset of macrophages that contributes to hyaluronan remodeling in the tumor microenvironment.

#0160 FGFR1+ cancer associated fibroblasts (CAFs) produce an extracellular matrix (ECM) that curbs infiltration of phagocytic tumor-associated macrophages (TAMs)..

N. Di Siervi, M. Revuelta, N. Zamponi, G. Inghirami, L. Cerchietti;
Weill Cornell Medicine, New York, NY

About 40% of diffuse large B-cell lymphoma (DLBCL) pts do not respond to immunochemotherapy. In human and murine models, we and others have shown that the lymphoma microenvironment (LME) changes with disease progression and treatment resistance. This lymphoma cell-LME co-evolutionary process results in expansion of treatment-resistant lymphoma cells as well as reduced infiltration of T cells and reprogramming of CAFs and TAMs into immune suppressive entities. Our analysis of relapse or refractory (RR)-DLBCLs showed not only an immune depleted LME but also an enrichment of CAFs harboring activation of fibroblast growth factor receptor (FGFR1+). Since FGFR1 inhibitors (FGFR1i) are clinically available, we sought to determine its anti-neoplastic effect on DLBCL. We first confirmed that lymphoma cells, including murine and human, and primary and RR-DLBCLs, did not express FGFR1. Accordingly, no anti-tumoral effect was detected when the selective FGFR1i SSR128129E was administered in vitro to a lymphoma cell panel. However, oral administration of FGFR1i to pre-clinical lymphoma models including two RR-DLBCL patient-derived xenografts (PDX) and four syngeneic murine models representing distinct DLBCL genetic subtypes produced a significant anti-lymphoma effect in all cases. In addition to decreased lymphoma cells, we observed increase in the ECM and TAM infiltration, even in the murine models, suggesting that FGFR1i reprogrammed the CAFs. We thus conducted matrisome analysis (i.e., ECM proteomics) in a murine model (p53 mutant) and found a significant up-regulation of proteoglycans and the immune active glycoproteins decorin, lumican and byglican (q-value <0.05 vs. vehicle). To determine whether these ECM changes affect lymphoma cells, we performed 3D co-cultures of lymphoma cells embedded into de-celularized ECM obtained from FGFR1i vs. vehicle mice. We found that FGFR1i-ECM (vs. vehicle-ECM) modifies the secretome of lymphoma cells by upregulating several cytokines including IL6, IL16 and TNF-alpha. To further characterize the functional state of CAFs and TAMs, we conducted single cell RNA-seq in the two RR-DLBCL PDXs treated as before. We found that FGFR1-CAFs in the LME of FGFR1i tumors (vs. vehicle) were reprogrammed into inflammatory-like CAFs characterized by the expression of several monocyte/macrophage chemotactic factors including CCL2, CCL7, CXCL3, and CXCL12. Consequent with these findings we not only observed an increase infiltration of TAMs in the LME of FGFR1i tumors but also that they were reprogrammed in phagocytic phenotypes. In sum, our results suggest that CAF-FGFR1+ produce an immune “silent” ECM that characterizes RR-DLBCL while FGFR1i reverses this ECM phenotype ultimately resulting in the infiltration of antitumoral TAMs, delineating a novel ECM-directed therapeutic approach for this disease.

#0161 Aged mice decelerate bone metastasis of prostate cancer by decreasing infiltration of M2 macrophages.

X. Zhang, W. Yu, X. Huang, Y. Lu, J. Zhang;
Southern University of Science and Technology, Shenzhen, China

Bone metastasis is a major contributor to the mortality of patients with prostate cancer and results in the development of an immunosuppressive microenvironment in the bone marrow. While advanced age increases the risk of bone metastasis, effects of age-related changes on immune microenvironmental homeostasis are not yet clearly understood. To investigate interactions between cancer cells and the immune microenvironment in elderly individuals, we utilized murine-derived specific bone metastatic prostate cancer cells (RM1-BM), which we had previously isolated from bone metastatic mice and transfected with a luciferase-based reporter gene. We then injected the cells into the left ventricle of both 3–6 months and 22–24 months, male, wild-type mice to induce bone metastasis, using age-matched mice injected with PBS as a control. We employed *in vivo* imaging to compare the metastatic levels in both groups of mice every other day. On day 14, we extracted bone marrow cells for CyTOF analysis and femurs and tibias for Hematoxylin and Eosin staining. Interestingly, our preliminary results demonstrated that healthy aged mice exhibited a lower susceptibility to develop bone metastasis when compared to their younger counterparts. A further investigation of the immune subtypes revealed an increase in the percentage of macrophages in $CD45^+$ immune cells in young mice that developed bone metastasis as opposed to age-matched controls. However, the percentage decreased in aged mice, going from 12.20% to 9.92% (p = 0.001). Lastly, macrophages were isolated from the bone marrow of 3–6 months and 22–24 months old mice and were co-cultured with ovalbumin-transfected RM1-BM cells (RM1-BM-ova) *in vitro* for 24 hours. The flow cytometry results indicated that both groups consist mainly of $CD206^+$ (M2) macrophages. Nonetheless, those obtained from aged mice exhibited reduced ovalbumin presentation capability while maintaining a steady level of type I major histocompatibility complex (MHC-I). These findings suggested that increased infiltration of pro-inflammatory M2 macrophages within the tumor microenvironment may contribute to the bone metastasis of prostate cancer. Therefore, inhibiting M2 macrophages recruitment to the bone marrow microenvironment may prove a useful approach for treating patients with prostate cancer bone metastasis. This study was supported by the NSFC projects (81972420, 81972766, 82173336), and grants from the Shenzhen Science and Technology Innovation Commission (JCYJ20190809161811237, JCYJ20210324104214040).

#0162 Fatty acid synthesis blockade synergizes with immune checkpoint blockade by repolarizing macrophages and enhancing anti-tumor cytotoxicity in gastric cancer.

H. Wang, T. Shi, Y. Wang, Y. Luo, Y. Pan, X. Zhou, Y. Zhang, B. Liu, J. Wei;
The Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China

Background: Immune checkpoint blockade (ICB), which unleashes potent $CD8^+$ T cell-based anti-tumor responses, has emerged as a promising therapeutic option for several cancer types. However, response rates stay limited in gastric cancer (GC) patients, indicating the necessity of combinational strategies to overcome other immunosuppressive factors. Fatty acid synthesis (FAS) is an indispensable metabolic pathway proven to support cancer cell survival. The rate-limiting enzyme of FAS, FASN, is upregulated in several cancers and could contribute to cancer immune escape. Though some investigations propose that specific gene alterations can cause FASN upregulation under the GC setting, the immunoregulatory role and therapeutic value of FASN in the tumor microenvironment (TME) of GC have not been fully elucidated.
Methods: FASN expression was measured by Western Blotting and flow cytometry. Bioinformatic analysis was conducted via an online website (www.camoip.net). The syngeneic GC mouse model was established by subcutaneous inoculation of MFC cells in 615-line mice, treated by vehicles, FASN inhibitor (FASNi), anti-PD-1 antibodies, or FASNi+anti-PD-1 antibodies. TAM and $CD8^+$ T cell depletion was implemented by anti-CSF1R and anti-CD8α antibodies. Bone marrow-derived macrophages (BMDMs) were extracted from the femurs of 615-line mice, induced by M-CSF and stimulated by LPS or IL-4. The proportions and functional status of immune cells were identified by flow cytometry.
Results: FASN was upregulated in GC tissues and GC human cell lines. Bioinformatic analyses demonstrated that FASN expression was related to poor infiltration of cytotoxic lymphocytes, as well as the downregulation of pathways related to anti-cancer immune responses. FASNi inhibited tumor growth in a syngeneic GC mouse model, with elevated PD-1 and IFN-γ expression in $CD8^+$ T cells and increased NK cell infiltration, suggesting the enhancement in anti-cancer cytotoxicity. Meanwhile, FASNi induced a shift from M2-like to M1-like in tumor-associated macrophages (TAM). We detected that M2-like TAM and $CD8^+$ T cells harbored higher FASN expression than other immune cells in GC mouse tissues, and tumor-suppressing effects of FASN inhibition could be reversed by TAM and $CD8^+$ T cell depletion, which corroborated the key role of TAM and $CD8^+$ T cells in shaping FASN-mediated tumor regulation. FASNi could also repolarize BMDMs from M1-like to M2-like *in vitro*. Finally, FASNi exhibited synergistic tumor control with anti-PD-1 therapy in GC and melanoma mouse models.
Conclusion: This work sheds light on the impact of FASN on TME modulation of GC. We proved that FASNi could repolarize M2-like TAM to M1 phenotypes and promote cytotoxic lymphocyte-mediated anti-tumor immunity. Our results propose FASN inhibition as a potential therapeutic strategy to sensitize ICB therapy in GC.

#0163 Role of macrophages in the development of ovarian cancer stem-like cells during chemotherapy.

L. S. Cruz, D. Stevenson, M. Robinson, S. Mathew, I. Amador, G. Jordan, C. D. House;
San Diego State University, San Diego, CA

Ovarian cancer is a poorly understood disease with 75% death rate when identified after metastasis. Drug resistance and tumor recurrence are likely due to cancer stem-like cells (CSCs) that evade chemotherapy and induce relapse with phenotypes that are distinct from bulk tumor cells. It remains unclear how CSCs facilitate relapse and what role the tumor microenvironment (TME) plays in this process. Our preliminary data show that a secreted cytokine, tumor necrosis factor-like weak inducer of apoptosis (TWEAK), and its receptor Fn14 are overexpressed in ovarian tumors and increase after chemotherapy. TWEAK is a strong inducer of stem cell features and enhances survival of CSCs during chemotherapy exposure. The source of TWEAK has not been clarified, although clinical data from human ovarian tumors show that TWEAK mRNA was primarily observed in a subset of infiltrating immune cells known as tumor associated macrophages (TAMs). When we evaluated TWEAK expression in cells found in the ovarian TME, including PBMC and THP-1-derived macrophages, IMR-90 activated fibroblasts, and ovarian cancer cell lines, we found that PBMC macrophages were the primary source of TWEAK production. Since cytotoxic chemotherapy can enrich for different TAM populations, we propose that TWEAK producing TAMs support CSC survival and expansion and contribute to the high rate of relapse in ovarian cancer patients. We further found that treatment with a small molecule inhibitor of TAM polarization leads to decreased TWEAK production, fewer CSCs, and prolonged remission in mouse models of ovarian cancer relapse as compared to vehicle. Currently we are testing whether knockout of Fn14 in ovarian cancer cells co-cultured with TAMs reduces stem cell features dependent on TWEAK-Fn14 signaling. Identification of immune populations responsible for TWEAK production could lead to new therapeutic strategies for patients with high rates of relapse.

#0164 Genetic elimination of β-catenin using a doxycycline-regulated GEM model fails to restore checkpoint blockade efficacy due to persistent M2-like macrophages.

A. Cabanov, R. Tonea, J. Shapiro, A. Martinez, Y. Zha, T. F. Gajewski;
University of Chicago, Chicago, IL

Response to checkpoint blockade immunotherapy (CBI) is not universal, partly due to a wide variation in baseline immune cell infiltration in the tumor microenvironment (TME). One mechanism contributing to this variability is tumor cell-intrinsic activation of the β-catenin signaling pathway, which has previously been shown to result in a non-T cell-inflamed TME. Constitutive β-catenin signaling resulted in reduced Batf3-lineage dendritic cell (cDC1) recruitment, leading to reduced T cell activation and infiltration and loss of anti-CTLA-4+anti-PD-L1 therapeutic efficacy. Efforts to target the Wnt/β-catenin pathway to enhance immune responses in β-catenin-active tumors have seen limited success. A genetic experiment eliminating β-catenin expression after establishment of a non-T cell-inflamed TME might illustrate the maximal biologic effect that could be expected with blockade of the pathway. We developed a genetically engineered mouse (GEM) model that allows for dynamic regulation of β-catenin on and off. This model employs tyrosinase-driven tamoxifen-regulated Cre-recombinase to activate the BRAF V600E oncogene and delete the tumor suppressor gene PTEN, along with a transactivator for doxycycline-regulated expression of a non-degradable β-catenin. Topical application of 4-hydroxytamoxifen resulted in melanoma formation, and administration of doxycycline resulted in robust nuclear expression of melanocyte-specific β-catenin compared to non-treated controls. This was accompanied by a significant reduction in $CD3^+$ T cell infiltration within the TME, confirming the link between active β-catenin signaling and T cell exclusion. Discontinuing doxycycline treatment led to complete reduction of nuclear β-catenin expression in the tumor cells within seven days and a substantial return of $CD3^+$ T cells into the TME. However, despite the re-infiltration of $CD3^+$ T cells, the tumors previously expressing β-catenin (ex-β-catenin tumors) did not regain therapeutic responsiveness to anti-CTLA-4+anti-PD-L1. Single cell RNA sequencing of the ex-β-catenin tumors indicated the presence of an immunosuppressive-like macrophage population, characterized by the expression of Ccl8, Gas6 and Cd163. This finding suggests that the prior presence of β-catenin may induce long-lasting changes in the TME that suppress the immune response even after β-catenin levels are reduced. These data corroborate previous findings on the role of β-catenin in modulating the immunological landscape of melanoma and extend it by demonstrating the long-term persistence of immune evasion by suppressive myeloid cells even after β-catenin signaling is eliminated. These insights have implications for clinical strategies aiming to block Wnt/β-catenin signaling, which may additionally require myeloid cell modulation to restore immunotherapy efficacy.

#0165 PVRL2 upregulation by tumor-associated macrophages confers a regulatory phenotype and is associated with poor prognosis in high-grade serous ovarian cancer.

K. Murakami, H. Ando, M. Doucet, D. Ding, W. Huang, S. Ganguly;
Johns Hopkins University School of Medicine, Baltimore, MD

Advanced or recurrent high-grade serous ovarian cancer (HGSOC) are associated with poor prognosis. While HGSOC is moderately immunogenic, anti-PD-1/L1 therapy has fared poorly in trials. PVRL2 (Nectin2) is both a cell-adhesion molecule as well as a ligand for PVRIG, a novel co-inhibitory receptor. While PVRL2 is constitutively expressed by epithelial/tumor cells, it can also be upregulated by macrophages. Whether macrophage-expressed PVRL2 functions exclusively as an immunoregulatory ligand in HGSOC is not known. $CD45^+$ tumor infiltrate from 6 treatment-naïve and 3 neoadjuvant chemotherapy-treated patients with HGSOC was evaluated by CITE-seq. Multiplex immunofluorescence (mIF) of PanCK, CD68 and PVRL2 was performed on 28 FFPE sections. *In vivo*, we monitored survival of wild-type and $PVRL2^{-/-}$ mice as well as corresponding bone marrow chimeras orthotopically implanted with ID8-Vegf-Defb29 ovarian tumors. CITE-seq was run on $CD45^+$ cells sorted from wild-type vs $PVRL2^{-/-}$ tumors and ascites. In tumor-bearing mice, macrophages, CD8 or NK cells were depleted and differences in survival assessed. *In vitro*, M1 and M2 macrophages were differentiated from steady-state bone marrow progenitors and myeloid gene profiles were analyzed. CITE-seq of patient-derived immune cells revealed that PVRL2 expression was restricted to macrophage clusters. Macrophages with low PVRL2 expression showed M1 polarity and abundant expression of inflammatory cytokines and chemokines. Overall macrophage counts and PVRL2 expression were lower in post-chemotherapy cases. In mIF, PVRL2 staining was observed on CD68-positive cells as well as tumor cells. In addition, PVRL2-expressing macrophages accumulated in tumor areas, especially in residual tumor areas after chemotherapy. $PVRL2^{-/-}$ mice and PVRL2 bone marrow chimeras had significantly improved survival compared to their respective control cohorts. Macrophage depletion significantly shortened the prognosis of $PVRL2^{-/-}$ mice compared to wild-type mice. In contrast, depletion of CD8 T cells or NK cells had no effect on survival of wild-type and $PVRL2^{-/-}$ mice. M1 macrophages from $PVRL2^{-/-}$ mice expressed higher levels of inflammatory cytokines and chemokines compared to their wild-type counterparts. Furthermore, CITE-seq showed that tumor-infiltrating macrophages in $PVRL2^{-/-}$ mice exhibited M1 polarization compared to those from wild-type tumors. However, the inflammatory phenotype appeared to be linked more with the tumor-infiltrating macrophages than with ascites macrophages. In conclusion, our research suggests that PVRL2 upregulation by tumor-infiltrating macrophages polarizes towards a pro-tumor phenotype and affects prognosis of HGSOC. PVRL2-deficient macrophages exert their antitumor effects via inflammatory tumor killing and not via antigen-presentation to effector T cells.

#0167 Modulation of PD-1/PD-L1 by simvastatin in TNBC and macrophages and its impact on the efficacy of immunotherapy.

S. Lee[1], J. Kim[2], A. Park[1], J. Baik[1], J.-J. Jung[3], H.-B. Lee[2], W. Han[1];

[1]Seoul National University Graduate School, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Seoul, Korea, Republic of, [3]Seoul National University College of Medicine, Seoul, Korea, Republic of

Introduction: Statins, known as inhibitors of HMG-CoA, not only reduce cholesterol but also exhibit pleiotropic effects which include anti-tumor activities by targeting tumor microenvironments. They inhibit the synthesis of FPP and GGPP, which is important for prenylation of signaling proteins. Although PD-1/PD-L1 inhibitors has been approved for treatment for TNBC patients with PD-L1 positive, the response remains unsatisfactory. Also, it has been reported that statins affect PD-L1 expression in other tumors, but it is still uncertain in TNBC. Therefore, we aimed to identify the effect of statins on the expression of PD-L1 in TNBC and to verify the efficacy of combination therapy with statins and immune checkpoint inhibitors.

Methods: Human and mouse TNBC cell lines, mouse macrophage cell line (RAW 264.7), and clinically approved simvastatin were used. Flow cytometry, western blot, proliferation assay, qRT-PCR, immune phenotyping and immunohistochemistry were conducted. A co-culture of macrophages and cancer cells was performed. An orthotopic syngeneic mouse model by injection of EMT6 cells into mammary gland fat pad were produced. Mice were treated with simvastatin(20mg/kg) by oral gavage daily and anti-PD-1(200μg) by intraperitoneal injection two times per week.

Results: Among thirteen human TNBC cell lines, we confirmed that TNBC cell lines showed various PD-L1 expression, and especially MDA-MB-231 and HCC38 highly expressed endogenous/constitutive PD-L1. Statins reduced PD-L1 expression and exerted anti-proliferative effects in MDA-MB-231, HCC38, and EMT6 in a dose- and time-dependent manner. Phosphorylation of AKT and STAT3 was reduced when simvastatin was treated. Mice with combination therapy of anti-PD-1 and simvastatin had less effective inhibitory effect on tumor growth than mice with anti-PD-1 monotherapy, which showed the highest tumor suppression effect. In immune phenotyping, tumor-infiltrated T cells did not have significant differences among groups. However, M1:M2 macrophage ratio was highest in anti-PD-1 group but decreased in combination therapy group with simvastatin. To determine the effect of simvastatin on macrophages, RAW264.7 cells were stimulated with MDA-MB-231 conditioned medium, revealing an upregulation of PD-1 expression.

Conclusions: Our findings show that simvastatin has an anti-tumor effect, which reduces Pd-L1 expression and kills breast cancer cells, reducing phosphorylation of STAT3 and AKT. However, when combined with PD-1 checkpoint inhibitor, it reduces the anti-tumor effect by increasing PD-1 expression in macrophages and promoting M1 to M2 polarization. Further study is needed to demonstrate the mechanism by which simvastatin regulate polarization of macrophages and to confirm the polarization of macrophages in samples of TNBC patients who had been taking simvastatin.

#0169 Prevalence, immune checkpoint expression and spatial interplay of intraepithelial lymphocytes, macrophages, and dendritic cells in 4740 human carcinomas.

Z. Huang[1], T. Mandelkow[1], J. H. Muller[1], A. H. Marx[2], T. Krech[3], G. Sauter[1], J. Ebner[1], M. Lennartz[1], R. Simon[1], M. Kluth[1], C. Hube-Magg[1], S. Minner[1], E. Bady[1], N. C. Blessin[1];

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Academic Hospital Fuerth, Fuerth, Germany, [3]Clinical Center Osnabruck, Osnabruck, Germany

Background: Although there is raising evidence that the density and the level of immune checkpoint expression of immune cell subpopulations that are in direct contact to the tumor cells (intraepithelial) can predict response to immune checkpoint therapy and patient's outcome, a comprehensive assessment of intraepithelial immune cell subpopulations and their spatial interplay is lacking.

Material and methods: To comprehensively assess the density, level of immune checkpoint expression, and spatial interplay of 48 immune checkpoint expressing intraepithelial leukocyte subpopulations in 46 carcinoma entities, 4740 tumor samples in a tissue microarray format were stained with 21 antibodies using our BLEACH&STAIN mfIHC approach. A deep learning-based framework comprising 18 different convolutional neuronal networks (U-Net and DeepLabv3+) were used for image analysis.

Results: The mean intraepithelial immune cell density of $CD8^+$ cytotoxic T-cells, $CD4^+$ T-helper cells, $FOXP3^+$ Tregs, $CD20^+$ B-cells, M1/ M2 macrophages and $CD11c^+$ dendritic cells varied markedly between tumor entities and individual tumors. For example, 88 (±90) cells/ mm^2 were found in tubular breast cancer, 661 (±729) cells/ mm^2 in colorectal cancer, and 1280 (±1334) to 2325 (±2131) cells/ mm^2 in squamous cell cancers from various origins. The abundance of T-cell subpopulations, M2 macrophages, and dendritic cells was highly concordant (range r=0.49 to 0.92) across all tumor entities, while the density of M1 macrophages was unrelated (r=0.1, p<0.001). Unsupervised hierarchical clustering across all tumor entities revealed a cluster A of 634 patients from almost all different tumor entities with an exceptionally high density of intraepithelial immune cells, thus a highly inflamed tumor microenvironment that was characterized by the strongest interaction between intraepithelial $CD8^+$ T-cell and $CD4^+$ T-helper cells, M2 macrophages, as well as dendritic cells (DC, p<0.002 each) along with the highest expression level of TIM3, PD-1, CLTA-4 and PD-L1. In contrast, a cluster C of 2245 patients with the lowest intraepithelial immune cell infiltration was characterized by a significantly increased M1 proportion (p<0.001) and an enriched proportion of regulatory T-cells (p<0.001). Across all analyzed tumor entities, the intraepithelial highly inflamed cluster A was significantly linked to low pT (p<0.001).

Conclusion: The data from this study provide a comprehensive characterization of intraepithelial immune cells across 46 different human carcinomas and identify an inflamed phenotype defined by strong interactions of intraepithelial $CD8^+$ cytotoxic T-cells, $CD4^+$ T-cells, dendritic cells, and M2 macrophages along with highest levels of TIM3, PD-1, PD-L1, and CTLA-4 expression that is linked to a favorable tumor phenotype.

#0170 Targeting of macrophage PI3Kyin prostate cancer using Eganelisib (IPI-549) reprograms immune-suppressive infiltrating macrophages to enhance anti-tumor immune responses and promote immunologically mediated tumor growth.

K. M. Adusei[1], T. R. Nirschl[1], A. J. Lee[1], F. Shen[1], X. Wang[1], M. Praharaj[1], J. Alvarez[1], I. Gross[1], K. A. Lombardo[1], T. L. Lotan[1], J. A. Varner[2], J. C. Zarif[1]; [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of California, San Diego, La Jolla, CA

Background: Prostate cancer (PCa) is traditionally considered an immunologically 'cold' indication, as evidenced in part by significant infiltration of immunosuppressive tumor associated macrophages (TAMs) and few activated effector $CD8^+$ T cells. Attempts to (re)invigorate an anti-prostate cancer immune response with immune checkpoint blockade (ICB) such as anti-CTLA-4 and anti-PD-1 have been largely ineffective clinically, despite promising results in other cancers. This is likely due to a multitude of immunosuppressive cell types and secreted factors within the tumor microenvironment (TME) that diminish T cell activation and trafficking. Reducing the immunosuppressive burden intratumorally by targeting TAMs is a clinically attractive approach and offers opportunity to sensitize PCa to immune checkpoint blockade. While PI3K signaling is ubiquitous in most cell types, specific catalytic isoforms and regulatory elements are differentially expressed depending on cell type, with PI3Kγ being significantly enriched in myeloid cells and therefore offering a unique therapeutic opportunity for specific targeting.
Methods: Utilizing novel syngeneic prostate cancer tumors, PI3Kγ deletion and antagonism using Eganelisib (a small molecule inhibitor for PI3Kγ), we tested our hypothesis that targeting PI3Kγ signaling in PCa TAMs would lead to tumor growth inhibition and anti-tumor immune responses.
Results: We show here that PCa tumor cells do not express the PI3Kγ isoform and, therapeutic inhibition of PI3Kγ with Eganelisib reduces the TAM suppressive phenotype. We also show PI3Kγ signaling is essential to monocyte anti-apoptotic signaling, and inhibition of PI3Kγ can enhance anti-tumor immune responses in preclinical models of PCa. Specifically, inhibition of PI3Kγ alone is sufficient to enhance anti-tumor immune responses in the less aggressive B6CaP PCa model, but insufficient in the more aggressive RM-1 PCa model. However, treatment of RM-1 tumors with Eganelisib produces improved tumor control when combined with anti-PD-1 therapy, relative to Eganelisib or anti-PD1 as a monotherapy.
Conclusions: Altogether, these data highlight the integral role of PI3Kγ signaling in TAMs and the potential for therapeutic targeting with Eganelisib to sensitize PCa to ICB.

#0171 Chemotherapeutic agent, cisplatin, influences the proportion of TREM2 (+) M2 macrophages in the TME of LUAD.

Y. Cha, M. Park, Y. Chang;
Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Triggering receptor expressed on myeloid cells (TREM2) serves as an immune signaling hub that senses and interacts with a wide range of ligands arising from damaged tissues in pathologic conditions. Despite TREM2's diverse role in casting immune suppressive environment, the effects of chemotherapy on tumor microenvironment (TME), TREM2 and their interactions are not well established. In this study, we aimed to investigate the characteristics of TREM2 (+) Mφ within the lung TME (Tu), focusing on the impact of chemotherapy on the immune dynamics of lung adenocarcinoma (LUAD).
Method: Changes in the number and distribution of Mφ subclusters in normal appearing lung tissue (NL) and Tu were examined using open-source single cell RNA sequencing (scRNA-seq) datasets and immunofluorescent staining of lung cancer-induced Kras-G12D mouse tissue. Clinical measures affecting the expression of TREM2 were explored using the TCGA-LUAD and -LUSC datasets, and the effects of anticancer drugs and the apoptotic cells on Mφ were observed by differentiating THP1 cells into M0, M1, and M2.
Results: scRNA-seq analysis on LUAD datasets showed that Mφ were the second most abundant cell population that constitutes the lung TME, and the proportion of Mφ in the Tu decreases compared to NL. Among the Mφ subclusters in Tu, a subcluster which specifically increased in Tu shows enrichment of apoptotic cell clearance gene sets, including TREM2. In lung cancer induced Kras-G12D mouse, compared to NL the Tu has an increase in M2 proportion, showing the characteristics of interstitial Mφ in addition with overexpression of TREM2 and enrichment of monocyte chemotaxis gene set enrichment. Among TCGA-LUAD, the high TMB group has low TREM2 expression, and the proportion of TREM2 (+) M2 in the Tu decreases in cisplatin-treated Kras-G12D mouse Tu, suggesting the expression of TREM2 in M2 is suppressed by either cisplatin treatment itself or active immunity in Tu. Additionally, we are going to observe the effect on TREM2 expression by adding cisplatin treated A549-GFP cells or cisplatin alone, to the THP-1 cells that were differentiated into M0, M1, or M2 state.
Conclusion: In addition to changes in the lung immune environment due to the tumor, anticancer treatment changes in the characteristics of M2 in TME, in terms of decrease in TREM2 (+) Mφ fraction. Considering that TREM2 plays a central inhibitory role in the tumor immune environment, the effect of anticancer chemotherapeutic agents should be considered in the development TREM2 targeting agents.

#0172 Targeting the poliovirus receptor to activate T cells and induce myeloid-derived suppressor cells to differentiate to M1-like macrophages via the IFNγ-pSTAT1-IRF8 axis in cancer therapy.

M. Feng, S. Tan, Q. Ma, B. Zhang, Y. Chen, Q. Li, Y. Wang;
West China Hospital of Sichuan University, Chengdu City, China

T cell immunoglobulin and ITIM domain (TIGIT) is one of the most important immune checkpoints expressed on lymphocytes, and poliovirus receptor (PVR, also CD155) serves as the most crucial ligand for TIGIT, harboring an important function in cancer cells and influencing the tumor microenvironment (TME). While it's well-established that TIGIT blockade could reverse immunosuppression, the question of whether direct inhibition of PVR yields comparable results remains to be fully elucidated. In this study, we generated a mouse gene Pvr knock out (KO) Lewis lung cancer (LLC) cell line and found that the Pvr-KO tumors tended to develop a pro-inflammatory TME, as reflected by a downregulation of monocytic-myeloid derived suppressor cells (M-MDSCs) and an upregulation of CD8+ central memory T cells. Through bulk RNA-seq and multi-cytokines measurement, we quantified the transcription and protein levels of immunostimulatory cytokines and chemokines and found they were significantly upregulated in Pvr-KO TME, including GM-CSF, IFN-γ, TNF-α, IL-2/4/6/10, CCLs (including CCL2/3/4/5) and CXCLs (including CXCL1/2/5). We further employed single-cell RNA sequencing (scRNA-seq) on 20,026 intra-tumoral CD45+ immune cells. Using a conserved MDSCs gene set and the 'AddModuleScore' function of Seurat package, we identified the clusters of MDSCs and found the differentiation ability of M-MDSCs in Pvr-KO TME was enhanced. Through pseudo-temporal ordering, we found the M-MDSCs in the Pvr-KO TME have a trend to differentiate towards M1-like macrophages, which could play an essential positive role in anti-tumor immunity. We further focused on the scRNA-seq of T cell subsets and found the enhanced function of cytotoxic CD8+ T cells, leading to increased production of IFN-γ. In the intercellular communications analysis, a significant upregulation of the IFNG-IFNR signal between T cells: MDSCs in the Pvr-KO group was observed. Moreover, we found that Irf8, a key factor in myeloid cell differentiation, was significantly upregulated in the M-MDSCs of Pvr-KO tumor. We then employed CUT & Tag sequencing and confirmed that IFN-γ induces phosphate Stat1, which then binds on the promoter of Irf8. These findings suggest that the IFN-γ-Stat1-Irf8 axis plays a crucial role in MDSCs differentiation and may be a potential target for therapeutic intervention in cancer. Next, an anti-PVR nanobody was synthesized and its efficacy was evaluated in the context of LLC and 4T1 tumor grafts. When in combination with anti-PD-1 therapy, anti-PVR exhibited a remarkable capacity to reduce tumor size in both tumor models with no notable indications of toxicity observed. Our findings provide new insights into the role of PVR in modulating the TME and offer potential strategies for enhancing the effectiveness of immunotherapy.

#0173 Studying the interaction between macrophages and solid stress in novel models of the tumor immune microenvironment.

A. Burchett, S. Siri, H. Chen, S. Howard, M. Datta;
University of Notre Dame, Notre Dame, IN

Glioblastoma (GBM) is one of the most aggressive forms of cancer, resisting conventional and immune-based therapies and typically killing patients within two years of diagnosis. This is largely due to the immunosuppressive GBM tumor microenvironment (TME), mediated in large part by tumor-resident macrophages. Macrophages' role as immune regulators, as well as their sheer quantity in brain tumors, makes them attractive therapeutic targets. The GBM TME also features mechanical abnormalities. As a tumor grows, it expands into the surrounding brain, generating compressive solid stress. Macrophages can contribute to up to half of tumor mass and are known to respond to mechanical cues, allowing them to both contribute to and respond to solid stress, but this relationship has not yet been explored experimentally. To isolate the contribution of macrophages on solid stress, we incorporated RAW264.7 murine macrophages into agarose gels with varying stiffnesses. Over time, spheroids form as the cells proliferate. Because cells cannot alter agarose, cell aggregates must generate stress as they grow and displace the surrounding gel matrix. The resulting agarose-embedded spheroids were stained with calcein AM to observe spheroid viability and morphology. Using confocal microscopy and image processing, we obtained the final spheroid geometry and imported it into COMSOL to model the solid stress resulting from spheroid formation. Our initial experiments show that macrophages have distinct growth patterns dependent on the stiffness of their surrounding gel. At larger sizes, the spheroids adopt an ellipsoid shape and generate a distinct stress field compared to spheroidal shapes. To stimulate the solid stress that macrophages experience within a growing mass, we applied a custom weight to macrophages grown on a porous membrane. This applies 0.15 kPa of compressive solid stress, corresponding to the stress measured in murine glioma models. After 24 hours of compression, macrophages upregulate expression of both nitric oxide synthase and arginase-1, canonical M1 and M2 markers, respectively. This indicates that compression causes a more complex phenotype than can be described by the traditional M1/M2 axis, something that has been observed in tumor-associated macrophages. We also found an apparent difference in the fluorescence lifetime of compressed and uncompressed macrophages, indicating that compression alters macrophage metabolism. Both the spheroid and compression culture models are unique in the context of macrophages. This work will elucidate key pathways involved in myeloid "immunomechanics" and inform strategies to target the innate immune system in cancers such as GBM, as well as other immunological diseases.

#0174 Cholesterol efflux protein ABCA1 skews macrophages towards an anti-tumor phenotype and consequently impacts breast cancer progression.

S. V. Bendre[1], N. Krawczynska[1], S. Bhogale[1], E. Weisser[1], S. Han[1], B. Hajyousif[1], A. Singh[1], R. K C[1], Y. Wang[1], C. P. Schane[1], A. T. Nelczyk[1], A. DasGupta[1], H. E. V. Gamage[1], K. T. VanBortle[1], E. Tajkhorshid[1], S. Sinha[2], W. Cho[3], E. R. Nelson[1];

[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Georgia Institue of Technology, Atlanta, GA, [3]University of Illinois Chicago, Chicago, IL

With a lifetime risk of approximately 1 in 8, breast cancer maintains in its position as the most prevalent form of cancer and ranks second in terms of cancer-related fatalities in women. The primary cause of mortality is often attributed to the recurrence of metastatic breast cancer. While immune therapy shows some effectiveness, many patients do not exhibit meaningful responses, likely due to immune-suppressive factors present within the tumor microenvironment. These factors include myeloid cells such as Macrophages(MΦ), therefore, there is a strong need to devise strategies to shift (MΦ) from a pro-tumor to an anti-tumor phenotype. Our previous research has uncovered the susceptibility of MΦs to disruptions in cholesterol metabolic balance. Considering these findings, coupled with epidemiological evidence linking elevated plasma cholesterol to unfavorable prognosis, the impact of cholesterol homeostasis in tumor associated MΦs on breast cancer becomes evident. An in-depth computational screen helped us identify ABCA1—a cholesterol efflux protein with elevated mRNA expression associated with increased survival. Beyond cholesterol efflux, ABCA1 also facilitates the movement of cholesterol from the inner membrane layer to the outer layer. Previous work has shown that cholesterol within the inner membrane layer can directly interact with and activate various receptors on the membrane's surface, initiating downstream signaling events. Consequently, the activities of ABCA1 in cholesterol efflux and translocation likely hold substantial regulatory implications. Underscoring the clinical significance of ABCA1 are our findings that heightened ABCA1 expression within breast tumors correlates with augmented levels of cytotoxic T cells, T cell effector enzymes (Prf-1 and Gzmb), and improved survival rates. Crucially, our in vitro investigations indicate that ABCA1 modulates multiple functions of MΦs to adopt an anti-cancer phenotype, encompassing: (1) the ability to infiltrate tumor spheroids, (2) angiogenesis, (3) efferocytosis—an immune-suppressive phagocytic process devoid of antigen presentation, and (4) the expansion, migration, and activity of cytotoxic T cells. ABCA1 transports cholesterol from macrophages to a lipid poor ApoA1 protein and facilitates the formation of nascent HDL via reverse cholesterol transport. We leveraged this mechanism to therapeutically target ABCA1 using ApoA1 mimetics 5A and 4F. Our data so far indicates that these ApoA1 phenocopy ABCA1 overexpression in MΦs. Together, our data provides compelling evidence for the involvement of ABCA1 in the pathophysiology of breast tumors. The anticipated outcomes of this research will establish the basis for the future utilization of ABCA1 and its downstream effects for therapeutic purposes.

#0175 Tumor-associated monocytes and neutrophils: Targets for immunotherapy?.

K. Jung;
Seoul National University, Seoul, Korea, Republic of

Cancer is the leading cause of deaths worldwide. However, current anti-VEGF therapies for solid cancers provide limited survival benefit as tumors rapidly develop resistance to these agents.We have uncovered an immunosuppressive role for non-classical Ly6C^{low} monocytes that mediates resistance to anti-VEGFR2 treatment. We found that the chemokine CX3CL1 was upregulated in both human and murine tumors following the VEGF signaling blockade, resulting in recruitment of CX3CR1^{+} Ly6C^{low} monocytes into the tumor. We also found that treatment with VEGF-A reduced expression of CX3CL1 in endothelial cells. Intravital microscopy revealed that CX3CR1 is critical for Ly6C^{low} monocyte transmigration across the endothelium in tumors. Moreover, Ly6C^{low} monocytes recruit Ly6G^{+} neutrophils via CXCL5 and produce IL-10, which inhibits adaptive immunity. Preventing Ly6C^{low}monocyte or Ly6G^{+} neutrophil infiltration into tumors enhanced inhibition of tumor growth with anti-VEGFR2 therapy. Furthermore, we developed a gene therapy using a nanoparticle formulated with a siRNA against CX3CL1, which reduced Ly6C^{low} monocyte recruitment and improved outcome of anti-VEGFR2 therapy.Taken together, we identified immunosuppressive non-classical Ly6C^{low} monocytes as key players in tumor resistance to anti-angiogenic therapy in cancers. We also revealed molecular mechanisms underlying anti-angiogenic treatment resistance, suggesting potential immunomodulatory strategies to enhance the long-term clinical outcome of anti-VEGF therapies, proven by state-of-the-art *in vivo* imaging modalities.

#0176 Stearic acid induces pro-inflammatory macrophage response important for lung cancer development.

A. Roy[1], M. Davis[1], S. Weinberg[2], A. Mallisetty[1], A. Hulbert[1], F. D. Weinberg[1];
[1]University of Illinois Chicago, Chicago, IL, [2]Northwestern University, Chicago, IL

Background Survival is improved with early detection and treatment initiation in patients with lung cancer (LC) emphasizing the importance of tumor initiation and biomarker development in individuals at high risk for developing LC and those with early-stage LC. Recent studies suggest that immunologic and metabolic changes within the microenvironment are pivotal for tumor formation. We recently demonstrated that in patients with resectable, early-stage LC, elevated levels of stearic acid (SA), a long chain fatty acid, and macrophage inflammatory protein 1β (MIP-1β/CCL4) were predictive of tumor affected lung lobes. Therefore, we hypothesize that SA promotes LC initiation through the activation of macrophages (MΦ) and production of proinflammatory cytokines like CCL4.
Methods and Results: We performed untargeted metabolomics utilizing LC-MS from the plasma of patients with various stages of LC and found elevated levels of SA in patients with early-stage LC. To further study the mechanistic role of SA in tumorigenesis, cell lines including immortalized lung epithelial , LC cells, and immune (MΦ and T) cells were treated with SA. We found that physiological concentrations of SA did not affect cellular viability. However, in MΦ, SA induced expression of inflammatory (IL6, iNOS), and immunomodulatory (Arg1, CD206) genes suggesting a role for SA in promoting a pro-tumorigenic immunologic state. Additionally, analysis of the secretome from SA stimulated MΦ using single cell proteomic analysis (Isolight, Bruker Cellular Analysis, Inc), indicated a significant enrichment of polyfunctional MΦs with enhanced secretion of enriched effector and stimulatory cytokines. Furthermore, conditioned media derived from SA stimulated MΦ led to increased proliferation, as well as anchorage independent growth, of BEAS2B immortalized lung epithelial cells.
Conclusion: Our data demonstrates plasma levels of SA are increased in early-stage compared to late-stage patients with LC. This observation corresponds to our prior data demonstrating enrichment of SA in the tumor affected lobes of patients with early-stage LC. Recent studies demonstrating the induction of inflammatory responses through MΦ activation in obese patients by circulating SA in blood corroborates our observations as well. Our data suggests that the SA effect on MΦ, is critical in LC initiation not only increasing proliferation but also induction of neoplastic transformation of immortalized lung epithelial cells. Furthermore, our data indicates that blood plasma levels of SA, a fatty acid understudied in tumor biology, could also be exploited as a potential biomarker for LC development in individuals at high-risk for LC development as well as those patients with early-stage disease.

#0177 Targeting murine or human KLRG1 exerts potent anti-tumor efficacy involving both CD8T cells and NK cells.

T. A. Jones[1], S. Sinicrope[1], K. Yasuda[2], J. Pinkas[2], T. F. Gajewski[1];
[1]University of Chicago, Chicago, IL, [2]Pyxis Oncology, Boston, MA

Clinical response to anti-PD-1 immunotherapy is correlated with patients who have a T cell-inflamed tumor microenvironment. Some patients with immune cell infiltration fail to respond, and some patients experiencing an initial clinical response develop acquired resistance. It is likely that additional immune-regulatory pathways need to be targeted to expand the efficacy of immunotherapies. To identify a broader array of therapeutic relevant immunotherapy molecules in T cell-inflamed tumors, our lab utilized gene expression profiling to characterize tumor antigen-specific dysfunctional $CD8^+$ T cells in the tumor microenvironment. One molecule that was found to be overexpressed on these $CD8^+$ T cells was C-type lectin inhibitory receptor, KLRG1. KLRG1 is an ITIM domain-containing receptor mostly explored on NK cells, and the known ligands are N- and E- cadherins which are broadly expressed in solid cancers. Analysis of single cell RNA-Seq data from tumor biopsies of melanoma patients classified as responders or non-responders to anti-PD-1 therapy revealed significantly higher expression of KLRG1 expression on tumor-infiltrating T cell subsets in non-responders, suggesting a possible salvage immune suppressive role. To determine the potential functional relevance of KLRG1 on tumor control, we generated KLRG1 knockout (KO) mice, then implanted tumors and assessed tumor growth rate *in vivo*. KLRG1 KO mice showed markedly slowed B16 melanoma tumor growth compared to WT mice, arguing it is a critical negative regulator of anti-tumor immunity. Both antigen-specific $CD8^+$ T cells and NK cells were expanded in these tumors, and depletion of $CD8^+$ T cells or NK cells eliminated this tumor control. Genetic deletion of N-cadherin from B16 cells also resulted in slowed tumor growth, suggesting that tumor cells are providing the functionally relevant ligand.
To assess the degree of inhibitory function of human KLRG1, we generated a humanized KLRG1 knock-in mouse model. We confirmed that human KLRG1 can biochemically interact with murine cadherins. Knock-in mice with the humanized KLRG1 protein had significantly increased tumor growth compared to both WT and KLRG1 KO mice, indicating a stronger immunosuppressive effect of human KLRG1 compared to murine KLRG1. An antagonistic antibody blocking interaction of human KLRG1 with its ligands was generated, which potentiated human T cell activation *in vitro*. Administration of anti-human KLRG1 Ab to tumor-bearing humanized KLRG1 mice led to markedly reduced tumor growth.
In summary, our data support KLRG1 as a functionally critical negative regulator of the anti-tumor immune response and that blocking KLRG1-cadherin interactions has potential as a therapeutic candidate.

#0178 Adipose tissue upregulates expression of RANKL in B-cell acute lymphoblastic leukemia through prostaglandin E2 signaling.

M. Cohen[1], J. Tan[1], T. Kuk[1], B. Nadeak[1], I. Ahn[1], X. Yang[1], E. Orgel[2], S. D. Mittelman[1];
[1]UCLA Mattel Childrens Hospital, Los Angeles, CA, [2]Children's Hospital Los Angeles, Los Angeles, CA

Obesity increases the risk of developing cancer and worsens treatment outcome. Our lab has shown that adipose tissue contributes to B-cell acute lymphoblastic leukemia (B-ALL) resistance to chemotherapy both *in vitro* and *in vivo*. However, the mechanisms by which adipose tissue causes ALL cell resistance are complex and not completely understood. We therefore implanted obese mice (n=3) with syngeneic BCR/ABL B-ALL cells and performed single-cell RNA sequencing (scRNAseq) of ALL collected from epididymal adipose tissue vs. bone marrow. Our data uncovered a strong adipose microenvironment effect on the ALL transcriptome, identifying 577 differentially expressed genes using a $\log_2$ fold threshold of 0.25 and Bonferroni corrected p-values <0.05. Notably, we found that ALL cells in adipose tissue upregulate expression of *Tnfsf11*, the gene that encodes receptor activator of nuclear factor kappa beta ligand (RANKL). 93% of ALL cells in adipose tissue express RANKL compared to 33% in marrow, along with a $\log_2$ fold expression increase of 2.12 ($p<1x10^{-100}$, Wilcoxon test). Because ALL expression of RANKL has been linked to bone resorption and CNS invasion, both of which have increased incidence in obese patients, we elected to explore this further. *Ex vivo* culture with human visceral adipose tissue validated ALL cell RANKL upregulation, demonstrating a 1.63 and 17.5-fold increase in gene expression after 48 hours in BV173 and RS4;11 B-ALL cell lines, respectively (n=4-6, both $p<0.01$, paired t test). Soluble RANKL was not detected in media from ALL cells cultured alone, detectable in media conditioned by human adipose tissue (0.018 pM), but increased in media from adipose-ALL cocultures (RS4;11: 0.065 pM, BV173: 0.317 pM, n=1). One potential candidate signal to stimulate ALL cell RANKL expression is the inflammatory mediator prostaglandin E2 (PGE2), which is known to be released by adipose tissue. Physiological concentrations of PGE2 (200 ng/mL) caused a similar increase in ALL cell RANKL gene expression as adipose tissue in both cell lines (n=6). PGE2 treatment also caused a mild resistance of ALL cells to daunorubicin chemotherapy *in vitro*, increasing the EC_{50} from 27±4 to 53±12 nM in RS4;11 (n=6, $p<0.05$), and from 39±11 to 62±19 nM in BV173 (n=6, $p=0.06$). Adipose tissue induction of RANKL expression was partially blocked by the addition of PGE2 receptor EP2 and EP4 blockers. Taken together, our results suggest that PGE2 produced by the adipose microenvironment activates ALL cell RANKL expression, which could potentially contribute to CNS invasion, bone breakdown, and chemoresistance.

#0179 Identification of a novel crosstalk between MDSC and NKregs in immunotherapy resistant triple negative breast cancer.

M. Das[1], S. Henry[2], S. Singh[1], C. D. Santos[2], R. Chakrabarti[1];
[1]University of Miami Sylvester Centr.-I, Miami, FL, [2]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

Triple-negative breast cancer (TNBC) is one of the most aggressive forms of breast cancer and lacks standard treatment options. Although immunotherapy shows some response in these patients along with chemotherapy, heterogeneity of tumor cells and immune cells results in significant low response to immunotherapy treatment. Based on single cell sequencing which enables identity of heterogenous population at single cell level and functional studies involving preclinical mouse models, our laboratory recently identified distinct $CD56^{bright}SOCS3^{high}CD11b^{-}CD27^{-}$ immature NK cells subpopulations, with diminished cytotoxic granzyme signatures that promote TNBC tumor progression. However, the precise characterization and functionality of these rogue tumor promoting NK cells remains unclear in clinical samples. Here, we aimed to illustrate mechanistic insight of these novel immature NK subpopulation in context of immunotherapy resistant TNBC patient samples. The scRNA seq analysis of TNBC patient samples identified four specific subclusters of NK cells in TNBC. We further found that NK2 and NK3 subclusters are $CD56^{dim}$ $Granzyme^{high}$ cytotoxic NK cells and the other two subclusters (NK0 and NK1) are $CD56^{bright}$ immature NKs. Interestingly, the NK0 and NK1 subcluster specifically exhibit distinctive characteristics and functions. Notably, $CD56^{bright}$ immature NK1 cells, identified as tissue-resident NK cells, were engaged in direct communication with myeloid-derived suppressor cells (MDSCs). The $CD56^{bright}$ NK0 possesses moderate to low SOCS3 expression and moderate to high granzyme expression with elevated early NK activation markers and inhibitory receptor expressions, suggesting its regulatory property (NKregs). scRNA seq and flow cytometry analysis showed higher NKregs and immunosuppressive MDSC population, specifically with high monocytic-MDSCs (mMDSCs) in non-responder TNBC (to adjuvant combinational treatment of chemo and immunotherapy) patient samples rather than responder patients' tissue. Based on *in silico* analysis, we further found a potential crosstalk between these mMDSC & NKreg within the tumors of non-responsiveness of TNBC patients. Overall, our studies show a connection of MDSCs and NKregs in TNBC patients, who do not respond to immunotherapy, highlighting a possible mechanism for immunotherapy resistance, which could be targeted in near future for better treatment options in TNBC.

#0180 *LINC00261* is functionally linked to tumor DNA mutational burden and tumor immune microenvironment composition in lung adenocarcinoma.

J. Castillo, T. Xue, M. Norwood, S. Joseph, A. L. Epstein, W. D. Wallace, A. W. Kim, C. N. Marconett;
University of Southern California, Los Angeles, CA

Immunotherapy has emerged as a breakthrough in the improvement of survival outcomes for lung adenocarcinoma (LUAD), however effective response requires the combination of blocking inhibitory signals on the tumor surface and antigen presentation to the tumor surface for proper immune recognition. Several commercially available and robust methods exist for identification of tumors displaying immune-inhibitory surface receptors, such as PD-L1, however it is currently difficult to predict effectiveness of antigen presentation on the cell surface. To address this, we utilized clinical and next-generation sequencing data from The Cancer Genome Atlas (TCGA) to identify gene signatures that are correlated to tumor mutational burden (TMB) within cancers of epithelial origins as a surrogate for neoantigen signatures. We identified *LINC00261* as a top gene correlated to TMB, whose expression activates DNA damage response pathways *in vitro* along with resistance to cisplatin. *LINC00261* expression was also significantly correlated to MHC class I and II genes involved in endogenous neoantigen presentation expression within the TCGA-LUAD cohort. This relationship was confirmed *in vitro* through ectopic reintroduction of *LINC00261* for key MHC class II presentation genes. Interferon gamma-induced MHC gene activation *in vitro* was also able to induce endogenous expression of *LINC00261*. Staining of primary human lung cancer sections suggested that loss of *LINC00261* is associated with an immunosuppressive tumor microenvironment. Taken together, our results suggest there is a mechanistic relationship in the silencing of *LINC00261* in LUAD and compromised DNA repair, accumulation of mutations, and reduced antitumor immune response.

#0182 Cyclooxygenase-2 blockade is crucial to restore natural killer cell activity before anti-CTLA-4 therapy against high-grade serous ovarian cancer.

F. Gomez-Valenzuela[1], I. Wichmann[2], F. Suarez[1], S. Kato[1], E. Ossandon[1], M. Hermoso[3], E. Fernandez[4], M. A. Cuello[1];
[1]Pontificia Universidad Catolica de Chile, Santiago, Chile, [2]Stanford University School of Medicine, Santiago, CA, [3]University of Chile, Santiago, Chile, [4]Fundacion para el Progreso de la Medicina (CONICET), Facultad de Ciencias Exactas, Fisicas y Naturales, Universidad Nacional de Cordoba, Cordoba, Cordoba, Argentina

Objective: Here our goal was to evaluate the impact of the immunosuppressive enzyme cyclooxygenase-2 (COX-2) expression on the immune effector capacity against high-grade serous ovarian cancer (HGSOC) tumor cells through bioinformatic tools and *in vitro* validation.
Methods: We performed an integrated bioinformatics analysis from transcriptomic data based on RNAseq (TCGA-OV, n=368; Australian cohort AOCS, n=80) and RNA microarrays (GSE26193, n=62; GSE30161, n=45). We estimated the proportion and characteristics of immune cells employing Gene Set Variation Analysis (GSVA), MIXTURE and Ecotyper cell deconvolution algorithms. Survival curves and Cox-regression models were built up according to known risk factors and immune scores predicted by *in-silico* analysis. Afterward, we validated these results using flow cytometry and cytotoxicity assays on circulating NK cells collected from advanced HGSOC patients treated at our institution (n=5). After three days of incubation, isolated NK cell cultures were stimulated with three pulses of a selective COX-2 inhibitor (celecoxib) or MOCK, daily. An anti-CTLA-4 monoclonal antibody (ipilimumab) or MOCK was added at the third pulse. Two ovarian cancer cell lines (SKOV3 and HeyA8) were treated similarly. Next, NK cells were co-cultured with SKOV3 or HeyA8 and cytotoxicity on these cells was examined using lactate dehydrogenase (LDH) cell viability assay.
Results: Transcriptomic data evidenced a non-linear relationship between COX-2 gene, *PTGS2*, and *CTLA4* in advanced stages of HGSOC. Hence, *PTGS2*/*CTLA4* ratio allows us to investigate how COX-2 influences changes in the immune profile of these patients. Based on bioinformatics, a high *PTGS2*/*CTLA4* ratio determines particularly dysfunctional NK cell states, along with the reduction of NK gene score associated with infiltration, cytotoxicity, and survival in HGSOC. Additionally, selective COX-2 blockade improves NK cell cytotoxicity against HGSOC cell lines independently of the CTLA-4 signaling. In fact, ipilimumab effect was almost absent in those cases with high COX2 activity. Interestingly, previous treatment with celecoxib on NK cells mainly explains the difference in cytotoxicity ($p= 0.0253$, two-way ANOVA test with Tukey's multiple comparisons).
Conclusions: This work represents the first evidence of the influence of COX-2 on NK cell function as a crucial factor for the efficacy of anti-CTLA-4 therapy in HGSOC patients who exhibited high tumoral levels of CTLA-4. HGSOC patients present dysfunctional circulating NK cells preferentially due to the strong CO-2 expression. Last, we emphasize the modulation of chronic inflammation to direct an immune pattern with greater antitumor capacity in HGSOC. (Funding: Fondecyt 1201083 and FONDAP 152220002 [MAC], CONICYT/Doctorado Nacional 2019-Folio 21190421 [FGV], CONICYT FONDAP 15130011 [MAC, IW]).

#0183 A novel bispecific antibody macrophage engager (BiME) designed for the treatment of solid tumors.

D. Sun, H. Jiang, Y. Geng, Y. Wu, R. Gao, Y. Lu, Q. Qiu, Y. Hu, Y. Liu, X. Guo, X. Niu, H. Lu;
Elpiscience Biopharma, Shanghai, China

Background: Anti-CD3-based bispecific T cell engagers (BiTE) showed limited clinical efficacy in solid tumors and caused significant cytokine storm. Similar to BiTE where T cells are activated by CD3 antibody, we constructed a novel bi-specific macrophage engager (BiME) platform where macrophage is activated by anti-SIRPa that is directed to a particular tumor via the targeting of the tumor-associated antigen (TAA), resulting in phagocytosis of the tumor cells. This BiME does not lead to cytokine storm and is particularly applicable for the treatment of solid tumors whose microenvironment contains plenty of macrophages. Tumor-associated macrophages are major component of immune cells in the tumor micro-environment (TME) that express an array of effector molecules leading to the inhibition of anti-tumor immune responses. Signal regulatory protein α (SIRPα) is a myeloid-lineage inhibitory receptor that restricts phagocytosis through engagement of its ligand CD47 expressed on tumors and normal tissues. Compared to anti-CD47 therapeutics, targeting myeloid-restricted SIRPα provides a differential pharmacokinetic, safety, and efficacy profile. Here, we report the construction of a SIRPα antagonist-based bispecific macrophage engager (BiME) platform, a potent tumor-killing bi-specific antibody platform.
Methods: We have generated a panel of single domain antibody (sdAb), scFv or Fab antibodies targeting different TAAs and SIRPa. We constructed BiME antibodies using different orientations, ratios, and IgG isotypes of anti-TAA arm and anti-SIRPα arm. These bispecific antibodies were evaluated for homologue binding, and CD47-SIRPα blocking properties by ELISA and FACS. In vitro function activity was determined by phagocytosis assay using human monocyte derived macrophage and mouse bone marrow derived macrophage. In vivo anti-tumor efficacy was tested in a syngeneic tumor model with hSIRPα knock-in mice. The pharmacokinetic (PK) and safety profile were assessed in hSIRPα knock-in mice or cynomolgus monkeys.
Results: Through Elpiscience proprietary BiME platform, we have generated a panel of TAA/SIRPα bispecific antibodies with TAA being Claudin18.2, EGFR, PDL1 and DLL-3. The BiME treatment demonstrated strong anti-tumor efficacy in multiple mouse syngeneic tumor models. Mechanistically, both myeloid and T cells were activated and contributed to antitumor activity of BiME bispecific antibody. the BiME bispecific antibodies were well tolerated in non-human primates (NHPs) and there is no hematotoxicity or cytokine release syndrome (CRS) observed after treatment of BiME antibodies.
Conclusions: These findings provide novel mechanistic insights into how myeloid and T cells can be uniquely modulated by the bispecific macrophage engagers (BiMEs) and demonstrate the potential and advantage of BiME in future clinical development for solid tumor treatment as compared to BiTE approach.

#0184 M1-like macrophage infiltration, CD8+ T cell activation, and increased cancer cell apoptosis in immunologically cold Lewis lung carcinoma treated with tumor-trophic Salmonella Typhimurium expressing anticancer proteins in immunocompetent C57BL/6 mice.

Q. He, L. R. Brncick, B. Gong, J. L. Flowers;
Purdue University, West Lafayette, IN

Immunotherapy has revolutionized cancer treatment with immune checkpoint inhibitors (ICIs) and genetically engineered T-Cells expressing chimeric antigen receptors (CARs). CAR-T treatment of hematologic malignancies has achieved outstanding patient response rate. CAR-T cell therapy, however, is thwarted in solid tumor treatment due to two major factors: the immune-suppressive tumor microenvironment that inhibits T-cell infiltration and T-cell function. In addition, T-cell dysfunction also renders ICIs ineffective in solid tumor treatment. This research aims to activate proinflammatory anticancer immune responses in immunologically cold solid tumors using the genetically engineered Salmonella typhimurium VNP20009 strains that express anticancer proteins. Previously, we have shown that the Salmonella Typhimurium VNP20009 strains expressing recombinant methioninase (rMETase) and/or Tumor Necrosis Factor (TNFα) caused rapid tumor destruction of cold Lewis Lung Carcinoma (LLC) grown on immunocompetent C57BL/6 mice. In this investigation, several mechanisms of this tumor tropic anti-cancer bacteria were studied including the innate and adaptive immune system responses and cancer cell apoptosis. In a pilot study, we selected eight tumor tissues treated with several different bacteria strains and performed histological analysis to observe the effectiveness of each. We found that in the tumor tissues treated with VNP20009_rMETase_TNFα, there was infiltration and activation of CD8+ T cells coupled with reduced amounts of T regulatory cells, as well as an increased ratio of M1-like to M2-like macrophages. We also observed increased tumor apoptosis associated with an elevated detection of an apoptosis biomarker and a suppressed amount of the Ki67 tumor growth signal. These findings indicate that VNP20009_rMETase_TNFα anticancer bacteria can disrupt the tumor microenvironment in the cold LLC tumors and active innate and adaptive anti-cancer immune responses in immunocompetent mice. Further, we are investigating additional cold solid mouse tumor models to validate our findings and how this can apply to bacteria-based immunotherapy.

#0186 Tumor exosome-macrophage interactions: The role of tumor-associated glycans and scavenger receptor class A.

F. Jousheghany[1], E. S. Blitz[1], S. V. Jenkins[1], S. R. Post[1], V. Raj[2], R. A. Kore[1], A. Jamshidi-Parsian[1], R. J. Griffin[1], T. J. Kelly[1], B. Monzavi-Karbassi[1];
[1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]University of Arkansas at Pine Bluff, Pine Bluff, AR

Introduction: Increased macrophage infiltration and polarization towards a breast tumor-supportive phenotype have been linked to therapy resistance, immune suppression, and poor patient prognosis. Despite their importance, the specific interactions that drive tumor-associated macrophage (TAM) polarization remain poorly understood. The class A scavenger receptor (SR-A) is a pattern-recognition receptor expressed by macrophages, and the accumulation of SR-A-expressing TAMs has been correlated with poor patient outcomes. Our preliminary data show that SR-A binds to tumor-associated glycans (TAGs) on the surface of breast cancer cells. However, how macrophages bind tumor cell ligands in the tumor microenvironment (TME) is not clear. Tumor-derived exosomes (TDEs) are secreted extracellular vesicles that resemble the tumor cell membrane, carrying cargo that may mediate an immune response within the TME. In this study, we investigated whether TDE glycans represent tumor cell-surface TAGs and whether TDEs interact with macrophages through SR-A.
Methods: TDEs were isolated from the murine breast cancer cell line (E0771) by ultracentrifugation of the cell culture medium and then sized and counted using nanoparticle tracking analysis and electron microscopy. The glycans present on the tumor cell surface and TDEs were characterized using plant lectins in flow cytometry and sandwich ELISAs. The isolated TDEs were then fluorescently labeled, and their binding to the murine macrophage cell line Raw 264.7 was assayed by flow cytometry and fluorescence microscopy.
Results: SR-A binds strongly to breast cancer cell lines, and a significant portion of the binding depends on the presence of cell surface N-linked glycans. Lectins reactive with sialylated and fucosylated terminal structures showed differential binding to tumor cells and TDEs. We observed that the glycan profiles of E0771 cells and exosomes isolated from E0771 cultures were similar. Our results indicate that TDEs interact with Raw 264.7 cells, and the interaction is mediated by SR-A.
Conclusions: TDEs released in the TME can potentially interact with TAMs through SR-A. The glycan profile of TDEs is representative of host cells and may contribute to SR-A-mediated interaction with TAMs.

#0187 Macrophage instead of leukemia cell expressed PD-L1 drives T cell exhaustion and immune evasion of BCRABL1 chronic myeloid leukemia.

X. Lu, H. Fang, X. Fang, A. Matsunaga, K. Liu, J. Cortes, J. K. Cowell, T. Hu;
Medical College of Georgia, Augusta, GA

BCR-ABL1 fusion gene is the hall marker of chronic myeloid leukemia (CML). Currently, the immune microenvironment of BCRABL1 CML remains largely unexplored. Our recent investigation in a transgenic mouse model of BCRABL1 CML revealed a continuous increase in CD11b+Ly6C^{int} PMN-MDSC with the progression of the disease. Concurrently, there was an increase in CD11b+Ly6C^{high} M-MDSC and F4/80+ macrophages. However, The levels of CD4+ T cells, CD8+ T cells, CD19+ B cells, and CD49b+ NK cells, which are essential for tumor-killing significantly decreased. This immune phenotype was consistently observed in both primary leukemia induction and following serial transplantation of cells from primary leukemic mice. Intriguingly, only recipient mice subjected to sublethal irradiation developed the disease, while mice with intact immune system remained disease-free, which underscores the vital role of the immune system in the development of CML. The predominant presence of CD11b+Ly6C^{int} PMN-MDSC in the peripheral blood, bone marrow and spleen implies these cells may be at least partially consisted of CML leukemia cells. To examine the hypothesis, qRT-PCR and immunofluorescence (IF) staining were conducted. In both assays, Ly6G+ cells from BCRABL1 mice coexpressed the BCRABL1 oncogene. Furthermore, when co-cultured with CD4 T cells, the division of T cells was significantly inhibited, implying immune suppression by the Ly6G+ PMN-MDSCs and/or CML leukemia cells. In addition, the immuosuppressive pathway genes including Arg1, Hif1a, Enptd1, TGFβ were significantly upregulated. To investigate the possible role of the PD1/PDL1 axis in the BCRABL1 model, flow cytometry analysis was conducted. Unexpectedly, PDL1 was barely expressed in CML leukemia cells, whereas the expression of PDL1 in M-MDSCs and macrophages significantly increased, accompanied by remarkable upregulation of PD1 expression on CD4 T cells and CD8 T cells during leukemia progression. In other words, PDL1 expression on macrophages, rather than leukemia cells, was found to induce T cell exhaustion. For translational purpose, mice transplanted with the primary CML leukemia cells were treated with chemotherapy drugs ponatinib alone or in combination with the anti-PD1 antibody. Compared with the chemotherapy alone group, the mice in the combinational therapy group exhibited rapid remission and better disease control. Most importantly, the disease relapse occurred at a slower rate after treatment discontinuation, suggesting the value of combinational therapy in achieving treatment free remission. In summary, our study not only revealed the dynamic changes of immune microenvironment in the BCRABL1 CML mouse model, but also revealed the different mechanisms underlying immune evasion of BCR-ABL1 CML leukemia cells, which sheds light on a combinational treatment for achieving the treatment free remission of CML.

#0188 Investigating the macrophage and microglia response to ferroptosis in glioblastoma.

S. Y. Chih[1], M. Tang[1], S. Kim[1], T. Lu[1], R. Harter[2], J. Thorpe[1], W. Li[1];
[1]Penn State College of Medicine, Hershey, PA, [2]Penn State University, University Park, PA

Glioblastoma (GBM) is the most common malignant primary brain tumor. The median survival is less than two years. The mesenchymal (MES) subtype of GBM is particularly associated with treatment resistance, poor prognosis, and enriched infiltration of immune cells, including tumor-associated microglia and/or macrophages (TAMs). Despite promising results in preclinical studies, clinical trials targeting TAMs have been unsuccessful. Necrosis is a hallmark of GBM and correlates with unfavorable outcomes, but how necrosis results in poor prognosis is not well understood. We previously showed that neutrophils promote tumor necrosis and GBM progression by inducing ferroptosis, a form of regulated cell death due to iron-dependent lipid peroxidation. Understanding the effects of GBM ferroptosis on TAMs can provide further insights into how tumor necrosis ultimately leads to poor prognosis in GBM. We developed an orthotopic xenograft GBM mouse model harboring a constitutively active mutant of the Hippo pathway transcriptional coactivator with PDZ-binding motif (TAZ). Tumors of this model displayed MES characteristics and developed necrosis to an extent similar to patients with GBM. Using this model, confocal microscopy and flow cytometry studies revealed the presence of immune cells positive for markers of neutrophils and macrophages/microglia in the necrotic region of the tumor. Although we have yet to establish an in vitro model to study these cells, we found that conditioned media (CM) derived from ferroptotic GBM cells induced more macrophage differentiation from bone marrow cells when compared to live GBM CM. This led us to hypothesize that ferroptosis in GBM is immunogenic and orchestrates the immune response mounted by TAMs. We conducted an RNA sequencing (RNA-seq) study of bone marrow cells cultured in ferroptotic CM. Compared to live CM, ferroptotic CM upregulated several pro-inflammatory cytokine signaling pathways. We validated the mRNA expression levels of the identified cytokines by RT-qPCR. RNA-seq analysis also revealed the activation of phagosome formation pathway. Through phagocytosis assay, we showed that macrophages preferentially engulfed ferroptotic GBM cells over necrotic or live cells. To identify transcriptional changes in GBM cells undergoing ferroptosis, we carried out an RNA-seq study showing that ferroptotic GBM cells also upregulated several pro-inflammatory cytokine signaling pathways, which were validated by RT-qPCR. We also found that ferroptotic GBM cells released ATP extracellularly, where such release temporally coincided with the increase in pro-inflammatory cytokines. Our results suggest that ferroptosis in GBM is immunogenic and induces a pro-inflammatory response in macrophages/microglia. We are conducting further in vitro and in vivo studies to better understand how these macrophages/microglia modulate other immune cells and play a role in GBM progression.

TUMOR BIOLOGY: Membrane, Biophysical, and EMT Aspects of Motility/Metastasis
Poster Session

#0192 Orchestrating CDC42 turnover to regulate membrane protrusion and tumor metastasis.
S.-Y. Hsieh;
Chang Gung Memorial Hospital - Taoyuan Branch, Taoyuan, Taiwan

F-actin cytoskeleton remodeling is essential for cell migration, organ development, and immune responses. CDC42, a factor orchestrating F-actin remodeling for membrane dynamics, switches between its inactive GDP- and active GTP-bound forms. However, the biological and clinical significance of the mechanisms regulating CDC42 protein turnover remains unclear. Here we show that KLHL23-mediated CDC42·GTP polyubiquitylation for degradation and RhoGDI-mediated CDC42·GDP sequestration away from the plasma membrane co-inactivate CDC42 in a spatiotemporal context, influencing membrane dynamics and homeostasis during migration. Via a functional genomic screen, we identified KLHL23 as a suppressor of tumor invasion. Decreased KLHL23 level was associated with tumor metastasis and poor clinical outcomes in patients with liver and pancreas cancers. KLHL23 functions as the E3 ligase responsible for CDC42 polyubiquitylation and degradation. KLHL23 shares with RhoGDI the switch II region of CDC42 for binding, enhancing selective targeting of CDC42·GTP and CDC42·GDP, respectively. KLHL23 depletion in cells leads to F-actin and membrane over-protrusion, as well as epithelial-mesenchymal transition and tumor metastasis. Fluorescence resonance energy transfer assays reveal that the KLHL23—CDC42·GTP interaction plays a primary role in quenching CDC42 activity during membrane protrusion-retraction, while the RhoGDI—CDC42·GDP interaction occurs lately. Our results demonstrate the spatiotemporal interplay between RhoGDI and KLHL23 in regulating CDC42 turnover for membrane dynamics. As KLHL23/RhoGDI—CDC42 axis dysregulation causes tumor metastasis, our findings open avenues for exploring novel therapeutics.

#0193 Melanoma cytoskeletal dynamics, membrane remodeling, and motility are regulated by TRIM9.

Kimberly Lukasik, Jordan Brooks, Sam Redinbo, James Bear, Stephanie Gupton

University of North Carolina at Chapel Hill, Chapel Hill, NC

Cell shape change and motility are essential in metastasis and involve remodeling of the actin cytoskeleton, cell adhesions, and plasma membrane. How these cytoskeletal and membrane remodeling are regulated and coordinated remains largely unknown. We previously identified TRIM9 as a regulator of actin dynamics and exocytosis in developing neurons. Deletion of murine *Trim9* impairs neuronal migration, netrin-induced axon turning, and axonal and dendritic branching, and increased exocytosis and filopodial stability. In addition, we have shown TRIM9 alters dynamics of the actin polymerase VASP at filopodia tips via non-degrative mono-ubiquitination. TRIM9 is expressed in other motile cells, but the non-neuronal role of TRIM9 remains unknown. TRIM9 was identified as a possible prognostic biomarker in melanoma and high expression correlates with low patient survival. Melanomas undergo phenotype switching, where three distinct phenotypes exist that are associated with differences in gene expression. The three phenotypes consist of a melanocytic proliferative state, a neural crest-like invasive state, an intermediate state. Single cell RNAseq (scRNASeq) data from patient-derived melanoma indicate TRIM9 is highly expressed in the proliferative melanocytic state, which correlates with poor prognosis. *We hypothesize that TRIM9 coordinates actin dynamics, adhesion, and exocytosis in melanoma.* We show that TRIM9 protein is enriched in several human melanoma lines. Here we examine the role of TRIM9 in regulation of focal adhesions, exocytosis, migration, and invasion in two of these lines. Genetic loss of TRIM9 increased random migration velocity but reduced directional persistence. Interestingly, we find that TRIM9 plays a role in promoting bleb-like morphology and inhibits the ability to durotax on shallow gradients on soft substrate. Fluorescence recovery after photobleaching (FRAP), Total internal reflection fluorescence microscopy (TIRF), and widefield microscopy revealed that loss of TRIM9 results in increased focal adhesions, cell size, and altered dynamics of focal adhesion proteins VASP, zyxin, and paxillin dynamics. In addition, TRIM9 knockout cells exhibit reduced filopodial length and density and altered filopodial localization of VASP. In-gel zymography indicates that TRIM9 knockout cells also display an increased degradative capacity. Current studies are investigating how loss of TRIM9 alters parameters of cell contractility, lamellipodia, invadopodia, and exocytosis to define the role of TRIM9 in melanoma motility. Together these findings suggest TRIM9 reduces adhesion and migration, increases proliferation and blebbing and may be an important regulator of phenotype switching in melanoma.

#0194 Single-cell mechanical analysis reveals that astrocytes and glioblastoma cells have similar viscoelastic properties.

J. Najera, K. Onwudiwe, L. Holen, A. A. Burchett, D. Rodriguez, M. Zarodniuk, S. Siri, M. Datta;
University of Notre Dame, Notre Dame, IN

Despite recent advances in treatment, the survival rate of glioblastoma (GBM) patients remains low due to the cancer's resistance to current treatment modalities. Solid tumors like GBM are known to harbor physical abnormalities at the tissue and cell level. An understanding of GBM cell mechanics may therefore lead to the identification of novel disease mechanisms, biomarkers, and therapeutic strategies to improve treatment outcomes. In this study, we aimed to compare the mechanics of human GBM cells and their normal counterpart, immortalized human astrocytes (IHAs). To accomplish this, we used a parallel-plate flow system to expose single cells to physiological fluid shear stress and recorded the resulting deformation using a camera-coupled microscope. We then utilized digital image correlation analysis to create strain-time profiles of individual cells and fit the profiles with a three-parameter generalized Maxwell model to characterize their nuclear and cytoplasmic viscoelastic properties. We also used fluorescence microscopy and atomic force microscopy to quantify actin density and alignment and adhesion energy in both cell types, respectively. Our results showed that, contrary to extracranial cancer cells, the viscoelastic properties of GBM cells are similar to their normal counterpart. This may explain why metastasis in GBM patients is rare and conventional treatment options are unsuccessful. We also found that actin organization and localization and adhesion energy is different between GBM cells and IHAs. Thus, future research which links the genetic and microenvironmental factors that modulate these unique mechanical features may lead to the development of rational and novel clinical strategies against GBM.

#0196 *In vitro* modeling of pediatric solid tumor lung metastases.

M. Zylka[1], C. Hafemeister[1], L. Watzke[2], U. Mann[2], D. Surdez[3], E. Sweet-Cordero[4], B. Liegl-Atzwanger[5], M. Dettmer[6], M. Farlik[2], F. Halbritter[1], M. Metzelder[2], H. Kovar[1], B. Radic-Sarikas[1];

[1]St. Anna Children's Cancer Research Institute, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria, [3]Universitatsklinik Balgrist, Balgrist, Switzerland, [4]University of California, San Francisco, San Francisco, CA, [5]Medical University Graz, Graz, Austria, [6]Klinikum Stuttgart, Stuttgart, Germany

Metastasis remains the main cause of death in pediatric cancer patients with the lung being one of the most common affected organs. Our inability to cure these patients is largely due to insufficient knowledge about tumor and metastatic niche plasticity, while existing models are not fully effective in mirroring the response seen in clinical setting. Our goal is to overcome these limitations by establishing *in vitro* lung metastasis models using tumor/lung organoid co-cultures to study lung infiltration of pediatric solid tumors. We successfully established patient-derived lung organoids from pediatric lung tissue and characterized them according to the presence and the localization of the respective lung epithelial cell types. Co-culture conditions of lung organoids with PDX-derived Ewing sarcoma and osteosarcoma cells were optimized and models established, while the establishment of models for other pediatric solid tumor entities is ongoing. We have observed infiltration of the lung organoids by tumor cells, and our preliminary findings suggest distinct patterns of infiltration among different tumor entities. Furthermore, we have performed single-cell RNA sequencing analysis on these co-cultures in comparison to the parental lung organoids and tumor cells, aiming to uncover the specific signaling pathways activated in the lung metastatic niche in response to tumor cell invasion. Additionally, experiments using conditioned medium suggest that the lung organoid secretome is sufficient to induce homing of osteosarcoma and Ewing sarcoma cells to the organoids, with the CXCL12/CXCR4 signaling axis as a prime candidate driver. To ascertain the extent to which our *in vitro* model recapitulates the *in vivo* lung metastatic niche, we performed spatial transcriptomics (using VISIUM/10X Genomics) on formalin-fixed paraffin-embedded (FFPE) tissue blocks of paired primary tumors and lung metastasis samples for Ewing sarcoma and osteosarcoma. Comprehensive data analysis is currently ongoing, which will instruct a stepwise incorporation of additional factors into our modular organoid co-culture model, resulting in a better representation of the lung metastatic niche. Further, the analysis of patient-derived material will elucidate the spatial organization of solid tumor lung metastases and contribute to the identification of signaling pathways implicated in lung infiltration. In conclusion, our study not only unravels the complexities of pediatric solid tumor metastasis, but also lays the foundation for exploring the anti-metastatic potential of pathway-specific compounds targeting tumor/lung interactions using the established *in vitro* lung metastasis models. This study is supported by grant 35353-B of the Austrian Science Fund.

#0197 The GPR52-MCAM axis as a novel regulatory mechanism of breast cancer cell clustering and metastatic potential.

S. Z. Hanif[1], C. C. Au[1], I. Torregroza[1], B. Bhinder[1], L. Dow[1], O. Elemento[1], T. Evans[1], **K. A. Brown**[2];
[1]Weill Cornell Medicine, New York, NY, [2]University of Kansas Medical Center, Lawrence, KS

Background: Breast cancer is the most diagnosed cancer worldwide and is the second leading cause of cancer death among women in the United States. Despite breakthroughs in targeted therapies for breast cancer, the 5-year survival rate for women with metastatic breast cancer is 30%. There is a strong rationale to explore the therapeutic potential of G-protein coupled receptors (GPCRs), which comprise the largest class of proteins successfully targeted by FDA-approved drugs. Importantly, at least one-third of GPCRs are “orphans” and remain largely uncharacterized. One of these orphan GPCRs is GPR52. To date, there is no literature on the role of GPR52 in any cancer type, but we find from publicly available clinical data that low mRNA expression of GPR52 in breast tumors correlates with reduced overall survival (hazard ratio=0.67 [0.53-0.83], logrank P= 0.00035) and that GPR52 mRNA levels tend to be lower in tumor metastases compared to primary tumor (n>80, p=4.45e-17). Therefore, we hypothesize that loss of GPR52 may support breast cancer metastasis.
Results: We used CRISPR-Cas9 to knockout (KO) GPR52 in triple-negative breast cancer cell lines MDA-MB-468 and MDA-MB-231, and in the non-cancerous breast epithelial cell line MCF10A, and confirmed the generation of frameshift mutations by Sanger sequencing. Interestingly, we observed that GPR52 KO cells clustered together *in vitro* in 2D and hypothesized that this characteristic may allow GPR52 KO breast cancer cells to increase their metastatic potential. We conducted invasion assays though Matrigel and found that GPR52 KO cells were more likely to invade as sheets or clusters. To determine the *in vivo* impact of GPR52 loss, we injected MDA-MB-468 GPR52 KO cells in zebrafish (*Danio rerio*) two days post-fertilization and observed that GPR52 loss led to increased metastatic foci and total cancer surface area thirty hours post-injection ($n \geq 12$, $p<0.05$). We determined from RNA-sequencing (n=3, p<.0001) and confirmed with western blotting that the melanoma cell adhesion molecule (MCAM) is upregulated in the MCF10A and MDA-MB-468 GPR52 KO cells. Increased mRNA expression of MCAM has been associated with reduced overall survival in breast cancer patients (hazard ratio=1.33 [1.05-1.62], logrank P= 0.02)
Conclusion: Knockout of GPR52 from breast cancer cells promotes increased cell clustering *in vitro* and metastasis in zebrafish. These data support the investigation of GPR52 as a biomarker of cancer aggression and a potential therapeutic target for breast cancer patients whose tumors express GPR52.

#0198 Selective targeting of endothelial mTORC1 reduces transendothelial fatty acid delivery to improve anti-tumor immunity and suppress metastatic outgrowth.

D. N. Edwards[1], S. Wang[1], W. Song[1], L. C. Kim[2], Y. Hwang[1], J. Chen[1];
[1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University, Nashville, TN

Tumor metastasis requires sufficient nutrients to support outgrowth of disseminated tumor cells. Cancer cells utilize fatty acids as a key source of energy and biomass, but these nutrients impair the cytotoxic activities of T cells, serving to support metastatic progression. Blood is a rich source of fatty acids, but the vascular endothelium serves as a barrier to limit access to the surrounding tumor tissue. However, it is unclear how long-chain fatty acid delivery to early metastatic tumors is regulated. Here, we report that endothelial mTORC1 promotes transport of fatty acids into developing metastatic tumors, leading to reduced anti-tumor immune responses and improved outgrowth. Using a murine model of metastatic outgrowth in the lung, tumor burden was significantly reduced upon targeted deletion of Raptor, an essential component of the mTORC1 complex, in endothelial cells ($Rptor^{ECKO}$). We employed a multifaceted approach using metabolomics, transcriptomics, and molecular assays to identify a Raptor/mTORC1-mediated mechanism of transendothelial fatty acid transport via RAB and CLSTN1 cargo trafficking. In vivo uptake of a fluorescent palmitic acid analog in tumor cells and T cells was reduced in $Rptor^{ECKO}$ lung metastatic tumors, which correlated with improved markers of cytotoxicity. Combination of low-dose RAD001/everolimus, which selectively inhibits mTORC1 in endothelial cells, with anti-PD1 reduces metastatic disease and impairs long-chain fatty acid uptake in T cells, corresponding to improved anti-tumor immunity. These findings describe a novel mechanism of transendothelial fatty acid transportation during metastatic outgrowth, supporting future development of therapeutic strategies to target endothelial mTORC1 activity.

#0199 Fluid shear stress enhances metastatic potential and rapidly alters metabolism of circulating tumor cells.

D. L. Moose, **A. N. Pope**, M. Dykstra, E. B. Taylor, P. Breheny, M. D. Henry;
Carver College of Medicine, University of Iowa, Iowa City, IA

Background and Purpose: Circulating tumor cells (CTCs) are exposed to mechanical and biochemical stresses including fluid shear stress (FSS) and oxidative distress. Recently we have shown that viable CTCs actively resist destruction when exposed to FSS by a mechano-adaptive mechanism that depends on RhoA-actomyosin activity [PMID: 32187555]. Since the RhoA-actomyosin axis is implicated in other cellular behaviors that might contribute to metastasis; herein, we explored the hypothesis that exposure to FSS alters the biology of viable CTCs to promote metastatic colonization.
Methodology: To determine if exposure to FSS alters metastatic potential, we exposed PC-3 prostate and MDA-MB-231 breast cancer cells to FSS prior to injection into the tail-vein of NCG mice. We then monitored metastatic colonization by weekly bioluminescence imaging. Further, we examined if FSS exposure altered the invasive potential of PC-3 and MDA-MB-231 cells, as well as their ability to survive/proliferate under anchorage-independent conditions. We conducted GC/LC-MS metabolomic profiling and measured lactate production following FSS exposure. To investigate oxidative burden on FSS exposed cells, we used dihydroethidium to measure general ROS production and a lipid peroxide sensor.
Results: We found that FSS exposure shortens the time for metastatic colonization for both cell lines. We found that FSS exposure leads to approximately two-fold increase in invasion through collagen matrix, which, for PC-3 cells, is RhoA dependent. Moreover, FSS exposure resulted in increased proliferation (~25%) under anchorage independent conditions in both cell lines. Metabolomic profiling revealed that FSS exposure resulted increased glycolysis, reduced entry into the TCA cycle, and increased lactate levels. We blocked glycolysis in PC-3 and MDA-MB-231 cells with 2-deoxyglucose and found that this increased the fraction of cells destroyed by FSS ~20-30%. We also investigated redox stress and found that compared to cells held in suspension, those exposed to FSS demonstrate lower ROS burden. Interestingly, cells exposed to FSS exhibit lower levels of lipid peroxides in a manner that depends on RhoA.
Conclusion: Our findings demonstrate that brief pulses of FSS exposure can enhance metastatic potential, increase invasive and anchorage-independent proliferative capacity and rapidly alter metabolism. The phenotypic changes driven by exposure to FSS depend in part on RhoA activation but may also reflect other mechanisms by which cancer cells sense and respond to FSS. The rapid changes in metabolism may act to reduce oxidative distress while CTCs are in suspension. In summary, our data indicate that FSS exposure in the circulation not only represents a physical force that CTCs must overcome to survive, but it also provides instructive cues that may enhance the metastatic behavior of some CTCs.

#0200 OA inhibits the development of breast cancer through K1108 acetylation of Zeb1.

M. Guo, Y. Wang, Y. Shi, S. Yang;
Nankai University, Tianjin, China

Background: Olive oil has long been considered a healthier edible oil, rich in 75% oleic acid (OA) as its main component. OA is a monounsaturated fatty acid, and recent studies have shown that it is no longer limited to protecting cardiovascular and cerebrovascular systems, but can also reduce the risk of cancer. However, there is limited research on the specific mechanism. After fatty acid is ingested into the body, through fatty acids β-oxidation produces acetyl-CoA, which is a donor of protein acetylation. EMT is an important process to regulate tumor metastasis, and Zeb1 is one of the important EMT transcription factors. Therefore, we explored whether OA could inhibit the progress of breast cancer by affecting the acetylation modification of Zeb1.
Methods: Western blotting, CCK8 assay, and Transwell were used to test the impact of gradient doses of OA on breast cancer cells. Immunoprecipitation and Immunoprecipitation mass spectrum were used to determine the acetylation modification sites of Zeb1. Coimmunoprecipitation, IF, and pull-down were used to test and verify the acetylase and deacetylase of Zeb1. Knockdown endogenous *ZEB1* and then reconstructed stable cell lines of Zeb1 wild-type ($Zeb1^{K1108WT}$), acetylation activated ($Zeb1^{K1108Q}$), and inactivated mutants ($Zeb1^{K1108R}$) by lentivirus. Detection of Zeb1 acetylation in patient tissue samples and mouse models under OA treatment using Zeb1-specific acetylation-modified antibodies.
Results: OA inhibits the proliferation and migration of breast cancer cells in a concentration gradient-dependent manner, and inhibits the expression of Zeb1, N Cadherin, and upregulates E Cadherin. Among numerous fatty acids, only OA can promote the acetylation of Zeb1 by adjusting the ratio of acetyl-CoA and NAD+/NADH. K1108 is a biologically functional acetylation site of Zeb1, $Zeb1^{K1108R}$ exerts the cancer promoting function of Zeb1, while $Zeb1^{K1108Q}$ does not. OA can promote acetylation of $Zeb1^{K1108WT}$, but cannot promote acetylation of $Zeb1^{K1108R}$.
Conclusions: OA inhibits the development of breast cancer through K1108 acetylation of Zeb1. These results suggest that breast cancer may be ameliorated through dietary interventions.

#0201 Morphological changes to the vulvar squamous carcinoma cell line, A431, resulting from clobetasol-induced upregulation of vimentin.

J. E. Lewis, K. Haering, K. Yokoyama;
SUNY Geneseo, Geneseo, NY

Vimentin is recognized as an important marker in the epithelial-mesenchymal transition (EMT) of several cancer cell types. The overexpression of vimentin appears to coincide with increased tumor growth, migration, and poor prognosis. The vulvar cancer cell line, A431, is of squamous cell origin and displays hallmarks of a squamous cell including expression of cytokeratins 8 and 18 as well as E- and P-cadherin. We have found that treatment of A431 cells with the glucocorticoid, clobetasol, results in upregulation of vimentin which is accompanied by change to a more mesenchymal-like morphology. Despite this change in morphology, the cells continue to express cytokeratins 8 and 18. This suggests that the vimentin has a greater impact on cell morphology than does cytokeratins 8 and 18. However, we previously reported that the analogous glucocorticoid, dexamethasone, also downregulates E- and P-cadherin in these cells which may account for the observed change in morphology. Here we examine more closely the impact of vimentin on cellular morphology in the clobetasol treated A431 cells by both immunofluorescence microscopy and Raman imaging.

#0202 Spry1 targeting enhances E-cadherin expression in cutaneous melanoma.

Barbara Montico[1], Giorgio Giurato[2], Roberto Guerrieri[1], Annamaria Salvati[2], Francesca Colizzi[1], Lorena Baboci[1], Luca Sigalotti[1], Alessia Covre[3], Michele Maio[3], Agostino Steffan[1], Tuula Anneli Nyman[4], Alessandro Weisz[2], Maurizio Mongiat[1], Eva Andreuzzi[5], Elisabetta Fratta[1]

[1]Centro di Riferimento Oncologico IRCCS, Aviano, Italy,[2]'Scuola Medica Salernitana', University of Salerno, Salerno, Italy,[3]Center for Immuno-Oncology, University Hospital of Siena, Siena, Italy,[4]Institute of Clinical Medicine, University of Oslo, Oslo, Norway,[5]Institute for Maternal and Child Health IRCCS Burlo Garofolo, Trieste, Italy

Background: Cutaneous melanoma (CM) is a very aggressive malignancy that still represents the deadliest form of skin cancer. About 50% of CM harbors the activating $BRAF^{V600}$ mutation which exerts most of the oncogenic effects through the MAPK signaling pathway. In the last years, a number of MAPK modulators have been identified, including Spry1. In this context, we have recently reported that Spry1 knockdown ($Spry1^{KO}$) reduced the expression of several markers of epithelial-mesenchymal transition (EMT) both *in vitro* and *in vivo*. Loss of E-cadherin is a hallmark of EMT in CM, and the presence of aberrant E-cadherin expression in CM is usually associated with a significantly worse overall survival. Based on these premises, in this study we wondered to explore whether Spry1 influences EMT through the modulation of E-cadherin expression.

Material and Methods: SPRY1 gene was knocked-out using the CRISPR strategy in BRAF wild-type (wt) and in BRAF-mutant CM cell lines. By using *in vitro* and *in vivo* models, the effects of $Spry1^{KO}$ on E-cadherin expression and localization was investigated through RNA-sequencing (RNA-seq), quantitative real-time PCR, western blot, and immunofluorescence analyses. To gain insight into Spry1 interactome, immunoprecipitation coupled to mass spectrometry (IP-MS) was performed.

Results and Discussion: E-cadherin mRNA and protein levels were significantly increased both *in vitro* and *in vivo* in $Spry1^{KO}$ clones. In addition, immunofluorescence analysis revealed a sustained redistribution of E-cadherin to the plasma membrane following Spry1 loss, thus confirming that Spry1 plays a role in EMT in CM. E-cadherin requires p120-catenin (p120) to maintain cell adhesion and functional adherens junctions. Indeed, p120 dysregulation results in the rapid turnover of E-cadherin complexes. Intriguingly, IP-MS analyses identified several Spry1 protein partners, including p120. Although a number of functional studies are still ongoing, preliminary western blot analysis of cytosolic and mitochondrial proteins indicated that Spry1 and p120 were mostly located in mitochondria.

Conclusion: Spry1 reduced E-cadherin expression *in vitro* and *in vivo*. Starting from preliminary data, we hypothesized that Spry1-p120 interaction might influence E-cadherin distribution over the plasma membrane.

#0203 Promotion of metastasis of ERBB2-positive breast cancer by mesenchymal stem cells via exosomes-mediated activation of ERBB2/ERBB3→PI3K/Akt singaling pathway.

Y. Wu[1], L. Chen[1], Y. Cao[2], Q. Huang[1], H. Niu[1], X. Lai[1], M. Zhao[1], H. Yan[1], H. Lyu[3], B. Liu[4], S. Zhang[1], **S. Wang**[1];
[1]Affiliated Dongfang Hospital of School of Medicine (the 900th Hospital), Xiamen University, Fuzhou, China, [2]Fuzhou General Clinical Medical School, Fujian Medical University, Fuzhou, China, [3]Stanley S. Scott Cancer Center, School of Medicine, Louisiana State University (LSU) Health Sciences Center, New Orleans, LA, [4]Stanley S. Scott Cancer Center, School of Medicine, Louisiana State University (LSU) Health Sciences Center, Fuzhou, LA

Elevated expression of ERBB3 receptor correlates with increased distant metastasis of breast cancers with amplification and/or overexpression of *ERBB2* (*HER2/neu*), which the underlying molecular mechanism remains unclear. In recent years, cumulative studies have demonstrated that mesenchymal stem cells (MSCs), one of the important cellular components in tumor microenvironment, play important roles in multiple hallmarks of cancer including invasion and metastasis. However, its role in metastasis of ERBB2-positive breast cancer as well as the precise mechanisms are largely unrevealed. In our current study, we found that co-culture with MSCs or treatment with exosomes derived from MSCs can significantly promote the epithelial-mesenchymal transition (EMT), migration and invasion of ERBB2-positive breast cancer cells. MSCs exhibited significantly higher expression of NRG-1, a known ligand of ERBB3, as compared with ERBB2-positive breast cancer cells. The presence of NRG-1 in exosomes derived from MSCs was also evidenced. Mechanistically, co-culture with MSCs or treatment with exosomes derived from MSCs induced upregulation of ZEB1 and Slug via activation of downstream PI3K/Akt singaling to promote EMT of ERBB2-positive breast cancer cells. In addition, the expression of MMP2 was also upregulated by treatment with MSCs-derived exosomes, which enhanced the migration and invasion of ERBB2-positive breast cancer cells simultaneously. Interestingly, our study further demonstrated that treatment with MSCs-derived exosomes could significantly downregulate the expression of PTEN, the key negative regulator of PI3K/Akt singaling, via transferring three PTEN-targeting miRNAs (miR-21-5p, miR-23a-3p, and miR-148a-3p). Taken together, we presented here that MSCs may, on the one hand, directly activate the ERBB2/ERBB3→PI3K/Akt signaling pathway in ERBB2-positive breast cancer cells through the expression and secretion of NRG-1 via exosomes. Meanwhile, miR-21-5p, miR-23a-3p, and miR-148a-3p targeted delivery by exosomes specifically downregulated the expression of PETN, thus reliefs the negative regulation of PI3K/Akt signaling in ERBB2-positive breast cancer cells. These effects of MSCs act in concert to promote the metastasis of ERBB2-positive breast cancer. Our study lays a theoretical foundation and preliminary experimental basis for the development of novel combined therapies for patient with ERBB2-positive breast cancer through co-targeting MSC-derived NRG-1 and miR-21-5p, miR23a-3p, miR148a-3p/PTEN axis in tumor microenvironment in the future.

#0204 Quantitative evaluation of biomarkers for TGF-β-induced epithelial-mesenchymal transition in biochemical, cellular, and 3D spheroid model systems.

A. W. Wood[1], E. Heimsath[2];
[1]Cell Signaling Technology, Inc., Danvers, MA, [2]Agilent Technologies, Inc., Winooski, VT

Epithelial-mesenchymal transition (EMT) is a cellular differentiation process whereby epithelial cells lose epithelial features and acquire mesenchymal, fibroblast-like properties, leading to reduced cell-cell contacts and increased motility. EMT is a fundamental biological process required for normal embryonic development, but may be co-opted by malignant epithelial tumors to facilitate metastatic spread. A known driver of EMT is the TGF-β superfamily of growth factor ligands, which elicit receptor-mediated responses in cells, primarily via TGF-β/SMAD signaling pathways. In these pathways, receptor-mediated SMAD (R-SMAD) proteins serve as the primary downstream effector molecules, the activities of which are regulated through receptor-mediated phosphorylation. The magnitude and duration of ligand-induced receptor activation influences the level of SMAD phosphorylation, which in turn influences the magnitude of the downstream cellular response(s). In this study, we describe high-throughput methods to quantitatively evaluate the biochemical and cellular responses to TGF-β/SMAD pathway activation in a cellular model of TGF-β-induced EMT. Effects of pathway activation are examined at different levels of biological complexity (biochemical, cellular, and multicellular), using 2D and 3D (spheroid) models. Collectively, these approaches enable a comprehensive evaluation of TGF-β/SMAD pathway activation that is amenable to high-throughput analysis platforms.

#0205 Adaptive membrane trafficking activated by epithelial-to-mesenchymal transition drives lung adenocarcinoma progression.

O. E. Obaleye, K. L. Fulp, G.-Y. Xiao;
University of Kentucky, Lexington, KY

Cancer cells can become metastatic and develop resistance to targeted therapies through epithelial-to-mesenchymal transition (EMT), which is regulated by epigenetic factors. Our ultimate objective is to understand the molecular mechanisms behind EMT-driven cancer progression and identify potential targets for preventing cancer metastasis. Recently, we made groundbreaking discoveries indicating that EMT can modify membrane trafficking machinery to coordinate cancer cell invasion and immunosuppression in the tumor microenvironment (TME) of lung adenocarcinoma (LUAD). To dissect the “adaptive” membrane trafficking program, we initiated a CRISPRi *in vivo* screen to assess more than 2000 trafficking-related genes in syngeneic mouse LUAD models for their requirements for tumorigenesis both with and without immune selective pressure. We identified a panel of membrane trafficking regulators that specifically “dropped out” in immunocompetent mice, suggesting their essential roles in the immunosuppressive TME. Of particular interest is REEP2. REEPs are an evolutionarily conserved protein family that is critical to the endoplasmic reticulum (ER) function and potentially regulates secretory trafficking. We discovered that REEP2 is specifically linked to poor prognosis in LUAD patients and is highly correlated with a z-normalized, 16-gene EMT score (P = 1.32e-27) that was previously reported. Our previous studies demonstrated that the EMT activator, ZEB1, accelerates membrane trafficking dynamics by silencing a microRNA network that targets multiple membrane trafficking components. Analysis of REEP2 3’-untranslated regions (3’-UTRs) identified predicted binding sites for several microRNAs, which are silenced by ZEB1. Thus, we hypothesize that ZEB1 coordinates a microRNA network to activate REEP2-driven ER trafficking. We show that REEP2 depletion significantly reduces the invasion of cancer cells but does not affect their migration and proliferation. These findings suggest that REEP2 plays a significant role in extracellular matrix (ECM) modification to enhance the invasion of metastatic cells, conferring a vulnerability in EMT-driven LUAD metastasis.

#0206 Intratumoral accumulation of CD38 enhances immune evasion and metastasis in models of breast cancer with EMT plasticity.

T. Visal;
The University of Texas MD Anderson Cancer Center, Houston, TX

Background- Triple-negative breast cancer (TNBC) is challenging to treat due to fewer clinically detectable targets and its propensity to metastasize. Epithelial to mesenchymal transition (EMT) is a key feature of the metastatic cascade. Recent data highlights the enhanced metastatic potential of hybrid epithelial-mesenchymal (EM) phenotypes from partial activation of EMT. However, mechanistic insights and targetable vulnerabilities within hybrid EM remain elusive. We identified that hybrid EM tumors are enriched in CD38, an immunesuppressive molecule associated with worse clinical outcomes in liquid malignancies. Hence, we sought to investigate role of CD38 in hybrid EM-driven metastasis. We hypothesize that hybrid EM tumors drive metastasis via intratumoral accumulation of CD38, promoting an immunosuppressive tumor microenvironment (TME).
Methods- Reverse Phase Protein Array, cell migration/invasion assays, flowcytometry and immunohistochemistry were used to evaluate phenotype, immune cell populations and molecular mechanisms upon CD38 knockdown (KD) and overexpression (OE) *in vivo*.
Results- CD38 KD weakened the process of EMT and reduced cell migration and invasion. Tumors lacking CD38 showed increased infiltration of CD8 T cells and M1-like (anti-tumor) macrophages coupled with a decrease in immunosuppressive regulatory T cells (T_{regs}) and M2-like (pro-tumor) macrophages. In contrast, cancer cells with CD38 OE maintained a hybrid phenotype through co-expression of epithelial and mesenchymal markers and also showed significant increase in cell migration and invasion. Tumors arising from CD38 OE cells displayed a significant increase in T_{regs}. Most strikingly, hybrid EM tumors that no longer express CD38 show reduction in lung metastases and circulating tumor cell colonies. Taken together, these findings suggest that CD38 is important for the metastatic and immune evasive potential of hybrid EM breast cancers.
Conclusion- Our data exposes CD38 as a survival strategy in hybrid EM tumors to suppress immune cells and sustain metastasis with strong implications in other carcinomas which have hybrid EM properties.

#0207 Tumor suppressive role of NKX2-1 in advanced thyroid cancer progression.

Y.-T. Shirai, S. Kimura;
National Institutes of Health, National Cancer Institute, Bethesda, MD

NKX2-1 is a homeodomain transcription factor, known as a master regulator of thyroid development. NKX2-1 is also crucial for lung epithelium differentiation, and the involvement of NKX2-1 in lung carcinogenesis and cancer progression has been intensely investigated. However, the role of NKX2-1 in thyroid cancer progression remains elusive. The Cancer Genome Atlas (TCGA) dataset analysis demonstrated that papillary thyroid cancer (PTC) patients with low *NKX2-1* mRNA expression had significantly poorer prognosis than those with a combination of intermediate and high mRNA expression of *NKX2-1.* Lentivirus-transduced tetracycline (Tet)-inducible system was used to achieve NKX2-1 overexpression in advanced follicular thyroid cancer (FTC) cell lines, FTC-238 and WRO, and an anaplastic thyroid cancer (ATC) cell line 8305C, in which NKX2-1 expression is barely/not detected. All these thyroid cancer cell lines showed significant suppression of cell proliferation with NKX2-1 overexpression. In addition, NKX2-1 overexpression inhibited migration of FTC-238 cells. The levels of mRNA and protein expression of mesenchymal markers, matrix metalloproteinase-2 (MMP-2) and fibronectin, were decreased by NKX2-1 overexpression in FTC-238 cells, suggesting a possibility that NKX2-1 partially inhibits epithelial-mesenchymal transition (EMT). SNAIL and SLUG are essential EMT transcription factors involved in metastasis in cancer progression. *NKX2-1* mRNA expression was significantly lower in high *SNAI1* (encoding SNAIL) expressing PTC in TCGA database. Indeed, suppression of SNAIL protein expression was found upon overexpression of NKX2-1 in FTC-238 cells which naturally express high level of SNAIL. These findings suggest that NKX2-1 may inhibit the migration of advanced thyroid cancer cells through SNAIL-induced EMT. Similarly, suppression of SLUG protein expression by overexpression of NKX2-1 was observed in WRO and 8305C cells which express high level of SLUG protein. Whether NKX2-1 overexpression inhibits migration and invasion of WRO and 8305C cells through SLUG-induced EMT is currently under examination. The Tet-inducible NKX2-1 expressing thyroid cancer cells will be used for *in vivo* evaluation of their metastatic ability using an immunocompromised mouse model. The findings so far suggest that NKX2-1 exerts a tumor suppressive activity in advanced thyroid cancers through suppression of cell proliferation, and cell migration presumably via suppression of EMT transcription factors.

#0208 FGFR2 splice variant as a cell fate adjudicator determines clinical outcomes in non-small cell lung cancer.

H. Yu[1], M. Horie[2], A. Lindberg[1], M. Backman[1], N. Hekmati[1], J. Mattsson[1], N. Miyashita[3], H. Brunnstrom[4], F. Ponten[1], A. Saito[5], C. Strell[1], P. Micke[1]; [1]Uppsala University, Uppsala, Sweden, [2]Kanazawa University, Kanazawa, Japan, [3]Duke University School of Medicine, Durham, NC, [4]Lund University, Lund, Sweden, [5]The University of Tokyo, Tokyo, Japan

The splice variants specific protein expression in tumor cells presents promising targets for cancer therapy. The concept is supported by the recent introduction of the splice variant-specific antibody against FGFR2 IIIb (FGFR2b) in gastric cancer. Indeed, signaling of the two FGFR2 splice variants FGFR2b and FGFR2 IIIc (FGFR2c), whose expression is mutually exclusive on a cellular level, is mediated by different ligands and distinct downstream responses that can contribute to many aspects of tumorigenesis. Our study aimed to characterize the expression FGFR2b and 2c in non-malignant lung and non-small cell lung cancer (NSCLC) tissue and relate splice variant-specific expression to the histological and molecular background of cancer and its clinical impact.FGFR2b/FGFR2c isoforms expression was determined in RNA-seq data from 180 NSCLC patients and 19 tissues from normal lung (patient-matched). Cell-type specific expression and pan-cancer analysis of FGFR2 were explored using a public database, including DBTSS (NSCLC: 26, normal lung epithelium: 1, normal lung fibroblast 1) and CCLE (Total: 1019, NSCLC: 131), GTEx (normal lung tissue: 578) and HPA (scRNAseq for lung).Our results confirm a cell-specific expression in normal cells with dominance of FGFR2b in epithelial cells and FGFR2c in mesenchymal cells. In normal lung tissue, the FGFR2b variant showed high abundance. Pan-cancer analysis revealed FGFR2c dominant cancers (e.g., CNS tumors, kidney, liver) as well as FGFR2b dominant cancer types (e.g., breast, colon, lung cancer). The RNAseq data from our NSCLC cohort showed a chief expression of FGFR2b in 116 cases (64%), FGFR2c in 31 cases (17%), and a mixed FGFR2c/FGFR2b transcriptomics (18%). The ratio of FGFR2b/FGFR2c as a metric for splice variant dominance was associated with squamous histology, higher stage, and KRAS mutations. Differential gene expression analysis of cancer tissue and cell lines revealed an association of the splice variant FGFR2c to epithelial-mesenchymal transition (EMT) and the regulation of genes (ZEP1, ERSP1, CDH1) involved in the TGF-beta signal pathway. Finally, the ratio of FGFR2b /FGFR2c demonstrated a strong association with overall survival in NSCLC patients with the FGFR2c variant as unfavorable predictors (High vs low ratio, $p = 0.01$). Our study indicates cell-specific splice variant expression in non-malignant and malignant cells. The prognostic unfavorable impact of the FGFR2c variant on NSCLC patient survival might be explained by its association with TGF signaling and EMT. The observed clinical and biological difference between FGFR2b and FGFR2c dominated cancers gives further rationale to exploit splice variants as therapeutical targets.

#0210 Carcinogenic influence of e-cigarette aerosols on breast and lung cancer models.

R. Begum, S. Thota, N. Chintala, B. Sapkota, A. Pandit, J. Francis;
Louisiana State University, Baton Rouge, LA

Background and Purpose: With the rising popularity of E-cigarettes among the youth, there is an urgent need to understand their long-term health implications, particularly the potential for carcinogenesis. Although tobacco smoking is established as a major cancer risk factor, the carcinogenic potential of E-cigarettes remains underexplored. Given that metastatic cancer accounts for most cancer-related deaths in the United States, elucidating the biological impacts of E-cigarette aerosols on cancer progression is critical for developing effective interventions. This study aims to address this critical gap by exploring the effects of E-cigarette aerosols on cellular models pertinent to breast and lung cancer.
Methods: Mouse breast epithelial cells (HC11), triple-negative breast cancer cells (4T1), and human lung adenocarcinoma cells (Calu-3) were exposed to E-cigarette aerosol at the air-liquid interface for one hour, followed by a 24-hour recovery period.
Results: Our study revealed that E-cigarette aerosols with mint flavor induce epithelial-to-mesenchymal transition (EMT) in both normal mammary epithelial and breast cancer cells. Furthermore, we also observed activation of the TGF pathway and an increased expression of stemness-related markers (OCT4, SOX2, NANOG, KLF4, and c-MYC) in 4T1 cells exposed to mint and menthol-flavored E-cigarette aerosols in both 2D and 3D cell culture environments. Microscopic examination at a 10X magnification level revealed that 4T1 and Calu-3 cells exposed to menthol-flavored E-cigarette aerosols exhibited signs of cellular disassociation and detachment whereas the control cells maintained discoidal aggregate morphology.
Conclusion: The data presented here illuminate a potential link between E-cigarette use and carcinogenic processes, challenging the notion of E-cigarettes as a safe smoking alternative. This research is of paramount importance to cancer research as it unveils possible new avenues for tumor progression, emphasizing the necessity for a critical evaluation of E-cigarette products.

#0211 Applying cellular thermal shift assays to uncover novel regulators of epithelial to mesenchymal transition in triple negative breast cancer.

Jessica A. Lidster[1], Ser Yue Loo[2], Zhengwei Wu[2], Lingyun Dai[3], Seow Qi Ng[2], Nayana Prabhu[4], Dennis Kappei[1], Wai Leong Tam[2]

[1]Cancer Science Institute of Singapore, Singapore, Singapore,[2]Genome Institute of Singapore, Singapore, Singapore,[3]Nanyang Technological University, Singapore, Singapore,[4]Institute of Molecular and Cell Biology (IMCB), Singapore, Singapore

Metastatic Breast Cancer is accountable for over half a million deaths worldwide each year, the majority of which are from the triple negative breast cancer (TNBC) subtype, known to be highly aggressive, metastatic and resistant to targeted therapy. Metastasis is driven by the ability of cancer cells to undergo epithelial to mesenchymal transition (EMT), a cell state transition involving a gain of stemness, cell motility and chemoresistance. EMT has been well characterized using a range of techniques based upon quantitative proteomics and transcription profiling, yet targeting EMT to prevent tumor metastasis and chemoresistance is an obstacle that remains to be fully overcome. Using a cellular thermal shift assay coupled with mass spectrometry (CETSA-MS), we have measured changes in protein stability upon induction of EMT and have uncovered key enzymes in the citric acid (TCA) cycle that are stabilized during EMT of human mammary epithelial cells. Such enzymes are responsible for the conversion of TCA cycle intermediates required for a recently discovered post-translational modification. In TNBC cells, we find that loss of these enzymes causes not only global changes to crucial post-translational modification of mitochondrial proteins, but very specific alterations in several cytoskeletal proteins, leading to altered EMT status as well as reduced tumor growth and initiation both *in vitro* and *in vivo*. This demonstrates the importance of TCA cycle-controlled post-translational modification of cytoskeletal proteins in tumorigenesis and establishes basis for further investigation into their role in EMT and metastasis of breast cancer. Through pharmacological inhibition and immunofluorescence imaging, we discovered regulators of post-translational modifications that may be viable drug targets to overcome chemoresistance and relapse in TNBC patients with limited and inefficacious options.

#0212 Repression of NKX2-1 promote epithelial-mesenchymal transition and tumor neutrophil recruitment in lung cancer progression.

S.-H. Chiou, P.-H. Tsai, M.-L. Wang;
National Yang-Ming University, Taipei, Taiwan

Background: Malignant transformation is associated with tumor aggressiveness and poor patient outcome. This cellular alteration is due to either activation of oncogenes or the silencing of tumor suppressor genes. NKX2-1 was identified as a lineage-specific gene downregulated in poorly differentiated lung adenocarcinoma (LUAD). However, the molecular mechanism and functional role of infiltrated immune cells in NKX2-1-negative tumors are not clearly understood.

Methods: Clinical relevance of NKX2-1 expression and disease status were evaluated by immunohistochemical analysis of LUAD tissue arrays and the overall survival analysis of TCGA databases. *In vitro* and *in vivo* experiments were applied to confirm the role and mechanisms of NKX2-1 actions in transformed cells. The secretion of chemokines was evaluated by using chemokine array. Flow cytometry and single-cell RNA sequencing analysis of mouse tumor tissue were used to demonstrate the infiltration of neutrophils in mouse models.

Results: Low expression of NKX2-1 was observed in high-grade LUAD tumors. LUAD patients who express a pattern of NKX2-1^{high}/TGF-β^{low} had better survival outcomes than those with NKX2-1^{low}/TGF-β^{high}. Mechanistically, TGF-β induced the downregulation of NKX2-1 which led to enhanced epithelial-mesenchymal transition (EMT), cell motility, and CXC chemokine expression. The high release of these chemoattractants promoted the recruitment of neutrophils. Meanwhile, NKX2-1-dependent suppression of CXC chemokines gene expression may be via repressive histone methylation at the promoter region of CXC chemokines in lung cancer cells. In the *in vivo* syngeneic LUAD models, exacerbated neutrophil infiltration was noted. Single-cell RNA sequencing and flow cytometry both revealed that neutrophils were recruited via CXCLs/CXCR2 activation in LUAD tumors with NKX2-1 knockdown.

Conclusion: Our data showed that NKX2-1 represses tumor growth, metastasis, and neutrophil recruitment via the CXCLs/CXCR2-dependent mechanisms. Notably, targeting CXCR2 in NKX2-1-negative tumors may improve LUAD patient outcomes.

#0213 NEK1-mediated phosphorylation of YAP1 is key to prostate cancer progression.

D. M. Olatunde, I. Ghosh, A. De Benedetti;
Louisiana State University Health Sciences Center, Shreveport, LA

The key to preventing metastatic castration-resistant prostate cancer (mCRPC) progression is understanding how androgen-sensitive (AS) PCa cells progress to independence and modify accordingly their transcriptional repertoire. We recently identified a novel axis of the Hippo pathway characterized by the sequential kinase cascade induced by androgen deprivation, AR⁻>mTOR>TLK1B>NEK1>pYAP1-Y407, leading to CRPC adaptation. Phosphorylation of YAP1-Y407 increases upon androgen deprivation therapy (ADT), correlated with increased NEK1 activity, and this is suppressed in a YAP-Y407F mutant. Overexpression of wt-GFP-YAP but not the Y407F SDM resulted in dramatic morphologic changes. In fact, LNCaP expressing wt-YAP were AI whereas the Y407F mutant were AS, and LNCaP expressing wt-GFP-YAP underwent EMT transformation. This, largely reflecting transcriptional differences in both AR-dependent genes (FKBP5, PSA) and some involved in EMT (ZEB1, TWIST, E-CAD); all of which could be effectively reversed with J54-mediated inhibition of TLK1>NEK!>YAP signaling. We found that J54, a pharmacological inhibitor of the TLK1>NEK1>YAP1 nexus led to degradation of YAP1, suggesting that the Y407 phosphorylation is critical for transcriptional activation and stabilization of YAP. Specifically, Nek1-mediated phosphorylation of YAP-Y407 increases its productive interaction with transcriptional activators like TEAD or AR, resulting in its nuclear retention and stabilization. This was later demonstrated by coIP of TEAD4 or the AR with GFP-YAP antiserum, as well as via LUC expression transfections using ARE and Hippo reporter plasmids in LNCaP expressing wt-GFP-YAP or Y407F proteins, as well as by ChIP for key AR-responsive gene promoters. Further, in NEK1 haploinsufficient TRAMP mice we determined reduced YAP1 expression, a key transcriptional activator of CRPC progression, and, if castrated at 12 weeks, the mice failed to show to overt prostate carcinomas, even while displaying reduced E-Cadherin (E-Cad) expression in hyperplastic ductules. Finally, IHC examination of prostate cancer biopsies revealed that pYAP1-Y407 nuclear signal is low in samples of low-grade cancer but elevated in high GS specimens.

TUMOR BIOLOGY: Organoid Models of Cancer 1
Poster Session

#0217 Establishment of a spatially defined co-culture model of non-small cell lung cancer organoids and cancer-associated fibroblasts to investigate phenotypic heterogeneity.

C.-K. Park, R. Navab, E. D'Arcangelo, Q. Li, H. Ogawa, N. Radulovich, N.-A. Pham, M.-S. Tsao;
Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Cancer-associated fibroblasts (CAFs) are heterogeneous, with CAF subtypes being localized in spatially defined areas of tumors. However, it remains unclear which CAF subsets specifically play a role in fundamental processes such as tumor growth, invasion, and response to therapy. This study aims to establish a novel *in vitro* model that recapitulates the *in vivo* tumor-stroma spatial relationship to investigate CAF heterogeneity and its impact on tumor cell growth in non-small cell lung cancer (NSCLC).
Methods: The *in vitro* model was established using NSCLC patient-derived CAFs and tumor organoids as a 6:1 ratio. Tumor cells originating from xenograft-derived organoids (XDOs) were embedded in a hydrogel containing CAFs (Day 0) and co-cultured for 5 days. Confocal microscopy was utilized to characterize and measure the proliferation of the XDO tumor cells in the co-culture setup, and the proliferation rate was defined as differences in tumor spheroid area between Day 1 and 5. Single-cell RNA-sequencing (scRNAseq) and gene set enrichment analysis (GSEA) were then used to assess the gene expression and signaling pathways dominant in mono- and co-culture to characterize CAF heterogeneity in this model.
Results: Initially, the culture media formulations and the matrix for the growth of both CAFs and tumor cells were screened to assess the compatibility of different culture elements. Both CAFs and XDO tumor cells proliferated well in reduced organoid media (M27RD). This reduced medium and the novel matrix composition (50% Matrigel/50% Rat Tail type I collagen) also allowed for maintaining CAF contractility and XDO proliferation. Utilizing these harmonized media and matrix conditions, a spatially defined co-culture model, which incorporated XDOs as a central cluster surrounded by CAFs, was generated. In confocal microscopy, the proliferation rate of tumor cells was significantly higher in co-cultures with CAFs (adjusted p-value < 0.01), while not significant in mono-culture of tumor cells. The GSEA using the Hallmark gene sets on scRNAseq data generated in three co-cultures identified the heterogeneity among CAFs: two CAFs showed significantly higher effect on tumor cell proliferation with the most highly differential expressed genes (DEGs) enriched with inflammation and mitosis and the top high DEGs associated with epithelial-mesenchymal transition, while the other CAF has no effect.
Conclusion: The harmonized co-culture conditions for NSCLC organoids and CAFs enabled the characterization of both cell phenotypes and the building of an informed model architecture to study tumor-stroma communication. The presence of CAFs increased tumor cell growth with enrichment in secreted proteins involved in epithelial-mesenchymal transition.

#0218 Deciphering tumoroid-CAF interactions through a spatially segregated coculture model.

S. Kim[1], Y. Ko[1], H. Park[1], S. Jang[2];

[1]AMIST, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of, [2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

In the context of lung cancers, cancer-associated fibroblast (CAF) plays a pivotal role as a key component of the tumor microenvironment (TME), affecting tumor growth, invasion, metastasis, immune modulation, and drug resistance. Despite the recognized impact of CAFs, the precise interaction between the CAF and tumor cell remains elusive. Previous studies have reported that CAFs stimulate tumor cell growth both *in vitro* and *in vivo*. However, our tumoroid models reveal an intriguing phenomenon where CAFs inhibit tumoroids growth within Matrigel. This led us to hypothesize that paracrine signaling might be the primary mode of interaction between CAFs and tumor cells. To unravel the intricacies of this interaction, we developed an innovative coculture method. Using hydrophobic barrier, we segregated the coculture of nine sets of CAFs and tumoroids within a single well, preventing CAFs from infiltrating the tumoroid culture area. This setup enabled interaction solely through paracrine signaling. Surprisingly, cocultured tumoroids exhibited no significant differences compared to individually cultured tumoroids. Conversely, cocultured CAFs displayed a remarkable increase in growth compared to their individually cultured counterparts. This suggests that tumoroids influence CAF growth, while CAFs do not significantly impact tumoroid growth. Furthermore, in three coculture sets, tumor cells within the Matrigel migrated towards the CAF culture area, indicating that CAFs induce tumor cell metastasis. Immunofluorescence staining confirmed this metastatic phenomenon. To identify the paracrine factors influencing CAFs and tumoroids, we employed RNA-sequencing, single-cell RNA-sequencing, and proteomic analysis of culture soup. Proteomic analysis revealed a substantial increase in proteins and signaling pathways related to the extracellular matrix in cocultures compared to single cultures. Our findings suggest that tumor cells recruit CAFs, promoting CAF growth to establish and fortify their TME, ultimately leading to drug resistance, metastasis, and immune modulation

#0219 Molecular and therapeutic characterization of a large-scale collection of metastatic colorectal cancer patient-derived xenografts and matched organoids for translational oncology.

S. M. Leto, E. Grassi, M. Avolio, V. Vurchio, F. Cottino, M. Ferri, E. R. Zanella, L. Di Blasio, A. Puliafito, L. Primo, A. Bertotti, L. Trusolino;
Candiolo Cancer Institute - IRCCS, Candiolo, Italy

Strong evidence supports the use of patient-derived xenografts (PDXs) as faithful models reflecting patient outcomes. Since not all research can support the use of animals, exploiting patient-derived *in vitro* models such as organoids (also know as tumoroids) is essential. However, current biobanks of metastatic colorectal cancer (mCRC) tumoroids have important limitations, such as small sample size and a lack of systematic *in vivo* validation with paired xenografts, which decreases the translational value of tumoroid-based pipelines. Here we describe XENTURION, a unique open-science resource of XENografts and Tumoroids for Research In ONcology that encompasses 129 sibling pairs of mCRC PDXs and PDX-derived tumoroids (PDXTs) with accompanying molecular and therapeutic characterization.The vast majority of XENTURION models were analyzed for mutations (targeted next-generation sequencing of 116 relevant CRC genes), gene copy number architecture (DNA shallow sequencing) and global transcriptomics (RNAseq) and benchmarked against large patient datasets (TCGA and MSK-IMPACT). Results showed that the PDX-PDXT collection proved to be representative of the genetic heterogeneity of mCRCs and displayed high genetic and transcriptional similarity between matched pairs. A PDXT-based population trial with the clinically approved anti-EGFR antibody cetuximab was performed in 116 PDXTs, revealing variable sensitivities that were consistent with clinical response biomarkers and with tumor growth changes in 79 matched PDXs. Cetuximab response profiles also recapitulated the outcome of EGFR knock-out by CRISPR-Casp9 technology in 13 representative PDXTs. Adaptive signals upregulated by EGFR blockade both in tumoroids and PDXs were computationally and functionally prioritized. Top candidates were screened in PDXTs and 3 surviving compounds were identified as actionable co-extinction targets with cetuximab in 12 PDXT models. Results were finally validated in PDXs.To our knowledge, this is the first large-scale study in which a systematic comparison of molecular and therapeutic profiles between PDXT-PDX pairs was attempted. As a publicly available resource, XENTURION will offer a knowledge base of disseminatable methods, resources and information to streamline preclinical studies and accelerate new treatments for patients with mCRC.

#0220 Thresholding response assessment in biliary tract cancer organoids to inform sensitivity to chemotherapy across molecular subtypes.
E. Riedl, A. Stram, M. Hossan, E. Lin, J. Warner, L. Koeppel, J. D. Kratz;
University of Wisconsin - Madison, Madison, WI

Background: Cholangiocarcinoma (CCA) remains a highly morbid cancer for which accurate models. Patient-derived cancer organoid (PCOs) have been generated in CCA, however their utility in clinical prediction has not been validated. Z' factoring often fails in assessing CCA organoid response. Prior analysis for organoid response has shown an effect size by Glass's Delta (GΔ) of ≥1.25 in growth inhibition is predictive of clinical response. Here, we present subclonal organoid response across a diverse set of CCA models in response to therapy by growth and organoid level viability response.
Methods: PCOs were expanded from the NCI's Patient-Derived Model Repository (PDMR), tissue biopsy, and rapid autopsy. Organoid response was tracked from growth using Z-stacked high content imaging (Cytation5) with endpoint at 144h and stained using established viability markers, Caspase-3/7 (C3/7) and ToPro3. Treatment groups included media control, positive control of cycloheximide 200uM continuous, gemcitabine (gem) 10uM 24h, cisplatin (cis) 5uM 48h, combination gem+cis, and FGFR2 inhibitor futibatinib (futi) 300nM continuous.
Results: Across models, PCO growth directly correlated with Z' factor thresholding (R= 0.868). NCI PDMR organoids, CK11523 and CK10519 are *IDH1*mutant *(*mt), and both showed superior response to gem when compared to cis by growth (gem GΔ 1.18 and 0.44 v. cis GΔ 0.11 and 0.23) and C3/7 (gem GΔ 3.25 and 2.34 v. cis GΔ 1.46 and 0.33). *BRCA1*mt CCA was found to achieve modest growth inhibition with gem and gem+cis (GΔ 1.09 and 1.17) and yet significant increase in C3/7 (gem GΔ 1.68 and gem+cis GΔ 1.36) and ToPro3 (gem GΔ 1.65 and gem+cis GΔ 1.82). Despite this result, the patient developed early clinical recurrence after neoadjuvant gem+cis chemotherapy (<3 months). *FGFR2-HPGDS* fusion CCA achieved no meaningful difference in growth response with gem+cis (GΔ 0.94) or futi (GΔ 0.36). These findings were consistent with the clinical outcome of primary chemotherapy resistance and progression on futi. However, we observed increase in C3/7 positivity with both gem+cis (GΔ 2.11) and futi (GΔ 1.37).
Conclusions: Primary resistance to both targeted and chemotherapy remains a formidable barrier to therapeutic development in CCA. While growth inhibition remains a validated marker of clinical response, further work is needed to understand thresholds for C3/7 and ToPro3 across physiologic drug dosing. This is the first report of modeling the novel *FGFR2-HPGDS* fusion CCA in organoids. Ongoing work is evaluating therapeutic sensitivity across prospective specimens of CCA in support of establishing thresholding for response to apoptosis (C3/7) and necrosis (ToPro3).

#0221 Novel organotypic patient derived primary tumor tissues for oncology drug safety and efficacy studies.

S. Ayehunie[1], M. Groves[2], B. Bryda[1], A. Armento[1], A. Tolcher[2];
[1]MatTek Corporation, Ashland, MA, [2]Next Oncology, San Antonio, TX

Organotypic, three-dimensional (3D) cancer tissue models (OCTM) have enabled investigators to develop predictive markers that can be used in preclinical cancer drug development. However, a drawback of the existing models is that they are mostly based on cell lines based are not physiological. In vitro development of 3D tumoroids using patient derived primary tumors (PDPT) in tumor microenvironment (TME) will have clinical significant and can predict human responses to cancer therapeutics. Here, we describe the generation of OCTM from patient-derived metastatic colorectal cancer, the second most deadly cancer. PDPT were grown in Matrigel for 5 passages and for biobanking purposes tumoroids were further expanded in faCellitate 384 well plates or Sun Bioscience plates to harvest large amounts of well-defined tumoroids cultured for over 21 days. Expanded tumoroids were collected and cryopreserved or gently mixed several times using a pipet tip to break up tumoroids into smaller fragments. These tumor fragments were mixed with endothelial cells, dendritic cells, fibroblasts and embedded in a collagen matrix to simulate TME. The collagen-cell mixture was then added to Transwells and induced to gel to form a collagen gel matrix that simulates TME. The tumoroids were cultured with a specialized medium that supports the growth of complex cell types. The tumor development was monitored daily using bright field microscopy and image analysis was used to monitor tumor size. To evaluate the utility of the OCTM, treatment was initiated at day 10 of the culture period by exposing tissues with the chemotherapeutic drug Cisplatin on days 0, 2, 4, 7, 9, and 11. After each treatment, OCTM tissues (N=2) were fixed for H&E and live/dead staining. Overall, the results of the study showed that: 1) PDPT can be expanded for 5 passages (this low passage number is not expected to change the phenotype of the tumor) and further expanded in high throughput format, 384 well plates, 2) the PDPT could be cultured with multiple cell types in a collagen-gel matrix to recreate the TME, 3) histological evaluation of the OCTM showed a glandular-like tumoroid, 4) immunohistochemical staining revealed that the PDPT in the in vivo-like microenvironment were positive for CK20, and 5) the PDPT shrank following 3 treatment cycles with Cisplatin (day 4). Conclusion: The data shows metastatic colorectal PDPT can be expanded in vitro and cultured in a complex tumor microenvironment on tissue culture inserts. These OCTMs can be used to screen drug safety and efficacy. This study opens new avenues for high-throughput cancer drug screening format using PDPT embedded in a in vivo like TME. This model can be used as a tool for personalized oncology drug testing and for translational assays tailored to other cancer types from our patient derived primary tumor pool.

#0222 Establishment of patient-derived tumor organoids from head and neck cancers for predicting response to treatments.

M. Perreard[1], V. Bastit[1], L. Lecouflet[2], G. Desmartin[2], R. Florent[2], C. Jeanne[3], J. Thariat[2], E. Babin[1], L. Poulain[2], L.-B. Weiswald[2];
[1]Universite de Caen Normandie / CHU de Caen / Centre Francois Baclesse, Caen, France, [2]Universite de Caen Normandie / Centre Francois Baclesse, Caen, France, [3]Centre Francois Baclesse, Caen, France

The risk of relapse or recurrence of Head and Neck Squamous Cell Carcinoma (HNSCC) is high despite the combination of surgery and radiochemotherapy, responsible for high toxicity. It is crucial to develop new therapeutic strategies and to identify patients likely to benefit from these treatments. Patient-Derived Tumor Organoids (PDTO) are three-dimensional multicellular structures derived from patient tumor samples and faithfully reproduce the histological and molecular characteristics of the original tumor. A growing body of research indicates that PDTO may predict the clinical response, representing a major opportunity for the development of new therapeutic strategies and precision medicine. The purpose of this translational study is to generate PDTO from HNSCC patients to evaluate their predictive value. PDTO were obtained after dissociation of tumor specimen of HNSCC patients through the setup of the clinical study ORGAVADS (NCT04261192). Tumor cells were embedded in extracellular matrix and cultured in specific medium. Histological and immunohistochemical characterizations were performed to validate the resemblance between PDTO and their original tumor. Response of PDTO to chemotherapy, radiotherapy and innovative therapies were evaluated by live-cell imaging and viability assays. The culture conditions were optimized to improve the success rate of PDTO establishment which now exceeded 50%. Twenty-one PDTO lines have been established and showed histological characteristics close to the original tumor. Expression of immunohistochemical tumor markers p53, p40, p63, and p16 were similar in tumors and paired PDTO. Functional assays were performed on 15 PDTO to analyze the response to treatments (cisplatin, olaparib, X-Rays) and heterogeneity of response was observed between the models. When clinical response was available, PDTO derived from good responders showed high sensitivity to treatments while PDTO from bad responders showed low sensitivity to treatments. Interestingly, two PDTO lines derived from HPV+ oropharyngeal tumors displayed very high sensitivity to cisplatin, matching with the patient's profile and response. Our results showed feasibility to derive PDTO from HNSCC and to perform functional assay to assess their response to different treatments. The first studies of correlation between PDTO and patient responses are promising and will be further investigated in more patients. This will allow to demonstrate the predictive value of PDTO from HNSCC with the purpose to develop a clinically compatible predictive functional assay.

#0223 Precision medicine-based platform to guide the treatment of EML4-ALK fusion lung cancers and other NSCLC.

Nathan M. Merrill[1], Aaron Udager[1], Angel Qin[1], Kiran Lagisetty[1], Liwei Bao[1], Xu Cheng[1], Hamadi Madhi[1], Ananya Banerjee[1], Ananya Banerjee[1], Marziyeh Salehi Jahromi[1], Laura Goo[1], Varun Kathawate[1], Bryce Vandenburg[1], Marisa Aikins[1], Mark Slayton[1], Peter Ulintz[1], Zhaoping Qin[1], Chia-jen Liu[1], Habib Serhan[1], John Jefferies[2], Muhammad Sajawal Ali[3], Vishal Navani[4], Michael Monument[4], Johannes Kratz[5], Amber Smith[6], Andrew Chang[1], Gregory Kalemkerian[1], Sunitha Nagrath[1], Peggy Hsu[1], Matthew B. Soellner[1], Sofia D. Merajver[1]

[1]University of Michigan, Ann Arbor, MI,[2]University of Tennessee Health Science Center, Memphis, TN,[3]Weill Cornell Medicine, New York, NY,[4]Tom Baker Cancer Centre, Calgary, AB, Canada,[5]University of California San Francisco, San Francisco, CA,[6]The Rare Cancer Research Foundation, Durham, NC

Background: Lung cancer (LC) remains the top cause of cancer-associated mortality worldwide, with a 10-year overall survival rate of only 5%. While most LCs are smoking related, in the US, 25% of non-small cell LC (NSCLC) are diagnosed in patients with little or no smoking history. Fusions involving anaplastic lymphoma kinase (ALK) are the oncogenic driver in ~3-7% of NSCLC. While inhibitors targeting the kinase domain of ALK (TKIs) have proven extremely effective, inevitably, resistance develops with limited effective treatment options. Additionally, NSCLCs without identified molecular alterations have limited treatment options beyond radiation, immunotherapy, chemotherapy, and resection.
Methods: We developed a precision medicine-based platform (PMP) to screen patient-derived material (PDM) directly from the operating room with curated panels of drugs. PDM collected during clinically indicated procedures is plated in 3D-culture to generate patient-derived organoids (PDOs) and screened with drugs curated to each tumor type. PDOs are screened at therapeutically relevant doses, drawing from pharmacokinetic data for each drug. We have optimized an assay to rapidly screen for EML4-ALK fusions and can perform next-generation sequencing in real time (~7 days) to integrate with drug screening results.
Results: To date, we have screened 83 cases, including 8 EML4-ALK NSCLC. We have demonstrated an ability to produce high quality data from low input samples (biopsies). In one EML4-ALK NSCLC we were able to collect PDM from two distinct anatomic spaces (pleural effusion and peritoneal fluid) and screen with the same panel of drugs, with nearly identical results, highlighting the reproducibility and consistency of our assay. Screening of EML4-ALK tumors which have progressed to second or higher line TKIs, demonstrate sensitivity to earlier generation ALK TKIs, a known phenomenon. Characterization of tumors with unknown clinical drivers identifies ~1/3 tumors with no prioritized variants and particularly poor response to chemotherapies. Our results recapitulate known resistance/progression in samples previously exposed to therapy, demonstrating a strong negative predictive value. Longitudinal assessment will be required to robustly assess positive predictive value (PPV).
Conclusions: Our PMP captures robust and reproducible results that are consistent with known clinical pathogenesis. Moving forward, we are collecting longitudinal data from enrolled patients in parallel with clinical trials to demonstrate the PPV of our PMP. We additionally strive to demonstrate reproducibility to obtain Clinical Laboratory Improvement Amendments approval and to deliver results to patients and physicians to help guide clinical care.

#0224 Combining functional precision medicine and radiotherapy with bio-printed organoids in head and neck squamous cell carcinoma.

L. Lin, K. K. Bommakanti, A. V. Sannajust, Y. Alhiyari, B. Mo, L. Evans, P. Tebon, M. St. John, A. Soragni;
UCLA - University of California Los Angeles, Los Angeles, CA

The study aims to establish a high throughput *ex vivo* organoid-based drug screening platform for head and neck squamous cell carcinoma (HNSCC) to investigate interactions between radiotherapy and different chemotherapies or targeted therapy agents and ultimately provide functional precision medicine therapeutic suggestions. HNSCC is the sixth most common cancer worldwide. Both HPV+ and HPV- cancers can be treated with surgery, radiotherapy, chemotherapy, or a combination of these. Cetuximab is currently the only FDA-approved targeted agent for HNSCC. Few clinical trials to date have shown an improved clinical outcome when combining targeted agents with radiotherapy, thus there is a need to identify new therapeutic combinations to improve outcomes.

In order to characterize HNSCC tumor behavior and sensitivity to therapy, we have leveraged our high throughput 3D tumor organoid screening platform. Our approach entails seeding tumor cells in extracellular matrix around the perimeter of tissue culture wells in ring-like structures, which we have successfully deployed in other cancer types (Phan et al, 2019; Al Shihabi et al, 2022; Nguyen et al, 2022; Al Shihabi et al 2023). To optimize a chemoradiation platform, we used the HN30, HN31, and SCC154 cell lines representing HPV- primary, HPV- metastatic, and HPV+ head and neck tumors. The cell-line-derived 3D models are exposed to both radiotherapy and various chemotherapy or targeted therapy drugs. We measured cell responses by ATP-release assays and by applying our machine learning-based brightfield image analysis pipeline (Al Shihabi et al, 2022).

Our results showed that the HPV+ SCC154 was the most sensitive line to radiotherapy while HPV- metastatic HN31 was the most resistant. HN31 was resistant to most drug treatments except for gemcitabine, docetaxel, and mitomycin c, while HN30 and SCC154 were sensitive to a broader set of agents. We have investigated combinatorial efficacy of radiation and chemotherapy as well as targeted agents and extended this platform to HNSCC patient-derived tumor organoids. Our proof-of-concept study highlights how our organoid-based drug screening platform can be used to test chemoradiation approaches that are more effective and personalized.

#0225 Integration of patient-derived tumor organoids and patient clinical multimodal data to investigate the role of organoids in predicting treatment response.

K. A. Burke[1], B. Larsen[1], Y.-H. C. Tan[1], J. Barbeau[1], C. Brinkman[1], E. Moore[1], N. Callamaras[1], J. R. Dry[1], I. Huerga[1], K. Sasser[1], J. A. Borgia[2]; [1]Tempus Labs, Inc., Chicago, IL, [2]Rush University, Chicago, IL

Introduction: Patient-derived organoids (PDOs) enable the ex vivo study of tumor heterogeneity and its effect on response to treatment. Our previous work demonstrated that our robust pan-cancer organoid platform shows genetic and transcriptomic concordance with clinical tumor samples and can be deployed for high-throughput drug response screening. Here, we ran a standard of care (SOC) panel on PDOs with paired de-identified clinically curated data to enable a comparison of patient response to the same drugs ex vivo and exploration of potentially more effective treatment alternatives.
Methods: Patient tumor samples were cultivated into tumor PDOs in extracellular matrix + chemically defined media. PDOs underwent pathological review to ensure development of malignant tissue. PDOs were identified by clusters of Hoechst-positive cells and live and dead cell counts for each PDO were determined using fluorescent stains. The median number of cells per PDO in the well was calculated, excluding PDOs with <3 cells and the top 1% of PDOs by area. Drug screens were run with 6 doses of the compound and the inverse area under the curve of ToPro3 live cell measurements was calculated to quantify response. Tempus xT DNA-seq and xR whole-transcriptome assays were used to perform NGS on organoids and patient samples where available. Data was processed through our standard pipeline to identify targetable mutations, neoantigens, copy number variants (CNVs) and fusions.
Results: We analyzed 38 PDOs with paired patient data across 9 different cancer types comprising mostly lung (n=14) and colorectal (n=12); 17 PDOs had responses associated with treatment given close to the biopsy collection date. Across the full PDO cohort, we observed a range of responses to SOC compounds, providing a platform to better understand biomarkers and mechanisms of response. Treatment response in PDOs correlated with patient response in many cases. In the 3 patients with progression-free survival >1 year and outcomes of either complete response or stable disease, all showed strong responses to the corresponding drugs in the SOC panel. For most patients with progressive disease recorded after treatment the corresponding PDO cluster showed limited response to treatment. The SOC panel includes several targeted therapies that provide insight into how patients respond to treatment beyond chemotherapy. For two patients with limited response to treatment in both patient and PDO, we identified targeted therapies relevant to their clinico-genomic landscape. One patient showed improved clinical outcomes to a later line of therapy with a similar mechanism of action to the drug that showed response in the organoid.
Conclusion: These results suggest that PDOs may serve as a powerful tool for predicting patient response to treatment and aid the development of new therapies.

#0226 Effect of MCL-1 inhibitor on organoids derived from cholangiocarcinoma patients with IDH1 mutation.

S. Suzuki[1], J. Matsuzaki[1], T. Muramatsu[1], Y. Kanai[2], Y. Saito[1];
[1]Keio University Faculty of Pharmacy, Tokyo, Japan, [2]Keio University School of Medicine, Tokyo, Japan

Cholangiocarcinomas are highly aggressive malignancies with a poor prognosis. The global incidence of cholangiocarcinoma patients appears to be on the rise. While surgical resection remains the curative option for cholangiocarcinoma patients, the majority of cases are diagnosed at an advanced stage, resulting in poor outcomes. Patients with inoperable cholangiocarcinomas typically undergo chemotherapy regimens, including Gemcitabine, but their efficacy is limited, leading to low 5-year survival rates. Recent advancements in organoid culture technology allow for the in vitro replication of tissue structures by culturing tissue stem cells in three dimensions, offering great promise for personalized medicine. Utilizing patient-derived organoids has proven effective in predicting the outcomes of therapeutic drugs. We have successfully established organoids using cancer tissue derived from cholangiocarcinoma patients, and stably culturing and maintaining them, promoting their application to personalized medicine (Saito Y et al. Cell Rep. 27, 1265, 2019, Saito Y et al. Cancer Cell 40, 226, 2022). IDH1 mutations have been identified in approximately 15% of intrahepatic cholangiocarcinomas and are known to convert α-ketoglutarate (α-KG) in the TCA cycle to produce 2-hydroxyglutarate (2-HG), which is observed in gliomas and acute myeloid leukemia. 2-HG acts as an antagonist to α-KG-dependent dioxygenases, promoting cancer development. This study aims to develop a novel treatment for cholangiocarcinomas with IDH1 mutations. Metabolomic analysis of patient-derived cholangiocarcinoma organoids revealed 2-HG accumulation and reduced ATP production in IDH1-mutated cholangiocarcinoma organoids compared to IDH1 wild-type cholangiocarcinoma organoids. This may suppress the protein synthesis of MCL-1 and mTOR signaling through the activation of AMPK kinase, suggesting that further inhibition of MCL-1 could be lethal in IDH1-mutated cholangiocarcinoma organoids. Indeed, exposure to S63845, an MCL-1 inhibitor, significantly inhibited cell proliferation in IDH1-mutated cholangiocarcinoma organoids, unlike in IDH1 wild-type cholangiocarcinoma organoids. Furthermore, the combination of MCL-1 inhibitor and BCL-XL inhibitor demonstrated a synergistic and potent growth inhibitory effect on cholangiocarcinoma organoids. These findings indicate that the MCL-1 inhibitor holds promise as a new therapeutic agent for cholangiocarcinoma patients with IDH1 mutations.

#0227 Novel and easy-to-use approach to triple-negative breast cancer tumoroid culture.

B. Balhouse, C. Yankaskas, C. Paul, S. Salen, S. Beam, P. Shahi Thakuri, M. Dallas, D. Kuninger;
Thermo Fisher Scientific, Frederick, MD

Triple-negative breast cancer (TNBC) accounts for 15-20% of all breast cancer diagnoses in the United States. Patients with metastatic TNBC have a low survival rate, driven in part by limited treatment options for the disease. Tumoroids, also known as cancer organoids, have been shown to better maintain tumor-specific mutational and gene expression profiles over long-term culture, and evidence is growing that the functional response of tumoroids to therapeutics better recapitulates in vivo response. These improved preclinical models of TNBC may facilitate the development of new therapies, but tumoroids are yet to be widely adopted due to challenging culture methods. In this study, we show that two TNBC tumoroid models publicly available through the National Cancer Institute Patient-Derived Models Repository can be expanded in suspension culture using Gibco™ OncoPro™ Tumoroid Culture Medium supplemented with FGF10 and beta-estradiol. We compared the bulk tumoroid morphologies, growth rates, maintenance of mutational and gene expression profiles, and molecular phenotypes of cells grown in the NCI-recommended medium in embedded culture, and the OncoPro medium in embedded culture and suspension culture. We saw comparable morphologies and growth rates in all culture conditions. A multivariate analysis of the allelic frequencies of single nucleotide variants and ploidy values of copy number variants for cells expanded in all experimental conditions revealed >95% and >88% correlation, respectively, with the initial material. Interestingly, despite the change in the medium formulation, gene expression was also highly correlated between the initial material and the OncoPro medium conditions for >20,000 RefSeq genes (Pearson r>0.94) and for a cancer-gene specific panel of 1,423 genes (r>0.87). Further analysis showed unchanged expression levels in 97% of total genes analyzed and the basal molecular subtype was maintained for both lines in all conditions. The OncoPro media system was also used to derive a new TNBC tumoroid line, which demonstrates consistent growth rate and maintains the patient-specific mutational profile of the original breast tumor. Differential gene expression analysis revealed that changes in the gene expression profile were largely due to the loss of non-malignant cell populations from the original tumor. Finally, we utilized this new tumoroid line to examine donor-specific killing efficiencies of primary natural killer cells in a co-culture experiment. The discrepancy in the dynamics of killing a tumoroid line versus the standard K562 cell line indicates that tumoroids may offer an improved approach for screening new cell therapies. In summary, the easy-to-adopt OncoPro medium and culture method does not change the characteristics of existing models and may be used to derive new tumoroid lines, both of which can be leveraged for preclinical studies to develop critical new therapies for TNBC.

#0228 Patient-derived gbm organoids reflect tumour heterogeneity and treatment sensitivity in patients..

M. A. Vooijs[1], L. Hoosemans[1], J. Piepers[1], M. Verduin[1], M. Vanmechelen[2], M. Van Heumen[1], F. De Smet[2], A. Hoeben[1];
[1]Maastricht UMC+, Maastricht, Netherlands, [2]KU Leuven, Leuven, Belgium

Glioblastoma (GBM) is the most common and incurable adult primary brain tumour. Treatment resistance and relapse is the primary cause of death in GBM. Tumour heterogeneity is one of the significant determinants of treatment failure. Patient-derived cancer organoids have been shown to maintain genetic and phenotypic tumour features and recapitulate intratumoral heterogeneity. Here, we report the development and molecular characterisation of patient-derived GBM organoid (PGO) models to study treatment response to existing and new treatment combinations. GBM biopsies were dissociated, suspended in Cultrex, and cultured in a brain stem cell medium. PGOs were characterised by whole-exome (WES) single-cell karyotype (scKaryoSeq) and RNA sequencing. The IC-50 and viability of PGO upon temozolomide (TMZ) and small molecule inhibitors were determined. Gene expression profiling was performed before and after TMZ treatment. Single-cell spatial heterogeneity was determined using Multiplex Immunostaining of PGO and matched patient samples. PGOs were established with a success rate of 80% (n=31). WES analysis between PGOs from the same patient at multiple time points (1-3 months) showed high maintenance of Single Nucleotide Variants (92.3%-97.7%). In PGOs key somatic oncogene variants and copy number variations were retained compared to the primary tumour (58%-90%). scKaryoseq (N=7) of different clinical GBM subtypes showed a high degree of genetic heterogeneity, with some PGO having up to 10 subclones. Single-cell phenotypic landscaping of patient biopsies showed mixed cellular states maintained after long-term culture in the matched PGO. PGOs showed a differential response to TMZ, corresponding with MGMT methylation and patient mutation status. RNAseq of PGO revealed TMZ-responsive genes, including upregulation of the prognostic JUN kinase pathway. Combination treatment of a JUN kinase inhibitor and TMZ showed a synergistic effect. In addition, PGOs were screened for their sensitivity to clinically approved brain-penetrable small molecule inhibitors targeting key GBM driver pathways. Combining small molecular inhibitors of MEK/PI-3/CDK4/EGFR kinase strongly reduced cell viability and activation of cell death pathways. phosphoKinome screens detected compensatory pathway activation upon kinase inhibition (MEK/CDK4 inhibitor) in several PGO. Data will show novel kinase interaction pathways that increase drug sensitivity in PGO. These data show that PGOs can be used as a stable phenotypic and genetic representative of the patient's tumour and have the potential to function as patient avatars for adaptive treatment selection and actionable drug target discovery.

#0229 Molecular-genomic characterization of metastatic gastric cancer organoids and establishment of organoid-immune cell co-culture model.

H. Mun[1], j. Park[2], J. Jang[3], J. Che[3], T. Kim[3], W. Kwon[3], H. Chung[4], S. Rha[4];

[1]Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Song-Dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University Health System., Seoul, Korea, Republic of

Advanced gastric cancer (AGC) showed marked molecular heterogeneity with aggressive behavior and treatment resistance, especially AGC with ascites from peritoneal metastasis. Tumor organoids are valuable *in vitro* model for mimicking organ characteristics and are used for developing therapeutic strategies. Therefore, we aimed to understand the characteristics of organoids established from AGC patient-derived fluids. Also, we are in progress of setting up an organoid-immune cell co-culture model for drug screening of immune checkpoint inhibitors (ICI) for AGC. All established organoids from peritoneal and pleural fluid of AGC patients were authenticated through short tandem repeat (STR) profiling, comparing with their matched PBMCs. We compared the morphological characteristics using Operetta High Content Imaging (Perkin Elmer). Also, the *in house* targeted sequencing and RNA sequencing data were obtained from the genome database of the Song-Dang Institute for Cancer Research and it was verified using molecular methods. Then, we co-cultured organoids with healthy donor PBMCs that were pre-activated using anti-human CD3/CD28 Dynabeads (Gibco). 3D spheroids, rather than single cells, and the PBMCs were co-cultured in matrigel (Corning Inc.) for more than 3 days. The overall success rate of the organoid establishment was 53.8% (78/145), with different sources of peritoneal (54%, 61/113) and pleural fluids (53.1%, 17/32). The organoid success rate was various as in EBV positive (66.7%, 2/3) and dMMR (0%, 0/4). Based on the analysis of 91 patients eligible for histopathology, the success rate of HER2-negative (57.5%, 46/80) is higher than that of HER2-positive (36.4%, 4/11). The organoids were observed in a variety of morphologies categorized in 3 groups such as grape-like, compact and glandular structure. Based on genomic data of 31 organoids, we could subgrouping for TCGA subtypes and EMT subtype. RTKs were amplified in 10 organoids, including the amplification of ERBB2 (n=2), MET (n=4) and FGFR (n=4). And KRAS alterations including amplification (n=2) and G12A/D (n=2) mutation were also detected. Then, we established the condition for organoid-immune co-culture model with PBMCs with Dynabead activation for 3-10 days. We confirmed that higher dose of PBMCs killed the tumor cells with reduction of organoid size and partial disintegration. We established the proper PBMC dose and characterization to maintain the organoids co-culture for further drug (ICI) sensitivity testing. In conclusion, we evaluated phenotypic and molecular characteristics of gastric cancer organoids established from malignant peritoneal and pleural effusion. The established organoid-immune cell co-culture models can be utilized to evaluate a variety of drug screenings, including ICI and various combinations, helping in the selection of drugs for individual patient.

#0230 Deep learning embedding-based segmentation for morphological analysis in organoids.

A. Sureshkumar[1], S. Bisht[2], H. Easwaran[2];
[1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Background: The organoid model is a useful tool for modeling the cellular microenvironment of the organ from which they are derived. Organoids recapitulate the self-organization of heterogenous cell types and the microenvironment. Quantifying the morphological features of organoids can provide valuable insights into cellular organizational defects and growth characteristics, which can facilitate drug discovery. Measurement of these characteristics in live organoids can be performed quickly and easily directly in culture using widefield microscopy. The current state-of-the-art method to detect and identify the shape of individual organoids in brightfield images uses the U-Net Convolutional Neural Network (CNN) with a watershed transform to label pixels. However, this method yields jagged shape proposals and cannot detect overlapping regions. We propose the use of an embedding-based segmentation network based on the Branched ERF-Net to solve these issues.

Methods: Organoids were established from the proximal colon of $Braf^{V600E}$ heterozygous mice, and 50 phase-contrast images of the organoids were acquired at 2.5x and 4x magnification. Organoids present in acquired images were labeled manually. The network was trained on this collection of manually labeled images and validated on a separate validation dataset.

Results: The network accurately labels organoids. Overlapping organoids are segmented correctly and shape proposals are smoother. Detection of overlapping organoids with the Branched ERF-Net architecture yields an accurate organoid count, verified against manual counting. Smoother shape proposals also enable the use of convexity defects to measure organoid budding.

Conclusions: Deep-learning analysis of widefield images enables the rapid assessment of morphological characteristics, such as size, count, and budding, which are key to understanding proliferation and differentiation changes. The modified Branched ERF-Net architecture we propose for organoid segmentation is a robust and versatile method to quantify organoid morphology.

#0231 Live cell painting of drug responses in high grade serous cancer organoids.

D. W. Andrews, B. Li, W. Schormann, A. Buzina, L. Gien, H. MacKay;
Sunnybrook Health Sciences Centre, Toronto, ON, Canada

While most patients with high grade serous ovarian cancer (HGSC) respond to platinum-based chemotherapy, the response is rarely durable and recurrence almost inevitable. A characteristic of HGSC is defective DNA repair. A class of drugs called PARP inhibitors (PARPi) exploit this vulnerability and have proven useful in delaying recurrence. However, resistance is inevitable. In models of HGSC a protein that frequently confers resistance is called Bcl-xL, a member of the Bcl-2 family of proteins that prevent apoptosis. If treating the patients with a PARPi makes cancer cells dependent on Bcl-xL then adding an inhibitor of Bcl-xL to their treatment would be sufficient to cause the cancer cells to die. To test this, we have initiated companion studies for a clinical trial in which patients that have had a recurrence after receiving platinum-based therapy will first be treated with the PARPi Olaparib and then, an inhibitor of Bcl-xL, Navitoclax, will be added to their course of treatment. The idea is that for some women this will provide the one-two-punch needed to eliminate the cancer or at least dramatically prolong response. However, Bcl-xL is only one of the five known inhibitors of apoptosis. To identify which women will benefit most from adding Navitoclax to their treatment we need a biomarker(s). An ideal biomarker would also let us determine for other women which inhibitor of Bcl-2 proteins would be best combined with a PARPi.

Our hypothesis is that patient derived organoids can be used as a pragmatic way to identify for individual patients which Bcl-2 protein inhibitor will synergize with a PARPi to optimize treatment.

We are using organoids to develop biomarkers for High Grade Serous Cancer (HGSC) treatment response. Organoids generated from biopsy samples acquired prior to treatment for HGSC promise to be efficient and reliable experimental models that recapitulate in vitro patient tumors faithfully enough to facilitate translation to therapeutic decisions for patients. By adapting the relatively new technique of conditional reprogramming and combining it with novel methods for cell aggregation and hydrogel based synthetic ECM supports we can reproducibly generate HGSC patient-specific tumor organoids models in weeks with greater than 90% success. Organoids grown 384 well format are stained with novel non-toxic dyes enabling live cell painting of chemoresponses to drugs alone and in combination with drugs targeting anti-apoptotic proteins. Our data suggest that this approach captures the inherent heterogeneity of the disease, albeit local to the sampled site. We are now employing deep learning AI algorithms to enable automated analyses of 3D confocal image stacks of organoids to infer drug responses that will be compared to patient responses in ongoing clinical trials.

#0232 Multi-dimensional patient-derived organoid analysis highly correlates with progression-free survival of pancreatic cancer patients in a retrospective clinical trial.

A. Lin[1], M. Le Compte[1], T. Gilcrest[2], E. Cardenas De La Hoz[1], G. Roeyen[3], F. Lardon[1], C. Deben[1];
[1]University of Antwerp, Antwerp, Belgium, [2]Orbits Oncology, San Francisco, CA, [3]University Hospital Antwerp, Antwerp, Belgium

Patient-derived tumor organoids (PDOs) are promising cancer models, since they preserve the clonal heterogeneity, mutational landscape, and histological architecture of the originating patient tumor[1-2]. Recent studies have even provided first evidence that PDOs responded similarly to the corresponding patient when treated with the same standard of care therapy, but these studies were only able to predict clinical responses in a subset of patients[3,4]. This restriction was largely due to the limitation of current analysis methods. The gold-standard analysis method for PDO-based research, CellTiter-Glo 3D,[5,6] fails to account for the heterogeneity of PDOs by relying on a bulk lysis approach, and thus only extracts a fraction of the clinically-relevant information that PDOs could provide[7]. Therefore, we hypothesized that using higher-dimensional analysis methods, will further unlock the predictive performance of PDOs and facilitate translation of research. In this study, we developed an artificial intelligence-driven analysis platform for live-PDO imaging. By combining drug screening metrics with dynamic quantification of organoids on a single-organoid resolution, we unraveled patient-specific tumor heterogeneity and PDAC aggressiveness in response to therapies[8]. Using a fully characterized a PDAC organoid panel (n=8) we matched our PDO analysis with retrospective clinical patient response to standard of care therapies (gemcitabine-paclitaxel and FOLFIRINOX). Our results demonstrated that our PDO analysis method identified patient-specific sensitives to therapy that were in-line with clinical outcomes. Moreover, our PDO readouts highly correlated with progression-free survival of matched patients (R=0.97), which was a significant improvement to the current, conventional drug response readouts. Taken together, our approach increased the clinical translatability of PDOs by more accurately recapitulating and measuring the complexity of human tumors. This work highlights the potential applications (extendable to other tumor types) and clinical translatability of our approach in drug discovery and clinical care, in the emerging era of personalized medicine. #0234 Microfluidic chip for drug response studies in non-small cell lung carcinoma patient-derived organoids.

Q. Luan, I. Pulido, A. Isagirre, **J. Zhou**, T. Shimamura, I. Papautsky;
University of Illinois Chicago, Chicago, IL

Background. Organoids have been widely accepted as 3D tumor models for patient-specific drug response. However, research involving non-small cell lung cancer (NSCLC) organoids is hampered by the lack of appropriate platforms. Although dome cultures show promising results, the relatively large size variability of patient-derived organoids (PDOs) hinders their application in drug response studies. Here, we report a microfluidic chip for maintaining high uniformity and requiring miniscule sample volume for PDO drug screening.
Methods. The microfluidic chip includes a bottom microwell layer and a top microchannel layer. Each chip has 5 channels for parallel treatment conditions, with 30 U-shaped microwells (400μm dia x 250μm deep) per channel. PDOs were loaded from side channels and trapped by filters adjacent to microwells. NSCLC PDOs F231/F671 (NCI PDMR) were cultured and treated by $KRAS^{G12C}$ inhibitor adagrasib (0-2000nM, 72h). PDO drug response was assessed via viability using fluorescent dyes.
Results. On-chip PDO size after one-week incubation exhibited the coefficient of variation (CV) of 28% for F231 and 36% for F671, which was notably lower than measurements obtained using Matrigel dome (126%, n=3) and low attachment plate (80%, n=4). The F231/F671 showed viability >81% after 1wk (n=20). On-chip cytotoxicity results showed that both $KRAS^{G12C}$ PDOs exhibited sensitivity to adagrasib, matching the clinical response, with IC_{50} values of 830 nM (F231) and 1324nM (F671). When cultured with fibroblast (WI-38) supernatant, the cytotoxic effect was mitigated due to the fibroblast-induced resistance, with IC_{50} increasing ≥2×. No statistical difference was observed for the fibroblast effect in the open-format microwells and our microfluidic chip (69.6±16.9% to 80.2±9.0% vs. 69.0±12.2% to 82.2±4.1%, respectively, following 500nM adagrasib for 72h), further underscoring the reliability of our chip for PDOs' drug response studies. Application of continuous perfusion at 70nL/min yielded no statistical difference in viability from static conditions.
Conclusions. Our microfluidic chip offers uniform PDO growth with perfusion allowing drug screening in almost real time. The on-chip response to adagrasib was clinically relevant. Resistance due to tumor microenvironment (TME) can be readily assessed using fibroblast supernatant, and could be expanded to other TME components in future studies to investigate their impact on treatment resistance.

#0235 Application of high-grade serous ovarian cancer organoids in functional precision medicine.

Wojciech Senkowski[1], Laura Gall-Mas[1], Matias M. Falco[2], Yilin Li[2], Kari Lavikka[2], Aura Crispino[1], Jaana Oikkonen[2], Daria Bulanova[1], Yan-Jun Chen[1], Elena M. Doncel[1], Karolin Vo?grone[1], Erdogan P. Erkan[2], Jun Dai[2], Anastasia Lundgren[2], Jutta Huvila[3], Kaisa Huhtinen[2], Johanna Hynninen[4], Sampsa Hautaniemi[2], Anna Vaharautio[2], Krister Wennerberg[1]

[1]University of Copenhagen, Copenhagen, Denmark,[2]University of Helsinki, Helsinki, Finland,[3]University of Turku, Turku, Finland,[4]Turku University Hospital, Turku, Finland

High-grade serous ovarian cancer (HGSC) is the most frequent and lethal ovarian cancer type. Despite responding favorably to first-line therapy, most HGSC patients eventually relapse. HGSC is characterized by high interpatient genomic heterogeneity and few recurrent mutations that could be used as therapeutic biomarkers. Thus, except the introduction of PARP inhibitors for BRCA1/2-mutated patients, there has been little progress with personalizing HGSC treatment. Functional precision medicine - tailoring personalized therapies based on functional assays on patient-derived cells - has been applied in cancer clinical trials to address this issue. Organoids - three-dimensional cell cultures, recapitulating aspects of original tumors' structure and function - have often been used as models in these efforts. However, inefficient and time-consuming organoid derivation protocols have been hindering the application of HGSC organoids in functional precision medicine clinical trials, due to the short time during which the therapy must be selected.

To address this, we here aimed to establish whether we could predict second-line therapy drug sensitivities in relapsed HGSC using organoids from tumor material from first-line therapy. We have previously derived a collection of 23 organoid models from 16 patients, sampled sequentially at different times of their treatment (1). Here, for several organoid primary-relapse pairs, we performed drug screens using a library of 370 compounds (approved, in clinical development or tool compounds). We found that 90% of the hit compounds in the primary organoids also were hits in the matched relapse-derived organoid models. In several patients, we observed a pronounced cytotoxicity of several cyclin-dependent kinase (CDK) inhibitors, all of which potently inhibit CDK9, including two selective inhibitors (AZD4573 and VIP152) in clinical development. Screening of CDK9 inhibitors in an extended panel of organoid models revealed that most organoids are sensitive to CDK9 inhibition in nanomolar range. CDK9 inhibitors also prevented organoid outgrowth in long-term culture (>1.5 month) in drug-free medium.

Taken together, we demonstrate that HGSC organoids from material sampled during first-line treatment predict most drug sensitivities of relapse-derived organoids. This suggests a feasibility of functional precision approach for selection of second-line therapy using only primary tumor material, circumventing the problem of limited time available for the therapy choice after tumor sampling. This work also highlights that CDK9 inhibitors, currently in clinical development for hematological malignancies, are worthwhile to be explored in HGSC.

#0236 Modeling multi-step retinoblastoma genesis with cone reporter retinal organoids.

J. Bai[1], D. S. Koos[1], K. Stepanian[1], K. Stachelek[1], B. Bhat[1], S. Fraser[2], R. Moats[1], D. Cobrinik[1];
[1]Children's Hospital Los Angeles, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA

Purpose: This study aims to develop a human retinoblastoma organoid (RBRO) model that recapitulates the cell-of-origin and multi-step retinoblastoma genesis.
Background: Retinoblastomas originate from maturing cone photoreceptor precursors with biallelic *RB1* inactivation. *Rb1* mutant animal models fail to recapitulate retinoblastomagenesis with a cone precursor cell-of-origin, likely due to human-specific cone development features. In explanted fetal retina, pRB-depleted post-mitotic cone precursors proliferate, followed by a 3-5 month premalignant indolence phase before retinoblastoma-like masses emerge at tissue ages similar to retinoblastomas *in vivo*. However, tissue availability limits research with this disease model. *RB1*$^{-/-}$ retinal organoids (ROs) provide a potential alternative, as they demonstrate cone proliferation, but they deteriorate before forming indolent premalignant lesions or malignant retinoblastoma foci. Here, we developed methods with which to examine the effects of cone precursor pRB loss in otherwise healthy retinal tissue.
Methods: We generated cone-reporter GNAT2-EGFP iPSC lines through CRISPR knock-in of EGFP-P2A at the N-terminus of *GNAT2* in WTC11-mTagRFPT-LMNB1. A second round of CRISPR editing produced homozygous *RB1* knockout. Chimeric *RB1* WT ROs and *RB1*-null RBROs were generated from cone reporter iPSCs mixed with unedited parental iPSCs. ROs and RBROs were embedded in hydrogel and live-imaged episodically to track EGFP+ cone proliferation dynamics. scRNA-seq was carried out on FACS isolated EGFP+ *RB1*-null cones at various ages.
Results: In *RB1* WT ROs, EGFP+ cone precursors appeared at d34 and adopted cone morphology at ~d120, with rapid inner segment growth between ~d120 and ~d150. Immunohistochemistry confirmed cone-specific EGFP expression. In *RB1*-null RBROs, bi-weekly live confocal imaging revealed initial EGFP+ *RB1*$^{-/-}$ cone proliferation followed by a pre-malignant indolence phase starting at ~d150. The majority of the initially proliferating cones were Ki67-negative with some adopting mature cone photoreceptor morphology. Nascent retinoblastoma-like foci co-expressing EGFP, cone markers, and Ki67 formed in five of six RBROs after d281, a tissue age that equates to the first post-natal month when early retinoblastomas typically emerge. scRNA-seq of EGFP+ *RB1*$^{-/-}$ cones from the initial proliferation, indolence, and retinoblastoma-like stages revealed distinct molecular signatures.
Conclusions: We generated a human retinoblastoma organoid model that recapitulates the cell-of-origin and timing of multi-step retinoblastomagenesis, with each tumorigenesis stage harboring distinct molecular signatures. This model may enable the identification of epigenetic and transcriptomic changes underlying malignant progression and screening for compounds that efficiently block this process.

#0237 Establishment of an *ex vivo* tissue culture model as a potential preclinical drug testing platform for hepatocellular carcinoma.

H. Feng[1], M. Cieri[2], C. Esposito[3], K. Guja-Jarosz[3], D. Liberati[3], L. Bubendorf[1], S. D. Soysal[1], M. Coto-Llerena[1], L. M. Terracciano[2], O. Kollmar[1], S. Piscuoglio[3]; [1]University Hospital Basel, Basel, Switzerland, [2]Humanitas Clinical and Research Center,IRCCS, Milan, Italy, [3]Department of Biomedicine, University of Basel, Basel, Switzerland

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related deaths worldwide, and there is a critical need for more effective treatments. The development of new therapies, especially those aiming to modulate the tumor microenvironment (TME), is limited by the lack of *in vitro* and *in vivo* models that recapitulate the complexity of the TME and spatial architecture of HCC. Here, we aimed to establish an HCC model to assess the treatment response and hepatotoxicity of selected drugs by *ex vivo* culturing fresh human liver tumor tissue and adjacent normal tissue, respectively.
Materials and Methods: Fresh human liver tissues, including 5 malignant and 20 adjacent-normal, were obtained from surgical resections. PDX tumors were generated from patient-derived organoids. Tissue resections were cut into ultra-thin slices (from 150µm to 350µm) using a vibratome. Related culture conditions such as high oxygen partial pressure, air-liquid interface (ALI) culture, artificial extracellular matrix (AEM), and delay duration were evaluated to optimize the protocol. As a readout, cell viability was quantified by an expert pathologist using Hematoxylin/Eosin staining. The preservation and complexity of the TME were evaluated by immunohistochemistry or flow cytometry using specific antibodies for each cell population (T cells, anti-CD3; stroma cells, a-SMA; endothelial cells, CD34; Kupffer cells, CD68). Liver cell function was tested by measuring ALT/AST activity, albumin release, and CYP340 activity.
Results: The highest tissue viability was observed in normal and tumor tissue with a thickness of 150µm and 250µm, respectively. Compared to standard conditions, the combination of ALI and high-oxygen partial pressure conditions dramatically improved tissue viability, with most of the samples having 70% and 50% cell viability at days 3 and 5 of *ex vivo* culture, respectively ($p<0.05$). AEM could prevent the efflux of cellular components ($p=0.016$). The impact of the time delay between the liver resection and the start of slicing was minimal when the slicing occurred within two hours after hepatectomy ($p<0.05$). Key cellular components including hepatocytes, T cells, fibroblasts, and Kupffer cells also remained better preserved throughout the 5-day culture period in optimized conditions.
Conclusion: Our study has successfully optimized the *ex vivo* tissue culture model of liver tissue, capable of maintaining the tissue for several days while preserving the unique TME. These results highlight the potential of using the *ex vivo* tissue culture model in the preclinical setting to further investigate and evaluate TME-related treatments and their hepatotoxicity in HCC tissues.

#0238 Investigating size-dependent invasion behaviors and therapeutic responses of the 42MGBA glioblastoma spheroids.

S. Fok, Y. Ivanova, V. Kriuchkovskaia, B. Harley;
University of Illinois at Urbana-Champaign, Champaign, IL

Introduction: Glioblastoma (GBM) is one of the most aggressive malignant brain tumors. Many studies have reported that the tumor microenvironment (TME) contributes greatly to invasion and drug resistance of GBM. Our lab has previously described a tri-culture model using methacrylamide-functionalized gelatin (GelMA) with brain microvascular endothelial cells (BMVEC), human normal astrocytes (NHA), and human brain vascular pericyte (HBVP) recapitulated the *in vivo* brain microenvironment. However, phenotypic drug response was only observed under supraphysiological dosage. To evaluate therapeutic response more precisely, we decided to combine the Tri-culture system with the IdenTx3 microfluidic device (AIM Biotech). By separating the immature perivascular network from the GBM spheroids, we are hoping to generate a model that can more realistically mimic the TME. While many studies have used cancer spheroid in GBM studies, little is known about the impact of spheroids size. Since spheroid size correlates with nutrient and oxygen gradients, we are also curious to find out whether an increase in spheroid size increases the necrotic population and affects drug response and invasion.

Materials: Wild-type (WT) and TMZ resistant 42MGBA cell lines were seeded at different cell numbers to generate spheroids of different sizes. Spheroids were dissociated for flow analysis to quantify the necrotic population. In the invasion assay, spheroids were encapsulated in GelMA hydrogel with or without the addition of perivascular cells including BMVECs, HBVP, and NHA (3:1:1). Vasculature formation inside the chip was initiated 5 days prior to the introduction of GBM spheroids.

Results: 42MGBA-WT and 42MGBA-TMZres spheroids demonstrated phenotypical and proliferative differences. Spheroids sizes showed a direct relationship with necrotic cell numbers. Small spheroids (1000 cells) and large spheroids (10,000 cells) were encapsulated inside the hydrogel and subjected to different treatments of temozolomide. A difference in invasion area and proliferation was found when subjected to bulk or metronomic dosages. The two 42MGBA cell lines displayed an increase in invading area when co-cultured with perivascular cells. This result coincided with our previous finding that perivascular network increases GBM proliferation and invasion in GBM6 spheroid (Ngo et al, 2022). In addition, a different invasion behavior was observed between the 42MGBA-WT and 42MGBA-TMZres spheroids when introduced inside the microfluidic device. Surprisingly, the wildtype showed a larger invading area compared to the TMZ resistant.

Conclusion: We demonstrated a direct relationship between size and necrotic population in the 42MGBA spheroids. We also showed that bulk or metronomic treatment exert different effects on the cancer spheroids. Finally, we have verified that TME is critical to invasion and drug resistance.

#0239 Establishing a murine intratumoral bacterial model.

Ryan A. Hannon, Dongqing Xu, Fengyi Wan

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: Long thought to be sterile spaces, current evidence now suggests that host microbiota can be found within cancerous tissue. Emerging data has illuminated that microbes are integral components of tumor tissue itself, which may correlate with tumor progression, treatment responsiveness, and disease prognosis. A recent *Cell* article from *Fu et al.* demonstrated that tumor-resident intracellular microbiota can promote metastatic colonization in breast cancer. Others within this research landscape see therapeutic opportunity - harnessing the tropism of these microbes to deliver TME modifying payloads directly to cancerous lesions.
Purpose: Before studying the mechanism underlying their tropism to solid tumors, it is necessary to first establish a murine model that would allow for an oncotropic bacteria to be detected and quantified within tissues of interest. My research entailed the design and execution of pilot experiments developing xenograft melanoma and genetic colorectal models for future research projects.
Methods: In all mouse studies, an *E. coli* Nissle 1917 strain called "*NisLux*" was used, who's integration with a *luxCDABE* cassette allowed it to be selectively identified via luminescence using traditional exposure photography or endpoint luminescence detection using a 96-well plate reader. A xenograft melanoma model was developed using C57BL/6J mice and a B16-F10 murine melanoma line. A genetics model was developed using C57BL/6J-*Apc*^{min} mice which spontaneously develop colorectal adenomas as they age. Tumors, spleens, and healthy tissue were harvested and processed following tail vein injections of either *NisLux* or PBS solution. Harvested tissue was normalized by weight and concentration of resident *NisLux* was calculated from serially diluted samples plated on LB agar.
Results: In both the xenograft and genetics murine models, *NisLux* exhibited tropism to tumor sites, enriching at a concentration above that of healthy background tissue. *NisLux* dosing correlated with splenomegaly without changes to the mass of the primary lesion compared to control.
Conclusions: *NisLux* exhibits tropism to tumor sites in our xenograft and genetics murine models. Both models should undergo further procedural and control optimization. Two possible modifications to future melanoma xenograft experiments include the collection of non-cancerous skin negative control samples and a further delayed takedown day for tissue processing. In future C57BL/6J-*Apc*^{min} mice experiments, healthy colon sections from *NisLux* dosed C57BL/6J mice should be used as negative controls. Overall, the results from both models were promising and encourage future exploration of the mechanism underlying *NisLux*'s tropism to solid tumors. Subsequent experiments could involve comparing the tropism of engineered KO strains to WT *NisLux* or performing comparative sequencing of isolated tumor resident *NisLux* to the initial dosing population.

#0240 Mix and match - A comprehensive pipeline for matched patient-derived PDX and PD3D® modelsfor cancer research and preclinical drug development.

J. Loskutov[1], E. Oswald[2], **L. Wedeken**[1], C. J. Reinhard[1], J. Schueler[2], C. R. A. Regenbrecht[1];
[1]CELLphenomics GmbH, Berlin, Germany, [2]Charles River Laboratories, Freiburg, Germany

Relevant *in vivo* and *in vitro* cancer models have been invaluable for our current understanding of cancer biology, as well as for therapy development. Using appropriate models in the drug development process significantly supports reliable and swift decision making in proceeding along the value chain. In parallel, animal experiments can be designed more specific to the scientific and regulatory needs, resulting in shorter development cycles and eventually the availability of better therapies for cancer patients. Patient-derived xenografts (PDX) are generated by implantation of cancerous tissue from a patient's tumor either under the skin (ectopic) or into the organ of tumor origin (orthotopic) of an immunocompromised mouse and are the most used *in vivo* model for preclinical drug development. Patient-derived 3D cell culture models (PD3D®) are gaining increasing significance as relevant *in vitro* cancer models that recapitulate the original tumor tissue's biology and are suitable for high-throughput drug screening. The combination of both platform's increases the translational relevance of the development pipeline and offers the possibility to enlarge the respective panels of tumor models. Tackling an unmet medical need, we initially created matched mesothelioma PD3D® and PDX models. Mesothelioma is an aggressive cancer with poor prognosis and limited treatment options. Development of new therapies is hampered by shortage of available relevant tumor models. We created PD3D® models from PDX mesothelioma models and vice versa and generated drug sensitivity profiles with standard of care such as Gemcitabine, platinum derivates and a number of targeted agents to confirm their suitability as matched models for future projects. We were able to prove that models express stable histological, phenotypic features and drug sensitivity profiles across the two platforms. With this proof-of-concept study, the feasibility to combine the PD3D® biobank comprising more than 500 models from CELLphenomics with the PDX bank from CRL including 700 PDX models, has gained momentum. In consideration of the changing regulatory landscape, the combination of *in vitro* and *in vivo* platforms is a crucial step towards a drug development pipeline that incorporates the principles of 3R and increases its translational value due to fully human technologies being the corner stones of the drug development process.

#0241 Patient-derived organoids as a reliable screening platform for assessing ADC efficacy and specificity.

D. Mori, V. Adegbenro, F. Morales, R. Overmeer, S. Lukovac, S. Boj, M. Derksen;
HUB Organoids, Utrecht, Netherlands

Antibody-drug conjugates (ADCs) are a new class of pharmaceutical drugs designed to deliver cytotoxic agents to cells expressing specific antigens selectively. Based on Paul Ehrlich's "magic bullet" concept, ADCs are designed to target cancer cells, minimizing systemic toxicity typical of conventional chemotherapy. ADCs structurally consist of a particular monoclonal antibody linked to a cytotoxic agent.
Patient-derived Organoids (PDOs) provide a new tool for studying cancer biology and patient stratification. PDOs are adult stem cell-based culture systems maintaining the patient-specific genetic and phenotypic characteristics, including surface marker expression. HUB Organoids has generated a large biobank of PDOs characterized on the genomic and transcriptomic level.
The work presented here shows the suitability of the organoid platform for performing ADC screening. Organoids were selected based on their target-antigen (TA) expression, assessed by flow cytometry and RPKM. Organoid killing was assessed with a viability readout (CellTiter Glo) after six days of treatment. Results of viability screening show a correlation between TA-targeting ADC-induced organoid killing and TA expression in the organoids.
These results reveal that PDOs hold value for the preclinical development of ADCs and for evaluating their tumor specificity. Moreover, PDOs have the potential to predict patient specific response to ADCs.

#0242 Development of organoids-bacteria co-cultures for medium-to-high throughput screening.

E. Valle-Encinas[1], M. Doorn[1], F. Pourfarzad[1], L. San Mateo[2], P. Gokare[2], D. Pocalyko[2], S. F. Boj[1], **C. S. Verissimo**[1];
[1]HUB Organoids, Utrecht, Netherlands, [2]Janssen Research & Development LLC, Philadelphia, PA

HUB patient derived organoids, (HUB-Organoids™ or PDOs) are self-organized epithelial cell structures with near-physiological features, extensively used to model aspects of cancer initiation and progression. Microinjection of colibactin-producing pks+ *E. coli* into the lumen of PDOs resulted in the appearance of two co-occurring mutational signatures identified in a subset of colorectal cancer (CRC) patients, demonstrating that pks+ *E. coli* plays a causative role in CRC development. The scalability of PDO bacteria microinjection is, however, limited and represent a bottleneck in the screening of preventive therapies for these patients. Here we develop a bacteria-PDO co-culture system (PDO-fragment exposure model), alternative to PDO microinjection, that is compatible with medium-to-high throughput screening methods. We validated the genotoxicity of colibactin-producing bacteria and showed the potential of the PDO fragment exposure model for the screening of drugs targeting colibactin-dependent genotoxicity.

#0243 Organoid co-cultures with allogenic T cells to assess toxicity and efficacy of bispecific antibodies.

C. Oyarce, V. Bruno, L. Spagnuolo, C. Beaurivage, J. Frias Aldeguer, F. Pourfarzad, R. G. J. Vries, **S. F. Boj**;
HUB Organoids B.V., Utrecht, Netherlands

Recent advances in cancer immunotherapy positively impacted the life expectancy of patients for an extensive range of clinical indications. With new treatment strategies, druggable targets and biomarkers being identified at an increasing pace, the number of patients eligible for cancer immunotherapy is expected to expand steadily. For example, the emerging Bispecific T cell Engagers (BiTEs) designed to simultaneously target CD3 and tumor-specific antigens and promote T cell cytotoxicity have seen recent clinical success. While BiTEs have been approved for the treatment of hematologic malignancies, promising therapeutic developments for solid tumors face hurdles in translating preclinical findings into therapy since conventional two-dimensional cancer models fail to recapitulate the immune cell interactions in the tumor microenvironment and therefore hold low clinical predictive value. We developed an innovative alternative, building on the discovery that adult stem cells proliferate and organize into three-dimensional organotypic structures that maintain complex characteristics of the original parental tissue, including molecular heterogeneity and morphological and functional traits.
Here, we show the development of a patient-relevant preclinical platform for immunotherapy development in which colorectal (CRC) and non-small cell lung cancer (NSCLC) organoids are co-cultured with allogenic or autologous T cells to evaluate the activity and assess the cytotoxic potential of a BiTEs. The expression of tumor-specific BiTE target antigens is determined in patient-derived organoids (PDOs) by flow cytometry. Following this assessment, T cell-induced organoid death is quantified and characterized in real-time by image-based analysis of fluorescent live/dead dyes. Additionally, we measure cytokine secretion as a read-out of T cell activation and function. In our co-cultures, T cell-induced PDO death was increased upon BiTEs treatment. Similarly, IFNγ secretion correlated with expression levels of the targeted tumor antigen. In addition, PDO apoptosis and IFNγ secretion increased in a dose-dependent fashion in the presence of the TA-targeting TCB.
In summary, our organoids and T cell co-cultures offer a powerful platform for developing and validating immunotherapies such as T cell-bispecific antibodies and will significantly contribute to our understanding of the critical factors determining successful immunotherapies.

#0244 Patient-derived organoids: A pre-clinical model to assess infection and killing capacity of viral vectors for cancer therapy.

F. Morales-Rodriguez[1], M. Sasso[2], T. Bezhaeva[1], S. Bailey-Bucktrout[2], K. Lai[1], F. Gkogkou[1], **S. Boj**[1];
[1]HUB Organoids, Utrecht, Netherlands, [2]Akamis Bio Limited, Abingdon, United Kingdom

HUB's patient-derived organoids (PDOs) are *in vitro* models that preserve tissue morphology and original cellular complexity. Additionally, PDOs are compatible with (high) throughput screening methods, enabling informed decision-making early in the drug development pipeline and significantly improving the odds of positive outcomes in clinical trials. Akamis Bio has developed experimental viral vector-based tumour gene therapies that have the potential to treat a variety of solid tumours by driving the expression of immunologically active biomolecules and therapeutic proteins hampering tumour immune evasion. These vectors are based on a replication competent, chimeric group B adenovirus backbone that selectively replicates and expresses transgene payloads in tumor cells, and additionally exerts oncolytic activity. To evaluate the efficacy of such a virus-based gene delivery strategy, HUB set up a proof-of-concept study to assess the propagation capability of Akamis Bio's viral vectors in tumour PDOs. Intact PDOs from primary pancreatic tumours were infected with several viral loads, ranging from 0.1 viral particles per cell (PPC) to 100 PPC. The viral vector encoded a GFP reporter gene to identify infected cells using fluorescence imaging. The cultures were imaged daily for 14 days, allowing the assessment of cytotoxicity and infection efficiency and dynamics. Independently of PPC, infections always started in the exterior of PDOs in a few GFP-positive cells. The gradual increase over time in GFP-signal toward the interior of PDOs suggests the high likelihood of secondary infection events. Crucially, GFP intensity was correlated with cell death in PDOs, as evidenced by morphological features detected in brightfield images. Moreover, the infection dynamics were dose-dependent, as the GFP intensity peak arose later with decreasing PPC. These results show the capacity of HUB PDOs to study the infection dynamics of Akamis viral vectors . This pre-clinical platform permits rapid and efficient screening and dose evaluation for oncolytic virotherapies. Unique access to extensive tumour PDO biobanks with characterized genomic landscapes allows best-in-class stratification of treatment response based on tumour type and genetic heterogeneity.

TUMOR BIOLOGY: Stem Cells in Tumor Initiation and Progression
Poster Session

#0248 HSPA9/mortalin regulates erythroid maturation through a TP53-dependent mechanism in human CD34+ hematopoietic progenitor cells.

T. Liu[1], C. Butler[1], M. Dunmire[1], G. Szalai[2], A. Johnson[2], J. Choi[3], M. Walter[3];
[1]West Virginia School of Osteopathic Medicine, Lewisburg, WV, [2]Burrell College of Osteopathic Medicine, Las Cruces, NM, [3]Washington University in St. Louis, St. Louis, MO

Mortalin, encoded by the HSPA9 gene, is a highly conserved heat-shock chaperone belonging to the HSP70 family. It is predominantly presented in the mitochondria, and is critical in regulating a variety of cell physiological functions such as response to cell stress, control of cell proliferation, and inhibition/prevention of apoptosis. Myelodysplastic syndromes (MDS) are a group of hematopoietic stem cell malignancies characterized by ineffective hematopoiesis, increased apoptosis of bone marrow cells, and anemia. Up to 25% of MDS patients harbor an interstitial deletion on the long arm of chromosome 5, also known as del(5q), creating haploinsufficiency for multiple genes including HSPA9. Our prior study showed that knockdown of HSPA9 induces TP53-dependent apoptosis in human CD34+ hematopoietic progenitor cells, consistent with cytopenia observed in MDS patients. Since anemia is another featured symptom of MDS, we hypothesize that HSPA9 plays a role in regulating erythroid maturation. To test our hypothesis, we inhibited the expression of HSPA9 using various methods and measured the erythroid maturation in human CD34+ cells. We used siRNA targeting HSPA9 and found that HSPA9 siRNA significantly inhibited the cell growth, increased cell apoptosis, inhibited erythroid maturation (using CD71 as a surrogate marker), and increased p53 expression ($p<0.01$) compared to control siRNA in human CD34+ cells. Pharmacologic inhibition of HSPA9 by the chemical MKT-077, an inhibitor of HSP70 protein family members including mortalin, also increased p53 expression and inhibited erythroid maturation in human CD34+ cells. In addition, knockdown of HSPA9 by shRNA showed significant inhibition of erythroid maturation in human CD34+ cells compared to control shRNA. In order to test whether the regulation of erythroid maturation by HSPA9 is TP53-dependent or not, we constructed shRNAs targeting TP53 genes and simultaneously transduced lentivirus containing shRNAs targeting HSPA9 and TP53 respectively in human CD34+ cells using double antibiotics selection (puromycin for shRNA targeting HSPA9 and hygromycin for shRNA targeting TP53). We found that TP53 knockdown partially rescued the erythroid maturation defect caused by HSPA9 inhibition, suggesting that erythroid maturation inhibition by HSPA9 knockdown is partly mediated through a TP53 mechanism. Collectively, our results suggest that the increased apoptosis and reduced erythroid maturation observed in del(5a)-associated MDS is TP53-dependent. HSPA9/mortalin may be a potential target to treat anemia in del(5q) MDS patients, although simultaneous loss of multiple genes on del(5q) likely contributes to the complex phenotypes observed in MDS. Thus, our study not only uncovers some underlying mechanisms of del(5q) MDS, but also provides potential therapeutic indications through gene targeting in clinical MDS treatment.

#0249 Deciphering the impact of TRIB3-ELF4 interaction in regulating CDK6 on cancer stem cell activity in endometrial cancer.

W.-L. Wang, W.-W. Chang;
Chung Shan Medical University, Taichung, Taiwan

Background: Endometrial cancer (EC) is the most common gynecological tumor among women worldwide, posing a serious threat to women's health. ELF4 (E74 like ETS transcription factor 4), a member of the ETS family, plays a role in facilitating cancer progression. Our previous work demonstrated the role of direct binding between ELF4 and tribbles pseudokinase 3 (TRIB3) in promoting β-catenin expression. In this study, we further explore ELF4's involvement in the maintenance of cancer stem cells (CSCs) in EC.
Methods: The vital role of ELF4 in EC was determined through gain- and loss-of-function assays. ELF4 was silenced in two EC cell lines, AN3CA and HEC-1A, and primary EC cells from a Taiwanese patient (EMC6), using RNA interference techniques. The expression of ELF4, TRIB3, and CDK6 in human EC samples was assessed using immunohistochemistry. Tumorsphere formation assays, quantitative real-time PCR, and immunoblotting quantified CSC activity and the involvement of related signaling pathways. Transcriptional regulation associated with ELF4 was investigated using luciferase reporter assays and chromatin immunoprecipitation.
Results: Analysis of the TCGA database via the TISIDB web tool revealed that elevated ELF4 levels correlated with higher histological grades, advanced clinical stages, and poorer overall survival in EC patients. A grade-dependent increase in ELF4 expression was observed using tissue microarrays. Knockdown of ELF4 in EC cell lines and patient-derived EC cells significantly reduced cell proliferation, cell cycle progression, migration, invasion, and CSC activity. RNA-seq data analysis of ELF4-knockdown EC cells identified CDK6 as a potential downstream target of the ELF4/TRIB3 interaction. Knockdown of ELF4 and TRIB3 significantly downregulated CDK6 expression. Co-expression of TRIB3 and ELF4 enhanced CDK6 expression, and their expression was positively associated with CDK6 in EC specimens. We also demonstrated that CDK6 facilitates EC-CSC activity. Knockdown of CDK6 significantly attenuated tumorsphere formation and reduced the levels of cancer stemness-related proteins, including OCT4, NANOG, and c-MYC.
Conclusion: Our study demonstrates the essential roles of ELF4 and TRIB3 in regulating CDK6 expression, contributing to the maintenance of EC-CSCs.

#0250 Sex differences in cancer stemness among individuals with early onset colorectal cancer.

O. Aladelokun[1], K. Sumigray[2], S. A. Khan[2], C. Johnson[1];
[1]Yale School of Public Health, New Haven, CT, [2]Yale University, New Haven, CT

Since 1990, the overall incidence and mortality rates of late onset colorectal cancer (LOCRC ≥50 years) have been decreasing due to improvements in access to screening and available treatment options. However, the rates for early onset CRC (EOCRC ≤ 49 years) have steadily increased in men and women. Less than 30% of LOCRC patients present with late-stage tumors (clinical stages III or IV) at the time of diagnosis compared to 70% of EOCRC patients. Despite this, the cellular and molecular mechanisms underlying the incidence and stage are unclear, as are appropriate strategies for prevention of recurrence in men and women with EOCRC. Effective prognostic markers are therefore urgently needed. To address this issue, we performed a detailed bioinformatics analysis based on Gene Expression Omnibus database (GSE39582; n=585 patients), wherein we identified 7 prognostic biomarkers for EOCRC: *KRAS, LGR5, CTNNB1, MYC*, *BMI1, CD44* and *ASNS*. Importantly, Kaplan Meier analysis revealed tumor onset at a younger age was significantly (p = 0.0082) associated with poorer 5-year survival in men with EOCRC only, after adjusting for KRAS status. *CTNBB1* and *CD44* transcript levels were higher in men with EOCRC versus men with LOCRC. Conversely, female EOCRC had a higher frequency of *KRAS* mutations (52.6%) compared to their LOCRC counterpart (38.8%), and an increased expression of markers of tumor stem cell and metabolic reprogramming including *LGR5, MYC, BMI*, and *ASNS.* A single CRISPR-Cas9 deletion of *ASNS* in HCT116 cell lines, a pre-clinical model of EOCRC, caused an inhibition of 3D spheroid formation compared to HCT116 *ASNS* wild type cells. In vivo study using a cell line derived R2G2 mouse xenograft model showed that ASNS disruption caused a reduction in tumor burden that was accompanied by low *Lgr5* and *Myc* transcripts compared to the *ASNS* wild type group, indicating that ASNS may regulate cancer stemness. Together, this data suggests a unique molecular fingerprint for EOCRC and highlights sex-specific influences on cellular metabolism during EOCRC progression.

#0251 MCAM controls mammary cell state in luminal progenitor-derived breast cancer and alveologenesis.

B. L. Gates[1], O. Balcioglu[1], D. W. Freeman[1], B. M. Hagos[2], B. T. Spike[1];
[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]Oregon Health and Science University, Portland, OR

To establish and maintain functional and properly formed tissues, cells must integrate cues from their environment into fate decisions. External cues—from other cells and the extracellular matrix for instance—must be met with appropriate responses to ensure cell fate decisions that control lineage plasticity and favor proper development, maintenance, or regeneration of tissues while suppressing neoplastic transformation. MCAM (CD146; MUC18; S-endo-1; and Gicerin) is an integral membrane glycoprotein whose misexpression is associated with a variety of epithelial cancers, including breast cancer. However, the mechanisms by which MCAM conveys extracellular cues into malignant cellular outputs is not well understood. Our observation that MCAM is normally expressed in transplantable fetal and adult mammary stem cells (MaSCs) with multilineage potential, suggested it could control mammary cell state plasticity in both neoplastic and normal mammary tissue. Using a plastic, mouse mammary tumor cell line derived from the MMTV-PyMT mouse (Py230) that has been reported to exhibit mammary stem cell and luminal progenitor features, we tested the role of Mcam in controlling the tumorigenicity and lineage/cell-state relationships of mammary tumor cells. We found that Mcam knockdown in Py230 cells increases STAT3 expression, activation, and downstream target transcription, leading to a shift in the predominant cell state away from a luminal progenitor state toward more differentiated alveolar and basal phenotypes. Mechanistically, these changes involve altered activity of casein kinase II (CK2) against multiple substrates including STAT3 and PTEN. This effect may be mediated by direct coupling and sequestration of CK2 to various substrates via the cytoplasmic tail of MCAM. We have also found that inhibition of Ck2 or Stat3 reversed the transcriptional state change elicited by *Mcam* knockdown. In grafted tumors *in vivo*, this state switch correlates with reduced overall tumorigenicity and attenuated expression of Sox10, a gatekeeper of neural crest-like invasive features. In the normal gland, we hypothesize that this activity regulates multilineage stem cell potential upon transplantation and multilineage regenerative potential across lactation/involution cycles as we found reciprocal expression patterns for MCAM and STAT3 in alveolar mammary epithelial cells. These data point to an integral role for MCAM in lineage plasticity of normal mammary epithelial cells that is co-opted during transformation to potentiate tumor cell plasticity, progression, and evasion of targeted cancer therapies.

#0252 Functional and lineage atlas of salivary gland regeneration charted by rapid in vivo gene targeting.

Q. Gan, Z. Ying;
Icahn School of Medicine at Mount Sinai, New York, NY

The crucial function of the salivary gland of keeping the oral cavity lubricated to facilitate breathing, swallowing, and lingual communication is often compromised following cancer radiotherapies. Due to the ultra-high radiosensitivity and low regeneration potential of the salivary epithelium, radiation-induced damage is largely permanent, representing a major clinical challenge. To solve this problem, we have developed a scalable rapid gene targeting system in the murine salivary gland using in-utero injection of lentiviruses. This allows us to transduce ectodermal progenitors of salivary glands with high efficiency and full randomness. Barcoded lentiviral lineage tracing suggests that every major salivary gland originated from a defined number of progenitors, each progenitor-derived clone has relatively equal expansion potential during development and equally contributes to regeneration post radiation challenge. This observation indicates that the major salivary glands of a single mouse can be used as a platform to study lineage dynamics or test up to ~2600 different genetic conditions during regeneration. With this robust approach in hand, we identified major barriers to salivary gland regeneration from among hundreds of differentially regulated signaling pathways and genes post-irradiation. Based on these discoveries, we are currently in the process of 1) Understanding the molecular mechanisms underlying the top regeneration barriers; 2) Dissecting the cell fate dynamics of salivary gland regeneration with or without regeneration barriers; and 3) Testing if we can restore the salivary gland in situ via combinatorial removal of regeneration barriers. Our work will provide unbiased functional and lineage roadmaps of post-irradiation salivary gland regeneration and potentially serve as the cornerstones of future therapeutic interventions.

#0253 Investigating key molecular players in putative stem cell subpopulations of prostate cancer.

W. Cheng[1], M. D. Menna[1], F. Bonollo[1], P. Chouvardas[1], G. N. Thalmann[2], S. Karkampouna[1], M. K. d. Julio[1];
[1]University of Bern, Bern, Switzerland, [2]Inselspital Hospital, Bern, Switzerland

Background: Androgen deprivation therapy is the standard treatment for prostate cancer (PCa). Nevertheless, despite initial effectiveness, pre-existing cancer stem cell (CSC) populations invariably lead to incurable castration-resistant prostate cancer. CSCs are a subset of cancer cells possessing self-renewal properties, driving tumor progression and regrowth. CD44+ PCa cells exhibit more stemness features and are enriched in tumorigenic and metastatic progenitor cells. Here, we aim to explore different subpopulations in tumors based on levels of CD44 expression and investigate whether they have distinct molecular properties and functional characteristics.
Material and Method: The number of CD44+ cells was evaluated in a tissue microarray from primary prostate cancer patient samples (EMPACT cohort) with clinical follow-up. Flow cytometry sorted the CRPC model LAPC9 tumor into CD44 high (CD44-H) and CD44 low (CD44-L) cells. RNA sequencing was performed on these subpopulations to explore their transcriptomic profiles. CD44 expression was validated at the cDNA and protein levels using qPCR and Western blot (WB) analysis. Sorted cells were maintained as organoids in vitro. To trace the dynamics of CD44-H and CD44-L subpopulations in vivo, LAPC9 tumor was labeled by fluorescent and luciferent markers. The CD44 status was determined by flow cytometry when tumor growth.
Results: Patients with elevated expression of CD44 (higher number of CD44+ cells) at the time of surgery exhibited a greater propensity for clinic progression (5-year progression-free survival: 75% vs 95%, P=0.03). Furthermore, CD44-H cell ratio increased in the LAPC9 after castration, indicating that CD44-H cells can survive after treatment. Subsequent WB analysis confirmed that CD44 was highly expressed in sorted CD44-H cells, validating the flow cytometry results. Analysis of the CD44 RNA-seq data showed CD44 transcript variants CD44v10 (CD44-201) and CD44v7-10 (CD44-209) were notably upregulated in CD44-H cells. In organoid culture, sorted CD44-H cells displayed enhanced formation, indicating they possessed higher proliferative capacity and clonogenicity than CD44-L cells. Furthermore, when GFP-labeled CD44-H cells and RFP-labeled CD44-L cells were recombined in vivo, CD44-H cells exhibited robust proliferation, while CD44-L cells transitioned to a CD44hi state to facilitate tumor growth. Moreover, those GFP and RFP subpopulations displayed the same CD44hi cell ratio at the endpoint.
Conclusion: Elevated CD44 expression is related to an increased risk in primary PCa. In addition, CD44-H cells exhibit high tumorigenicity in vitro and in vivo and can convert to each other. Moreover, the ratio of CD44-H cells in tumor at endpoint is consistent despite the starting CD44 expression status. Furthermore, the upregulation of CD44v10 and v7-10 in the CD44-H subpopulation may promote tumor formation and metastasis.

#0254 Triggering head and neck cancer cell cornification leads to mucosa-like differentiation, chromatin remodeling, and loss of cell malignancy.

F. Oppel[1], S. Gendreizig[1], L. Martinez-Ruiz[2], J. Florido[2], A. Lopez-Rodriguez[2], H. Pabla[1], L. Loganathan[1], L. Hose[1], P. Kuhnel[1], P. Schmidt[1], M. Schurmann[1], J. M. Neumann[3], F. Viyof Ful[1], L. Scholtz[1], I. Todt[1], L. Dina[4], F. Brasch[4], N. Karsten[3], G. Escames[2], T. Busche[1], J. Kalinowski[1], P. Goon[5], H. Sudhoff[1];
[1]University Hospital OWL of Bielefeld University, Bielefeld, Germany, [2]Institute of Biotechnology, Biomedical Research Center, Health Sciences Technology Park, University of Granada, Granada, Spain, [3]Bielefeld University, Bielefeld, Germany, [4]Klinikum Bielefeld, Bielefeld, Germany, [5]National of University of Singapore and National University Health System, Bielefeld, Singapore

Head and neck squamous cell carcinoma (HNSCC) is the 6th most common tumor disease worldwide with a death rate of about 50%. As mortality and morbidity of affected patients were not substantially improved in recent decades, new treatment options are urgently needed. HNSCCs that are negative for the human papillomavirus are characterized by areas of differentiated keratinized tissue. Dissecting the mechanisms regulating this terminal differentiation of HNSCC cells may unravel targets with high potential for anti-tumor therapy. Using primary tumor-initiating spheroid cells, we established a model of HNSCC cell differentiation by cornification and observed a deprivation of cell malignancy leading to the adhesion of spheroid cells, loss of single-cell cloning capacity, and diminished tumor-initiating potential in immunodeficient mice. Analysis of our differentiation model employing ATAC-seq, RNA-seq, and proteomics showed an increased accessibility of small promoter regions despite overall genome closure, activation of a wound healing-associated signaling program, and upregulation of the stress keratin 17 (KRT17) as well as cornification markers including SPRR3. These results suggest that the differentiation of HNSCC cells resembles the differentiation process in other stem cell-maintained tissue systems. Multi-marker immunofluorescence analysis of human tissue revealed a reversion of the role of KRT17 from a basal stem-cell marker in normal mucosa to an early differentiation marker in HNSCC tissue and dysplastic mucosa preceding cornification. This proposes KRT17 as potential biomarker for HNSCC prevention screening. Human tissue analysis identified distinct cell differentiation states shared between HNSCC tissue and normal mucosa that were detected in higher and lower differentiated tumor tissue of distinct anatomical sub-locations. Cornification was observed to be induced at the interface between vital tumor tissue and necrotic, immune-infiltrated areas in human HNSCCs, suggesting a promoting influence of pro-inflammatory stimuli on cell differentiation. Treatment of tumor spheroids with inflammatory mediators resulted in cell attachment and cornification, indicating a potential strategy to stop the self-renewal of HNSCC cells. Our study thus reveals that the targeted differentiation of HNSCC tumor-initiating cells could be used as a future therapy approach against squamous cell carcinomas of the head and neck and other tissues.

#0255 Redefining SOX2 as a bifunctional mediator of transcription and adjusted translation control.

N. Mittal[1], M. Ataman[1], H. Wang[2], S. Candido[1], J. Lotscher[1], S. Velychko[3], L. Tintignac[1], T. Bock[1], A. Borsch[1], J. Ba?ler[4], T. Nageswara Rao[5], J. Zmajkovic[6], S. Roffeis[1], J. Loliger[1], F. Jacob[1], A. Dumlin[1], C. Schurch[1], A. Schmidt[1], R. C. Skoda[1], C. Hess[7], H. R. Scholer[8], H. Zaehres[9], E. Hurt[4], M. Zavolan[1], C. Lengerke[10], **T. Schaefer**[1];

[1]University of Basel, Basel, Switzerland, [2]Shanghai University of Medicine and Health Sciences, Shanghai, China, [3]Harvard Medical School, Boston, MA, [4]University of Heidelberg, Heidelberg, Germany, [5]Cantonal Hospital St. Gallen, St. Gallen, Switzerland, [6]IMP, Vienna, Austria, [7]University of Cambridge, Cambridge, United Kingdom, [8]Max Planck Institute for Molecular Biomedicine, Munster, Germany, [9]Ruhr University Bochum, Bochum, Germany, [10]University Hospital Tubingen, Tubingen, Germany

The vertebrate transcription factor SOX2 (SRY Homology Box 2) is essential for stem cell maintenance, a prominent (co)inductor of pluripotency in reprogramming technology, and an oncogenic driver of transformation, therapy resistance, and disease relapse in cancer. These cell fate discriminatory events are currently understood as SOX2-imposed changes in DNA activity and the resultant co-transcriptional rewiring inside the cell's nucleus. Cytoplasmic forms of SOX2, on the other hand, receive comparatively little scientific attention and are typically marginalized as a molecular reservoir for nuclear entry. We now challenge this notion as we identify further cell fate discriminatory significance selectively within the cytoplasmic pool of SOX2.

Specifically, we find extra-nuclear forms of SOX2 in physical association with the ribosome where they modulate the translation rate of selected, SOX2-imposed mRNAs in the cytosol. These translational adaptations occur independent of nuclear structures or DNA and involve protein segments that have no DNA-binding capacity on their own. Very intriguingly, whereas transcriptional SOX2 targets impose stemness and pluripotency phenotypes, the newly identified co-translational targets predominantly relate to morphogenesis and differentiation events. This matches natural expression patterns in early ontogenesis, where SOX2 stains the nuclei of the inner cell mass (i.e., embryonic stem cells, ESCs), but the cytosol of the surrounding trophectoderm (i.e., differentiating non-stem cells). Most importantly though, we find the ribosome modulatory activity of SOX2 functionally abolished by a disease-linked human polymorphism, indicating a (patho)physiological relevance of our discovery.

Taken together, we present experimental evidence that redefines SOX2 as a bifunctional modulator of transcription and translation control, which may pave the way for further refinements in reprogramming technology and the fight against cancer.

#0256 A novel transcriptional complex of OLIG2-STAT5 mediates glioma stem cell self renewal and invasion.

A. Miller[1], C. Lo Cascio[2], M. Blomquist[1], J. B. McNamara[2], K. Orndorff[2], M. Dufault[2], C. Sereduk[1], J. Loftus[1], S. Mehta[2], N. L. Tran[1];
[1]Mayo Clinic College of Medicine and Science, Scottsdale, AZ, [2]Barrow Neurological Institute, Phoenix, AZ

Glioblastoma (GBM) is the most common and lethal primary brain tumor in adults, despite current treatment options. One of the major contributing factors to this dismal outcome is a subset of cells called glioma stem cells (GSCs) that are highly tumorigenic, invasive, and resistant to conventional treatments. Thus, studies that focus on the properties of GSC biology are needed to develop novel therapies to improve overall survival. Here we report a novel role of STAT5 in GSC stemness and survival. In GBM tumors, STAT5 has been shown to be active in the infiltrative, residual population of cells remaining post-surgery. Knockdown of STAT5 results in the decrease in GSC stemness and therapeutic resistance. Interestingly, we find that expression of OLIG2, a key cell fate factor important for the tumorigenic potential of GSCs, affects STAT5 activation with a positive correlation between OLIG2 and STAT5 mRNA expression in GBM tumors. Furthermore, we find that in GSCs expressing EGFRvIII, STAT5 interacts with OLIG2 and pharmacological inhibition of STAT5 activation or knockdown of STAT5 expression results in decrease of OLIG2-mediated GSC invasion. Together, these data suggest a novel transcriptional complex, STAT5-OLIG2, in the potential role for GSC survival, maintenance, and invasion.

#0257 Plasticity of preneoplastic cells drives esophageal squamous cell cancer initiation.

K. Ko, J. Zhang, S. Jun, J.-I. Park;
UT MD Anderson Cancer Center, Houston, TX

Esophageal squamous cell carcinoma (ESCC) accounts for over 80% of esophageal cancer, with a poor prognosis mainly due to a lack of early-stage symptoms. Early detection of ESCC is challenging due to its origin in the basal cell layer and invasion into the lamina propria upon becoming neoplastic. Thus, understanding the transition mechanism from preneoplasia to neoplasia is crucial for early-stage detection of ESCC before dissemination. To dissect the mechanisms of ESCC preneoplasia and neoplasia, we utilized both spatial and temporal datasets of ESCC in conjunction with a genetically engineered organoid model. For spatial datasets, we conducted comparative analyses of single-cell transcriptomes from healthy esophageal tissues, normal tissue adjacent to cancer (NAC), and paired ESCC tumors to identify distinguishable preneoplastic cells. Notably, unlike normal or ESCC, NAC harbors a distinct preneoplastic cell cluster characterized by the exclusive expression of the *CELF2* (CUGBP Elav-Like Family Member 2) gene, high gene copy number variations, cell hyperproliferation, and apoptosis, reminiscent of a 'crisis state'. Consistently, we detected a significant presence of CELF2 positive (+) cells at the stage of inflammation, a very early lesion preceding neoplasia in a temporal model of ESCC development. Copy number variations were also already abundant from the inflammation stage, as we observed in the NAC dataset. Interestingly, both spatial and temporal preneoplastic cells showed decreased scores of *TP53* and *CDKN2A* signaling pathways, of which mutations are observed in 68% of ESCC patients. To recapitulate this phenotype, we employed genetically engineered esophageal organoids and found that the loss of *Trp53* and *Cdkn2a* (PC) generated preneoplastic CELF2$^+$ cells. Intriguingly, these preneoplastic CELF2$^+$ cells exhibited remarkable cellular plasticity in two ways. Firstly, CELF2$^+$ cells of PC display increased stemness mediated by SOX2-driven reprogramming with disrupted normal esophageal cell lineage. Second, CELF2$^+$ cells of PC undergo epithelial-mesenchymal plasticity to generate fibroblast-like cells, releasing cytokines involved in immune remodeling. Consequently, preneoplastic CELF2$^+$ cells developed significant tumors compared to CELF2-negative cells in transplantation assays. Our study identified preneoplastic CELF2$^+$ cells driven by *TP53* and *CDKN2A* loss as pivotal drivers in ESCC initiation via cell-autonomous (cellular reprogramming) as well as non-cell autonomous (immune niche remodeling) processes, proposing CELF2$^+$ cells and their molecular signatures as potential biomarkers and therapeutic targets for early-stage ESCC.

#0258 An organoid model for investigating Lynch syndrome tumorigenesis.

Caroline Guild, Christopher Heinen, Samantha Nadeau

Center for Molecular Oncology, University of Connecticut Health Center, Farmington, CT

Lynch syndrome (LS) is the most common inherited predisposition for developing colon cancer and is caused by germline variants in mismatch repair (MMR) genes. Still, the mechanism of tumorigenesis in these patients is unknown. An LS patient inherits one defective copy of an MMR gene. At some point in their lifetime, the remaining wild-type allele is lost in a cell rendering it entirely MMR deficient. MMR deficiency increases mutational rate and the chance of acquiring mutations in an oncogene or tumor suppressor that drive tumor initiation. However, loss of MMR in cells also leads to increased resistance to certain forms of DNA damage. Thus, our question is whether this phenotype imparts a selective advantage in colonic cells that may lead to clonal expansion of MMR-deficient cells as a first step towards tumorigenesis in LS patients.

To test this, we are using stem cell-derived human colonic organoids and CRISPR gene editing to examine competition between MMR-deficient (MMRd) and MMR-proficient (MMRp) colonic cells over time. We have initially observed that MMRd stem cells are much more efficient at generating colonic organoids that grow larger and survive longer, consistent with our hypothesis of a selective advantage. To mimic the spontaneous loss of heterozygosity that occurs in LS patients' colonic crypts, we are forming organoids from differentially labeled MMRd and MMRp stem cells. Live fluorescent imaging of individual organoids is used to quantify changes in cell population over time. Preliminary data indicate that MMRd cells can outgrow MMRp cells resulting in a shift in the ratio of green to red cells over a two-week time period while challenged with a DNA-damaging agent. These results suggest that loss of MMR function imparts an immediate selective advantage in colonic cells in response to DNA damage.

#0259 Zebrafish empowered large-scale drug screen to uncover novel targets of self-renewal in T-cell acute lymphoblastic leukemia initiating cells.

M. Al-Hamaly[1], Y. Chernyavskaya[1], E. Arvin[1], L. Turner[1], M. Haney[2], J. Blackburn[1];
[1]University of Kentucky, Lexington, KY, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

T-cell Acute Lymphoblastic Leukemia (T-ALL) patients who experience relapse have a dismal prognosis, with 5-year overall survival rates of 10% for adults and 36% for children. Relapse is attributed to cytotoxic chemotherapy's inability to target Leukemia Initiating Cells (LICs) that have the potential to re-populate the cancer. There is a need for novel therapeutic strategies to target LIC self-renewal in T-ALL with improved safety profiles and better chances of transition to clinical development. This project utilized a transgenic zebrafish model that accurately recapitulates the most aggressive form of the human T-ALL. This model offered several advantages, including a high frequency of LICs and suitability for drug testing. Over 770 FDA-approved drugs were screened, *in vivo* using >2,500 syngeneic CG1 zebrafish. Further secondary screening in human T-ALL cells narrowed down the potential hits into 4 compounds that specifically interfere with self-renewal. Finally, the hit drug Amiloride was confirmed by a limiting dilation assay (LDA), resulting in a more than 4-fold decrease in the LIC frequency (p=0.0026). The top hit, Amiloride, which reduced the frequency of LICs in zebrafish and human T-ALL cells, is an inhibitor of the Sodium Hydrogen Exachanger-1 (NHE1). NHE1 has been previously linked to the proliferation, migration, and drug resistance of different cancers. In addition, Amiloride treatment was found to impair mitochondrial function in cancer cells, offering a possible mechanism for the inhibition of LICs. Research has not yet investigated how NHE1, and the altered mitochondrial dynamics related to its inhibition affect the development and persistence of LICs in T-ALL. In our human T-ALL cells, we found that Amiloride significantly reduced mitochondrial basal respiration (p=0.0074), ATP production (p=0.0008) and increased the expression of genes associated with mitochondrial stress such as *TFAM*, *PINK1*, *PARKIN* and *MT-CO1.* Experiments using shRNA mediated knock down of the NHE1 in human T-ALL cells are underway and will be followed by investigating the impact of NHE1 inhibition on primary patient-derived T-ALL cells in a mouse model. Overall, this project showcases of the power of the zebrafish in cancer research in an efficient and accurate large-scale screen for drugs that impact LIC self-renewal. We have identified Amiloride as a top hit that reduces the frequency of LIC *in vivo* and *in vitro*. Finally, we are continuing to investigate the role of the NHE1 in self-renewal in human T-ALL and the associated mitochondrial alterations.

#0260 Depletion of *Ezh2* in the intestinal adenoma induced by *JAK2V617F* mutation leads to the malignant neoplasm.

Nardana Esmaeili[1], Ahmed Bakheet[1], Wen Gao[1], Haifeng Li[2], Dan Cai[1], **Xiaonan Han**[1]

[1]Department of Medicine, MetroHealth Medical Center, Case Western Reserve University School of Medicine, Cleveland, OH,[2]Chinese Academy Institute of Medical Sciences (CAMS) and Peking Union Medical College (PUMC), Beijing, China

Background The increased JAK2 and EZH2 plays a critical role in the colorectal or colon cancer (CRC) progression. Targeting aberrant JAK2 expression caused by JAK2 gain-of-function (GOF) mutation, *JAK2V617F* and deregulated EZH2 kinase activity, JAK2 and/or EZH2 inhibitors have been used to treat the advanced CRCs. However, it is unclear whether the aberrant JAK2 can directly induce CRC or intestinal epithelial (IEC) malignancy.
We **hypothesize** that the overexpressed JAK2 driven by *JAK2V617F* GOF mutation increases IEC neoplasia in which depletion of EZH2 can lead to IEC malignant neoplasm.
Materials and Methods Colorectal samples were collected from 20 cases of CRC patients. Immunohistochemistry staining (IH), confocal immunofluorescence staining (IF) and bulk RNAseq were used to determine LGR5, Ki67, JAK2, EZH2, mutant β-catenin and *JAK2V617F* GOF mutation. Crypt-derived organoids or tumoroids were used to determine the JAK2 and EZH2 in the proliferative LGR5 cells ($Ki67^{hi}LGR5^{+}$) and were treated with JAK2 and/or EZH2 inhibitors. The mice with JAK2 and/or EZH2 deficiency in IECs were generated by crossing *VilCre*ER mice, floxed-*Jak2* and/or floxed-*Ezh2* mice to determine the intestinal and colonic neoplasia. Lgr5, Ki67, Cdx2 Jak2, Ezh2, and mutant β-catenin IH or IF, organoids culture and peritoneal xenograft were used to determine the malignant neoplasm. The *JAK2V617F*-transfected HT29 or Caco-2 cells were used to determine the migration induced by *JAK2V617F* GOF mutation, then treated with EZH2 inhibitors to determine the effects of EZH2 inhibition on *JAK2V617F* GOF mutation-induced migration. The spheres were formed with Caco-cells with *JAK2V617F* GOF mutation and were used to observe the effects of *JAK2V617F* GOF mutation on IEC neoplasia formation.
Results JAK2 and/or EZH2 overexpression are positively correlated with the probability of CRC initiation. JAK2 and EZH2 are highly expressed in the CRC tumoroids. Inhibition of EZH2 increases the CRC tumoroids growth and spheroid formation, and reduces budding numbers while reducing the proliferation of organoids from healthy crypts. *Jak2* over-expression in IECs increases intestinal microadenoma, and depletion of EZH2 in the adenoma increases mutant β-catenin and severity of intestinal adenoma, suggesting that depletion of EZH2 enhances the malignancy of overexpressed *Jak2*-derived IEC neoplasia. Consistently, J*AK2V617F* GOF mutation increases HT29 or Caco-2 cell migration.
Conclusion *JAK2V617F* GOF mutation can drive IEC neoplastic proliferation and adenoma, depletion of EZH2 in the adenoma leads to IEC malignant neoplasm. Our research suggests that loss of *Ezh2* may synergistically cooperate with the *Jak2V617F* mutation in the pathogenesis of IEC malignant neoplasm.

#0261 Akt1 and Cyclin D1 govern polarity of self-renewing divisions in breast cancer stem cells.

X. Jiao[1], X. Sun[2], Z. Li[1], X. Ju[2], D. Li[1], R. Harish[1], G. Robertson[3], A. W. Ashton[4], **R. G. Pestell**[1];
[1]Baruch S. Blumberg Institute, Wynnewood, PA, [2]Thomas Jefferson University, Philadelphia, PA, [3]Dxige Research Inc., Courtenay, BC, Canada, [4]Lankenau Institute for Medical Research, Wynnewood, PA

Background. Stem-like cells contribute to the development and progression of human cancers. Genes that control symmetric cell divisions have an evolutionarily conserved role in the regulation of cell polarity and in tumorigenesis. Two cells generated by asymmetric divisions have reduced proliferative potential compared with symmetric divisions. The cell survival oncoprotein Akt (Protein Kinase B) is encoded by three isoforms that are altered in human cancers. The Akt isoform-specific impact on breast cancer stem cell function and polarity is controversial, with Akt1 either reducing (1) or promoting (2) cell polarity and migration in tissue culture. Deletion of *Akt1* reduced mammary tumor progression and metastasis in transgenic mice (2,3).
Methods. Analysis of *Akt1*, cyclin D1 and Notch signaling was conducted from public databases, and human as well as murine breast cancer samples. Cells derived from *Akt1* gene deletion MMTV-ErbB2 breast oncomice (MMTV-ErbB2/Akt1$^{+/+}$ and MMTV-ErbB2/Akt1$^{-/-}$) and from the human MCF-7 breast cancer cell line with regulated expression of cyclin D1 and p53 were analyzed for the symmetry of cell division, stem cell function, and signaling pathways.
Results. In breast tumors derived from MMTV-ErbB2 transgenics, associated with reduced metastasis, Akt1 genetic deletion reduced the frequency of symmetric cell divisions and the production of mammospheres. *Akt1* deletion increased p53 and reduced cyclin D1. Pharmacological reactivation of p53 with Nutlin correlated with the reinduction of asymmetric cellular divisions and reduction in mammospheres in murine and human BCa cells. *Akt1* deletion abrogated Nutlin-mediated induction of asymmetric cell divisions. Cyclin D1 induced symmetrical cell divisions, mammosphere formation and reduced p53 and Numb.
Conclusions. Akt1 promoted symmetrical cell division at least in part via cyclin D1 suppression of Numb, and induction of γ secretase activity and thereby Notch signaling.

#0262 Gastrin-dependent suppression of CCK2R+ antrum stem cells inhibits gastric atrophy and cancer initiation in C57BL/6 mice.

B. Zheng, G. Lian, E. Malagola, H. Kobayashi, R. Tu, F. Wu, J. Qian, Q. Waterbury, Y. Ochiai, L. Zamechek, T. Wang;
Columbia University Medical Center, New York, NY

Background The cholecystokin-2/gastrin receptor (CCK2R) is expressed by rare epithelial cells in the gastric antrum that are bone fide +4 gastric stem cells. CCK2R+ antral stem cells are relatively quiescent, divide asymmetrically, and lineage trace entire antral glands. Their stemness is sustained over time through gastrin/CCK2R signaling (Cell Stem Cell 26, 739-754, May 7, 2020). However, the role of gastrin/CCK2R signaling in antral stem cells during mucosal injury and regeneration has not been explored.
Methods We generated CCK2R-CreERT2; Gastrin-BAC-DTR-P2A-TdTomato; Rosa26-ZsGreen mice in a C57BL/6 background. Hypogastrinemia was induced through diphtheria toxin-dependent ablation of antral G cells, while hypergastrinemia was achieved via Alzet pump gastrin infusion. Lineage tracing from antrum CCK2R+ stem cells was assessed quantitatively during homeostasis and also during injury in chronic H. pylori infection and MNU injury models.
Results Our findings revealed that G cell ablation increased lineage tracing of CCK2R+ antral stem cells at day 14 and increased proliferation of antral epithelial cells (Ki67+ cells) ($P<0.05$). Moreover, sorted antrum CCK2R+ cells (24 hours post-tamoxifen induction) from DT-treated mice had increased organoids forming capacity and in vitro cell growth, consistent with an increase in active progenitors, while hypergastrinemia reduced their growth ($P<0.05$). Numb staining showed that G cell ablation led to increased symmetric division of CCK2R+ stem cells, while gastrin infusion maintained asymmetric division ($P<0.05$). In the chronic H. pylori infection model, after 3 months of infection, the G cell ablation group exhibited more severe gastric antral atrophy compared to controls. In the MNU injury model, after 18 weeks of injury, the G cell ablation group had a higher dysplasia score, with dysplastic lesions largely derived from CCK2R+ cells ($P<0.05$). In our ongoing studies of MNU injury, the G cell ablation group at 36 weeks showed significantly greater tumor number and size than the control groups. Single-cell RNA-seq data showed that G cell ablation led to the proliferation and expansion of CCK2R+ antral stem/progenitor cells.
Conclusions In conclusion, while gastrin maintains long-term antral stem cell quiescence and self-renewal, hypogastrinemia over the short-term leads to expansion and proliferation of CCK2R+ antral stem cells, thus predisposing over the long-term to antral atrophy and cancer initiation. In C57BL/6 mice, hypergastrinemia appears to be a protective factor against antral cancer development.

#0263 RNA Editing ADAR1 Deaminase Activation Responsive (READAR) platforms for dynamic detection of clonal myeloproliferative neoplasm stem cell fitness.

I. van der Werf[1], L. Balaian[1], J. Pham[1], W. Ma[1], A. Mohebbi[1], E. Klacking[1], A. Ruiz[1], K. Mack[1], J. Mascarenhas[2], T. Whisenant[3], L. Alexandrov[3], S. Morris[1], C. Jamieson[1];

[1]Sanford Stem Cell Institute, Division of Regenerative Medicine, Department of Medicine, Moores Cancer Center, University of California, San Diego, La Jolla, CA, [2]Icahn School of Medicine, Mount Sinai, New York, NY, [3]University of California, San Diego, La Jolla, CA

Introduction Myeloproliferative neoplasms (MPNs) are clonal hematopoietic stem cell (HSC) derived disorders that can progress to acute myeloid leukemia (AML) at variable rates depending on macroenvironmental stressors and microenvironmental inflammatory cytokines. The total symptom score (TSS) and variant allele frequency (VAF) of mutations have proven valuable predictors of therapeutic response. Recently, we discovered inflammatory-cytokine-responsive ADAR1 RNA editing enzyme overexpression during MPN progression. However, dynamic prediction of clonal MPN stem cell fitness and progression to AML remains challenging.

Methods We performed longitudinal 150-gene next-generation sequencing (NGS) analyses for 129 MPN patients. We developed single-cell RNA Editing ADAR1 Deaminase Activation Responsive (READAR) platforms to quantify ADAR1 activity with a novel ADAR1 nanoluc-GFP reporter assay, whole transcriptome RNA editome analyses, and MPN stem cell replating assays. To identify novel RNA editing sites, we performed whole genome sequencing on $CD34^+$ cells from 43 MPN patients and whole transcriptome sequencing on FACS-purified HSC and progenitor cells from 32 MPN patients and 24 non-MPN controls.

Results Sequential NGS analysis was performed with a median follow-up of 958 days (range 0-4214; interquartile range (IQR) 314-1350). On average, 6 NGS analyses (range 1-19; IQR 3-9) were performed for each patient. In our cohort, 58.9% of patients were JAK2 V617F+, while mutations in CALR and ASXL1 were observed in 11.6% and 14.0% of cases, respectively. In total, 44.2% (N=57) of patients in our cohort received Inrebic, with 56% reaching the maximum dose of 400mg. Notably, most patients on Inrebic were JAK2 V617F+ (N=38, 67.7%). In JAK2 V617F+ patients on Inrebic, 50% (n=19) experienced a reduction in the JAK2 V617F VAF from their peak value with a median drop of 16% (range 4-57). Our analyses using READAR platforms revealed increased RNA editing levels in JAK2 V617F+ patients from whole transcriptome sequencing analyses compared with JAK2 wild-type patients. Transduction of our ADAR1 nanoluc-GFP reporter into $CD34^+$ cells from MPN patients (N=7), enabled us to quantify ADAR1 activity in an ex vivo setting. Moreover, $CD34^+$ cells from MPN patient samples (n=7) treated in stromal co-cultures with ADAR1 inhibitor, Rebecsinib, demonstrated inhibition of self-renewal in replating assays. A significant reduction in ADAR1-GFP reporter activity was observed in MPN $CD34^+$ cells following Rebecsinib treatment of stromal co-cultures. Also, humanized ADAR1-GFP-luciferase reporter AML mouse models showed a significant reduction in ADAR1 activity and leukemia stem cell self-renewal following Rebecsinib treatment.

Conclusion These READAR platform results suggest that ADAR1 activity can be utilized to predict clonal MPN stem cell fitness and progression.

#0264 Differentiation therapy: Esculetin as a potent agent to alter cellular plasticity of leukemic & solid tumor stem cells.

A. Mathur, D. Saluja;
University of Delhi, Delhi, India

Background The “Differentiation therapy” has been emerging as a promising and more effective strategy against acute leukemia relapses.
Objective In extension to the revolutionising therapeutic outcomes of All Trans Retinoic Acid (ATRA) to induce terminal differentiation of Acute Promyelocytic Leukemic (APL) blast cells, we decipher the potential effect of a natural compound “Esculetin” to serve as a differentiating agent in Acute Myeloid Leukemia (AML) as well as solid tumour cells. Underlaying role of Wnt signaling pathways in esculetin mediated blast cell differentiation was also evaluated.
Methods Human acute myeloid leukemic cells (Kasumi-1) with t(8;21/AML-ETO) translocation were used as a model system. Growth inhibitory and cytotoxic activity of esculetin were analysed using growth kinetics and MTT assay. Morphological alterations, cell scatter characteristics, NBT reduction assay and cell surface marker expression pat- terns were analysed to detect terminally differentiated phenotypes. We employed RT2profiler PCR array system for the analysis of transcriptome profile of Wnt signaling components. Calcium inhibitors (TMB8 and Amlodipine) and Transforming growth factor beta (TGF-β) were used to modulate the Wnt signaling axes. To investigate whether esculetin exerts the similar effects on the invasive solid tumour cancer stem cells subset, we used a cellular model system of colon carcinoma HCT116 cells reflecting EMT phenotype.
Results We illustrate cytotoxic as well as blast cell differentiation potential of esculetin on Kasumi-1 cells. Morphological alterations akin to neutrophilic differentiation as well as the corresponding acquisition of myeloid lineage markers indicate terminal differentiation potential of esculetin in leukemic blast cells. Exposure to esculetin also resulted in downregulation of canonical Wnt axis while upto ~ 21 fold upregulation of non-canonical axis associated genes. Esculetin also showed potential to revert the CSC marker expressions and concurrent EMT consistent with reduced functional aggressiveness in colon cancer cells.
Conclusions Our study highlights the importance of selective use of calcium pools as well as “axis shift” of the canonical to non-canonical Wnt signaling upon esculetin treatment which might abrogate the inherent proliferation to release maturation arrest and induce the differentiation in leukemic blast cells as well as CSC stem cells. The current findings provide further therapeutic interventions to consider esculetin as a potent differentiating agent to counteract relapses.

#0265 Reconstructing the early steps of breast tumor initiation.

Anais Grandon, Shuheng Lin, Martin Castagne, Julien Wicinski, Olivier Rosnet, Christophe Ginestier, Emmanuelle Charafe-Jauffret

Cancer Research Center of Marseille, Marseille, France

Breast cancer screening programs, detect not only the early stages of the disease but also various preneoplastic lesions which are very difficult to predict if and when they may develop into cancer. This uncertainty can lead to over-diagnosis, over-treatment and stress for millions of screened women. As consequence, discovering reliable biomarkers of this evolution could make it possible to monitor these patients appropriately and propose an effective prevention strategy. To meet this challenge, we urgently need to better understand the mechanisms that regulate human mammary homeostasis during early steps of tumor initiation. The hierarchy and the composition of human mammary epithelium, composed of stem, myoepithelial, luminal progenitors and mature luminal cells, are complex. This complexity raises the question of whether a given mammary epithelial cell is equally likely to be the cell-of-origin of breast cancer. Interestingly, increasing evidences show that disruption of lineage integrity can be a precursor of breast tumor initiation, and the basal and the luminal lineages respond differently to a given oncogenic stress and may each follow their own rule towards malignant transformation. These results strongly suggest that each lineage may have its own pliancy to be transformed by a given oncogene, hijacking the inter-tumoral heterogeneity observed in breast cancers. The objectives of this study are to develop a model to reconstruct the early steps of breast tumor initiation and understand the interplay between the initiating oncogenic event and the cell-of-origin. To answer these questions, we used a human mammary epithelial cell lines (HME) that maintains a cellular hierarchy with mammary stem cells (MaSC) and luminal cells (LC). Upon oncogenic expression of $HRAS^{G12V}$ or c-Myc, we observed different modifications of cell homeostasis, with altered proportions of the lineages populations in the cell line. Depending on the oncogenic stress induced, we also demonstrated a modification in the morphology and the cellular composition of HME organoids, as well as in the capacity to form tumors. $HRAS^{G12V}$ induces increase of MaSC compartment, formation of more branched organoids and generate aggressive basal-like tumors. Conversely, c-MYC leads to an almost loss of MaSC and formation of more proliferative unbranched organoid and generate tumors with limited growth. To address more precisely how cell-of-origin and lineage plasticity influence malignant transformation, we are developing for the first time a lineage tracing model in human mammary epithelium with HME. Moreover, a single cell RNA-seq was performed at different early time points during HME cellular differentiation in homeostasis and upon oncogenic stress to decipher the molecular mechanisms that underpin the very earliest steps of breast tumor initiation.

#0266 The effects of retinoid agents and retinoic acid receptor genotype on proliferation, differentiation, and stem cells in colorectal cancer.

V. O. Hunsu, C. O. B. Facey, B. M. Boman;
Helen F. Graham Cancer Center & Research Institute, Newark, DE

Understanding how to therapeutically target colonic stem cells (SCs) is important because SC overpopulation drives CRC growth and development. Our *goal* is to therapeutically sensitize cancer SCs (CSCs) to the differentiation-inducing effects of retinoid agents. We previously found that ALDH specifically marks normal and malignant colonic SCs. We also found that retinoic acid (RA) receptors and other RA signaling components are selectively expressed in ALDH+ SCs, indicating that RA signaling occurs through ALDH+ SCs. Because all-trans retinoic acid (ATRA) is a highly effective treatment for acute promyelocytic leukemia, which is caused by a genetic translocation involving retinoic acid receptor alpha (RARA), we conjecture that the response of RA agents may be effective against solid tumors depending on their pathway genotype. Our bioinformatics analysis on mutations and overexpression of RA signaling component genes in CRC showed that most of the RA pathway genes are altered in human CRCs. Therefore, we *hypothesize* that the ability of retinoid agents and retinoid metabolism blocking agents to induce differentiation of CSCs depends on the RA pathway genotype of CRC cells.Testing the effect of various retinoid drugs on cell proliferation shows that RA pathway genotype affects the response of RA agents in CRC cell lines. HCT116 and SW480 CRC cell lines, which have RA receptor mutations, displayed resistance to ATRA. In contrast, HT29 CRC cells that have wild-type RA receptors are sensitive to ATRA. All three cell lines however showed similar dose responses to the ATRA metabolizing enzyme, CYP26A1 inhibitor Liarozole. This finding indicates that regardless of RA receptor mutations, inhibition of ATRA metabolism can increase intracellular RA levels in a similar manner on all three cell lines to induce anti-proliferative effects. We used CRISPR-Cas9 gene editing to knock out the *RARA* gene in HT29 cells and evaluated its response to ATRA compared to HT29 cells. The *RARA* knockout derived lines showed reduced sensitivity to ATRA treatment and a slower rate of cell division compared to HT29 control cells. Additionally, Nanostring mRNA profiling analysis shows that ATRA treatment of HT29 cells increases expression of *RARA*, *CYP26A1*, and *KRT20* (differentiation marker); and decreased decreases expression of CSC markers *LGR5* and *ALDH1A1*. Altogether, these findings indicate that upregulated RA signaling can reduce cell proliferation, increase differentiation, and decrease CSC numbers in CRCs. Overall, our findings indicate that colon SCs are regulated by RA signaling mechanisms and dysregulation of RA signaling contributes to the SC overpopulation that drives CRC growth. Thus, therapeutically sensitizing CSCs to differentiation-inducing effects of retinoid agents should provide insight into designing new SC-targeted therapies for CRC.

TUMOR BIOLOGY: Stroma Interactions
Poster Session

#0270 Dissecting the effects of p53 mutation and p53 loss on pancreatic tumor microenvironment.
Y. Chen;
UT MD Anderson Cancer Center, Houston, TX

Pancreatic ductal adenocarcinoma (PDAC) is a devastating malignant disease with a dismal prognosis. In the past decades, a plethora of genetically engineered mouse models (GEMMs) with autochthonous pancreatic tumor development have greatly facilitated the studies of pancreatic cancer. Commonly used GEMMs of PDAC often harbor the oncogenic KRAS driver mutation (*Kras*^{G12D}), in combination with either p53 mutation by knock-in strategy (*Trp53*^{R172H}) or p53 loss by conditional knockout (*Trp53*^{cKO}) strategy, in pancreatic cell lineages. However, the systematic comparison of the tumor microenvironment between *Kras*$^{G12D;}$ *Trp53*^{R172H} (KP^{mut}) mouse models and *Kras*$^{G12D;}$ *Trp53*^{cKO} (KP^{loss}) mouse models is still lacking. In this study, we conducted cross-dataset single-cell RNA-sequencing (scRNA-seq) analyses to compare the pancreatic tumor microenvironment from KP^{mut} mouse models and KP^{loss} mouse models, especially focusing on the cell compositions and transcriptomic phenotypes of major cell types including cancer cells, B cells, T cells, granulocytes, myeloid cells, cancer-associated fibroblasts, and endothelial cells. We identified the similarities and differences between KP^{mut} and KP^{loss} mouse models, revealing the effects of p53 mutation and p53 loss on oncogenic KRAS-driven pancreatic tumor progression.

#0271 The effects of B-cell acute lymphoblastic leukemia cells on the adipose tissue microenvironment.

J. Tan, M. Cohen, J. Ding, I. Ahn, X. Yang, S. D. Mittelman;
UCLA Mattel Childrens Hospital, Los Angeles, CA

Obesity increases the risk of developing many cancers, including breast, colon, kidney, and acute lymphoblastic leukemia (ALL). We have previously shown that ALL cells are recruited to migrate into adipose tissue, where they are protected from chemotherapy. In vitro, ALL cells induce significant changes in adipocytes which may contribute to these protective effects. However, how ALL cells affect the complex cell populations found in adipose tissue in vivo remains unknown. We therefore conducted single-cell RNA sequencing (scRNAseq) of the non-adipocyte stromal vascular fraction (SVF) from adipose tissue in obese mice with and without implanted syngeneic BCR-ABL positive ALL. Differential expression analysis was performed on individual SVF cell types to compare ALL vs. control adipose tissue and pathway enrichment analysis was used in identifying altered molecular processes between conditions. SVF from leukemic mice showed substantial differences in gene expression compared to control mice, suggesting that the ALL potentially induces changes in the microenvironment. Some of the largest differences were found in adipose tissue macrophages, and pathway enrichment analysis identified neutrophil recruitment and regulation as one of the top ten pathways upregulated in adipose macrophages from leukemic mice (4.10 fold enrichment, p<1x10-17 by Fisher's exact test). Selected macrophage genes of interest in this pathway included CYBB (Cytochrome B-245 Beta), a neutrophil interaction gene that has been associated with macrophage infiltration in gastric cancer, was expressed 2.28 log2-fold higher in macrophages from leukemic compared to nonleukemic mice ($p<1x10^{-99}$ by Wilcoxon test). ITGAL (Integrin subunit alpha L), which has been shown to be involved in neutrophil recruitment and implicated in cancer cell growth and transformation was expressed 2.85 log2-fold higher in macrophages from leukemic mice ($p<1x10^{-99}$). Interestingly, adipose from leukemic mice showed a population of neutrophils (1.9% of SVF cells), while neutrophils were largely absent in adipose from nonleukemic mice (<0.1% of SVF cells), which is consistent with macrophage involvement in neutrophil recruitment. Our findings highlight the importance of adipose tissue in the leukemia microenvironment and show that ALL cells can influence this microenvironment in complex ways. Further work will confirm and investigate these cell-cell interactions, potentially improving our understanding of how adipose tissue contributes to cancer mortality.

#0272 Novel role for eIF4E in homing of acute myeloid leukemia cells.

L. M. Martinez[1], E. Caldas Lopes[1], M. Sugita[1], J. Gasiorek[2], K. Alilovic[1], K. L. B. Borden[2], M. L. Guzman[1];
[1]Weill Cornell Medicine, New York, NY, [2]Institute for Research in Immunology and Cancer, Universite de Montreal, Montreal, QC, Canada

Acute myeloid leukemia (AML) remains with dismal outcomes, mostly attributed to the inability of therapies to eliminate leukemia stem cells (LSCs) leading to relapse. LSCs home to the bone marrow (BM) niche where they maintain their quiescence state once in contact with mesenchymal stromal cells (MSCs). Therefore, understanding what controls AML-niche interactions could lead to therapeutic approaches that can prevent relapse.
First, we implemented a novel 3D in vitro system to mimic human AML-niche interactions. This 3D structure consists of a spheroid formed with BM-MSCs (HS5 cell line), recreating a hypoxic microenvironment. When AML cells (MM6 cell line) are added to the spheroid in a 1:1 proportion, AML cells migrate to the spheroid. After 24 hours, 0.18% of the AML cells home/colonize the spheroid (n=8). Next, we assessed the cell cycle status of AML cells in co-culture with the spheroid and compare to those in liquid culture or placed on a MSC monolayer (2D). We found that cells upon contact with MSCs increased their quiescence, 18.63% G0 in 2D and significantly higher in 3D conditions (25.03%; p=0.0048). It is also important to point out that colonizing cells have a lower proliferate capacity than non-colonizing cells after 7 days of co-culture (p=0.0286). This quiescence feature suggests a stem-like behavior of cells homing to the spheroid.
Eukaryotic translation initiation factor 4E (eIF4E) has been found altered in AML. While the capacity of eIF4E to increase cell migration and growth has been shown in solid cancers, the mechanism of eIF4E to accelerate AML progression remains unknown. Thus, we hypothesized that eIF4E may play a role in homing of AML cells to the niche. To this end, we used CRISPR to deplete eIF4E in MM6 cells and found that CRISPR 4E cells have significantly decreased homing capacity to the spheroid compared with control cells (p=0.0065). Importantly, we found a lower percentage of CRISPR 4E cells underwent quiescence after co-culture with MSCs (2D or 3D) (p<0.0001). We corroborated observations using xenograft mice. After 20 hours of intravenous injection, we observed a higher percentage of AML cells in the blood of the mice injected with CRISPR 4E cells compared with control cells (p=0.0286), suggesting that CRISPR 4E cells are not able to effectively exit from peripheral blood to home to their niche.
Altogether, we stablished a novel in vitro 3D model that mimics stem cell features of the AML-BM niche. We demonstrated that the depletion of eIF4E in AML cells decreases their homing and prevents them from acquiring niche-induced quiescence.

#0273 Extrinsic photoaging vs intrinsic aging in dermal fibroblasts: Its impact on the microenvironment and melanoma progression.

V. Wang[1], Y. Chhabra[2], L. Hueser[2], A. Weeraratna[1];
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Public Health, Baltimore, MD

Melanoma is the deadliest form of skin cancer, with chronological aging as a major negative prognostic factor due to the influence of intrinsic aging on the tumor microenvironment (TME) to promote tumor initiation and progression. Ultraviolet radiation (UVR) exposure, which is a major risk factor for melanoma, also can cause a physical premature aging phenotype, known as extrinsic photoaging, from chronic UVA irradiation of the underlying dermis. Photoaging of the skin often occurs in tandem with chronological aging, and contributes to similar physical alterations in normal skin structure. However, the molecular mechanisms of how photoaging compares to chronological aging in changing the TME and on tumor progression is still lacking. Here we found that extrinsically photoaged fibroblasts have a higher level of secretion of lysosomal proteases, Cathepsins, which have been shown to be secreted via lysosomal exocytosis and play a functional role in extracellular matrix (ECM) remodeling at neutral PH levels. We found that Cathepsins B and D are secreted at higher levels in both extrinsically photoaged young fibroblasts and in intrinsically aged fibroblasts and upregulated at the endogenous protein level. Cathepsin B has been shown to be highly expressed in metastatic but not primary melanoma patient samples, and cleaves ECM proteins such as fibronectin and tenascin. Immunofluorescent staining of *in-vitro* fibroblast derived matrices (CDMs) confirmed that photoaging disrupts subsequent deposited extracellular matrix proteins similarly to that of intrinsically aged healthy fibroblasts and these matrix changes influences the growth pattern of melanoma lines plated on these CDMs. Mass spectrometry analysis of secreted proteomics confirmed that aged fibroblasts secrete more cathepsins than intrinsically young fibroblasts, and Cathepsins B and D were also detected in extracellular vesicle (EV) cargo proteomics. Single-Particle Interferometric Reflectance Imaging (SP-IRIS) of EVs showed that UVA irradiation induced a significant increase in the total number of secreted of exosomes and in expression of tetraspanin protein CD63 , which plays a role in cargo sorting and has been detected in high levels in the plasma of melanoma patients. We hypothesize that extrinsic photoaging of fibroblasts induces the secretion of exosomes packaged with Cathepsins that play an integral role in ECM remodeling and matrix degradation in a beneficial manner for melanoma invasion. Further studies will assess the influence on secreted cathepsins on melanomagenesis and melanoma invasion through both mechanical and biochemical changes in the TME with *in-vitro* and *in-vivo* studies.

#0274 Cancer-associated fibroblasts exhibit increased motility under hypoxic conditions via interaction with cancer cells.

J. Park[1], S. Lee[1], J. M. Kurie[2], Y.-H. Ahn[1];
[1]Ewha Womans University, Seoul, Korea, Republic of, [2]University of Texas MD Anderson Cancer Center, Houston, TX

Cancer-associated fibroblasts (CAFs) are key components of the tumor microenvironment, playing various roles through interactions with cancer cells and other stromal cell types. In a 3D co-culture system of CAFs and lung cancer cells, a specific subgroup of CAFs exhibited increased motility, while another subgroup of CAFs remained stationary. Using the photoconvertible fluorescent protein Dendra2, we isolated these distinct CAF subgroups and conducted RNA sequencing. Gene set enrichment and gene ontology analysis revealed that upregulated genes in motile CAFs are associated with hypoxia and glycolysis. Conditioned medium from mesenchymal-like cancer cells enhanced the expression of genes related to hypoxia and glycolysis in CAFs. Among these genes, Aldoa and Ldha were chosen for knockdown in CAFs, resulting in a reduction in CAF motility. We confirmed that mesenchymal-like cancer cells promoted CAF motility and intensified hypoxic conditions within the co-culture system, which was monitored using a hypoxia reporter. Ceruloplasmin (CP) was identified as a secretory protein from mesenchymal-like cancer cells through mass spectrometry. Knockdown of CP led to the inhibition of CAF motility. In conclusion, the motility of CAFs is enhanced under hypoxic conditions facilitated by the secretion of CP from mesenchymal-like cancer cells in the lung tumor microenvironment.

#0275 Deciphering biphasic responses to Sonic Hedgehog pathway inhibition in breast cancer: Insights from a tumor-fibroblast spheroid model and PDXs.

H. M. Rosado-Galindo[1], M. Acevedo-Esquillin[1], W. Torres-Garcia[1], A. M. Reyes-Ramos[1], G. Ortiz-Soto[2], M. M. Martinez-Montemayor[2], **M. Domenech**[1]; [1]University of Puerto Rico - Mayaguez, Mayaguez, PR, [2]Universidad Central del Caribe, Bayamon, PR

A significant subset (30-40%) of triple-negative breast cancer (TNBC) cases exhibit hyperactivation of the sonic hedgehog (SHH) pathway, correlating with poor clinical outcomes. However, the therapeutic efficacy of SHH inhibitors in TNBC has yielded inconsistent results, showcasing biphasic tumor responses going from complete remission in some patients to faster disease progression in others. Such tumor response discrepancies underscore the need for more relevant culture models to elucidate how stromal cells respond to SHH signals and impact tumor cell reprogramming.We have developed a tumor-fibroblast spheroid model of robust paracrine SHH signaling to examine alterations in aggressive tumor cell phenotypes resulting from altered SHH pathway activity levels to understand better how SHH therapy leads to biphasic effects in tumor tissues. Specifically, tumor stemness alterations were examined as a function of SHH signal strength altered by tumor-fibroblast proximity, and findings were confirmed in two PDX models of TNBC of divergent sensitivity to pharmacological SHH pathway inhibition. In vitro, results show that tumor stemness potency is enriched by tumor-fibroblast proximity and inversely correlates with SHH pathway activity levels. Tumor stemness potency was determined via a mammosphere forming assay and resistance to chemotherapy using docetaxel as treatment. CD44+ sorted tumor cells derived from adjacent fibroblast cultures showed higher mammosphere forming efficiency and docetaxel sensitivity than those from mixed cultures. These effects correlated with differences in SHH pathway activity strengths and were reverted by pharmacological inhibition of SHH confirming pathway activity involvement. In two PDX models, both exhibiting high SHH pathway activity and similar tumor vascularization, we observed variable response to pharmacological SHH inhibition. PDX2 displayed favorable responses with minimal alpha-smooth muscle actin-positive (SMA+) fibroblast infiltration, while PDX1 exhibited no benefit from SHH therapy, accompanied by a high level of SMA+ fibroblasts. Spatial transcriptomic analysis confirmed stemness enrichments in the PDX1 model treated with SHH inhibitor- a scenario our mixed co-culture model resembled. Stemness-enriched tumor regions were positive for the Ki67 proliferation marker and confined to areas of high SMA+ cell abundance. Plotting Ki67 vs SMA+ cell levels revealed a positive correlation, suggesting that SMA levels may predict tumor response to SHH pathway inhibition.In summary, our studies demonstrate that pharmacological SHH inhibition can induce altered tumor plasticity by favoring stemness phenotypes. Strategies targeting tumor stemness may mitigate biphasic effects in response to SHH inhibitors, offering insights for optimizing TNBC therapeutic approaches.

#0276 Artificial intelligence-powered analysis of tumor-stroma ratio and fibroblast density as prognostic indicators in colorectal cancer.

M. Jung[1], J. Kim[1], M. Kang[2], J. Lee[2], S. Song[2], T. Lee[2], W. Jung[2], S. Cho[2];
[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Lunit, Seoul, Korea, Republic of

Introduction: The tumor microenvironment (TME) plays a critical role in cancer prognosis. In colorectal cancer (CRC), the tumor-stroma ratio (TSR) and cancer-associated fibroblast (CAF) density are emerging as prognostic markers. However, accurately quantifying them remains challenging. Recent studies have shown that artificial intelligence (AI)-powered analyzers can quantify features in the TME including these.
Methods: Lunit SCOPE IO, an AI-powered H&E whole-slide image analyzer that detects fibroblasts and segments cancer area and stromal area, was applied to evaluate TSR and CAF density in treatment-naive, stage II or III CRC surgical specimens (N = 207) from Severance Hospital. TSR was calculated as the ratio of the area of the cancer area (CA) to the sum of the CA and the cancer stromal area (CS) within a slide. CAF density was evaluated as the fibroblast density within the CA or CS, or the ratio between them. Cox survival analysis determined the hazard ratios (HRs) in progression-free survival (PFS) between the high/low TSR/CAF groups, defining high/low groups based on optimized hazard ratio (HR) cutoffs.
Results: The study found a mean TSR of 0.481±0.126 and CAF densities of 69.96±37.53/mm² (cancer area) and 1844.29±440.31/mm² (stromal area). Higher TSR, lower CAF density in CA, and higher CAF density in CS were linked to better prognosis (Table 1). The mean CAF ratio (CAF density of CS divided by CAF density of CA) was 33.92±25.35, and a group with high values showed a favorable prognosis. Dividing patients based on TSR and CAF ratio, we found that high levels in either or both metrics predicted better outcomes compared to low levels in both.
Conclusions: In this study, we found a favorable prognosis in the group with higher TSR or higher density of CAF in CS compared to CA. This result suggests that AI-enhanced analysis of TSR and CAF can effectively predict prognosis in CRC, highlighting the potential roles of these markers in cancer prognosis.

Table 1. Prognosis by tumor-stroma ratio (TSR) and cancer-associated fibroblast (CAF) density

Factor	Group	Hazard ratio (95% confidence interval)	Mean progression-free survival (months)	p-value
TSR (cutoff: 0.351)	Low (N = 34)	Reference	43.7	<0.001
	High (N = 173)	0.32 (0.19 - 0.56)	67.2	
CAF density of cancer area (CA) (cutoff: 46.8)	Low (N = 62)	Reference	69.3	0.056
	High (N = 145)	1.86 (0.98 - 3.50)	60.7	
CAF density of cancer stromal area (CS) (cutoff:1,901)	Low (N = 116)	Reference	58.2	0.015
	High (N = 91)	0.50 (0.29 - 0.88)	69.9	
The ratio of CAF density of CS to CA (CAF ratio) (cutoff: 53.1)	Low (N = 187)	Reference	61.5	0.043
	High (N = 20)	0.13 (0.02 - 0.94)	80.9	
Combination of TSR and CAF ratio	Both low (N = 32)	Reference	41.2	<0.001
	TSR high, CAF ratio low (N = 155)	0.32 (0.19 - 0.56)	65.8	
	TSR low, CAF ratio high (N = 2)	0.00 (0.00 - ∞)	83.4	
	Both high (N = 18)	0.06 (0.01 - 0.45)	80.2	

#0277 Cancer-associated fibroblasts, educated by tumor cells, differentially facilitate cancer cell invasion in cell-line based human gastric tumoroids.

H. Hwang, S.-B. Lee, **H.-J. Kuh**;
Catholic University of Korea, Seoul, Korea, Republic of

Purposes: Gastric cancer can be categorized into two subtypes: intestinal and diffuse. The latter is notorious for frequent peritoneal metastasis, resulting in a poorer prognosis. Cancer-associated fibroblasts (CAFs) in the tumor microenvironment play crucial roles in tumor invasion and metastasis. However, little is known about whether CAFs are associated with the differential progression between the two subtypes of gastric tumors. This study investigated whether differential cancer invasion may be attributed to tumor-specific CAF activation, using a cell-line-based human gastric tumoroid model.
Methods: Heterotypic tumor spheroids (TS) were prepared with human gastric cancer lines of intestinal (MKN28, MKN74) and diffuse type (MKN45, KATO III) mixed with human gastric fibroblasts (HGFs) using a minipillar-array chip previously developed. Invasion phenotype and expression of epithelial-mesenchymal transition (EMT)-related proteins were evaluated in heterotypic TSs. mRNA expression in HGFs isolated from heterotypic TSs was analyzed and compared between the two subtypes.
Results: While both heterotypic TSs displayed increased invasion by HGFs, the diffuse type TS showed a higher level of invasion with individual or amoeboid migration and loose binding of cancer cells with HGF. In contrast, the intestinal type TS showed collective migration and tight binding between cancer cells and HGFs. HGFs in each heterotypic TS exhibited differential morphology, matrix remodeling patterns, and gene expression in a tumor subtype-specific manner. Compared to normal HGFs, HGFs isolated from diffuse heterotypic TS showed enriched expression of cytoskeleton-associated genes and several integrins, whereas those of intestinal heterotypic TS exhibited increased expression levels of inflammatory cytokines.
Conclusions: This study established tumoroid models for human gastric cancer subtypes, intestinal and diffuse, using heterotypic TS culture. Our results suggest that the subtype-specific invasion ability of tumor cells is driven by CAFs that are differentially educated by tumor cells in the tumor microenvironment. Our model not only advances our understanding of CAFs' role in tumor progression but also offers an *in vitro* model for assessing potential therapeutic targets and drug candidates for human gastric cancers.

#0278 Investigating the functional role of cancer-associated fibroblasts in the emergence of drug-tolerant persisters in ovarian cancer.

A. S. N. Ng[1], N. Bui[2], L. Ailles[1];
[1]University of Toronto, Toronto, ON, Canada, [2]Princess Margaret Cancer Centre, Toronto, ON, Canada

Chemoresistance remains a major clinical challenge for the treatment of high-grade serous ovarian cancer (HGSC), the most lethal gynecologic malignancy. The majority of patients who initially respond to first-line platinum/taxane-based chemotherapy eventually relapse with chemoresistant disease, leading to poor survival outcomes. It is increasingly recognized that cancer cells can enter a reversible drug-tolerant persister (DTP) state through non-genetic mechanisms to evade chemotherapy-induced cytotoxicity prior to the development of chemoresistance. However, how environmental signals and extracellular factors from the tumor microenvironment drive the process remains poorly understood. Cancer-associated fibroblasts (CAFs) are a functionally heterogeneous population of activated fibroblasts. CAFs play a critical role in shaping the tumor microenvironment and tumor behaviors, including promoting tumor growth and mediating therapy resistance. Here, we demonstrated that HGSC cell lines co-cultured with patient-derived FAP-high CAFs, a subpopulation of CAFs previously identified in our lab to be tumor-promoting, significantly increase the formation of DTPs upon prolonged carboplatin treatment compared to the mono-cultured condition. Interestingly, the extracellular matrix (ECM) organization signature is enriched in FAP-high CAFs compared to their FAP-low counterparts, and we found that ECM deposited by FAP-high CAFs also facilitates the emergence of DTPs in HGSC cells. Future work will focus on elucidating the mechanisms by which FAP-high CAFs and the associated ECM promote DTP formation in HGSC cells through transcriptomic and proteomic profiling. This will aid the identification of potential therapeutic vulnerabilities to target cancer cells in the DTP state in FAP-high HGSC patients.

#0279 Iatrogenic immunosuppression emplaces tacrolimus to drive squamous skin cancer progression and influence the microenvironment.

E. Kumah[1], Y. Chhabra[2], V. Wang[2], A. Dixit[2], A. Weeraratna[2], K. Bibee[1];
[1]Johns Hopkins Medicine, Baltimore, MD, [2]Johns Hopkins School of Public Health, Baltimore, MD

One in thirteen organ transplant recipients (OTRs) develop post-transplant cutaneous squamous cell carcinoma (cSCC), leading to significant morbidity upon disease progression. Although chronic ultraviolet (UV) exposure primarily underlies keratinocyte carcinogenesis, long-term immunosuppression is a critical etiologic risk factor due to reduced systemic surveillance of dysplasia. Calcineurin inhibitors such as tacrolimus are commonly administered to suppress the immune system by blocking T-cell proliferation and preventing donor organ rejection. Contrarily, studies have evinced the off-target effects of immunosuppressives, namely azathioprine and cyclosporine, but not tacrolimus — the most widely used in all immunosuppression. In addition, the preclinical research literature has overlooked the contribution of stromal fibroblasts in the cSCC tumor microenvironment (TME). Hence, we hypothesize that tacrolimus exerts direct carcinogenic effects on keratinocytes and fibroblasts in the skin. We further postulate that tacrolimus enables a tumor-permissive microenvironment by activating dermal fibroblasts to cause aggressive and invasive keratinocyte carcinoma in OTRs. To examine this cellular crosstalk phenomenon, we used human keratinocytes, primary dermal fibroblasts and cSCC cells in mono- and co-cultures to mimic cutaneous and tumor complexities. Next, we assessed the molecular mechanisms utilized by tacrolimus to potentiate tumorigenesis pertinent to cell survival, proliferation and invasion. Herein, we show that tacrolimus promotes cell survival dose-dependently in cSCC cells. We also found that a fibroblast-cSCC spheroid co-culture significantly enhances cell invasion. In a wound-healing migration assay, tacrolimus increased the migratory capacity of normal keratinocytes and cSCC cells. However, cell proliferation remains nebulous due to cyclical dose-response effects in vitro. We then queried whether cell proliferation is affected in vivo using immunodeficient mice, and similar results were observed. We confirmed via immunoblotting that tacrolimus induced elevated expression of proliferation markers at distinct drug concentrations. Altogether, our findings illuminate keratinocyte-stroma interactions and particularly isolate the contributory role of tacrolimus in non-immune mediated cSCC pathogenesis. This knowledge suggests newer immunosuppressives that do not inhibit calcineurin activity may help relieve cutaneous malignancies in transplant recipients.

#0280 Aberrant β-catenin signaling from the bone marrow niche leads to transformation of *IDH1/2*-mutant hematopoietic stem cells and compromises response to IDH1/2 inhibitors.

P. Vgenopoulou[1], L. Flores[1], I. Mosialou[1], J. Zhao[1], X. Liu[1], P. Sung[2], V. Penard-Lacronique[3], M. Carroll[4], S. Kousteni[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [3]Institut Gustave Roussy, Villejuif, France, [4]University of Pennsylvania, Philadelphia, PA

Our purpose is to identify stromal-derived signals required for *IDH1/2*-mut hematopoietic stem cells (HSCs) to become leukemogenic. Mutations in *IDH* genes are found in 20% of acute myeloid leukemia (AML) patients and are not transformative. They produce the oncometabolite 2HG which inhibits key epigenetic regulators. We explored whether epigenetic changes in the bone marrow (BM) niche could provide cooperative signals to IDH-mut HSCs leading to their transformation and disease development. We found that 2HG is elevated in the BM plasma of MDS/AML patients with *IDH1/2* mutations as compared to *IDH*-wt patients. Interestingly, 2HG is taken up by BM stromal cells (BMSCs) suggesting it may induce aberrant methylation patterns in them. Indeed, methylome analysis showed hypermethylation in BMSCs of AML patients with *IDH1/2* mutations compared to wt. Among the most hypermethylated genes in the *IDH*-mut stroma are *AXIN1*, *AXIN2* and *NDK2,* all negative regulators of β-catenin; this pathway activation was previously shown to cause MDS/AML in mice and present in 38% of patients. In agreement with these findings βcat activation in the stroma of *IDH*-mut vs *IDH*-wt AML patients showed a strong positive correlation as 50% of *IDH*-mut patients had activated βcat in their BMSCs. Inquiring whether stroma methylation precedes HSC transformation, we analyzed samples from healthy individuals with *IDH*-mut clonal hematopoiesis. They exhibited increased global and *AXIN1* promoter methylation compared to samples without such clones, but not active βcat in osteoblasts, indicating this might be a later step along with disease development. In fact, transplantation of HSCs from *Idh2*-mut mice to recipients expressing active βcat in osteoblasts led to increase in blasts and shortened survival compared to wt mice transplanted with *Idh2*-mut HSCs. As many patients relapse following treatment with IDH inhibitors, we investigated a potential role for βcat signaling in treatment outcome. *IDH*-mut AML patients who do not respond to treatment with the IDHi present more frequently with activated βcat in osteoblasts compared to responders. Analyzing samples from the same patient pre- and post-treatment with IDHi, we found before treatment most patients were positive for βcat stromal activation, whereas after treatment, all patients with complete response were negative, while patients with progressive disease remained positive. Our model suggests *IDH*-mut HSCs secrete 2HG inducing epigenetic alterations in the niche, some of which cause activation of the βcat pathway. In turn, this additional signal leads to the transformation of HSCs to dysplastic cells and MDS/AML development. This work uncovers a new mechanism for transformation to MDS/AML and resistance to IDHi treatment. Thus, targeting βcat activation in the stroma, in combination with IDHi, could improve treatment outcome.

#0281 The function of FGFR2+ cancer-associated fibroblasts on cancer stem cell expansion of esophageal squamous cell carcinoma.

Y. Wang, P. Feng, T.-c. Jiang, X.-y. Guan, Y.-f. Xia;
Sun Yat-sen University Cancer Center (SYSUCC), Guangdong, China

Aims: FGFR2+ fibroblasts were reported to promote tumor progression, but the mechanisms remained unexplored in esophageal squamous cell carcinoma (ESCC).Methods: Multiplex immunohistochemistry (mIHC) displayed the distributions of FGFR2+ fibroblasts and cancer stem cells (CSCs). After FGFR2+ fibroblast isolation, tumor cells were stimulated with fibroblasts supernatant to assess radioresistance and CSC properties. RNA-seq analysis identified the downstream BMP5 expression.Results: In our preliminary study, the immunohistochemistry results showed that FGFR2+ fibroblasts were always represented in the area near cancer stem cells (CSCs), and FGFR2+ fibroblasts infiltration was associated with poor outcomes. When we cocultured FGFR2+ fibroblasts with tumor cells, we found the proportion of CSCs were upregulated. The results of RNA sequencing and ELISA showed that FGFR2+ fibroblasts overexpressed BMP5. Using FGFR2+ fibroblasts or BMP5 to stimulate cancer cells, the proportion of cancer stem cells was increased, the capabilities of sphere formation and survival after radiation were enhanced. Both RNA sequencing and immunoblotting results indicated that BMP5 affected H2AX phosphorylation in DNA repair pathway and activated its potential upstream pathway MAPK signaling pathway. In vivo experiments also showed that FGFR2+ fibroblasts could upregulate CSCs proportions.Conclusions: Our findings suggested that BMP5 derived from FGFR2+ fibroblasts might induce CSCs expansion and led to poor prognosis in the ESCC.

#0282 *SFRP4+* cancer associated fibroblasts activate epithelial to mesenchymal transitions in malignant cells and dictate adverse clinical outcomes in stomach cancer.

Seungho Lee[1], Austin Cho[2], Hyoung-Il Kim[3], Hoon Hur[4], Jae-Ho Cheong[5], Tae-Min Kim[6]

[1]Department of Surgery, Seoul National University Hospital, Jongro-gu, Korea, Republic of,[2]Department of Genetics, University of Minnesota, Minnesota, MN,[3]Department of Surgery, Yonsei University Health System, Jongro-gu, Korea, Republic of,[4]Department of Surgery, Ajou University School of Meedicine, Soowon, Korea, Republic of,[5]Department of Surgery, Yonsei University Health System, Seodaemoon-gu, Korea, Republic of,[6]The Catholic University of Korea, Seocho-gu, Korea, Republic of

Cancer-associated fibroblasts (CAFs), a pivotal component in the tumor microenvironment (TME) of gastric cancer (GC), play a crucial role in tumor progression and resistance to treatment. In this study, we performed analyses to build a comprehensive cellular landscape of fibroblasts in GC EMT using three single-cell RNA cohorts including ours (GSE183904, GSE134520 and GSE167297). We observed distinct fibroblast subtypes (CXCL14+/POSTN+, CXCL14+/APOE+, SFRP4+, and SFRP2+ fibroblasts). Among the subtypes, we observed that SFRP4+ fibroblasts sharing cellular origins with normal tissue-residing SFRP2+ myofibroblasts. Notably, SFRP4+ fibroblasts showed a regional prediction for tumor and deep tumor layers compared to normal and superficial tumor layers, respectively. To further understand the role of these fibroblasts, we employed spatial transcriptome data. Spatially resolving the cellular interactions within the TME, the adjacency of SFRP4+ CAFs to malignant cells undergoing epithelial-to-mesenchymal transition (EMT), was observed. Ligand-receptor analyses demonstrated SFRP4+CAFs regulate key genes of EMT in malignant cells (TGFBI, COL1A1, SPARC, COL3A1, COL1A2, and BGN). The regulatory roles of SFRP4+ CAFs in driving the epithelial-mesenchymal transition (EMT) of malignant cells were further validated in vitro. Clinical relevance was also demonstrated with the correlation between the abundance of SFRP4+ CAF and clinical outcomes, i.e., high SFRP4+CAF abundance was consistently associated with shorter survival of GC patients across cohorts. Thus, we present SFRP4+ CAFs as major fibroblast subtypes in GC TME. Spatial cellular architectures and in vitro evidence support that SFRP4+fibroblasts activate the EMT of malignant cells along with their association with patient prognosis. This study advances our understanding into the mechanistic roles of SFRP4+ fibroblasts in GC pathogenesis and progression, paving the way for potential targeted therapeutic strategies.

#0283 Fibroblast diversity and immune microenvironment in pseudoangiomatous stromal hyperplasia (PASH): Associations with breast cancer risk.

N. Cruz-Reyes[1], M. Rossi[1], M. Stallings Mann[1], B. McCauley[2], T. Hoskin[2], R. Vierkant[2], S. Winham[2], A. Degnim[2], M. E. Sherman[1], D. C. Radisky[1];
[1]Mayo Clinic College of Medicine and Science, Jacksonville, FL, [2]Mayo Clinic College of Medicine and Science, Rochester, MN

Benign breast disease (BBD) affects over one million women annually in the United States and is diagnosed in nearly half of all women during their lifetime. Pseudoangiomatous stromal hyperplasia (PASH), a common BBD subtype, is characterized by an overaccumulation of tissue fibroblasts. Current research suggests a pivotal role of the immune microenvironment in progression of BBD to breast cancer, suggesting its composition as a determinant of breast cancer risk. Our study evaluates whether fibroblast variations and immune microenvironment differences in BBD biopsies containing PASH lesions are associated with subsequent breast cancer development. We evaluated BBD biopsies from women who subsequently developed breast cancer (cases, N=5) or remained cancer-free (controls, N=5). Using Opal-based multiplex immunofluorescence (mIF) assays, we mapped expression of fibroblast markers linked to breast cancer associated fibroblasts (CAFs), including vimentin (VIM), smooth muscle actin (ACTA2), fibroblast specific protein-1 (S100A4/FSP1), fibroblast associated protein (FAP), integrin beta-1 (CD29/ITGB1), and platelet derived growth factor receptor beta (PDGFRβ) and markers of key immune cells (T cells: CD4, CD8; dendritic cells: CD11c; B cells: CD20; and macrophages: CD68) along with MKI67 as a proliferation marker. Our results revealed marked differences in fibroblast marker expression and immune cell populations between these groups in the normal lobules in the BBD biopsies. PASH cases showed elevated PDGFRβ and CD29/ITGB1 expression in VIM-positive fibroblasts, markers characteristic of CAF subtypes known to accumulate in more aggressive tumor microenvironments. Conversely, a higher percentage of FSP1+/VIM+ cells, similar to that of a different CAF subtype, was noted in the lobules of PASH controls. This difference in biomarker expression, along with corresponding variations in immune cell counts, suggests a complex interplay between fibroblast composition and immune response that ultimately modulate cancer risk in PASH-containing BBD tissues. Additionally, increased MKI67 expression in PASH cases potentially signals the higher likelihood of cancer development. This work advances our understanding of fibroblast heterogeneity in BBD and its implications for breast cancer risk and progression, and paves the way for innovative strategies to improve clinical outcomes for BBD patients to reduce their incidence of breast cancer.

#0284 Crosstalk with postmenopausal obese mammary adipocytes impacts breast cancer cell metabolism and promotes tumorigenesis.

R. Roy[1], R. Aldakhlallah[2], S. Cobbs[2], E. Man[2], C. Hallinan[2], K. Lee[1], M. Lotz-Bousvaros[3], S. Pories[4], M. A. Moses[1];
[1]Boston Children's Hospital, Harvard Medical School, Boston, MA, [2]Boston Children's Hospital, Boston, MA, [3]Mount Aurburn Hospital, Cambridge, MA, [4]Mount Auburn Hospital, Harvard Medical School, Cambridge, MA

Introduction: Obesity is associated with an increased risk and a poor prognosis of breast cancer (BC) in postmenopausal (PM) women. The mechanism(s) underlying obesity-related PM BC are not clearly understood. We hypothesized that the increased local presence of 'obese' mammary adipocytes within the breast tumor microenvironment (TME) promotes the acquisition of an invasive BC cell phenotype and markedly accelerates tumor proliferation and progression.
Methods: We asked whether cancer-associated mammary adipocytes (CA-MAd) differ from normal mammary adipocytes (N-MAd) in their ability to promote tumorigenesis of dormant BC cells and if so, what the underlying mechanism(s) might be. Using a 2D transwell model, BC cells (ER- and ER+), were cocultured with obese PM CA-MAd isolated from breast cancer patients or obese mammary N-MAds from PM disease-free women and analyzed for migration, proliferation, phenotypic, signaling and metabolic alterations.
Results: Compared to monoculture (MC) conditions, BC cells cocultured (CC) with CA-MAd displayed significantly increased migration and proliferation. Quantitative phase imaging indicated that CA-MAd secretome-treated BC cells displayed increased motility, speed, distance covered and cell size/area compared to N-MAd. Consistent with these results, mesenchymal markers such as fibronectin, vimentin and SNAIL were upregulated whereas the epithelial marker E-cadherin was downregulated in CC *vs*. MC conditions suggesting that Ads in the TME promote EMT in BC cells. Interestingly, mature Ads CC with BC cells underwent delipidation and dedifferentiation as indicated by reduced Oil Red staining, decreased lipid content and reduced expression of Ad maturation markers such as *FABP4*, *ADIPOQ* and *PLIN1*. Consistently, we determined that CC BC cells exhibited increased lipid uptake and BODIPY staining and upregulated pAMPK, pACC and CPT1A signaling when compared to MC BC cells. Short term treatment of BC cells with both N-MAd and CA-MAd secretomes resulted in increased oxygen consumption rate (OCR), basal respiration, ATP-linked respiration and proton-linked respiration compared to control and as determined by the Seahorse extracellular flux assay. CC with MAds significantly downregulated OCR and all respiration parameters in BC cells suggesting decreased glucose uptake and glycolytic flux.
Conclusions: Compared to MC, CC with obese M-Ads promoted functional, phenotypic and metabolic changes in BC cells. Taken together, our results indicate that crosstalk between BC cells and obese MAds promotes delipidation of MAds and a concomitant lipid uptake in BC cells and a switch to lipid metabolism signaling pathways that may, in turn, drive a metabolic shift in BC cells and promote tumor growth. [Supported by NIH RO1CA185530, the Breast Cancer Research Foundation, the Karp Family Foundation and the Nile Albright Research Foundation]

#0285 Targeting TXNDC5 in stromal fibroblasts resolves desmoplasia and resistance to immune checkpoint blockade in mesenchymal-type colorectal cancer.

Kai-Lin Cheng[1], Chih-I Chen[2], Shu-Han Yu[3], Huai-Wen Liang[4], Yi-Wei Tsai[1], Chen-Ting Hung[1], Yu-Shan Lin[1], Yi-Shiuan Tzeng[5], Sung-Jan Lin[6], Yueh-Feng Wu[6], Jen-Kuang Lee[7], Chia-Hui Yu[8], Shuei-Liong Lin[8], Shih-Yu Chen[5], Tzu-Tang Wei[1], Yun-Ju Huang[9], Ruey-Hwa Chen[10], Ching-Chow Chen[1], Kai-Chien Yang[1]

[1]Department and Graduate Institute of Pharmacology, National Taiwan University College of Medicine, Taipei City, Taiwan,[2]Division of Colon and Rectal Surgery, Department of Surgery, E-Da Hospital, I-Shou University, Kaohsiung, Taiwan,[3]Institute of Biotechnology, National Taiwan University, Taipei City, Taiwan,[4]Division of Cardiology, Department of Internal Medicine, E-Da Hospital, I-Shou University, Kaohsiung, Taiwan,[5]Institute of Biomedical Sciences, Academia Sinica, Taipei City, Taiwan,[6]Department of Biomedical Engineering, National Taiwan University, Taipei City, Taiwan,[7]Division of Cardiology, Department of Internal Medicine, National Taiwan University Hospital, Taipei City, Taiwan,[8]Graduate Institute of Physiology, National Taiwan University College of Medicine, Taipei City, Taiwan,[9]Graduate Institute of Oncology, National Taiwan University College of Medicine, Taipei City, Taiwan,[10]Institute of Biological Chemistry, Academia Sinica, Taipei City, Taiwan

Objectives: Mesenchymal-type colorectal cancer (CRC), characterized by strong stromal infiltration and immune tolerance, resists immune checkpoint blockade and has poor outcomes. Cancer-associated fibroblasts (CAFs), abundant in tumor stroma, actively remodel the extracellular matrix (ECM), modulate immune evasion, and drive tumor progression. We have recently identified thioredoxin domain-containing protein 5 (TXNDC5), a protein disulfide isomerase (PDI), as a critical mediator of fibroblast activation and ECM remodeling in organ fibrosis. We hypothesized that TXNDC5 could contribute to fibroblast activation, stroma formation and disease progression in cancer, especially in the stroma-enriched fibrogenic mesenchymal-type CRC.
Methods: Transcriptome databases of CRC were re-analyzed to determine the clinical relevance of TXNDC5. Experimentally, CRC was induced in mouse lines by azoxymethane (AOM) and dextran sulfate sodium (DSS) stimuli, a model sharing multiple characteristics with human mesenchymal-type CRC. Human colonic fibroblast line CCD-18co was used to investigate the molecular mechanisms by which TXNDC5 regulates colonic fibroblast activities. Fibroblast-specific TXNDC5 knockout (*Col1a2-Cre/ERT2*TXNDC5*$^{fl/fl}$) mice were generated, combining with single-cell RNA sequencing analyses on AOM/DSS-induced CRC tumors in these animals, to clarify how fibroblast TXNDC5 impact tumor microenvironment, CRC progression and response to immune checkpoint blockade.
Findings: TXNDC5 was predominantly expressed in stromal fibroblasts of human and mouse CRC. Fibroblast-specific deletion of *Txndc5* lessened CAF activation, attenuated tumor fibrosis and reduced tumor burden in AOM/DSS-induced CRC. Mechanistically, increased TXNDC5 levels augments TGFβ signaling in CAF by post-translational stabilization of TGFBR1 through its PDI activity. In addition, deletion of *Txndc5* in CAFs led to less tumor desmoplasia, decompressed tumor vessels and attenuated intra-tumoral hypoxia, thereby easing immune tolerance and increasing cytotoxic T cell infiltration in CRC. Single-cell transcriptome analysis revealed a marked change of intra-tumoral immune cell populations upon fibroblast-specific deletion of TXNDC5, shifting from myeloid-derived suppressive cells to cytotoxic tumor-infiltrating lymphocytes. Importantly, depletion of TXNDC5 in CAFs potentiated the anti-tumor effects of immune checkpoint blockade with anti-PD1 therapy in CRC.
Conclusions: Our data suggest an important yet previously unrecognized role of fibroblast TXNDC5 in CRC progression, through enhancing CAF activation, stroma formation and immune escape. Combining immune checkpoint blockade with TXNDC5 deletion synergistically improved anti-tumor effects in CRC. Targeting TXNDC5, therefore, can be a novel therapeutic approach for CRC patients.

#0286 Multiplex imaging of human pancreatic tumors reveal novel dynamics of dysplastic stem cells, remodeling of associated fibroblasts and cell-to-cell spatial dependencies.

M. Batardiere[1], S. Ayman[1], C. Beaussier[1], J. Baig[1], Z. Ghanmeh[2], M. Farias-Gonzalez[1], J. Wong[1], A. Archambault-Marsan[1], L. Rousseau[3], S. Turcotte[1], A. Means[4], M. Tan[4], K. DelGiorno[5], E. Dianati[1], V.-H. Trinh[1];

[1]University of Montreal, Montreal, QC, Canada, [2]Concordia University, Montreal, QC, Canada, [3]Centre Hospitalier Universite de Montreal, Montreal, QC, Canada, [4]Vanderbilt University Medical Center, Nashville, TN, [5]Vanderbilt University, Nashville, TN

This study aims to investigate human normal pancreatic tissue, pancreatic precursor lesions, and invasive pancreatic ductal adenocarcinoma to provide the most extensive spatial characterization as disease progress by mapping dysplastic stem cells (DSCs) - a reservoir of cancer cells - and fibroblast populations which modulate the tumor microenvironment and participate in disease progression. We performed 12 cycles of multiplex immunofluorescence using 26 validated antibodies covering fibroblasts [CXCL12, αSMA, FAP, CD74, CD105, PDGFRA, COL1A1], DSCs diversity [CD44v9, CD133, CD166, SPP1, S100P], and immune populations, onto tissue samples from 75 patients screened for normal, low grade, high grade dysplasia, and invasive cancer. We used our codes in Python, R, and QuPath 0.4.3. The pipeline includes shading correction, whole slide image registration (at subcellular level), region of interest and stromal mask annotations by a pathologist [normal duct, acinar to ductal metaplasia (ADM), low grade, high grade, invasive], automatic cell detection, and signal extraction. We developed a novel Python code for cell-to-cell spatial dependency analysis by using the x,y centroid positions of one cell from the tumor to other cells from the stroma mask based on pre-defined distances.

For this abstract, we interrogated 264,732 cells and observed SPP1+, S100P+ DSCs expansion from low grade to high grade dysplasia, whereas CD133+ and CD166+ populations contract ($p<0.0001$). S100P+ DSCs gradually expand as disease progress reaching 74.13% of invasive cells being positive. CD44v9 follows dynamic changes variations, being expressed in 59.6% of cells undergoing ADM, dropping to 5.4% in dysplasia, and re-increasing to 25.4% in invasive cancer (all $p<0.0001$). Focusing on stromal composition, CXCL12+, CD105+, αSMA+, CD74+ fibroblasts expand whereas FAP+ fibroblasts contract from low- to high grade (p-values <0.0001). COL1A1 expression increases at each step of the normal duct - ADM - low grade - high grade - invasive cancer sequence (all $p<0.0001$). The pattern of CD44v9 tumor population showed dynamic alterations with the CD105 fibroblast population, as CD44v9 and CD105 are highly expressed in coordination during ADM. However, in dysplastic lesions and invasive cancer, mutual exclusivity between the tumor CD44v9 populations and the underlying CD105 fibroblast populations is observed, confirmed by our spatial algorithm within 50 µm of cell-to-cells distance ($p<0.0001$). In tumors, when CD44v9 tumor cell populations are expressed, the adjacent fibroblasts were CD105 negative.

Multiplex imaging reveals dysplastic stem cells and fibroblasts dynamics in low- to high grade transition. The high-throughput capabilities of this method lead to the discovery of the CD44v9 tumor and CD105 fibroblast dependencies in pancreatic tumors.

#0287 Analysis for the role of antigen-presenting cancer-associated fibroblasts in tumor microenvironment of colorectal cancer.

Yasuhiro Fukui[1], Hiroaki Kasashima[1], Zizhou Wang[1], Ken Yonemitsu[1], Kishu Kitayama[1], Yuichiro Miki[1], Mami Yoshii[1], Tatsunari Fukuoka[2], Tatsuro Tamura[1], Masatsune Shibutani[1], Takahiro Toyokawa[1], Hiroaki Tanaka[3], Shigeru Lee[1], Masakazu Yashiro[2], Kiyoshi Maeda[1]

[1]Gastroenterological Surgery, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan,[2]Molecular Oncology and Therapeutics, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan,[3]Surgery, Fuchu hospital, Osaka, Japan

A new subset of cancer associated fibroblasts (CAFs) called antigen presenting CAF (apCAF) was recently identified, and modulation of the tumor immunity might be associated with tumor progression. We examined the markers of apCAF, such as IRF5, HLA-DRA and HLA-DQA1 by bioinformatics analyses of human colorectal cancer (CRC) datasets. The expression of apCAF markers were upregulated in CAFs isolated from human CRCs and liver metastases compared with their normal counterparts. Kaplan-Meir analysis of 172 human CRC samples clarified that the patients with apCAF marker positive expression in the tumor stroma had worse prognosis than that with negative expression. In addition, the origin of apCAFs was reported to be mesothelial cells, therefore, we established cancer-associated mesothelial cells (CAmes) from ascites of human CRC patients with peritoneal dissemination. Consistently, the expression of antigen-presentation markers was highly upregulated in CAmes, however, allo-mixed lymphocyte reaction analysis demonstrated that their stimulating activity of $CD4^+$ T lymphocytes was diminished. In an in vivo study, we applied a rectal orthotopic transplant model with mouse tumor organoid (MTO) to investigate the effect of apCAF on tumor progressions. Using fluorescence-activated cell sorting (FACS), we examined the ratios of apCAF, myCAF, and iCAF in orthotopic rectal tumors. The percentage of apCAF was highest in the 6-week-tumors and the percentage of myCAF was highest in the 9-week-tumors. Interestingly, the percentage of apCAF was higher in liver metastases than in primary tumor, consistent with bioinformatics analysis. The apCAF increased during the stage of tumor growth, and the percentage of myCAF increase in the later stage of tumor progression with fibrosis. In summary, apCAF might be associated with tumor progression in CRC.

#0288 Middle-aged murine models of triple negative breast cancer (TNBC) show significant differences in tumor immune and stromal environments when compared to classic 6-8 week old models; Challenges and opportunities for preclinical efficacy studies.

P. Falvo[1], S. Gruener[2], S. Orecchioni[1], G. Talarico[1], G. Bravetti[1], G. Mitola[1], F. Pisati[3], I. Barozzi[2], **F. Bertolini**[1];
[1]IEO - European Institute of Oncology, Milan, Italy, [2]University of Vienna, Vienna, Austria, [3]Cogentech, Milan, Italy

The immune system orchestra suffer a deficit of function during aging, and the incidence of the large majority of cancer types is significantly increased in elderly humans. Although BC can occur in young women, it is way more common in middle-age and elderly women. There is evidence that a tonic immune system is pivotal for the success of therapies aimed at awakening a dormant or exhausted immunological response against cancer cells by mean of checkpoint inhibitors (CI). However, rodent models of cancers are currently using very young mice of a few weeks of age, which have a fully functional and tonic immune system and thymus and thus might be poorly representative of adult human cancer patients. We have recently reported that that a triple therapy (TT) involving antigen-presenting cell activation by vinca alkaloids and the generation of new TCF1+ stem cell-like T cell (scT) clones by an alkylating agent can significantly improve the efficacy of the CI anti-PD-1 in models of cancer known to be otherwise CI-resistant such as TNBC and lymphoma (Falvo et al, Cancer Res 2021; Orecchioni et al, JCM 2023). TT effect was due to T cells, as it was abrogated by their in vivo depletion. In the present study we investigated differences in TNBC growth kinetics, TT preclinical activity and tumor microenvironment (TME, including intratumoral immune and stroma cells) in young (6-8w, representative of a 6y old human) versus adult (12m, representative of 40y humans) mice. Models included 4T1 and EMT6 TNBC cells, the former generating a mostly lymphoid TME and the latter generating a mostly myeloid TME. In both models, TT efficacy was similar in young and in adult mice, as the treatment abrogated TNBC local and metastatic growth. CD8+ (but not CD4+) scTs, likely crucial players in TT efficacy, were only slightly reduced in adult mice in spite of age-related thymus involution. This notwithstanding, single cell RNA (10x), IHC and flow cytometry analyses of immune (CD45+EPCAM-) and stroma (CD45-EPCAM-) cell populations indicated major differences in the TME of young vs adult mice. Adults had significantly less CD4+ scTs, B naïve and NK cells and significantly increased memory B cells. TME matrix CAF were skewed in young, while pro-inflammatory stromal populations and myofibroblasts were skewed in adults. Matrix CAFs down regulated a signature involved in different ECM-remodeling abilities, and up regulated metabolic and hypoxic pathways. Expression of genes encoding for glycoproteins, basement membrane components, and collagens were also upregulated. Our data indicate profound differences between young and adult mice immune and stromal TMEs that should be taken into consideration when selecting the age of mice to be used in preclinical efficacy studies in orthotopic immune competent mice.

#0289 Temporal and spatial dynamics of glial cells apolipoprotein E expression in astrocytoma microenvironment.

T.-Y. Chien, C.-S. Chiang;
National Tsing Hua University, Hsinchu City, Taiwan

Introduction: Brain tumors have proven challenging to treat due to the complex and sensitive architecture of the brain. Previous research has shown that GBM cells depend highly on cholesterol uptake, and apolipoprotein E (APOE) is required to transport cholesterol among tissues or cells. APOE is primarily synthesized by astrocytes and has been extensively studied in neurodegenerative diseases. While extensively studied in neurodegenerative diseases, limited studies are focusing on their roles in brain tumor development. Here, we analyzed the temporal and spatial expression of APOE during brain tumor progression in a murine astrocytoma tumor model.

Material and method: ALTS1C1 astrocytoma cells were intracranially injected into the mouse brain. The animal was sacrificed, and the left hemisphere, right hemisphere, and tumor tissue were collected for flow cytometry analysis. CD45, CD11b, and GFAP were used to recognize macrophages, microglia, and astrocytes. CD68, TMEM119, and GFAP were used for tissue immunostaining to label macrophages, microglia, and astrocytes, respectively.

Results and Discussion: Flow cytometry analysis revealed upregulated APOE in tumor-infiltrating microglia, macrophages, and lymphocytes. $GFAP^{high}$ astrocytes displayed lower APOE levels than $GFAP^{low}$ astrocytes. IHC analysis showed that CD68+ macrophages exhibited higher APOE expression at the tumor edge than normal tissue. On the contrary, GFAP+ astrocytes at the tumor edge displayed a lower APOE signal than the normal tissue. Previous studies have shown the participation of APOE in regulating immune response in various cancers. Further studies to analyze the dynamic change of APOE on the gene expression level with *in situ* hybridization and the quantification of cholesterol levels in the microenvironment may help uncover their roles in the glioma microenvironment.

Conclusion: This study demonstrated that APOE was temporal and spatial differentially expressed in macrophages and astrocytes in the brain tumor microenvironment. Tumor-infiltrating cells showed an elevated APOE expression, while $GFAP^{+}$ astrocytes expressed reduced APOE levels. Although the mechanism of these alterations remains unclear, this study provides a basis for future studies about the roles of APOE in the brain tumor microenvironment.

#0290 The role of tumor stromal topography-regulated genes in modulating the cellular landscape of tumor stroma in breast cancer.

C.-Y. Su;
National Yang Ming Chiao Tung University, Taipei City, Taiwan

The tumor remodels the surrounding extracellular matrix fibers to become topographically aligned at the tumor front, further facilitating cancer cell migration. Our recent studies show that aligned tumor stromal topography promotes the detachment of breast cancer cells from the main tumor, then, in the following cell migration, upregulating genes such as genes encoding the cytochrome P450 family 1 subfamily A member 1 (CYP1) and inhibitor of DNA binding (ID) proteins. In this study, we further explored the role of topography-regulated genes in modulating the cellular landscape of tumor stroma. By analyzing the correlation of topography-regulated genes with stromal cell infiltration in bioinformatics databases, we found significant positive correlations between the RNA expression levels of most topography-regulated genes and the infiltration levels of cancer-associated fibroblasts and endothelial cells. Notably, the strongest correlation was between the expression level of ID3 and the infiltration levels of cancer-associated fibroblasts ($r = 0.509$) and endothelial cells ($r = 0.506$). Additionally, ID3 remained highly expressed in circulating tumor cells but exhibited low expression at distant metastatic sites. These findings suggest that genes regulated by tumor stromal topography, especially ID3, may play a role in neovascularization and fibrosis of the tumor microenvironment and the survival adaptation of cancer cells in circulation, thereby promoting metastasis.

#0291 Unveiling heterogeneity of cancer-associated fibroblasts (CAFs) across multiple solid cancer types.

A. Kravets, B. Shpak, A. Zotova, M. Savchenko, S. Kust, O. Golubeva, M. Abdou, F. Grigoryev, I. Bulusheva, B. Sargsyan, P. Pavlovich, V. Maximov, V. Kushnarev, M. Goldberg, N. Kotlov, A. Bagaev;
BostonGene, Corp., Waltham, MA

Background: Stromal cells, including CAFs, are a heterogeneous group of cells in the tumor microenvironment. Many models describe their heterogeneity like the classification into 3 main subtypes in breast cancer: myCAF (myofibroblasts), iCAF (inflammatory CAF), and PVL (perivascular-like) cells. However, a pan-cancer model has not been established to exhaustively characterize stromal cell heterogeneity, undermining efforts in targeting CAFs with anti-tumor therapies. We investigated the heterogeneity of stromal cells in diverse diagnoses with single-cell RNA sequencing (scRNA-seq) data and bulk RNA-seq of sorted stromal cells to define consistent subtypes.
Design: First, a meta-cohort of 11 scRNA-seq open-source datasets (>500,000 cells, >100 patients, 6 diagnoses) was analyzed. We also generated a scRNA-seq dataset of CD90+ cells derived from tumor tissue of an ovarian cancer patient. Additionally, bulk RNA-seq of 6 PVL, 2 iCAF, and 4 myCAF sorted cell samples across four solid cancers was performed. scRNA-seq data was analyzed with the SCANPY Python package.
Results: Stromal cell clusters were defined as positive for PDGFRB, THY1 (CD90), and COL1A1 expression, and negative for the expression of known non-stromal and endothelial cell markers, by separately analyzing the open-source scRNA-seq datasets. Analysis of stromal cell heterogeneity revealed that the CAFs were consistently classified into 3 subtypes across all datasets: myCAF (high expression: FAP and ACTA2), PVL (high expression: MCAM (CD146) and ACTA2), and iCAF (high expression: APOD and cytokines IL6, CXCL12, CXCL2). Differential gene expression analysis of the scRNA-seq meta-cohort allowed us to develop functional gene expression signatures to define each subtype. All scRNA-sequenced CD90+ cells from ovarian cancer tissue were classified into the CAF subtypes. The myCAF and PVL signatures were specifically upregulated in the corresponding cell types ($p<0.01$, Mann-Whitney U test). While the iCAF signature was enriched in both iCAFs and myCAFs, myCAF and PVL signatures were downregulated in iCAFs. Finally, we developed a fluorescence-activated cell sorting (FACS) panel to separate CAF subtypes, using negative markers (CD45, CD31, EPCAM), a positive marker for stromal cells (CD90) and cell-type surface markers (CD146, FAP, CD91, CD44) for myCAF, iCAF and PVL cells. The high expression of CAF-specific genes in the sorted CAF populations denoted high sample purity. Importantly, the 3 CAF subpopulations separated by gating based on different levels of cell-type surface markers showed expression patterns congruent with the developed signatures across diagnoses.
Summary: Altogether, the consistent classification of stromal cells with our cell-specific expression profiles demonstrated that the 3 CAF subtypes are conserved in many cancer types, offering groundwork for a pan-cancer model of stromal cell heterogeneity.

#0292 Cell non-autonomous downregulation of the tumor suppressor DAB2IP in the cancer microenvironment: Molecular mechanism and biological implications.

A. Bellazzo[1], R. De Florian Fania[2], C. Agostinis[3], R. Bulla[2], I. Segatto[1], B. Belletti[1], V. G. D'Agostino[4], I. M. Bonapace[5], L. Collavin[2];
[1]Centro di Riferimento Oncologico di Aviano (CRO) IRCCS, Aviano, Italy, [2]University of Trieste, Trieste, Italy, [3]Institute for Maternal and Child Health, IRCCS Burlo Garofolo, Trieste, Italy, [4]University of Trento, Trento, Italy, [5]University of Insubria, Busto Arsizio, Italy

Background and Purpose: The tumor suppressor DAB2IP is a cytoplasmic Ras-GAP and an adaptor protein that restrains oncogenic signaling by extracellular inputs, contributing to modulate the dynamic crosstalk established between tumor cells and their stromal compartment. In human malignancies, DAB2IP is frequently disabled by epigenetic and post-transcriptional means. DAB2IP loss-of-function in cancer cells promotes their aberrant proliferation, dissemination, and tumor-promoting inflammation, potentially favor progression of tumors. Intriguingly, endothelial-specific DAB2IP depletion in mouse models fosters the formation of a pro-metastatic niche, implicating that also the loss-of-function of DAB2IP in stromal cells might dramatically impact cancer progression. We previously found that the secretome of prostate cancer cells reduced DAB2IP levels in non-transformed prostate epithelial cell lines, and in primary endothelial cells, thereby fostering their proliferation, migration and expression of angiogenesis markers. Accordingly, cell non-autonomous DAB2IP inactivation in the stromal compartment may reprogram the response to paracrine and autocrine signals, thus supporting a tumor-promoting behavior; however, molecular basis and clinical implication of this phenomenon await clarification. Materials and
Methods: We used conditioned medium (CM) from prostate (PCa) and breast (BCa) cancer cell lines, to study its effects in mediating DAB2IP downregulation and in inducing tumor-associated phenotypes in endothelial cell and fibroblasts. Through multiple approaches, we isolated extracellular vesicles from PCa and BCa conditioned media, to test their involvement in mediating DAB2IP downregulation in recipient cells. Finally, we used cancer cells'CM or specific siRNAs to study the consequence of DAB2IP loss in fibroblasts.
Results: The treatment with CM from PCa and BCa cells induces DAB2IP downregulation in immortalized and in primary fibroblasts, and in endothelial cells. Analysis of DAB2IP levels in primary fibroblasts from PCa and BCa surgical samples confirmed differential expression of DAB2IP protein in normal vs. tumor-associated fibroblasts. Exploring the biochemical nature of extracellular signals involved in DAB2IP downregulation by cancer cells' CM, we found that DAB2IP inhibition in recipient cells is partially mediated by miR-149-3p contained in extracellular vesicles. Finally, we found that DAB2IP reduction potentiates fibroblasts proliferation and invasion, facilitates gel contraction and extracellular matrix remodeling, and fosters expression of markers of activated fibroblasts.
Conclusions: Together, these data support the hypothesis that cancer cells can modulate DAB2IP levels in nearby stromal cells, pushing them to acquire a metastasis-supporting phenotypes.

#0293 Distinctive roles of mammary adipomes in breast cancer progression: Insights from functional analysis and differential gene expression.

H. Thangavel[1], K. Lizardo[1], R. I. Glazer[2], J. F. Nagajyothi[1];
[1]Center for Discovery and Innovation (Hackensack Meridian Health), Nutley, NJ, [2]Georgetown University, Washington, WA

Breast Cancer (BC) is a heterogeneous disease that impacts treatment response. This is due in part to the tumor microenvironment (TME), which contributes significantly to BC pathogenesis, including metastasis. Women with higher breast density and reduced breast fat face an increased BC risk across multiple tumor subtypes. This is exemplified by the correlation between increased tumor progression, the appearance of fibrosis and the loss of mature adipocytes. While the role of adipokines in this process has been studied extensively, the contribution of adipocyte-derived extracellular vesicles (EV) or "adipomes" in tumorigenesis and metastasis remains poorly understood. To address this question, we developed a novel technique for isolating intact adipomes from normal mammary fat (MF) obtained from wild-type C57BL/6 mice as well as from tumor-associated MF (TAMF) obtained from mice inoculated orthotopically with EO771 mammary tumor cells. Adipome isolation involved high-speed centrifugation to separate macro- and micro-vesicles, purification using the ExoQuick EV isolation system, and immunomagnetic capture of adipomes. Characterization of adipomes by transmission electron microscopy revealed two adipome populations, large L-adipomes of ~350 nm, and small S-adipomes of ~40 nm. Notably, the quantity of L-adipomes in tumor-associated mammary fat (TAMF) was 10-fold greater than the amount of L-adipomes in the MF of non-tumor-bearing mice. To identify possible functional roles of L-adipomes in the pathogenesis of BC, lipidomic profiling was undertaken. L-Adipomes from TAMF showed significantly altered lipid species in comparison to MF-derived L-adipomes. Adipomes were further characterized by treating EO771 cells for 72 hr with TAMF- or MF-derived adipomes at a cell to adipome ratio of 1:10, followed by RNAseq analysis. Differentially upregulated genes in TAMF-derived L-adipomes included Esr1, Erbb2, Tgfb1, Bcl2, MMP2, and Notch associated with fibrosis, EMT, angiogenesis and invasion and downregulation of genes linked to tumor suppression, apoptosis, and mitochondrial metabolism. Overall, our study illustrates the importance of tumor-associated adipomes in regulating gene expression in tumor cells, which emphasizes the specificity of adipome content relating to the cell-of-origin and the host's pathologic and metabolic state and in modulating signaling pathways involved in BC progression.

#0294 The HOXB7 protein promotes breast cancer cell growth through activation of the CCL5/CCR5 pathway in the crosstalk of adipocyte.

A. G. Akume, **K. Jin**;
Albany College of Pharmacy & Health Sciences, Albany, NY

Homeobox genes are regulatory genes that encode nuclear proteins acting as transcription factors during normal development and differentiation. One such gene, HOXB7, plays a role in various developmental processes, including hematopoietic differentiation, lymphoid development, and mammary gland development. However, the role of HOX genes in breast cancer development remains largely unexplored. Our previous studies revealed that HOXB7 expression was significantly elevated in primary cancer and distant metastasis. HOXB7 overexpression promoted cell proliferation in SKBR3 breast cancer cells, leading to robustly vascularized xenografts in immunodeficient mice. Furthermore, HOXB7 enhanced tumor growth through TGF beta signaling and recruitment of macrophages, indicating the role of HOXB7 in the crosstalk of stromal components. We found evidence that HOXB7 overexpression in ER+ breast cancer cells promotes tumor cell growth through increased expression and signaling of CCL5/CCR5 in crosstalk with adipocytes. By screening secreted factors in adipocytes induced by TCM of MCF-7-HOXB7 cells, it was also found that CCL5 is highly expressed in HOXB7-overexpressing MCF-7 cells. The CCR5 inhibitor, maraviroc, sensitized MCF-7-HOXB7 cells compared to control cells. These findings suggest that blocking the interaction between CCL5 and CCR5 signaling significantly inhibits ER+ breast cancer with HOXB7 overexpression. We aim to further investigate if HOXB7 overexpression in ER+ breast cancer cells promotes tumor cell growth through increased expression and signaling of CCL5/CCR5 in crosstalk with adipocytes and the role of CCL5 in breast cancer cell growth and migration.

#0295 Fibroblast-specific endoglin deletion alters colonic immune infiltrate in premalignant colorectal lesions.

Subinuer Abudukelimu, Mark J. A. Schoonderwoerd, Madelon Paauwe, Eveline S. M. de Jonge-Muller, Stef G. T. Janson, Nadine van Montfoort, Lukas JAC Hawinkels

Gastroenterology and Hepatology, Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: Endoglin expression on cancer-associated fibroblasts has been reported to promote tumor growth and metastasis, especially in colorectal cancer (CRC). However, little research has been done on the function of endoglin-expressing fibroblasts in the early stages of CRC and how it interacts with the host immune system. Here, we investigated the role of endoglin expression on fibroblasts during intestinal inflammation and tumorigenesis in a chemically induced colitis-associated CRC model.

Methods: We generated two inducible fibroblast-specific endoglin (ENG) knockout mice Collagen1a1 CreERT2.ENGfl/fl ($ENG^{Col1a1-/-}$) and Collagen1a2-CreERT.ENGfl/fl ($ENG^{Col1a2-/-}$). Cre-mediated recombination in mice was induced by oral administration of tamoxifen for three consecutive days. Polyp formation was induced by a single injection of azoxymethane (AOM), followed by three cycles of dextran sodium sulphate (DSS). Analysis of the immune cell composition in the colons and polyps was done using flow cytometry. Hematoxylin and eosin (H&E) staining was performed to evaluate intestinal inflammation.

Results: $ENG^{Col1a1-/-}$ mice showed a considerably higher number of colonic lesions than non-induced controls, whereas in the $ENG^{Col1a2-/-}$, surprisingly no significant difference in the number of lesions was observed. Flow cytometry analysis revealed, compared to controls, the lesions of $ENG^{Col1a1-/-}$ mice had a significant increase in $F4/80^{+}$ $Ly6C^{-}$ macrophages and $Ly6G^{+}$ neutrophils, while those of $ENG^{Col1a2-/-}$ mice had a marked decrease in $CD11C^{+}$ dendritic cells. Given the changes in immune cell infiltration, we also assessed acute inflammation, using a short-term DSS experiment. Interestingly, $ENG^{Col1a1-/-}$ mice lost significantly more weight compared to controls, indicating increased inflammation. Although weight loss did not differ in Col1a2 mice between the two groups, $ENG^{Col1a2-/-}$ mice had a much lower H&E staining score, indicating less colonic damage and inflammation. Furthermore, a decrease in $F4/80^{+}$ $Ly6C^{-}$ macrophages was observed in the colons of both $ENG^{Col1a1-/-}$ and $ENG^{Col1a2-/-}$ mice, despite no change in the overall $CD45^{+}$ immune cell population. Notably, the number of $Ly6G^{+}$ neutrophils was decreased in the colons of $ENG^{Col1a1-/-}$ mice but increased in $ENG^{Col1a2-/-}$ mice. In addition, a decrease in $CD11C^{+}$ dendritic cells was seen in the colons $ENG^{Col1a2-/-}$ mice.

Conclusion: Our results suggest that AOM/DSS-induced polyp formation and infiltrating immune cells differ in $ENG^{Col1a1-/-}$ and $ENG^{Col1a2-/-}$ mice. Fibroblast-specific deletion of endoglin can reduce macrophage and dendritic cell infiltration, colonic damage, and protect mice from DSS colitis.

#0296 BRAFi-induced ROCK-mediated non-canonical nuclear β-catenin shuttling drives a phenotypic switch in cancer-associated fibroblasts..

B. da Silva Soley[1], R. Athalye[1], R. Zhang[1], T. Andl[2], Y. Zhang[1];
[1]University of Cincinnati, Cincinnati, OH, [2]University of Central Florida, Orlando, FL

The discovery of BRAF mutations in around 60% of melanoma patients and the subsequent development of targeted inhibitors to counter the hyperactive BRAF-driven pro-tumorigenic signaling pathway have marked a significant milestone in melanoma therapy. However, despite this progress, the long-term outcomes remain unsatisfactory for many patients due to the occurrence of drug resistance. We previously reported that cancer-associated fibroblasts (CAFs) are stimulated by BRAF inhibitors (BRAFi) to drive matrix remodeling and therapeutic escape pathways in melanoma cells. However, the underlying mechanism by which CAFs are reprogrammed by BRAFi to obtain enhanced phenotypes remains elusive. Here, we present compelling evidence showing that BRAFi (PLX4032), but not CRAF inhibitor (GW5074) or pan-RAF inhibitor (RAF709), induces the accumulation of nuclear β-catenin in CAFs harboring wild-type BRAF, a process mediated by BRAF and CRAF but not ARAF isoform. BRAFi binding to BRAF and CRAF leads to robust RAF kinase dimerization, including BRAF and CRAF homodimer and BRAF: CRAF heterodimer. RAF dimers are subsequently recruited to the plasma membrane, where BRAF and CRAF are phosphorylated on residues Thr599 and Ser338, respectively, and activated in a RAS-GTP-dependent manner. RAF activation stimulates the downstream Rho kinase (ROCK) and MEK/ERK signaling pathways simultaneously. Notably, ablating RAS and RAF isoforms effectively suppressed BRAFi-induced activation of ROCK1/2 signaling in CAFs, further confirming that the ROCK pathway is a downstream effector of BRAFi-driven RAF activation and is intricately linked to increased nuclear β-catenin in CAFs. The pharmacological blockade of ROCK activity, using HA-1077, diminished BRAFi-induced nuclear β-catenin accumulation in CAFs, suggesting BRAFi-driven cytoskeletal remodeling plays a pivotal role in the nuclear shuttling of β-catenin. Using a mouse model that mimics human BRAF-mutant melanoma, we found that elevated level of nuclear β-catenin drives the conversion of fibroblasts into α-SMA-positive CAFs, leading to elevated collagen deposition and contributing to melanoma progression *in vivo*. In summary, BRAFi reprograms the transcriptional activity in CAFs by driving increased nuclear β-catenin to increase their ability to remodel the tumor ECM and promote melanoma cell proliferation. Collectively, the data offer new insights into the molecular mechanisms that underlie the paradoxical reprogramming of CAFs by BRAFi in melanoma therapy through the non-canonical β-catenin pathway.

#0297 Role of purine metabolism in CLL cell pathobiology and CLL disease progression.

S. Sinha[1], W. Han[1], Z. Wang[1], K. G. Rabe[1], S. L. Slager[1], C. E. McCabe[1], D. R. O'Brien[1], S. A. Parikh[1], E. Braggio[2], Y. Chen[3], F. Tan[4], S. P. Anthony[3], Y. Chen[3], B. Dai[3], Y. Shen[4], N. E. Kay[1];

[1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Phoenix, AZ, [3]Newave, Pleasanton, CA, [4]Lupeng Bio, Guangzhou, Guangdong, China

The treatment of Chronic lymphocytic leukemia (CLL) has been revolutionized in recent years, however CLL is still incurable, and the leukemic cells often develop drug resistance. Previous studies show that the interaction of CLL cells with the bone marrow (BM) microenvironment promotes spontaneous and drug induced survival. But the nature of this interaction is still in need of a full understanding. To pursue this we discerned RNA profiles using RNA-seq in paired CLL cells isolated from untreated blood and BM (n=6) and in untreated patients CLL cells (n=4) cultured alone or cocultured with BM stromal cells (BMSCs). CLL cells from blood/BM and CLL cells cultured alone or with BMSCs were examined by Western blot (WB), untargeted metabolomics (LCMS+GCMS) and preclinical drug sensitivity assays. We found upregulation of 232 genes in CLL cells from BM vs the paired blood and 917 genes in cocultured CLL cells compared to CLL cells cultured alone (p&lt0.05, fold change &gt1.5). Here we detected only 13 genes that overlap between BM and cocultured CLL cells. When we analyzed the expression of these 13 genes in blood CLL cells from a cohort of 162 untreated patients by RNA-seq we found a positive relationship between 4 (*PNP*, *C16orf54*, *MOB3A*, *CDK2AP2*) with CLL patient clinical outcome including overall survival (OS), progression free survival (PFS), and time to first treatment (TTFT) [multivariable Cox proportional hazards models, p&lt0.05]. Out of the 4 genes, purine nucleoside phosphorylase (*PNP*), an enzyme in the purine salvage pathway, showed the most significant association for patient's OS, PFS, and TTFT. Metabolomic profiling indicated an increased level of purine salvage pathway metabolites adenosine, inosine, and hypoxanthine in cocultured CLL cells. WB analysis using blood CLL cells from untreated patients showed a variable PNP protein expression (high, low /no PNP) and induction in PNP protein levels were found in blood CLL cells expressing low/no PNP only when in contact with BM/BMSCs**.** But PNP inhibitor forodesine did not show any significant killing in high vs low/no PNP group. When we treated CLL cells from untreated patients with Bcl2 inhibitors venetoclax, S55746 and LP-118 (Bcl-2/Bcl-xl inhibitor, Newave), CLL cells showed increasing sensitivity to the Bcl2 inhibitors associated with their PNP expression (high&gtlow&gtno PNP). But a covalent and non-covalent BTKi LP-168 (Newave) cultured with CLL cells showed no difference in drug sensitivity associated with CLL PNP levels. In contrast CLL cells when treated with both venetoclax and LP-168, showed more drug sensitivity in the high PNP expressing CLL cells vs low/no PNP. These results indicate that active purine metabolism in CLL cells can contribute to differential novel agent drug responses of CLL patients. Future studies to understand the exact mechanism of how PNP relates to this differential drug sensitivity should be instructive in regard to alternate maneuvers to treat CLL.

#0298 Contribution of cancer associated fibroblasts to treatment response and resistance in high-risk multifocal prostate cancer.

N. Lupsa[1], E. Heninger[1], A. Ding[1], S. R. Reese[1], X. T. Hazelberg[1], A. M. LeBeau[1], B. P. Johnson[1], P. P. Geiger[1], D. J. Beebe[1], D. A. Quigley[2], J. M. Lang[1]; [1]UW-Madison, Madison, WI, [2]UCSF, San Francisco, CA

Patients with multifocal, locally advanced prostate cancer are at the highest risk of recurrence and death. Neoadjuvant therapies have limited response rates in this patient cohort and there remains a critical need to develop curative treatments. Prostate cancer (PC) shows marked heterogeneity, which is not limited to tumor cells but extends across immune and stromal compartments and has been linked to metastatic disease and therapeutic resistance. Cancer associated fibroblasts (CAFs) have been proposed to play a critical role in PC progression and invasion, but it is still unclear how CAFs interact with tumor cells. We evaluated CAFs from prostatectomy specimens as drivers of resistance to neoadjuvant androgen receptor signaling inhibitor (ARSi) and chemotherapy and assessed treatment response in co-culture systems in the context of CAF presence.

We have utilized a novel radio-pathology tool that integrates PSMA PET/MRI scans to identify regions of interest that associate with heterogenous treatment response. MRI scans were utilized to print patient-specific 3D molds to micro dissect live tissue for subsequent cell sorting and molecular analyses. We have established a multi-parameter flow cytometry panel to characterize primary prostate fibroblasts from tumor foci and adjacent normal prostate tissue. In addition, co-culture assays were performed including immortalized CAF (hPrCSC-44) and MSC-derived fibroblast. To examine the tumor-promoting role of CAFs, fibroblasts were co-cultured with androgen-sensitive 3D tumor PC spheroids (LNCaP, C42B and LAPC4) in the integrated microfluidic STACKs platform that allows for the assessment of spatio-temporal interaction in a variety of culture microenvironments to model complex interactions. Cytotoxicity in 3D PC spheroids was assessed after Apalutamide, Darolutamide, or Docetaxel treatment by confocal microscopy.

Integrated DNA, RNA, and radiology analysis of tumor biopsies have identified gene signatures associated with early biochemical recurrence. Most biopsies had low tumor purity, evidence of the cytotoxic impact of chemohormonal therapy while high tumor purity predicted high tumor expression. Poor clinical outcome was significantly associated with elevated stromal scores while epithelial and stromal enrichment were inversely correlated (rho= -0.80, $p< 5x10^{-16}$). The presence of CAFs significantly decreased Docetaxel (C42B only vs C42B+CAF, 86.07% vs. 44.57%, respectively, $p<0.001$; LAPC4 only vs LAPC4+CAF, 70.98% vs 26.64%, respectively, $p<0.001$) and Darolutamide-induced (C42B only vs C42B+CAF, 52.59% vs 37.87%, respectively, $p=0.0407$).

In conclusion, recurrent PC is linked to increased stromal content and the presence of CAFs supported tumor survival in response to ARSi and Docetaxel treatment. The molecular drivers of this phenomenon are currently being investigated.

#0299 FAP/αSMA association with tumor visibility and progression in prostate cancer.

Jenni Saila[1], Timo-Pekka Lehto[2], Annabrita Schoonenberg[3], Katja Valimaki[3], Andrew Erickson[2], Antti Rannikko[2], Olli Kallioniemi[3], Tuomas Mirtti[2], Teijo Pellinen[3]

[1]Research Program in Systems Oncology (ONCOSYS), Faculty of Medicine; FIMM, University of Helsinki, Helsinki, Finland,[2]Research Program in Systems Oncology (ONCOSYS), Faculty of Medicine, University of Helsinki, Helsinki, Finland,[3]FIMM, University of Helsinki, Helsinki, Finland

Introduction Prostate cancer (PCa) ranks as the second most frequently diagnosed cancer in the male population worldwide. The challenge in effectively managing PCa is the absence of well-established biological markers, which often leads to both over and under treatment. To address this issue, a deeper understanding of the molecular alterations within PCa is essential for more accurate patient stratification. In this research, we embark on a comprehensive examination of how the presence of fibroblast activation protein (FAP) and alpha smooth muscle actin (αSMA) in PCa tissue associates with the visibility of the disease in Magnetic Resonance Imaging (MRI) and their impact on cancer progression. The objective of this study is to analyze cell compartmental expression of FAP and aSMA using an AI based image analysis method. We also study the role of FAP and αSMA expression in predicting disease progression and mortality.

Materials and Methods We applied FAP (ab207178, Abcam)/αSMA (M0851, DAKO) double chromogen immunohistochemical (IHC) staining to three independent cohorts of formalin-fixed paraffin-embedded (FFPE) prostate cancer tissue microarrays. All together, we analyzed 835 patients' samples. First cohort consists of 387 patients with preoperative multiparametric MRI and robot-assisted laparoscopic prostatectomy (RALP) as primary treatment. Second cohort was case vs control cohort of Grade group 2-4 localized PCa at radical prostatectomy (RP) with 168 patients. Third cohort consists PCa patents from continuous, population-based collection of radical prostatectomies of 319 patients. Image analysis was performed with Aiforia Create, which is cloud-based deep-learning artificial intelligence software that provides platform for training and validating automated image analysis pipelines using convolutional neural networks. Analysis algorithm in this project was based on semantic, pixel-level area segmentation.

Results FAP expression was higher and αSMA lower in MRI-visible tumors compared with MRI-invisible tumors. Stromal and epithelial FAP expression associate with tumor progression. We could also see statistically significant differences in FAP positivity between clinically significant (GS ≥7) and insignificant (GS ≤6) tumors. Hazard ratios imply that FAP and αSMA have significant impact on risk of biochemical recurrence in patients with MRI-visible tumors.

Conclusions FAP is closely linked to tumor MRI visibility, cancer progression, and Gleason scores, marking it as a valuable biomarker in PCa assessment. High stromal αSMA is primarily associated with MRI visibility. Our automated AI-based image analysis method has demonstrated reliability, aligning with our previous findings. This advances the potential for more accurate and efficient prostate cancer diagnosis and prognosis, offering a potential benefit to future patient care.

#0303 Revealing molecular mechanism of G protein-coupled receptor kinase 2 (GRK2)-mediated extracellular matrix remodeling in ovarian cancer.

W. Lei[1], S. Yu[2], C. Lei[1], Z. Zhang[1], T. Liu[1], W. Chang[1], L. Lee[1];
[1]University of Macau, Macao, Macao, [2]Second Affiliated Hospital of Harbin Medical University, Harbin, China

G protein-independent pathway (β-arrestin dependent signaling cascade) is initiated by activated GPCRs phosphorylated by G protein-coupled receptor kinases (GRKs), triggering multiple signaling pathways. The purpose of this research is to reveal the role of GRK2 on the tumor microenvironment (TME). Through *in vitro* assays, we showed that GRK2 overexpression led to loss of cell-matrix and cell-cell adhesion. The cell spreading assay further indicated that the loss of focal adhesion (FA) assembly and cell size decreased in GRK2-overexpressing cells. *In vivo* experiments demonstrated that tumor formation and metastasis were suppressed in xenograft mouse models implanted with GRK2-overexpressing ovarian cancer cells. In addition, label-free imaging detection of the collagen pattern suggested that GRK2 overexpression caused bundle loss but the formation of thicker, twisted collagen fibers in xenograft tumor samples. Together with the transcriptome and proteomic data, we hypothesize that GRK2 suppresses cell motility and metastasis by reducing FA and extracellular matrix (ECM) remodeling in ovarian cancer. This research revised the mechanisms underlying GRK2-mediated ovarian cancer metastasis and suggested the potential to target the GRK2-meditated pathway for cancer suppression.

#0304 The role of DDR1 mediated E-cadherin stability in collective colon cancer cell migration.

H.-C. Chen, Y.-C. Wang, Y.-C. Ching, C.-P. Cheng, C.-E. Ku, S.-R. Lee, W.-T. Chao;
Tunghai University, Taichung City, Taiwan

In cancer metastasis, the mechanism of single cell migration and collective cell migration are investigated. The dynamics of E-cadherin is critical in collective cell migration as the important mechanism of metastasis. DDR1 (Discoidin Domain Receptor 1) has been shown to promote E-cadherin stability at adherens junction in epithelial cells by regulating endocytosis of E-cadherin. However, in the growth of epithelial cell cluster and collective cell migration, the role of DDR1 in the cell-cell contacts is not clear. In this study, HT-29 colon cancer cells with epithelial phenotype were used in the experiments. Cells were treated with epidermal growth factor to stimulate E-cadherin turnover or applied with lysosome inhibitor chloroquine to interfere cellular vesicle transport. DDR1 and E-cadherin were revealed by immuno-confocal microscopy. The immunostaining results showed DDR1 was localized at cell-cell contacts and co-localized with E-cadherin. When cells were treated with epidermal growth factor, the phosphor MAPK activity was increased and DDR1 was localized at cell-cell contacts intensively. When lysosome activity was blocked by chloroquine treatment. The cellular vesicle transport and collective cell migration was reduced and furthermore inhibited DDR1 translocation to the cell-cell contacts. This study demonstrated DDR1 co-localized with E-cadherin is responsible for epidermal growth factor stimulation in cell cohort. Lysosome activity is required for E-cadherin turnover and affected DDR1 translocation. Chloroquine maybe the potential drug to suppress tumor nest growth and collective cell migration by interfere DDR1 mediated E-cadherin stability.

#0305 Bioinspired synthetic hydrogel in pancreatic cancer organoid matrix modeling.

M. Hossan[1], A. Stram[1], E. Lin[1], S. McIlwain[1], C. Lebakken[2], W. Richards[2], J. D. Kratz[1];
[1]University of Wisconsin-Madison, Madison, WI, [2]Stem Pharm, Inc., Madison, WI

Background: Pancreatic ductal adenocarcinoma (PDAC) is a leading cause of cancer mortality with a primary hallmark, including dense collagen matrix in the desmoplastic stroma. Organoid technologies often rely on commercially available EHS mouse sarcoma matrix materials, and it remains uncertain how batch-to-batch variability of this matrix impacts the consistency of cancer signaling. Here, we present a novel photo-activated hydrogel tuned to the properties of the desmoplastic stroma in PDAC organoid cultures.
Method: We designed multiple synthetic hydrogel materials with tunable mechanical properties, including SP-139 (Stem Pharm, Inc), a polyethylene glycol-based hydrogel functionalized with norbornene and formed with both degradable and non-degradable crosslinking peptides and a cell adhesion peptide (CRGDS). We used rheometry to measure the elastic modulus of the polymerized hydrogel after visible light photoactivation (395 nm) and expanded multiple cancer organoid cultures. RNAseq was performed from patient-derived xenografts to expanded organoids across matrix designs (Cultrex® v. SP-139) and analyzed by GSVA pathway analyses.
Result: We optimized the ratio of non-degradable v. degradable crosslinking peptide to support culture expansion and enzymatic digestion with dispase II (125 µg/mL) and collagenase II (1 mg/mL). Using rheometry, SP-139 at 75% v/v had increased elastic modulus versus Cultrex RGF BME matrix Type 2 at 100% v/v (4992±76.3 v. 68.4±5.6 Pa, $p<0.0001$). Phenotypic growth was confirmed across serial passages (>8) and a diversity of gastrointestinal cancer types (n=5). Baseline growth rates were identical over 48h between SP-139 (75% v/v) and Cultrex (50% v/v) (+13.4% v. +13.0, $p=0.75$). Growth remained consistent for SP-139 yet increased with Cultrex at interval of 48-96h (+12.9% SP-139 v +22.4% Cultrex, $p<0.005$) and interval of 96-144h (+13.6% SP-139 v +24.0% Cultrex®, $p<0.0001$). Therapeutic response was assessed using 3D CellTiter-Glo® using gemcitabine 100 µM (24h) with comparable inhibition of normalized cell viability in SP-139 v. Cultrex® (35.4±1.9% v. 52.3±6.5%, n.s.) and qualitatively with viability staining using calcein AM and Caspase 3/7 ^{FITC}. RNAseq revealed Cultrex, when compared to SP-139, yielded down regulation of epoxygenase p450 pathways ($p_{adj}<0.012$) and negative regulation of the p38 MAP kinase cascade ($p_{adj}<0.048$).
Conclusions: Functionalized PEG-based synthetic hydrogel matrix materials can be tuned for physical properties to mimic cancer tissue microenvironments more accurately. SP-139, designed to mimic the desmoplastic stroma of the pancreatic cancer microenvironment, has favorable properties including controlled growth rates and compatibility with high content imaging by luminescence and fluorescence. RNAseq pathway analysis shows SP-139 maintains pathways of p450 and MAP kinase signaling of importance with therapeutic resistance.

#0306 The role of exosomal UBE2R2 in colorectal cancer drug resistance.

C. Maeng[1], M. Choi[2];
[1]Kyung Hee University, Seoul, Korea, Republic of, [2]Kyung Hee University Hospital, Seoul, Korea, Republic of

Background: Ctherapy resistance has been a major barrier against successful theratment. Exosome (EV), an important intercellular communication mediator, participates in a highly and complex network that drug resistance of cancer cells. EV has been reported to be able to transfer drug resistance from drug-resistant tumor cells to adjacent drug-sensitive cells. We identified a novel target, UBE2R2, based on our previous exosome proteomics analysis of resistant colorectal cancer cell lines. The main goal of this study is to validate the underlying mechanisms leading to chemotherapy resistance.
Methods: We isolated EV from drug resistant cancer cell lines including coloractal cancer cell lines (HCT116-OXAR, DLD-1 OXA-R, DLD-1-OXA-R/SN38) its parental cell lines (HCT116, DLD-1) using the ExoLutE isolation kits based on a combination of multiple isolation techniques. Based on the existing data (proteomic analysis), we conducted experiments to elucidate the functions and mechanisms involved in cancer resistance of the identified UBE2R2. Cell viability assay and invasion asaay were performed to assess the effects of EVs drived from drug resistance colorectal cells on oxaliplatin and irinotecan resistance. In addition, cells transfected with siControl and siUBE2R2 were treated with oxaliplatin to access the relative UBE2R2 drug resistance effect. To explore the related mechanisms, we performed real time PCR and western blot to identify the UBE2R2-SMYD3-P53 pathway, and FACS analysis to confirm apoptosis. Additionally, TMA samples were utilized to confirm resistance according to patient stage, and UBE2R2 expression was validated by immunohistological methods.
Results: UBE2R2, which is involved in ubiquitination, was most prominently expressed in resistant cell lines compared to controls in our previous proteomic analysis. Based on these results, we found that cell lines treated with exosomes which were derived from resistant cell lines showed lower sensitivity to the drug. Notably, treatment of resistant cell lines with siUBE2R2 resulted in increased sensitivity, confirming the involvement of UBE2R2 in resistance. As a possible mechanism in which UBE2R2 may be involved, western analysis targeting the SMYD-P53 mechanism showed that the combination of UBE2R2-SMYD3-p53 promoted the ubiquitination and degradation of p53. Analyzed using TMA patient samples, we found that the expression of UBE2R2 increased towards more advenced stage.
Conclusion: Our results suggest a novel mechanism of chemotherapy resistance may be associated with UBE2R2. Exosome (including UBE2R2) which was drived from drug resistance cells may induce oxaliplatin and irinotecan resistance in parental colorectal cells via regulation of SMYD3-UBE2R2-P53 signaling pathway, which will be useful for investigating a potential clinical target in prediction drug resistance.

#0307 Generation and characterization of a glioblastoma stem cell model with acquired resistance to LSD1 inhibition.

K. H. Patel, L. Stitzlein, D. Nam, F. Lang, J. Gumin, J. Chandra;
MD Anderson Cancer Center, Houston, TX

Epigenetic modifications play an important role in the initiation of various cancer types, including glioblastoma (GBM), and in the development of therapeutic resistance. Patients with GBM, a common malignant brain tumor, have an average survival of 12-15 months after first-line therapy. Lysine-specific demethylase 1 (LSD1) is a histone demethylase that is overexpressed in glioblastoma stem cells (GSCs) and functions to promote proliferation, inhibit differentiation, and enhance motility. Previous work from our group has investigated LSD1 as a therapeutic target in glioblastoma and identified genes that may predict resistance to pharmacological LSD1 inhibitors using RNA-seq. Five upregulated genes, HKDC1, RAB3IL1, RAB39B, FTH1, and FAM213A, were associated with LSD1 inhibitor (LSD1i) resistance and were validated in brain tissue of a GBM model treated with GSK-LSD1 after succumbing to tumor burden. In order to determine whether selection pressure from LSD1 inhibitor treatment caused upregulation of these genes, we created a model of acquired resistance in GSC lines in vitro. Isogenic resistant lines were generated by treating MDA-GSC17 cells with increasing concentrations of LSD1i or diluent (DMSO), as tolerated starting at 50 uM (which was five fold below the IC50 for these lines). In parallel, MDA-GSC17 controls were exposed to DMSO. The resistant line was created over 4 weeks and monitored by cell number and viability to reach 90%. To assess the change in gene expression, we conducted quantitative PCR for the five genes in the parental and resistant MDA-GSC17 line and saw upregulation in 3 of the 5 genes. Two genes, HKDC1 and RAB3IL1, were unable to be assessed due to low basal expression. However, 3 genes were upregulated which are RAB39B, FTH1, and FAM213A. RAB39B is a Ras-analog in brain (RAB) small GTPase and a member of the RAS oncogene family, involved in vesicular trafficking. High expression of ferritin heavy chain 1 (FTH1) is correlated with high-grade gliomas and poor prognosis in glioblastoma. Lastly, the redox regulatory protein, FAM213A, can activate antioxidant proteins and elevated expression is associated with worse outcomes for AML patients. This suggests that modulating the RAS signaling pathways and specific redox pathways may overcome LSD1 resistance. Understanding the changes in gene expression as the cells acquire resistance to LSD1 inhibitors will help us understand the mechanism of resistance to LSD1 inhibitors in glioblastoma and to design new treatment strategies.

#0309 AHNAK nucleoprotein 2 tune oxidative stress and resistance to chemotherapy in triple negative breast cancer.

N. Hao;
The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: Resistance to chemotherapy is a major reason for the poorerprognosis in patients with triple negative breast cancer (TNBC). Growing evidence suggests that oxidative stress induced by reactive oxygen species (ROS) is an important factor in both tumourprogression and responses to chemotherapies, however, many signalling pathways and key molecular underlying the regulation of cancer cells to the ROS metabolism remains unclear.
Aim: (i) To investigate the mechanistic role of AHNAK nucleoprotein 2 (AHNAK2) in TNBC and its links with breast cancer mortality, particularly caused by chemotherapeutic resistance; and (ii) to test a hypothesis that AHNAK2 facilitates the abnormal activation of ROSscavenging system, result in the resistance to chemotherapy in TNBC.
Methods: The expression level of AHNAK2 was determined by immunohistochemical staining and analysed the mRNA expression profiles from The Cancer Genome Atlas of triple negative breast tumors. Roles of AHNAK2 in cancer cell growth, metastasis, chemotherapeutic resistanceand activation of oxygen scavenging systemwere determined by molecular and cell biology methods. A jetPEI nanocarrier was used as the vehicle for anti-AHNAK2 siRNAs in mouse models of cancer therapeutics.
Results: AHNAK2 is a novel triple negative breast cancer target, which is overexpressed in TNBC tissues and significantly associated with clinical pathology of chemotherapeutic resistance and poor prognosis of tumour patients. Mechanistically, AHNAK2 antagonizes the ROS accumulation induced by epirubicinvia activating JAK-STAT signaling pathway and transportingphosphorylated STAT1 & STAT4 to the nucleus to promote the expression of SOD2, a key gene in ROS metabolism.And epirubicin enhanced AHNAK2 expression by induced the accumulation of ROS,which hence the Sp1-driven transcription of AHNAK2,result inde novo resistance. Furthermore, AHNAK2-specific siRNAs encapsulated by jetPEI nanocarriers prominently inhibit tumor growth and epirubicin-induced resistance in vivo.
Conclusions: AHNAK2 plays a key role in resistance to chemotherapyby regulating the oxidative stressand ROS metabolism,representing a future biomarker and therapeutic target of TNBC.

#0310 Cadherin-dependent modulation of chemosensitivity in oral tumor progression.

A. Mody, C. Decker, K. R. Lawson;
Midwestern University - Glendale Campus, Glendale, AZ

The progression of healthy oral epithelia to an oral carcinoma often involves aberrant expression of a group of calcium-dependent transmembrane proteins called cadherins. Histological studies of human tumors have demonstrated increased expression of the epithelial-resident placental (P-cadherin) and ectopic expression of the mesenchymal neuronal (N-cadherin) cadherin in oral dysplasia. We hypothesized that these changes in cadherin expression during early oral tumor development could facilitate increases in survival signaling. We genetically modified dysplastic oral keratinocytes to overexpress P-cadherin or suppress endogenous expression of N-cadherin. P-cadherin overexpression and N-cadherin suppression independently elicited a 3-6-fold decrease in apoptosis levels in response to docetaxel treatment compared to similarly treated controls. We found that in untreated dysplastic cells, P- and N-cadherin expression had positive and negative correlations, respectively, with the activation of the survival-associated enzymes focal adhesion kinase (FAK), mitogen-activated protein kinase (MAPK), and AKT kinase. The total levels of nuclear factor kappa B (NFkb) were positively correlated with P-cadherin overexpression and reciprocally correlated with levels of N-cadherin. In docetaxel-treated dysplastic cells, we observed the reverse effect compared to untreated cells: the increased level of N-cadherin was positively correlated with FAK activity whereas FAK activity was suppressed by P-cadherin. P-cadherin expression in docetaxel-treated cells also increased activation of both MAPK and AKT, whereas alteration of N-cadherin levels had no effect. Because N-cadherin levels are known to increase in late-stage oral tumors, we extended these signaling studies to oral squamous carcinoma cells (OSCCs) expressing low or high levels of N-cadherin. In contrast to its suppression of survival pathways in docetaxel-treated dysplastic cells, in docetaxel-treated OSCCs, N-cadherin expression strongly enhanced phosphorylation of MAPK and AKT, and increased expression of NFkb. N-cadherin overexpression during this treatment also increased expression of the antiapoptotic proteins Mcl-1 and suppressed phosphorylation of the apoptotic regulator signal transducer and activator of transcription 3 (pSTAT3). Increase cadherin expression in all untreated cell lines increased expression of an inducer of epithelial to mesenchymal transition, the transmembrane protein mucin-1 (MUC1). N-cadherin overexpression also increased motility in both cell lines. Taken together, our data demonstrate antiapoptotic signaling directed by increased levels of P-cadherin in oral dysplasia and N-cadherin in OSCC, whereas increased levels of N-cadherin in dysplastic cells directed cellular signaling that were associated with a proapoptotic phenotype.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Advances in Genomic Sequencing Platforms, Methodologies, and Interpretation 1

#0313 Benchmarking immune repertoire sequencing technologies.
S. Maheshwari, C. Morrison, S. Taylor, BCR-SEQC consortium;
10X Genomics, Pleasanton, CA

In the past decade, single cell gene expression technologies have transformed basic and translational research and are more frequently found in the toolbox of immunologists alongside the standard bulk B-cell receptor (BCR) sequencing and transcriptome profiling assays. While conventional bulk BCR assays capture the frequency of single chains, single-cell immune profiling reveals the frequency of *paired* heavy and light chains along with the cells transcriptional profile. Here we present the results of a single-blind benchmarking experiment conducted in collaboration with the U.S. Food and Drug Administration (FDA) that compares the performance of standard bulk DNA and RNA BCR repertoire sequencing assays, with the 10x Genomics Single Cell Immune Profiling solution. The FDA selected nine unambiguously monoclonal BCR-expressing cell lines to generate a reference mixture that was shared with each study participant, without revealing the input proportions. This reference cell line mixture was also diluted to 10% and 1% with B-cells sorted from peripheral blood mononuclear cells (PBMC) to further test the limits of clonotype detection.
For each experiment, we targeted ~10,000 cells and in aggregate generated a paired gene expression and V(D)J dataset from ~100,000 cells. BCR clonotypes were detected in 78% of the captured cells across all samples profiled. Each of the 9 top unique clonotypes observed in our dataset corresponded to a cell line in the reference mixture, allowing us to decode the mixing percentages of each BCR-expression cell line. In addition, we were able to identify rare cell line clonotypes to as low as 0.01% in the dilution experiments. Furthermore, the multimodal nature of the single cell data also resolved the transcriptional profile of each cell line into its own cluster thus enabling independent verification of clonotype proportions.
In summary, we have generated a resource for the immunology community to evaluate and compare data generated with different repertoire sequencing technologies.

#0314 Fixative eXchange (FX)-seq reveals single nucleus transcriptional landscapes of archived clinical cancer FFPE specimens.

H.-E. Park, Y. Lee, J. Lee, J. Lee, H. Ji, Y.-L. Song, Y. Han, H. Kim, C. Sohn;
Yonsei University, Seoul, Korea, Republic of

The wide availability of FFPE tissues stored in hospitals and biobanks could potentially be an invaluable resource to gain insights for improved medical treatment towards precision medicine by combining genomic and transcriptomic data with pathological annotations and medical records. Nevertheless, the majority of current single-cell sequencing methods depend on fresh or fresh-frozen samples to generate high-quality transcriptome data due to the limited reverse transcription (RT) yields in FFPE samples. Consequently, single-cell level transcriptomic studies of FFPE samples have been a longstanding challenge. Here, we present Fixative-eXchange (FX)-seq, a highly scalable snRNA-seq method for heavily paraformaldehyde (PFA)-fixed and/or FFPE samples. We successfully analyzed a total of nearly 320k nuclei from various samples, including PFA-fixed tissue, FFPE blocks, FFPE and hematoxylin and eosin (H&E)-stained sections from mouse brain and human clinical cancer specimens. In a human gastrointestinal stromal tumor (GIST) FFPE sample, we observed rare transcriptomic transitions toward increased epigenetic modifications affected by acquired resistance in response to prolonged imatinib treatment. Furthermore, in an archived human colorectal cancer (CRC) FFPE sample, spatially-contextualized FX-seq with pathologist annotation distinguishes tumor cells from epithelial progenitors along with identification of the tumor microenvironment (TME) such as cancer-associated fibroblasts (CAFs). We then proceeded to investigate transcriptional programs associated with drug resistance and lack of response in immunotherapy observed in CRC patients. With a hypothesis-driven curation, we compared transcription profiles at the single-nucleus level observed in MSS and MSI-H CRC patients from archived FFPE blocks and found distinctive transcriptional profiles from each group. Overall, FX-seq holds promise for clinical research, precision medicine, biomarker discovery, and molecular diagnosis using archived clinical FFPE specimens.

#0315 Cost-effective, comprehensive detection of gene fusions from DNA and RNA using the UG100 sequencer.

G. Lithwick-Yanai[1], S. Pollock[1], D. Lebanony[1], K. Ben Simhon[1], S. Benjamin[1], D. Bogumil[1], N. Iremadze[1], M. Sexton[1], P. Winer[1], M. Levy[1], S. Gilad[1], J. Haimes[2], G. Corbet[2], J. Pavlica[2], D. Lipson[1];

[1]Ultima Genomics, Fremont, CA, [2]Watchmaker Genomics, Inc., Boulder, CO

Background: Gene fusions, resulting from chromosomal rearrangements, play a critical role in the oncogenesis of various cancers, often acting as diagnostic markers and therapeutic targets. Their detection is important for understanding tumor biology and guiding personalized treatment strategies. With the evolution of economical sequencing technologies, hypothesis-free gene fusion detection in cancer genomics is becoming more accessible. This study demonstrates the use of the cost-effective Ultima Genomics UG100 platform for a comprehensive analysis of gene fusions, uniquely integrating Whole Genome Sequencing (WGS) and Whole Transcriptome Sequencing (WTS). This integration capitalizes on the strengths of both methods: WGS, which enables a broad analysis of structural variations including extragenic events, and WTS for more functional characterization of expressed gene fusions and abnormal isoforms, offering a synergistic approach that enhances the detection and characterization of genomic rearrangements.

Methods: Five cancer cell lines (K562, THP-1, NCI-H660, Kasumi-1, MV4-11) with 29 previously detected gene fusions were sequenced, using both WTS and WGS, in addition to a standard fusion reference sample (Seraseq Fusion RNA Mix, with 16 RNA fusions). The libraries were sequenced on a UG100 sequencer using single ended reads of length ~250bp and analyzed with publicly available software: STAR-Fusion, combined with FusionInspector were used to detect RNA fusions; Manta and GridSS were used to detect DNA structural variations, including translocations.

Results: 93% of the documented fusion events were detected in DNA and in RNA, in addition to the 16 evaluated just in RNA (100% detected). Sequence data from both WTS and WGS on the UG100 platform successfully identified a spectrum of gene fusions in both DNA and RNA, thereby confirming the platform's detection capabilities in both types of assays. The structural variation events detected in the WGS were comprised mainly of translocations, but also deletions and duplications.

Conclusions: The Ultima Genomics UG100 sequencer has proven to be a cost-effective and efficient tool for the genome-wide discovery and validation of gene fusions, which can be impactful in clinical oncology settings. This study underscores the potential of using an integrated WTS and WGS approach on a single platform to advance our understanding of the genomic complexity of cancer, paving the way for more effective diagnostic and therapeutic strategies.

#0316 A novel, high-throughput full-length scRNA-seq workflow for improved biomarker discovery.

P. Xu[1], J. Liu[1], Y. Ryan[1], K. Tori[1], X. Li[1], H. Anbunathan[1], M. Covington[1], T. Uchiyama[1], M. Fallahi[1], X. Qu[2], X. Xing[2], T. Wang[2], B. Bell[1], **S. Chen**[1], Y. Yun[1], A. Farmer[1];

[1]Takara Bio USA, San Jose, CA, [2]Washington University in St. Louis, St. Louis, MO

Objective: Single-cell RNA-seq (scRNA-seq) analysis has been widely applied in oncology research for biomarker discovery. Although droplet-based methods are commonly used for such studies owing to their high throughput, they still miss important insights due to their lack of full-length transcript coverage. While full-length methods are available, to date, they have not been able to meet the throughput demands of many researchers. Moreover, both droplet and full-length scRNA-seq methods do not currently provide adequate readouts for non-coding genes, thereby limiting investigation of gene regulatory networks to protein coding genes. To close these gaps, we have developed a new high-throughput full-length scRNA-seq workflow that comprehensively profiles both protein-coding and non-coding genes in up to 60,000 cells within two days.

Methods: Our new high-throughput workflow uses two rounds of combinatorial indexing, starting with a 96-well plate format for the first barcoding step followed by an automated second barcoding step in a 5,184-nanowell chip using an automated nanodispensing system. Initial testing demonstrated that our method could handle up to 60,000 cells without generating significant levels of doublets due to barcode collisions. To further illustrate the capacity of the new scRNA-seq approach, we profiled a total of approximately 11,000 isogenic A549 cells that either express WT TP53 or are TP53 null. In addition, both isogenic cell lines were treated with epigenetic therapy or mock treatment. Libraries were generated and sequenced using an Illumina® NextSeq®2000 sequencer. The sequencing data was then analyzed to define differential gene expression for both protein-coding and non-coding transcripts as a function of TP53 genotype and treatment condition, using Cogent™ NGS software.

Results: Preliminary analysis showed that, on average, approximately 11,000 genes and 40,000 transcripts were detected per single cell at a read depth of 100,000 reads per cell. UMAP-based clustering confidently separated the cells according to their genotypes and treatment conditions using either protein-coding genes or non-coding genes. Furthermore, differential expression analysis identified both protein-coding and non-coding transcripts with significant expression differences, underscoring biological significance.

Conclusion: Our new high-throughput full-length scRNA workflow enables preparation of high-quality full-length RNA-seq libraries for up to 60,000 cells with only two rounds of barcoding and shows high sensitivity and specificity in gene/transcript detection and quantification. The technology significantly improves the ability to identify new biomarkers by enabling comprehensive profiling of both protein-coding and non-coding full length transcripts.

#0317 Using the Biomek NGeniuS Next Generation Library Prep System to automate the Illumina TruSight Oncology 500 assay.

Z. Smith;
Beckman Coulter Life Science, Indianapolis, IN

Cancer researchers using next generation sequencing (NGS) need reliable sample preparation methodologies that generate high-quality, sequence-ready libraries from often-challenging samples. This process can be aided using automated liquid handling systems.

The Biomek NGeniuS Next Generation Library Prep System from Beckman Coulter Life Sciences is a reliable, easy-to-use, purpose-built liquid handler for NGS library preparation ideal for laboratories requiring more flexibility and less hands-on time. The user-friendly software requires no programming skills, making it easy to set up and run. Biomek NGeniuS Next Generation Library Prep System's hardware features include an on-deck thermal cycler, gripper, temperature-controlled reagent storage, and high-density tip storage which reduces user interventions and enables more walkaway time. An extensive and growing library of complimentary demonstrated NGS sample prep protocols allows the user to select from a variety of applications for NGS workflows. One such workflow is Illumina TruSight Oncology 500 assay, which represents a comprehensive NGS assay targeting the full coding regions of 523 genes implicated in the pathogenesis of solid tumors. Using enrichment-based library preparation techniques for use with formalin-fixed, paraffin-embedded (FFPE) samples, the Illumina TruSight Oncology 500 assay, when running the DNA Only workflow, can detect single nucleotide variants (SNVs), indels, amplifications, and multinucleotide variants (MNVs) in a single sequencing run. The Illumina TruSight Oncology 500 assay also detects immunotherapy biomarkers for tumor mutational burden (TMB) and microsatellite instability (MSI) in DNA samples. The Illumina TruSight Oncology 500 assay also offers a combined RNA/DNA workflow that also allows for the assessment of fusion events.

In this poster, we show the utility of the Biomek NGeniuS Next Generation Library Prep System to perform the Illumina TruSight Oncology 500 assay, which saves researchers valuable hands-on time and offers a highly streamlined setup process for users new to liquid handling automation.

#0318 Demystifying tumor heterogeneity with a fully automated, high-throughput single-cell DNA-Seq (scDNA-seq) workflow.

X. Li, R. Mendoza, S. Leong, H. Anbunathan, M. Covington, M. Fallahi, B. Bell, S. Chen, Y. Yun, A. Farmer;
Takara Bio USA, San Jose, CA

Objective: Genetic heterogeneity is a key factor underlying tumor drug resistance and metastatic potential. Understanding this heterogeneity is therefore vital to improving both prognosis and treatment. Next-generation sequencing is a valuable tool for analyzing the genetic makeup of tumors. However, bulk sequencing methods lack the sensitivity to fully resolve tumor heterogeneity. While single cell methods provide a powerful approach to dissect such heterogeneity, to date, these methods have been limited in their throughput. To address this bottleneck, we have developed a fully automated workflow for generating scDNA-seq libraries based on PicoPLEX® whole genome amplification (WGA) technology. This high-throughput method, which has been optimized on our ICELL8® cx Single-Cell System, enables the generation of WGA libraries for >1,000 single cells within one day.
Methods: We first sought to demonstrate the ability of this new high-throughput method to generate WGA libraries of comparable quality to the standard PicoPLEX workflow in terms of genome coverage, GC bias, and other typical quality metrics. We additionally assessed copy number variant (CNV) detection sensitivity using two cell lines with well-characterized small segmental CNVs: GM22601 (~25Mb deletion on chromosome 4) and GM05067 (~45Mb gain on chromosome 9). We also analyzed a lymphoblastoid line (K562) that carries a range of chromosomal aneuploidies. A total of 1,288 single-cell WGA libraries were generated and sequenced to a depth of 250K paired-end reads per cell. Data analysis was done using the Ginkgo CNV pipeline with an average bin size of 500 kb. As a final proof of principal, we also generated single cell data using tumor and adjacent normal tissue from two clear cell renal cell carcinoma (ccRCC) samples.
Results: Libraries generated using our high-throughput workflow had a high mapping rate, with 94.1% of the reads being uniquely mapped. Additionally, the libraries were comparable to those generated with the standard PicoPLEX workflow in terms of coverage uniformity, GC bias and other metrics. Moreover, the segmental aneuploidies in both GM22601 and GM05067 were reliably detected in >90% of cells at a read depth as low as 250,000 reads per cell. Analysis of the ccRCC samples revealed subclonal heterogeneity with various CNVs common to ccRCC, including deletion of chr. 3p, amplification of chr. 5q, and duplication of chr. 2.
Conclusion: By adapting PicoPLEX technology to high throughput using the ICELL8 cx Single-Cell System, we have obtained single-cell WGA libraries from up to 1,200 cells at once and enabled the reliable detection of CNVs and tumor subclones at a shallow sequencing depth. In addition, by leveraging the automated nanoliter-dispensing capabilities of ICELL8 cx system this method provides a significant reduction in reagent use and labor compared to plate-based methods.

#0319 Demonstrating the use of Archer VARIANT*Plex*™and FUSION*Plex*™assays in observing variants at sub-0.1% allele frequencies and low transcript number fusions in acute myeloid leukemia relevant genes.

L. A. Johnson, M. Washburn, P. Kalavakur, D. Legare;
IDT, Boulder, CO

The presence of acute myeloid leukemia (AML) residual disease is valuable for understanding cancer progression. Studies have shown that variants detected at allele frequencies as low as 0.01% are useful for stratifying acute myeloid leukemias [1]. Both low limits of detection and high specificity are required for an assay to be useful in this context. Therefore, labs must choose an assay that has inherently low levels of background noise and that employs robust error suppression techniques.

Here we demonstrate the use of IDT's Archer Next Generation Sequencing-based VARIANT*Plex* and FUSION*Plex* assays (RUO) and accompanying software, Archer Analysis, for the application of detecting low allele frequency and low transcript number fusions with high levels of sensitivity and specificity. Currently available Archer assays and software solutions target AML-relevant variants and are compatible with multiple sequencing platforms. Using Archer technology, key AML-related mutations were detected at allele frequencies less than 0.1%, and low transcript numbers of myeloid relevant fusions were identified. In addition, greater than 95% of the bases in the targeted region of interest were powered to detect variants at allele frequencies of less than 0.1% in the VARIANT*Plex* libraries. Finally, error correction and noise filtering techniques remove many false positive variants in order to reduce the false positive variant calling rate.

To generate the input material, 1,000 ng total gDNA or 200 ng total RNA from commercially available cell lines containing myeloid relevant variants was diluted into a background of wild type gDNA at a mass ratio of 1:100 or RNA at a mass ratio of 1:20 to assess analytical sensitivity. Libraries were prepared using the catalog panels VARIANT*Plex* AML Focus or the FUSION*Plex* Pan Heme assay. Libraries were sequenced on Illumina and Element Biosciences sequencing platforms. Data were analyzed with Archer Analysis using a pipeline which includes read cleaning, deduplication, error correction, variant calling, and reporting steps.

In conclusion, the VARIANT*Plex* AML Focus assay used with Illumina or Element sequencers demonstrated the ability to detect variants down to allele frequencies of 0.05%, and the FUSION*Plex* Pan Heme assay was used to detect low transcript number fusions which may be useful for AML minimal residual disease research.

#0320 Development and automation of a streamlined targeted enrichment method for cancer mutation detection.

Z. Wu[1], M. Baird[1], C. Mechlen[2], P. Hahn[2], J. M. Shaffer[1];
[1]QIAGEN, Inc., Frederick, MD, [2]QIAGEN GmbH, Hilden, Germany

Next Generation Sequencing (NGS) of DNA is a powerful tool for the detection of genetic variations, including single nucleotide polymorphisms, copy number variation, and small insertions/deletions. Target enrichment technologies enhance DNA sequencing by enabling users to analyze specific regions of interest only, which helps to effectively increase sequencing depth and sample throughput while minimizing cost. However, many targeted DNA library construction workflows are not optimal for routine genetic testing needs due to inconsistent, lengthy workflow. This poses significant challenge to application like cancer mutation profiling that requires detection sensitivity down to 1% or below due to heterogeneous nature of tumor tissue. In addition, high throughput testing with minimal hands on time is desirable with the rapid advance of precision medicine. Magnetic bead separations are commonly used between the individual reactions of targeted DNA library preparation workflows for cleanup and size selection. These bead clean up reactions are not only labor-intensive and tedious procedures but can also greatly contribute to sample-to sample variation especially when employing automated library preparation procedures. With the sophisticated QIAseq Targeted DNA Pro, we developed a novel streamlined targeted DNA workflow that greatly reduces handling variation by replacing the majority of bead clean up steps with enzymatic reactions, which now can be finished in as little as six hours. In combination with the newly developed QIAseq Normalizer kit, the protocol has been successfully implemented on the Hamilton NGS Star liquid handling platform resulting in up to 96 highly uniform, complex and ready-to-sequence libraries that can be effortless generated in one run. This complete automated solution saves researcher up to four hours of hands-on time. When using commercial reference samples, cancer mutations down to 1% were consistently detected with this automated workflow. The presented data demonstrate that this integrated and streamlined workflow does not only provide an automation friendly workflow but also allows to reliably identify low frequent cancer mutations. The applications presented here are for research use only. Not for use in diagnostic procedures.

#0321 Optimized RNA Seq library preparation for fusion calling from FFPE samples.

G. Corbet, J. Haimes, T. Sanders, M. Ranik, T. Harrison, E. Casas, K. Reed, D. Wendel, K. Giorda, A. Hanek, J. Pavlica, B. Kudlow;
Watchmaker Genomics, Boulder, CO

Gene fusions due to chromosomal rearrangement, duplication, or deletion can be important drivers of cancer. Detection of gene fusions plays a valuable role in selecting targeted therapies. A widely used method for detecting fusion transcripts is targeted RNA sequencing, which focuses sequencing reads on known fusions but does not allow for the detection of novel fusions. Whole transcriptome analysis (WTA), where the entire transcriptome is interrogated, offers an opportunity to detect both known and novel fusions.

Herein we examine the effect of sample quality, input mass, increased reverse transcriptase (RT) and insert size on fusion calling. Libraries are prepared using the Watchmaker RNA Library Preparation Kit with or without Polaris Depletion and, for target enrichment, the Twist Exome 2.0 panel prior to paired end 2x150 Illumina sequencing. First, control samples, specifically Seraseq Fusion RNA v4 high quality and FFPE samples, are used to determine if any of the parameters interrogated increase the number of breakpoint spanning reads both in a WTA and targeted sequencing context. Once established, the optimized workflow is applied to real FFPE samples.

Targeted sequencing results in a higher number of breakpoint spanning reads, compared to WTA, when controlling for sequencing depth, resulting in a higher number of reads supporting each fusion call. Longer insert sizes, achieved by modified SPRI ratios, maintain library complexity and may enhance fusion calling. Taken together, these data demonstrate an optimized protocol for fusion calling from FFPE and demonstrate the utility of both WTA and targeted sequencing for fusion detection.

#0322 Ultraplex genome and exome sequencing of rare single cells.

I. Andreou[1], **S. Rulli, Jr.**[2], K. Heitz[1], S. Huebner[1], C. Meerschiff[1], E. Lader[2];
[1]QIAGEN GmbH, Hilden, Germany, [2]QIAGEN Sciences, Frederick, MD

Single-cell genome analysis enables researchers to gain novel insights into tumor heterogeneity. Conducting single-cell genomic analysis using next-generation sequencing (NGS) methods has traditionally been challenging since the amount of genomic DNA present in a single cell is limited. PCR-based amplification methods normally have high error rates, low coverage uniformity, and extensive allelic drop-outs making interpretation of SNVs and CNVs challenging.Here we introduce a new whole-genome amplification method which utilizes an optimized isothermal DNA amplification reaction with a Hi-fidelity, error correcting polymerase and downstream library preparation protocol to allow pooling of amplified DNA. The key DNA amplification steps use multiple displacement amplification (MDA) technology to amplify gDNA directly from single cells, nuclei or previously isolated genomic DNA. During the MDA reaction, sample-barcodes are incorporated into the newly synthetized DNA, allowing the amplified DNA to be pooled and processed in to one ultraplex library. This method saves library preparation time, reduces DNA library costs and limits plastic consumable usage.Our current workflow allows 24 samples to be multiplexed in one library and 24 libraries to be produced for a total of 576 samples per sequencing flow cell. This method can be used to investigate chromosomal instability with low pass sequencing or SNV and CNV analysis following whole genome, exome-capture workflows.

#0323 Optimization of a liquid biopsy assay to accommodate low cfDNA samples and increase throughput.

M. Salmans[1], D. Kim[2], A. Carson[1], M. Wang[1], B. Lee[1], B. Leatham[1];
[1]Genece Health, Inc., San Diego, CA, [2]GC Genome, Yongin-si, Korea, Democratic People's Republic of

Molecular testing that interrogates cell free DNA (cfDNA) from plasma has significant potential value across the cancer care continuum, including early cancer detection, driver mutation identification, and disease recurrence monitoring. To achieve this potential, liquid biopsy assays must be optimized to address multiple challenges. For one, cfDNA quantity in the blood is highly variable, with different amounts present depending on malignancy and stage of progression. This requires optimization to detect low concentrations of circulating tumor DNA (ctDNA) and to accommodate variable tumor fractions. In addition, minimizing assay costs will improve test accessibility and adoption. To address these issues, Genece Health is optimizing their lung cancer liquid biopsy assay to accommodate minimal cfDNA input into library preparation. Furthermore, Genece is testing algorithms that tolerate reduced read depths from low-pass whole genome sequencing (LP-WGS) while maintaining high performance. The Genece lung cancer liquid biopsy assay profiles fragment end-motif and size (FEMS) and fragment coverage signals using LP-WGS (Illumina) and proprietary machine learning algorithms. This study first tested the frequency of end motifs in pooled ctDNA after modifying library preparation (IDT) to reduce reagent volumes from 1X down to 0.5X, 0.25X, and 0.1X of manufacturer specification. A range of cfDNA input from 0.25 ng to 6 ng was tested with each library preparation volume. In addition, LP-WGS read coverage from 5X to 1X was evaluated to assess impact on end motif frequency and assay sensitivity. Performance characterization was further evaluated with a cohort of 50 clinical lung cancer and 100 healthy donor plasma samples tested at 1X and 0.25X library reagent volume. We observed an expected increase in library complexity at higher cfDNA input and library reagent volume. Assay performance was minimally impacted by variable cfDNA input and library reagent volume. However, reducing sequencing read depth is tolerated down to 1.25X depth before increasing the variability of end motif frequencies. These observations are corroborated in the 150 clinical sample cohort. This data shows that by altering standard library preparation conditions and reducing unique read depth, liquid biopsy assays can accommodate a wider range of cfDNA, while concurrently decreasing overall costs.

#0324 Comparison of xGen Exome Hyb Panel v2 (IDT) kit and Twist Exome 2.0 (TWIST) kit for whole exome sequencing optimization from low input and degraded FFPE samples.

R. Rock, N. Prasad, M. Robinson, D. Wildman, O. Montoya, M. Sykes, B. Umylyn, T. Halsey;
Discovery Life Sciences, Huntsville, AL

FFPE is the most common method used to store precious clinical samples at room temperature for extended periods (sometimes>15 years). FFPE samples are therefore one of the most commonly available samples that can be used for discovery and diagnosis. Whole Exome Sequencing (WES) is one of the most used NGS assays that is used for profiling somatic and tumor mutations. With future clinical trials moving towards less invasive collection methodology, core needle biopsy samples are becoming a method of choice. The FFPE fixation process leads to the degradation of nucleic acids due to cross-linkage and the availability of sufficient nucleic acid from CNB fixed samples for downstream NGS assays is becoming limited. Here we report a comparison of two Whole Exome capture kits from several degraded FFPE samples, NA12878, OncoSpan gDNA HD827 and SeraSeq Breast CNV mix gDNA samples using the xGen Exome Hyb Panel v2 (IDT) Kit and the Twist Exome 2.0 (TWIST) Kit. Libraries were prepared in triplicate at 50ng, and 10ng using the Ultra™ II DNA Library Prep (NEB) kit. Pre-capture libraries were evaluated to determine the total DNA library available for capture using the KAPA Library Quantification Kit (Roche) kit. The recommendations for input amount vary between the kits, with IDT recommending 500ng, and TWIST recommending 200ng per library. KAPA Library Quantification Kit kit was used to assess the nanomolar amounts of ligated libraries. Final libraries were pooled equimolar and then sequenced as 2x100bp Paired-end sequencing on the NovaSeq 6000 instrument to achieve a target of 150-300X overall coverage. The performance of each capture kit was evaluated on the number of libraries eligible for capture, percent duplication rate, median insert size, and mean target coverage. IDT capture had 49% of libraries eligible at recommended input of 500ng, with 34% of libraries generating between 100-499ng input and the remaining 17% failing to generate 100ng input for hybridization. TWIST capture had 83% of libraries eligible at recommended input of 200ng, with 4% of libraries generating between 50-199ng input and the remaining 13% failing to generate 50ng input for hybridization. Most notably, 96% of libraries at 50ng DNA input were eligible for TWIST capture, while only 46% of libraries at 50 ng DNA input were eligible for IDT capture. The average Q30 for IDT and TWIST capture were 93-94% respectively. Both IDT and TWIST capture kits produced similar duplication rates and average mean target coverage was comparable. Taken together, our testing shows that TWIST and IDT kits generated comparable sequencing metrics. However, the TWIST Kit outperforms the IDT Kit in percent eligible libraries qualifying for hybridization capture. TWIST Kit is a great qualifier for highly degraded FFPE samples, especially those with limited input DNA material.

#0325 Validation of Aventa FusionPlus: An LDT NGS assay for comprehensive cancer genomic profiling.

S. Melnyk, J. Belton, S. Nomikou, K. Powell, D. Heiney, R. Khalife, D. Jones, A. Schmitt, C. Wilson, M. Won, A. Magliocco, C. Roberts;
Aventa Genomics, Orlando, FL

Next-generation sequencing (NGS) assays play a pivotal role in illuminating the genomic landscape of cancer by providing insights into gene regulation and biomarker detection for the purpose of guiding therapeutic decisions to advance personalized medicine. We validated the Aventa FusionPlus Test, a Laboratory-Developed Test (LDT) that integrates HiC technology to enhance detection of actionable gene fusions and rearrangements in solid tumors, including those that are missed by current standard of care tests. This is a DNA-based test that is robust to DNA degradation in FFPE specimens, in contrast with RNA-seq and long-read technologies. The test utilizes the Element Biosciences AVITI sequencing platform to achieve high quality sequencing data at low cost per sample. The Aventa FusionPlus test enables gene-level detection of structural variants near or within 361 medically actionable or diagnostically relevant cancer genes. The 3D structure and long-range linkages captured by the test amplify the signal counts for each rearrangement. The test integrates the Arima-HiC+ FFPE sample prep and the Arima Library Prep Kit workflow. After dewaxing and rehydrating the FFPE tissue, the chromatinized DNA is fragmented and the fragmented ends are filled in with a biotinylated nucleotide. Next, spatially proximal fragmented ends of DNA are ligated, capturing the 3D structure of the genome. The proximally-ligated DNA is then purified and further fragmented, and the biotinylated ligation fragments are enriched. DNA libraries are prepared from these enriched fragments and sequenced in “paired-end” mode. Genes involved in genomic rearrangements were detected using the Arima-SV pipeline along with manual curation.

The test achieved robust detection of structural variants, with accuracy of 98.8% relative to reference methods. FFPE tumor specimens from 10 different tissue types and a wide range of tumor content (20%-100%) were included. No correlation between tumor cellularity and sensitivity was observed, suggesting that samples with as low as 20% tumor cellularity can be tested. When comparing to RNA-based and other targeted reference methods, we found additional fusions nearby oncogenes missed by these reference methods. As an example, in a breast cancer case, a fusion of genomic regions neighboring BRAF and MYC oncogenes on chromosomes 7 and 8 respectively, was missed by the reference method but was successfully detected by the Aventa FusionPlus test.

The Aventa FusionPlus test is a highly sensitive, specific, and accurate method for comprehensive cancer genomic profiling. The enhanced understanding of gene fusions and rearrangements positions the test as a valuable tool for clinical decision-making in oncology.

#0326 Matched fresh frozen and FFPE patient tissues reveal the enhanced sensitivity and data quality of a novel DNA library prep method.

M. R. Heider, J. Sun, B. Sexton, B. W. Langhorst, L. Blum, P. Liu;
New England Biolabs, Inc., Ipswich, MA

In cancer genomics, a common source of DNA is formalin-fixed, paraffin-embedded (FFPE) tissue from patient surgical samples, where in most cases high quality fresh or frozen tissue samples are not available. FFPE DNA poses many notable challenges for preparing NGS libraries, including low input amounts and highly variable damage from fixation, storage, and extraction methods. It is difficult to obtain libraries with sufficient coverage and the sequencing artifacts arising from damaged DNA bases confound somatic variant detection. Additionally, many laboratories process FFPE tumor samples alongside matched, high quality, normal DNA and many library prep workflows are not readily compatible with both sample types.

We developed a novel NGS library prep method compatible with both high quality and very low quality FFPE DNA samples, employing a novel enzymatic DNA repair mix, enzymatic fragmentation mix, and PCR master mix. To validate this workflow on real patient sample sets, we obtained DNA extracted from matched tumor and normal tissue of various tissue types preserved by both fresh frozen and FFPE methods. The FFPE DNA samples ranged in quality from DNA integrity number (DIN) 1.5 to 6.8, including samples stored for nearly 3 decades. We prepared libraries using this method compared against other library prep workflows and sequenced them by WGS and target capture. We assessed the performance of these workflows by library yield, library quality metrics, depth and evenness of coverage, and somatic variant calling with fresh frozen-extracted DNA providing the gold standard for library quality and mutation content.

This new enzymatic fragmentation-based library prep workflow not only reduced the false positive rate in somatic variant detection by repairing damage-derived mutations in FFPE DNA samples but also improved the library yield, library quality metrics (including mapping, chimeras, and properly-paired reads), library complexity, coverage depth and uniformity, and hybrid capture library quality metrics. Comparing the variant calls from matched FFPE and frozen tissues revealed an improved sensitivity and accuracy of variant calling using this library prep method compared to mechanical shearing and other enzymatic fragmentation library prep approaches.

This new suite of enzyme mixes allows even highly damaged FFPE samples to achieve high quality libraries with a greater sensitivity for somatic variant identification. The workflow is robust and flexible, compatible with both FFPE DNA and matched high quality DNA samples as well as automation-friendly for convenience in sample processing.

#0327 A comparison of Illumina and Element Biosciences sequencing platforms.

S. Johnson, **K. Lee**, N. Riccitelli;
Navigate BioPharma Services, Carlsbad, CA

Introduction: Advancements in sequencing technologies have revolutionized the field of genomics, enabling scientists to study the genetic information of organisms at unprecedented scale and speed. Next Generation Sequencing (NGS) has been utilized in clinical oncology from discovering and characterizing oncogenic driver mutations to providing personalized treatment of cancer. Among sequencing technologies, Illumina has emerged as the market leader, however, in recent years several alternatives have emerged. Herein, we evaluate the performance of NextSeq2000 and NextSeq550Dx platforms by Illumina to the Aviti platform from Element Biosciences.

Method: Eight (8) Archer Core Myeloid Panel libraries previously sequenced on NextSeq550Dx as part of a validated workflow were selected, normalized to 100 nanomolar (nM), pooled and sequenced on NextSeq2000 and Aviti sequencers with 2x150 paired-end sequencing. Samples included the HD829 myeloid DNA control from Horizon Discovery, a well-characterized HAPMAP sample, and a mixture of HD829 in HAPMAP. Prior to sequencing on the Aviti system, libraries were circularized with the Elements Adept chemistry. Fastq files from both Aviti and NextSeq2000 sequencing were uploaded to Archer Analysis Software, standardized filtering was applied to all generated datasets, and results compared across platforms.

Result: Aviti and NextSeq2000 platforms exhibited comparable sequencing reads, with an average total reads per sample of 76,205,719 and 74,201,570 from Aviti and NextSeq2000, respectively, while the lower throughput NextSeq550 platform yielded an average 17,619,350 reads per sample. Standardized filtering across all platforms provided 100% detection of true positives, however additional false positives (FP) were present in all samples and platforms that mapped to regions requiring normal dataset correction as part of the validated NextSeq550 workflow. The lowest numbers of FPs were detected on the Aviti platform, while both NextSeq550 and NextSeq2000 derived results contained several FP calls at elevated (>10%) variant allele frequency (VAF).

Conclusion: The three platforms compared in this study were able to detect all true positives of the tested samples using the same filtering criteria. The performance metrics of NextSeq2000 and Aviti were comparable and higher than NextSeq550Dx, in line with expectations due to the higher sequencing capacity. Although the Aviti platform required additional hands-on time, it in-turn generated cleaner data with less FP variants in comparison to Illumina's sequencing platforms. Overall, these results indicate robust sequencing throughout all three platforms.

#0328 A comprehensive genomic profiling of myeloid malignancies demonstrates mutational spectrum of DNA variants, FLT3-ITDs, and gene fusions.

J. Huang[1], H. Gu[2], J. Orton[2], M. Sedova[1], S. Rozenzhak[3], F. Hyland[1], G. Liu[2];
[1]Thermo Fisher Scientific, South San Francisco, CA, [2]Sonora Quest Laboratories, Phoenix, AZ, [3]Thermo Fisher Scientific, Carlsbad, CA

Introduction: Myeloid malignancies encompass diverse hematopoietic disorders, including acute myeloid leukemia (AML), myeloproliferative neoplasms (MPN), myelodysplastic syndromes (MDS), chronic myeloid leukemia (CML), chronic myelomonocytic leukemia (CMML), and juvenile myelomonocytic leukemia (JMML). We developed two assays to address the genetic complexity of myeloid malignancies, Oncomine™ Myeloid Assay and Oncomine™ Myeloid Assay GX v2, detecting mutations in 45 DNA genes and >30 fusion driver genes, including >700 fusion isoforms. Our panel includes genetic alterations such as *FLT3*-Internal Tandem Duplications (ITDs), *IDH1/2*, *CEBPA*, *CALR*, and *TP53*.
Methods: Here we describe the genomic profiles of 8503 clinical research samples (including AML, MPN, MDS, CML, CMML, or JMML). A total of 4723 samples were run on the Ion GeneStudio™ S5 System and analyzed using the Oncomine™ Myeloid Research workflow on Ion Reporter™ 5.18. A total of 3780 samples were run on the Ion Torrent™ Genexus Software 6.6 and analyzed using the Oncomine™ Myeloid Assay GX v2.
Results: On Genexus, the turnaround time (the time between starting the run and NGS data report) was 23-25 hours and the hands-on time was around 1 hour. The success rate of the samples was 100%.
Frequency of relevant mutations and variant allele frequency by gene: Genes like *TET2* (detected in 12.6% of samples), *ASXL1* (9.3%), *DNMT3A* (7.8%), *TP53* (7.5%) exhibited high mutation rates. 56.4% of samples had mutations, averaging 2.3 mutations per sample. Common co-occurring mutations included *ASXL1-TET2* and *SRSF2-TET2*. Variant allele frequency varied greatly, e.g., *ANKRD26* had a median VAF of 66%, while *MYD88* had only 7%.
Mutation spectrum of FLT3ITD variants: *FLT3*-ITD was observed in 3% of samples, with an average VAF of 0.32, featuring a multi-modal length with the highest peak at around 34 bp and maximum length at 151 bp.
Mutation spectrums of fusions: 710 (8.4%) samples were fusion-positive with read counts ranging 21-113,000. *ABL1* was the most common driver and *BCR-ABL1* was the most common gene pair. Other common drivers included *KMT2A*, *MYH11*, *RARA*, and *RUNX1*. 17 distinct driver genes, 49 gene pairs, and 110 gene isoforms were observed, including rare fusions like *ZMYM2-FGFR1* and *KAT6A-CREBBP* that are not detectable by traditional methods like qPCR (quantitative polymerase chain reaction) or FISH (fluorescence in-situ hybridization).
Conclusions: The Oncomine Myeloid Assay is a fast, robust, and reproducible solution for comprehensive genomic profiling of myeloid malignancies. We describe the mutational spectrum of DNA variants and RNA fusions in a range of clinical research samples. (For research use only. Not for use in diagnostic procedures.

#0329 NanoTelo: A workflow for detecting telomere absolute length based on nanopore sequencing technology.

J. Lang, Y. Chen, Z. Yang, B. Huo;
Qitan Technology (Beijing) Co., Ltd., Beijing, China

Background: Telomeres are specialized nucleoprotein structures located at the end of linear chromosomes in eukaryotic cells, and protect the ends of chromosomal DNA from degradation, end-to-end fusion and abnormal recombination. Changes in telomere length have become an important biomarker, which is closely related to cellular aging, all-cause mortality and a variety of diseases. However, there are still challenges in quantifying telomere absolute length, due to repeats of nucleotide sequence (5'-TTAGGG-3')n in single-stranded G-rich telomeric region, and lack of a method for nucleotide separation and enrichment of individual telomeres.
Methods: We developed NanoTelo, a workflow for detecting telomere absolute length based on nanopore sequencing technology. For experimental steps, a self-designed telomere adapter was first connected to the C-rich strand at the end of the chromosome by utilizing the 3' end overhang. And the 5' end of the telomere adapter was complementary to the sequencing adapter, allowing the antisense telomere chain to perform single-strand extension sequencing in the 5' to 3' direction, thus into the sub-telomeric region from the telomere end. The sequencing library was nanopore-sequenced on the QPursue-6k according to the manufacturer's instructions. For data analysis, reads were strictly extracted (dataset B) with the telomere adapter and library structure in raw sequencing data (dataset A). The reads of dataset A and dataset B were corrected, aligned to the human reference genome (T2T-CHM13v2.0), and calculated the telomere length distribution of each chromosomal (autosomes and sex chromosomes) p/q-arm, respectively. Defined the mean telomere length of all chromosomes represented the overall telomere length, the estimated results of dataset A and dataset B were weighted to obtain the final telomere absolute length.
Results: We selected 5 cell lines, which was HCT116, 293T, T24, IMR90 and WI38, and performed 2 experimental replicates for each one. We found that the estimated telomere lengths for each cell line were 3,528/3,512 bp, 4,298/4,311 bp, 2,745/2,685 bp, 4,926/4,915 bp and 4,143/4,096 bp, respectively. A comparative analysis with results from the Pacbio sequencing platform for each cell line in the *Tham et al.*'s paper, showed that there was no significant statistical difference (two-tailed T-test: *p-value*=0.98), and the mean absolute difference for estimated telomere length between the two platforms was 7.7 bp (95% CI: 5.4-10.0 bp).
Conclusions: NanoTelo demonstrated the possibility of measuring telomere absolute length with a single chromosomal p/q-arm at nucleotide-level resolution. We hope that NanoTelo can not only be used as an important tool for estimating telomere length to dynamically monitor aging, but also provide strong technical support for scientific research and/or clinical application related to human anti-aging and disease intervention.

#0330 FusionPlex™-HT and VariantPlex™-HT: Automation ready solutions for anchored multiplex PCR.

David Knupp, Christine Troutman, Allison Hadjis, Dhruti Legare, Paula Kalavakur, Michael Washburn

Integrated DNA Technologies, Inc., Boulder, CO

Introduction: Anchored Multiplex PCR (AMP™) assays, VariantPlex and FusionPlex are amplicon-based, next generation sequencing (NGS) workflows that identify genomic variations present in DNA or RNA input, respectively. AMP reagents are available in a lyophilized format which are user-friendly and convenient to store. However, lyophilized reagents are not suitable for liquid handlers or high-throughput environments. Thus, we developed AMP reagents in liquid format to satisfy the need for a platform-agnostic method of high-throughput (-HT) AMP library preparation.
Methods: The performance of our liquid reagent-based VariantPlex-HT and FusionPlex-HT workflows were evaluated relative to legacy lyophilized reagents using several input of varying quantity, quality and type. In addition, we examined liquid reagent performance across multiple AMP panels, which target solid tumor and blood cancers variants. Prepared libraries were then sequenced and analyzed using Archer™ Analysis v7.0 software.
Results: When using 50ng SeraSeq® Myeloid DNA input (LGC Clinical Diagnostics, Inc.) and the VariantPlex Core Myeloid panel (37 gene targets), both the lyophilized VariantPlex and VariantPlex-HT detected 100% (22/22) known variants ranging from 3.8% to 20.4% allele frequency (AF). When using low-quality FFPE and the VariantPlex Complete Solid Tumor panel (430 gene targets), both workflows captured 28/28 (AF: 1.4%-20.2%) and 11/11 (AF:1.2%-18.9%) single nucleotide variants (SNVs) and Insertion and Deletions (InDels) when 50ng of SeraSeq compromised FFPE or 200ng Horizon Severe FFPE was used as input, respectively. The FusionPlex-HT workflow consistently showed increased library complexity using the FusionPlex Lung V2 panel with 20ng or 50ng of Seraseq RNA Fusion Mix v4 input. This, coupled with greater on-target percentage resulted in an average increase in fusion supporting reads of 1.95x ± 0.53 and 2.2x ± 0.41 for 20ng and 50ng input, respectively. Next, we prepared a dilution series of SeraSeq RNA Fusion Mix v4 FFPE material at 100%, 25%, 10% and 5% dilutions. We utilized our FusionPlex Pan Solid Tumor panel (137 gene targets) which covers all expected fusions in this input material. At 100% and 25% dilutions, all expected fusions were detected by lyophilized FusionPlex and FusionPlex-HT workflows. However, at 10% and 5% dilutions FusionPlex-HT detected 100% and 91% of expected fusions, respectively, while legacy lyophilized reagents detected 80% and 60% of expected fusions.

#0331 Ion Torrent™ NGS sequencing of the TERT promoter hotspots with Ion AmpliSeq™ HD technology.

A. Sharma[1], G. Luo[1], N. Li[1], G. Pea[2], F. Hyland[3];
[1]Thermo Fisher Scientific, Carlsbad, CA, [2]Thermo Fisher Scientific, Milan, Italy, [3]Thermo Fisher Scientific, South San Francisco, CA

Introduction: Recurrent mutations C228T and C250T in the *TERT* gene promoter are prevalent in cancer and serve as important biomarkers for aggressive disease. Ion Torrent™ NGS sequencing, combined with Ion AmpliSeq™ HD technology, enables comprehensive genomic profiling with ultra-high sensitivity for low-frequency variants in cell-free DNA (cf-DNA) and highly heterogeneous solid tumor samples. However, the high GC content (>80%) and the presence of G repeats that are known to adopt a compact stacked three-G-quadruplex conformation in the *TERT* gene promoter region pose sequencing challenges such as low read depth and strand-bias, i.e. prematurely truncated reads on one strand.
Methods: We designed nine AmpliSeq™ HD panels with amplicon sizes of 70 to 104 bp, ideal for cf-DNA and FFPE samples, to target the recurrent *TERT* promoter hotspots. The designs were tested alone and combined with a larger Ion AmpliSeq™ HD DNA research panel resulting in highly multiplexed libraries. The libraries were used for Ion 540™ chip template preparation on the Ion Chef™ instrument and subsequently sequenced using the Ion GeneStudio™ S5 System. Sequencing data was used to evaluate coverage of the target hotspots by each design for each condition, and additional panels were designed to test single amplicons covering both *TERT* promoter hotspots.
Results: Through performance evaluation, we selected two overlapping amplicons, each effectively amplifying one of the two hotspots. Individually tested, these amplicons yielded approximately 3000 families each from a 10ng gDNA input and when combined into the larger Ion AmpliSeq™ HD DNA research panel, they produced several thousand reads across various libraries, providing molecular coverage of around 200 functional molecules. While capture efficiency was lower compared to *TERT* amplicon-only libraries, these improved amplicons allow downstream analysis of variants. A single-pool solution (single amplicon/s covering both hotspots) will be explored further using the second batch of amplicons/primers.
Conclusions: The optimized amplicons in two pools developed in this study enable the detection of challenging yet clinically significant *TERT* promoter hotspot mutations using the ultra-sensitive Ion AmpliSeq™ HD technology.

#0332 Improved high-throughput genomic analysis of urine samples using pixelated-ultrasound to enable personalized genomic profiling and therapeutic developments in cancer.

M. Evans-Holm[1], N. Lumbres[1], **R. Sen**[2], P. Montilla-Perez[2], M. A. Paradise[2], P. Lentz[1];
[1]Convergent Genomics, South San Francisco, CA, [2]Active Motif, Carlsbad, CA

Here we address some of the existing challenges in liquid biopsy workflows which can potentially benefit urine analysis from bladder cancer patients because approximately 1/4th of all human cancers are urological tumors. Globally, bladder cancer is the 10th most prevalent, and the 9th cause of mortality due to malignancy. The challenge addressed here is an improvement to sample preparation for sequencing. Among genders and disease states, urine samples vary in terms of cell count and hence, in DNA concentration. Therefore, it is critical to obtain consistent DNA fragments from variable samples across large cohorts of patients so that the sequencing leads to accurate identification of biomarkers of disease risk, progression, and treatment-response. In this direction, we present the advantages of a novel pixelated ultrasound technology which significantly improves sample-preparation in a very fast, economical, and high-throughput manner. Here, DNA is extracted from human urine samples and subjected to sonication to generate fragment sizes. Extracted DNA was loaded onto a regular 96-well round-bottom plate, which is sealed and placed inside the system where 12 columns of the 96-well plate are individually programmed and run simultaneously, hence enabling quick optimization. The system does not require time- and labor-intensive processing of the samples before or after the sonication which is required for other similar technology. Overall, the DNA samples were processed with significant improvement over other similar technology in terms of consistency, speed, and economy. Subsequently, the fragment sizes were analyzed. Analysis of results, as presented in the figures, show that the DNA fragment had the average size as predicted, uniform shearing, and very consistent across the 96-well plate containing different samples with no cross-contamination. The time, labour, expense, and risk turned out to be very low compared to other similar technology. The sizes were appropriate for library preparation and sequencing. The technology works consistently for both low and high cell numbers which is a critical factor for heterogenous samples from patients. In conclusion, the study presents improvements to library preparation for sequencing which fit into the larger workflow of non-invasive liquid biopsy using urine samples. The ability to obtain consistent DNA fragments in a quick and economical manner will greatly enable unique fingerprinting of an individual's cancer or cancer risk across large cohorts, with the potential for integration in automation workflows.

#0333 Stability and performance of a partially used 8-lane microwell cartridge on single-cell capture and immune response profiling.

H.-W. Song[1], R. A. Acob[2], Z. Hlathu[2], X. Zhao[2], J. Moskwa[2], L. Wang[2], A. Ayer[2];
[1]BD Biosciences, San diego, CA, [2]BD Biosciences, San Jose, CA

In this study, we introduce an innovative microwell-based approach, offering the capability to capture up to 500,000 single cells and show stability of a partially used 8-lane microwell cartridge up to 6 months after first use. Stability of microwell cartridges used for single-cell capture and the integrity of the individual lanes are crucial factors in genomics research to ensure the accuracy and reliability of generated data. Stability is paramount to ensure consistent results over multiple experiments. High-quality materials and manufacturing processes are essential to prevent wear and tear, ensuring that the microwell cartridges function optimally for an extended period. Integrity between the individual lanes must also be intact to prevent cross-contamination between samples. To demonstrate partial use stability of the 8-lane microwell cartridge, multiple assay combinations were performed on different lanes of the cartridge, collected at different time points. Whole transcriptome amplification (WTA) together with AbSeq antibody-oligonucleotide conjugates for cellular indexing of transcriptomes and epitopes (CITE-Seq) was performed on peripheral blood mononuclear cells (PBMCs), loaded and captured in Lanes 1 and 2, on Day 1; sample multiplexing was used with targeted mRNA assay on Jurkat and Ramos cells, loaded and captured in Lanes 3 and 4, after four months; and WTA together with the AbSeq Assay was performed on PBMCs, loaded and captured in Lanes 5 and 6, after six months. The different time points collected were compared to a single-lane microwell cartridge. Our data showed that assay performance was not compromised with the storage of a partially used cartridge, and there was no contamination detected between the lanes. High-throughput cell load and capture using WTA and the AbSeq Assay also showed that each lane of the 8-lane microwell cartridge was able to process up to 65,000 cells with no limit of detection on assay sensitivity. By maintaining cartridge stability and stringent measures to prevent contamination, researchers can ensure the reliability and accuracy of their data. This is vital for various applications such as developing targeted immunotherapies and precision medicine approaches, ultimately enhancing our capacity to combat a wide range of diseases.

#0334 Flexible and high-throughput microwell-based single-cell capture for multiomic ATAC-seq and RNA-seq profiling.

R. Nguyen[1], H. Huang[1], Q. Bao[1], P. Narayan[1], H.-W. Song[2], E. Hatami[2], Z. Zhang[2], T. McCarthy[1], Y. Kim[1], R. Li[1], C. Gordon[1], L. Wang[1], A. Ayer[1];
[1]BD Biosciences, San Jose, CA, [2]BD Biosciences, San Diego, CA

The simultaneous profiling of chromatin accessibility and gene expression is an active area of interest for researchers studying how epigenetic changes regulate gene expression at the single-cell level. Here, we demonstrate the feasibility of single nuclei assay for transposase-accessible chromatin (snATAC) seq either with or without simultaneous gene expression profiling using the microwell-based BD Rhapsody™ HT Xpress System. Taking advantage of an eight-lane microwell cartridge, the BD Rhapsody™ HT Xpress System can support the snATAC seq assay with nuclei input ranging from 1,000 to 400,000 nuclei in a single experiment. To demonstrate the flexible throughput capabilities, 1,000 to 50,000 nuclei from cryopreserved peripheral blood mononuclear cells (PBMCs) were tagmented and loaded onto a single lane of the BD Rhapsody™ HT Xpress System. The snATAC assay libraries were prepared and sequenced, revealing multiple high-quality ATAC-seq metrics: high counts of unique ATAC fragments, high fraction of reads in peak regions (FRiP), and high transcriptional start site (TSS) enrichment score. The data were obtained consistently across the wide range of input nuclei with use of the gentle and robust nuclei loading capabilities of the BD Rhapsody™ HT Xpress System. Moreover, after capturing ATAC fragments, the BD Rhapsody™ Enhanced Cell Capture Beads are stable and can be stored at 4 °C for up to 3 months, allowing researchers the flexibility in sequencing subsets of nuclei or lanes for QC purposes before sequencing the entire library and returning to samples for complete sequencing. Furthermore, to demonstrate the consistency of both open chromatin profiling and mRNA gene expression as a combination (multiomic snATAC + snRNAseq), firstly, we compared snRNAseq data from a whole transcriptome assay (WTA) with snRNAseq from an ATAC+mRNA multiomic assay using the same sample. This strategy enabled us to show that there is negligible gene expression differences between snRNAseq from the BD whole transcriptome assay and snRNAseq from the multiomic scATAC and scRNA assay. Likewise, the snATACseq assay and snATACseq assay with simultaneous whole transcriptome profiling shows that chromatin accessibility profiling is equivalent with and without gene expression profiling. Enabling this new scATAC assay on the BD Rhapsody™ HT Xpress System can advance the study of epigenetic regulation of gene expression with a robust and flexible workflow. This will allow researchers to analyze both open chromatin and mRNA at varying nuclei inputs with single-cell resolution to understand the underlying molecular mechanisms in gene expression regulatory pathways. This assay can be readily extended to broader samples to gain greater understanding of disease states in immunology and immuno-oncology studies. For Research Use Only. Not for use in diagnostic or therapeutic procedures.

#0335 BD®OMICS-Guard Sample Preservation Buffer preserves mRNA and cell surface epitopes for single-cell sequencing applications.

S. X. Shi[1], C. Sakofsky[2], Z. Zhang[1], S. Vadrevu[2], X. Shi[2], H.-W. Song[1], A. Ayer[2];
[1]BD Biosciences, San Diego, CA, [2]BD Biosciences, San Jose, CA

Multiomics has emerged as a powerful tool to derive insights on the transcriptomic and proteomic data of human cancer samples and preclinical models of blood and tumor malignancies. Due to the sensitivity of sequencing techniques, sample quality and stability can potentially interfere with results. BD® OMICS-Guard Sample Preservation Buffer (SPB), a novel preservation solution, allows cells and bulk tissues to be stored for up to 72h at 4 °C, while reliably capturing the true biology of cells. This reagent gently preserves mRNA and protein integrity without the traditional cross-linking and harsh fixatives, increasing flexibility and expanding options for study designs. Here, we showcase the preservation properties ofthis reagent for multiomic readouts in human cells and mouse tissue across three different timepoints.BD® OMICS-Guard SPB's preservation of mRNA from human PBMC and bulk mouse spleen tissues wasevidenced by WTA for differentially expressed genes in samples preserved for 24, 48 and 72h comparedto fresh/unpreserved controls. Protein epitope preservation was demonstrated via CITE-Seq assay withthe BD® AbSeq Human Immune Discovery Panel (human PBMC) or a 30-plex panel of anti-mouse BD®AbSeq Antibody-Conjugated Oligonucleotides (mouse splenocytes) and confirmed with multicolor flowcytometry. For both sample types, high correlation R^2 values (>0.87) were calculated for the preservation time points versus fresh controls. Concomitant flow cytometry analysis of major cell types and surface protein expression was consistent with sequencing data for all samples. Specificity and sensitivity of major cell type markers and cell surface proteins across cell types and time is visualized in the BD®AbSeq Antibody-generated heatmap for each sample. Additionally, BD® OMICS-Guard SPB maintains mRNA integrity in targeted gene assays and VDJ full-length assays, suggesting robust preservation of select transcripts readily interrogated in single-cell profiling. Batch effect across time and technical replicates for both sample types was limited with the BD Rhapsody™ HT Xpress System and delineated by donor/sample specific tSNEs across time. We demonstrate that the BD® OMICS-Guard Sample Preservation Buffer effectively preserves both mRNA and surface proteins for single-cell experiments. BD® OMICS-Guard SPB allows the convenient preservation of samples such as tumor biopsies to be collected and stored for up to 72h at 4 °C while maintaining mRNA and protein integrity, allowing the flexibility for precious samples to be potentially shipped to a central sequencing site to ensure standardized sequencing workflows. For Research Use Only. Not for use in diagnostic or therapeutic procedures.BD and BD Rhapsody are trademarks of Becton, Dickinson and Company or its affiliates.

#0336 Genome integrity assessment by optical genome mapping for cell manufacturing/bioprocessing applications.

A. Hastie, **A. W. C. Pang**, A. Chaubey;
Bionano, San Diego, CA

Cells and cell lines are used for multiple applications such as bioprocessing, therapy, and research. To ensure quality of cells and downstream applications, appropriate quality control (QC) methods are critical. Historically, karyotyping has been employed, but it is limited by its very low resolution and tedious laboratory workflow. Other methods such as PCR and targeted sequencing can characterize only small genomic variants at specific loci. Whole genome sequencing can detect small variants genome-wide but has limited sensitivity in detecting structural variants (SVs). Optical genome mapping (OGM) is a novel genome analysis technique that can fill many of the gaps in current capabilities for assessing genome integrity. To find clonal variants, 400 Gbp of data is collected from the parental/control and test samples. For both samples, a *de novo* assembly is constructed, and homozygous or heterozygous SVs are assessed. Subsequently, the dual variant annotation pipeline identifies unique SVs in the test sample compared to the parental sample. To discover subclonal SVs down to 5% variant allele fraction (VAF), the workflow leverages the generation of 1.5 Tbp of data, requiring a simple adjustment to longer data collection time. Comparison of test sample to parental sample enables easy determination of acquired variants. Finally, generation of ~5 Tbp of data, requiring 2-3 flowcells to be run, enables the detection of SVs at ultra-low VAF down to ~1%. In this study, several dilutions and simulations were performed to examine OGM's limit of detection. Targeting a coverage of 5 Tbp and analysis using the somatic SV-analysis workflow revealed that OGM has the sensitivity to detect deletions >50kbp, insertions >20kbp, duplications >100 kbp, and translocations at ~1% VAF. We have applied the clonal and somatic workflows to verify genomes' integrity after cell immortalization, induced pluripotency, transgene-integration, and gene-editing. The data using the robust and sensitive workflows demonstrate that the OGM platform is a cost-effective solution for cell manufacturing/bioprocessing QC applications.

#0337 Balanced-strand sequencing for highly efficient duplex variant calling in circulating tumor DNA.

A. Widman[1], A. P. Cheng[2], A. Sossin[2], S. Rajagopalan[3], M. Al Assaad[3], S. Deochand[2], Z. Steinsnyder[2], D. Manaa[2], M. Marton[2], C. Reeves[2], I. Rusinek[4], E. Meiri[4], O. Barad[4], Z. Shipony[4], S. Gilad[4], A. Jaimovich[4], M. Sigouros[3], J. Manohar[3], A. King[3], D. Wilkes[3], J. Otilano[3], O. Elemento[3], B. M. Faltas[3], J. M. Mosquera[3], D. A. Landau[3];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]New York Genome Center, New York, NY, [3]Weill Cornell Medicine, New York, NY, [4]Ultima Genomics, Newark, CA

Several approaches for the detection of circulating tumor DNA (ctDNA) are anchored in the accurate identification of cancer-specific single nucleotide variants (SNVs) in plasma. Such approaches are limited in ultra-low tumor fraction (TF) contexts, such as early cancer detection or the identification of postoperative minimal residual disease, where ctDNA SNVs are difficult to distinguish against background sequencing error. ctDNA detection in these critical low TF contexts is further limited by the sparse amount of cell free DNA (cfDNA) in plasma (Zviran et al., 2020). To reduce single-stranded artifact and base calling errors, duplex sequencing can be used to jointly analyze corresponding Watson and Crick strands to detect true, double-stranded variants. Recent work has demonstrated that duplex sequencing can decrease error rates to 10^{-7} (Hoang et al., 2016) and can be deployed in the whole-genome sequencing (WGS) setting (Cheng et al., 2023). A significant limitation for existing duplex techniques is the need to analytically pair matching DNA strands through exhaustive sequencing, resulting in inefficient use of scarce input material, particularly in plasma cfDNA. These techniques typically capture 1-5% of sequenced molecules, restricting duplex coverage depth. We present balanced-strand sequencing, a PCR-free approach that leverages the hydrogen bonds of complementary DNA to carry matched native strands directly into sequencing, enabling massively scalable duplex sequencing. The approach relies on Ultima Genomics sequencing, where DNA denaturation is not required prior to clonal amplification. In balanced strand sequencing, double-stranded DNA is partitioned and clonally amplified on sequencing beads through emulsion-PCR. Each double-stranded DNA molecule contributes to a single sequencing read, allowing for a linear increase in duplex recovery with increasing sequencing depth. The approach does not require redundant sequencing and therefore maximizes unique molecule throughput. We applied balanced strand sequencing to cfDNA, input as low as 5 ng, and achieved 7-35x whole-genome duplex coverage, roughly 20-fold higher than our prior duplex WGS. We further developed a machine-learning guided single read mutation calling framework, which when combined with duplex error suppression, reduced error rates to 10^{-7} and enabled accurate ctDNA detection at concentrations $<10^{-5}$. Use of our analysis framework in APOBEC-mutant bladder cancer plasma samples allowed us to identify APOBEC signatures in plasma and platinum exposure signatures indicative of prior chemotherapy treatment. Altogether, balanced strand sequencing radically enhanced duplex efficiency and has broad applications across cancer. In cfDNA applications, balanced strand sequencing enhances error-correction in tumor-informed ctDNA detection and paves the way for non-tumor informed WGS ctDNA detection.

#0338 Unraveling layers of proteogenomic complexity in cancer through multiomic exploration of archived FFPE tissue.

A. J. O'Hara, Y. Han, I. DeVito, L. Turner, H. Latif;
GENEWIZ from Azenta Life Sciences, South Plainfield, NJ

Formalin Fixed Paraffin Embedded (FFPE) tissues are a staple in clinical diagnostics associated with solid tumor. The preserved tumor tissue can be interrogated using classical histopathology and complemented with molecular approaches to elucidate cancerous SNPs, indels, structural variants, repeat expansion, copy number expansions, and mutational burden. Increasingly, approaches are being deployed to interrogate tissue not only through individual datasets but through integrated approaches that provide spatial information that defines the tumor microenvironment. Here, we illustrate using FFPE blocks from various tissues a multiomic workflow that allows for deep exploration of the molecular underpinnings of cancerous tissue. FFPE blocks were serially sliced into various FFPE slides with a single slide H&E stained. Individual slides were then utilized to explore the genome, epigenome, single cell RNA-seq, and digital spatial profiling. Genome information was captured using hybrid capture based approaches (whole exome sequencing and targeted cancer panel) followed by deep NGS on an Illumina platform and analyzed for a variety of variants and tumor mutational burden. DNA methylation was detailed using target capture probes targeting DNA methylation sites. Single cell approaches were applied to explore the transcriptome using 10X Genomics scRNAseq Flex kit. Digital spatial profiling was done using the NanoString for both transcriptomics and proteomics, with the GeoMx Whole Transcriptome Atlas and Human Core and Pan-Tumor protein panels. Aggregating these data illustrates the expanding landscape of information that can be extracted from FFPE derived tissue and the potential for novel discovery and diagnostic power integrating these complex data types holds.

#0339 Universal synthetic TCR/BCR spike-in controls to evaluate immune receptor profiling assay and next-generation sequencing performance.

A. Chenchik, **T. Liu**, M. Makhanov, D. Hu, K. Ghias, P. Diehl;
Cellecta, Inc., Mountain View, CA

Adaptive immune receptor (AIR) repertoire diversity assays are susceptible to biases arising from variations in conditions in the RT-PCR and next-generation sequencing (NGS) steps. We designed synthetic TCR and BCR spike-in controls to mitigate these biases and to serve as universal standards for any PCR-based immune receptor profiling assay. We synthesized 48 BCR constructs representing different IGH, IGK, and IGL genes and 39 TCR constructs for TRB, TRA, TRG, and TRD genes. The spike-in controls were tested as (16x3) BCR constructs and (13x3) TCR Triplex isoform pools added to multiple samples in the same batch to detect cross-contamination across samples. We successfully discriminated between controls and background sequences by combining a unique molecular identifier (UMI)-based correction strategy with spike-in controls at the data analysis step. We also tested 48 BCR and 39 TCR Premixed Controls by spiking into peripheral blood mononuclear cells (PBMC) RNA samples before reverse transcription using Cellecta's DriverMap™ Adaptive Immune Receptor Profiling Assay that uses a multiplex RT-PCR approach with gene-specific primers and UMIs. We successfully used it to evaluate assay performance by adding premixed controls at different concentrations. Results showed a linear trend as the number of spike-in molecules increased. Our analysis revealed an average sequencing error rate of 0.4%-0.8% per base, aligning with the reported error rate range of Illumina sequencing. This suggests the reliability of our spike-in controls, which can be used to rectify biases in the AIR protocol and accurately estimate error and mutation rates for the DriverMap AIR assay or any other sequencing-based immune receptor profiling assay. This innovative approach enhances the robustness of immune receptor profiling technology, facilitating more accurate assessments of repertoire diversity.

#0340 Validation of TSO500 NGS panel for comprehensive genomic profiling from FFPE tumor samples.

J. Li[1], Z. Yan[1], W. Liu[1], L. Shi[1], C. Spittle[1], C. Galderisi[2];
[1]ICON Clinical Research, Inc., Cambridge, MA, [2]ICON Clinical Research, Inc., Portland, OR

Comprehensive genomic profiling (CGP) of tumor sample using large targeted NGS panels (e.g. MSK-IMPACT) has been shown to allow the detection of biomarkers from hundreds of cancer relevant genes involved in targeted and immunotherapy. Illumina TruSight Oncology 500 (TSO500), a commercial CGP assay, allows concurrent analysis of DNA and RNA to simultaneously detect multiple types of variants across 523 genes. The assay is intended to detect single nucleotide variants (SNV), insertions and deletions (indel), and multinucleotide variants (MNV), copy number gain (CNV), tumor mutational burden (TMB) and microsatellite instability (MSI) in DNA, and fusions and splicing variants (exon skipping) in RNA. Here we aimed to validate TSO500 assay for its analytical performance on FFPE tumor samples. The validation samples include commercial controls, cell lines, clinical FFPE from NSCLC, CRC, Uterus and GIST (tumor content ≥20%). Library preparation was performed from minimum of 40 ng DNA and 40ng RNA. The data analysis is performed using TruSight Oncology 500 Local App software (LRM v2.2). A custom script (v1.0) was used to add SNP annotation for small variants and combine data output into cumulative format. For SNV and indel detection QC, 61 of 64 DNA libraries (95%) passed the QC for library size (median insert size ≥70bp) and coverage (median exon coverage ≥150). The percentage of DNA libraries passing QC for CNV and MSI are 95% and 88%, respectively. All 64 RNA libraries passed QC. The analytical performance of TSO500 was summarized in the Table below. In summary, the results showed that all the acceptance criteria were met and the TSO500 assay can be utilized for genomic profiling of FFPE tumor samples. The study also identified a few limitations of the Illumina LRM software e.g. potential false positive SNV within a indel background, potential false negative of complex indel, and the challenge of long indel detection.

Summary of analytical performance of TSO500

	Sensitivity and specificity	Assay LoD	Accuracy by concordance	Inter-run reproducibility
SNV/Small indel	Sensitivity for SNV and indel detection are 99.24% and 99.36%. Specificity for SNV and small indel detection are 99.9998% and 100.00%, respectively.	The LoD for SNV is 3-5%, for DEL is 5-10% and for INS is 3-5%.	PPA for SNV detections is 96.64% (115/119; 95% CI: 91.68%, 98.69%) and for small indel is 92.86% (13/14; 95% CI: 68.53%, 98.73%) between TSO500 and comparator assays.	The positive call rate across all SNV and small indel variants is 98.7% (42842/43419).
MSI	Sensitivity and Specificity for MSI detection are both 100%.	NA	MSI status for all samples were detected with 100% of concordance by three assays; PPA is 100% (95% CI: 51.01%, 100%) and NPA is 100% (95% CI: 34.24%, 100%).	MSI concordance for MSI-H is 100% (95% CI: 60.97%, 100.0%) and for MSS is 100% (87.13%, 100.0%).
TMB	NA	NA	TSO500 reported TMB is well correlated and comparable to exome determined TMB.	The CV values for samples are acceptable.
CNV	NA	NA	All positive CNVs detected by the comparator assay were detected by the TSO500 assay with similar fold changes; PPA between TSO500 and OCAV3 assays is 100% (95% CI: 51.01%, 100%).	The overall reproducible call rate is 91.5% (43/47).
Fusion	Sensitivity and specificity for fusion detection is 91.94% and 100%, respectively.	NA	All TSO500 assay detected fusions were confirmed by other assays;PPA is 100% (95% CI: 60.97%, 100%) and NPA is 100% (95% CI: 75.75%, 100%)	The reproducibility of fusion call is 92.59% (25/27; 95% CI: 76.63%, 97.94%).
Splicing	Sensitivity and Specificity for splicing variant detection are 91.67% and 100.00%, respectively.	NA	The splicing variant detections were confirmed by OCAV3, OFA and Archer assays; PPA is 100% (95%% CI: 20.65%, 100%) and NPA is 100% (95% CI: 83.18%, 100%)	The overall reproducibility of positive call is 100% with 95% CI (43.85%, 100%) and negative call reproducibility is 100% with 95% CI (87.13%, 100%).

#0341 Co-detection of BCR::ABL1 common and atypical fusion and mutation using a novel NGS assay, Dup-Seq BCR-ABL1.

J. Li[1], Z. Yan[1], L. Shi[1], W. Li[1], W. Liu[1], C. Spittle[1], C. Galderisi[2];
[1]ICON Clinical Research, Inc., Cambridge, MA, [2]ICON Clinical Research, Inc., Portland, OR

The clinical management of CML and Ph+ ALL patients requires the identification of BCR::ABL1 transcript variants and drug resistance mutations. Currently these assessments need to be performed using separate assays resulting in higher sample requirements, longer turnaround times and higher costs. In this study a custom NGS assay (Dup-Seq BCR-ABL1) was developed and validated that enables co-detection and identification of transcript variants (common and atypical) and resistance mutations. The assay design covers BCR exon 1 to ABL1 exon 10 and employs duplicate PCR amplification of BCR-ABL1 from a single source of the 1st strand cDNA initiated by ABL1 specific priming. The custom data analysis pipeline enables overlapped mutation calling from duplicates as well as transcript determination. The assay minimizes the low-level artifacts that can be seen with other NGS-based BCR::ABL1 assays. This study demonstrates that the Dup-Seq BCR-ABL1 assay achieves high accuracy (PPA for fusion: 0.985; PPA and NPA for mutation at 0.978 and 0.9999, respectively) and sensitivity (LoD for mutation detection at 3% from 10,000 copies of BCR-ABL1 input). The use of the Dup-Seq BCR-ABL1 assay for both transcript variant identification and mutation detection provides comprehensive and accurate results for the clinical management of CML and Ph+ ALL patients while reducing sample requirements, testing costs and turnaround time.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Apoptosis and Ferroptosis

#0346 Trop-2 induces apoptosis via transcriptional activation of TRAIL, FAS-FASL, CD40-TNFRSF5.

S. Alberti[1], E. Guerra[2], A. Moschella[1], M. Ceci[2], L. Pantalone[2], R. Di Pietro[2], M. Trerotola[2];
[1]University of Messina, Messina, Italy, [2]University of Chieti-Pescara, Chieti, Italy

Trop-2 is a transmembrane signal transducer that activates cancer growth and metastatic diffusion (1). However, this does not occur in all tumor types, as Trop-2 is associated to better disease outcome in some cancers, e.g. breast and lung tumors. A prototypic pattern of Trop-2 expression in normal multistratified epithelia, e.g. epidermis, esophagus, is that of preferential expression in non-proliferating, terminally differentiated cells. The corresponding expression gradient parallels that of induction of programmed cell death, e.g. in the corneum layer of skin keratinocytes. This led us to explore Trop-2 function as a trigger of apoptosis. We thus assessed NS-0 myeloma Trop-2 transfectants for apoptosis induction by dynamic cell morphometry and quantification of membrane blebbing and cell fragmentation. This was shown to be preceded by phosphatidyl-serine membrane exposure, and was followed by nuclear pyknosis and karyorrhexis. DNA fragmentation was shown by TUNEL and DNA laddering, and was accompanied by a dramatic increase of apoptotic death of Trop-2-expressing cells. Transcriptomic analysis at early time points of apoptosis induction indicated overexpression of TRAIL, FAS/FASL and CD40/TNFRSF5 transmembrane death receptors. This paralleled upregulation of downstream death-inducing signaling complex components and of executioner Caspases 8 and 3, suggesting Trop-2 as a trigger of extrinsic apoptosis pathways. Apoptosis induction translated into diminished tumor growth in vivo, which was shown to be proportional to Trop-2 expression levels. However, apoptosis induction was found to parallel stimulation of NS-0 cell growth and of defence mechanisms from apoptosis, as increased levels of inhibitory transcription factors, Rb-binding protein, survivin, Myd-118. These findings suggest a previously unappreciated balance between stimulation of cell growth and triggering of cell death by Trop-2, and may pave the way for selective anticancer therapy approaches in Trop-2-expressing cancers.(1) Trerotola M. *et al.*, Neoplasia 23: 415-428 (2021).

#0347 Tumor necrosis factor related apoptosis inducing ligand (TRAIL)-induced cytokine production in TNBC promotes neutrophil chemotaxis and immune suppression.

M. Kundu[1], Y. E. Greer[1], L. A. Ridnour[2], D. Wink, Jr.[2], Y. S. Ng[1], R. Weigert[1], S. Lipkowitz[1];
[1]National Institute of Health, Bethesda, MD, [2]National Institute of Health, Frederick, MD

Background: TRAIL induces apoptosis in many preclinical cancer models including breast cancers and has been extensively studied as a potential cancer therapeutic. However, its efficacy in clinical trials is limited, suggesting an unknown modulatory mechanism responsible for lack of TRAIL activity *in vivo*. Here, we describe that TRAIL treatment elicits transcriptional changes in TNBC cells that alter the immune milieu.
Method: We performed RNAseq of MDA-MB-231 cells treated with TRAIL for different time points, followed by validation with RT-PCR in various TNBC cells. RNAi, silencing key differentially regulated genes, along with RT-PCR, ELISA and CHIP assays, were used to validate RNAseq findings. Elucidation of the functional relevance of the outcome was supported both *in vitro* and *in vivo* by chemotaxis assay, cytotoxicity assay, RNAseq analysis of donor isolated neutrophils and intravital microscopy, CODEX analysis in TNBC xenografts from mice treated with the TRAIL respectively.
Results: TRAIL treatment of the TNBC significantly induced expression of several cytokines, such as CXCLs 1, 2, 3, 8,11 and IL6, both *in vitro and in vivo* which are known to affect neutrophil function. Mechanistically, induction of these cytokines was predominantly mediated by death receptor 5 and caspase-8 protein, but not caspase-8 enzymatic activity. GSEA of the RNAseq data indicated that NFKB pathway was significantly enriched. Concordantly, we confirmed that both canonical NFKB1 and non-canonical NFKB2 pathways were activated by TRAIL in *vitro and in vivo*. However, the induction of the cytokine mRNAs was primarily dependent on the NFKB2 pathway. Neutrophils isolated from healthy human donors incubated with supernatants from TNBC cells *in vitro* indicated that TRAIL-induced CXCLs and IL6 significantly increased neutrophil chemotaxis. Additionally, CODEX analysis as well as intravital imaging confirmed that TRAIL treatment increases the number of neutrophils in the tumor. Preincubation of neutrophils with supernatants from TRAIL-treated TNBC significantly inhibited their cytotoxic effect against TNBCs. Further, transcriptome analysis of neutrophils incubated with either TRAIL or supernatant of TRAIL treated TNBC revealed significant enrichment of expression of inflammatory cytokine genes, immune modulating and immune checkpoint genes like PDL1. Functional studies with these neutrophils confirmed their suppressive effect on T cell function as well as the effect of TRAIL on decreased neutrophil apoptosis.
Conclusion: Collectively, our study suggests the novel role of TRAIL-induced NFKB2-dependent cytokine production promoting neutrophil chemotaxis and immune suppression. This study implies that alterations in the innate immune system may modulate the effects of TRAIL on TNBC tumors.

#0349 The role of RELTfms and FLNA in human cancer and cellular apoptosis.

E. Chou[1], E. Chang[1], I. Abed[1], A. Christensen[1], K. Nguyen[1], A. Yanumula[1], Y. Shyu[1], A. Abram[1], J. Alcaide[1], G. Cusick[1], M. Batiste[1], Y. Shi[2], E. Mohammed[1], J. Cusick[1];

[1]California Northstate University, Elk Grove, CA, [2]California Pacific Medical Center Research Institute, San Francisco, CA

Receptor Expressed in Lymphoid Tissues (RELT) is a Tumor Necrosis Factor Receptor family member implicated in several cancers. RELL1 and RELL2 (RELT-Like 1 and 2) are RELT homologs that bind RELT; the three proteins are collectively referred to as RELT family members (RELTfms). We sought to evaluate the role of the OXSR1 kinase and actin-binding protein Filamin A (FLNA) in modulating RELT-induced apoptosis of cancer cells. We also assessed RELTfm expression in human breast and lung cancer biopsies and their ability to sensitize breast cancer cells to chemotherapeutic agents.

Methods: Empty vector or expression plasmids for RELTfms were transiently transfected into MDA-MB-231 (231) breast cancer cells with TransfeX reagent. Cell death was assessed by morphology assays and ATP luciferase assays. Apoptosis of 231 cells was assessed by Annexin V/PI staining using Flow cytometry (FC). Immunohistochemistry (IHC) was used to assess RELT expression in human breast and lung cancer biopsies. IHC and western blotting were utilized to determine RELT cellular localization.

Results: All three RELLfms were co-immunoprecipitated by a C-terminal fragment of FLNA. RELT overexpression induced death in 231 cells, and this effect was increased with co-transfection of a FLNA S215A mutant, an important phosphorylation site that protects FLNA from cleavage. 231s transfected with RELT and RELL2 demonstrated increased Annexin V/PI signal in comparison to vector control, demonstrating that these RELTfms induce death via an apoptotic pathway. Co-transfection of a mutated plasmid for the OXSR1 kinase did not abrogate RELT-induced apoptosis. A RELT construct with a mutated binding site for the OXSR1 kinase induced apoptosis to a similar extent as wild-type RELT. An increase in doxorubicin-induced apoptosis was observed when 231 cells were transfected with RELL2 versus vector control. IHC results showed increased RELT expression in malignant breast cancer biopsies compared to patient-matched benign tissue. Interestingly, RELT was localized in the nucleus of some malignant lung cancer biopsies, and western blot analysis indicates that RELT translocates to the nucleus and interacts with chromatin in 231 cells.

Conclusions: Collectively, these results demonstrate that RELTfms induce apoptosis of breast cancer cells, and potentially increase the sensitivity of breast cancer cells to chemotherapeutic agents. Furthermore, this work enhances our understanding of the interaction between RELT and FLN, a protein that is implicated in many cancers, including breast cancer. Phosphorylation by OXSR1 was previously shown to be required for RELT to activate the p38 pathway, yet the OXSR1 kinase is not required for RELT-induced death. RELT expression is enhanced in breast cancer biopsies, and interestingly, RELT can localize to the nucleus in cancerous cells. Collectively, these findings significantly enhance our understanding of RELTfms and cancer.

#0350 Targeting prohibitins by fluorizoline leads to the activation of ISR and apoptosis through DELE1 and HRI by an impairment of the mitochondrial protein import machinery.

I. Sanchez-Vera[1], N. Maritorena-Hualde[1], M.-H. Schuler[2], A.-. Cosialls[1], R. Lavilla[1], G. Pons[1], L. Jae[2], D. Iglesias-Serret[1], **J. Gil**[1];
[1]Universitat de Barcelona, Barcelona, Spain, [2]Ludwig-Maximilians-Universitat Munchen, Munchen, Germany

Prohibitins are ubiquitously expressed within the cell, but they are mainly located at the inner mitochondrial membrane. These proteins are closely associated with tumour progression, invasion, and apoptotic resistance, being overexpressed in various primary tumours such as lymphoma and endometrial cancer. Notably, we have developed a novel synthetic molecule, fluorizoline, which induces apoptosis by selectively targeting PHBs in different cancer cell lines and primary samples from various haematological neoplasias. We have previously described that fluorizoline-induced apoptosis is mediated through the activation of the pro-apoptotic branch of the integrated stress response (ISR) pathway in HeLa and HAP1 cells, concretely, by the ATF4-CHOP-NOXA axis. In a recent study, we identified compensatory mechanisms for four ISR-related kinases. Importantly, HRI emerged as the primary kinase responsible for activating this pathway and promoting apoptosis, suggesting that mitochondrial stress could lead to this activation of the ISR.Here, we investigate the OMA1-DELE1-HRI molecular pathway responsible for sensing mitochondrial stress and activating the ISR cancer cell lines. Firstly, we demonstrate that fluorizoline treatment triggers the cleavage of large DELE1 (L-DELE1) to its cleaved form (S-DELE1) through western blot analysis, and its subsequent sorting to the cytosol as confirmed by confocal analysis. Using DELE1 KO lines generated by CRISPR/Cas9 technology, we demonstrate that DELE1 is involved in the activation of the ISR and apoptosis induced by fluorizoline. However, although we cannot rule out OMA1 involvement, fluorizoline-induced ISR activation does not strongly depend on OMA1. Interestingly, our data suggests that targeting PHBs, either by fluorizoline or by their downregulation, could result in mitochondrial protein import machinery impairment. This impairment may potentially be the cause of DELE1 accumulation in the cytosol, leading to the subsequent activation of the ISR by HRI upon fluorizoline treatment.

#0351 Quaratusugene ozeplasmid mediated TUSC2 upregulation in EML4-ALK bearing non-small cell lung carcinoma can induce cellular apoptosis.

A. Banerjee[1], N. Busette[1], M. S. Berger[2], M. B. Soellner[1], A. Qin[1], S. D. Merajver[1], N. M. Merrill[1];
[1]University of Michigan, Ann Arbor, MI, [2]Genprex, Inc., Austin, TX

Anaplastic Lymphoma Kinase (ALK), a potent oncogenic driver in Non-Small Cell Lung Carcinoma (NSCLC), is found to be rearranged and fused to Echinoderm microtubule-associated protein-like 4 (EML4), contributing to approximately 5% of NSCLC as a distinct clinicopathological subset. Tumors bearing the EML4-ALK fusion are sensitive to ALK Tyrosine Kinase Inhibitors (TKIs), that form the first and second line of treatment for these patients. However, ALK+ lung cancers develop resistance to ALK inhibitors, creating the need for newer treatment strategies in ALK+ NSCLC. Tumor Suppressor Candidate 2 (TUSC2) is a tumor suppressor gene that is known to have low endogenous expression in NSCLC in general but data on TUSC2 in ALK+ lung cancers are not available. Quaratusugene ozeplasmid, developed by Genprex, is an immunogene therapy that upregulates TUSC2 expression in cancer cells by delivering the functional TUSC2 gene. It consists of the TUSC2 gene expressing plasmid encapsulated in non viral lipid nanoparticles. We evaluated TUSC2 expression in 3 ALK+ cell lines, both before and after exposure to quaratusugene ozeplasmid and to a TUSC2-containing plasmid. Controls were non-ALK+ cell lines and transfection with a plasmid containing no insert. Our studies in ALK+ lung cancer reveal that overexpressing TUSC2 using quaratusugene ozeplasmid treatment of ALK+ lung cancer cell lines is able to suppress colony formation by 50%, the effect being more significant than using a TUSC2-containing plasmid. Furthermore, we have observed a robust pro-apoptotic response to TUSC2 expression in ALK+ NSCLC, as both quaratusugene ozeplasmid and TUSC2-containing plasmid induced an increase in caspase 3/7 activity in the cancer cells, accompanied by an increase in cleaved PARP expression. Taken together, our data indicate that overexpression of TUSC2 in ALK+ NSCLC cell lines with quaratusugene ozeplasmid or with TUSC2-containing plasmid is effective in decreasing growth and proliferation through the activation of apoptotic pathways and warrants further investigation as an anti-ALK NSCLC strategy.

#0353 Investigate the role of homoharringtonine in treating B-cell acute lymphoblastic leukemia.

Emilie An An Jiao, Kei Ching Yuen, Bai Lin Li, Chun Fung Sin

Pathology, University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Pok Fu Lam, Hong Kong

B lymphoblastic leukemia (B-ALL) is an aggressive and highly lethal hematolymphoid malignancy and it is the most common cancer in children. Although the incidence of B-ALL in adult is lower than that in children, adult patients with B-ALL have a poor prognosis. Relapse/refractory disease is still the main cause of death in B-ALL patients. Homoharringtonine (HHT) is a plant alkaloid that was approved to treat chronic myeloid leukemia (CML) by FDA. Herein, we aimed to investigate the anti-leukemic activity of HHT in B-ALL. Cell viability was reduced in a time and dose-dependent manner upon treatment with HHT. Moreover, HHT was able to induce apoptosis in B-ALL cell lines by downregulating the MCL-1 protein level after 24 hours of treatment. Cell cycle analysis indicated G1 phase arrest, and western blot analysis demonstrated downregulation of CDK-4 and CDK-6. A proteomics study using label-free protein quantitation revealed enrichment of proteins involved in fatty acid oxidation, and further analysis showed downregulation of acyl-CoA desaturase after HHT treatment. Additionally, HHT significantly reduced the leukemic burden and prolonged survival in NSG mice injected with the PALL-2 cell line. Overall, the findings suggest that HHT is effective in treating B-ALL by inducing cell cycle arrest, with a potential inhibitory effect on fatty acid oxidation. Further studies will be conducted to evaluate the mechanism of modulation of fatty acid oxidation.

#0355 BCLxL inhibition enhances copanlisib response in colorectal cancer.

A. E. Schmitz, R. A. DeStefanis, A. K. DeZeeuw, A. M. Olson, A. L. Lippert, K. J. Maduscha, K. A. Johnson, S. Kraus, C. A. Pasch, D. A. Deming;
University of Wisconsin - Madison, Madison, WI

Background: Anti-apoptotic signaling, including through BCLxL, is a potential mechanism of resistance to PI3K inhibition in *PIK3CA* mutant cancers. We have previously demonstrated enhanced activity of PI3K inhibition in combination with BCLxL inhibition in *PIK3CA* mutated colorectal cancer (CRC) models. Here we examine the potential impact of BCLxL expression in *PIK3CA* mutant CRCs and the mechanism of treatment response with the combination of copanlisib and navitoclax.

Methods: *PIK3CA* mutant CRCs were identified within TCGA colorectal adenocarcinoma data set and two cohorts were generated based on *BCL2L1* (gene that encodes protein BCLxL) expression. Differentially expressed genes and gene set enrichment analysis were performed. CRC cell lines SW48 and SW48PK (Horizon Discovery, SW48 with a *PIK3CA*$^{H1047R/+}$ mutation) were treated with copanlisib (copan) (1-100 nM) and navitoclax (250 nM). Immunoblotting was performed quantified using ImageJ to evaluate PI3K and apoptotic signaling. Flow cytometry using annexin V and propidium iodide (PI) was performed as a measure of apoptosis. Immunohistochemistry (IHC) using Ki67 was performed as a measure of cell proliferation on SW48PK xenografts and quantified as percent positive nuclei at 40x field of view (FOV).

Results: Two datasets comprised of *PIK3CA* mutant CRC patients with either high or low *BCL2L1* expression containing 39 and 47 patients, respectively, were used in the TGCA analysis. There was no difference in age, gender, or staging between these two datasets. An increase in DNA repair (false discovery rate q-value= 0.034) and interferon alpha signaling pathways (q= 0.022) was seen in *PIK3CA* mutant and high *BCL2L1* expression compared to *PIK3CA* mutant and low *BCL2L1* expression patients. *PIK3CA* mutant patients with low expression of *BCL2L1* had a greater disease-free and overall survival (p= 0.037 and p= 0.042, respectively). Combination of copan and navitoclax treatment of the SW48 and SW48PK cell lines resulted in a reduction in activated ribosomal protein S6 (pRPS6) as compared with control or navitoclax alone at both 6 and 24. Cleaved PARP increased in SW48PK cells treated with 100 nM copan plus navitoclax versus control at both 6 and 24 hour timepoints (p= 0.03, p= 0.049). SW48 and SW48PK cells that were treated with copan and navitoclax for 24 hours had an increase in annexin v, a marker for apoptosis, compared to cells treated with control or single agents. In SW48PK xenografts, a significant reduction in Ki67 percent positive nuclei was seen in combination compared to control (median percent positive nuclei: 20.5, control: 33.2, p<0.001).

Conclusions: High BCLxL expression is a sign of poor prognosis for *PIK3CA* mutant CRC. Inhibiting BCLxL can enhance the sensitivity of PI3K inhibition in *PIK3CA* mutant cancers and deserves further investigation clinically.

#0356 Developing a multiplex assay to monitor apoptosis and necrosis using the Cellaca® PLX Image Cytometer.

J. Mukherjee, M. Pierce, Y. Huang, A. Lin, L. L. Chan;
Revvity Health Sciences, Inc., Lawrence, MA

Apoptosis is a critical pathway for programmed cell death that cancer cells can evade to ensure survival. For pharmaceutical drug discovery, it is important to characterize and compare cancer therapeutics (i.e., small molecules, antibody drugs, cell therapies) that can initiate the process of apoptosis, allowing for the identification of potential therapeutic candidates. In this work, we developed and demonstrated a multiplex detection method for monitoring apoptosis and necrosis with Annexin V, Caspase 3/7, and Propidium Iodide (PI) using the Cellaca® PLX Image Cytometer. First, apoptosis was induced in Jurkat and K562 cell lines with staurosporine over the course of 24 h, and were monitored at 0, 1, 1.5, 2, 4, 20, and 24 h timepoints. Samples were stained with Hoechst 33342 (total dye), Annexin V-APC (early-stage apoptosis), Caspase-3 488 (late-stage apoptosis), and PI (necrosis) at each timepoint and evaluated using the Cellaca® PLX. Results showed that apoptotic factors and cascades were successfully detected along the pathway from early to late-stage apoptosis, and ultimately necrosis. A clear trend was observed during the first 2 h showing differences of up to 25% between the single Annexin V+ and Caspase-3+ populations in treated Jurkat cells, however, a significant increase in double positive apoptotic/necrotic cells for Annexin V+PI+ and Capase-3+PI+ was not observed until 20 h. Upon further analysis amongst apoptotic populations, Annexin V+ only populations were higher than Caspase-3+ only populations by up to 30% between 0-2 hours. Conversely, K562 cells did not exhibit a notable change in apoptotic and necrotic populations due to low sensitivity to staurosporine. The proposed image-based detection method using the Cellaca® PLX may provide an effective and efficient tool for rapid and reliable simultaneous detection of early, late-stage apoptosis, and necrosis. This may allow researchers to better characterize and screen potential cancer therapeutic drug candidates in a high-throughput manner to determine their treatment efficacy.

#0357 Reducing reagent-resistant transferrin receptor 1 dimer is a specific marker for ferroptosis.

J. He[1], M. Kelleher[1], L. Reynolds[1], H. Tanczos[1], Z. Huang[1], B. McLaughlin[1], W. Huang[2], L. Pope[3], G. Veeckmans[4], T. Vanden Berghe[4], S. J. Dixon[3], Y. Shah[2], Z. T. Schafer[1];

[1]University of Notre Dame, Notre Dame, IN, [2]University of Michigan, Ann Arbor, MI, [3]Stanford University, Stanford, CA, [4]University of Antwerp, Antwerp, Belgium

Ferroptosis is an iron-dependent cell death caused by the catastrophic accumulation of lipid peroxidation. Despite the burgeoning ferroptosis research, there remains a void for an intrinsic and comprehensive ferroptosis indicator. Here we reported a simple and cost-effective way to detect ferroptotic cell death using reducing reagent-resistant (RRR) transferrin receptor 1 (TfR1). The TfR1 RRR dimer strongly correlates with ferroptosis induced by various ferroptosis-inducing conditions and relies on lipid peroxidation, which is not observed in other types of cell death. Through iron-overloading and tumor xenograft mouse models, we validate the in vivo ferroptosis detection using this technique. Furthermore, we identify the presence of TfR1 RRR dimers in extracellular vesicles isolated from the plasma of mice with ferroptosis-related diseases. Since TfR1 is a ubiquitously expressed protein, the increase of TfR1 RRR dimer can be used as a specific and endogenous ferroptosis marker with potential clinical applications.

#0358 Ferroptosis modulates melanoma progression in an age-specific manner through changes in the tumor microenvironment.

M. R. Rocha, Y. Chhabra, L. Huser, E. I. Harper, A. Dixit, V. Wang, A. E. Carey, C. Palm, F. Huang, A. T. Weeraratna;
Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Aging is an independent prognostic factor for melanoma, the most aggressive form of skin cancer. Although immune therapy has shown a dramatic improvement in melanoma treatment, resistance to it still occurs in some patients. Higher oxidative damage in tumor cells as well as lipid and iron accumulation are singular characteristics of the aged tumor microenvironment (TME). Here, we investigate the impact of these characteristics of the aged TME in the promotion of ferroptosis, a caspase independent iron mediated type of cell death, and as possible modulators of the response to checkpoint blockade therapy. Lipid peroxidation levels were assessed through immunohistochemical staining for the marker 4-HNE in tumors of young and aged mice injected intradermally with Yumm1.7 cells.Correlation analysis between transcriptomic data (TCGA-SKCM) was performed to identify common denominators among proteins associated with the aged TME, ferroptosis pathway and IFN-y signaling. Our in vitro experiments consisted of viability assays with combinations of IFN-y, young and aged skin fibroblast conditioned media (CM), arachidonic acid (AA) or ferroptosis inducers such as RSL-3. Protein levels of ferroptosis related markers in melanoma cells treated with fibroblast conditioned media, and in Wnt5a high/low cell lines were analyzed through western blot (WB). Tumors from aged mice showed stronger staining with 4-HNE antibody when compared to young. Wnt5a (present in the aged TME) showed a strong correlation with several ferroptosis related transcripts. WB analysis of Wnt5a high/low lines indicate differences in GPX4, FTL1, SLC3A2, GCH1 and DHODH. Wnt5a levels show an inverse correlation with ferroptosis resistance and anti-ferroptotic proteins. Our data indicate that aged TME favors ferroptosis death in melanoma cells. To understand how ferroptosis impacts tumor growth in young and aged mice, we used a syngeneic tumor model injecting Yumm1.7 cells intra-dermally in mice and treated with a lipid peroxidation inhibitor, Liproxstatin, or an ferroptosis inducer, IKE. Liproxstatin lead to reduced tumor growth only in young mice followed by changes in immune cell populations such as monocytes and macrophages. IFNy induction of these events might be associated with changes in proteins of the pathway or alterations in fatty acid uptake as suggested by lipid accumulation and AA potentiation of its cytotoxic effects. Further exploration of ferroptosis will impact our understanding on how aged TME modulates immune cell killing and provide evidence to target or revert resistance to checkpoint blockade therapy associated with an IFN-y signature and new strategies for treatment of older patients.

#0359 The Hippo pathway on breast tumor recurrence <and> collateral vulnerability to ferroptosis.

C.-C. Lin, J.-T. Chi;
Duke University, Durham, NC

Comparing with primary breast tumors, recurrent breast cancers are generally considered more aggressive and incurable. Therefore, novel molecular strategies are urgently needed to target these type of cancers. Here, we report that murine recurrent breast tumor cells are highly susceptible to ferroptosis, a novel form of cell death. Discoidin Domain Receptor Tyrosine Kinase 2 (DDR2), the receptor for collagen I, is upregulated in ferroptosis-sensitive recurrent tumor cells. Ferroptosis inducer, erastin treatment leads to DDR2 upregulation and phosphorylation, independent of collagen I. Furthermore, DDR2 silencing not only prevent ferroptosis but also abolished the robust cell proliferation of murine recurrent tumor cells. Both the ferroptosis protection and reduction of active cell growth may be compatible with the compromised YAP/TAZ upon DDR2 inhibition. Collectively, these findings suggest the role of DDR2 in recurrent breast tumors to drive aggressive cell growth but at the same time reveals its weakness to YAP/TAZ-mediated ferroptosis, providing potential molecular mechanism to target recurrent breast cancers.

#0360 Dissecting the role of oncogenic KRAS and ferroptosis within colorectal cancer.

A. Rosa-Vazquez[1], V. Bernard-Pagan[2], J. Chen[2], C. Taniguchi[2];
[1]Universidad Central del Caribe School of Medicine, Bayamon, PR, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Ferroptosis is a novel iron-dependent regulated cell death mechanism triggered by a toxic accumulation of membrane lipid peroxidation. This mechanism is counteracted by ferroptosis defense systems, such as the GPX4/GSH system, which function as antioxidants that limit lipid peroxidation. Oncogenic KRAS ($KRAS^{mut}$) is a key driver for many aggressive cancers, including colorectal cancer (CRC). Previous studies have suggested that oncogenic KRAS plays a pleiotropic role in the ferroptosis pathway. Yet, the interplay between oncogenic KRAS and ferroptosis has not been fully elucidated in CRC. Here, we aimed to dissect the role of oncogenic KRAS in ferroptosis using CRC as a cancer model.
Methods: Cells from a KRAS-inducible model (iKAP) were seeded and treated with ferroptosis-inducing drugs (e.g., Erastin and RSL3) and/or a KRAS inhibitor (MRTX1133). Lipid peroxidation was then measured by BODIPY assay followed by flow cytometry to detect the quantity of BODIPY-stained cells. Protein expression of known ferroptosis defense mechanisms was also profiled (e.g., SLC7A11 [xCT] and GPX4).
Results: Results from this study demonstrate that $KRAS^{mut}$ activation leads to a reduction in mean fluorescence intensity when compared to $KRAS^{WT}$ of BODIPY-stained cells. This decreased mean fluorescence intensity is indicative of lower levels of lipid peroxidation and, consequently, ferroptosis. $KRAS^{mut}$ cells were also found to be resistant to ferroptosis following treatment with ferroptosis inducers. To replicate a pharmacologically induced $KRAS^{WT}$ phenotype, iKAP cells were treated with MRTX1133, which led to a significant decrease in viability when combined with RSL3. We observed a decreased protein expression of the membrane antiporter xCT following treatment with MRTX1133, which we believe works synergistically with the GPX4 inhibition of RSL3.
Conclusion: We observed that $KRAS^{mut}$ may induce resistance to ferroptosis *in* vitro in CRC cells. Genetic and pharmacological inhibition of KRAS resulted in sensitization to ferroptosis inducers. Future work will uncover mechanisms through which oncogenic KRAS leads to ferroptosis resistance in CRC. More importantly, understanding the interaction between ferroptosis, oncogenic KRAS, and its antagonist systems has significant therapeutic potential in oncology.

#0361 Targeting the suppressor of ferroptosis to improve the treament effeciency of glioblastoma.

J. Wang;
Sun Yat-sen University Cancer Center (SYSUCC), Guagnzhou, China

Glioma is the most frequent tumor in central nervous system (CNS), which makes up about 30% of CNS tumors. The current standard strategy for glioma treatment is surgery plus adjuvant chemotherapy and concurrent radiotherapy. Even though, the prognosis of glioma is still poor. It's encouraging that temozolomide (TMZ) prolongs the overall survival of glioma patients, but the following TMZ resistance is really frustrating. It's urgent to figure out efficient ways to improve the long term prognosis of patients, such as antagonizing the TMZ resistance. Ferroptosis was a newly discovered type of regulated cell death characterized by iron-dependent aberrant lipid peroxidation and membrane damage in the last decade. Ferroptosis-associated iron transport proteins modulate the process precisely through controlling the iron content. ZIP14, also known as SLC39A14, is an eight-transmembrane protein which could transport divalent metal ion like Mn^{2+}, Zn^{2+} and Fe^{2+}. Our preliminary data showed that the expression level of ZIP14 was higher in tumor tissues than paired normal tissue, which was corelated with poor prognosis of glioma. Knock down ZIP14 could induce cell death, and which could be rescued by inhibitors for ferroptosis but not for apoptosis or necrosis. Knock down ZIP14 decreased the ferroptosis inhibition by Ferroptosis suppress protein 1 (FSP1) which through reduction of lipid peroxidation, and sensitized cells to TMZ. Furthermore, we found that ZIP14 formed a complex with Ubiquinone. And it was known that FSP1 is critical in the switch of ubiquinone to ubiquinol. Therefore, we propose that ZIP14 suppress lipid peroxidation through blockage of the transition of ubiquinone to ubiquinol. While ZIP14 was knocked down, the complex with Ubiquinone wad damaged, and could not further change to Ubiquinol, so the suppression to lipid peroxidation was released, and then, ferroptosis was upregulated. In this study, we are going to figure out the molecular mechanism about how ZIP14 suppress ferroptosis and find out efficient small molecule inhibitors to activate ferroptosis by abolishing ZIP14 and improve the prognosis of glioma patients.

#0362 Arsenic sulfide triggers ferroptosis in hepatocellular carcinoma cells via TRPC6/GPX4 signaling.

S. Lu, Y. Cai, C. Zhu, Z. Feng, S. Chen, S. Chen;
Xin Hua Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Ferroptosis is critically involved in the pathological process of various human diseases, including cancer. Due to this, ferroptosis-inducing drugs are gaining more attention for the clinical treatment of tumors.
Methods: The cell counting kit-8 (CCK-8) assay was conducted to observe cell viability of hepatocellular carcinoma (HCC) cell lines. Ferroptosis was determined by levels of Fe^{2+}, lipid reactive oxygen species (ROS), malondialdehyde (MDA) and transmission electron microscopy. Enzyme-linked immunosorbent assay (ELISA), western blot, quantitative polymerase chain reaction and immunofluorescence staining were utilized to evaluate glutathione peroxidase 4 (GPX4) and transient receptor potential channel 6 (TRPC6). Co-immunoprecipitation assay was conducted to determine the binding between GPX4 and TRPC6.
Results: Arsenic sulfide initiated ferroptotic cell death in HCC cells, which was concomitant with ROS accumulation, lipid peroxidation, and GSH depletion. Arsenic sulfide -mediated cell death in HCC cells was blocked by ferroptosis inhibitors ferrostatin-1 (Fer-1), but not Z-VAD-FMK, necrosulfonamide, or chloroquine, suggesting that ferroptosis contributed to arsenic sulfide -induced cell death. Furthermore, TRPC6 expression was notably inhibited under arsenic sulfide intervention and the overexpression of TRPC6 rescued the effects of arsenic sulfide on cell viability and ferroptosis of HCC cells. Furthermore, GPX4 was identified to interact with TRPC6 through confocal microscopy images and co-immunoprecipitation assay.
Conclusion: Our findings led us to conclude that arsenic sulfide could be considered as a prospective drug for liver cancer treatment.

#0363 Genetic or pharmacological inactivation of CREBBP sensitizes B-cell acute lymphoblastic leukemia to ferroptotic cell death upon BCL2 inhibition.

A. Garcia Gimenez, J. Ditcham, D. M. A. Azazi, E. Meduri, R. Asby, N. Sakakini, C. K. Lopez, N. Narayan, J. Bagri, T. Beinortas, S. Agrawal Singh, G. Giotopoulos, M. P. Murphy, S. J. Horton, B. J. P. Huntly, S. E. Richardson;
University of Cambridge UK, Cambridge, United Kingdom

B-cell acute lymphoblastic leukemia (B-ALL) is an aggressive hematological malignancy of B lineage progenitors. It remains a leading cause of death in childhood, while outcomes in adults are dismal. There is therefore a need to better understand drivers of high-risk B-ALL and to develop novel therapeutic approaches targeting these challenging patient cohorts. Loss-of-function mutations affecting *CREBBP* are recurrent second-hit mutations across multiple genetic subtypes of B-ALL and are associated with adverse features, including high-risk genetic subtypes and persistent measurable residual disease. In addition, they have been mechanistically associated with chemoresistance and are more frequently found in relapse. We sought to identify novel treatment options for *CREBBP*-mutated high-risk B-ALL. *CREBBP*-mutated isogenic human B-ALL cell lines were genome-engineered to provide a platform for synthetic lethal drug screening. We subjected these cell lines to a targeted drug screen focused on clinically-actionable drugs in classes that have either been implicated or hypothesized to show differential sensitivity patterns in published models of B cell lymphoma and other *CREBBP*-mutated malignancies. Unexpectedly, *CREBBP*-mutated cells were not differentially sensitive to traditional cytotoxic chemotherapy, and paradoxically showed a degree of sensitization to the glucocorticoid Dexamethasone, used in current ALL induction regimens. As anticipated, and validating our screen design, inhibitors of the *CREBBP* paralogue *EP300* (the CREBBP/EP300-specific bromodomain inhibitor Inobrodib and the CREBBP/EP300 acetylase inhibitor A485) exhibited synthetic lethality, consistent with previous reports in B-cell lymphoma. The most potent hit was the BCL2 inhibitor Venetoclax, which we show acts through a non-canonical, but BCL2-dependent mechanism resulting in ferroptotic programmed cell death. *CREBBP*-mutated cell lines were transcriptionally and functionally characterized, revealing underlying differences in cell-cycle, metabolism and response to oxidative stress. Acquisition of resistance to Venetoclax further dysregulated these pathways and resulted in a transcriptionally-convergent state. Lastly, we demonstrate that small-molecule inhibition of CREBBP sensitizes B-ALL cells, regardless of genotype, to Venetoclax-induced ferroptosis *in vitro* and *in vivo*, providing a potential novel drug combination for broader clinical translation in B-ALL. In summary, we have identified a number of actionable compounds that specifically target *CREBBP*-mutated high-risk B-ALL, demonstrate a novel mechanism-of-action for the BCL2 inhibitor Venetoclax in B-ALL and propose CREBBP-inhibitors and Venetoclax as a novel treatment combination for B-ALL across genotypes.

#0364 Targeting LILRB1 to sensitize human myeloma to ferroptosis through disrupting cholesterol homeostasis.

M. Xian, Q. Yi, Q. Wang, L. Xiao, L. Zhong, c. zhang, y. Li, J. Qian;
Houston Methodist Hospital, Houston, TX

Multiple myeloma (MM) is a hematologic malignancy characterized by the uncontrolled clonal proliferation of plasma cells in the bone marrow (BM). Despite the demonstrated benefits of novel therapies, relapses are frequent, and acquired resistance to MM treatment eventually emerges in most, if not all, patients. MM patients who suffer more aggressive progression usually result in poorer survival. The genes driving such unfavored outcomes in MM have not been fully understood. Therefore, there is an urgent need to identify the genes and mechanisms that contribute to the aggressive behaviors of MM in order to develop improved therapeutic strategies for the disease. To discover new potential therapeutic targets for MM patients, we analyzed gene-profiling data of MM patients and identified leukocyte immunoglobulin-like receptor B1 (LILRB1), a transmembrane receptor conducting negative immune response, as one of the top-ranked genes associated with poor prognosis. LILRB1 on immune cells was reported to bind to its ligand, b2-microglobulin, on tumor cells. This interaction leads to immune suppression responses in various immune cells. However, the function of tumor-derived LILRB1 in tumor biology remains unclear and the role of LILRB1 in MM has been poorly studied. Our further analysis of the patient data demonstrated that MM patients with high expression of LILRB1 are closely related to higher MM recurrence rates, advanced stages, and lower survival rates, indicating that LILRB1 is an important player in MM pathogenesis and thus a promising target for MM therapy. Interestingly, RNA-seq data of human MM cells from the BM of MM-bearing mice showed that knockdown (KD) of LILRB1 activated cholesterol metabolism- and ferroptosis-related pathways in murine BM. Moreover, KD of LILRB1 significantly impaired tumor progression in murine models. Consistently, in vitro experiments also demonstrated that LILRB1 protected MM cells from ferroptosis inducer-caused lipid ROS and ferroptotic cell death, indicating that LILRB1 promotes the progression of MM cells by protecting them from ferroptosis. Further study were then conducted to reveal the underlying mechanism. LC-MS/MS analysis followed by co-IP demonstrated that LDLRAP1, an adaptor protein that interacts with LDLR, bound with LILRB1 and formed a complex together with LDLR. KD of LILRB1 inhibited LDL uptake by disrupting the interaction between LDLR and LDLRAP1 and triggering the compensatory cholesterol synthesis by upregulating the expression of SQLE that converted squalene to (S)-2,3-epoxysqualene. With less squalene to protect MM cells from lipid peroxidation, MM cells were more susceptible to the induction of ferroptosis. Thus, this study uncovers a novel function of LILRB1 in regulating cholesterol metabolism and protecting MM cells from ferroptosis during MM progression and implicates LILRB1 as a promising therapeutic target for MM patients.

#0365 Proteomic analysis of cytoplasmic lipid droplets and whole cell lysates reveal ferroptosis regulation by fatty acid synthase-derived lipid droplets in metastatic breast cancer.

C. Andolino[1], K. K. Buhman[1], M. F. Coleman[2], S. D. Hursting[2], M. Layosa[1], M. K. Wendt[1], D. Teegarden[1];
[1]Purdue University, West Lafayette, IN, [2]University of North Carolina, Chapel Hill, NC

Breast cancer remains a serious public health concern, where metastasis accounts for the majority of patient mortality. Lipid accumulation in metastases is associated with reduced treatment response and poorer patient outcomes, although the mechanisms linking lipid accumulation and metastasis are not clear. We previously demonstrated that metastatic MCF10CA1a breast cancer cells have higher *de novo* lipogenesis and cytoplasmic lipid droplets (CLDs) compared to non-metastatic MCF10A-*ras* cells. Additionally, fatty acid synthase (FASN)-derived TAG stores sustained key metastatic processes in the MCF10CA1a cells. The proteome of CLDs is diverse and plastic, reflecting differing CLD functions; therefore, we sought to identify proteins differentially abundant on CLDs from vehicle-treated and FASN-inhibited MCF10CA1a breast cancer cells. We performed untargeted, global proteomics analysis on whole cell lysates (WCLs) and CLDs from vehicle-treated and FASN-inhibited (TVB-3166) MCF10CA1a cells to determine protein pathways differentially enriched on CLDs. Together, 2,416 and 3,539 proteins were identified within CLD fractions and WCLs, respectively. Of the proteins identified in CLD fractions, ~30% (717) were commonly identified within both conditions. Interestingly, 1,571 proteins were unique to the CLD fraction from vehicle-treated cells, whereas only 19 proteins were unique to the CLD fraction from FASN-inhibited cells. Proteins unique to CLDs from vehicle-treated cells include those known to reduce cancer cell survival and progression, such as proteins involved in cadherin-binding and cell cycle regulation. Proteins known to reduce cancer progression that associate with CLDs may prevent them from functioning at their normal site of action. Interestingly, an inhibitor of ferroptosis, glutathione peroxidase 4 (GPX4), was only detected in the vehicle-treated CLD and WCL samples, whereas proteins that promote ferroptosis were more abundant on CLDs of the more migratory cells, although their levels between WCLs were similar. Taken together, these data suggested that the machinery for ferroptosis may be mislocalized in TAG-rich cells, thereby protecting them from ferroptosis. Indeed, FASN-inhibited cells had nearly 30% more intracellular iron compared to the vehicle-treated cells, an important prerequisite for ferroptosis, thus indicating higher levels of ferroptotic stress. Functionally, the vehicle-treated cells were 25% more readily rescued by N-acetylcysteine from ferroptosis induced by erastin than were FASN-inhibited cells, despite comparable sensitivity to erastin. These preliminary findings suggest that FASN-derived CLDs in metastatic cells may aid in protecting against ferroptosis to promote breast cancer progression.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Cellular Stress Responses 1
Poster Session

#0369 In silico investigation of hypoxia and its association with disease outcome and ecDNA detection in TRACERx.

N. Sharma[1], C. Bailey[2], C. Richard[1], J. Kittel[1], W. K. Liu[1], A. M. Frankell[3], G. Satvrou[1], D. Moore[1], M. Sivakumar[1], M. J. Hanjani[1], C. Swanton[2], N. Kanu[1]; [1]UCL Cancer Institute, University College London (UCL), London, United Kingdom, [2]The Francis Crick, London, United Kingdom, [3]University of Cambridge, Cambridge, United Kingdom

Tumors exhibit dynamic gradients of oxygen diffusion and consumption leading to regions of hypoxia. The presence of hypoxia is associated with poor clinical prognosis and elevated genomic instability. Genes can be amplified extrachromosomally as ecDNA, which are acentric circular structures that can rapidly generate large genomic copy number amplifications. The amplification of oncogenes on ecDNA is unstable thus providing cells with an advantage to adjust and survive the changing environment. Here, we have analysed the effect of hypoxia on disease outcome and ecDNA formation in the multiregional longitudinal NSCLC TRACERx (TRAcking Cancer Evolution through therapy (Rx)) cohort. We have analysed next generation sequencing, clinical and histopathological data available from the tumours that were harvested at the time of surgery from patients recruited into the lung TRACERx study. Hypoxia was first quantified using the mRNA-based Buffa hypoxia gene signature. Complexheatmap from R-Bioconductor package was used for clustering based on mRNA expression of gene signature. Moreover, hypoxia scores for each region were established using the Gene Set Variation Analysis (GSVA) from R- Bioconductor package. The impact of hypoxia on overall and disease-free survival was performed using the survminer package. Histopathological data was used to study the association between hypoxia and necrosis. The genetic instability was analyzed using whole exome sequencing. The amplicon architect tool was used to study the association of hypoxia with ecDNA detection. Our preliminary results demonstrate that the extent of hypoxia varies widely both within and between primary tumours, suggestive of the presence of inter and intratumour hypoxia heterogeneity. High hypoxia status is associated with worse overall and disease-free survival in adenocarcinoma but not in squamous-cell carcinoma. The presence of necrosis in the primary tumour was associated with higher hypoxia. Moreover, higher hypoxia scores correlate with circulating tumour DNA (ctDNA) shedding in pre-surgery plasma samples (p value< 0.05). Higher hypoxia was significantly associated with increased wGII scores, indicative of genomic instability. Also, hypoxia resulted in increased detection of ecDNA in both lung adenocarcinoma and squamous cell carcinoma. In conclusion, there is inter and intratumoral heterogeneity in hypoxia levels in lung TRACERx. Moreover, the presence of hypoxia is associated with the detection of necrosis and ctDNA shedding. The increased genomic instability and detection of ecDNA in this study could be associated with the poor prognosis that is observed with hypoxic tumours and could merit further investigation.

#0370 BACH1 metastatic activity is regulated by oxygen-dependent proline hydroxylation in triple-negative breast cancer.

Thomas Li[1], Long Chi Nguyen[1], Christopher Dann[1], Madeline Henn[1], Dongbo Yang[1], Emily Shi[1], Lydia Robinson-Mailman[1], Kazuhiko Igarashi[2], Marsha R. Rosner[1]

[1]Ben May Department for Cancer Research, University of Chicago, Chicago, IL,[2]Tohoku University School of Medicine, Sendai, Japan

Hypoxia, low oxygen availability at the tissue level, is a key driver of metastasis in solid tumors. Oxygen-sensitive activation of hypoxia-induced transcription factors is in part regulated by prolyl hydroxylase domain proteins (PHDs). We and others previously showed that the BTB and CNC homolog 1 (BACH1) transcription factor promotes metastasis in various cancer types. In accompanying work, we show that BACH1 is prolyl-hydroxylated and degraded in an oxygen-dependent manner in triple-negative breast cancer (TNBC). Here we show that BACH1 lacking its hydroxylated proline sites (i.e., mutant BACH1) expressed in TNBC cells exhibits increased DNA binding to a canonical BACH1 binding site as well as greater transcriptional output of metastasis and hypoxia-response-related genes relative to wild-type BACH1. Furthermore, *in vivo* assays showed that mutant BACH1 promotes greater tumor metastasis of TNBC cells than wild-type BACH1. Our findings suggest that the proline hydroxylation of BACH1 directly regulates BACH1's transcriptional activity by modulating its DNA-binding activity. Together, these results reveal a mechanism underlying oxygen-sensitive regulation of BACH1 that could potentially contribute to BACH1-mediated pro-metastatic signaling and therapeutic resistance under hypoxia in TNBC.

#0371 Hypoxia-induced centrosome loss as a driver of chromosomal instability in prostate cancer.

J. M. Ryniawec, G. C. Rogers, A. E. Cress;
University of Arizona, Tucson, AZ

PURPOSE: This study aims to identify a causal mechanism of centrosome loss previously observed in primary prostate cancer. Prostate cancer progression is accompanied by bursts of chromosomal instability (CIN), including chromosomal translocations, oncogene amplifications, and chromothripsis. While high CIN correlates with most metrics of aggressive disease, we lack a mechanistic understanding of how CIN originates in prostate cancer. Recently, we discovered that cells in primary prostate tumors lack centrosomes, cytoplasmic organelles that ensure the fidelity of chromosome segregation by organizing the shape of the mitotic spindle. Experimental elimination of centrosomes in immortalized, non-tumorigenic prostate cell lines was sufficient to generate extensive CIN, resulting in oncogenic transformation of these lines when sub-cutaneously injected into NSG mice. Because we identified centrosome loss as a potential driver of CIN, we sought to understand mechanisms that can trigger centrosome loss in the prostate. Although centrosome loss naturally occurs during the development of some tissues, for example centrosome elimination during oogenesis, the mechanisms that trigger loss are not known. Therefore, we first investigated microenvironmental changes in early prostate cancer as a potential cause. Hypoxia, pathologically low oxygen concentration, is common in the aging prostate due to loss of vasculature and is associated with poor prostate cancer prognosis and high CIN. Therefore, we hypothesized that hypoxic exposure induces centrosome loss in prostate cells. Indeed, we found that exposure to 1% oxygen concentrations leads to progressive centrosome loss in non-tumorigenic, immortalized prostate epithelial cell lines. Using immunofluorescence of centrosomes in cultured cells, we found that hypoxia-induced centrosome loss is independent of HIF transcription but requires activation of the confluence-dependent Hippo signaling pathway. Mechanistically, we found that centrosome disassembly begins with the removal of the pericentriolar material (PCM), the outer shell of the centrosome that nucleates microtubules. We were able to block centrosome disassembly by over-expressing a constitutively-active mutant of Polo-like Kinase 1, which normally strengthens the PCM during mitosis to promote centrosome maturation. Furthermore, centrosome loss was prevented by treatment with the Protein Phosphatase 2A (PP2A) inhibitor Okadaic Acid. Using RNAseq, we have identified potential PP2A regulatory subunits that are up-regulated in cells undergoing hypoxia-induced centrosome loss. Our model is that hypoxia induces dephosphorylation of the PCM, mechanically weakening the centrosome and leaving it vulnerable to disassembly. Together with previous findings, we conclude that hypoxia-induced centrosome disassembly is a plausible driver of CIN in early prostate cancer.

#0372 Cell polarity proteins as novel regulators of macropinocytosis in pancreatic cancer.

G. Lambies Barjau[1], S.-W. Lee[2], C. Commisso[1];
[1]Sanford Burnham Prebys Med. Discovery Inst., San Diego, CA, [2]Crinetics Pharmaceuticals, San Diego, CA

Pancreatic ductal adenocarcinoma (PDAC) is considered one of the deadliest cancers. This is likely because it is detected at a very late stage and the therapeutic approaches that have been used for its treatment have proven to be quite ineffective. Therefore, new therapeutic strategies are needed for a better prognosis in patients suffering of pancreatic cancer. PDAC cells often rewire their metabolism to survive and progress. This metabolic rewiring permits the acquisition of nutrients by the cells when these are exposed to a poor nutrient microenvironment. One of the most used processes in nutrient stress conditions is the “cell-drinking” pathway macropinocytosis, an endocytic pathway that cancer cells exploit to support cancer metabolism in such unfavorable conditions. Macropinocytosis inhibition has shown to suppress PDAC growth in mice and thus, it has become a promising therapeutic target for PDAC treatment. Here, we describe that atypical Protein Kinase C (aPKC) isoforms Protein Kinase C zeta (PKCζ) and Protein Kinase C iota (PKCι) regulate PDAC macropinocytosis in the context of glutamine stress. Genetic depletion and pharmacological inhibition of aPKC impair macropinocytosis promotion in PDAC cells exposed to a glutamine-deprived environment and in cells treated with DON, a glutamine analog that blocks glutamine metabolism. In epithelial cells, aPKCs are known to regulate the establishment of cell polarity in association with the scaffold proteins Par3 and Par6, constituting the cell polarity complex, which controls the function of different targets such as Par1 kinases. Loss of Par3, Par6 and Par-1a affects glutamine stress associated macropinocytosis in a similar extent than aPKC depletion, presenting a novel role of the cell polarity protein network in the modulation of macropinocytic uptake.

#0373 Transcriptional and post-transcriptional positive regulatory loops between HIF-1a and the RNA-Binding protein hnRNPA18.

E. Solano-Gonzalez, **F. Carrier**;
Univ. of Maryland Marlene & Stewart Greenebaum Cancer Ctr., Baltimore, MD

Hypoxia, the scarcity of oxygen, is a hallmark of solid tumors to which they adapt by activating the hypoxia-inducible transcription factor 1 (HIF-1). HIF activates the transcription of genes bearing hypoxia responsive elements (RE) in their promoter regions including genes related to angiogenesis, glucose metabolism, cell proliferation, survival, invasion, and metastasis. The HIF-1 pathway is thus an attractive target to prevent cancer aggressiveness and improve the effectiveness of cancer therapy. HIF-1α activity is known to be mainly regulated through post-translational modification by prolyl hydroxylase domain (PHD) enzymes, but accumulating evidence indicate that it is also regulated by other mechanisms such as transcriptional initiation, translational initiation, protein-protein interaction, post-translational modifications and post-transcriptionally, primarily through the action of trans-acting factors (noncoding RNAs and RNA-binding proteins) that interact with the HIF-1α mRNA to regulate its decay and translational rates. We recently identified the RNA binding protein hnRNP A18 as a regulator of HIF-1α translation under hypoxic conditions. hnRNP A18 is a nuclear stress responsive protein that translocates to the cytosol in response to cellular stress including hypoxia to bind to a recognition motif in the 3'UTR of its targeted transcripts including HIF-1α to stabilize the transcripts and increase their translation. Using a bicistronic reporter plasmid containing a HIF-1α internal ribosome entry site (IRES) we now show that hnRNP A18 can also regulate HIF-1α through its IRES in the 5'UTR. In fact, cells expressing hnRNP A18 significantly increase translation of a reporter CAT protein under the control of HIF-1α IRES in the presence of the hypoxia mimetic agent $CoCl_2$. On the other hand, deletion of hnRNP A18 prevents the translation of the CAT reporter protein even in the presence of $CoCl_2$. Moreover, we also identified several HIF-1α REs in hnRNP A18 promoter. Two of the predicted HIF-1α REs, located at -57 and -226 upstream of the hnRNP A18 start codon were validated as bonafide HIF-1α binding sites by Electromobility Shift Assay with recombinant HIF-1α protein and by Chromatin Immunoprecipitation assay in human pancreatic cancer cells Panc 01. These data thus indicate that a positive regulatory loop between hnRNP A18 and HIF1-1α exist to amplify HIF-1α expression under cellular stress. hnRNP A18 can upregulate HIF1α protein expression by stabilizing its transcript at the 3'UTR and by binding to its IRES. On the other hand, HIF-1α can upregulate hnRNP A18 by binding to its proximal promoter. Targeting hnRNP A18 could thus provide a new mechanism to regulate HIF-1α expression and sensitize cancer cells to therapies.

#0374 Hypoxia-induced mitochondrial glutathione transporter expression causes drug resistance in colorectal cancer.

C.-C. Lin;
National Cheng Kung University, New Taipei City, Taiwan

Colorectal cancer (CRC) is the third most common type of cancer worldwide, with higher incidence and mortality rates. In order to adapt stress conditions during cancer progression, the cancer cells will be subject to metabolism reprogramming to increase energy production and remove hazardous substances. One of the important organelles, mitochondria is responsible for cellular ATP production, ion homeostasis, and several metabolic pathways. Therefore, mitochondria require a series of transporters called solute carrier family 25 (SLC25) to transport metabolites crossing the mitochondrial inner membrane, and dysregulation of those transporters causes abnormal cell morphology and diseases. In this study, members of the SLC25 family were analyzed in CRC via bioinformatics analysis, and a mitochondrial glutathione transporter was identified to overexpress in several public datasets of CRC and our own clinical specimens. In addition, its role has not been reported in any disease, including cancer. To systemically analyze the underlying mechanism causing overexpression of glutathione transporter during CRC progression, several stress conditions had been applied to colon cancer cells. However, only hypoxia was identified to induce its protein expression but not mRNA expression. Since a previous study reported that glutathione deprivation induced its protein expression, hypoxia didn't alter the abundance of glutathione level suggesting that another glutathione-independent regulatory mechanism might be involve it. Interestingly, our findings revealed that hypoxia-induced glutathione transporter protein expression was mediated through the activation of internal ribosome binding site-mediated translation under hypoxia. To identify the potential role of glutathione transporter during colon cancer progression, its mitochondrial metabolite profiles from knockout cells of previous studies were further analyzed and identified that the changes of metabolites were associated with the urea cycle which had been reported to be associated with the sensitivity of oxaliplatin and 5-fluorouracil (5-FU) in cancer treatment. Importantly, our results showed that hypoxia-attenuated those chemotherapeutic effects were abolished by loss of glutathione transporter in colon cancer cells, indicating its crucial role in hypoxia-induced drug resistance. In conclusion, our study shows that glutathione transporter increased by hypoxia might lead to drug resistance of cancer therapy in colon cancer.

#0375 Lipogenic phenotype is an adaptation to nutrient stress in the tumor microenvironment.

C. Griffith, D. Abrahams, A. Ortiz, A. Tassielli, J. Johnson, R. Gatenby, **S. Pillai**;
Moffitt Cancer Center, Tampa, FL

The nutrient and oxygen poor microenvironment combined with acidosis arising from fermentative metabolism imparts strong selection pressure on cancer cells that promotes evolution of more aggressive cancer types. Poor nutrient availability in the tumor microenvironment forces cancer cells to adapt to alternate routes of metabolism, nutrient scavenging and autophagy leading to a shift in their metabolic phenotype. These adaptations promote evolution of invasive and aggressive phenotypes. To test this hypothesis and to characterize the evolution of cancer cells under nutrient stress, we generated nutrient stress adapted cells from MCF7-GFP cells by subjecting them to multiple cycles of nutrient starvation and repletion. Distinct clones that outgrew were selected as nutrient stress adapted cells (NSA). Here we show that MCF7-NSA cells that are adapted to grow in low nutrient conditions exhibited robust accumulation of lipid droplets compared to parental MCF7-GFP cells as shown by confocal microscopy after neutral lipid staining as well as immunofluorescence staining for PLIN2 (Perilipin 2), a lipid droplet coat protein. In addition, MCF7-NSA cells showed elevated expression of the nuclear receptor PPARγ and the adipokine FABP4 indicating an adipogenic/lipogenic signature. Strikingly, these nutrient stress adapted cells were capable of nutrient scavenging by macropinocytosis compared to control cells even under nutrient replete conditions. Macropinocytosis was assessed by DQ-BSA processing and TMR-Dextran uptake. NHE inhibitor EIPA (ethyl isopropyl amiloride), that blocks macropinocytosis, but not receptor mediated endocytosis confirmed dextran uptake through macropinocytosis. Similarly, macropinocytosis inhibitor KH7 blocked dextran uptake in these adapted cells. Furthermore, MCF7-NSA cells showed high expression of TFEB and TFE3, master regulators of autophagy and lysosomogenesis suggesting that the necrotic cell debris scavenged through macropinocytosis and processed through autolysosome machinery might be contributing to *de novo* lipogenesis. Although control and adapted cells exhibited similar growth kinetics *in vitro*, when implanted in mammary fat pads (MFP) of NSG mice, NSA cells formed significantly smaller and slow growing primary tumors. Interestingly, 80% of these mice showed metastasis to other organs (lung, liver, kidney) whereas control mice did not develop metastasis as parental MCF7 is not an aggressive cell line in xenograft models. MCF7-NSA cells were more migratory *in vitro* in wound healing assays and were capable of developing lung metastases in a mouse model where primary tumor from mammary fat pad was resected to allow for metastases to develop. Taken together, our data suggest that lipogenic phenotype confers survival advantage in the harsh tumor microenvironment and selects for more invasive and aggressive phenotypes.

#0376 Targeting the convergence on HIF-1α of CDK4/6 and MAPK pathway: Implications for enhanced anticancer strategies.

S. Zhao, L. Zhou, S. Zhang, W. S. El-Deiry;
Brown University, Providence, RI

Hypoxia-inducible factor 1-alpha (HIF-1α) plays a pivotal role in orchestrating cellular responses to hypoxia, influencing cancer cell survival and progression. Our previous work identified a non-canonical mechanism wherein Smurf2 mediates HIF-1α degradation under CDK4/6 inhibition. Through proteomic analysis, we discovered that serine 451 phosphorylation occurs on HIF-1α but not in palbociclib-treated samples. Point mutations at this site, substituting serine with alanine, resulted in decreased HIF-1α levels and enhanced interaction with Smurf2. Intriguingly, under palbociclib treatment, we observed phosphorylation at the serine 643 site. This site has been previously associated with MAPK-dependent regulation of HIF-1α localization and activity (Ilias Mylonis, *et al*., 2006), particularly relevant given the reported MAPK reliance in acquired CDK4/6 inhibitor-resistant scenarios (Renée de Leeuw, *et al*., 2018). To explore therapeutic implications, we investigated the impact of combined CDK4/6 (palbociclib) and MEK1/2 inhibition (trametinib, selumetinib, PD98059, U0126). Dual inhibition robustly reduced HIF-1α expression in colorectal cancer cells (HCT116, SW480) and suppressed HIF-1α activity in luciferase reporter assays. This effect extended to synergistic inhibition of cell viability under both normoxia and hypoxia in HCT116 and SW480 cells. Such effect is also applicable to other cancer types and cell lines (*e.g.* U251). In summary, our findings unveil a phosphorylation site on HIF-1α associated with CDK4/6 activity, influencing its protein stabilization. This discovery supports the rationale for combining CDK4/6 and MEK1/2 inhibition as a promising strategy in the treatment of solid tumors.

#0377 Saturation mutagenesis of KEAP1 to identify pathogenic mutations in lung cancer patients and gain insight into KEAP1 molecular function.

N. Kastelowitz, S. Shrishrimal, S. Jun, A. M. Y. Zhang, R. Wang, I. Ilerten, M. Diehn;
Stanford University School of Medicine, Stanford, CA

Introduction: KEAP1 and NFE2L2 (NFR2) mutations occur in roughly 20% of non-small cell lung cancer (NSCLC) patients and are associated with resistance to a broad range of therapies including radiotherapy, chemotherapy, targeted therapies, and immunotherapy. In prior work, we demonstrated that not all KEAP1 mutations observed in NSCLC patients are pathogenic. These benign mutations have a wild-type phenotype that does not impart therapy resistance. However, only roughly 100 of ~13,000 (<1%) possible KEAP1 single amino acid substitution mutations have been characterized. Here, we performed saturation mutagenesis of KEAP1 to comprehensively evaluate all possible point mutation phenotypes *in vitro*.

Methods: Saturation mutagenesis was accomplished using the High-throughput Mutagenesis by Integrated TilEs (MITE) method. In brief, the KEAP1 sequence was divided into 21 tiles each containing a 90 bp variable region flanked by a 30 bp constant region. At each codon position, mutations representing the 20 possible natural amino acids and a stop codon were included for a total of 13,076 KEAP1 variants. The tiles were assembled such that each full length KEAP1 construct contained a single desired mutation. The KEAP1 MITE lentivirus library was transduced into H1299-KEAP1^{NULL} cells that were then treated with vehicle or H_2O_2 for 24 days. The KEAP1 ORF was amplified from gDNA and mutations were quantified by next generation sequencing. Mutation enrichment analysis was used to derive functional annotations.

Results: Oxidative stress resulted in a bimodal distribution of KEAP1 mutations. Cells with KEAP1 nonsense mutations were enriched while cells with silent mutations were depleted. Using a threshold of 95% specificity for silent mutations to distinguish benign from pathogenic mutations, 94% of nonsense mutations and 88% of previously characterized pathogenic mutations were identified as pathogenic. While the majority of KEAP1 mutations were benign (64%), analysis of mutations found in TCGA NSCLC patients showed an enrichment of pathogenic mutations (72%). Overlaying mutation calls onto the KEAP1 structure showed enrichment of pathogenic mutations in the BTB homodimerization interface, hydrophobic core of the oxidative stress sensing IVR domain, and NRF2 binding pocket of the Kelch domain.

Conclusions: Saturation mutagenesis of KEAP1 generated a comprehensive list of pathogenic KEAP1 single amino acid substitutions. Assignments strongly agreed with biologic function and prior literature. The assessment of KEAP1 mutation phenotypes is important as benign mutations occur in a significant subset of NSCLC patients and are not expected to impart therapy resistance. Our results will allow identification of benign and pathogenic KEAP1 mutations in clinical studies, which will enable testing of personalized therapeutic strategies for patients with KEAP1 mutations.

#0378 PHD3 dependent stabilization of β3-adrenoceptor induces HIF-1αactivation in Ewing sarcoma.

A. Pasha, L. Zocca, F. Carrozzo, C. Banella, R. Amato, A. Tondo, C. Favre, M. Calvani;
Meyer Children's Hospital - IRCCS, Firenze, Italy

Hypoxia is a condition of oxygen deficiency which occurs in most growing solid tumors and stimulates a cascade of cell signals through a family of transcription factors named as hypoxia inducible factors (HIFs) that transactivate several regulatory genes involved in tumor proliferation. β3-adrenoceptors (β3-ARs) are involved in several hypoxic scenarios and in pathological conditions where hypoxia leads to important steps for cancer progression. Studies showed that β-AR blockade of mice suppressed hypoxia induction of renal HIF-1α accumulation, erythropoietin production, and erythropoiesis in vivo. In this work we assumed that through PHD3 activity, β3-AR mediates hypoxia sensing needed for HIF-1α stabilization, thus we investigated a putative correlation between β3-AR/HIF-1α and PHD3. Data showed a similar outcome of β3-ARs and HIF-1α at short time of hypoxia, and that β3-AR antagonist, SR59230A reduced HIF-1α protein expression under hypoxia. β3-AR silencing under hypoxia revealed an evident reduction of HIF-1α protein expression that confirmed the β3-AR modulation of HIF-1α expression. SR59230A treatment strongly reduced the HIF-1α target genes as GLUT1, HK-2 and HIF-1α expression at long time treatment confirming the β3-AR modulation of HIF-1α transcriptional activity. Conversely, the HIF-1α-transcriptional inhibitor Topotecan did not affect β3-AR expression confirming that β3-AR mediates HIF-1α activation. Immunofluorescence and nuclear-cytoplasmic fragmentation showed that β3-AR co-localized with the nucleus under hypoxia, more than normoxia, and presence of both β3-AR and HIF-1α in the nucleus. Co-immunoprecipitation of β3-AR/HIF-1α revealed that under hypoxia, HIF-1α dissociates from β3-AR binding, but this process was abrogated by SR59230A. HIF-1α, released under hypoxia from the link with β3-AR, can play its transcriptional activity in the nucleus, while the binding with β3-AR blocks its transcriptional activity. Moreover, the β3-AR upregulation under hypoxia occurs trough an early inhibition of PHD3 activity that did not influence HIF-1α expression. Hypoxic PHD2 inhibition results after PHD3 leading to HIF-1α upregulation. Moreover, the blockade β3-AR by SR59230A, inhibited HIF-1α upregulation by increasing PHD2 activity.

#0379 Landscape of HIF-1α expression across 24,186 solid tumors using comprehensive immune profiling.

H. I. Parikh[1], S. Pabla[1], M.-F. Senosain[1], R. Seager[1], E. Vanroey[1], S. Gao[1], Y. Pulivendula[1], P. DePietro[1], M. Nesline[1], D. Dash[1], J. Conroy[1], S. Hastings[2], H. Ko[2], K. Strickland[2], R. Previs[2], E. Severson[2], T. Jensen[2], S. Ramkissoon[2], M. Eisenberg[3], B. Caveney[3];
[1]OmniSeq Inc. (Labcorp Oncology), Buffalo, NY, [2]Labcorp Oncology, Durham, NC, [3]Labcorp, Durham, NC

Background: Transcription factor Hypoxia Inducible Factor-1α (HIF-1α) is a key regulator of various cellular and systemic responses to hypoxia, with HIF-1α mediated pathways playing an important role in tumor progression and metastasis. Recent studies have highlighted the correlation between *HIF-1α* expression with tumor cell survival, angiogenesis, and invasion. In this study, we explore the landscape of *HIF-1α* expression across 35 solid tumor histologies, its co-expression with immune checkpoint and angiogenesis-related genes, as well as its association with outcomes from a retrospective cohort of patients with non-small cell lung cancer (NSCLC) treated with pembrolizumab.
Methods: A discovery cohort of 24,186 solid tumors across 35 types were evaluated by comprehensive immune profiling assay. *HIF-1α* gene expression was normalized and ranked against a reference population of 735 samples yielding a percentile rank values [0-100], with rank classified as high (≥75), moderate (≥25 and <75) and low (<25). We investigated the distribution of *HIF-1α* expression, cellular proliferation signature, and co-expression with other immunotherapy targets using Spearman correlations (r_s). Additionally, Kaplan-Meier analysis and Chi-squared tests were utilized for overall survival (OS), progression free survival (PFS) and objective response rate (ORR) differences in a retrospective cohort of 72 patients with NSCLC, treated with pembrolizumab.
Results: Pan-cancer analysis confirmed a broad distribution of *HIF-1α* expression, with highest median expression levels observed in brain and central nervous system (CNS) (median=64), thyroid (median=49) and uterine (median=42) cancers. Significant associations ($p<0.001$) were observed between PD-L1 positivity (TPS≥1%, CPS≥1) and HIF-1α expression, with 60% of HIF-1α high cases (n=1,314/2,193) being PD-L1 positive, whereas 53% of HIF-1α low cases (n=4,834/9,135) were PD-L1 negative. Significant correlations ($p<0.05$) of ranked expression of HIF-1α with immune checkpoint blockage targets like PD-1 and CTLA-4, as well as angiogenesis-related genes like *VEGFA* and *PTEN* were observed. Within our pembrolizumab-treated retrospective cohort, there were no significant differences in OS and PFS between HIF-1α high and HIF-1α low tumors. However, the response to pembrolizumab was significantly higher in HIF-1α low tumors (ORR=58.82%, $p<0.01$) compared to HIF-1α high tumors.
Conclusion: In clinically tested solid tumors, *HIF-1α* showed a dynamic expression range, with highest levels observed in brain, thyroid and uterine cancers. Significant co-expression of *HIF-1α* with various downstream genes, especially angiogenesis-related genes, enabled identification of gene signatures that characterize the hypoxic tumor microenvironment and may aid in the development of novel combination therapy strategies.

#0380 Co-downregulation of GRP78 and ATR enhances apoptosis in pancreatic ductal adenocarcinoma.

S. Lee[1], A.-R. Nam[1], K.-S. Oh[1], J.-M. Kim[1], J.-H. Bang[1], Y. Jeong[1], S. Choo[1], H. Kim[1], J. Yoon[2], T.-Y. Kim[2], D.-Y. Oh[2];
[1]Seoul National University, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Seoul, Korea, Republic of

Background: Targeting endoplasmic reticulum (ER) stress is a potential therapeutic strategy in preclinical models of pancreatic duct adenocarcinoma (PDAC). GRP78 is known as the master regulator of the unfolded protein response (UPR) pathway, regulating ER stress by activating the UPR pathway to avoid cell apoptosis and regulates the activation of UPR pathway signals by binding PERK. Overexpression of GRP78 in PDAC results in the retention of misfolded and unassembled proteins, as well as the accumulation of ROS, leading to the promotion of genomic instability. However, there has been limited research on targeting GRP78 as a therapeutic strategy in PDAC. In this study, we aimed to investigate the anticancer effects of BOLD-100, an inhibitor of GRP78, in PDAC.
Methods: We used 9 PDAC cell lines (Capan-1, AsPC-1, HPAFII, MIA-PaCa2, Panc-1, Capan-2, SNU-213, SNU-324, SNU-2918). The mouse xenograft model of Capan-1 was established for in vivo study. BOLD-100 (GRP78 inhibitor), AZD6738 (ATR inhibitor), NAC (N-Acetylcysteine; ROS scavenger) and TUDCA (Tauroursodeoxycholic acid; ER stress inhibitor) were used. MTT assay, CFA assay, cell cycle analysis, RT-PCR, western blot, immunoprecipitation, DCF-DA staining and Annexin V assay were used to elucidate the action of BOLD-100. The combination of BOLD-100 with AZD6738 has been evaluated in both *in vitro* and *in vivo* model.
Results: BOLD-100 suppressed the proliferation of PDAC cells and decreased the mRNA level of GRP78, which in turn disrupted the interaction between GRP78 and PERK. BOLD-100 increased ER stress and ROS, leading to activation of PERK, eIF2a, and CHOP. Activation of UPR pathway induced CHOP-dependent apoptosis and inhibited PDAC cell growth. Moreover, TUDCA reversed the ROS accumulation induced by BOLD-100, confirming that ER stress regulates ROS levels. The accumulation of ROS upregulated the active forms of ATR and CHK1, suggesting the activation of the DNA damage repair pathway. Notably, the treatment of NAC abrogated the activation of ATR-CHK1 axis by BOLD-100-induced ROS accumulation. AZD6738 synergized with BOLD-100 in *in vitro* and *in vivo*, by suppressing BOLD-100-induced ATR phosphorylation.
Conclusion: GRP78 could serve as one of the potential therapeutic targets in PDAC. The combination of BOLD-100 and AZD6738 demonstrates a synergistic effect suggesting GRP78/ATR dual targeting as a promising therapeutic option for patients with PDAC.

#0381 DUSP12 in glioblastoma: Insights into nucleolar stress and DNA damage response.

V. K. Boell, F. L. Forti;
IQ USP, Sao Paulo, Brazil

Glioblastoma (GBM), an extremely aggressive brain tumor, presents molecular complexities that require enormous challenges for its better understanding. The relatively unexplored dual-specificity phosphatase 12 (DUSP12) is an attractive target due to its zinc finger-like domain suggesting potential interactions with nucleic acids and ribonucleoproteins. This highly conserved enzyme plays a pivotal role in ribosome biogenesis across eukaryotes. Importantly, cell cycle arrest induced by DNA damage often coincides with alterations in ribosome biogenesis, a phenomenon termed nucleolar stress, linked to changes in the localization and activity of nucleophosmin (NPM) and p53 proteins. Bioinformatic analysis of public databases revealed elevated DUSP12 expression in glioblastoma samples compared to normal tissue, displaying strong positive correlations with p53 and NPM. While DUSP12 expression did not impact tumor progression in wild-type p53 patients, its lower expression was associated with increased tumor progression in p53-mutant cases, emphasizing the significance of p53 status in understanding DUSP12's roles in GBM. Gene ontology analysis of DUSP12-correlated genes in glioblastoma patients showed robust enrichment in biological processes like ribosome biogenesis, chromosome organization, cell cycle, and DNA repair, with a substantial number of nucleoplasmic and nucleolar proteins being recently identified by our group through mass spectrometry as DUSP12 partners in other tumor models. A substantial difference in DUSP12 protein levels between the GBM cell lines U87MG (wild-type p53) and U138MG (mutant p53) was observed, with the latter presenting higher levels of this phosphatase. Some biological responses of these cell lines were assessed after exposure to the topoisomerase inhibitors doxorubicin (DX) and camptothecin (CPT) through viability assays in adherent and spheroid cultures, γH2AX foci formation, and ATM/Chk2 activation, showing marginal differences between the cell lines. Notably, DX treatment displayed strong nucleolar stress features, such as alterations in the number and size of nucleoli observed by NPM subcellular distribution changes in both cell lines, and induction of p21 expression only in the p53-profficient U87MG. These alterations were accompanied by nuclear accumulation of DUSP12, underlining its potential regulatory role in this process. The knockdown of DUSP12 with specific siRNA led to a substantial decrease of the treatment responsiveness in U138MG, consistent with the lower levels of this phosphatase associated with a more aggressive phenotype in mutant p53 patients. In summary, DUSP12 emerges as a pivotal player in glioblastoma, influencing nucleolar stress dynamics and tumor aggressiveness, particularly in the context of p53 mutations.

#0382 Pancreatic cancer-derived organoids alter muscle fiber type and increased energy consumption leading to cachexia.

B. Han[1], S. Zhao[1], z. Yang[1], J. Trevino[2], S. Grossman[1], H.-J. Lenz[1], B. X. Hoang[1];
[1]Keck School of Medicine of USC, Los Angeles, CA, [2]Virginia Commonwealth University, Richmond, VA

Cachexia, marked by continuous skeletal muscle mass loss and severe metabolic disturbances, presents a substantial challenge for pancreatic ductal adenocarcinoma (PDAC) patients. Despite its prevalence and the adverse impact on quality of life and survival rates, effective clinical treatments for cachexia remain elusive. This study aims to bridge this gap by employing innovative in vitro models to investigate the underlying mechanisms of cachexia and identify potential therapeutic targets. To enhance the relevance of cell culture models, modifications were introduced to replicate in vivo conditions, where the muscle is exposed to the ongoing kinetics of constant tumor secretion of active factors. Patient-derived PDAC cells were cultured in a dense 3D stiffness extracellular matrix (ECM) to mimic the hypoxic desmoplastic tumor microenvironment. The conditioned medium from prolonged cultured patient-derived organoids (PDOs) was then used to supplement C2C12-derived myotubes. The investigation focuses on dynamic adaptations in muscle fiber type and metabolism when exposed to tumor paracrine factors. Metabolomic investigations of PDO-conditioned medium (PDO CM) on myotubes revealed distinct metabolic differences compared to non-treatment controls. Discriminatory metabolites included those associated with glycolysis, lipid, amino acid, and fatty acid metabolism. PDO CM induced a significant shift in muscle fiber type from slow-twitch to fast-twitch phenotypes, accompanied by de novel expression of embryonic and neonatal Myosin Heavy Chain (MyHC) isoforms. Fast fiber (F59) staining also confirmed the protein expression. Concurrently, PGC-1a, a master regulator of mitochondrial biogenesis and oxidative metabolism, significantly decreased, along with reduced ATP and Mito tracker staining, indicating a metabolic switch under the influence of tumor paracrine factors. Metabolome results on C2C12 myotubes treated with PDO CM also revealed significantly changed ABC transporter-related pathways, an adaptive process required to optimize substrate use under the influence of tumor secretome. However, the genes involved in the proteasome degradation process, such as MAFbx and MuRF1, did not show altered expression. The establishment of an in vitro cachexia model, focusing on changes in energy metabolism and utilizing muscle fiber type alterations as markers, will deepen our understanding of the mechanisms of cancer-associated cachexia. The insights gained may pave the way for identifying potential therapeutic targets to mitigate muscle wasting in PDAC patients and improve overall outcomes.

#0383 Mic19 regulates mitophagy in non-small cell lung cancer under hypoxic microenvironment.

H. Huang[1], C. Ding[1], Z. Zhang[1], D. Wu[1], C. Chen[2], Y. Li[2], H. Liu[2], **J. Chen**[1];

[1]Department of Lung Cancer Surgery, Tianjin Medical University General Hospital, Tianjin 300052, People's Republic of China, Tianjin, China, [2]Tianjin Lung Cancer Institute, Tianjin Key Laboratory of Lung Cancer Metastasis and Tumor Microenvironment, Tianjin Medical University General Hospital, Tianjin 300052, People's Republic of China, Tianjin, China

Background: Mitophagy is a pivotal cellular process crucial for maintaining homeostasis in hypoxic conditions, selectively eliminating dysfunctional mitochondria through autophagy. This process is implicated in various diseases, including cancer. Non-Small Cell Lung Cancer (NSCLC), known for its prevalence and aggressiveness, often encounters hypoxic microenvironments. Mic19, a core protein of the mitochondrial cristae membrane, plays vital roles in maintaining mitochondrial architecture and function. However, its involvement in mitophagy in hypoxic NSCLC and the underlying molecular mechanisms remain inadequately explored.

Methods: NSCLC cells were cultured under conditions with 1% O2 oxygen concentration to simulate a hypoxic microenvironment. Protein expression levels of Mic19 were analyzed using Western Blot and immunofluorescence (IF). Cellular proliferation and metastasis capability were assessed through CCK8 and transwell experiments. Immunoprecipitation experiments were conducted to validate the interaction between Mic19 and key mitophagy regulatory proteins. IF, confocal microscopy, ATP measurement, oxygen consumption rate (OCR), mitochondrial membrane potential, and transmission electron microscopy were employed to assess the formation of mitochondrial cristae and the level of mitophagy.

Results: In hypoxic conditions, Mic19 exhibited up-regulation in NSCLC cells. Subsequent in vitro experiments confirmed Mic19's pivotal role in promoting the growth and metastasis of lung cancer cell lines. Through clinical data analysis, Mic19 emerged as an independent prognostic indicator for NSCLC. Inhibition of Mic19 expression exacerbated the disruption of mitochondrial morphology and structure in lung cancer cells, accompanied by the loss of mitochondrial cristae. Notably, Mic19 expression closely correlated with ATP and OCR production in tumor cells. Assessment of mitochondrial membrane potential and transmission electron microscopy revealed Mic19 as a critical downstream target of hypoxia, mediating mitophagy. Overall, these findings not only underscore the significance of Mic19 in regulating mitochondrial dynamics but also highlight its multifaceted role in tumor progression, positioning Mic19 as a promising therapeutic target and prognostic biomarker for NSCLC.

Conclusion: This study provides novel insights into the mechanistic understanding of hypoxia-induced mitophagy in NSCLC, emphasizing the regulatory role of Mic19. Mic19 emerges as a potential therapeutic target for future interventions in NSCLC patients.

#0384 SLC7A11 modulates sensitivity to the first-in-class mitochondrial peroxiredoxin 3 inhibitor thiostrepton (RSO-021) via a ferroptosis independent pathway.

T. Messier[1], V. Gibson[1], A. Bzura[2], J. Dzialo[2], C. Poile[2], S. Stead[1], A. Saaman[1], G. N. Naumov[3], D. A. Fennell[2], **B. Cunniff**[1];
[1]Larner College of Medicine at The University of Vermont, Burlington, VT, [2]University of Leicester and University Hospitals of Leicester, Leicester, United Kingdom, [3]RS Oncology, Cambridge, MA

Mitochondrial peroxiredoxin 3 (PRX3) has been identified as an actionable cancer vulnerability that is currently being investigated in the first-in-human phase 1 clinical trial, MITOPE (NCT05278975). RSO-021 (thiostrepton or TS) is a redox-active drug that inhibits PRX3's peroxidase activity via covalent adduction of its active site peroxidatic and resolving cysteine residues, forming an irreversible crosslink across the protein dimer. Covalent inhibition of PRX3 results in tumor cell death due to a diminished ability to remove high levels of mitochondrial reactive oxygen species (ROS) in cancer cells. To better understand the mechanism underpinning sensitivity and resistance, TS-tolerant human mesothelioma cell lines were generated under constant TS pressure and subjected to a drug-screen comprising chemotherapeutic agents, metabolic inhibitors, ROS modulating agents and ferroptosis-inducing compounds, to identify synergistic interactions compared with TS- sensitive cell lines. Erastin, an SLC7A11 inhibitor exhibited the greatest synergy when combined with TS, potentiated PRX3 covalent crosslinking and cellular ROS levels. Synergy with TS was enhanced by cystine depletion and could be phenocopied by siRNA knockdown of SLC7A11. SLC7A11 was up-regulated in TS-tolerant cells and resistance could be overcome with erastin. TS-tolerant cell lines have significantly reduced glutathione levels and slowed proliferation. Ferroptosis inhibitors ferrostatin-1 and liproxstatin-1 did not inhibit TS or TS in combination with erastin. In summary, SLC7A11 up-regulation confers tolerance to TS through a mechanism involving a cysteine-dependent modulation of the redox state independent of canonical ferroptosis, that can be overcome by the addition of an SLC7A11 inhibitor. The correlation between SLC7A11 with response to TS in a 33-patient primary mesothelioma explant co-clinical trial, and patients enrolled into the MITOPE phase 1/2 trial will be presented.

#0385 Stress-induced pentraxin 3 enhances anoikis resistant-associated metastasis and post-chemotherapeutic recurrence in head and neck cancer.

T.-W. Chang[1], W.-C. Chang[2], B.-K. Chen[1];
[1]National Cheng Kung University, Tainan, Taiwan, [2]Taipei Medical University, Taipei, Taiwan

Head and neck squamous cell carcinoma (HNSCC) is one of the most aggressive cancer with the properties of local recurrence and lymphatic metastasis. During metastatic process in blood circulation, cancer cells lose the interaction with extracellular matrix and encounter the anoikis stress, resulting in successfully extravasate and form micrometastasis in distal organs. However, most patients develop chemo-drug resistance during the metastatic recurrence which leading to poor prognosis. Thus, it is a pressing matter to elucidate the molecular mechanisms involved in cancer metastasis and the behaviors of the post-chemotherapy treated HNSCC cells. Our previous studies suggest that growth factor signaling stimulated HNSCC cells metastasis by the expression of pentraxin 3 (PTX3). Moreover, recent findings also reveal that chemotherapy mediated oxidative stress induce PTX3 expression and poor progression. Here, we raise the hypothesis that the expression of PTX3 through stress signal may promote cancer cells against from anoikis and promote the post-chemotherapeutic survival. The first, we identified that the secondary messenger-reactive oxygen species (ROS) dominate the gene activation of PTX3 by spheroid culture and platium-based agents' treatment. The ROS scavenger, NAC, inhibited cisplatin (CDDP)-induced PTX3 expression and rescue the cell viability by decreasing the ROS level. The oxidative stress inducer-H2O2 treatment also verify the PTX3 expression through AKT and NF-κB pathways. In addition, both the spheroid selection and CDDP-induced PTX3 regulated the EMT phenotype and further strengthen the growth factor signaling. In addition, we found that PTX3 also regulate the survival during spheroid selection and drug treatment. The post-selected cells also exhibit the unique glycosylated modification on PTX3. Disrupted the PTM modification of PTX3 could inhibit the spheroid survival and cell invasion. The animal studies revealed that both spheroid selection and CDDP-treated HNSCC cells had stronger extravasation ability than parental cells in NOD-SCID mice. Depletion of PTX3 also repressed the HNSCC cells extravasation ability. The results indicate that PTX3 were essential for oxidative stress-induced tumor metastasis and recurrence. It also speculates that the combination of antioxidants and PTX3 antibody may prevent tumor metastatic recurrence after chemotherapy in HNSCC.

#0386 BACH1 is a key regulator of the tumor hypoxia response.

L. C. Nguyen[1], C. Dann[1], D. Yang[1], M. Henn[1], E. Shi[1], T. Li[1], L. Stock[1], W. Liu[1], M. Matossian[1], A. Valdespino[1], Y. J. Han[1], J. Zhang[1], G. Yerradoddi[1], Y. Li[1], M. Matsumoto[2], O. I. Olopade[1], K. Igarashi[2], M. R. Rosner[1];

[1]University of Chicago, Chicago, IL, [2]Tohoku University, Sendai, Japan

Hypoxia is an important hallmark of aggressive solid tumors and a key driver of metastasis and resistance to therapy. Hypoxic stress induces the activation of various factors, such as hypoxia-inducible factors (HIFs), which facilitate cellular adaptation and promote tumorigenesis. Given the complexity of this mechanism, identifying novel targets that sensitize hypoxic tumors to therapy could have significant clinical impact. Here we show that the pro-metastatic BTB and CNC homology 1 (BACH1) transcription factor is prolyl-hydroxylated by the HIF Prolyl Hydroxylase (PHD), similar to HIFs, in an oxygen-dependent manner. We describe two major prolyl hydroxylation sites in BACH1 and demonstrate that prolyl hydroxylation increases protein turnover and decreases DNA binding in normoxia. We further demonstrate HIF-independent induction of BACH1 within multiple TNBC (Triple-Negative Breast Cancer) cell lines and patient-derived organoids under hypoxic conditions. Utilizing ChIP-seq, bulk, single-cell and spatial transcriptomics across diverse BACH1 knockout tumor models, our study revealed that BACH1 selectively and directly modulates the transcriptional response associated with hypoxia and stress in TNBC. Our findings identify BACH1 as a clinically relevant target for attenuating hypoxia induced, pro-metastatic signaling and therapeutic resistance in cancers.

#0387 Ionizing radiation induces lipid metabolism-associated vulnerabilities in glioblastoma multiforme.

A. R. Izawa-Ishiguro, S. Nandakumar, N. Carbone, A. V. Ferrotta, R. Raziuddin, K. C. Vogt, D. A. Heller, I. K. Mellinghoff;
Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Glioblastoma multiforme (GBM) is the most common primary malignant brain tumor in adults. It is highly resistant to its current standard-of-care regimen, which includes surgical resection followed by adjuvant ionizing radiation and temozolomide. Therapy resistance can be attributed to the abundance of genomic alterations in GBM tumors that evolve over time, which contribute to intra-and inter-tumoral heterogeneities that render targeted therapies as inadequate treatment options. Thus, there is an urgent unmet need for effective therapies targeting primary and recurrent GBM. Here, we investigated the impact of ionizing radiation on the transcriptome of patient derived GBM tumor spheres to identify key alterations and biological pathways involved in therapy resistance.

Materials and methods: We acquired four independent human GBM tumor sphere cell lines, which were derived from patients and cultured in serum-free media. Tumor spheres were treated with either a sham radiation or a single dose of 10Gy. Using poly-A enrichment whole transcriptome sequencing, we evaluated transcriptional alterations occurring in GBM tumors spheres at 96h post-radiation. To do so, we performed differential expression analysis and gene set enrichment analysis (GSEA) to identify top differentially expressed genes and significant changes in biological phenomena. Additionally, we evaluated the cell viability response of these GBM tumor spheres to radiation.

Results and discussion: PCA analysis of the four human GBM tumor sphere cell lines demonstrates that cell type has a substantial impact on variation among samples compared to non-irradiated and irradiated treatment conditions. Upon analysis of genes in common that are either upregulated or downregulated followed by GSEA, we identified enrichment of genes associated with inflammatory responses and ferroptosis repression (e.g., NUPR1, PTGS1, AOX1), and depletion of genes involved in fatty acid metabolism (e.g., INSIG1, PLA2G3, ACAT2). Furthermore, the GBM tumor sphere cell viability responses allowed us to stratify our models into radiosensitive and radioresistant subgroups.

Conclusion: Radiosensitive human GBM tumor spheres exhibit transcriptional alterations in genes linked to inflammation and fatty acid metabolism to a greater extent compared to radioresistant tumor spheres. Our study characterizes the radiation response of patient derived GBM models, which is to be leveraged for combating therapeutic resistance.

#0388 Identifying synthetic lethalities in GCN2 KO tumors using an *in vivo* targeted CRISPRi screen.

N. R. Sommers, R. A. Cordova, A. J. Klunk, R. C. Wek, K. A. Staschke;
Indiana University School of Medicine, Indianapolis, IN

The integrated stress response (ISR) is an intracellular signaling pathway that fosters cell adaptation to diverse stresses. The ISR is mediated by a family of four eIF2 kinases that each sense distinct cellular stresses. Activation of the eIF2 kinases results in reprogrammed gene expression through translational and transcriptional mechanisms that help prevent stress damage. Previously, we reported that prostate cancer (PCa) cells rely on GCN2 eIF2 kinase for maintenance of amino acid (AA) homeostasis to sustain growth (Cordova et al., 2022 *eLife* 11:e81083). GCN2 inhibition through pharmacological or genetic means results in decreased expression of AA transporters, depletion of intracellular AAs, and reduced growth of PCa cells in culture and mouse xenograft models. Although loss of GCN2 results in a significant reduction in PCa cell growth, minimal cell death is observed. We hypothesize that loss of GCN2 in PCa cells results in vulnerabilities that can be exploited and targeted to induce cell death. To optimize GCN2-targeted therapies for PCa, we utilized a targeted CRISPR-interference (CRISPRi) screen in castration-resistant 22Rv1 cells with functional wild type (WT) GCN2 or those with it deleted (GCN2 KO). The CRISPRi screen was performed in cells grown in culture or grown as tumor xenografts in mice and featured a guide library targeting genes that encode druggable targets, including kinases, phosphatases, and metabolic enzymes. While reduced expression of 152 genes was synthetically lethal with loss of GCN2 in the *in vitro* screen, more genes (202) were synthetically lethal with loss of GCN2 *in vivo*. Of note, reduced expression of many metabolic enzymes was synthetically lethal with GCN2 ablation only in the *in vivo* screen, potentially due to the abundance of nutrients in standard culture media. A group of six metabolism-related genes, identified as hits in the *in vivo* screen and targets of FDA-approved drugs, were selected for follow-up studies. One of these metabolic enzymes was GART, a trifunctional enzyme that carries out 3 of the 10 enzymatic steps in *de novo* purine biosynthesis. Based on our findings showing that GCN2 maintains AA levels to support nucleotide pools in PCa cells, we initially focused on this critical enzyme. Inhibition of GART using antifolates, including the FDA-approved Pemetrexed, resulted in minimal cell death of parental and GCN2 KO PCa cells cultured in standard culture media. However, when cultured in reduced nutrient media that better mimicked reduced nutrient availability *in* vivo, GART inhibition resulted in selective death of GCN2 KO cells. Our CRISPRi screening strategy uncovers new vulnerabilities in GCN2-inhibited PCa cells and reveals a general strategy to identify actionable targets with the potential to combine with GCN2 inhibitors for the treatment of PCa.

#0389 The role of endoplasmic reticulum stress in immune surveillance and effectiveness of immunotherapy in renal and ovarian carcinoma.

M. Svoboda[1], L. Moran[1], B. Vavrusakova[1], L. Krejci[1], K. Souckova[2], K. Vasickova[1], M. Holanek[1];
[1]Masaryk Memorial Cancer Institute (MMCI), Brno, Czech Republic, [2]CEITEC - Central European Institute of Technology, Brno, Czech Republic

In complex tumor-host interactions, the immune response has a dual role, with the capacity to both promote and suppress tumor growth, requiring complex interactions of regulatory molecules within the cellular network of the tumor-immune microenvironment (TIME). Various factors in TIME, such as low pH and hypoxia, cause Endoplasmic Reticulum Stress (ERS). Immune cells exposed to ERS lack antigen presentation, exhibit a suppressor phenotype, and can initiate apoptosis. Therefore, relieving ERS can benefit immune surveillance and response to immunotherapy. Our research is focused on tumor-immune cells interaction, specifically in ovarian and renal cancers. We conducted in vitro co-cultures of these cancer cells with peripheral blood mononuclear cells (PBMC) and manipulated ERS using a well-established ERS inducer tunicamycin and a chemical chaperone tauroursodeoxycholic acid (TUDCA). We then employed various techniques such as MTT, RT-qPCR, western blotting, immunofluorescence staining, scratch wound assay, and 3D co-cultures to analyze cellular viability, gene expression, protein levels of ERS markers (e.g., BiP, CHOP, PERK), immune cell activity (e.g., IL-2, INFγ, FoxP3, PD-1), migration, invasiveness, interaction, spheroid formation, and immune cell infiltration. Furthermore, we examined ERS and immune profiles in tumor samples from patients with ovarian and renal cancer who underwent conventional therapy or immunotherapy.Relieving ERS increased the infiltration of PBMC into tumor spheroids and reduced the expression of BiP and PERK in PBMC. In vitro, the viability of ovarian and renal cancer cells increased when cultured alone after ERS alleviation. However, when co-cultured with PBMC, their viability decreased, indicating enhanced immune cell response. Additionally, the growth and migration of ovarian and renal cancer cells were limited in these co-cultures, along with increased expression of BiP and CHOP and an elevated CHOP/BiP ratio. We connected these findings to the molecular background of ERS in patient samples and observed a positive correlation between a favorable clinical outcome, higher lymphocyte infiltration at the tumor site, and increased levels of BiP and CHOP in cancer cells. We further applied these results to OC and RCC in vivo syngeneic mouse models, currently with very promising outcomes.Based on these results we expect ERS alleviation as a suitable approach to improving the survival and effectiveness of immune cell populations within hostile tumor-induced microenvironment with positive effects on anticancer immunotherapy. *Supported by Ministry of Health of the Czech Republic, grant nr. NU21-03-00539, and by the Johannes Amos Comenius Programme, project SALVAGE nr. CZ.02.01.01/00/22_008/0004644.*

#0390 Direct interaction of Pin1 with HIF-prolyl hydroxylase 2: Implications for breast cancer cell growth and survival.

Y. N. Guillen Quispe[1], S.-J. Kim[1], S. Saeidi[1], G.-J. Choi[1], C. Chelakkot[1], T. Zhou[2], S.-B. Bang[1], T.-W. Kim[1], Y.-K. Shin[1], Y.-J. Surh[1];
[1]Seoul National University, Seoul, Korea, Republic of, [2]The University of Edinburgh, Edinburgh, United Kingdom

Prolyl hydroxylase domain 2 (PHD2) is the main hypoxia-inducible factor (HIF)-prolyl hydroxylase. PHD2 in normoxia hydroxylates specific proline residues in HIF-1α and HIF-2α, which facilitates their ubiquitination and proteasomal degradation. Although the activity of PHD2 is reduced in hypoxia, significant levels of residual activity of this monooxygenase are still detected under hypoxic conditions. However, its role under hypoxia is poorly understood. Peptidyl-prolyl isomerase (Pin1) binds to target proteins containing phosphorylated serine or threonine residues followed by proline (pS/T-P). As PHD2 harbors several pS/T-P motifs, it may be a potential substrate of Pin1. We found for the first time interaction between Pin1 and PHD2 in human breast cancer MDA-MB-231 cells in normoxic and hypoxic conditions. Additionally, the breast cancer tissue array showed elevated expression of PHD2 as well as Pin1 in tumors compared to adjacent normal tissues. LC-MS/MS spectrometry identified three amino acid residues (S125, T168, and S174) of PHD2 undergoing phosphorylation. Among these, serine 125 was found to be the principal site required for Pin1 binding. As a novel binding partner of Pin1, oncogenic PHD2 can be explored as a therapeutic target for the treatment of breast cancer.

#0391 Role of NRF2 in HIF-2α-mediated cancer stem cell phenotype.

M.-K. Kwak, S. P. Hallis;
The Catholic Univ. of Korea College of Pharmacy, Bucheon, Korea, Republic of

The acquisition of cancer stem cell (CSC) properties is influenced by the microenvironment, with tumor hypoxia playing a pivotal role. Elevated levels of nuclear factor erythroid 2-like 2 (NRF2), a redox balance-maintaining transcription factor, have been linked to enhanced tumor growth and therapy resistance. This study investigates the potential role of NRF2 in hypoxia-inducible factor-2α (HIF-2α) regulation in cancers. First, in a model of a 72-hour hypoxic incubation, chronic hypoxia led to CSC characteristics, including increased expression of KLF4 and OCT4, heightened cancer migration, and spheroid growth, which are associated with HIF-2α accumulation. NRF2 inhibition mitigated these effects, while NRF2 activation enhanced chronic hypoxia-induced CSC traits. Mechanistically, NRF2/miR181a-2 signaling emerged as a regulator of HIF-2α-mediated CSC phenotypes in chronic hypoxic conditions. Second, in clear cell renal cell carcinoma (ccRCC), characterized by pVHL gene mutation and constitutive HIF-2α elevation, the role of NRF2 in aggressive cancer phenotypes was explored. Silencing of *NRF2* impaired aggressive phenotypes in multiple ccRCC cell lines with a reduction in HIF-2α expression. Promoter analysis elucidated that NRF2 directly upregulates HIF-2α expression through antioxidant response elements in the human *HIF-2α* gene. Collectively, our study suggests the involvement of NRF2/miR181a-2 signaling in the development of HIF-2α-mediated CSC phenotypes in sustained hypoxic environments and also proposes NRF2 as a promising target for mitigating HIF-2α-mediated CSC traits in ccRCC.

#0392 MYB regulates a specific subset of hypoxia-induced genes and exhibits altered genomic occupancy under hypoxia.

S. Anand, M. Khan, K. Vikramdeo, S. Singh, A. Singh;
USA Health Mitchell Cancer Institute, Mobile, AL

Hypoxia, an unavoidable microenvironmental stress, greatly influences the tumor cell behavior and therapeutic outcomes. Under low oxygen condition, tumor cells undergo transcriptional reprogramming, largely mediated through hypoxia-inducible factors (HIFs), triggering adaptive response pathways. We recently demonstrated a significant role of MYB in hypoxic survival of pancreatic cancer cells by facilitating adaptive changes in cellular metabolism in collaboration with HIF1α. Here, we employed genome-wide deep sequencing approaches to study the impact of hypoxia on transcriptional reprogramming of pancreatic cancer cells and investigate the role of MYB in the hypoxia-dependent processes. A large number of differentially expressed genes (DEGs) were identified in pancreatic cancer cells subjected to hypoxia (1% O_2) and associated with multiple adaptive response pathways. Specifically, we found that pathways related to autophagy, cell migration, epithelial-to-mesenchymal transition, endocytosis, cytoskeleton reorganization were induced, while those associated with RNA processing, ribosome biogenesis, DNA replication and cell cycle were suppressed. To analyze the role of MYB in these adaptive responses, we compared the relative abundance of transcripts in MYB-overexpressing control and MYB knockout (KO) pancreatic cancer cells when cultured under normoxic or hypoxic conditions. We observed that the transcriptional output of MYB was drastically changed under hypoxia with a vast majority of genes being distinctly altered in response to the loss of MYB expression under normoxia and hypoxia. To examine if it resulted from altered genomic occupancy of MYB under normoxia and hypoxia, we compared MYB ChIP-seq peaks under these conditions. We observed a decrease in overall MYB-bound genomic regions under hypoxia despite the fact that we did not observe a decrease in nuclear MYB expression. More interestingly, the genomic occupancy of MYB shifted substantially from regions proximal to transcription start site to distal intergenic or intronic regions under hypoxia. Studies are currently underway to examine the mechanisms underlying the altered MYB genomic occupancy and its impact on adaptive physiological response of pancreatic cancer cells under hypoxia. Together, our findings bring unprecedented insight into the mechanistic role of MYB in hypoxia adaptation and pancreatic cancer pathobiology.

#0393 RAS and PI3K activation promote glioblastoma progression and ischemia-associated tumor cell death.

S. Kim, M. Tang, S. Chih, J. Thorpe, T. Lu, H.-G. Wang, W. Li;
Penn State College of Medicine, Hershey, PA

Glioblastoma multiforme (GBM) is the most common and aggressive brain tumor in adults. Despite the association of tumor necrosis and a poor prognosis in GBM, the mechanisms underlying tumor necrosis formation remain unclear, likely due to the lack of appropriate experimental models to examine the development of tumor necrosis. In our study, we developed mouse models with tumor necrosis by intracranially injecting human GBM cells expressing KRAS or PI3K active mutants into immunodeficient mice. Surprisingly, despite all tumors displayed similar sizes, the control tumors expressing an empty vector (EV) did not exhibit tumor necrosis. This intriguing observation led us to explore the potential role of KRAS and PI3K in promoting cell death within the tumor microenvironment. Ischemia, which is characterized by insufficient nutrients and hypoxia, is often found in GBM. Under an in vitro ischemia mimetic condition, we found that the KRAS or PI3K activated GBM cells showed more cell death compared to EV cells. Mechanistically, ischemia activates the p38 MAPK-MK2 pathway to induce cell death, a process further enhanced by KRAS or PI3K. Notably, we observed elevated expression of p-MK2 in the peri-necrotic areas of GBMs harboring KRAS or PI3K mutants compared to the cellular tumor zones. Moreover, we revealed that ischemia induces the unfolded protein response (UPR) pathway. Among UPR-related molecules, KRAS and PI3K upregulate ERN1, which encodes the transmembrane protein kinase IRE1, in ischemic conditions. Inhibition of ERN1 not only prevented ischemia-induced cell death but also inhibited the p38 MAPK-MK2 pathway. Furthermore, we observed an increase in the expression of pro-inflammatory cytokine IL-8 under ischemic conditions, a response that was prevented by inhibitors of p38 MAPK or MK2. Lastly, we found that ischemia induces ATP release and calreticulin exposure, indicating the cell death possessing certain immunogenic cell death features. In summary, our findings revealed a pivotal role of KRAS and PI3K in inducing cell death in the ischemic GBM tumor microenvironment through activating the IRE1-p38 MAPK-MK2 pathway. The cell death under this circumstance displays pro-inflammatory and immunogenic properties. Therefore, the IRE1-p38 MAPK-MK2 pathway may be exploited for the treatment of GBM in which RAS or PI3K is activated.

#0394 Preclinical evaluation of ERX-208, a potent inducer of ER stress for the treatment of ovarian cancer.

S. Viswanadhapalli[1], T.-K. Lee[2], S. Elmore[2], G. Sharma[3], R. Gopalam[1], K. Parra[3], T. Reese[3], M. Hsieh[3], U. P. Pratap[1], X. Yang[1], B. Ebrahimi[1], H. Neal[2], C.-Y. Chen[2], K. Kassees[2], C. Cervantes[1], Z. Xu[1], E. Kost[1], G. R. Sareddy[1], R. R. Tekmal[1], J.-M. Ahn[2], G. V. Raj[3], R. K. Vadlamudi[1];
[1]UT Health Science Center at San Antonio, San Antonio, TX, [2]UT Dallas, Richardson, TX, [3]UT Southwestern Medical Center at Dallas, Dallas, TX

Background: Ovarian cancer (OCa) is the deadliest kind of gynecologic cancer in the United States. The long-term survival rate for OCa is less than 20% after five years. Intra-tumoral and inter-tumoral heterogeneity is implicated in tumor resistance to conventional therapies and the unsatisfactory clinical outcomes. Addressing these issues necessitates innovative therapies that target intrinsic common vulnerabilities within OCa. Recent studies have highlighted that high basal level of endoplasmic reticulum stress (ERS) in OCa as a critical vulnerability. We have identified a promising compound, ERX-208 that potently induces ERS in cancer cells. The objective of this study is to characterize the mechanisms and activity of ERX-208 using preclinical models.
Methods: The biological activity of ERX-208 was examined across 17 distinct OCa cells, representing 5 diverse OCa subtypes. Mechanistic studies utilized Western blotting, immunohistochemistry (IHC), RNA-Seq analysis, and CRISPR/Cas9 knockouts (KO). Pharmacokinetics (PK) and toxicity studies were performed on C57BL/6 mice. Comprehensive preclinical assessments were carried out through cell line-derived xenografts (CDXs), patient-derived xenografts (PDXs), organoids (PDOs) and explants (PDEs).
Results: ERX-208 demonstrated an IC_{50} of approximately 50-100 nM inducing ERS and reducing cell viability in OCa cells. Conversely, normal ovarian surface epithelial cells exhibited minimal effects from ERX-208. *In vitro* experiments revealed strong ERX-208-induced apoptosis in OCa cell lines. Mechanistic studies employing RNA sequencing, Western blotting, and RT-qPCR, confirmed activation of ERS pathways observed as early as 5 hours post-ERX-208 treatment. Our studies identified LIPA as a potential target, and KO of LIPA significantly diminished ERX-208 activity. Moreover, LIPA KO substantially impeded *in vivo* OCa tumor growth. ERX-208 up to a dose of 25 mg/kg showed no observable organ toxicity and had no effect on the mice's body weight. Dose range studies identified 10 mg/kg intraperitoneal as the minimal effective dose, achieving more than 50% tumor reduction. In preclinical models, ERX-208 inhibited the growth of OCa CDXs, PDXs, and ex vivo PDEs and PDO's. IHC analyses indicated reduced proliferation (Ki-67) and increased activation of ERS markers, such as GRP78 and p-PERK.
Conclusions: Collectively, our findings underscore the preclinical promise of ERX-208 as a potential therapeutic agent for treating OCa. Conflict: The patents surrounding ERX-208 are licensed to EtiraRx.

#0395 An alternating magnetic field suppresses tumor growth.

Masanari Umemura[1], Taisuke Akimoto[2], Rafikul Islam[3], Kazuhito Kishi[4], Akane Nagasako[5], Rina Nakakaji[1], Takashi Yamaguchi[4], Yuto Mizuno[5], Soichiro Ishikawa[6], Tetsuya Yamamoto[2], Yoshihiro Ishikawa[7]

[1]Yokohama City Univ. Graduate School of Med., Yokohama, Japan,[2]Neurosurgery, Yokohama City Univ. Graduate School of Med., Yokohama, Japan,[3]Biochemistry and Molecular Biology, University of Arkansas for Medical Sciences (UAMS), Little Rock, AR,[4]Ricoh Company, Ltd., Yokohama, Japan,[5]Cardiovascular Research Institute (CVRI), Yokohama City Univ. Graduate School of Med., Yokohama, Japan,[6]Department of Oral and Maxillofacial Surgery, Yokohama City Univ. Graduate School of Med., Yokohama, Japan,[7]CVRI, Yokohama City Univ. Graduate School of Med., Yokohama, Japan

Application of physical forces, ranging from ultrasound to electric field, is recommended in various clinical practice guidelines, including those for bone fracture or cancer treatment. However, mechanistic information for such treatments has been poorly provided, due to the lack of comprehensive study model. Here, we show an alternating magnetic field (AMF) per se exhibits direct anti-cancer effect through enhancing oxidative phosphorylation (OXPOHS) and thus metabolic reprograming. Proliferation of human glioblastoma cells (U87 and LN229), but not normal human astrocytes (NHA), was inhibited upon exposure to AMF within the narrow frequency range. Extracellular acidification rate was decreased while oxygen consumption was increased. These data indicated that AMF induced metabolic reprograming. This was accompanied by increased reactive oxygen species (ROS) production. Mouse models grafted with human glioblastoma cells showed that AMF exposure, 30 minutes per day for two weeks, suppressed the tumor growth and prolonged the overall survival. Our results suggest that the AMF exposure may be a simple strategy to inhibit cancer cell growth by utilizing oxidative stress via metabolic reprograming.

#0396 Effects of hypoxia on cell proliferation and lipidome profile in treatment-resistant prostate cancer cells.

A. Siltari[1], K. Valitalo[1], T. Laamanen[2], K. Tornberg[1], A. Saarinen[1], J. Kreuzer[3], H. Syvala[1], T. L. J. Tammela[4], P. Ilmonen[2], P. Kallio[4], T. J. Murtola[4];
[1]Tampere University, Tampere, Finland, [2]Aalto University School of Science, Espoo, Finland, [3]BioGenium Microsystems Ltd, Tampere, Finland, [4]Tampere University Hospital, Tampere, Finland

Background: Low tissue content of oxygen i.e. hypoxia is typical in prostate cancer (PCa) tumor microenvironment. Hypoxia is also associated with PCa progression and treatment resistance. Modulation of lipid and cholesterol metabolism seems to be one way how tumor cells adapt to hypoxia. However, not much is known about lipidomic profiles in hypoxic condition in advanced PCa and treatment resistance. Aim: The aim of this study was to evaluate the impact of hypoxia on treatment-resistant PCa cells and investigate alterations in the lipidome under hypoxic conditions.
Material and Methods: Testosterone (T)-sensitive, T-independent (castration-resistant), and enzalutamide (enza)-resistant VCaP PCa cells were cultured for three days under hypoxia (1% O_2) and compared with cells grown under normoxia (21% O_2). Additionally, cells were treated with the drugs SREBP-inhibitor fatostatin and mevalonate-pathway inhibitor simvastatin to examine the effects of modulating lipid and cholesterol production on hypoxia responses. Relative cell growth by crystal violet staining and live/dead cell ratio were evaluated after each treatment. Intracellular lipidome was measured using liquid chromatography coupled with MS/MS method. Random forest classification was used of the selection of the lipids. Based on the classification, concentration differences between the groups were calculated.
Results: Growth of the T-sensitive and castration-resistant cells was decreased under hypoxia compared to normoxia. However, enza-resistant cells tolerated hypoxic conditions. Lipid-modifying drugs exhibited similar inhibitory effects on cell growth in both normoxia and hypoxia. Based on live/dead cell ratio, hypoxia induced cell death. Lipidome profiles varied markedly by oxygen content and cellular treatment resistance profile. Simvastatin treatment also influenced lipidome profiles.
Conclusions: Enza-resistant advanced PCa cells tolerated hypoxic conditions better compared to T-sensitive and T-independent cells. Lipidome was different between cell lines but also in hypoxia compared to normoxia, supporting its importance for PCa cells under varying conditions. Interference with lipid metabolism leads to growth inhibition regardless of hypoxia. These findings could be used in identifying potential markers for predicting or delaying disease progression in advanced PCa. Future studies should explore the efficacy of various lipidome-modulating drugs in delaying disease progression in PCa.

#0397 Exploring the role of MDM2-TP53 pathway and ATM in regulation of ferroptosis in dedifferentiated liposarcoma.

C.-C. Yen, S.-C. Chen, C.-H. Chen, J.-Y. Wang, C.-M. Chen, P.-K. Wu, M.-H. Yang, W.-M. Chen;
Taipei Veterans General Hospital, Taipei, Taiwan

Background: Ferroptosis, a process involved in accumulation of lipid-based reactive oxygen species (ROS), is a form of cell death with unique morphologic features and regulatory mechanism. Tumor suppressor p53 (TP53) is a key factor in regulation of ferroptosis through multiple pathways. Mouse double minute 2 homolog (MDM2), a key oncogene of dedifferentiated LPS (DDLPS), is one of the negative regulators of the TP53. In our previous study, we had showed that nutlin-3, a MDM2 inhibitor, could exert synergistic cytotoxicity with ferroptosis-inducing agent (erastin and RSL3) on DDLPS in a sequential manner, possibly through upregulation of SLC3A2 with altered cystine/glutamate exchange (AACR Annual Meeting 2023 abstract#4777). Mutated in Ataxia-Telangiectasia gene (ATM) is a critical gene in DNA damage response. ATM could regulate ferroptosis either directly through altered iron pool, or indirectly through activating TP53 by phosphorylation of MDM2. In this study, we explored the role of ATM and MDM2-TP53 pathway, as well as interaction between them, in regulation of ferroptosis of DDLPS. We also studied the potential role of combination of DNA damaging agent (DDA), such as cisplatin, with ferroptosis-inducing agents in the treatment of DDLPS.
Methods: We explored the possible synergistically cytotoxic effect of cisplatin and ferroptosis-inducing agents in DDLPS cell lines. We also investigated the role of ATM in this synergistic effect by using siRNA or ATM inhibitor. In addition, we used cystine uptake assay (measurement of altered cystine/glutamate exchange) and iron level assay (measurement of labile iron pool) to study the functional change responsible to ferroptosis-inducing effect of cisplatin. Finally, we used immunoblotting study to reveal the potential molecular mechanism responsible for synergistic effect of cisplatin and ferroptosis-inducing agent.
Results: Cisplatin and erastin showed synergistic cytotoxicity in DDLPS cell line, most likely through ferroptosis-inducing effect. Cisplatin could activate ATM, with resultant dissociation of TP53 and MDM2. Cisplatin could exert ferroptosis-inducing effect through down-regulation SLC7A11A with resultant decrease cystine uptake, as well as increase labile iron pool. ATM inhibition could offset the ferroptosis-inducing effect of cisplatin by reversing both effects.
Conclusion: Modulation of ferroptosis is a potential treatment strategy in DDLPS. MDM2-TP53 pathway and ATM as well as interaction of both may play an important role in regulation of ferroptosis in DDLPS. Combination of DDA, such as cisplatin, and ferroptosis-inducing agents is a potential strategy in DDLPS treatment.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: DNA Damage and Repair 1

#0401 The impact of DNA structural variants on *PRKN* gene function and colorectal cancer pathogenesis.

E. J. van Bree[1], S. Lakbir[2], C. Rubio-Alarcon[1], R. de Wit[3], A. Bolijn[1], P. Delis-van Diemen[1], M. Tijssen[1], E. Stelloo[4], H. Feitsma[4], G. A. Meijer[1], B. Carvalho[1], S. Abeln[5], R. J. A. Fijneman[1];

[1]The Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Vrije Universiteit Amsterdam, VU Bioinformatics, Department of Computer Science; Netherlands Cancer Institute, Department of Pathology, Amsterdam, Netherlands, [3]The Netherlands Cancer Institute, Department of Pathology, Amsterdam; Utrecht University, AI Technology for Life Group, Department of Information and Computing Sciences and Department of Biology, Utrecht, Netherlands, [4]Cergentis B.V., a Solvias company, Utrecht, Netherlands, [5]Vrije Universiteit Amsterdam, VU Bioinformatics, Department of Computer Science, Amsterdam, The Netherlands; Utrecht University, AI Technology for Life Group, Department of Information and Computing Sciences and Department of Biology, Utrecht, Netherlands

Background: Cancer is caused by somatic DNA alterations, such as single nucleotide variants, somatic copy number alterations and structural variants (SVs). PRKN is among the genes most frequently affected by SVs in colorectal cancer (CRC), with 37% of primary cancers and 56% of metastatic lesions having focal deletions in PRKN. PRKN encodes the E3 ubiquitin ligase Parkin, which regulates the biological activity and degradation of substrates via post-translational modifications. The genomic location of PRKN is within a common fragile site. Therefore, it remains unclear whether the high frequency of SVs in PRKN are passenger events due to genomic instability or driver events of CRC pathogenesis.
Aim: Our study aims to investigate the impact of SVs on the functionality of Parkin in CRC pathogenesis.
Methods: We used publicly available DNA deep whole genome sequencing (WGS) and tumor-matched RNA sequencing data (n=394) to estimate the impact of SVs in PRKN on tumor biology. For this, the transcriptome-wide p-value distribution generated by differential expression analysis was used as a measure of biological impact. The HCT116-MLH1-repaired cell line and patient-derived adenoma organoids were genetically modified using CRISPR/Cas9 to mimic the SVs observed in patient material and analyze their impact. RNA-sequencing, whole proteome and ubiquitin remnant-specific proteomics were used to assess the effect of SVs on gene function and identify altered biological processes.
Results: Analysis of WGS and RNA sequencing of patient material showed that SVs in PRKN have a large impact on CRC biology, comparable to the impact of mutations in TP53 (impact score 0.379 vs 0.332). The most pronounced effects are seen in the ubiquitin-like, RING0 and RING1 domains. These domains are important for recognition and/or binding to ubiquitin, E2 ubiquitin-conjugating enzymes and substrates. In the HCT116-MLH1-repaired CRC cell line, hemizygous introduction of an SV in PRKN had minimal effects on genome-wide gene expression. In contrast, homozygous deletion altered the expression of nearly 2000 genes. Analyses of ubiquitin motif remnants showed differential ubiquitination of proteins involved in DNA repair following the introduction of an SV in PRKN in the CRC cell line. These proteins include TOP2A (Log_2 fold change (L_2FC) = -3.69, P = 5.71^{-5}), RAD18 (L_2FC = -4.55, P = 1.35^{-4}) and Spartan (SPRTN; L_2FC = -2.57, P = 7.43^{-4}).
Conclusion: SVs in *PRKN* have a high impact on tumor biology and result in aberrant gene expression and post-translational modifications of proteins related to DNA repair. Further research will expand to the patient-derived adenoma organoids and focus on understanding if these recurrent somatic alterations contribute to genomic instability and the development of CRC pathogenesis.

#0402 Aneuploidy-associated *SQLE* gain promotes prostate cancer aggressiveness by altering lipid metabolism.

Thomas Walter Janas[1], Xiaofeng A. Su[1], Konrad H. Stopsack[2], Daniel R. Schmidt[3], Duanduan Ma[3], Zhe Li[4], Kathryn L. Penny[2], Tamara L. Lotan[5], Lorelei A. Mucci[3], Matthew G. Vander Heiden[3], Elise DeArment[1], Angelika Amon[3], Paul A. Scheet[6]

[1]Center for Prostate Disease Research, Uniformed Services University, Bethesda, MD,[2]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[3]David H. Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Cambridge, MA,[4]Harvard Medical School, Boston, MA,[5]Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD,[6]Department of Epidemiology, The University of Texas MD Anderson Cancer Center, Houston, TX

Prostate cancer (PCa) is the second leading cause of cancer-related death in men in the US. Epidemiology studies on primary PCa cohorts in Physicians' Health Study and Health Professionals Follow-up Study (PHS and HPFS) have shown that high levels of whole-genome aneuploidy, featured by imbalanced chromosome numbers, correlate with lethal progression in PCa. However, details of the mechanisms of how aneuploidy drives PCa aggressiveness are still unclear. Here, we used the case of chromosome 8q (chr 8q, the long arm of chr 8) gain to study aneuploidy-associated prostatic malignancies. Chr 8q gains are the most frequent gain events that occur in approximately 23% of PCa cases. By using the PHS and HPFS cohorts, we modeled the increased expression of each gene located on chr 8q, for predicting the risks for lethal progression, and obtained each corresponding gene's odds ratio (OR). By ranking the ORs, we revealed that a cholesterol biosynthesis gene, squalene monooxygenase (*SQLE)*, is one of the top associators with lethal progression, amongst all chr 8q genes. SQLE plays a pivotal role in cholesterol synthesis. Previous lymphoma studies have shown that loss of SQLE contributes to cholesterol auxotrophy, and squalene build-up protects against oxidative cell death. In our experimental study, we have used normal and cancerous *TMPRSS2-ERG*-driven organoid models and found that over-expression of SQLE promotes formation of invasive structures and proliferation in cancer organoids. Interestingly, overexpression of SQLE decreased the protein levels of TMPRSS2-ERG, which appeared to be independent of androgen receptor levels. We also utilized the TMPRSS2-ERG positive VCaP cell line, which harbors gains of *SQLE* gene copies. We found that knocking down SQLE expression significantly upregulated ERG protein levels. Our recent study has shown that ERG (or other ETS) positive prostate cancers have a strong correlation with downregulation of fatty acid metabolism signature. We speculate that gain of SQLE can drive aggressiveness of prostate cancer by modulating lipid metabolism for growth and migration. Inhibition of SQLE could translate to better clinical outcomes regarding prostate cancer lethality.

#0403 APOBEC3 enzymes induce chromosomal translocations in solid cancer.

T.-C. Cheong, Q. Wang, A. Jang, E. Karaca-Atabay, R. Chiarle;
Children's Hospital Boston and Harvard Medical School, Boston, MA

Introduction: Chromosomal translocations are common oncogenic drivers in human cancers, and an increasing number of translocations are being considered as crucial diagnostic and prognostic markers in clinics. In B-cell lymphoma, a number of chromosomal translocations are directed by the off-target activity of the activation-induced cytidine deaminase (AID; a B-cell specific apolipoprotein B mRNA-editing enzyme, catalytic polypeptode-like (APOBEC) family enzyme). However, in solid tumors, no such enzymes capable of directing chromosomal translocations have been identified. Given recent findings on APOBEC-mediated mutagenesis in solid cancers, APOBECs may be involved in the formation of chromosomal translocations in solid tumors, like AID does in B cells. In human, the APOBEC3 (A3) family consists of seven members (A3A-A3H) and is associated with C
<t or="" c<g="" substitutions.="" recent="" evidence="" shows="" that="" a3a="" might="" be="" involved="" in="" chromosomal="" instability="" leading="" to="" drug="" resistance="" lung="" cancer.="" however,="" it="" has="" not="" been="" explored="" whether="" a3s="" generate="" dna="" dsbs,="" eventually="" translocations.="" this="" study,="" we="" investigated="" the="" role="" of="" and="" their="" mechanisms="" translocations="" solid="" cancer.Methods: We applied high-throughput genome-wide translocation sequencing (HTGTS) approach to map genome-wide chromosomal translocations induced by human A3s in mouse fibroblast and human epithelial cells. We correlated patterns of translocations induced by A3s with several other cellular features including transcription, DNA accessibility, DNA replication timing, and mutational signatures. We validated the contribution of A3 to the generation of oncogenic translocations in lung cancer.

Results: Ectopic expression of A3s significantly increased chromosomal translocations in mouse fibroblasts and human epithelial cells. A3s and AID preferentially induced translocations in different parts of the genome, but some of the translocation hotspots were shared among them. Hierarchical clustering of hotspots showed that A3-mediated translocations were distinguished from AID-mediated translocations. Notably, the junction distribution of breakpoint clusters showed three distinct translocation patterns based on the locations of breakpoint clusters: (1) AID-preferred; (2) A3-preferred; and (3) AID/A3-mixed. AID-mediated translocations were heavily enriched near the transcription start site, whereas A3-mediated translocations were dispersed across the gene body and transcription end site. Furthermore, DNA replication timing and genomic architectures were linked to the formation of A3-mediated chromosomal translocations in solid cancer. Finally, A3 contributed to the formation of oncogenic rearrangements in lung cancer.

Conclusions: A3 enzymes induced chromosomal translocations with distinct patterns compared to AID and facilitated chromosomal translocation formation in solid cancers.

#0404 LINE-1 retrotransposition promotes chromosomal translocations through RNA-templated DNA repair in human cancers.

J. Tao[1], L. Alessandri[1], C. Mendez-Dorantes[2], K. H. Burns[2], Q. Wang[1], R. Chiarle[1];
[1]Harvard Medical School and Boston Children's Hospital, Boston, MA, [2]Harvard Medical School and Dana-Farber Cancer Institute, Boston, MA

Introduction: Approximately 50% of human cancers have somatic integrations of long interspersed element-1 (LINE-1; also known as L1). L1 is a retrotransposon that copies itself through RNA and integrates into new genomic loci. Although L1 sequences comprise approximately 17% of the human genome, only 100-150 L1 loci have retained the ability to retrotranspose. These full-length, retrotransposition-competent L1s are typically repressed in human somatic cells, but there is evidence of their significant reactivation in human cancers. Therefore, L1 overexpression is a hallmark of many human cancers, particularly in highly malignant tumor types such as breast, ovarian, pancreatic, esophageal, lung, head-and-neck, colon, prostate, and liver cancers.
Results: In many cancers, chromosomal translocations are fundamental pathogenetic events initiated by the generation of DNA double-strand breaks (DSBs). Although LINE-1 (L1) retrotransposition events have been implicated in chromosomal rearrangements associated with most human cancers, the frequency and mechanisms by which L1 is involved in these rearrangements, including chromosomal translocations, remain poorly characterized. By combining high-throughput genome-wide translocation sequencing (HTGTS) and two sequencing techniques to detect L1 insertion sites (PolyA-seq and CELTICS-seq), we demonstrated that the presence of an active human L1 retrotransposition significantly increases the frequency of chromosomal translocations. By identifying L1-dependent translocation hotspots in HEK293T cells we highlight the requirement for the L1 reverse transcriptase (RT) activity and the crucial role of pre-existing DNA DSBs in promoting L1-mediated chromosomal translocations. L1-dependent translocation hotspots showed a marked preference for transcription end sites (TES) of active genes, early replication timing regions, and accessible chromatin regions. Therefore, while cancer genome analysis provides a static view of chromosomal rearrangements based on canonical L1 integrations, our functional studies reveal an unanticipated predominance of chromosomal translocations facilitated by non-canonical L1 retrotransposition via RNA-templated repair of existing DSBs, largely expanding our knowledge on the mechanism by which L1 retrotransposition induces genomic instability in human cancers.

#0405 Translocation detection in cancer using low-pass pore-c sequencing.

S. Hickey, X. Dai, S. Aganezov, J. Beaulaurier, E. Harrington, S. Juul;
Oxford Nanopore Technologies, New York, NY

Complex chromosomal rearrangements, including translocations, play a critical role in oncogenesis and are often identified as recurrent genetic aberrations in hematologic malignancies and solid tumors[1]. Translocation detection by karyotyping of an individual's metaphase chromosomes remains challenging for detection of balanced rearrangements, which have no gain or loss of genetic material. Rearrangement detection using whole-genome sequencing is a viable alternative, but it relies on breakpoint-spanning reads and requires high sequencing depth (30-60x) with long reads to achieve high sensitivity, especially in repetitive regions of the genome[2]. Here, we describe a workflow for translocation detection at low sequencing depth with Oxford Nanopore's long read chromatin conformation capture technique, Pore-C[3]. Importantly, for translocation calling, Pore-C does not rely on breakpoint-spanning reads but rather the high intrachromosomal interaction frequency of genomic regions around the breakpoint, thus largely lowering sequencing depth requirements and reducing mapping issues in low complexity regions. We prepared, barcoded, and sequenced Pore-C libraries of 3 cancer cell lines including lung cancer (A549), Acute Monocytic Leukemia (THP-1), melanoma (COLO 829) and its matching normal (COLO 829 BL) on a single Q20+ MinION flow cell (FLO-MIN114). Genome-wide contact maps of low-pass data (<1.5 Gbps per sample) were compared against higher depth (>30 Gbps per sample) Hi-C maps [4], revealing that low-pass Pore-C successfully captured large-scale genomic rearrangement. For example, chromosomal pairs chr8-chr11 and chr15-chr19 in A549, chr9-chr11 and chr1-chr20 in THP1, and chr7-chr15 in Colo829 were detected at <0.5X depth of sequencing coverage. These translocation events were further validated by breakpoint analysis using adaptive sampling, where targeted regions were previously confirmed by independent studies[4],[5]. Low-pass Pore-C detects translocations in an unbiased manner and does not require prior knowledge of the translocation structure. Combined with its simple sample-preparation workflow and the capability to provide genome-wide copy-number information in a single experiment, it can serve as a cost-effective and comprehensive tool for cancer genomic studies. [1] Chromosomal translocations in human cancer, Nature, 372, 143 (1994) [2] Hi-C as a tool for precise detection and characterisation of chromosomal rearrangements and copy number variation in human tumors, Genome Biology, 18, 125 (2017) [3] Identifying synergistic high-order 3D chromatin conformations from genome-scale nanopore concatemer sequencing, Nature Biotechnology, 40, 1488(2022) [4] Chromosomal translocations detection in cancer cells using chromosomal conformation capture data, Genes (Basel), 13, 7 (2022) [5] A multi-platform reference for somatic structural variation detection, Cell Genomics, 2, 6 (2022)

#0406 Characterization of whole genome duplication in a genomic cohort of over 14000 cell free DNA samples.

A. Gross, H. Wang, D. Tolkunov, C. Jenkins, S. Wienke, C. Barbacioru, H.-Y. Chuang;
Guardant Health, Palo Alto, CA

Background: Wide-scale rates of whole genome duplication (WGD) have previously been demonstrated in studies performed in tissue among genomically characterized tumors. Such studies report varied rates of WGD depending on tumor type and stage. Hallmarks of WGD include widespread loss-of-heterozygosity as well as associations with tumor proliferation and specific oncogenic driver events such as loss of function TP53 mutations. It has been proposed that presence of WGD could be a poor prognostic biomarker, leading to interest in profiling this genomic landmark in large retrospective cohorts to inform future clinical studies.
Methods: Samples that were run through the GuardantOMNI high content genomic profiling assay using cfDNA extracted from blood were analyzed. Only samples originating from individuals with primary breast, colorectal, or prostate cancer were considered due to limited sample size in other indications. We deployed a likelihood-based copy-number variant caller, which jointly selects tumor purity and ploidy while fitting normalized coverage and germline variant allele frequencies across genome-wide data. Only samples where we predicted to have greater than 10% tumor fraction from copy number variant (CNV) profiles were considered for statistical analysis. The presence of whole genome duplication was assessed by counting the median major chromosomal copy number. Presence of SNV/InDels were annotated, assessed for pathogenicity, and filtered to those with a pathogenic allele frequency greater than 10%.
Results: A total of 14,076 samples were analyzed, with 5362 passing the 10% observed tumor fraction cutoff. WGD was annotated in 2195 (41%) samples with varying rates across sub-cohorts (31%, 36%, and 54% of breast, colorectal, and prostate cancer, respectively). Mutation in TP53 was associated with a large increase in rate of WGD (odds ratio 6.9, 95% CI 6.1-7.8) which is consistent but higher in magnitude to similar studies in tissue samples. Amplification of CCNE1 and homozygous deletion of genes including WRN and RB1 were also associated with WGD, independent of TP53 mutation status and overall rates of aneuploidy.
Conclusion: WGD was detected in 41% of samples with greater than 10% tumor fraction in cell-free DNA across three cancer types. While this represents a substantial percentage of advanced cancers, more research needs to be done regarding the impact of these events on clinical outcomes and treatment response. Additionally, co-occurrence of these events with other advanced cancer biomarkers such as microsatellite instability or homologous recombination deficiency was not reported. Given the high rates of these events, future retrospective studies are warranted to correlate presence of WGD with patient outcomes and response.

#0407 RNA:DNA hybrid/R-loop determinants variation in distinct basal-like breast cancer cells.

O. Kapali, V. Kuznetsov;
SUNY Upstate Medical University, Syracuse, NY

Introduction: Despite progress in treatment methods and diagnosis, breast cancer remains one of the world's leading cancers causes of death. Among the various subtypes, basal-like breast cancer (BLBC) is highly diverse, low differentiated, most aggressive form with poor prognosis. Co-translational R-loops are created by combining G-rich RNA with complementary C-rich DNA (RNA: DNA hybrid), which creates a three-stranded nucleic acid structure. R-loops are often associated with genome instability and aggressiveness of cancers. However, their role in the diversity of BLBC remains controversial and poorly understood. This study aims to characterize RNA: DNA hybrid variations in BLBC from a cellular, genetic, and biochemical perspective.
Methods: This study investigates the variation of RNA: DNA hybrid formation in stable BLBC cells. We utilize a panel of stable basal-like cell lines (MDAMB231, MDAMB436, SUM149PT) and proliferative non-cancer cells (MCF10A). They represent different genetic and cell lineages in BLBC development which allows us to study R-loop distribution in different basal lineage cells . Luminal breast cancer cells (MCF7) were used in comparative analysis. To detect RNA: DNA hybrids, we optimized Immunofluorescence (IF) specificity using RNase III and H enzymes. Predictions from Quantitative Model of R-loop Forming Sequences (QmRLFS) identify RLFS in specific gene regulatory regions. This design allows us to define R-loop position and boundaries, and optimize primers for the DRIP-qPCR which quantifies RNA: DNA hybrid enrichment in transcription regulatory sites for several breast cancer-associated genes such as BRCA1, TP53, PTEN, and AURKA. The expression of these genes was detected using RTqPCR.
Results: Our IF and computational image analyses demonstrated that RNA: DNA hybrids are present not only luminal cells (as found by others), but also in the studied BLBC cells. The non-cancer proliferative cells (MCF10A) show low RNA: DNA hybrid signals bolstering our experimental technique. Variation of the RNA: DNA hybrid signals were distinct in various BLBC cells which was supported by the DRIP-qPCR and RTqPCR findings. The R-loop formation data variations was referred to the cell line contexts and the studied genes responsible for tumor suppression, DNA damage/repair signaling and impair apoptosis in breast cancer.
Conclusion: Our study suggests that RNA: DNA hybrids are formed and distributed heterogeneously in the genomes and gene regions of stable BLBC cell lines, while in basal proliferative (non-cancer) cells hybrid signals are weak. A subset of the RNA: DNA hybrids might be particularly significant at certain gene loci contributing to tumor progression, indicating their significance in BLBC pathogenesis. This study provides insights into the cellular and molecular basis of the BLBC heterogeneity and implicates the RNA:DNA hybrid as a potential diagnostic and therapeutic markers.

#0408 NEK1 phosphorylation modulates ERCC6 in transcription coupled nucleotide excision repair with implications for prostate cancer.

Oluwatobi M. Ogundepo, Arrigo De Benedetti

Biochemistry and Molecular Biology, Louisiana State University Health Sciences Center, Shreveport, Shreveport, LA

NER operates through two distinct pathways: global genome repair (GGR) and transcription-coupled repair (TC-NER). TC-NER, as its name suggests, is specifically dedicated to rectifying lesions that obstruct the progression of RNA polymerase during active transcription . This process is imperative for the maintenance of cellular homeostasis, as lesions encountered by the transcription machinery can lead to stalling, erroneous transcription, and ultimately, deleterious cellular outcomes. At the heart of the TC-NER pathway lies ERCC6, a helicase orchestrating the repair of DNA lesions within transcribed regions of the genome. ERCC6 (AKA CS-B) plays a pivotal role in detecting and coordinating the repair of transcription-blocking lesions and has been implicated in a plethora of cellular processes underscoring its multifaceted nature and its broader impact on genome stability and cellular health, as exemplified by the severity of syndromes in individuals with loss-of-function mutations. In the US, compared to Caucasians (CC), AA are at higher risk for developing PCa and have more aggressive disease that is refractory to treatment, to some extent explained by genetic differences in some cases attributed to alterations of their “Repairome”. GWAS revealed that, unlike CC, 89% of AA-PCa have at least one mutation in NER pathway genes. A defect in ERCC6 activity, either through reduced expression or mutation (e.g., M1097V found frequently in AA) may result in impaired TC-NER. This may be compounded by aging or obesity-related oxidative stress, resulting in progressive accumulation of damaged bases (e.g., 8-OG) and consequent (cancer-propensity) mutations, the correction of which involves BER or NER. This was investigated in part with PCa cell lines engineered via CRISPR-SDM to carry that particular genomic mutation, by studying their sensitivity to UV and the efficiency of removal of CPDs in vivo. In addition, we have begun investigation of its function in the variants (engineered and naturally found in PCa. Lines) in vitro, after IP from cells, by studying its intrinsic ATPase activity. We have also identified the kinase NEK1 as an important novel interactor and regulator of ERCC6. We previously identified NEK1 as being an early regulator of the adaptive response of PCa cells to ADT.

#0409 Deciphering chromosomal instability in consensus molecular subtypes (CMS) in CRC: Insights from an integrative multi-omics approach.

J. Bischof[1], J. Woodsmith[1], D. Church[2];
[1]Indivumed GmbH, Hamburg, Germany, [2]University of Oxford, Oxford, United Kingdom

CRC is a heterogeneous disease with different molecular subtypes, which can have a profound impact on treatment response and patient outcomes. CMS classification based on gene expression profiles has been shown to differentiate patients into clinically relevant sub-groups. However, deep multi-omics characterization of the CMS classes based on high quality patient data is lacking. Through the integration of multi-omics data, we aim to enhance our understanding of CRC's molecular heterogeneity and thereby facilitate the development of personalized therapeutic strategies.
We performed a multi-omics analysis of CRC patients to identify potential new features of CMS groups. 890 fresh-frozen, surgically resected CRC tumor and adjacent normal samples were used to analyze whole genome and RNA sequencing data. DNA and RNA was prepared using Qiagen AllPrep Universal and KAPA Hyper Prep kit (DNA), as well as TruSeq Stranded Total mRNA kits and sequenced on a NovaSeq6000 system. We identified CMS subtypes based on RNA-Seq data and performed all statistical analyses using R.
Our analysis revealed distinct molecular characteristics across the four CMS subtypes, including unique driver mutations, signaling cascades, and immune cell infiltration profiles. The poor prognosis associated with CMS4 patients was corroborated by our clinical data. Notably, we observed high global chromosomal instability (CIN) profiles for both CMS2 and CMS4 and identified recurrent global aneuploidy patterns within these subtypes that link alterations of known cancer genes to these large-scale structural events. We found higher levels of CIN in CMS2 compared to CMS4, which appears to be predominantly driven by numerical, rather than structural CIN. Specifically, in CMS2, SMAD2/4 is commonly impacted by deletion on chromosome arm 18q, while PLCG1 is more influenced by amplifications on 20q respectively, suggesting potential values as CRC CMS biomarkers.
In conclusion, our integrative multi-omics analysis offers a comprehensive understanding of CRC molecular subtypes, which can inform personalized treatment strategies. Our findings underscore the importance of considering not only specific driver mutations but also large-scale structural rearrangements in the context of CMS subtypes.

#0410 ASXL3 is a potential biomarker of response of SCLC to targeted therapies.

R. Wang, H. Wang, X. Wu, K. Mishra, S. Shiffka, F. Hernandez, M. Zhang, U. T. Tolunay, S. Gara, S. Xi, S. R. Carr, C. D. Hoang, D. S. Schrump;
National Cancer Institute, Bethesda, MD

Small Cell Lung Cancer (SCLC) has been designated a recalcitrant cancer and a priority by National Cancer Institute. Despite recent insights regarding mechanisms mediating stemness, heterogeneity, and metastatic potential, these advances have yet to be fully translated to effective regimens for the treatment of SCLC. Previously, we identified Additional Sex Combs Like-3 (ASXL3) as a novel mediator of pluripotency in human respiratory epithelia and potential therapeutic target in SCLC. ASXL3 is one of three members of the ASXL family, whereas the functions of ASXL1 and ASXL2 as components of the PR-DUB complex have been extensively studied, the functions and significance of ASXL3 during malignant transformation remain elusive. To further investigate the relevance of ASXL3 activation in SCLC, we initially studied ASXL3 expression levels in various SCLC subtypes by qRT-PCR, digital RT-PCR, RNA-seq, and western blotting analysis. These studies demonstrated that ASCL (A) and ASCL and NeuroD1 (A+N) subtypes of SCLC cells contain thousand-folds more ASXL3 ($ASXL3^{high}$) than Pou2f3 (P) and YAP1 (Y) SCLC subtypes ($ASXL3^{low}$). ASXL3 levels were elevated when cancer cells were cultured under stemness-enriched conditions. Under normal culture conditions, $ASXL3^{high}$ SCLC cells showed higher intrinsic DNA damage, evidenced by a high percentage of γ-H2AX positive cells compared to $ASXL3^{low}$ SCLC cells. Additionally, $ASXL3^{high}$ SCLC cells displayed 38% γ-H2AX positive metaphase cells, and 42% of abnormal chromosome segregations during mitosis, including lagging chromosomes, DNA bridges, and unequal chromosome segregation indicative of profound genome instability. One reason for this extensive genomic instability is that ATM pathway activation in response to DNA replication stress is impaired in $ASXL3^{high}$ SCLC cells. Following exposures to 1mM hydroxyurea (HU) for 4, 8, and 24 hours, ATM autophosphorylation levels in $ASXL3^{high}$ SCLC cells were much lower than in $ASXL3^{low}$ SCLC cells. This insufficiency significantly affected the activation of downstream cascade targets including CHK2, KAP-1 and EZH2. Consistent with these findings, $ASXL3^{high}$ SCLC cells showed reduced sensitivities to ATM inhibitors. However, $ASXL3^{high}$ SCLC cells exhibited higher activity of PLK1 and were more sensitive to hydroxyurea. Importantly, low dose HU reduced the IC50 values of the PLK1 inhibitors, BI2536 or NMS-P937 by 80-100-fold in $ASXL3^{high}$ but not $ASXL3^{low}$ SCLC cells, suggesting a strong synergy between these two drugs in $ASXL3^{high}$ SCLC cells. Collectively, these findings suggest that ASXL3 functions to protect cells from lethality induced by genomic instability through monitoring ATM activation. Experiments are underway using SCLC PDX models to demonstrate the efficacy of this combined treatment in-vivo as a prelude to possible evaluation of this drug combination in SCLC patients.

#0411 PI3K-AKT-mTOR signaling pathways play important roles in chromosomal instability-induced innate immune response in cancer cells.

R. Kamata[1], H. Saito[1], Y. Hakozaki[1], Y. Kashima[2], G. Yamamoto[1], T. Y. Morita[1], P. Lu[3], **A. Ohashi**[1];
[1]National Cancer Center Japan, Chiba, Japan, [2]The University of Tokyo, Chiba, Japan, [3]Frederick National Laboratory for Cancer Research, Frederick, MD

Background: Chromosomal instability (CIN) frequently exerts innate immune response, being expected to sensitize immunotherapy. cGAS-STING pathway is a hub to regulate CIN-mediated innate immune activation. We previously demonstrated that small-molecule inhibitors targeting Centromere-associated Protein-E (CENP-E) profoundly accumulated CIN in cancer cells, leading to activation of cGAS-STING and its related innate immune pathways. In this study, aiming to deeply understand molecular mechanisms of CENP-E inhibitor (CENP-Ei)-induced CIN and innate immune activation, we conducted large-scale chemical screening with ~1,400 kinase inhibitors in CENP-Ei-treated reporter cells for NF-κB and IRF. We also experimentally validated the effects of hit compounds on CENP-Ei-induced innate immune activation.
Material and Methods: GSK923295 and Cmpd-A were used as CENP-E inhibitors. HeLa, A549, A549 dual reporter cells were treated with the CENP-Ei at the indicated concentrations, subjected to immunofluorescent, transcriptome, FACS, reporter activity, or gene expression analyses. High-throughput screening (HTS) with ~1,400 kinase library was conducted in A549 dual reporter cells in combinational treatment with GSK923295. Combination effects of the representative hit compounds were confirmed in matrix-combination studies with the CENP-Ei.
Results: Treatment with the CENP-Ei, Cmpd-A and GSK923295, induced CIN (e.g., multinucleation) in both A549 and A549 dual reporter cells, which elevated NFkB and IRF reporter activities as well as gene expressions of inflammatory cytokines and chemokines in innate immune pathways. Transcriptome analyses also confirmed that gene ontologies (GO) for innate immune response, such as cytosolic DNA sensing pathway and cytokine-cytokine receptor interaction pathway, were significantly enriched in CENP-Ei-treated CIN cells. Next, we conducted HTS of IRF-reporter activity with ~1,400 kinase library in combination with GSK923295 in A549 dual reporter cells. The HTS revealed that a series of inhibitors targeting PI3K-AKT-mTOR signaling pathways intensively suppressed CENP-Ei-induced IRF activation, which occupied ~40% of hit compounds. The matrix-combination studies confirmed that sapanisertib (TORC1/2 inhibitor) significantly attenuated CENP-Ei-induced IRF activity.
Conclusions: CENP-Ei-induced CIN potently activates innate immune response pathways in cancer cells, in which PI3K-AKT-mTOR signaling pathway appears to be involved. We are initiating AI-based drug discovery to develop novel CENP-E inhibitors.

#0412 Discovery and preclinical characterization of ISM9342A, a novel, potent, and orally bioavailable WRN inhibitor that suppresses MSI-H tumor growth.

P. Zhao[1], W. Zhu[1], X. Ding[1], J. Wan[1], X. Chen[1], M. Zhang[1], X. Ding[1], S. Bavadekar[2], **S. Rao**[2], F. Ren[1], A. Zhavoronkov[1];
[1]Insilico Medicine, Shanghai, China, [2]Insilico Medicine, New York, NY

Loss of function mutations in DNA mismatch repair genes can result in microsatellite instabilities (MSI) and high levels of MSI (MSI-H) contributes to tumorigenesis and is frequently observed in endometrial carcinoma, gastric cancer, and colorectal cancer. Although immune checkpoint inhibitors have been approved for the treatment of MSI-H tumors, there is still a large proportion of patients with MSI-H tumors who fail to respond to these therapies. Recently, two independent genome-wide loss of function screens have identified Werner syndrome helicase (WRN) as the top dependency for MSI-H cancer cell viability. WRN plays important roles in DNA repair and in the maintenance of genome integrity. Given that WRN deficiency selectively impairs the viability of MSI-H but not microsatellite stable cancer cells, WRN is a synthetic lethal target for MSI-H tumors.
ISM9342A is a novel and potent WRN inhibitor exhibiting single digit nanomolar IC_{50} values in both ATPase and helicase assays. ISM9342A suppressed the proliferation and increased double strand break markers in MSI-H cancer cells. Moreover, ISM9342A demonstrated promising *in vivo* anti-tumor efficacy in an MSI-H xenograft model along with tumor regression. ISM9342A demonstrated good drug-like properties, including excellent *in vitro* ADMET profiles and good *in vivo* exposure, including low clearance and optimal oral bioavailability across multiple preclinical species. Collectively, these findings highlight the potential of ISM9342A as a highly potent WRN inhibitor for the treatment of MSI-H tumors

#0413 Aneuploid cells depend on the RAF/MEK/ERK pathway and on RNA degradation for overcoming DNA damage and transcriptional burden.

M. Ippolito[1], J. Zerbib[2], Y. Eliezer[2], E. Reuveni[2], S. Vigano[1], G. De Feudis[1], A. Kadmon[2], A. Ratti[1], S. Martin[1], K. Laue[2], Y. Cohen-Sharir[2], S. Scorzoni[1], F. Vazquez[3], U. Ben-David[2], S. Santaguida[1];

[1]IEO - European Institute of Oncology, Milano, Italy, [2]Department of Human Molecular Genetics and Biochemistry, Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Broad Institute of MIT and Harvard, Cambridge, MA

Aneuploidy, a state of karyotype imbalance, is a hallmark of cancer. Understanding the broad implications of aneuploidy at molecular, cellular, and physiological levels is crucial for effectively targeting aneuploid cancer cells. Aneuploidy often results in specific stress responses within cells, which must adapt to for survival and growth. Exploring these adaptive mechanisms to aneuploidy open avenues for targeted cancer therapies. Here, we induced aneuploidy in non-transformed RPE1-hTERT cells, generating multiple stable clones each exhibiting varying degrees of chromosomal imbalances. Employing a comprehensive genomic profiling strategy, we analyzed six isogenic clones using whole-exome and RNA sequencing. We uncovered a complex landscape, where each degree of aneuploidy brought its own set of changes and challenges. Additionally, we explored their cellular dependency landscapes, performing genome-wide CRISPR/Cas9 screenings along with extensive drug screens. As previously reported, we observed and confirmed increased DNA damage and p53 pathway activation in the aneuploid cells. We also found that the aneuploid clones triggered the DNA damage response (DDR), leading to an increased resistance to further DNA damage. Interestingly, we observed that aneuploid cells showed increased activity in the RAF/MEK/ERK pathway. Moreover, these cells demonstrated a heightened sensitivity to a range of clinically significant drugs that target this pathway, in particular in response to both genetic and chemical inhibition of CRAF. The activity of CRAF was found to be functionally connected to the resistance against DNA damage induction, and the inhibition of CRAF making aneuploid cells more susceptible to chemotherapies that induce DNA damage. Next, we observed increased of RNA synthesis and degradation in the aneuploid cells, along with heightened activity in both the nonsense-mediated decay (NMD) and the microRNA-mediated mRNA silencing processes. As a result, aneuploid cells displayed increased sensitivity to the perturbation of several key components of RNA degradation pathways. Furthermore, the dependencies of aneuploid cells on RAF/MEK/ERK activity and on intact RNA degradation were confirmed through examining a broad range of human cancer cell lines, emphasizing their significance in human cancer. Altogether, our results provide a comprehensive resource of karyotypically stable cells representing a range of aneuploidy states, and they reveal previously unidentified weaknesses in aneuploid cells that may be crucial for therapeutic developments.

#0414 Accelerating DDR related drug discovery through a customized cell panel.

Cong Huang, Xiaoqing Li, Zhengtai Li, Yan Tan, Huawei Pan, Lizhen Zhou, Kejun Mao, Yanyan Qin, Zhida An, Wanxiao Song, Yifan Li, Shuyu Jin, **Tiejun Bing**

ICE Bioscience, Inc., Beijing, China

DNA damage is a major threat to cell survival. Not properly repaired DNA damage can lead to cell senescence, apoptosis or tumor development. DDR (DNA Damage Repair) is a collection of bioprocesses which cells utilize in order to identify and correct the DNA damage of the genome. The usage of various compounds for targeting DNA damage responses as well as attenuating DNA repair is also an approach for cancer therapy that has been widely studied in recent years. Despite the success of drug discovery of DDR related inhibitor, drug resistance has become an emerging issue of the field. Here we have constructed multiple cancer cell lines which are either DDR gene, such as XRCC1 and FANCD2, knock-out or resistant to certain DDR inhibitors. Together with the corresponding parental cell lines, we have generated a DDR cell panel which covers 11 different cancer types. We have first validated those DDR inhibitor sensitive or resistant cell lines with functional cell proliferation assays. Additionally, RNAseq has been performed for all constructed resistant cell lines. In combination with a thorough bioinformatic analysis using our in-house generated algorithms, we can provide the genetic background information of the resistant cell lines and top features that potentially contribute to the resistance mechanism. The representative data in this study has shown that LINC02709, BDKRB1, and PRKCQ are the top featured genes in A375 Vemurafenib resistant cell. Meanwhile, cell cycle, ECM-receptor interaction, and DNA replication are the most enriched KEGG terms. Lastly, we have validated this cell panel against multiple inhibitors targeting different DDR vital proteins such as ATM, PARP, POLQ etc. The result has shown that our unique DDR cell panel is capable of providing fast and comprehensive evaluation of DDR related inhibitors, thus facilitate faster and more efficient discovery of DDR inhibitors in the cancer therapy field.

#0415 Keratin-fusion mutation promotes tumor aggressiveness via genomic instability induction.

H.-H. Chuang, B. Y. Kuo, K. Sriramadasu, Y.-C. Chen, J. J. Sheu;
National Sun Yat-sen University, Kaohsiung, Taiwan

Keratin intermediate filament is one critical component of cellular architectures, which provides necessary mechanical support to vanquish environmental stresses. Our previous study shows that keratin fusion mutation promotes tumor aggressiveness via enhancing cancer stemness in oral squamous cell carcinoma. It implies proper functions of keratins play a critical role in maintain cell integrity and fate determination. In the present study, keratin fusion mutation functions as a driver to promote genomic instability via centrosome overduplication and trigger the formation of polyaneuploid cancer cell (PACC). Interestingly, genes involved in DNA damage repair were found upregulated in keratin fusion expressing cells, an important feature for mitotic slippage during cancer progression. In addition, PACCs caused by keratin fusion render cancer cells insensitive to cisplatin treatment, which coupled with lower levels of γH2AX induction and higher survival rates. Transcriptome analyses revealed enhanced activity for Regulation_of_Actin_Cytoskeleton in the PACCs, leading to increased actin filament network and higher invasiveness. In summary, keratin fusion mutation promote cancer aggressiveness through genomic instability-mediated PACC formation and cytoskeleton remodeling, which lead to enhanced drug resistance and metastasis.

#0416 Development of substituted oxindole derivatives as a Ku-targeted DNA-PK inhibitors for cancer therapy.

D. Chauhan[1], P. L. Mendoza-Munoz[2], N. Kushwaha[1], H. Aruri[1], J. J. Turchi[2], **N. S. Gavande**[1];
[1]Wayne State University, Detroit, MI, [2]Indiana University School of Medicine, Indianapolis, IN

DNA double strand breaks (DSBs) are the most cytotoxic type of DNA damage. DSB repair pathway deficiency, often observed in cancer cells, results in translocations and genetic mutations that contribute to genomic instability. The generation of DNA DSBs is the primary mechanism of numerous chemo- and radio-therapeutic strategies used to treat various cancers. Modulating DSB repair pathways can have a profound impact on the clinical efficacy of DNA damaging therapies. DNA-dependent protein kinase (DNA-PK), which is composed of a DNA-PK catalytic subunit (DNA-PKcs) and Ku80-Ku70 heterodimer, acts as the molecular sensor for DSB and plays a prime role in DSB repair through non-homologous end joining (NHEJ). DNA-PK inhibitors become an attractive therapeutic target for cancer in combination with DSB-inducing radiotherapy and chemotherapy. There are at least 6-7 DNA-PK inhibitors in the preclinical and clinical stages which exhibit potential as treatment for various cancers. However, we have taken a unique and innovative approach to inhibiting DNA-PK via blocking the Ku70/80 heterodimer interaction with DNA, an essential step in DNA-PK activation and phosphorylation activity. Exploiting this unique mechanism of kinase activation, we have expanded our structure-activity relationships of pyrrolone derivatives. Modified synthetic schemes have been developed to allow a series of modifications to the X80 core structure. We have prepared furan, thiophene and pyrrole derivatives that enabled the identification of pharmacophores that impact in vitro potency and cellular off-target toxicity. Towards addressing cellular uptake and bioavailability, we identified substituted oxindole derivatives as potent Ku and DNA-PK inhibitors. These oxindole derivatives exhibited a better cellular uptake while retaining potent Ku inhibitory activity. Our data demonstrate that the cellular effects observed are a function of Ku inhibition and that this novel class of DNA-PK inhibitors can be further developed as anti-cancer therapeutics that can be used as an adjuvant to, or concomitant with radiotherapy and other cancer therapies that induce DNA damage.

#0417 Chromosomal instability leads to durable tumor suppression upon macrophage-checkpoint disruption, with induction of anti-tumor IgG.
D. E. Discher;
University of Pennsylvania, Philadelphia, PA

Solid tumors generally exhibit chromosome copy number variation caused by chromosomal instability (CIN) in mitosis, and the resulting aneuploidy associates with poor prognosis in various cancer types and poor Tcell checkpoint blockade response in melanoma. In such contexts, however, macrophages and the SIRPa-CD47 checkpoint are understudied. Here, CIN is induced pharmacologically in poorly immunogenic B16F10 mouse melanoma cells, generating micronuclei plus diverse aneuploidy and skewing macrophages towards an anti-cancer phenotype based on markers and short-term tumor studies. Mice bearing CIN-afflicted tumors with wild-type CD47 levels survive only slightly longer compared to chromosomally stable controls, but long-term survival can be maximized when anti-tumor IgG opsonization is combined with adoptive transfer of macrophages with SIRPa blockade or with CD47 knockout of the B16F10. Multi-epitope, *de novo* anti-cancer IgG in survivors promote phagocytosis of CD47 knockout B16F10 cells by macrophages and suppress tumoroids *in vitro* and growth of tumors *in vivo*. An unexpected benefit of pairing CIN with maximal macrophage anti-cancer activity is thus an anti-cancer vaccination-like response that can lead to durable cures and potentiate cell-mediated acquired immunity.

#0418 BLM helicase unwinds lagging strand substrates to assemble the ALT telomere damage response.

A. M. Krishnan[1], H. Jiang[1], T. Zhang[1], H. Kaur[2], T. Shi[1], Y. Kwon[2], P. Sung[2], R. A. Greenberg[1];
[1]University of Pennsylvania, Philadelphia, PA, [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX

The Bloom Syndrome helicase (BLM) is critical for Alternative Lengthening of Telomeres (ALT), a homology directed repair mediated telomere maintenance mechanism that is prevalent in cancers of mesenchymal origin. The DNA substrates that BLM engages to direct telomere recombination during ALT remain unknown. Here, we determine that BLM helicase acts on lagging strand telomere intermediates that occur specifically in ALT positive cells to assemble a replication stress associated DNA damage response. Loss of ATRX was permissive for BLM localization to ALT telomeres in S and G2 commensurate with the appearance of telomere C-strand specific single-stranded DNA. Moreover, DNA2 nuclease deficiency increased 5'-lagging strand flap formation and ALT in a BLM dependent manner, and BLM promoted ALT in response to telomere C-strand, but not G-strand, single-stranded nicks. These findings define the seminal events in the ALT DNA damage response, linking aberrant lagging strand DNA replication with a BLM directed HDR mechanism that sustains telomere length in a subset of human cancers.

#0419 Evolutionary trajectories of complex genome rearrangements in osteosarcoma.

I. Cortes Ciriano[1], J. Espejo Valle-Inclan[1], S. de Noon[2], K. Trevers[2], H. Elrick[1], A. M. Flanagan[2];
[1]European Bioinformatics Institute, Cambridge, United Kingdom, [2]University College London, London, United Kingdom

Whole-genome sequencing (WGS) studies have revealed that osteosarcoma genomes are riddled by remarkably intricate forms of structural variants (SV), collectively known as complex genomic rearrangements (CGR). Yet, most CGR detected in osteosarcoma remain unexplained, hinting at the possibility of undiscovered mechanisms that might lead to novel therapeutic strategies. To elucidate the mechanisms underpinning cancer genome complexity in osteosarcomas and the downstream consequences of CGR during tumor evolution, we uniformly processed exiting osteosarcoma WGS data sets and performed high-depth (>120x) multi-regional short- and long-read WGS for hundreds of osteosarcomas. We found that whole genome doubling and diverse types of CGR are frequent clonal events in most osteosarcomas. Through the integration of multi-regional WGS data, we discovered that in tumors with whole-genome doubling, cancer genome evolution and oncogene amplification are the consequence of multi-generational CGR triggered by whole-genome doubling and involving multiple mechanisms, especially chromothripsis and breakage-fusion-bridge cycles. By contrast, in tumors without whole-genome doubling, biallelic inactivation of TP53 and oncogene amplification frequently occur as part of a cascade of genomic instability initiated by a single double-strand break upstream of the TP53 locus. This process results in clonal diversification and rapid tumor growth suggestive of punctuated evolution. In addition, we found that subclonal CGRs are also frequent events. Indeed, clonal expansions triggered by the acquisition of subclonal CGR often colonize distant tumor regions, suggesting that CGR act as subclonal driver events. Finally, we show that some recurrent genomic alterations are prognostic of poor survival, which we validate in independent cohorts.
In sum, using WGS data, we have elucidated the mechanisms underpinning the complexity and evolution of osteosarcoma genomes. Our results indicate that diverse types of CGR, such as chromothripsis, are triggered by whole genome doubling and occur throughout tumor evolution, which primes the cancer genome for ongoing genomic instability, rapid karyotype evolution and clonal diversification. These results have implications for our understanding of the molecular basis of intra-tumor heterogeneity and drug resistance in osteosarcomas and other cancers driven by genomic instability.

#7119 Clinic-ready Polθ inhibitor SYX1097 suppresses solid tumors in vivo.

Y. Zhang, K. Jiang, X. Xu, L. Wu, C. Ge, Y. Xie, H. He, S. Liu, **X. Tang**, S. Shi;
SynRx Therapeutics, Hangzhou, China

A large fraction of tumors with BRCA1 or BRCA2 mutations only have weak responses to PARP inhibitor (PARPi) treatment, and often develop PARPi resistance. To address these challenges, we have developed SYX1097, a selective and potent oral Polθ inhibitor as a single agent or in combination with PARPi for treating tumors with BRCA mutations. Both Polθ and PARP1 play key roles in microhomology-mediated end joining for DNA double-strand repair and in single-strand DNA gap filling during DNA replication.

Using in vitro cellular assays and in vivo animal models, we show that SYX1097 alone or combined with PARPi without obvious side effects. SYX1097 dramatically inhibited proliferation in BRCA -/- isogenic cells with IC_{50} <20 nM, while only had very weak effect on their parental cells (>10000nM). SYX1097 also enhanced tumor cell sensitivity to Olaparib 5 to 15 times. SYX1097 *in vivo* efficacious started at 50mg/kg mono-therapy, and generate >50% tumor regression at 5mg/kg when combined with Olaparib. In a 20-day repeated dosing study, SYX1097 200mg/kg BID was fully tolerated by mice. When considering additive hematological toxicity, comparing with “ATRi + PARPi”, “SYX1097 + PARPi” manifested deep and durable tumor regression without significant body weight loss or reticulocytes decrease. Moreover, SYX1097 is found synthetic lethal with defect of genes **not** involved in homologous recombination repair and able to suppress tumors with specific gene defect in vivo, which indicated SYX1097 can be used as single agent guided by specific biomarker.SYX1097 has a clean safety profile tested with Safety-Screen 44^{TM} Panel, and is well tolerated in mice, rats and dogs. It possesses remarkable pharmacokinetic properties in various species, with no hematological toxicity observed during the preclinical toxicity studies. SYX1097 is advancing towards IND filing in 2024.Collectively, SYX1097 is a promising small molecule that may be utilized as a single agent or in combination with PARPi for cancer treatment not only limited by HR deficiency.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Metabolic Pathways 1
Poster Session

#0423 Cell state-specific genomics to define plasticity along the epithelial-mesenchymal transitioncontinuum.
D. K. Williams, N. Hou;
Columbia University, New York, NY

The epithelial-to-mesenchymal transition (EMT) is a biological process that allows epithelial cells to convert into a mesenchymal phenotype, acquiring increased mobility and the capacity to migrate. EMT has historically been represented as binary states; however, a growing consensus supports an EMT continuum involving multiple intermediate stable states. While we lack a comprehensive understanding of the EMT continuum, several reports indicate that the late stable states lead to optimal stem cell traits for cancer. In addition, it has been suggested that EMT heterogeneity within tumor cell populations is associated with poor patient prognosis. Hence, there is a clear need to define the genetic drivers of EM plasticity in heterogeneous cell populations along the EMT continuum. To fulfill this need, we will collect and analyze single cell RNA sequencing (scRNA-seq) data from EMT-cell-state specific genetic CRISPR screens on EMT-heterogeneous cell populations. Here, we apply a series of cloning techniques including polymerase chain reaction and Gibson ligation to engineer an adeno-associated virus (AAV) plasmid containing the avian TVA receptor gene under control of the N-cadherin promoter. Since N-cadherin is predominantly expressed in mesenchymal cells, this AAV enables us to generate cell lines that will exclusively express the TVA receptor when in a mesenchymal state. Consequently, we will be able to deliver mesenchymal-specific CRISPR gene edits via an avian retrovirus-derived RCAS system.

#0424 FDX2-KO induces global down-regulation of iron-sulfur cluster-containing proteins and senescence-like growth arrest or death in ovarian cancer cells.

S. Miyahara[1], M. Ohuchi[2], M. Nomura[2], K. Hayashi[2], M. Shimada[1], N. Yaegashi[1], N. Tanuma[2];
[1]Tohoku University Graduate School of Medicine, Sendai, Japan, [2]Miyagi Cancer Center Research Institute, Natori, Japan

Iron-Sulfur clusters (Fe-S) are synthetized in mainly mitochondria and binds to various proteins (Fe-S proteins). Fe-S proteins play important roles in various cellular functions including energy metabolism, nucleic acid synthesis or redox homeostasis. However, roles of Fe-S clusters in cancer cells are not fully understood. Here, we report that loss of Fe-S biosynthesis causes proliferation arrest with DNA-damage response or cell death depend on TP53 status in ovarian cancer (OVC) cells. CRISPR-screening of all metabolism-related genes identified that Fe-S biosynthesis is essential for OVC proliferation. We chose one of the Fe-S biosynthesis factors, FDX2, and developed a cell line that can maintain FDX2 expression doxycycline (Dox) -dependently. In these cells, FDX2-loss induced irreversible growth arrest. FDX2-KO cells also showed enlarged and flatten morphology, up-regulation of SASP factors, and DNA damage through p53/p21 pathway activation. These were all senescence like phenotypes. To know these mechanisms, we performed proteome analysis and found that FDX2-loss caused global but differential post-transcriptional down-regulation of Fe-S proteins, in turn perturbing mitochondrial respiration, iron-regulation and redox homeostasis. These results all associated with DNA damage. Furthermore, we found that FDX2-KO induced caspase dependent cell death in TP53-KO condition instead of growth arrests. These results suggest that Fe-S cluster biosynthesis is significant in OVC proliferation and fate of FDX2-KO cells depends on TP53 status (senescence or cell death). FDX2 or Fe-S biosynthesis may be a new therapeutic target of OVC.

#0425 GPD1L participates in glycerol-3-phosphate biogenesis and promotes tumor initiation and invasion in hepatocellular carcinoma.

T.-Y. Yu, L. Zhao, L. Tian, C. Kam, J.-F. Lee, D.-H. Ho, L.-K. Chan, Y.-M. Tsui, K.-F. Sze, I.-L. Ng;
Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong

Background: Metabolic reprogramming in hepatocellular carcinoma (HCC) has received rising interest. However, current studies often focus on fatty acid *de novo* synthesis or oxidation, but less on glycerolipids metabolism. Interestingly, in HCC, we observed frequent dysregulation in enzymes responsible for glycerol-3-phosphate shuttle, which potentially links glycolysis and glycerolipids metabolism. Hence, we aimed to identify the functional significance of glycerol-3-phosphate dehydrogenase 1 like (GPD1L), an enzyme for the shuttle, and its regulation of expression in HCC.
Methods: We utilized transcriptomic analysis of clinical HCC samples to validate the frequent overexpression of GPD1L in tumor cells and examined its association with clinicopathological features. *In vitro* and *in vivo* assays were performed to explore the functional significance of GPD1L in HCC initiation and progression. Furthermore, with targeted metabolomics analysis, we investigated the role of GPD1L in glycerol-3-phosphate shuttle in HCC. We also performed promoter study to understand the transcriptional regulation on GPD1L expression.
Results: Among GPD family members, GPD1L was consistently upregulated at mRNA level in clinical HCC samples in The Cancer Genome Atlas-Liver Hepatocellular Carcinoma (TCGA-LIHC) (N=50) and our in-house RNA-sequencing cohorts (N=41), and in a separate independent in-house cohort as examined by RT-qPCR (N=80). GPD1L overexpression was associated with increased tumor invasiveness (p=0.008) and poorer overall survival (p=0.0017) in HCC patients. Functionally, knockdown of GPD1L suppressed HCC migration (fold change ≤ 0.43) and invasion (fold change ≤ 0.40). GPD1L knockdown also inhibited tumor initiation abilities, as shown by reduced colony (fold change ≤ 0.37) and sphere formation (fold change ≤ 0.41) *in vitro*, and lower stem cell frequency (p=1.96e-9) *in vivo*. Furthermore, GPD1L knockdown enhanced sensitivity of HCC cells to chemotherapeutic drugs, sorafenib and doxorubicin. Metabolically, GPD1L facilitated synthesis of glycerolipids precursor, glycerol-3-phosphate (G3P) from glycolysis intermediate dihydroxyacetone phosphate (DHAP) in HCC. Lastly, with chromatin-immunoprecipitation and Luciferase reporter assays, we demonstrated ELF1 bound to GPD1L promoter directly to enhance the gene transcription, while knockdown of ELF1 suppressed GPD1L mRNA and protein expression.
Conclusion: Our study demonstrated the overexpression of the glycolysis-related gene, GPD1L, in HCC. GPD1L promoted tumor initiation, invasion and chemoresistance, and in turn might lead to worse clinical outcome. Metabolically, it was responsible for DHAP-to-G3P conversion in HCC and might serve as a linkage between glycolysis and glycerolipid metabolism. Our results also identified the novel role of ELF1 as the transcriptional activator of GPD1L in HCC.

#0427 A molecular signature for the G6PC3 / SLC37A2 / SLC37A4 interactors in glioblastoma disease progression and in the acquisition of a brain cancer stem cell phenotype.

S. Torabidastgerdooei, **B. Annabi**;
Universite du Quebec a Montreal (UQAM), Montreal, QC, Canada

Background: Glycogen plays an important role in glucose homeostasis and contributes to key functions related to brain cancer cell survival in glioblastoma multiforme (GBM) disease progression. Such adaptive molecular mechanism is dependent on the glycogenolytic pathway and intracellular glucose-6-phosphate (G6P) sensing by brain cancer cells residing within those highly hypoxic tumors. The involvement of components of the glucose-6-phosphatase (G6Pase) system remains however elusive.
Objective: We questioned the gene expression levels of components of the G6Pase system in GBM tissues and their functional impact in the control of the invasive and brain cancer stem cells (CSC) phenotypes.
Methods: In silico analysis of transcript levels in GBM tumor tissues was done by GEPIA. Total RNA was extracted and gene expression of G6PC1-3 as well as of SLC37A1-4 members analyzed by qPCR in four human brain cancer cell lines and from clinically annotated brain tumor cDNA arrays. Transient siRNA-mediated gene silencing was used to assess the impact of TGF-β-induced epithelial-to-mesenchymal transition (EMT) and cell chemotaxis. Three-dimensional (3D) neurosphere cultures were generated to recapitulate the brain CSC phenotype.
Results: Higher expression in G6PC3, SLC37A2, and SLC37A4 was found in GBM tumor tissues in comparison to low-grade glioma and healthy tissue. The expression of these genes was also found elevated in established human U87, U251, U118, and U138 GBM cell models compared to human HepG2 hepatoma cells. SLC37A4/G6PC3, but not SLC37A2, levels were induced in 3D CD133/SOX2-positive U87 neurospheres when compared to 2D monolayers. Silencing of SLC37A4/G6PC3 altered TGF-β-induced EMT biomarker SNAIL and cell chemotaxis.
Conclusion: Two members of the G6Pase system, G6PC3 and SLC37A4, associate with GBM disease progression and regulate the metabolic reprogramming of an invasive and CSC phenotype. Such molecular signature may support their role in cancer cell survival and chemoresistance and become future therapeutic targets.

#0429 A novel regulatory role of FLT3/ITD mutation in lipid metabolism of leukemia cells: The mechanism and therapeutic implications.

Y. Hu, F. Yin, M. Zhao, W. Lu, T. Yu;
Sun Yat-sen University Cancer Center, Guangzhou, China

Internal tandem duplication in FMS-like tyrosine kinase 3 (FLT3/ITD), is a common type of activating mutation and frequently detected in AML. FLT3/ITD is associated with poor prognosis of AML. In this study, we investigated the regulation of FLT3/ITD mutation on sterol regulatory element-binding protein (SREBP) and the therapeutic vulnerabilities of lipid metabolism in FLT3/ITD leukemia. With the transcriptomics analysis we found that FLT3/ITD controlled lipid metabolism via the transcription factor SREBP. The analysis of TCGA_LAML dataset revealed that a gene signature involved in fatty acid and cholesterol metabolism, which is regulated by SREBP, was upregulated in FLT3/ITD patients compared with FLT3/wild-type patients. The upregulation of SREBP protein expression in FLT3/ITD leukemia was confirmed using a genetically engineered mouse model. We further demonstrated that FLT3/ITD regulates the protein degradation of SREBP through the PI3K/AKT-GSK3β axis. The metabolomics analysis further showed that FLT3/ITD primarily regulates glycerophospholipid synthesis, which contribute to the key structure lipid in the membrane, specifically, the cardiolipin. Moreover, pharmacologic inhibition of SREBP activation and its downstream enzyme fatty acid synthase (FASN) sensitized FLT3-ITD AMLs to the treatment of FLT3 inhibitor quizartinib. Collectively, our findings reveal a novel regulation of FLT3-ITD in metabolic reprogramming and indicate a targetable vulnerability in a subset of refractory leukemia.

#0430 Precision diet and lipid modulating agents to induce lipid oxidation in breast cancer.

M. Yavari[1], J. Torpey[1], M. Sabatier[1], A. Carmona[1], K. Szylo[1], M. Flores[1], M. Palma[1], C. Fraser[1], Y. Liang[1], S. Hui[1], O. Zeleznik[2], H. Eliassen[1], J. Ubellacker[1]; [1]Harvard School of Public Health, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA

Metastasis is the primary cause of breast cancer-related mortality, and understanding the intricate relationship between the tumor microenvironment, lipid metabolism, and metastasis is crucial for preventing cancer progression. Previous work from our group demonstrated that high exogenous levels of oleic acid, a monounsaturated fatty acid (MUFA), in the lymph node environment protects melanoma cells from ferroptosis. Ferroptosis is an iron-dependent form of cell death induced by accumulation of lipid peroxides, which are commonly formed from polyunsaturated fatty acids (PUFAs), but not MUFAs. Here, we hypothesized that increasing dietary PUFAs would alter the exogeneous lipid content of the lymph node environment, thus rendering breast cancer cells more sensitive to ferroptosis. To test this, we determined the in vitro sensitivity of 4T1 triple negative breast cancer cells to ferroptosis when treated with various PUFAs and MUFAs. We also assessed the impact of various PUFA and MUFA fatty acid-enriched diets on breast cancer metastasis and ferroptosis resistance in the lymph nodes in vivo. In concordance with previously published work, our results demonstrated that pharmacological induction of ferroptosis in vitro increased lipid oxidation and was mitigated by fatty acid treatments with higher MUFA compared to PUFA content. In vivo, cancer cells in lymph nodes of mice on palm oil diets had lower lipid oxidation compared to cancer cells from tumors in the mammary fat pad. These findings support the hypothesis that dietary lipids can alter ferroptosis response and the extent of lipid oxidation in breast cancer cells within lymph nodes. Our research has the potential to further reveal mechanistic connections between dietary lipids, the lymphatic microenvironment, and breast cancer progression.

#0431 Malic enzyme 2 inhibition reveals metabolic vulnerability in serine-dependent triple-negative breast cancer.

M. D. Slayton[1], Z. A. Farah[1], J. Jeon[2], A. Achreja[2], B. Krinkel[3], B. Nilaj[1], Y.-H. Eu[1], J. Sung[1], A. Rosenfeld[1], A. Lui[1], M. Collard[1], L. Bao[1], X. Cheng[1], C. Kleer[1], K. Loomes[3], D. Nagrath[2], S. D. Merajver[1];

[1]University of Michigan, Michigan Medicine, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Auckland, Auckland, New Zealand

Background & Hypothesis: Treatments for triple-negative breast cancer (TNBC) are limited to chemotherapy, PARP inhibitors and immunotherapies. Tumor metabolism seeks to identify metabolic pathways preferentially utilized by cancer. Malic enzyme 2 (ME2) has a role in the malate-aspartate shuttle and pyruvate and NADPH production, contributing to the redox balance and metabolite synthesis. We demonstrated that ME2 knockdown inhibits growth of TNBC cells with upregulated serine biosynthesis pathway. We hypothesized that ME2 knock-down (kd) would be growth inhibitory *in vivo*.

Methods: We used a non-tumorigenic control (MCF10a) and TNBC lines (BT20, MDA-MB-468, HCC1806, HCC70, Hs578T, SUM149). Nude mice received mammary fat pad xenografts of MDA-MB-468, to assess the impact of ME2-shRNA on growth. ME2 relevant metabolite profiling was achieved through the Promega Metabolite-Glo assay, measuring NAD, NADH, NADP, NADPH, Malate, and Glutamate. Cellular proliferation was quantified via the BioTek BioSpa 8 system and Promega CellTiter Glo. Comprehensive profiling of metabolic genes was achieved with the Nanostring nCounter across all cell lines. The potential therapeutic efficacy of NPD-389, MDSA, disodium embonate and doxorubicin was evaluated, alone or in combination, through targeted drug assays. Metabolic flux analyses, specifically mitochondrial and glycolytic function, were conducted using the Seahorse XF96, contrasting ME2-shRNA modified and control cells.

Results: ME2 kd resulted in reduced proliferation in several TNBC cell lines to varying degrees, in contrast to control MCF10a, and to Hs578T. In response to the loss of ME2, several cell lines upregulated serine biosynthesis genes, including PSAT1. MDA-MB-468 ME2 kd cells developed significantly smaller tumors in a nude mouse xenograft model. Increased malate levels, but reduced NADH and NADPH, were detected in TNBC cells with inhibited growth post-ME2 kd, but not in MCF10a or Hs578T cells. Among the tested ME2 inhibitors, NPD-389 had superior efficacy vs. MDSA and disodium embonate. Metabolic flux analysis showed compromised mitochondrial and glycolytic processes in the TNBC cell lines exhibiting growth inhibition upon ME2 kd.

Conclusions: ME2 knockdown selectively impairs cell proliferation and tumor growth in TNBC cell lines, validating its potential as a therapeutic target. The differential metabolic response, including altered malate and NADH/NADPH levels, confirms ME2's importance in TNBC metabolism. NPD-389 effectively reduced growth in ME2-sensitive lines, meriting further investigation. These findings support targeting ME2 in as a novel treatment strategy.

#0432 The noncanonical mechanism of metabolic enzyme LDHA in cancer progression.

J. Liu, W. Hu, Z. Feng;
Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Metabolic reprogramming is a hallmark of cancer cells and a key contributor to cancer progression, which is a promising target for cancer therapies. The enhanced glycolysis, also known as the Warburg effect, represents the most widely recognized metabolic alteration in cancer, wherein the majority of cancer cells undergoes reprogramming to heavily rely on glycolysis for their accelerated growth and proliferation. The glycolytic enzyme lactate dehydrogenase A (LDHA) catalyzes the conversion of pyruvate to lactate in the final stage of glycolysis. LDHA is frequently overexpressed in cancers, which plays a critical role in promoting glycolysis and cancer progression. To deepen our understanding of the oncogenic mechanism of LDHA, we screened for LDHA-interacting proteins in human breast cancer cells by liquid chromatography mass spectrometry (LC/MS) analysis. Through this strategy, small GTPase Rac1 was identified as an LDHA-interacting protein. LDHA interacted with the active form of Rac1, Rac1-GTP, and impaired the interaction of Rac1-GTP with its negative regulators, GTPase-activating proteins, leading to Rac1 activation independently of the glycolytic enzyme activity of LDHA. In addition, LDHA overexpression was significantly associated with increased Rac1 activity in clinical breast cancer specimens. Inhibiting Rac1 significantly attenuated the oncogenic effect of LDHA. Combining small-molecule inhibitors targeting LDHA enzyme activity and Rac1 activity displayed a synergistic inhibitory effect on breast cancers with LDHA overexpression in mouse models. Thus, our results revealed a novel and critical noncanonical mechanism of LDHA in promoting cancer progression through its direct interaction and activation of Rac1. Given that LDHA is frequently overexpressed in cancer, LDHA overexpression constitutes an important mechanism contributing to aberrant Rac1 activation in cancer. Importantly, our findings also suggest that pharmacologically targeting LDHA enzyme activity and Rac1 activity simultaneously is a promising strategy to treat breast cancers with LDHA overexpression.

#0433 BCAT1 promotes HCC metabolic reprogramming and survival through HIF-1α stabilization.

Misty Shuo Zhang[1], **Kenneth Kin-Leung Kwan**[1], Weixing Li[2], Adonia E. Papathanassiu[2], Irene Oi-Lin Ng[1], Carmen Chak-Lui Wong[1]

[1]Department of Pathology, The University of Hong Kong, Pok Fu Lam, Hong Kong,[2]Ergon Pharmaceuticals, Silver Spring, MD

Hepatocellular carcinoma (HCC) is a highly lethal primary liver malignancy characterized by hypoxia, a common feature of solid tumors, particularly in HCC. Hypoxia-inducible factors (HIFs) play a pivotal role in mediating various cellular processes, such as metabolic adaptation, to support the survival of hypoxic cells. The cytosolic form of branched-chain amino transferase (BCAT1) is responsible for the reversible transamination reaction between branched-chain keto-amino acids (BCKAs) and branched-chain amino acids (BCAAs), facilitating the interconversion between α-ketoglutarate (α-KG) and glutamate. Interestingly, we found that in the context of HCC, BCAT1 consumes α-KG, thereby favoring the stabilization of HIF-1α through suppressing the α-KG-dependent prolyl hydroxylase (PHD). Knockdown (KD) or knockout (KO) of BCAT or BCAT inhibitor (ERG245) suppressed HIF-1 stability, as well as HIF-1 dependent transcriptomic and metabolic changes. Mass spectrometry (MS)-based isotopic carbon tracing showed that KD/KO or ERG 245 suppressed hypoxia/HIF-1-induced glycolytic flux. Interestingly, ERG245 effectively inhibited the proliferative output of hypoxic HCC cells and suppressed HCC growth. ERG245 also profoundly inhibited HCC growth *in vitro* and *in vivo* together with Sorafenib, a tyrosine kinase inhibitor (TKI) used in HCC by increasing the apoptotic cell death. Furthermore, we confirmed that the expressions of BCAT1 and the HIF-1α-targeted metabolic genes are positively correlated in human HCCs. Our findings unequivocally demonstrate
that BCAT1 confers a growth advantage to HCC cells by stabilizing HIF-1α and orchestrating HIF-1α-mediated metabolic reprogramming. Consequently, targeting BCAT1 emerges as a promising therapeutic strategy for HCC patients.

Funding Support: This work was supported by the Centre for Oncology and Immunology under the Health@InnoHK initiative funded by the Innovation and Technology Commission, The Government of Hong Kong SAR, China and National Natural Science Foundation of China (NSFC) (82173123, C.C.-L.W.)

#0434 Understanding metabolic heterogeneity of estrogen receptor positive metastatic breast tumors using spatial transcriptomics and geographic information systems approaches.

J. Yoo[1], S. Akter[1], N. Varma[1], A. Jain[2], A. Soliman[2], Z. Madak Erdogan[1];
[1]University of Illinois Urbana-Champaign, Urbana, IL, [2]National Center for Supercomputing Applications, Urbana, IL

The tumor microenvironment consists of numerous cell populations showing diverse metabolic preferences, causing metabolic heterogeneity and therapy resistance. Fulvestrant, a clinically approved selective estrogen receptor (ER) degrader, is the standard of care for ER-positive breast cancer, yet resistance has been reported among metastatic breast cancer patients. In our previous studies, we showed such resistance is attributable to metabolic heterogeneity in the tumor microenvironment. Despite metabolic heterogeneity posing a common challenge in cancer research, current methods, such as histology and Magnetic Resonance Imaging, cannot explore nutrient uptake at transcript-level resolution with spatial context, making it difficult to understand the heterogeneity that affects cellular growth and metabolism. Visium Spatial Transcriptomics, a method that shows regional gene expression, is emerging as a powerful spatial analysis tool, and we integrated this method with geographic information systems to investigate the tumor microenvironment heterogeneity and highlight the importance of cell-microenvironment interactions. We developed a computational pipeline to visualize hotspots of spatially relevant genes using breast cancer metastatic samples from xenograft models and human patients. This pipeline integrates Visium tools and geospatial methods for processing transcriptome profiling data. We analyzed the degree of local spatial association based on Local Moran's I to estimate regions with significant co-localization of single and multiple gene expressions within a tumor. We then leveraged the co-localized areas in the process of biomarker identification and revealing biological pathways. We also used unsupervised clustering of the complete transcriptome profiles to test the resemblance between identified clusters and hotspots as well as any disruption in the spatial structure of clusters in response to therapy or metastasis. Gene set enrichment analysis of these clusters revealed several glucose or lipid metabolism pathways, and mapping of the genes corresponding to each pathway showed mutually exclusive gene expression patterns in the sample. We also observed minimal co-localization of two metabolic pathways but extensive co-localization between metabolic genes and ER target genes, suggesting distinct metabolic preferences and spatial distributions of endocrine therapy resistant cell populations. Altogether, our analysis pipeline established a computational framework for characterizing the link between tumor microenvironment, local metabolism, and changes in transcriptional response to external stimuli. Our findings support the development of strategies to target different endocrine resistant regions using a combination of ER and metabolic signaling inhibitors.

#0435 A key regulatory role of the translation initiation factor DAP5 in the metabolic reprogramming of metastatic breast cancer.

E. Mitaishvili[1], G. H. Souza Bomfim[2], A. Zou[2], M. Sauane[3], R. Lacruz[2], C. de la Parra[3];
[1]The Graduate Center, CUNY, New York, NY, [2]New York University College of Dentistry, New York, NY, [3]Herbert H. Lehman College, CUNY, New York, NY

Triple negative breast cancer (TNBC) is one of the most aggressive subtypes of breast cancer, accounting for 10-15% of all breast cancers in women. The frequency of metastasis in TNBC is disproportionally high compared to other subtypes of breast cancer and is the primary cause of patient mortality. At the cellular level, TNBC's aggressive nature demands rapid adaptation of the tumor cells to navigate cellular stressors for survival and metastatic transformation. These survival adaptations include a cancer cell's ability to reprogram its metabolism and regulate mRNA translation control, coordinating alternative pathways to retain a selective proteome and metabolites that will aid in survival, proliferation, and migration. Advanced cancers, including TNBC, are generally highly glycolytic, and have lower rates of mitochondrial respiration (OXPHOS), a phenomenon known as the Warburg effect. This metabolic shift prioritizes the generation of essential metabolic intermediates, to facilitate the production of cellular biomass and fuel proliferation. Another notable alternative pathway is mediated by the ubiquitously expressed translation initiation factor, Death Associated Protein 5 (DAP5). DAP5 is a homolog of eIF4G and mediates translation independently of the canonical mTORC1/eIF4E pathway. Our findings suggest that this alternative translation initiation plays a crucial role in regulating the metabolic reprogramming of metastatic breast cancer. This non-canonical pathway via DAP5 facilitates the selective translation of 20-30% cap-dependent mRNAs, many of which are essential in cancer cell survival, migration, and metabolism. Importantly, it has recently been shown that DAP5 is critical for breast cancer metastasis but not in primary tumor development. Furthermore, TNBC patient data shows that elevated levels of DAP5 mRNA are correlated with poor survival and metastasis. Our data, using the highly metastatic TNBC cell line, MDA-MB-231, demonstrated that silencing DAP5 significantly reduced glycolytic rate and glycolytic capacity. Consistent with these findings, translatome profiling, showed that DAP5 silencing reduced numerous metabolic targets including glycolytic enzymes and metabolite transporters. Calcium (Ca^{2+}) signaling, which has an important role in cancer progression, migration, and cellular bioenergetics is also affected by DAP5 in TNBC cells. Collectively, our findings indicate that breast cancer cells utilize the translation initiation factor DAP5 to selectively translate mRNAs that support metabolic reprogramming and cell migration, suggesting that DAP5 has a key regulatory role in the cancer's transformation.

#0436 Extracellular glutathione catabolism as an alternative cyst(e)ine source in cancer.

F. Hecht[1], M. Zocchi[1], E. Tuttle[1], G. Asantewaa[1], T. Scales[1], F. Alimohammadi[1], N. Ward[2], G. DeNicola[2], I. Harris[1];
[1]University of Rochester, Rochester, NY, [2]Moffitt Cancer Center, Tampa, FL

Glutathione (GSH) is the most abundant antioxidant in the human body and plays essential roles in physiology and disease. Unchecked oxidative stress is involved in tumor initiation and progression. Paradoxically, clinical and laboratory data show that ROS-scavenging molecules such as glutathione not only fail to impede tumor growth but, in many cases, accelerate it. Still, preliminary data from our lab show that genetically ablating tumors' ability to synthesize GSH does not affect their growth. This finding suggests that the favorable influence of glutathione on tumor growth may arise from external sources. Yet, the mechanism cancer cells employ to take advantage of extracellular glutathione in this context is unknown. Here, we show that γ-glutamyl-transpeptidase 1 (GGT1), an enzyme that localizes on the outer side of the cell's membrane, can break down extracellular GSH, yielding glutamate and the dipeptide cysteinylglycine. Cysteinylglycine can be further metabolized, generating cysteine and glycine to the cells. We found that the addition of exogenous GSH, as well as cysteinylglycine, can mitigate cell death, proliferation arrest, and oxidative stress caused by cystine depletion. The overexpression of human GGT1 in cancer cells significantly reduces the amount of glutathione needed to rescue cell fitness. Accordingly, pharmacologic inhibition of GGT1 activity prevented GSH's ability to rescue cell proliferation. Moreover, an unbiased pharmacological screening revealed that GGT1-mediated cysteine acquisition renders cancer cells resistant to inhibitors of cystine uptake and utilization, supporting the role of GGT1 as a source of cyst(e)ine. Our findings reveal that cancer cells can access cysteine, a vital yet scarce amino acid, through GGT1's ability to break down glutathione, which is present in remarkably high concentrations within the tumor microenvironment. Although the downstream proteins involved in the transport and utilization of GSH breakdown products are yet to be identified, we anticipate this pathway has the potential to uncover novel therapeutic avenues for cancer treatment by targeting alternative pathways of nutrient acquisition that are potentially implicated in cancer progression and therapy resistance.

#0437 Hydrogen sulfide switches the glucose metabolism through sulfhydration on pyruvate kinase M2.

P.-C. Chien[1], R.-H. Wang[1], P.-R. Chen[1], Y.-T. Chen[1], Y.-C. Chen[1], Y.-H. Chu[1], C.-C. Chien[1], S.-Y. Lo[1], Z.-L. Wang[1], M.-C. Tsou[1], S.-Y. Chen[1], G.-S. Chiu[1], W.-L. Chen[2], Y.-H. Wu[1], H.-C. Wang[1], S.-Y. Lin[2], W.-C. Wang[1], H.-J. Kung[3], L.-H. Wang[4], H.-C. Cheng[1], K.-T. Lin[1];

[1]National Tsing Hua University, Hsinchu, Taiwan, [2]National Health Research Institutes, Taiwan, Miaoli, Taiwan, [3]Taipei Medical University, Taupei, Taiwan, [4]China Medical University, Taiwan, Taichung, Taiwan

Cancer cells reprogram their glucose metabolism from oxidative phosphorylation to aerobic glycolysis. This metabolic transformation is partly based on the activity alterations of a rate limiting enzyme known as the pyruvate kinase M2 (PKM2), which is responsible for the conversion of phosphoenolpyruvate (PEP) into pyruvate. Attributed to its critical regulatory role. PKM2 is recognized as the pivotal enzyme in cancer glucose metabolism By reducing the enzyme activity of PKM2, cancer cells attain a greater fraction of glycolytic metabolites for macromolecule synthesis needed for rapid proliferation. Hydrogen sulfide (H_2S), an endogenously produced gasotransmitter that acts as a critical mediator in multiple physiological processes, modifies proteins mainly through the persulfide (-SSH) bond formation, which is called sulfhydration. Our preliminary study demonstrates that H_2S stimulates PKM2 sulfhydration at multiple cysteine residues, including cysteine 326, leading to the destabilization of active tetrameric PKM2 form into dimers or monomers. The PKM2 dimer/monomer further translocates into the nucleus to simulate the activation of glycolytic related genes. Blocking PKM2 sulfhydration at cysteine 326 through amino acid mutation stabilizes PKM2 tetramer and crystal structure further indicates that the tetramer organization of $PKM2^{C326S}$ is different from the currently known T or R states, revealing $PKM2^{C326S}$ as a newly identified intermediate form. Blocking PKM2 sulfhydration at cysteine 326 inhibited cell proliferation and tumor growth in xenograft mouse model. In summary, our current study illustrates that H_2S-mediated sulfhydration induces the dissociation of the PKM2 tetramer, resulting in the reduced PKM2 activity and subsequently inhibits breast cancer cell proliferation and tumor growth. Targeting the sulfhydration site of PKM2 emerges as a promising therapeutic target specific for cancer metabolism.

#0438 Inhibition of *de novo* lipogenesis with PUFA supplementation induces ferroptosis in advanced prostate cancer.

S. D. Rodrigues, I. Ferrari Teixeira, P. Vitale Nuzzo, H. Pakula, D. Nanus, M. Loda;
Weill Cornell Medicine, New York, NY

Background: Metabolic alterations are recognized as a hallmark of cancer progression. In prostate cancer (PCa), in particular, a notable lipid reprogramming occurs with increased expression levels of multiple enzymes involved in the fatty acid synthesis pathway to fulfill the metabolic and structural demands of cancer cells. Fatty acids are vital for membrane building, ATP production through B-oxidation, and storage in lipid droplets for high-energy demands. In castration-resistant prostate cancer (CRPC), the aberrant overexpression of Fatty Acid Synthase (FASN), the rate-limiting enzyme in *de novo* lipogenesis (DNL), results in synthesis of saturated (palmitate) and monounsaturated fatty acids (SFA and MUFA). If DNL is inhibited, polyunsaturated fatty acids (PUFAs) are taken up from the environment. These could undergo lipid peroxidation generating reactive oxygen species (ROS) and contribute to ferroptosis. We hypothesize that combining the inhibition of DNL with the addition of exogenous PUFAs could increase cell death by ferroptosis.
Methods: PCa cells (LNCaP, 22Rv1 and C4-2) and human organoids were exposed to pharmacologic FASN inhibition and PUFAs for 6 days. Cell viability, lipid peroxidation, superoxide production and, protein carbonylation as a measure of intracellular ROS as well as lipidomic profiling, were assessed.
Results: FASN inhibition significantly increased lipid peroxidation and intracellular ROS, with subsequent membrane potential hyperpolarization in prostate cancer cells. These effects were partially rescued by palmitate, while FASNi supplemented with PUFA potentiated protein carbonylation. Expression levels of GPX4, the main regulator of ferroptosis, were reduced after DNL inhibition and rescued with palmitate addition. Suppression of DNL combined with supplemental addition of PUFAs resulted in significant cell growth inhibition in prostate cancer cells and organoids. Finally, lipid profiling demonstrated that the suppression of DNL triggers increased acyl chain length in phospholipid and several other lipid classes. Again, this effect was significantly potentiated when combining FASN inhibition with PUFA supplementation.
Conclusion: FASN inhibition produces a cascade of intracellular events, including lipid remodeling, increased ROS production and ferroptosis, all potentiated by PUFAs. These findings provide compelling evidence for the use a combined approach involving DNL inhibition and PUFA supplementation as a novel therapeutic avenue to treat advanced prostate cancer.

#0439 Tackling oxidative phosphorylation of glioblastoma stem cells through the specific impairment of transmembrane chloride intracellular channel 1.

Francesca Cianci[1], Ivan Verduci[1], Riccardo Cazzoli[2], Saverio Minucci[2], Michele Mazzanti[1]

[1]University of Milan, Milan, Italy,[2]European Institute of Oncology, Milan, Italy

Solid cancer cells show higher energy and biomolecules requirements compared with healthy cells, making the targeting of cancer metabolic dysfunctions an appealing therapeutic approach. Tackling the tumor metabolism is a daunting task, due to the ability of cancer cells to re-organize their metabolism switching between glycolysis and oxidative phosphorylation. Cancer metabolic plasticity and re-programming is partially supported by altered ionic channels expression and activity. Our laboratory has described the chronic presence transmembrane form of Chloride Intracellular Channel 1 (tmCLIC1) as a marker of malignancy in tumor cells and a possible therapeutic target since it is mainly absent in healthy cells. CLIC1 is described as a metamorphic protein able to shuttle between the cytoplasmic form to a transmembrane conformation. In the present investigation, we show that tmCLIC1 acts as a privileged metformin target in glioblastoma stem-like cells. Metformin is the first-line drug for type 2 diabetes and has been proposed as an antineoplastic drug, but no direct evidence of its' membrane permeability nor of a specific membrane receptor in cancer cells has been found yet. Here we demonstrate that metformin impairs tmCLIC1 activity by direct and specific binding coordinated by arginine 29. This residue mutation prevents metformin from tmCLIC1 binding and abolishes the drug's effect on glioblastoma cells in 2D and 3D models and its actions on mitochondrial respiration. *In vivo* experiments in zebrafish embryos and mice orthotopically engrafted with glioblastoma cells and treated with metformin have shown that metformin binding to tmCLIC1 is crucial for its anti-neoplastic effect.

#0440 BAP1 deubiquitinates ACLY to promote lipogenesis yet predisposing cholangiocarcinoma to iron overload and ferroptosis.

P. Classon[1], S. Jaramillo[1], D. Carlson[1], I. Yan[2], T. Patel[2], S. I. Ilyas[1], R. L. Smoot[1], G. J. Gores[1], **D. Povero**[1];
[1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Jacksonville, FL

Background: Cholangiocarcinoma (CCA) is a highly lethal and aggressive epithelial cell malignancy of the liver and biliary tract. CCA survival remains poor and response to chemotherapy or immunotherapy is limited. We AIM to identify metabolic vulnerabilities that render CCA susceptible to ferroptosis, an iron-dependent and caspase-independent cell death driven by lipid peroxidation.
Materials and Methods: We treated human and mouse CCA cell lines with ferroptosis inducers (RSL3, Erastin), inhibitors (Fer-1, Lip-1), necroptosis inhibitor and a pan-caspase inhibitor. Cell viability, intracellular and mitochondrial iron, lipid peroxidation, mitochondrial structure, and function by cell-based and biochemical assays. Gain- and loss-of-function strategies, TURBO proximity-dependent biotin identification, and metabolic techniques were used for mechanistic studies. *In vivo*, orthotopically implanted C57B/6 mice were treated with RSL3 or vehicle intraperitoneally, followed by assessment of tumor burden and immunophenotyping analysis. Epcam-aptamer coated nanoparticles (tMNPs) packaged with siRNA against GPX4 were used for selective ferroptosis induction.
Results: We identified ferroptosis-sensitive and -resistant human and mouse CCA cells. Ferroptosis-sensitive cells, rescued by ferroptosis inhibitors but not by necroptosis or pan-caspase inhibitors, exhibited elevated intracellular free iron and mitochondrial iron overload. This led to significant mitochondrial dysfunction and structural changes associated with ferroptosis. Mitochondrial free iron triggered reactive oxygen species generation and lipid peroxidation. We identified BRCA-associated protein 1 (BAP1) as a potential driver of ferroptosis sensitivity. BAP1, mutated in 22-25% of human CCAs, is a tumor suppressor and deubiquitinase (DUB). BAP1 knockdown by siRNA protected cells from ferroptosis, while re-expression of BAP1 sensitized cells to ferroptosis. Subcellular fractionation identified BAP1 in extranuclear compartments, including mitochondria and cytosol. We found that BAP1 interacts and deubiquitinates ATP citrate lyase (ACLY), which converts iron chelator citrate to oxaloacetate and acetyl-CoA. Inhibition of mitochondrial citrate export, protected cells from iron overload and ferroptosis. *In vivo*, RSL3-induced ferroptosis significantly reduced tumor burden, as compared to vehicle-treated mice. RSL3-induced ferroptosis promoted an immunogenic tumor immune microenvironment. Lastly, tMNPs with siGPX4 induced marked ferroptosis of mouse CCA cells and showed maximal enrichment in liver orthotopic tumors *in vivo*.
Conclusions: Our findings indicate that BAP1 deubiquitination of ACLY predisposes CCA cells to iron overload by exhausting citrate to support lipogenesis. CCA vulnerability to ferroptosis opens up novel therapeutic opportunities for CCA.

#0441 Bioluminescent dehydrogenase assays: A novel approach for metabolic profiling and inhibitor screening in cancer biology.

K. Haupt, N. Karassina, A. Lauer, K. Sylvester, J. Vidugiriene;
Promega Corporation, Madison, WI

Dehydrogenases play a pivotal role in cellular metabolism, acting as gatekeepers in key metabolic pathways. Their activity reflects the metabolic state of the cell, which is particularly relevant in the context of cancer and the immune response, where metabolic reprogramming is a hallmark of tumor progression and differentiation stages. Here, we present the development and application of novel bioluminescent dehydrogenase assays for direct measurement of metabolic activity in cell lysates. Our assays are highly sensitive, requiring as few as 100-500 cells, and have been successfully miniaturized to a 384-well plate format conducive to high-throughput screening. This technological advance allows for the precise monitoring of dehydrogenase activity across the pentose phosphate pathway, glycolysis, and the mitochondrial tricarboxylic acid (TCA) cycle. We demonstrate how shifts in dehydrogenase activity can serve as indicators of the metabolic status of cells, and their modulation during differentiation. Moreover, our bioluminescent assays provide a rapid screening platform for pathway-specific metabolic inhibitors, with potential applications in identifying new therapeutic targets within cancer metabolism. Our data reveal a dynamic landscape of metabolic activity during T cell maturation, underscoring the potential of dehydrogenase activity profiling in cancer immunobiology and the development of targeted cancer therapies.

#0442 Exploring targetable pathways: Unveiling changes in tumor physiology through dietary modification by a ketogenic diet.

O. Hajihassani, M. Zarei, S. Tahhan, P. Gallagher, W. Beegan, J. Choi, S. Lei, A. Murray, A. Loftus, K. Lebo, H. Cheng, A. Mudigonda, S. Alibeckoff, K. Ji, J. Hue, H. Graor, J. Winter;
Case Western Reserve University School of Medicine, Cleveland, OH

Background: A ketogenic diet, with high fat (90% kCal) and low carbohydrate (5% kCal) intake, induces ketosis [2], altering cancer cell carbon utilization toward the tricarboxylic acid cycle (TCA) [3]. While the overall impact on cancer growth is unclear, most literature suggests an anti-cancer effect. Our hypothesis aims to uncover pancreatic cancer cell adaptations to the ketogenic diet, revealing metabolic vulnerabilities for informed therapeutic strategies.
Methods: Mice on a ketogenic or normal diet (control) underwent pancreatic cancer xenograft observation. Tumor metabolites were analyzed with LC/GC-MS, oxidative stress with NAD(P)+/NAD(P)H, and Lipid Peroxidation assays. Western blot assessed enzyme expression. In vitro studies used Seahorse FX Analyzer for mitochondrial function and PicoGreen for cell growth quantification. Ivosidenib and CB839 were used for combination therapies.
Result: A ketogenic diet induces a metabolic shift in pancreatic cancer, altering nutrient and metabolite levels in diverse in vivo models. Besides the expected increase in TCA metabolites, heightened amino acid anaplerosis, particularly with glutamine and glutamate, was observed. Examination of the diet's impact on oxidative phosphorylation enzymes revealed increased BDH1 expression, aiding ketone body utilization, and upregulation of cytosolic IDH1 for antioxidant defense. Enzymes involved in glutamine uptake and conversion, like ASCT2 and GLS, showed altered expression.
Simultaneously, we explored tumor microenvironment vulnerabilities, detecting a significant increase in reactive oxygen species (ROS) levels, specifically lipid peroxidation, in mice on the ketogenic diet.
Given these pancreatic cancer adaptations, we hypothesized that combining therapeutics to elevate ROS levels and target the glutamine pathway would substantially impede tumor growth. To test this, we combined a ketogenic diet with an IDH1 inhibitor for antioxidant defense hindrance and a glutaminase inhibitor to impair mitochondrial function, resulting in a marked reduction in tumor proliferation compared to individual treatments.
Conclusion: A ketogenic diet demonstrates a robust anti-tumor effect in various pancreatic cancer mouse models, likely arising from the diminished glucose and increased fatty acid load inherent in the diet. Metabolic adaptation towards an oxidative phosphorylation (OXPHOS) phenotype makes pancreatic cancer especially susceptible to antioxidant and mitochondrial inhibitors, as well as inhibitors of glutamine-metabolizing enzymes.

#0443 Unsaturated fatty acids promote cell cycle progression and proliferation of platinum resistant ovarian cancer cells.

A. Isac, G. Zhao, H. Cardenas, D. Matei;
Robert H. Lurie Comp. Cancer Ctr. of Northwestern Univ., Chicago, IL

Introduction: Ovarian cancer (OC) depends on fat as fuel for metastasis and growth. We have previously demonstrated that cisplatin resistant (Pt-R) OC cells uptake higher amounts of fatty acids (FAs) compared to sensitive (Pt-S) cells- a process which facilitates cancer cell survival under cisplatin-induced oxidative stress. Here we aimed to determine which class of FAs promotes the Pt-R phenotype and to identify the mechanism through which FAs support cancer survival.
Materials and methods: We used two isogenic OC cell lines pairs, sensitive and resistant to cisplatin: OVCAR5 Pt-S (IC50 = 2.881μM) vs Pt-R (IC50 = 6.831 μM) and PEO1 (IC50 = 4.901 μM) vs PEO4 (IC50 = 8.285 μM). Cells were cultured under low serum conditions, supplemented with 50 μM oleic (OA) or 50 μM palmitic acid (PA), and used for viability assays, RNA-Seq, and cell cycle analysis. Quantitative RT-PCR measured expression of key FAs transporters in Pt-S and Pt-R cells.
Results: A viability assay showed that Pt-R cells were less viable under serum depletion compared to Pt-S OC cells. OA (unsaturated), but not PA (saturated), promoted proliferation of both OC cell lines, and rescued Pt-R vs Pt-S cells; 268.4% vs 91.6% for OVCAR-5 and 38.1% for PEO4 vs 12.1% for PEO1, suggesting that Pt-R cells depend more on unsaturated FAs compared to Pt-S cells. Quantification of key FAs transporters demonstrated that Pt-R cell expressed higher levels of FABP4, FABP5 and CD36 compared to Pt-S cells. Treatment with an FABP inhibitor reduced the Pt IC50 in Pt-R cells (from 11.893 μM to 5.0415 μM in OVCAR5 and from 8.285 μM to 6.968 μM in PEO4). RNA-Seq analysis analysed transcriptomic changes induced by 24 hour treatment with OA in OVCAR5 cells. There were 923 differentially expressed protein-coding genes, with 300 upregulated and 623 downregulated transcripts (FDR<0.05). Pathway analysis revealed cell cycle related pathways like: *cell cycle mitotic*, *cell cycle checkpoints*, *G2/M checkpoints* among the top 10 most significantly upregulated pathways and E2F1 was identified as the main effector. Cell cycle analysis confirmed that OA induced increased percentages of cells in S- and G2/M phases - from 6.95% to 11.6% ($p<0.05$), and 13.6 to 17.6% ($P<0.05$), respectively. Treatment with an E2F1 inhibitor significantly reduced the OA-induced cell proliferation.
Conclusion: Pt-R OC cells are dependent on unsaturated FAs compared to Pt-S cells and upregulate key transporters to allow increased uptake of FAs. OA supports proliferation of Pt-R cells and cell cycle progression from G1 to S- and G2/M phases. Ongoing experiments focus on key mechanisms activated by unsaturated FAs in Pt-R cells.

#0444 Lipid exposure re-wires cellular metabolism away from glycolysis toward the serine pathway conferring oncogenic properties to non-transformed breast cells.

Mariana Bustamante Eduardo[1], Gannon Cottone[1], Shiyu Liu[2], Flavio R. Palma[1], Maria Paula Zappia[3], Abul B.M.M.K. Islam[3], Elizaveta V. Benevolenskaya[3], Maxim V. Frolov[3], Jason Locasale[2], Marcelo G. Bonini[1], Navdeep S. Chandel[1], Seema Khan[1], Susan Clare[1]

[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Duke University, Durham, NC,[3]University of Illinois at Chicago, Chicago, IL

Introduction. A lipid metabolism gene signature is associated with the risk of estrogen negative breast cancer (ER-BC). In vitro, lipid exposure alters histone methylation affecting gene expression and increases flux through various metabolic reactions including those involved in serine, one-carbon, glycine (SOG) and methionine. We hypothesized that the metabolism of lipids in preference to glucose and glutamine results in a metabolic shift toward the serine pathway increasing S-adenosylmethionine (SAM) leading to histone methylation increases and changes in gene expression.
Methods. MCF-10A cells exposed to octanoic acid (OA) were utilized for U13C-glucose tracing. SAM, glutathione (GSH) and 2-hydroxyglutarate (2-HG) concentrations were measured following treatment with OA ± the PHGDH inhibitor CBR-5884. ROS-induced redox changes were monitored live in cells transduced with ORP1-roGFP2 vectors. CUT&RUN was performed for H3K4me3. Expression of OA-induced genes was measured by rt-qPCR upon exposure to OA ± CBR-5884 or OA ± the histone methyltransferase (HMT) inhibitor Piribedil. Alkaline comet assay was done to detect DNA breaks. Single-cell RNA-seq (scRNAseq) was performed on tissue-derived breast microstructures exposed to ± OA.
Results. Upon OA treatment, the Cancer index increased and 1C-THF was redirected to the methionine cycle increasing flux to methylation. OA significantly increased the production of SAM, GSH and 2-HG after 15 min. Blocking the first enzyme in the serine pathway, PHGDH, prevented these increases. After 5 min OA exposure, mitochondrial and nuclear ROS increased significantly ($p < 0.0001$), peaking at 15 min. H3K4me3 CUT&RUN revealed 661 differential peaks (FDR < 0.05) comparing OA to control. 73% of H3K4me3 OA-associated peaks were in regulatory regions of OA-induced genes (FDR < 0.01) including neural, EMT and ER- BC related genes. Motif analysis revealed an overrepresentation of binding sites for serine pathway transcriptional activators ATF3/4 ($p < 0.05$). Blocking PHGDH or HMT prevented OA-induced gene expression changes. Alkaline comet assay showed that OA significantly increased comet tails. scRNAseq revealed OA increased the numbers of cells within all cell clusters expressing ATF3 and PHGDH. Also observed was an increase in the percentage of basal BSL1, luminal progenitor LP3 and hormone sensing HS1 cells.
Conclusions. Metabolism of OA results in a metabolic shift toward the SOG and methionine increasing the production of SAM, GSH and 2-HG which have implications for oncogenesis. The increased SAM fosters epigenetic phenotypic plasticity via altered histone methylation. The increased proportion of specific cell types likely reflects the survival of cells able to mitigate oxidative stress. Increased 2-HG may produce metabolic BRCAness by inhibiting 2-oxoglutarate-dependent dioxygenases.

#0445 Determining the molecular and biologic effects of HER3 and IDH1 antagonism on liver endothelium-PDAC crosstalk.

C. S. Boutros[1], A. W. Loftus[1], M. Rathore[2], M. Zarei[2], K. Curry[2], J. M. Winter[1], R. Wang[2];
[1]Univ. Hospitals Case Medical Ctr., Cleveland, OH, [2]Case Western Reserve University, Cleveland, OH

INTRODUCTION: Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy due to the lack of early diagnosis and limited response to treatments. Austere and nutrient-deprived conditions typically present in the PDAC tumor microenvironment (TME) induce chemotherapy resistance. Therefore, novel therapeutic strategies are needed. We have previously demonstrated the primary tumor expresses IDH1 which supports the pro-survival oxidative phosphorylation (OXPHOS) metabolism, and has been successfully targeted by ivosidenib, an IDH1 inhibitor, in preclinical studies. Meanwhile, endothelial cells (ECs) from the liver, the most common site of PDAC metastases, secrete soluble factors in the conditioned medium (CM) that activate HER3, a receptor tyrosine kinase, involved in cell proliferation and metabolism.
OBJECTIVES: We sought to (1) uncover the mechanisms involved in driving the metabolic differences between primary and metastatic tumors through the utilization of ECs from the liver (2) conduct metabolic analyses to determine metabolic effects of HER3 activation, and (3) examine potential synergism of combination therapy against HER3 and IDH1 in primary and metastatic niches. METHODS: The effect of CM on PDAC cell growth was determined by PICO Green Assay. The effects of ECs HER3/IDH1 inhibitions on cellular metabolism were measured by multiple metabolic assays including Seahorse, CellTiter-Glo, lactate ELISA, and TMRE assays. HER3-specific antibody Seribantumab, HER3 inhibitor Sapitanib, and IDH1 inhibitor ivosidenib were used to block HER3 and/or IDH1. Moreover. A cell viability-based synergy study was performed to assess the effects of HER3-IDH1 combination. Effects of HER3 and IDH1 inhibitions on PDAC tumor growth and mouse survival in vivo were determined in syngeneic, orthotopic models with PDAC primary tumors and liver metastases. RESULTS: CM from liver ECs significantly increased cell growth in PDAC cells in vitro and increased glycolytic tropism in multiple HER3 positive PDAC cell lines measured by metabolic assays mentioned above. HER3 antibody and HER3 inhibitor both increased oxidative consumption rate (OCR), an indirect measure of OXPHOS, and decreased extracellular acidification rate (ECAR), a measure of glycolysis measured by Seahorse. Combination therapy utilizing HER3 and IDH1 inhibitors revealed synergy. In our in vivo tumor model, mice treated with combination therapy had significantly longer overall survival than those given either monotherapy or no treatment.
CONCLUSIONS: Our results demonstrated a paracrine role of liver ECs in promoting cell growth via activating HER3 in PDAC cells as well as reprograming cellular metabolism from OXPHOS towards glycolysis. Identification of the metabolic shift that takes place in metastatic PDAC to the liver due to HER3 activation gives way for the development of a potentially lethal drug combination.

#0446 Integrated spatial transcriptomics and lipidomics analyses of intraductal papillary mucinous neoplasm identifies enrichment of long chain sulfatide as an early metabolic alteration.

Y. Chen[1], M. Sans[1], F. Thege[1], R. Dou[1], J. Min[1], M. Yip-Schneider[2], J. Zhang[3], R. Wu[1], E. Irajizad[1], Y. Makino[1], K. Rajapakshe[1], M. Hurd[1], R. Leon-Letelier[1], J. Vykoukal[1], J. Dennison[1], K.-A. Do[1], R. Wolff[1], P. Guerrero[1], M. Kim[1], M. Schmidt[2], A. Maitra[1], S. Hanash[1], J. Fahrmann[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Indiana University-Purdue University Indianapolis, Indianapolis, IN, [3]Indiana University, Bloomington, IN

Purpose: To define the metabolic alterations associated with malignant progression of intraductal papillary mucinous neoplasm (IPMN).
Experimental Procedures: Matrix-assisted laser desorption/ionization (MALDI)-mass spectrometry (MS) was conducted for spatial characterization of lipid profiles on frozen tissue sections from resected human IPMN patients. The specimen set consisted of either low-grade dysplasia (LG) (n=15), high-grade (HG) dysplasia (n=4), or with an associated pancreatic ductal adenocarcinoma (PDAC) (n=4) as well as 15 PDAC tissues. Utilizing serial sections to the same human IPMN cases analyzed with MALDI-MS imaging, we used the Visium Spatial Gene Expression technology platform to characterize the spatiomolecular underpinnings of LG and HG IPMN. H&E images of the same tissue section used for the Visium workflow, were used to annotate the spots in the dataset covering the epithelial lining of the IPMN lesions ("epilesional" areas) and the spots covering the adjacent microenvironment surrounding the lesion ("perilesiopecific" area). Findings were compared with lipidomic analyses of cystic fluid from 89 IPMN patients. The anti-cancer efficacy of UGT8-IN-1, a selective small molecule inhibitor of ceramide galactosyltransferase (CGT, also known as UGT8), was assessed in vitro and in mutant Kras;Gnas allografts.
Results: MALDI/MS-based spatial imaging of human resected IPMN tissues and pancreata from a mutant Kras;Gnas mouse model of IPMN revealed long-chain hydroxylated sulfatides, particularly the C24:0(OH) and C24:1(OH) species, to be selectively enriched in the IPMN and PDAC neoplastic epithelium. Visium spatial transcriptomics data confirmed that the cognate transcripts engaged in sulfatide biosynthesis, including UGT8, Gal3St1, and FA2H, were co-localized with areas of sulfatide enrichment. Lipidomic analyses of cystic fluid from 89 patients with IPMN identified several sulfatide species to be significantly elevated in patients with IPMN/PDAC compared to those with low-grade IPMN. Inhibition of sulfatide metabolism via UGT8-IN-1 reduced viability of Kras;Gnas murine cell lines in vitro and attenuated tumor growth in an allograft IPMN model. UGT8-IN-1 treatment resulted in reduced levels of several sulfatide species, accompanied by a concomitant increase in a subset of quantified sulfatides precursor ceramides, accumulation of mitochondrial mass and reactive oxygen species and time-dependent increases in autophagy/mitophagy markers p62/SQSTM1 and LC-3B, suggesting impaired mitophagy.
Conclusion: Enhanced sulfatide metabolism is an early alteration in cystic pre-cancerous lesions of the pancreas that persists through invasive neoplasia. Targeting sulfatide biosynthesis might represent an actionable vulnerability for cancer interception.

#0447 Anti-tumor efficacy of ompenaclid, a creatine transporter inhibitor, in KRAS mutant tumors, including NSCLC.

P. Lo, V. Sanz Chavez, S. Takeda, M. Tavazoie, **I. Kurth**;
Inspirna, Inc., New York, NY

Background: Pre-clinical studies identified creatine metabolism to be activated in KRAS mutant metastatic colorectal cancer (CRC) as a mechanism to fuel the increased energy demands of RAS mutant tumors. Metastatic colon cancer cells overexpress and subsequently release creatine kinase-B (CKB) into the extracellular space, where it phosphorylates creatine to generate the high energy metabolite phosphocreatine. Ompenaclid is a small molecule inhibitor of the creatine transporter SLC6A8. Inhibition of SLC6A8 by ompenaclid prevents import of phosphocreatine/creatine, resulting in depletion of intracellular creatine, phosphocreatine and ATP levels. This results in tumor apoptosis and robust anti-tumor efficacy in CRC models with a wide range of KRAS mutant alleles. Ompenaclid is currently in a Phase 2 trial, in combination with FOLFIRI and bevacizumab, in patients with RAS-mutated second-line advanced/metastatic colorectal cancer. Here, we assessed efficacy of ompenaclid in tumors beyond CRC, including KRAS WT and KRAS mutant NSCLC.

Methods: Athymic mice were inoculated with CRC, pancreatic, gastric or NSCLC cancer cell lines and treated with ompenaclid once tumors reached ~150 mm^3, until termination. Plasma metabolites were quantified by LC-MS/MS and tumoral expression of CKB and SLC6A8 in NSCLC and CRC tumors was measured by qPCR after treatment with a control or ompenaclid-supplemented diet for ~10 days. Combination treatment with MRTX849, a KRAS G12C inhibitor, was conducted in a pancreatic MiaPaca xenograft model.

Results: Our studies demonstrate ompenaclid anti-tumor efficacy in NSCLC and pancreatic xenografts. Notably, and consistent with findings in CRC, efficacy in NSCLC was more robust in RAS mutant cancer models, relative to those bearing KRAS WT tumors. Metabolite analysis of the plasma of tumor-bearing mice at baseline revealed that mice harboring RAS mutant tumors had higher levels of p-creatine and lower levels of ATP, indicating that RAS mutant tumors utilize higher amounts of ATP, which may be converted to phosphocreatine by tumoral CKB, as confirmed by qPCR analysis. This finding is consistent with metastatic RAS mutant CRC tumors utilizing extracellular ATP to generate phosphocreatine and thus exhibiting greater dependency on creatine metabolism relative to RAS WT tumors. Treatment with ompenaclid also demonstrated additive efficacy in combination with KRAS G12C inhibitors. In summary, these data support development of ompenaclid in indications beyond CRC, including NSCLC, as well as in combination with KRAS G12C inhibitors.

#0448 Alterations in glycolytic pathway enzymes and metabolic plasticity in prostate cancer progression.

C. Sprenger, M. Munari, S. Sun, K. Soriano Epilepsia, S. Plymate;
University of Washington, Seattle, WA

Background: Although oxidative phosphorylation (OXPHOS) is the main ATP source in primary prostate cancer, as the tumor progresses to castration resistance and/or metastatic disease, glycolysis becomes increasingly prevalent. Dependence on glycolysis can further increase under hypoxic conditions found in advanced cancers. We previously demonstrated that a novel small molecule, BKIDC-1553, inhibits proliferation and tumor growth of prostate cancer cell lines and xenografts through a hexokinase-2 (HK2) dependent inhibition of glycolysis. HK2 is a glucose 6-phosphorylating enzyme that works in conjunction with glucose transporter-1 (GLUT1) to drive glycolysis in cells. While our previous work suggests that BKIDC-1553 works primarily through a HK2 dependent mechanism, the objective of this current project is to further examine how expression and function of HK2 and GLUT1 are altered in response to BKIDC-1553 treatment.
Methods: Hypoxic conditions are common in late-stage prostate cancer. Effects of hypoxia on cell proliferation and expression levels of HK1, HK2, and GLUT1 were examined with and without BKIDC-1553 treatment. To examine role of HK1, HK2, and GLUT1 in response to BKIDC-1553 treatment, we created CRISPR knockouts and shRNA knockdowns of HK1 and HK2 in the LNCaP prostate cancer cell line. GLUT1 was inhibited using a commercially available inhibitor, BAY-876. PCR and Western blots were used to confirm expression levels of HK1, HK2, and GLUT1. MTS proliferation assays were used to examine effect of KO and KD on response to BKIDC-1553 and BAY-876.
Results: GLUT1 levels, but not HK1 or 2, increased at 72 hrs under hypoxic conditions. HK1, HK2, and GLUT1 levels all increased in cells in response to 144 hrs of BKIDC-1553 compared with 72 hrs treatment in both normoxic and hypoxic conditions. The KO and KD studies were all conducted in normoxic conditions. Westerns blots demonstrated that HK2 KO, but not HK1 KO, results in increased levels of GLUT1. HK1 or HK2 KD, however, did not alter GLUT1 levels. HK2 KD cells, with GLUT1 levels remaining the same, displayed less growth inhibition than control cells in response to BKIDC-1553 treatment, while HK2 KO cells, with increased levels of GLUT1, remained sensitive to BKIDC-1553. Because GLUT1 levels increase in response to HK2 KO, we wanted to see if inhibiting GLUT1 in these cells could decrease their proliferation. We found that KO cells were indeed more sensitive to growth inhibition of BAY-876.
Conclusion/Summary: These studies indicate that KO of HK2 increases levels of GLUT1. These cells remain sensitive to BKIDC-1553 treatment, which could in part be due to the cells' continued reliance on glycolysis through increased GLUT1. A continued reliance on glycolysis allows BKIDC-1553 to continue to inhibit cell growth. Future studies examining how combination treatment with BKIDC-1553 and BAY-876 affects growth of advanced prostate cancer cells is underway.

#0449 Catabolism of GSH by GGT supports cancer cell survival.

M. Zocchi, F. Hecht Castro Medeiros, F. Alimohammadi, E. Tuttle, G. Asantewaa, T. Scales, I. S. Harris;
University of Rochester Medical Center, Rochester, NY

Cancer metabolism depends on amino acid sources to fuel tumor growth and drug resistance. Using amino acid restriction to treat tumors can enhance existing therapeutic techniques. The tripeptide Glutathione (GSH), which contains cysteine, glutamate, and glycine, is often considered an antioxidant, and its potential as an amino acid pool has been overlooked. GSH is ubiquitous in the tumor microenvironment and could provide a ready source of amino acids to tumor cells through its catabolism by the enzyme γ-Glutamyl transpeptidase (GGT), which has been shown to cleave GSH and its' conjugates in the extracellular space. It is unclear if the cleavage of GSH by GGT supports cancers in vivo. We find that inhibiting GGT with the pharmacologic agent GGsTop blocks GSH catabolism and decreases tumor growth. We show that cultured cells can be rescued from a lethal depletion of cystine upon supplementation with GSH or its catabolic product cysteinylglycine, but not under the conditions of GGT inhibition. Through pharmacokinetic methods, we identify a usable systemic dose of GGsTop and show GGT inhibition in tumor tissue. Further, we demonstrate that systemic GGT inhibition in vivo decreases tumor mass and volume. These findings support the hypothesis that GSH catabolism by GGT1 is a non-canonical source of amino acids for tumor metabolism. Understanding GSH catabolism by GGT could elucidate new metabolic pathways in tumors. Inhibiting GSH catabolism could provide new therapeutic approaches to inhibit tumor growth.

#0450 GCN2 protects cancer cells from hypertranslation and metabolic crisis.

M. Roman-Trufero[1], I. T. Kleijn[2], K. Blighe[3], P. Saavedra-Garcia[2], J. Zhou[2], A. Gaffar[2], M. Christoforou[2], M. Yuneva[4], A. M. Michel[5], G. R. Masson[6], V. Shahrezaei[2], H. W. Auner[1];

[1]CHUV Lausanne University Hospital, Lausanne, Switzerland, [2]Imperial College London, London, United Kingdom, [3]Clinical Bioinformatics Research, London, United Kingdom, [4]The Francis Crick Institute, London, United Kingdom, [5]EIRNABio Ltd, Cork, Ireland, [6]University of Dundee, Dundee, United Kingdom

It is widely assumed that cancer cells rely on high levels of protein synthesis to support growth and proliferation. However, protein synthesis, including ribosome biogenesis, is a highly resource- and energy-demanding process that needs to be coordinated with protein degradation and metabolic programs. GCN2 is an evolutionarily conserved kinase that is primarily activated by uncharged tRNAs when amino acid levels drop and activates the Integrated Stress Response (ISR), which encompasses a global reduction in translation and increased amino acid uptake and generation. GCN2 has been shown to support cancer cell survival under conditions of nutrient scarcity. Here, we used an integrated systems biology approach to delineate the multifaceted role of GCN2 in cancer cells that do not suffer from nutrient shortages.

We carried out a broad array of multiomic analyses (RNA-seq, TMT-labelling based proteomics, Ribo-seq, LC-MS metabolomics) of melanoma cells in which GCN2 was inhibited (GCN2iB) or genetically depleted (constitutive and inducible shRNA) in cell culture and *in vivo* in murine xenografts, supplemented by puromycinylation-based quantification of global protein synthesis.

GCN2 inhibition in A375 cells triggered a transcriptome and proteome response that was dominated by the induction of processes linked to protein and ribosome synthesis while suppressing metabolic pathways such as glycolysis and the proteasome. We confirmed these observations *in vivo* via RNA-seq of tumor samples from mice xenografted with A375 cells in which GCN2 was knocked down by induced shRNA expression and from xenografted mice that were treated orally with GCN2iB. Ribo-seq further demonstrated that, upon GCN2 inhibition, A375 cells expand their translational machinery. Notably, we identified 50 ribosomal genes that were translated at higher rate in GCN2-inhibited cells and whose expression was regulated exclusively at the translational level. GCN2 inhibition/depletion also resulted in an approximately 1.8-fold increase in global protein synthesis and altered the druggable proteome. Moreover, metabolite profiling of GCN2iB-treated cells revealed a loss of metabolic homeostasis including substantial alterations in glycolysis and both amino acid and lipid metabolism. In addition, we observed a significant decrease in ATP levels despite increased translation of mitochondrial ETC complex proteins. Proteomic and translatomic analyses revealed a failure of cells to increase proteasomal subunits and to maintain the production of ECM proteins. Last, but not least, we did not observe a role of GCN2 in preventing or resolving ribosome collisions.

Taken together, our findings reveal GCN2 as a master regulator of translation in cancer cells that do not suffer from nutrient scarcity that keeps protein synthesis in check to maintain metabolic homeostasis.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: microRNAs and Other Non-coding RNAs as Cancer Genes 1
Poster Session

#0454 microRNAs role in innate immunosenescence during anti-PD1 immunotherapy.
Z. Zhu, T. M. Rana;
UC San Diego, San Diego, CA

Checkpoint inhibitors have achieved durable responses and long-lasting immunologic memory in cancer patients. However, the initial and acquired resistance remains an unsolved problem. It's urgent to learn the molecular mechanisms causing resistance. microRNAs (miRNAs) are short transcripts that regulate many pathophysiological processes. Here, we investigated the miRNAs expression changes after GVAX combined with monoclonal PD-1 antibody treatment in the murine melanoma B16F10 tumors and identified microRNAs down-regulated in responsive tumors. Deletion of this family member in three different syngeneic mouse tumors did not affect their in vitro nor in vivo proliferation but sensitized anti-PD1 immunotherapy. The miRNA deletion with anti-PD1 therapy increased total CD45+ leukocyte infiltration with all types of hematopoietic cells except macrophages. Both tumor bulk RNA sequencing and single-cell RNA sequencing revealed activated innate sensing genes especially for pathogen recognition and phagosome formation. Importantly, we found specific miRNA-deletion effects rely on tumor resident macrophage, IFN-γ release in the tumor microenvironment (TME) and the miRNA regulating machinery protein Argonaut2 (Ago2). Notably, the miRNA expression status of melanoma patients correlates with the survival and innate immune sensing gene expression. Our results suggest that this family of miRNAs participate in initial resistance by escaping innate immunosurveillance. Deletion of the miRNA may turn immune "cold" tumors to "hot" tumors, providing potential therapeutic targets to overcome resistance in melanoma, colorectal, triple-negative breast cancer and possibly other cancers.

#0455 Identification of hsa-miR-6794-3p as a key regulatory factor in human pancreatic cancer metastasis.

H. Kim[1], E.-T. Oh[1], Y. Cho[2], H. Park[1];
[1]Inha University College of Medicine, Incheon, Korea, Republic of, [2]Inha University, Incheon, Korea, Republic of

Metastasis is a major factor in treatment failure in patients with pancreatic cancer, but the underlying mechanisms remain unclear, and new, effective treatment strategies are needed. Here, we sought to identify novel microRNAs (miRNAs) with a key role in pancreatic cancer metastasis. Using a microarray analysis to evaluate miRNA expression in metastatic and non-metastatic pancreatic cancer, we found that expression of the miRNA, hsa-miR-6794-3p, was significantly lower in metastatic pancreatic cancer tissues than in non-metastatic pancreatic cancer tissues. Methylation-specific polymerase chain reaction analyses revealed that hsa-miR-6794-3p expression was downregulated in metastatic pancreatic cancer cells by hypermethylation of CpG islands within the hsa-miR-6794-3p promoter. Gain- and loss-of-function approaches using the human pancreatic cancer cell lines, MIA-PaCa-2 and HPAF-II, expressing low and high levels of hsa-miR-6794-3p, respectively, suggested a role for hsa-miR-6794-3p in decreasing cell invasion, migration, and epithelial-mesenchymal transition (EMT) signaling. Notably, we found that hsa-miR-6794-3p exerts its effects by inhibiting expression of the chromatin remodeling factor, RBBP4, through direct binding to the 3'-untranslated region of its mRNA. The resulting suppression of RBBP4 expression increases levels of the transcription factor GRHL2, which is involved in regulating invasion, migration, and EMT signaling in metastatic pancreatic cancer cells. Thus, lower levels of hsa-miR-6794-3p disrupt GRHL2-mediated regulation of these pathways by disinhibiting expression of the GRHL2 negative regulator, RBBP4. Consistent with these findings, an investigation of the relationship between hsa-miR-6794-3p and clinicopathological features in pancreatic cancer patients using publicly available datasets and immunohistochemistry showed that low levels of hsa-miR-6794-3p are correlated with a poorer prognosis in pancreatic cancer patients. Additional preclinical experiments in nude mice clearly demonstrated that hsa-miR-6794-3p is capable of suppressing pancreatic cancer cell metastasis. Taken together, these results suggest that hsa-miR-6794-3p suppresses tumor metastasis and thus represents a promising prognostic biomarker and therapeutic target in pancreatic cancer.

#0456 A first comprehensive analysis of transcribed ultra conserved regions uncovers important regulatory functions of novel non-coding transcripts in gliomas.

M. K. Gibert, Jr., R. Abounader;
University of Virginia, Charlottesville, VA

Transcribed Ultra-Conserved Regions (TUCRs) represent a severely understudied class of putative non-coding RNAs (ncRNAs) that are 100% conserved across multiple species. We performed the first-ever analysis of TUCRs in glioblastoma (GBM) and low-grade gliomas (LGG). We leveraged large human datasets to identify the genomic locations, chromatin accessibility, transcription, differential expression, correlation with survival, and predicted functions of all 481 TUCRs, and identified TUCRs that are relevant to glioma biology. Of these, we investigated the expression, function, and mechanism of action of the most highly upregulated intergenic TUCR, uc.110, identifying it as a new oncogene. Uc.110 was highly overexpressed in GBM and LGG, where it promoted malignancy and tumor growth. Uc.110 activated the WNT pathway by upregulating the expression of membrane frizzled-related protein, by sponging the tumor suppressor miR-544. This pioneering study shows important roles for TUCRs in gliomas and provides an extensive database and novel methods for future TUCR research.

#0457 Persister cell state-associated lncRNA signatures in non-small cell lung cancer.

J. Gencel-Augusto, W. Wu, T. G. Bivona;
UCSF - University of California San Francisco, San Francisco, CA

Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related mortality worldwide, largely due to late-stage diagnosis and a 5-year survival rate of 9%. Targeted therapies for oncogene-dependent tumors like tyrosine kinase inhibitors (TKIs) improve outcomes yet their clinical efficacy is often limited by occult drug-tolerant persister cells (DTPCs), causing recurrence. Long non-coding RNAs (lncRNAs) are transcripts over 200 nucleotides and typically non-protein coding. They regulate cellular functions by interacting with substrates through their complex secondary structures. Their deregulation is linked to oncogenesis and therapy resistance. While their role in lung cancer has been documented, their involvement in the DTPC state remains unexplored. Our study aims to investigate the role of lncRNAs in mechanisms that drive failure to targeted therapy in NSCLC. We comprehensively analyzed single-cell RNA-seq data from 49 NSCLC biopsies, pre- and during TKI therapy (residual disease, RD). We identified several lncRNAs that were significantly, differentially expressed in RD when compared to treatment naïve (TN) tumors. We orthogonally validated these findings in a minimum of 2 lung cancer cell lines in TN or DTPCs (9-15 days upon TKI exposure in culture) [$p<0.05$, absolute log2 fold change > 0.3]. We found that *MALAT1, HCG11*, and *EPB41L4A-AS1* (lncRNA-UP signature) displayed significantly increased expression in RD relative to TN tumors and parental cell lines. We also found significant downregulation of *LUCAT1* and *LINC00152* (lncRNA-DOWN signature) in RD samples. We further performed Kaplan-Meier survival analysis in an independent set of RD samples stratified by differential expression of our lncRNA signatures (n=18/group). The analysis showed improved overall survival in patients whose DTPCs expressed a high level of the lncRNA-UP signature (hazard ratio, HR=0.56; log-rank test p=0.0331). We did not observe significant differences in survival for the lncRNA-DOWN signature. We additionally performed survival analysis using the GEPIA database for lung adenocarcinoma (primarily TN, n= 239/group). Consistently, the analysis showed improved overall survival for high levels of the lncRNA-UP signature (HR=0.71; p=0.029), whereas high levels of the lncRNA-DOWN signature were indicative of inferior outcomes (HR=1.4, p=0.046). We systematically identified DTPC-associated lncRNA signatures from our unique DTPC cohort, indicating that deregulation of lncRNA expression may play a role in acquired drug resistance in lung cancer. DTPC-associated lncRNA expression patterns are linked to differential overall survival, suggesting a possible tumor-suppressive or promoting role and highlighting their potential as predictive biomarkers and therapeutic targets. Further investigation into the functional roles of these lncRNAs and their interplay with coding molecules is warranted.

#0458 Nanoparticle-mediated delivery of miR-590-3p decreases recurrent GBM tumor growth by inhibits multiple oncogenic nodes.

H. Lopez-Bertoni[1], S. Sall[2], H. Khela[2], J. Korleski[1], K. Luly[1], M. Johnson[2], B. Lal[2], A. Johnson[1], S. Tzeng[1], J. Green[1], J. Laterra[1];
[1]Johns Hopkins School of Medicine, Baltimore, MD, [2]Hugo W Moser Institute at Kennedy Krieger, Baltimore, MD

Glioblastoma (GBM) is the most lethal and aggressive form of brain cancer. Despite aggressive therapy consisting of surgery followed by radio/chemotherapy GBM recurs in almost all patients and, currently, there are no proven therapies to treat recurrent GBM (rGBM). Recent developments in nanomedicine provide new and promising opportunities to develop new targeted therapeutics to treat brain tumors. We have recently developed PBAE nanoparticle formulations optimized for in vivo miRNA delivery to brain tumor stem cells, or GSCs. Carefully selecting one miRNA to target several mRNAs dysregulated within a pathway can allow the targeting of multiple nodes using a single agent, mimicking combinatorial therapies. To test this hypothesis, we performed bioinformatic analysis of RNA sequencing from GSCs and clinical rGBM specimens combined with gene set enrichment analysis (GSEA) and identified TGFBR2 signaling as a targetable pathway in rGBM. We show that SMAD2 signaling, a downstream effector of TGFBR2, is enriched in rGBM and that patients with elevated TGFBR2 transcripts respond poorly to current standard of care. Utilizing patient-derived xenograft lines from rGBM, we show that blocking TGFBR2 signaling using siRNAs or ITD1, a selective TGFBR2 inhibitor, decreases the stem cell capacity, cell viability and re-sensitizes clinical rGBM cells to temozolomide (TMZ) in-vitro. In vivo, we show that ITD1 is modestly effective in subcutaneous and ineffective in orthotopic rGBM models. Not surprisingly, these tumors exhibited classical growth patterns associated with acquisition of resistance. To overcome this obstacle, we performed a miRNA-based network analysis in rGBM and identified miR-590-3p as a putative tumor suppressor that targets SMAD2 signaling at multiple nodes in rGBM. In-vitro, transgenic miR-590-3p robustly decreased the expression of 37 putative oncogenes simultaneously concurrent with decreasing stem cell capacity, cell viability and re-sensitizing rGBM PDX cells to TMZ. In vivo delivery of miR-590-3p to established PDX-derived rGBM orthotopic tumors using novel PBAE nanocarriers robustly decreased tumor sizes and increased tumor necrosis. These results show that the promiscuous nature of miRNAs, in combination with cutting-edge nucleic acid delivery vehicles, can be leveraged as advanced targeted therapeutics for rGBM bypasses the resistance that is developed to standard of care and available small molecules.

#0459 Exosomal miRNA 16-5p/29a-3p secreted from pancreatic cancer induce adipose atrophy by inhibiting adipogenesis and promoting lipolysis.

S.-C. Tien[1], C.-C. Chang[1], I.-C. Chen[2], C.-H. Huang[1], H.-Y. Peng[3], Y.-T. Chang[3], M.-C. Chang[3], C.-M. Hu[1], W.-H. Lee[4];
[1]Genomics Research Center, Academia Sinica, Taipei, Taiwan, [2]Institute of Biochemistry and Molecular Biology, National Yan Ming Chiao Tung University, Taipei, Taiwan, [3]Department of Internal Medicine, National Taiwan University College of Medicine, Taipei, Taiwan, [4]Department of Biological Chemistry, University of California, Irvine, CA

Over 80% of the patients with pancreatic ductal adenocarcinoma (PDAC) have cachexia, which is associated with reduced survival, decreased quality of life, and higher rates of metastatic disease. To date, the diagnostic and therapeutic options of PDAC-associated cachexia remain limited due to the lack of a complete understanding of the underlying pathological mechanism. Here, we demonstrate that fat loss is the earliest feature of cachexia induced by PDAC through its secreted exosomes. By analyzing exosomal components of normal and cancer-derived exosomes through small RNA-seq, we identify miR-16-5p, miR-21-5p, miR-29a-3p and miR-125b-5p enriched in pancreatic cancer-derived exosomes and in the exosomes from sera of mice or patients with pancreatic tumor. Among these, miR-16-5p and miR-29a-3p play a key role in fat loss by inhibiting adipogenesis through decreasing Erlin2 and CMPK1 expression leading to C/EBPβ and PPARγ downregulation. Synergistically, miR-29a-3p increases ATGL expression to facilitate lipolysis by suppressing MCT1 expression. Furthermore, PDAC-derived exosomes deprived of miR-16-5p and miR-29a-3p fail to induce fat loss, suggesting that these two exosomal miRs are required for PDAC-induced fat loss. These findings unravel a precise mechanism of how PDAC causes adipose atrophy via exosomal miRs and may provide new diagnostic and therapeutic strategies for PDAC-induced cachexia.

#0460 Fecal microRNA and microbiome profiles in colorectal cancer patients: Are they predictor of survival and how do behave in longitudinal samples?.

B. Pardini[1], N. Keles[2], G. Ferrero[3], S. Tarallo[1], G. Francescato[3], A. Gagliardi[3], V. Alberini[3], C. Di Battista[4], V. Vymetalkova[5], F. Turkoglu[6], O. Duzgun[6], O. Ozkan[6], B. Tuna[2], P. Vodicka[5], S. Dogan[2], A. Naccarati[1];

[1]Italian Institute for Genomic Medicine (IIGM), Candiolo, Italy, [2]Yeditepe University, Istambul, Turkey, [3]University of Turin, Turin, Italy, [4]Fundacio de Recerca Clinic Barcelona-Institut d`investigacions Biomediques August Pi i Sunyer (FRCB-IDIBAPS), Barcelona, Spain, [5]Institute of Experimental Medicine of the Czech Academy of Sciences, Prague, Czech Republic, [6]University of Health Sciences, Umraniye Training and Research Hospital, Istambul, Turkey

Background: Colorectal cancer (CRC) is characterized by a high complexity that significantly influences treatment response and survival. There is still a lack of prognostic factors after surgery that could help predict postoperative survival. Currently, lymph node metastases are the single most important prognostic factor but it gives no clue on tumor aggressiveness and recurrence. Our group recently contributed to the identification of a fecal microRNA (miRNA) signature that accurately discriminates sporadic CRC and aimed at improving non-invasive diagnosis (Pardini et al, Gastroenterology 2023) as well as altered gut microbiome species associated with CRC (Thomas et al, Nat. Medicine 2019), but there are scanty evidence on the potentiality of such markers for prognosis.
Aims: In the same cohort, we investigated if the fecal miRNome and gut microbiome at diagnosis are associated with CRC patients' prognosis. Moreover, we assessed fecal miRNA in a new set of CRC patients collected longitudinally before and after the surgery to investigate whether such associations reflect miRNA profiles over time. Methods. We performed small RNA and shotgun metagenomic sequencing in stool samples in 3 cohorts from: Italy (IT, 128 CRC), Czech Republic (CZ, 69 CRC), and Turkey (TU, 34 CRC, 40 controls). Stool samples from TU CRC subjects were collected before surgery and after 6 months.
Preliminary Results: In the IT and CZ cohorts, an average of 479 fecal miRNAs were detected with 209 differentially expressed (DE) miRNAs significantly associated with survival, including miR-1246 which was present in the CRC-associated signature identified by us. Two miRNAs (miR-197-5p and miR-6081-5p) were significantly down-regulated in patients with the worst prognosis (adj.p<0.01, HR<0.50) in both cohorts. In TU cohort, 494 miRNAs were DE in CRC (pre-surgery) vs controls. Among them, the 25 DE miRNAs detected in our previous work were also significantly altered, including the 5-miRNA CRC signature (miR-149-3p, miR-607-5p, miR-1246, miR-4488, and miR-6777-5p) identified by machine learning. Notably, after 6 months from surgery, levels of such miRNAs reverted to those measured in controls (for miR-1246 p<0.001 in both controls vs pre- and vs post-surgery comparisons). More analyses on the longitudinal fecal miRNA data are ongoing as well as for the metagenome data assessing the abundancies of CRC-associated microbial species before and after tumor resection and their possible association with survival.
Conclusions: Fecal miRNAs may serve as biomarkers for CRC prognosis. Following tumor resection, CRC levels of altered miRNAs return in a range comparable with those of healthy controls in a time-dependent manner. These data further support the use of fecal miRNAs as accurate diagnostic CRC biomarkers and provide preliminary information on their possible translation as a prognostic tool.

#0461 Dual-kinase targeted miRNA nanotherapy for the treatment of triple-negative breast cancer.

G. Kara[1], P. Atalay Dundar[1], N. Kahraman[1], E. B. Denkbas[2], B. Ozpolat[1];
[1]Houston Methodist Research Institute, Houston, TX, [2]Baskent University, Ankara, Turkey

Triple-negative breast cancer (TNBC) represents 20% of breast cancer (BC) patients (51,000 cases/year in the US). It is associated with a highly aggressive course, early metastasis and relapses, and drug-resistant phenotype. About 40% of the patients die within 5 years despite available therapies. If the disease is metastatic, patients survive only 13 months. Since TNBC does not express targetable receptors such as ER, PR, and HER2, and it is a highly heterogeneous cancer with six genetically defined sub-types, currently, there are no common actionable molecular targets and no effective targeted therapies for TNBC. microRNAs (miRNAs) are 18-20 nt long non-coding RNAs and are often dysregulated in cancer cells. Tumor-suppressive miRNAs specifically silence their protooncogenic target genes (mRNAs) by binding specifically to their 3'-UTRs located in their target mRNAs, leading to inhibition of oncogenes that play critical roles in cell proliferation, cell cycle, migration, invasion, angiogenesis, drug resistance, tumor growth, and progression. We have previously demonstrated that Eukaryotic Elongation factor-2 kinase (eEF2K) and AXL are oncogenic kinases, and their higher expression is associated with poor survival in patients with TNBC. However, currently, there is no FDA-approved eEF2K and AXL-targeted therapeutics. To effectively co-target these kinases, we extensively analyzed miRNA databases using miRNA target prediction algorithms and recently, we discovered that miR-329-3p has a specific binding site at both 3'-UTRs of eEF2K and AXL mRNAs. Analyzing the TCGA TNBC database, we found that low expression of miR-329-3p is correlated with shorter overall survival in TNBC patients, and the expression of miR-329-3p is commonly reduced or lost in TNBC patient tumors. Since the successful clinical application of miRNA-based therapeutics requires safe and effective nano-delivery systems, we have developed magnetic iron-oxide-based nanoparticles (MNPs) for the delivery of miR-329-3p. We showed that miR-329-3p significantly suppresses cell proliferation, invasion, and migration by targeting both eEF2K and AXL and their downstream mediators such as SRC/FAK and Cyclin D1 in TNBC cell lines. In vivo systemic treatment with MNPs-miR-329 completely blocks tumor growth in orthotopic MDA-MB-231 and MDA-MB-436 TNBC xenograft models in mice. Analysis of tumors shows remarkable inhibition in eEF2K and AXL expression, and clinically significant downstream targets including SRC, FAK, and Cyclin D1. We also demonstrated that miR-329 nanotherapy induces apoptosis and inhibits intratumoral proliferation in TNBC tumors in mice. Toxicity markers in mouse blood samples show that miR-329 nanotherapy is safe and not toxic to mice. Taken together, our study suggests that miR-329-3p nanotherapy may be used as a novel potential therapeutic approach in TNBC patients.

#0462 Developing the miR-888 cluster as a therapeutic target for prostate cancer.

K. Routon[1], T. Fachko[1], V. Kasina[2], R. Bahal[2], **A. E. Kerscher**[1];
[1]Eastern Virginia Medical School, Norfolk, VA, [2]University of Connecticut, Storrs, CT

Prostate Cancer (PCa) is a serious health crisis in the United States. 20% of men diagnosed with PCa will progress to fast-growing, advanced disease. There are no curative treatment options for PCa that has spread to distant sites and the 5-year survival rate for metastatic disease remains 30%. Recognizing the need for better PCa therapeutics, we are developing novel anti-microRNA delivery reagents targeted against the noncoding RNA miR-888 cluster to block prostate tumor progression. Our lab identified these oncomiRs in a biomarker discovery screen as elevated in human metastatic PCa cell lines and prostatic fluids from patients with high-grade PCa. We noted that over-expression of miR-888 cluster members (miR-888, miR-891a) promoted prostate cell growth and induced invasiveness *in vitro*. miR-888 and miR-891a also accelerated xenograft tumor growth in mice. Treatment of aggressive PCa cells in culture with synthetic antisense inhibitors against individual cluster members reversed these growth and invasion phenotypes, highlighting their clinical potential. We are testing pH Low Insertion Peptide (pHLIP)-Peptide Nucleic Acid (PNA)-based antimiR conjugates against miR-888 and miR-891a. The delivery vehicle pHLIP is a 36-amino acid peptide that at low pH (< pH 6.5) adopts an alpha-helical conformational change and facilitates the insertion of its C-terminus across lipid bilayers to transport conjugated anti-miRNA cargo into cells. When administered systemically, pHLIP effectively targets solid tumors with acidic microenvironments. We found that these reagents are readily internalized by human PCa cells cultured at pH 6.0 and in prostate xenograft tumors when delivered systemically in mice. Treatment significantly repressed miR-888 and miR-891a and acted to slow prostate cell growth *in vitro.* We are currently moving these studies into mouse prostate models. Furthermore, we are investigating the downstream signaling pathways for the miR-888 cluster. Our work indicates that the miR-888 cluster network coordinates the repression of the Tissue Inhibitors of Metalloproteinase (TIMP) and SMAD4 anti-metastatic pathways to drive extracellular matrix degradation and prostate cell invasion, and as a consequence, induces matrix metalloproteinase (MMP) activity. Expression profiling arrays and luciferase reporter assays indicated that multiple members of the miR-888 cluster co-suppress TIMPs in the prostate and similarly elevate multiple MMPs as well as cadherins, fibronectin and heparinase, and co-modulated several immune response genes. We are currently studying the consequence of various CRISPR-mediated miR-888 cluster deletions to understand how this non-coding RNA cluster functionally overlaps to promote aggressive PCa. This work will establish new clinical tools for aggressive PCa and optimize patient treatment management.

#0463 The small nucleolar RNA SNORD46 and SNORD72 have tumor suppressor activity in diffuse large B cell lymphoma.

E. Y. Chung, F. Spriano, S. Napoli, G. Sartori, L. Cascione, **F. Bertoni**;
IOR - Institute of Oncology Research, Bellinzona, Switzerland

Background. Following the identification of an 11q24.3 gain upregulating the ETS factors ETS1 and FLI1 in diffuse large B cell lymphoma (DLBCL) (Bonetti et al. Blood 2013), we observed the anti-lymphoma activity of blocking the protein-protein interaction of ETS factors with RNA helicases, using YK-4-279 and its clinical derivative TK-216 (Spriano, Chung et al. CCR 2019). DLBCL cells exposed to the two small molecule inhibitors presented a significant upregulation of small nucleolar RNAs (snoRNAs). Besides their primary functions in rRNA processing, snoRNAs are often deregulated in cancers, with microRNA-like actions and direct interaction with proteins. Here, we characterized SNORD46 and SNORD72, the two snoRNAs most upregulated cells after YK-4-279 and TK-216 and mapped to the 1p34.1 locus recurrently lost in DLBCL.
Methods. Real-time PCR, immunoblotting, and shRNA silencing were conducted based on established protocols. RNA-Protein Interaction Prediction (RPISeq) was used to calculate the interaction probabilities of snoRNAs with proteins of interest. The prediction was made using both the Random Forest (RF) and the Support Vector Machine (SVM) classifiers, using a stringent threshold of >0.6.
Results. The time-dependent changes of SNORD46 and 74 were validated with real-time PCR in the U2932 activated B cell-like (ABC) DLBCL cell line exposed to YK- 4-279 for 4 or 8 h. Upregulation of SNORD46 and 74 were significantly upregulated compared to their host genes upon YK-4-279 treatment, suggesting these snoRNAs have different functions from the genes in which they are encoded. Across 48 lymphoma cell lines, SNORD74 was more expressed in ABC DLBCL than in the remaining cell lines (P 0.03) or GCB DLBCL (P 0.05), while SNORD46 did not differ. Stable lentiviral-based overexpression of SNORD46 and 74, U2932 ABC DLBCL demonstrated that both SNORD46 and SNORD74 overexpression impaired growth while SNORD92, the control did not SNORD74 overexpression inhibited pAKT-Ser473, suggesting it could exert its anti-tumor effect by negatively impacting BCR signaling. Since constitutive BCR is the main driver for the pathogenesis in ABC DLBCL, we studied the impact of BCR signaling on SNORD46 and 74 expressions. IgM stimulation downregulated the snoRNAs in U2932 and TMD8 ABC DLBCL cell lines at 1 and 2.5 h poststimulation, with a more substantial effect for SNORD74. Furthermore, the snoRNAs were upregulated in four ABCs and four GCB DLBCLs cell lines exposed to the PI3K/mTOR inhibitor bimiralisib. Bioinformatic analysis indicated the possible binding of SNORD46 and especially of SNORD74 to BCR signaling molecules (SYK, LYN, BTK, PI3Kδ, IRAK4, IRAK1, CARD11), RNA helicases (RHA, DDX21, DDX5) and essential DLBCL proteins (BCL6, IRF4).
Conclusions. SNORD46 and SNORD74 exert tumor suppressor activity in DLBCL cells, possibly as negative regulators of the BCR signaling.

#0464 Chromatin associated long non-coding RNAs involved in dormancy for late recurrence of ER-positive breast cancer.

N. Saitoh, M. Palihati, H. Tachiwana;
The Cancer Institute of JFCR, Koto-ku, Tokyo, Japan

Late recurrence is one of the major problems for hormone receptor-positive breast cancer patients. It is suggested that the risk of recurrence may be maintained by cancer cells that have been already disseminated in the body at surgery. They enter long-term dormancy, thus evade immune surveillance and become resistant to therapies. The detailed molecular mechanism for this process is largely unknown.Nuclear long noncoding RNAs, which are not translated to proteins, often function as epigenetic regulators and determine the phenotype of cells and individuals. We found that a cluster of long noncoding RNAs, ELEANORS, is specifically expressed in ER (estrogen receptor)-positive recurrent breast cancer cells, forms a molecular condensate (RNA cloud) in the nucleus, and activates the *ESR1* gene that encodes ER. ELEANORS define a large chromatin domain, the 0.7 Mb topologically associated domain (TAD), which contains the *ESR1* and three other breast-cancer-associated genes. ELEANORS also regulates the three-dimensional genome architecture. They mediate a long-range chromatin interaction of ESR1 and *FOXO3* genes, which are 42.9 Mb apart, and contribute to their cooperatively activate transcription, equilibrating cell proliferation (*ESR1*) and apoptosis (*FOXO3*). Upon ELEANOR knockdown, the ELEANOR clouds are disappeared, and *ESR1* gene transcription is repressed. Further, the two genes are dissociated and only the *FOXO3* gene remains transcriptionally active, resulting in the induction of apoptosis.Further analysis of clinical specimens revealed that ELEANOR expression in primary tumors correlates with recurrences over 5 years after surgeries, suggesting that ELEANORs are involved in late recurrence. We also found that ELEANOR activates transcription of *CD44,* a breast cancer stem cell marker gene. Cancer stem cell maintenance and equilibration of proliferation and apoptosis by ELEANOR may be involved in long-term tumor dormancy in late recurrence. This study suggests the possibility of ELEANORS as a biomarker to predict late recurrence, as well as a therapeutic target for ER-positive breast cancer.

#0465 Effect of Epstein-Barr virus *lnc-BARTs* on EBV genome maintenance in EBV-associated tumors.

J. Liu, B.-Y. Mok, H. Chen;
The University of Hong Kong, Hong Kong, Hong Kong

Most humans infected with Epstein-Barr virus (EBV) remain asymptomatic throughout the whole life. However, EBV is linked to several human cancers, including Burkitt's lymphoma, Hodgkin's disease, post-transplant lymphoproliferative disorder (PTLD), nasopharyngeal carcinoma (NPC), and gastric carcinoma. Among these EBV-associated tumors, EBV genome is present in 100% of NPC tumor cells. In NPC cells, EBV establishes a latent infection, expressing limited number of viral proteins but elevated levels of non-coding RNAs transcribed from the BamHI-A region of the EBV genome, also known as BamHI-A rightward transcripts (BARTs). The family of EBV BART RNAs includes BART-microRNAs (miRNAs) and long non-coding RNAs (lnc-BARTs). Although various functions of BART miRNAs have been identified, the role of EBV lnc-BARTs remains largely unknown. In this study, we provide evidence demonstrating that lnc-BARTs functions as a regulatory long non-coding RNA, referred to as lnc-BARTs. These lnc-BARTs play keys role in modulating the core networks that maintains EBV latency and promotes NPC oncogenesis through epigenetic mechanisms. Our study found that the apoptosis rate of NPC cells is significantly increased following the knockdown of EBV lnc-BARTs, indicating their anti-apoptotic role in EBV-associated tumors. Mass spectrometry analysis identified several host factors, including transcriptional regulators BRD4 and SC35' interact with EBV lnc-BARTs in NPC cells. RNA-FISH assays showed lnc-BARTs co-localized with BRD4 and SC35 complexes in nuclear s peckles and such interaction were disrupted by JQ1, a BRD4 competitive inhibitor. Binding of lnc-BARTs to BRD4 RNA was confirmed using immunoprecipitation and pulldown assays. ATAC sequencing and transcriptome analyses showed that BART knockdown in EBV-harboring NPC cell line C666-1 led to reduced chromatin accessibility, downregulation of oncogenes, and decreased EBV episome replication and maintenance. Quantitative qPCR and DNA FISH analyses of cell samples treated with shRNA targeting lnc-BARTs or BRD4 reduced EBV copy numbers and EBNA1 RNA expression levels in EBV-infected NPC cells. Finally, ChIP sequencing analysis revealed that lnc-BARTs is critical for BRD4 binding to the oriP region of the EBV genome. These findings support a mechanism by which EBV lnc-BARTs epigenetically regulate host gene expression through functional interactions with elongation regulatory machinery and contribute to the maintenance of EBV latent genome by interaction with BRD4 complex.

#0466 microRNA regulators of neuroendocrine differentiation in metastatic castration-resistant prostate cancer.

D. Asante, S. Nathani, T. J. Lee, A. Sharma, S. Saini;
Augusta University, Augusta, GA

Therapy-induced neuroendocrine prostate cancer (NEPC), an extremely aggressive variant of castration-resistant prostate cancer (CRPC), is increasing in incidence with the widespread use of highly potent androgen receptor (AR)-pathway inhibitors (APIs) via a reversible trans-differentiation process, referred to as neuroendocrine differentiation (NED). The molecular basis of NED is not completely understood leading to a lack of effective molecular markers for its diagnosis. We hypothesized that alterations in key miRNAs drive NED, leading to lineage switching and emergence of NEPC. The aims of our study are: (i) identify key miRNA alterations that occur as PCa cells undergo neuroendocrine differentiation; (ii) develop a miRNA-based classifier for predicting/diagnosing NEPC; (iii) understand the functional role of key miRNA alterations. To systematically investigate the key miRNAs alterations driving therapy induced NED, we performed small RNA-NGS in a retrospective cohort of human metastatic CRPC clinical samples + PDX models with adenocarcinoma features (CRPC-adeno) vs those with neuroendocrine features (CRPC-NE). Further, with the application of machine learning algorithms to sequencing data, we trained a ‘miRNA classifier’ that could robustly classify ‘CRPC-NE’ from ‘CRPC-Adeno’ cases. The performance of classifier was validated in additional cohorts of mCRPC patients acquired from independent sites by employing single model prediction algorithm. We further sought to understand the functional role of these miRNAs by overexpessing in PCa cell lines followed by functional assays. *In vivo* xenograft studies were performed using PC3 cells overexpressing miR-28/control miRNA. We demonstrate for the first time, that lineage switching to NE states is accompanied by key miRNA alterations. Our analysis, measured using receiver operating characteristic (ROC) curves, demonstrated an area under the curve (AUC) value of 0.8318, confirming the robustness of our classifier in distinguishing CRPC-NE from CRPC-Adeno. Furthermore, we identified a select group of 5 miRNAs that were pivotal in distinguishing between these two prostate cancer subtypes. We focused on miR-28-3p, little studied miRNA in prostate cancer. Our *in vitro* and *in vivo* data with prostate cancer cell lines and xenograft model suggests that miR-28-3p acts as a tumor suppressor miRNA in advanced stage prostate cancer. We further found mesenchymal gene Vimentin to be a direct miR-28-3p target. We propose that loss of miR-28-3p promotes epithelial-to-mesenchymal transition (EMT), thereby favoring NED. Our study has important clinical implications and transformative potential as our 'miRNA classifier' can be used as a molecular tool to stratify mCRPC patients into those with/without NED and guide treatment decisions. Further, we identify novel miRNA NED drivers that can be exploited for NEPC therapeutic targeting.

#0467 Genetic ablation of microRNA-10b improves treatment outcomes in mouse models of pancreatic cancer.

K. Kempinska, S. Samuel, S. Rajesh, C. Mallett, L. Sempere;
Michigan State University, East Lansing, MI

Pancreatic ductal adenocarcinoma (PDAC) is a recalcitrant and lethal disease with an overall 5-year survival rate of less than 12%. PDAC is a heterogeneous disease characterized by highly aggressive cancer cells, extensive desmoplastic reaction, and hypovascularity. These unique features endow PDAC tumors with an array of innate resistance mechanisms against standard-of-care (SOC) chemotherapy: gemcitabine/nab-paclitaxel or FOLFIRINOX. Thus, there is clinical need to develop novel targets that enhance treatment efficacy of SOC chemotherapy. microRNA-10b (miR-10b) expression is frequently upregulated in PDAC and correlates with poor outcome. High levels of miR-10b expression within cancer cells correlates with poor treatment response to gemcitabine-containing neoadjuvant chemotherapy and poor overall clinical outcome. We and others reported that miR-10b exerts cancer cell-intrinsic pro-survival, anti-apoptotic, and pro-metastatic functions via downregulation of key target genes (i.e., BIM, PTEN, TIAM1). We hypothesize that upregulation of miR-10b expression is a chemoresistance mechanism to increase cell survival and inhibit apoptosis in PDAC. To test this hypothesis, we generated a KPC model ($Kras^{G12D}$-driven, p53-deleted by Pdx1-Cre) with global *Mir-10b* gene knockout (Mir-10bKO). Animals were recruited when their tumor volume reached 200 mm^3 by multi-mouse MR imaging and were randomly assigned to control or treatment groups (100 mg/kg of gemcitabine q4d). Tumor growth was monitored by weekly MR imaging sessions throughout the duration of the treatment. Untreated KPC;Mir-10bKO animals survived several weeks longer than untreated KPC animals (21.7 vs. 18 weeks, $p = 0.056$), suggesting a weak but detectable tumor promoting role of miR-10b. Remarkably, loss of miR-10b activity enhances treatment response to gemcitabine and significantly prolongs survival in this KPC model. Treated KPC animals lived only 5 weeks longer than untreated KPC (23 vs 18 weeks, $p = 0.015$), whereas KPC;Mir-10bKO lived 9 weeks longer (27 vs 18 weeks, $p = 0.002$). Notably, we observed a more durable response in treated female KPC;Mir-10bKO animals ($n = 4$) compared to any other experimental group ($n > 5$). We are currently performing tissue and molecular analyses to identify direct target genes involved in chemoresistance and sex-specific modulation of treatment response.

#0468 Associations of circulating miRNAs with pancreatic cancer risk differ by years between blood collection & and cancer diagnosis.

H. Cai[1], V. Setiawan[2], X. Guo[1], J. Wu[1], R. Stolzenberg-Solomon[3], C. Zhu[4], Y.-T. Gao[5], J. Berlin[1], F. Ye[1], Q. Cai[1], W. Zheng[1], X.-o. Shu[1];
[1]Vanderbilt University Medical Center, Nashville, TN, [2]University of Southern California, Los Angeles, CA, [3]NIH, Bethesda, MD, [4]NCI, Bethesda, MD, [5]Shanghai Jiao Tong University, Shanghai, China

Pancreatic adenocarcinoma (PDAC) is one of the most fatal cancers and currently used biomarkers for PDAC diagnosis are not adequate for early detection. Therefore, new biomarkers for PDAC early detection are urgently needed. We conducted a large-scale study to prospectively evaluate the association of circulating miRNAs with PDAC risk. Specially, we aimed to examine whether the associations of miRNAs expression levels and changes of those levels from blood collection to cancer diagnosis (BCCD) with PDAC risk. We used pre-diagnostic plasma samples of 1307 PDAC cases from 5 cohort studies (290 from the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial, 395 from the Shanghai Women's and Men's Health Studies, 154 from the Southern Community Cohort Study, and 468 from the Multiethnic Cohort). Cancer free controls (n=1307) were selected and individually matched to index cases in each cohort. All miRNAs were measured by the NanoString nCounter Analysis System using the Human v3 miRNA Expression panel (798 miRNAs total). Data were pooled and quantile normalized prior to analysis. Associations of circulating miRNAs with PDAC risk were assessed by odds ratio per decile change in miRNA levels using conditional logistic regression. Fold-change of miRNA for cases versus controls by BCCD was analyzed via linear regression. Median time of BCCD was 7.13 years (range: 0.03-19.61 years). We first conducted the association analysis stratified by BCCD: < 5 years, 5-10 years, and >10 years. We found 20 miRNAs were significantly associated with PDAC risk in the <5 years after FDR correction. In the analysis of regressing fold-change of these 20 miRNAs on BCCD, we found the fold change of miR-155-5p was inversely associated with BCCD (β=-0.04, P<0.01), i.e., the case-control difference was larger when blood was drawn closer to PDAC diagnosis, suggesting its potential utility as disease biomarkers for early detection. Conversely, the fold-change of miR-93-5p (β=0.04, P=0.01), miR-223-3p (β=0.03, P=0.02), let-7i-5p (β=0.03, P<0.01), and miR-191-5p (β=0.05, P<0.01) were positively associated with BCCD, i.e., the case-control difference increased with an increasing the time interval of BCCD, indicating they are more likely biomarkers for PDAC risk. Ingenuity pathway analyses of these five significant miRNAs revealed that they were significantly enriched in ribonucleotide reductase signaling pathways at p<0.05. Notably, the silencing of ribonucleotide reductase M2 subunit suppresses tumorigenesis in pancreatic cancer by deactivating the PI3K/AKT/mTOR pathway, further supporting our findings.
Findings of this large-scale multiethnic study suggest that changes in circulating levels of let-7i-5p, miR-155-5p, miR-93-5p, miR-191-5p, and miR-223-3p may help identify individuals at an elevated risk of developing PDAC, allowing for screening tests and close surveillance.

#0469 PIWI-interacting RNA 50485 (piRNA-50485) is a novel lung tumor suppressor.

M. E. Reeves, Y. G. Amaar;
Loma Linda University and VA Loma Linda Healthcare System, Loma Linda, CA

Introduction: It is crucial to identify new driver genes and associated downstream pathways to facilitate the development of targeted therapies to effectively treat late-stage and metastatic lung cancer. One pathway involves the Ras association domain family 1 (*RASSF1*) gene which encodes multiple isoforms. Our laboratory has discovered that the RASSF1C isoform exhibits functional characteristics of an oncogene. We discovered that RASSF1C modulates the expression of PIWI-(Drosophila)-like 1 *(*PIWIL1, a stem cell renewal gene), as well as novel PIWI-interacting RNAs (piRNAs), which are regulators of the stem cell phenotype and have been linked to oncogenesis. While studying this pathway, we have identified novel piRNAs that are modulated by RASSF1C in non-small cell lung cancer (NSCLC) cells that appear to act as oncogenes or tumor suppressors.
Methods: We conducted a global microarray screen to identify RASSF1C PIWI-interacting RNA (piRNA) gene targets. Several piRNA genes that are up- and down-regulated by RASSF1C were identified and the expression of selected up-regulated and down-regulated target genes were confirmed by RT-PCR. We evaluated the impact of selected piRNAs on lung cancer cell proliferation and migration *in vitro*. We also assessed the expression of the validated piRNA target genes in lung tumor and matched normal tissues. Host and target genes for specific piRNAs were identified using a piRNA database (piRNAdb.org).
Results: Among the down-regulated piRNAs, we found that restoring piR-50485 expression drastically decreased lung cancer cell proliferation and invasion, suggesting that piR-50485 could be a potent inhibitor of lung cancer cell growth and progression. Consistent with this, we found that piR-50485 expression is significantly down-regulated in about 60% of human lung cancers. We also identified that the *ZHX3* gene (a transcription repressor), which is down-regulated in human lung cancers, is the host gene for piR-50485. In addition, we identified the *ZNF618* gene (a transcription co-regulator) that is up-regulated in lung tumor tissue, is a piR-50485 target gene. Consistent with this, treatment of lung cancer cells with piR-50485 mimics resulted in a significant decrease of ZNF618 protein levels, cell proliferation, and migration. Further, increased expression levels of ZHX3 are associated with higher lung cancer patient survival, while increased ZNF618 levels are associated with lower survival. Our novel findings suggest the hypothesis that the *piR-50485-ZHX3-ZNF618* gene axis could negatively impact lung cancer cell growth and progression.
Conclusion: Exploring the impact of the *piR-50485-ZHX3-ZNF618* gene axis on lung cancer growth is a novel concept about which nothing is currently known. We are studying piR-50485 to determine if it can be an effective therapy for lung cancer metastasis, and whether it provides important prognostic information about lung cancer outcomes.

#0470 AR-induced miRNA124-3p.2 suppresses the metastasis-promoting factor CCL2.

S. Aoyama, K. Izumi, A. Mizokami;
Department of Integrative Cancer Therapy and Urology, Kanazawa University Graduate School of Medical Science, Kanazawa-shi, Japan

Objective: The standard treatment for advanced prostate cancer is androgen deprivation therapy that blocks androgen receptor (AR) signaling, but this therapy becomes ineffective within a few years, resulting in castration-resistant prostate cancer. We have previously shown that blockade of AR signaling induces CCL2 and activates cancer cells through an autocrine mechanism, but why AR blockade induces CCL2 secretion has not been elucidated. Micro RNAs (miRs) are endogenous non-coding RNAs that regulate the translation of various proteins. In this study, we investigated whether miRs are involved in CCL2 induction.
Subjects and Methods: We used miRNA PCR Plate Array and Target Scan (https://www.targetscan.org) to search for miRs that are controlled by AR and bind to and repress the CCL2 gene. We knocked down the AR of human prostate cancer cell lines LNCaP and C4-2B with siRNA (siAR) and examined the expression of target miRs and CCL2. siAR-transfected LNCaP and C4-2B were transfected with target miR mimic and CCL2 expression was examined. siAR-transfected LNCaP, C4-2B, and C4-2B were transfected with target miR mimic and CCL2 expression was examined. siAR-transfected LNCaP and C4-2B were transfected with target miR mimic and CCL2 expression was examined. The target miR mimic was introduced into them, and the changes in migration ability were evaluated.
Results: miR-124-3p.2 was extracted as a candidate from miRNA PCR Plate Array and Target Scan. miR-124-3p.2 expression was upregulated in both LNCaP and C4-2B when DHT was added and downregulated when CCL2 was added. In siAR LNCaP and C4-2B, the expression of CCL2 was decreased when miR-124-3p.2 mimic was introduced. Furthermore, in siAR-transfected LNCaP, C4-2B, the introduction of miR-124-3p.2 mimic suppressed the migration.
Conclusion: AR suppresses CCL2 via miR124-3p.2. miR124-3p.2-mediated regulation of CCL2 may be a new therapeutic target for advanced prostate cancer.

#0471 Attenuation of circulating miR-17-5p, miR-20b-5p, and miR-106a-5p in low-risk prostate cancer patients following proton therapy.

J. Velasquez[1], C. Bryant[2], N. Mendenhall[2], L. Ricks-Santi[1];
[1]University of Florida, Gainesville, FL, [2]University of Florida Health Proton Therapy Institute, Jacksonville, FL

Introduction: Liquid biopsies offer a novel approach to diagnose, predict cancer outcomes, and monitor treatment response by analyzing tumor-derived substances. Circulating cell-free microRNAs (miRNAs) show clinical promise as biomarkers within prostate cancer (PCa) and have been implicated with PCa prognosis and outcomes. However, their potential for monitoring and assessing radiotherapy (RT) treatment response remains understudied. Understanding miRNA expression changes during RT is crucial, as they impact RT efficacy by directly affecting genes and proteins within RT-response pathways.
Aim: This study aimed to profile the expression of three oncogenes, miR-17-5p, miR-20b-5p, and miR-106a-5p and to determine their association with PCa risk groups in patients receiving proton therapy (PT).
Patients and Methods: Plasma was obtained from the University of Florida Health Proton Therapy Institute Outcomes Tracking Protocol biobank. Plasma was collected from men diagnosed with localized PCa without metastatic disease at three time points: prior to PT (PRE-PT), at 4 weeks following the start of PT (4WKSPD1), and at 8 weeks following the start of PT (8WKSPD1). The pilot study consisted of 38 patients, with 23 categorized as low-risk and 15 categorized as high-risk for PCa. MiRNA expression levels were evaluated using reverse transcription-polymerase chain reaction and quantified using the Livak method.
Results: The study revealed a downregulation of miR-17-5p in response to PT, with median gene expression levels decreasing from 0.73 at PRE-PT to 0.587 at 8WKSPD1. Low-risk PCa patients also showed distinct miRNA expression changes with all three miRNAs (miR-17-5p, miR-20b-5p, and miR-106a-5p) downregulated from 0.953, 1.037, and 1.010 at PRE-PT to 0.398, 0.216, and 0.298 at 8WKSPD1, respectively. Statistical analysis using a Kruskal-Wallis test followed by a Dunn's post-hoc test identified significant differences ($p=0.035$) specifically between PRE-PT and 8WKSPD1 for miR-17-5p.
Conclusion: The study revealed that PT led to a time-dependent reduction in miRNA levels, indicating a higher responsiveness in low-risk compared to high-risk PCa patients. This differential response highlights miR-17-5p, miR-20b-5p, and miR-106a-5p as potential PT response biomarkers, with clinical implications for personalizing PCa treatment. These results underscore the necessity for further validation of these miRNAs to maximize their clinical utility.

#0472 Long non-coding RNA MIR31HG-derived circRNA enhances the oncogenicity of oral carcinoma.

C.-H. Chou, H.-F. Tu, K.-W. Chang, S.-C. Lin;
National Yang-Ming University, Taipei, Taiwan

Introduction: Oral carcinoma (OC) represents a significant health challenge, with the role of non-coding RNAs, particularly microRNAs and long non-coding RNAs (LncRNAs), being well-established in its progression. However, the implications of circular RNAs (circRNAs) in this context are less well understood, presenting a notable gap in current research. Our study focuses on the MIR31HG LncRNA, identified as crucial in OC, particularly its role in producing circRNA, as evidenced by sequencing. This specific MIR31HG-derived circRNA, designated 31HGcircR, which contains a potential open reading frame (ORF), and may demonstrate phenotypic significances. Alterations to 31HGcircR, either through knockout or ORF mutation, result in remarkable phenotypic changes, highlighting its potential importance in the pathogenesis of OC.
Methods: We implemented 31HGcircR overexpression in OC cell lines, utilizing the TetOff system for gene expression control. CRISPR/Cas9 was employed for gene knockout, and siRNA for gene knockdown. Gene expression was quantified using qPCR. Additionally, the BaseScope assay was used to label and detect the spatial expression of overexpressed 31HGcircR within the cells. Assays to assess cell proliferation, invasion, migration, anchorage-independent growth (AIG), and clonogenicity were conducted.
Results: The findings revealed specific junctions of 31HGcircR and varied expression levels across different OC cell lines. There was a significant correlation among the expression of 31HGcircR, MIR31HG and miR-31-5p. Notably, the knockdown of 31HGcircR led to pronounced inhibition of cell growth, migration, invasion, AIG, and clonogenic activity. Conversely, overexpression of 31HGcircR or its ORFs augmented invasion and clonogenic potential in certain cell lines. The TetOff system demonstrated that minimal concentrations of Doxycycline effectively suppressed 31HGcircR expression, with reversible effects upon removal. Knocking out 31HGcircR resulted in reduced invasion and clonogenic capabilities.
Conclusion: This study provides clues demonstrating the oncogenic roles of 31HGcircR in OC, which simulate the functions of MIR31HG or miR-31-5p. The changes in cell phenotypes following 31HGcircR manipulation suggest its potential as a therapeutic target or biomarker in OC. These findings offer valuable insights, contributing to the evolving understanding of circRNAs in cancer research and potential treatment avenues.

#0473 PVT1 exon 9 overexpression induces AR null phenotype and cellular reprogramming in prostate cancer.

R. E. Sexton-Bonacci, C. Udekwu, B. Boylu, O. O. Ogunwobi;
Michigan State University, East Lansing, MI

Plasmacytoma variant translocation 1 (PVT1) is an oncogenic long-noncoding RNA (lncRNA) gene located directly downstream of MYC on chromosome 8q24. PVT1 is an oncogene overexpressed in prostate cancer (PCa) and can promote oncogenesis by altering gene expression directly or acting as a noncoding RNA sponge. Beyond functioning as a lncRNA, PVT1 gene encodes six microRNAs that each have independent functions. Our group identified overexpression of PVT1 exon 9 in PCa samples derived from men of African Ancestry and overexpression may explain why this population group experiences more aggressive disease. We overexpressed PVT1 exon 9 in RWPE1 prostate epithelial cells (RWPE1_ex9) and found enhanced migration and invasion compared to empty vector (RWPE1_ev). Implantation of RWPE1_ex9 cells into mice led to the formation of tumors with the neuroendocrine PCa (NEPC) phenotype that was histopathologically confirmed. RNA-sequencing analysis of PVT1 exon 9 overexpression showed significant (p-value < 0.05) upregulation of 141 genes. The majority of pathways impacted by PVT1 exon 9 overexpression were interferon type 1 signaling (*RSAD2, CMPK2)*, developmental NOTCH signaling (*HES7)*, cargo-transport (*STX16*) and tumor microenvironment promoting factors (*HS3ST3A1*). We found loss of androgen receptor (AR) expression at mRNA and protein levels in RWPE1_ex9 cells, a hallmark of NEPC, which further supports our hypothesis that PVT1 exon 9 overexpression plays a role in NEPC development. Validation of RNA-sequencing confirmed upregulation of *RSAD2, CMPK2, STX16, HES7* and *HS3ST3A1* within RWPE1_ex9 cells compared to RWPE1_ev and RWPE1 wild-type, suggestive of cellular reprogramming of prostate epithelial cells. We further analyzed expression profile in a novel circulating tumor cell model of castration-resistant 22RV1 cells (C22OH) and found enhanced expression of PVT1 exon 9, suppression of AR, phosphorylation of AR serine residue 308 and enhanced CDK11 activity compared to the primary 22RV1 cell line T22OH suggestive of a cell-cycle mediated regulatory mechanism. We further found enhanced expression of chromogramin A in the C22OH cell line, a marker of NEPC. These results suggest PVT1 exon 9 overexpression may play a critical role in NEPC development from normal epithelial cells via cellular reprogramming as well as facilitating a transition to NEPC from a castration resistant phenotype. PVT1 exon 9 may be a useful predictive biomarker that can identify populations which are likely to have disease progression from castration resistance to NEPC and further highlights the need to identify therapeutic strategies to target PVT1 exon 9 overexpression.

CHEMISTRY: Basic and Applied Nanotechnology and Therapeutics

#0477 Tumor treating fields (TTFields) targeted self assembling nanoparticles for pancreatic cancer treatment: *In vitro* and *in vivo* assessment.
P. P. Desai, S. Prabhu;
Western University of Health Sciences, Rancho Cucamonga, CA

Tumor Treating Fields (TTFields) is a novel, non-invasive and safe treatment modality, which is prescribed to be used in conjunction with classical anticancer chemotherapeutic drugs. TTFields when used alone are safe, but their use in combination with classical chemotherapy continues to offer drug related adverse reactions which ultimately impacts the patient compliance. To address this challenge, we earlier reported meticulously optimized self-assembling cationic-anionic polymer nanoparticles (S-CAP NPs) with average particle size of about 200 nM, encapsulation efficiency of 55-65 % and sustained drug release over 60 h. We also reported that, TTFields were capable of destabilizing the S-CAP NPs leading to targeted drug release. The results were also corroborated with in vitro cytotoxicity and colony formation studies in presence of TTFields using multiple pancreatic cancer cell lines. After establishing the proof-of-concept, the objective was to assess the in vitro cellular uptake of S-CAP NPs. For this, fluorescent dye loaded S-CAP NPs were developed and subjected to cellular uptake analysis. The in vitro cellular uptake studies confirmed the enhanced uptake of S-Cap NPs by passive diffusion in the pancreatic cancer cell lines compared to normal pancreatic epithelial cell line. The studies corroborated preferential cellular uptake of S-Cap NPs by the pancreatic tumor. Among all the formulations, the chitosan- bovine serum albumin S-CAP NPs was most optimum and was used for in vivo safety studies. For this, in vivo acute and repeated dose 28-day toxicity of the optimum placebo S-CAP NPs was conducted in Sprague Dawley rats (Western University of Health Sciences Protocol #R20IACUC031) and OECD guidelines. The in vivo studies showed a LD50 value above 2000 mg/kg and NOAEL value of 1000 mg/kg. These high doses safety of S-CAP NPs confirmed the potential of this approach for future preclinical efficacy studies followed by clinical translation. Lastly, the in vitro stability studies were conducted as per the ICH guidelines for a period of 36 months and the formulations were concluded to be stable. The tumor targeting potential, in vivo safety and stability of S-CAP NPs, establish their translational potential for TTFields triggered targeted drug release in cancer treatment. This approach will not only reduce the adverse effect associated with combination of TTFields and chemotherapy but can also be explored as a platform technology for management of other cancers. This study is supported by AACR-Novocure tumor treating fields research fellowship.

#0479 Enhanced payload delivery for acute myeloid leukemia treatment through CD37-targeting DNA nanobots.

N. Vantangoli[1], **P. D. Halley**[2], J. R. Spitzner[2], J. C. Byrd[3], K. T. Larkin[4], C. E. Castro[1], C. R. Lucas[2];
[1]The Ohio State University, Columbus, OH, [2]DNA Nanobots, LLC, Columbus, OH, [3]University of Cincinnati, Cincinnati, OH, [4]The Ohio State University Comprehensive Cancer Center, Columbus, OH

Acute Myeloid Leukemia (AML) treatment faces considerable challenges, in particular the delivery of therapeutics with sufficient potency and specificity. Traditional Antibody-Drug Conjugates (ADCs) offer a strategic approach to cancer therapy by combining the targeting capabilities of monoclonal antibodies with the cell-killing effect of cytotoxic drugs. However, the limitations in drug-to-antibody ratio (DAR) and the challenges in controlling the release kinetics have often hindered their therapeutic window suggesting novel approaches are necessary. Our approach integrates DNA nanobot technology to facilitate targeted delivery of anthracycline agents directly to CD37-expressing leukemic cells. CD37, a tetraspanin superfamily antigen, has shown promise as a target for AML due to its selective expression on immune cells and favorable internalization properties. By harnessing DNA origami assembly techniques, we developed a customizable platform capable of accommodating a significantly higher payload of chemotherapeutic agents than traditional ADCs. This increased payload potential, paired with the precision targeting of CD37, presents a potent therapeutic strategy with the possibility of reduced systemic toxicity. Here we present preclinical evidence demonstrating targeted delivery of our DNA nanobot drug delivery device and anthracycline payload to $CD37^+$ AML target cells *in vitro*. In addition, we show targeted efficacy *in vitro* and *in vivo* of our anthracycline-loaded DNA nanobot-enabled delivery system, which significantly outperformed free anthracycline in AML target cells. Collectively, our findings suggest an improvement in the therapeutic index of anthracycline and antimitotic agents as well as the ability to combine multiple drug pathways in a single delivery device. The implications of this work extend beyond AML, offering a versatile platform that could revolutionize ADC chemistry and targeted drug delivery. We propose that our DNA nanobot delivery system signifies a pivotal advancement in the field of targeted cancer therapy, with the potential to overcome longstanding barriers in the treatment of AML and potentially other malignancies.

#0480 Nanotherapeutic strategies to improve targeted radionuclide therapy.

D. Pal, M. T. Gonzaleza, A. N. Bibleb, B. Sanders, A. Plechaty, O. Kirpekar, M. Podar, S. M. Davern;
Oak Ridge National Laboratory, Oak Ridge, TN

Cancer is a leading cause of death worldwide. Several multidisciplinary approaches exist for cancer treatment, including radiotherapy and chemotherapy. Radiotherapy uses high-energy radiation to kill cancer cells; chemotherapy inhibits cancer cell proliferation and often kills cells by targeting the cell cycle. Resistance to radiotherapy and chemotherapy is a key determining factor in the outcome of therapeutic efficacy. Conventional nontargeted radiotherapy also affects distant nonirradiated cells, leading to DNA damage and changes in the cell cycle that are often linked to secondary carcinogenesis in patients. In recent years, targeted radionuclide therapy (TRT) has emerged as a promising personalized treatment strategy that delivers cytotoxic levels of radiation directly and specifically to cancer cells. Among radioisotopes,^{225}Ac exhibits desirable properties for TRT: multiple α-particle emission and high cytotoxicity. One of the challenges with ^{225}Ac is the nonspecific toxicity caused by the release and relocation of its decay daughters. Different approaches have been proposed to prevent the relocation of decay daughters, including nanoparticles. Nanoparticles have been pursued as a promising delivery vehicle of α-emitting radioisotopes to the tumor site. Here, we show specific targeting of Her2-positive breast cancer cells with ^{225}Ac-radiolabeled lanthanum orthovanadate (LaVO4) nanoparticles. Nanoparticles' surfaces were functionalized to improve biocompatibility and conjugated to target cancer cells, respectively. Cellular uptake and localization of these engineered nanoparticles were analyzed by a Confocal microscope and IncuCyte live cell analysis system. Results confirm its localization in the nucleus following the endolysosomal path, enhancing the nanoparticles' effectiveness as a delivery vehicle for α-emitting radioisotopes with the potential of increased treatment efficacy. Upon addition of cancer-targeting ligands, these nanoparticles can achieve higher efficiency by delivering the radioisotope to the tumor cells with a potential of safe encapsulation of all α-emitters in the decay chain. The anticancer efficiency of ^{225}Ac-radiolabeled nanoparticles was demonstrated by a dose-dependent effective killing of 3D breast cancer spheroids using both IncuCyte live imaging and the cell survival assays. Ultimately, the results of this study will be crucial in determining the future use of targeted radiolabeled nanoparticle-based delivery systems as an approach for more efficacious cancer treatment.

#0481 Proteomimetic polymers limit tumor growth in multiple models via potent antigen-specific T cell activation.

M. Wang[1], M. Choi[2], B. Zhang[2], N. Gianneschi[1];
[1]Northwestern University, Evanston, IL, [2]Northwestern University, Chicago, IL

Background: Patient-specific cancer vaccines derived from tumor antigen have been explored as a promising therapeutic strategy, however, challenges delivering vaccine components in a coordinated fashion to elicit antitumor responses remain. To overcome these, we utilize a novel nanoplatform called the Protein-Like Polymer (PLP), which allows for sustained and targeted delivery of tumor antigens in conjunction with adjuvants.
Methods: PLPs containing peptide antigens were synthesized via ring-opening metathesis polymerization (ROMP) and characterized. A library of compounds with different sidechain linkage chemistries, degrees of polymerization (DP), and inclusion/exclusion of Oligo-ethylene glycol (OEG) were made to determine design rules for immune activation. Cell uptake and functional assays using payload-specific T Cells were conducted. Immunization in three independent tumor models was done to show generalizability. Ability of PLPs to co-deliver adjuvants was tested by electrostatically coupling small molecule STING agonist, 2'3' cGAMP.
Results: Conjugating peptide antigens to the polymer via a cleavable disulfide linkage, which reduces intracellularly in APCs, resulted in increased endosomal localization, higher levels of induced T cell proliferation, cytokine production, and expression of activation markers in CTLs and APCs. Incorporating a diluent amount of OEG side chains reduced enzymatic degradation while increasing immunogenicity and uptake. Additionally, increasing the DP, and therefore the density of antigen side chains, further improved vaccine efficacy and resistance to proteolysis. Antigen-PLP conjugates enhanced dendritic cell activation and T-cell response only when paired with cells from their cognate system, with no activity in immune cells not expressing receptors for the payload demonstrating antigen-specificity. Mice bearing established B16F10, MC38, or TC-1 tumors treated with PLPs containing gp100, adpgk, or E7 respectively all showed increased survival times, reduced tumor burden with corresponding changes in immune cell profiles, and immunological memory upon rechallenge. Impressively, mice treated with STING-PLP complexes had significantly smaller tumors vs control at day 14 (0.038g vs 0.76g; $p < 0.0001$) and allowed for subcutaneous administration of 2'3' cGAMP, which traditionally requires intratumoral injection. Studies on the effects of vaccinating with pools of neoantigens multiplexed onto one PLP are ongoing.
Conclusion: This work validates the ability of PLPs to overcome major limitations in cancer vaccine development. The modularity of the platform allows for complex nano-architectures including systems capable of delivering challenging compounds, ie small molecule STING agonists, subcutaneously through electrostatic coupling, highlighting its potential to revolutionize cancer vaccinology.

#0482 Advancing treatment for metastatic triple negative breast cancer: Liposomal oncolytic adenovirus as a novel neoadjuvant therapy.

J. R. Shah, T. Dong, A. Phung, S. L. Blair, O. Aisagbonhi, W. C. Trogler, A. C. Kummel;
University of California San Diego, La Jolla, CA

Introduction: Adenovirus type-5 (Ad) is considered a prominent viral vector in cancer therapy due to its modifiability for the selective lysis of cancer cells. However, challenges are posed in Ad delivery to cancers lacking coxsackievirus and adenovirus receptors (CARs). In response to this limitation, Ad-encapsulated DOTAP-folate liposomes were developed, which improved Ad delivery and heightened therapeutic efficacy through membrane fusion and folate receptor-mediated endocytosis.
Methods: The 4T1 mammary carcinoma model, a CAR-negative triple-negative breast cancer (TNBC) cell line (ER-, PR-, HER2-), resistant to adenoviral infection, was utilized for studying the comparative in vitro transduction of green fluorescent protein (GFP)-expressing Ad (Ad-GFP). The study assessed Ad-GFP with and without DOTAP-folate liposomal encapsulation at a multiplicity of infection (MOI) of 50. Additionally, an oncolytic adenovirus, Ad-hTERT, with a human telomerase promoter, underwent liposomal encapsulation. CAR-negative 4T1 GFP-expressing cells and CAR-positive MDA-MB-231-GFP human breast adenocarcinoma TNBC cells were transduced in vitro at MOI 100 with Ad-hTERT, both with and without DOTAP-folate liposomal encapsulation.
Results: CAR-negative 4T1 cells exhibited superior Ad-GFP transduction when encapsulated in DOTAP-folate liposomes, compared to the unencapsulated form ($p < 0.001$). For oncolytic adenovirus Ad-hTERT, encapsulation resulted in 100% cell lysis within 24 hours in 4T1-GFP cells, contrasting with 13% with unencapsulated Ad-hTERT ($P < 0.0001$). In CAR-positive MDA-MB-231-GFP TNBC cells, encapsulated Ad-hTERT showed enhanced efficacy, resulting in 100% cell lysis within 24 hours compared to 75% with unencapsulated Ad-hTERT ($P < 0.001$).
Discussion: DOTAP-folate liposomal encapsulation enhances the efficacy of oncolytic Ad-hTERT in both CAR-negative and CAR-positive TNBC cells, establishing it as an optimal therapy for tumors with CAR heterogeneity. Ongoing in vivo studies with Balb/C immune-competent mice and the 4T1 tumor model will assess the effectiveness of encapsulation through intratumoral administration. This approach may extend the recurrence-free period post-surgical tumor removal.

#0483 Unraveling the impact of cancer cell derived membrane and cytosolic proteins using synthetic small extracellular vesicles.

Y. Chen[1], R. R. Lopez[1], T. Tsering[1], C. Zouggari Ben El Khyat[2], V. Nerguizian[2], J. V. Burnier[1];

[1]Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [2]Ecole de technologie superieure, Montreal, QC, Canada

Background: Extracellular vesicles (EVs) are couriers in cell-cell communication. Evidence suggests that EV biology, from cargo packing, biodistribution, to cell uptake is a non-random and well-orchestrated process. Substantial efforts have been devoted to studying the pathological roles and therapeutic potential of EVs. It is speculated that surface properties, such as membrane proteins, mediate the interaction between EVs and recipient cells, while the enclosed "messages" exert downstream effects. This concept is exemplified in cancer metastasis, where cancer cell-derived EVs were shown to establish pre-metastatic niches and guide cancer organotropism. We propose selectively loading cancer cell membrane and cytosolic proteins into synthetic vesicles (SVs) like liposomes. This approach allows for the isolated study of individual factors, in contrast to the complexity of naturally occurring EVs.

Methods: Cellular membrane and cytosolic proteins were extracted separately from a cancer cell line (MP41) (Mem-PER^{TM} Plus kit). Empty-SV, Mem-SV (with membrane proteins), Cyto-SV (with cytosolic proteins), and Complete-SV (with both) were synthesized in a 3D-printed microfluidic chip and subsequently dialyzed (1000 KDa) overnight. The volume of protein buffer was controlled in all SV syntheses. EVs were isolated from the conditioned medium by ultrafiltration (Amicon) followed by ultracentrifugation. The size (Nanosight), zeta potential (ZetaView), and morphology (Transmission Electron Microscopy) of SVs and EVs were analyzed. Proteins incorporated into SVs were validated by stain-free gel, western blot, and CytoFLEX. SVs and EVs were stained by sp-DiIC18 fluorescent dye. The number of fluorescent particles was quantified (CytoFLEX) and controlled in cell uptake analysis on hepatocytes (IHH) and fibroblasts (BJ) (Incucyte).

Results: All SVs were successfully synthesized with a mean size of ~100 nm. The zeta potential of both Mem-SV (-27.03 mV) and Complete-SV (-24.78 mV) is close to MP41 EVs (-26.01 mV) ($P > 0.05$) and are more negative than Empty-SV (-11.30 mV) and Cargo-SV (-13.38 mV) ($P < 0.05$). Total protein incorporation efficiency was estimated to be ~30%. The relative level of specific proteins (e.g. integrin av, TSG101) in Mem-SV and Cyto-SV matched the level in the raw membrane and cytosolic proteins by western blot. Integrin avb5 was detected on the surface of Mem-SV. Membrane and cytosolic protein incorporation increased the uptake efficiency of SVs compared to Empty-SVs, and the efficiency varied with cell type and protein content.

Conclusion: In this study, we demonstrate that membrane and cytosolic proteins differentially impact the physical (zeta potential) and functional (cellular uptake) properties of SVs. Investigating these distinct roles could further our understanding of cancer EV biology, as well as advance drug delivery systems.

#0484 Enhancing therapeutic responses in NSCLC using iron-oxide nanoparticles combined with pharmacological ascorbate.

M. Singhania, M. S. Petronek, C. F. Pulliam, K. A. Mapuskar, A. Zaher, D. R. Spitz;
University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA

High dose Vitamin C (pharmacological ascorbate; P-AscH$^-$ > 20 mM plasma levels) given intravenously (I.V.), has made a remarkable re-emergence as an adjuvant to combined modality approaches in cancer therapy. P-AscH$^-$ can be readily oxidized in the presence of redox active metals (i.e., P-AscH$^-$ serves as an iron reducing agent), which can result in increased fluxes of H_2O_2. This chemical phenomenon allows for the tumor-selective enhancement of chemo-radiation in NSCLC. We hypothesized that enhancing labile Fe^{2+} in cancer cells using iron-oxide nanoparticles (ferumoxytol, FMX) can increase the effectiveness of P-AscH$^-$ in enhancing cancer cell sensitivity to chemo-radiation in NSCLC by increasing H_2O_2 production. To test this hypothesis, we performed clonogenic cell survival assays in-vitro. To test the role of H_2O_2 in the combined effect of P-AscH$^-$ and FMX, we developed lentiviral-based doxycycline-inducible overexpression models for catalase, and to determine the changes in Fe, we used fluorescent probes that specifically detect changes in labile Fe^{2+}. Results from these experiments showed FMX enhanced clonogenic cell killing in NSCLC. Furthermore, catalase overexpression inhibited this effect, suggesting that enhanced H_2O_2 production plays a central role in the additive effect of P-AscH- and FMX. Finally, staining the cells with the fluorescent iron probes showed that FMX enhanced labile Fe^{2+} in cells treated with P-AscH$^-$. These studies continue to support the hypothesis that H_2O_2 plays a significant role in P-AscH$^-$ toxicity in cancer cells that can be exacerbated using iron oxide nanoparticles. Future studies will test these findings in-vivo using preclinical xenograft models.

#0485 Cancer killing effect of ultrasound-responsive mechanophore nanoparticles.

J. Wang, S. Zhao, J. Yi, Y. Sun, M. Agrawal, K. Li, J. S. Moore, M. Oelze, **Y.-S. Chen**;
University of Illinois at Urbana-Champaign, Urbana, IL

Radiotherapy, a mainstay in cancer treatment, often inadvertently damages healthy tissues while targeting malignancies with free radicals. As an alternative, Photodynamic Therapy (PDT) employs non-ionizing photons to generate reactive oxygen species (ROS) in tumors, offering precise targeting with minimal long-term effects. However, its efficacy is constrained to superficial tumors due to the limited penetration of light. Sonodynamic Therapy (SDT), an evolution of PDT, uses ultrasound to enhance tissue penetration while maintaining its non-invasive nature. Initial SDT studies suggest that ultrasound can activate PDT's photosensitizers to produce ROS, offering a potential pathway for tumor eradication. Nevertheless, the principal mechanisms of ROS generation in SDT, namely pyrolysis and sonoluminescence, raise concerns about potential tissue injury. In our research, we introduce an innovative approach employing mechanophores into nanoparticles. Mechanophores, molecular units within polymers sensitive to mechanical stress, undergo transformations under such conditions, including the release of small molecules or free radicals. We have developed injectable nano-sized mechanophore nanoparticles, designed to respond to high-frequency ultrasound (>100 kHz) more efficiently and with reduced energy requirements. This study focuses on nano-engineering the echogenicity of these mechanophore nanoparticles to enhance ROS generation. When agitated with focused ultrasound (FUS), these nanoparticles successfully induced ROS, leading to significant cell death, a result not observed with FUS alone in the absence of nanoparticles. In vivo experiments using mouse orthotopic cancer models demonstrated these nanoparticles' ability to inhibit tumor growth effectively. Under biocompatible ultrasound conditions, the nanoparticles cause effective cancer cell eradication with minimal impact on surrounding healthy tissues. Our findings not only introduce a novel approach to cancer treatment but also pave the way for broader applications of mechanophore nanoparticles in biomedicine. This study underscores the potential of ultrasound-activatable mechanophore nanoparticles as a versatile, effective, and safe option for cancer therapy.

#0486 Paclitaxel nanoformulation attenuates pancreatic tumor desmoplasia and alter tumor immune responses.

V. K. Kashyap, G. P. Darkwah, N. Chauhan, M. Sikander, E. N. H. Ghali, M. Kolli, B. B. Hafeez, M. M. Yallapu, S. C. Chauhan;
University of Texas Rio Grande Valley, McAllen, TX

Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal types of cancer with a 5-year survival rate of less than 13% due to the lack of effective diagnostic/therapeutic modalities. Paclitaxel (PTX) has been tested in pancreatic cancer (PanCa) therapy with marginally better clinical outcomes, but remains limited by its poor hemocompatibility, biodistribution, and intracellular accumulation in tumor cells. Gemcitabine (GEM) is the most effective therapy for PanCa. However, it shows only a marginal survival benefit of 6 months. The poor therapy response is attributed to high desmoplasia, unfavorable tumor microenvironment (TME), and excessive recruitment of immune suppressive cells. We have recently engineered a multi-layered Pluronic F127 and polyvinyl alcohol stabilized and poly-L-lysine coated paclitaxel loaded poly(lactic-co-glycolic acid) nanoparticle formulation (PPNPs), which effectively inhibits pancreatic tumor. In this study, we demonstrate that PPNPs effectively sensitize tumor cells to GEM *via* attenuation of tumor desmoplasia. Our findings also show that PPNPs synergize GEM therapy response in cell lines and in vivo mouse models. Mechanistically, PPNPs target the TME via inhibition of the sonic hedgehog (SHH) pathway and other oncogenic signaling axis that inhibits bidirectional tumor-stromal cell interaction as determined by qPCR and Western blot analyses. In addition, PPNPs effectively target tumor-associated macrophages (TAM) by repolarizing M2 into M1 phenotype *via* inhibiting expression of M2 markers and an increase in M1 markers in mouse macrophage cell line RAW264.7. M2 polarization of RAW264.7 cells were induced by culture with IL-4 (20 ng/mL) in the presence of PPNPs or vehicle control. Furthermore, PPNPs effectively increase phagocytic capacity in murine macrophages as determined by phagocytosis assay (Vybrant Phagocytosis Assay Kit). In conclusion, we observed that our novel PPNP nano formulation effectively targets TME, and facilitates GEM uptake by inhibiting the activation of SHH signaling and reprograming the tumor immune surveillance mechanisms. This study suggests that PPNPs have great potential for future clinical use in management of pancreatic cancer.

#0487 Peptide amphiphiles hitchhike on endogenous biomolecules for enhanced drug delivery.

J. M. Fischer, M. Stewart, M. Dai, S. Drennan, S. Sabuncu, B. Kingston, I. Dengos, L. Xiang, K. Bonic, X. Yi, S. Ranganathan, B. Branchaud, **A. Yildirim**; Oregon Health & Science University, Portland, OR

Peptide amphiphiles (PAs) have been applied as building blocks for self-assembled nanostructures with various morphologies. These self-assembled nanostructures are promising drug delivery platforms as they are naturally biodegradable and biocompatible with low immunogenicity. One primary focus in drug delivery using the PA nanostructures has been to develop strongly assembled structures to avoid disassembly in the blood and allow them to carry payloads to their intended targets. In this work, rather than developing stable self-assembled PA structures, we focused on weakly assembled PA nanostructures to investigate their interactions with blood components and to understand how these interactions affect their biodistribution. We found that weakly assembled PA nanostructures (SA-E) quickly disassembled in plasma and reassembled with lipoproteins (LPs), which significantly prolonged the blood circulation of SA-E in mice. We showed that SA-E crossed the endothelial barriers through transcytosis only when they were assembled with LPs. Cellular uptake studies showed that SA-E accumulated in cancer cells through lipid-raft-mediated uptake. Interestingly, their cellular internalization was independent of LP receptors, suggesting that SA-E assembles with different endogenous biomolecules in vivo. By exploiting these endogenous interactions, SA-E demonstrated high tumor accumulation in a myriad of small animal tumor models of breast, colon, pancreatic, brain, skin, prostate, or lung cancers. SA-E demonstrated large tumor-to-background signal ratios in live animals (>5), extended retention (>2 weeks), and excellent tissue distribution (tumor to liver signal >3) in these tumor models. Encouraged by the excellent tumor accumulation of SA-E, we prepared SA-E drug conjugate using a highly potent and toxic chemotherapeutic agent, Monomethyl auristatin E (MMAE). SA-E-MMAE conjugate demonstrated strong antitumor efficacy in aggressive breast and glioma models in mice with reduced side effects. With its simple and modular design and universal tumor accumulation mechanism, SA-E represents a promising platform for broad applications in cancer therapy.

#0488 Modulation of ENPP1 activity and 2'3'-cGAMP degradation in ovarian cancer cell lines via loadable pre-formed lipid nanoparticles.

David Taylor, Jiajia Ji, Phillip Rzeczycki, Margaret L. Collins, Lauren Clements, Aileen R. Ariosa

Cayman Chemical Company, Ann Arbor, MI

Ovarian cancer is a complex heterogeneous disease with various subtypes and diverse molecular mechanisms of pathogenesis. Among different forms, epithelial ovarian cancer is the most common, representing up to 90% of total reported cases. Due to the lack of early diagnostic tools, the prognosis is mainly poor, as most cases are typically identified in advanced stages. Thus, a more thorough understanding of the inherent complexities of the disease, in terms of its biochemical etiology, will allow for identification of specific molecular and genetic profiles that could lead to more effective treatment plans. Recent studies have shown that ENPP1 may play a role in cancer cell proliferation, migration, and invasion in ovarian and other types of cancer. ENPP1 is a glycosylated type II transmembrane protein acting as a pyrophosphatase and phosphodiesterase with broad specificity. ENPP1 substrates include mononucleotides and cyclic dinucleotides such as the second messenger, 2'3'-cGAMP, which binds to and activates STING. 2'3'-cGAMP is exported extracellularly by cancerous cells into the tumor microenvironment where uptake into neighboring cells can activate their STING-dependent type 1 interferon pathway and promote antitumoral immune responses. ENPP1 can hydrolyze extracellular 2'3'-cGAMP however, allowing cancer cells to evade such an immune response. In this study, we assessed the activity of ENPP1 in CaOV-3, SK-OV-3, and PA-1 ovarian cancer cell lines using a fluorometric cell-based assay. The effects of ENPP1 inhibition via a chemical inhibitor on extracellular 2'3'-cGAMP levels were characterized and compared with siRNA-mediated knockdown of ENPP1 via loadable pre-formed lipid nanoparticles, which enable small-scale encapsulation and transfection of nucleic acid cargo. In addition, we explored whether uptake of exogenous 2'3'-cGAMP into THP-1 and RAW immune cell lines can be enhanced through delivery via preformed loadable lipid nanoparticles. Corresponding immune cell activation was also assessed using immunoblotting and RT-PCR. Our results demonstrate how modulation of ENPP1 activity and 2'3'-cGAMP levels in ovarian cancer cell lines using unconventional, pre-formed loadable lipid nanoparticle transfection reagent can aid in elucidating mechanisms of immune evasion in cancer cells.

#0489 Unlocking immune resistance and metastasis of PDAC via dual acting circularized nanodisc.

Ahmed Elzoghby, **Hagar Emam**, Seungbin Yim, Cuiyan Xin, Mahmoud Nasr

Engineering in Medicine, Brigham and Women's Hospital, Boston, MA

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive and deadliest forms of cancer. While major progress in immunotherapy has been made in recent years, it remains poorly effective in this malignancy. Two key players stand behind immune resistance of PDAC and inadequate efficacy of immunotherapy to suppress its metastasis. First, the immune-resistant pancreatic cancer stem cells (CSCs) evade immune surveillance acting as a source for tumor relapse and metastasis. This immune resistance stems from low immunogenicity of PDAC cells as well as the inaccessible CSCs that reside deep in the tumor core. Second, pancreatic cancer associated fibroblasts (CAFs) fuel metastasis of PDAC cells by suppressing their immune recognition and establishing pre-metastatic niche at distant organs to help their colonization. Our hypothesis is to overcome immune resistance of PDAC and inhibit early steps of its metastasis via simultaneous immunogenic eradication of immune resistant CSCs and switching immunosuppressive and pro-metastatic CAFs into quiescent ones. Therefore, we engineered ultrasmall circularized nanodiscs (cND) that encapsulate oncolytic peptide LTX-315 and fibroblast remodeling Notch signaling inhibitor. The engineered oncolytic LTX-315 loaded cND successfully induced immunogenic cell death (ICD) of both bulk PANC1 and pancreatic CSCs. Compared to non-treated and free LTX-315 treated cells, LTX-315 cND resulted in enhanced release of DAMPs including ATP and HMGB-1 as well as surface translocation of calreticulin. The ultrasmall size (9 nm) of cND enabled its deep tumor penetration to eradicate resistant CSCs, as revealed using 3D PDAC heterospheroids. In parallel, the Notch blocking cND promoted quiescence of the activated pancreatic stellate cells as denoted by downregulation of SMA, FAP and collagen. In KPC syngeneic PDAC mouse model, the dual oncolytic/Notch blocking cND combined with aPD-L1 therapy significantly suppressed tumor growth and prevented its metastasis to liver compared to vehicle-treated mice. Immunophenotyping study showed marked reduction in the abundance of CSCs and CAFs in the tumor treated with the cNDs. Moreover, the tumor infiltration of CD86+ MHCII+ dendritic cells and cytotoxic CD8+ T cells was enhanced after treatment with the cND. Overall, our dual strategy of targeting pancreatic CSCs and CAFs via oncolytic/Notch blocking cND boosted the anti-tumor and anti-metastatic efficacy of aPD-L1 therapy to eliminate primary PDAC tumor and suppress its metastasis.

#0490 Significant anti-proliferative effects of targeted magnetoelectric nanoparticles as potential theragnostic tools.

Max Shotbolt[1], Elric Zhang[1], Emily Zhu[1], Wael El-Rifai[1], John Bryant[2], Ping Liang[3], Sakhrat Khizroev[1]

[1]University of Miami, Miami, FL,[2]Moffitt Cancer Center, Tampa, FL,[3]UC Riverside, riverside, CA

Although current electroporation therapies have been demonstrated to be effective not only in ablating tumor tissue, but also in eliciting an anti-tumor immune response, they are limited in their application due to the strong risk factors associated with the high voltages required. Current methods of interacting with the body's electrical currents are limited to traditional electrodes, which cause damage to surrounding tissue upon insertion, and require high voltages to create responses at the cellular level. Recent efforts at non-invasive interaction with the body's electric fields have led to the fabrication of magnetoelectric nanoparticles (MENPs), a novel technology which has the ability to convert harmless magnetic fields into strong local electric fields, all while maintaining a diameter of ~70nm. These particles have been demonstrated to trigger neuronal firing under magnetic stimulation both in vitro and in vivo, and have been able to release chemotherapeutic agents on command in vitro and in vivo. This demonstrates the ability for MENPs to wirelessly generate electric fields within the body on demand with high temporal and spatial resolution. This suggests the potential for non-invasive electroporation therapy which could be triggered by external magnetic fields. Given the particles are themselves magnetic, this could show potential as a theragnostic tool as their magnetic properties suggest they may act simultaneously as an MRI contrast and an ablative therapy. To explore this possibility, we fabricated MENPs consisting of a magnetostrictive $CoFe_2O_4$ spinel core coupled with a piezoelectric $BaTiO_3$ perovskite shell. These particles were then PEGylated to reduce agglomeration which is typical of magnetic nanoparticles. 50ul of a 1mg/ml PEG-MENP dispersion was deposited into a cell culture of SKOV-3 ovarian cancer cells. These cells were then stimulated by 120 10ms pulses of a 2kOe magnetic field over the course of 30 minutes. An cell-titre glo ATP assay was performed to indicate viability 24 hours after treatment. Treatment wells were compared to controls of no intervention, magnetic stimulation with no particles, and particles with no stimulation. The combination of particles and magnetic stimulation was the only group which showed significant decreases in viability, with a 32% reduction in viability. Particles on their own showed no effect on cell viability, neither did magnetic-only stimulation. This preliminary investigation into the use of MENPs as a non-invasive cancer treatment has shown some potential. The ability to wirelessly activate the particles provides an inherent targeting mechanism not found in traditional chemotherapeutics, while the nanometer diameter provides a non-invasive method to generate strong electric fields within the body.

#0491 Aerosol delivery of immunotherapy and hesperetin nanoparticles in murine lung cancer model.

S. Yasmin-Karim[1], G. Richard[1], A. Fam[2], A.-M. Ogurek[3], G. Makrigiorgos[4];
[1]Brigham and Women's Hospital, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA, [2]Northeastern University, Boston, Massachusetts, USA, Boston, MA, [3]Northeastern University, Boston, MA, [4]Brigham and Women's Hospital and Dana-Farber Cancer Institute, and Harvard Medical School, Boston, MA

Purpose: Radiation is the most common modality for lung cancer treatment method. Radiationinduces apoptosis, causing cancer cells to be fragmented and expose the cancer-associatedantigens to the tumor microenvironment. These can be recognized by antigen-presenting cells(APC) to induce the antineoplastic effect by activating cytotoxic T cells. Our prior studies showadding immunoadjuvant like AntiCD40 with radiation can further activate the APCs in its anti-tumor (M1) format. Recent studies have shown that flavonoids like Hesperetin, an ACE2receptor agonist also can induce apoptosis in cancer cells whereas ACE2 receptors are abundant in lung cancer cells.This project aims to develop a novel treatment for non-small cell lung cancer (NSCLC) using nanotechnology for inhalation drug delivery Hesperetin, a flavonoid with antioxidant and pro-apoptotic activity; bound to PLGA-coated nanoparticles (Hesperetin Nanoparticles, HNPs) andAntiCD40 aiming for localized targeted dosing to reduce the treatment-related systemic toxicity.We plan to test the efficacy and safety of this aerosol spray.
Methods: *In-vitro* studies were performed in human A549 (ATCC) and murine LLC1 (ATCC)lung cancer cell lines for growth (MTT) and clonogenic survival assays to demonstrate the anti-cancer cell activity of Hesperetin (Sigma). Next, HNP was prepared using NanoFabTx™ nano-formulation reagent kits (Millipore-Sigma). A syngeneic orthotopic murine model of Lungadenoma was generated in wild (+/+) C57/BL6 background mice with similar background LLC1cell lines. We developed syngeneic orthotopic murine lung tumors with luciferase genetransfected LL/2-Luc2 (ATCC) Lewis Lung Cancer cell line in wild-type C57BL/6 mice(Techonic). Lung tumor-bearing mice were treated with HNP, antiCD40, or both with aerosolspray with a control group treated with the solvent (dH2O) only. To assess the drug delivery withaerosol treatment ex-vivo lung tissue was analyzed for Fluorescence tagged antiCD40 andnanoparticle uptakes. A survival assay was performed to analyze the efficacy of aerosoltreatment of HNPs with or without AntiCD40. All cohorts were also analyzed for body score, body weight, and liver and kidney functions.
Results: We were able to successfully develop an aerosol drug delivery model to administer bothAnti-CD40 and HNP in a murine lung cancer model. In our analysis of an orthotopic murinelung cancer model, we demonstrate a high intake of the HNP and AntiCD40 by the cancer cellssparing the normal lung tissue. Moreover, the highest percentage of survival rate was observed with the combination aerosol treatment with HNP+AntiCD40 ($p<0.001$), compared to CD40alone ($p<0.01$) or HNP ($p<0.01$) alone.
Comments: This treatment model will allow us to make the lung cancer treatment method easilyavailable for the mass population without having hazardous radiation treatment in the lungcancer model.

#0492 Investigating solute carrier SLC46A3 to enhance nanotherapeutic delivery for cancer.

Julianna Kenny-Serrano[1], **Elizabeth B. Nelson**[1], Gil Covarrubias[1], Namita Nabar[2], Joelle Straehla[3], Aanchal Gupta[4], Natalie Boehnke[4], Paula Hammond[2]

[1]Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA,[2]Department of Chemical Engineering, MIT, Cambridge, MA,[3]Pediatric Oncology, Dana Farber Cancer Institute, Boston, MA,[4]Department of Chemical Engineering and Material Science, University of Minnesota, Minneapolis, MN

BACKGROUND: Nanoparticle therapeutics have multifaceted potential to improve efficacy and decrease toxicity of cancer treatments. Nanotherapeutics can encapsulate a range of cargos and have tunable surface chemistry that can enhance drug delivery to tumors. Cellular features also play a role in successful drug delivery, and predictive biomarkers may improve patient selection for clinical trials. In previous work, we identified SLC46A3, a poorly characterized lysosomal solute carrier, as a strong negative regulator of lipid-based nanoparticle uptake across many cancer models. We hypothesize that the expression of SLC46A3 will act as a predictive biomarker for therapeutic nanoparticles.
METHODS: To test this hypothesis, we used two engineered model systems to probe the relationship between SLC46A3 expression and therapeutic response: lentiviral overexpression in a natively low-expressing melanoma model and genetic deactivation in a natively high-expressing breast cancer model. A library of FDA-approved and experimental therapeutic nanoparticles were screened in both models under a range of conditions. Liposomal formulations of chemotherapeutics were included with high and low surface functionalization of polyethylene glycol to investigate the impact of this ubiquitous ‘stealth’ polymer on our biomarker of interest. Solid lipid nanoparticles with nucleic acid cargo were also included. Orthogonal methods were used to probe these interactions and the therapeutic efficacy of nanotherapeutics, including pulsed dosing viability assays and label-free live-cell imaging.
RESULTS: We found that SLC46A3 expression is a class-specific biomarker of lipid-based nanoparticle uptake and is predictive of distinctive patterns of response to therapy-loaded nanoparticles in both formulation and time-dependent manners. Additionally, we present a new technology for long-term, live cell imaging of nanoparticle uptake and trafficking that can discriminate mechanisms of cytotoxicity, accelerating the study of nano-bio interactions. These findings highlight a promising approach for the functional validation of nanoparticle-specific biomarkers using clinically relevant formulations that have the potential for rapid repurposing.

#0493 Unlocking solid tumors to nano-immunotherapy.

B. Carreira[1], R. C. Acurcio[1], A. I. Matos[1], L. M. Moura[1], A. C. Santos[1], R. Gouveia[1], J. Cordeiro[1], C. Peres[1], D. Vaskovich-Koubi[2], R. Kleiner[2], S. Pozzi[2], R. Satchi-Fainaro[2], **H. F. Florindo**[1];

[1]Universidade de Lisboa, Lisboa, Portugal, [2]Tel Aviv University, Tel Aviv, Israel

Despite the remarkable efficiency of cancer immunotherapies, only a low percentage of patients achieve long-lasting clinical responses. Non-tumor cells within the tumor microenvironment (TME), including tumor vasculature and immune stromal cells, dictate therapeutic efficacy. The presence of germinal centers (GC) within the TME of cancer patients, including infiltrating T follicular helper (Tfh) cells and B cells, has been considered predictive of response to immunotherapies. We are developing nano-immunotherapies to induce immunological memory to control tumor relapse without any follow-up treatment.Nanomaterials co-incorporated tumor-associated antigens, clinically relevant toll-like receptor ligands, and regulators of tumor progression, namely the PD-L1/PD-1 expression and the secretion of TGF-β. Nanoparticle (NP) physicochemical properties were fully addressed. The immunotherapeutic potential of this nano-immunotherapy was addressed in melanoma, colorectal cancer (CRC), pancreatic cancer, and triple-negative breast cancer (TNBC) 3D models. These were created using patient-derived tumor cells, cancer-associated fibroblasts, and endothelial cells, to which paired patients' peripheral blood mononuclear cells were added to assess T-cell infiltration and tumor sprouting to identify the best nano-immunotherapy dosage/schedule. Our in vivo studies evaluated tumor volume, and animals' survival, and characterized the tumor-infiltrating immune cells within TME, including the differentiation of Tfh cells and primary GC by flow cytometry.Our nano-immunotherapy remodeled the TME of B16F10 melanoma, MC38 CRC, 4T1 and E0771 TNBC, and KPC PDAC. Different TME subpopulations were identified as major blockers of anti-tumor immunity, and this knowledge guided the selection of combination approaches using modulators of those tumor immune evasion-related pathways (e.g., PD-L1, FAK). Our combination nano-immunotherapies tailored to address the tumor immune suppression profile found in vaccinated animals, significantly delayed tumor development, and increased disease-free survival rates. We found that the adjuvants delivered by our NP led to a ~4-fold increase in antibody production, being far more effective in generating GC responses. Thus, the effectiveness of combinational immunotherapy is at least partially related to the modulation of Tfh cells driving the formation of GC responses.Our nano-immunotherapy is a promising clinically translatable approach to defeating solid tumors.

Acknowledgments: This work was supported by PTDC/BTM-SAL/4350/2021 and LCF/PR/HR22/52420016.

#0494 Fluorescent carbon dots: A novel bioimaging tool to reveal the mechanism of action of anticancer drugs in cells.

A. Clermont-Paquette;
Concordia University, Montreal, QC, Canada

The mechanism of action of many cancer drugs at the subcellular level remains unknown. Yet, this knowledge could be critical in driving structure-activity-relationship studies to improve their efficacy and selectivity. To gain a deeper understanding of the mechanisms governing the action of anticancer drugs within cells, we are developing an innovative methodology to visualize drug interactions. Carbon dots (CDs) are carbon-based nanoparticles, distinguished not only by their remarkable optical properties but also by their minimal cytotoxicity, rendering them highly suitable for bioimaging applications. We recently found that amine-passivated CDs with a negative surface charge and amphiphilic properties were enriched in the cytosol of cultured human cells. These CDs emit fluorescence in the blue spectra with high quantum yields and are not cytotoxic. Importantly, their surface is decorated with amine functional groups that can be used for coupling to polyethylene glycol to create a linker that can be covalently attached to drugs of interest. First, we are covalently linking amine-passivated CDs to Doxorubicin (Dox), a well-known anti-cancer drug that intercalates DNA and also has fluorescence properties that differ from the CDs. This will permit us to monitor and validate the conjugation of Dox to CDs, their cellular uptake and localization. The next step will be to use this approach to reveal the cellular mechanism of action of novel anticancer drugs. Specifically, our group has rationally designed thienoisoquinoline compounds with selectivity and high efficacy for triple negative breast cancer cells. In vitro they disrupt microtubule polymerization in the nanomolar range. However, in cells they cause mitotic arrest and spindle phenotypes that are distinct from colchicine, another microtubule-targeting drug. Our approach will reveal if these compounds target the centrosomes and/or microtubules and if this varies with cell types. This innovative approach could yield profound insights into the intracellular mechanisms of anticancer drugs to facilitate structure-activity-relationship studies, to improve their efficacy and selectivity for drug development.

#0495 Targeting undruggable transcription factor HOXB13 in metastatic prostate cancer by CRISPR/Cas13d-based nanoparticle therapy.

Z. Cui[1], F. Huang[1], K. Fang[2], J. Yan[3], Y. Zhou[2], J. Everitt[1], Y. Zhao[4], W. Hankey[1], Z. Chen[1], H. Wang[1], V. X. Jin[2], Y. Dong[3], Q. Wang[1];
[1]Department of Pathology, Duke University School of Medicine, Durham, NC, [2]Medical College of Wisconsin Cancer Center, Medical College of Wisconsin, Milwaukee, WI, [3]Icahn Genomics Institute, Precision Immunology Institute, Department of Oncological Sciences, Tisch Cancer Institute, Friedman Brain Institute, Icahn School of Medicine at Mount Sinai, New York, NY, [4]Department of Pathology College of Basic Medical Sciences and The First Hospital of China Medical University, Shenyang, China

Background: The oncogenic transcription factor HOXB13, which is highly expressed in castration-resistant prostate cancer (CRPC), has been shown to promote CRPC growth and metastasis. However, HOXB13 is considered untargetable by traditional small-molecule-based drug design. Gene therapy is critical alternative strategy with potential to directly target such traditionally undruggable genes.
Methods: Selective cell in organ targeting (SCORT) nanoparticles for precise delivery of nanoparticles to metastatic cancer cells in an organ were constructed and characterized by the NanoAssemblr Spark, Zetasizer Nano ZS, and transmission electron microscopy (TEM); Cas13d mRNA with pseudouridine modification was synthesized using *in vitro* transcription; Hemi-spleen injection of CRPC cells was performed to build CRPC liver metastatic models; RNA-seq was employed to evaluate off-target effects of Cas13d targeting.
Results: By incorporating a prostate cancer-specific E3 aptamer to functionalized lipid-like nanoparticles (FTT5 LNP-E3), we have successfully constructed SCORT nanoparticles that enable preferential delivery of mRNAs to metastatic CRPC cells in the liver, as opposed to various normal cells in the surrounding liver tissue. We demonstrated that Cas13d-pre-g*HOXB13* mediates highly effective and specific *HOXB13* mRNA knockdown in CRPC cells. Significantly, systemic treatment of SCORT nanoparticles carrying Cas13d-pre-g*HOXB13* mRNA decreased HOXB13 expression in the metastatic tumors, inhibited metastasis, and prolonged survival of mice bearing androgen receptor (AR)-positive (AR+) or negative (AR-) tumors. Notably, long term (6 and a half weeks) administration of SCORT nanoparticle-Cas13d-pre-g*HOXB13* did not significant alter body weight, hepatic and renal function, chemokines and cytokines, and other factors, effectively highlighting its safety.
Conclusions: This study is the first to demonstrate that undruggable oncogenic transcription factors can be targeted using nanoparticle-delivered gene therapy based on CRISPR/Cas13 RNA-targeting. The SCORT-CRISPR/Cas13d system is a highly flexible technology that would impact the larger field of translational science by allowing the design of Cas13d-based, cancer cell-specific delivered nanoparticles targeting other previously-undruggable oncogenic transcription factors in metastatic prostate cancer and other solid tumors.

#0496 Insights into correlation between nanomechanical properties and cytokines expression during gold nanoparticle endocytosis.

T. Kulkarni, E. Wang, R. Angom, D. Mukhopadhyay, **S. Bhattacharya**;
Mayo Clinic Florida, Jacksonville, FL

Gold nanoparticles for therapeutic interventions have become a widely popular source due to the ease in surface chemistry available for modification. Several studies undertaken focusses on the size, shape of nanoparticles as well as the signaling mechanisms and yet, knowledge regarding the alteration in membrane dynamics such as nanomechanical properties and cytokines involved during their uptake has not been studies before. To overcome the knowledge deficit, we employed atomic force microscopy and qRT-PCR techniques to acquire nanomechanical attributes and cytokines expressions respectively, in Panc-1 and AsPC-1 cell lines treated with surface modified gold nanoparticles for 1- and 24-hours' time point. In nanomechanics paradigm, impetus was given on both linear attributes such as membrane stiffness, deformation, and adhesion as well as non-linear attributes such as drained Poisson's ratio, diffusion coefficient and pore size. On the other hand, qRT-PCR technique yielded alterations in relative mRNA expressions of pro-tumorigenic cytokines such as CCL2, CXCL1, CXCL2, CXCL3, IL8, IL11, IL18 and TGFβ-1. Further, using Pearson's correlation, we deduced the dependency between nanomechanical properties and cytokines expressions. We evaluated several criteria such as receptor dependent vs independent, PEGylated vs non-PEGylated and 1 hr vs 24hrs, to deduce correlations between cytokines and nanomechanical attributes. In Panc-1 cell line, we observed that PEGylation vs non-PEGylation of gold nanoparticles demonstrated most significant correlations, whereas in AsPC-1 cell line, receptor independent mechanism played a pivotal role in establishing significant correlations. For instance, D_C and P_D were highly correlated with CXCL1, CXCL2 and TGFβ-1 when non-PEGylated gold nanoparticles were up taken by Panc-1 cells. Similarly, D_C and P_D were highly correlated consistently with our cytokine panel except for TGFβ-1. In AsPC-1 cell line, deformation was significantly correlated with CCL2, CXCL2, CXCL3 and IL-8 whereas, D_C and P_D were significantly correlated with CCL2, CXCL1, CXCL3, IL-18 and TGFβ-1 in receptor independent scenario. This study demonstrated that during the uptake of gold nanoparticles, non-linear nanomechanical attributes are detrimental over linear attributes. Moreover, Surface modified gold nanoparticles induce varying levels of alteration in pro-tumorigenic cytokines. Taken together, this study boosts our insights into correlations describing cytokines regulating nanomechanical attributes in endocytosis paradigm.

#0497 Plant viruses against cancer.

N. F. Steinmetz, Y. Chung, M. Moreno-Gonzalez, Z. Zhao;
UC San Diego, La Jolla, CA

Immunotherapy has significantly transformed the landscape of cancer treatment; however, concerns about safety, efficacy, and long-term outcomes across various tumor types persist. We have developed an intratumoral immunotherapy strategy with an engineered plant virus nanotechnology and demonstrated efficacy in tumor mouse models and canine cancer patients. This method is designed to elicit a systemic (abscopal effect), safe, and enduring anti-tumor immune response that is not limited by tumor type. The power of immunotherapy lies in synergistic combination treatments and toward this goal, we are engineering the next-generation plant virus nanotechnologies. We demonstrate synergistic combination with chemotherapy and immunization strategies the hone in on tumor-associated antigens and key players of inflammation. The combinatorial immunotherapy strategies prevent recurrence post-surgery in mice and canine patients. We will discuss the engineering design principles leading toward synergetic combination immunotherapies to treat and prevent cancer; efficacy studies and underlying mechanism is elucidated through immunomics studies.

#0499 Enhancing neoantigen cancer vaccine efficacy with a self-assembling peptide conjugates nanoparticle platform.

Y. Wu, J.-D. Huang;
University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong

Tumor neoantigens, arising from genomic mutations during cancer cell proliferation, are absent in normal tissues, making them ideal immunotherapy targets. Predicting neoantigen peptide sequences using artificial neural networks (ANNs) like NetMHCpan offers a promising approach to developing personalized peptide cancer vaccines. However, limitations such as low affinity, short half-life, and weak immunogenicity hinder their efficacy. To address these challenges, we propose loading neoantigens into nanoparticles for protection and slow release within the body. We used ANN prediction to determine neoantigen peptide sequences for various cancer cell lines and engineered these peptides by conjugating them with Toll-like receptor 7 agonist (TLR7a) adjuvants, forming a self-assembling peptide conjugates nanoparticle (SPCN) platform. To assess the immunogenicity of the SPCN platform, we conducted enzyme-linked ELISpot assays and evaluated the activation of antigen-presenting cells (APCs) in draining lymph nodes using flow cytometry analysis. The therapeutic efficacy of the SPCN platform was determined by monitoring tumor growth curves in mouse models. The SPCN platform demonstrated broad applicability, carrying different neoantigens *in vivo*, resulting in robust and safe systemic anti-tumor responses. The SPCN enhanced immunogenicity, stimulating splenocytes to produce more interferon gamma and facilitating efficient absorption by antigen-presenting cells (APCs). Moreover, SPCNs loaded with neoantigens targeted different cancer models, including B16OVA, MB49, and RIL175. In conclusion, our self-assembling peptide conjugates nanoparticle platform enhances APC activation and neoantigen immunogenicity, leading to improved anti-tumor efficacy, offering valuable insights for developing synthetic peptide cancer vaccines.

#0500 Liposomal two-tailed topotecan (L-2TT) induces more apoptosis than topotecan hydrochloride on neuroblastoma xenografts.

S. L. Hernandez[1], I. Iwanicki[1], P. Viza-Gomes[1], L. Wu[1], M. Marquez[2], F. Flores-Guzman[1], R. Sundland[1], M. Tartis[2];
[1]University of Chicago, Chicago, IL, [2]New Mexico Tech, Socorro, NM

Background: Neuroblastoma (NB) is the second most common malignancy diagnosed in infants, accounting for 15% of pediatric tumor deaths. High risk NB have a <50% 5-year survival and often resist treatment, with acute and long-term toxicities. Topotecan, part of the standard of care in NB is a Topoisomerase1 inhibitor with a short half-life in circulation (30 minutes). We esterified phospholipid to topotecan at the phenolic hydroxyl group, producing the prodrug 2T-T. 2T-T was loaded onto liposome membranes (termed L-2TT); thus preventing drug leakage. We hypothesized L-2TT would be more efficient at inducing apoptosis than topotecan in NB models (in vitro and in vivo) in part due to its extended circulation time and endocytic uptake.
Methods: IC50 was determined on 8 NB cell lines using a WST assay, comparing equal dosages of L-2TT to topotecan (empty liposomes were assessed as controls). NB cells were imaged with DiD-tagged liposomes together with lysotracker green, under confocal microscopy 24 hrs. Non-tumor bearing mice received increasing L-2TT doses, assessing weight, body score over five days. Drug circulation time was estimated by following DiR-liposomes in vivo (IVIS) over 72 hrs. Nude mice received 1x10^6 NGP cells (NB cells) intrarenally. When tumors reached 1 gram, xenografts received 10mg/kg L-2TT (containing 3.33mg/kg topotecan) via retroorbital injection, 3.33 mg/kg topotecan-hcl or no drug. Tumors were harvested 24 hrs. later, immunohistochemical analysis (apoptosis marker TUNEL), counting the % of positive cells of total tumor area. Some mice received DiR-liposomes together with L-2TT, fixed in PFA and 50mm sections captured total DiR under confocal microscopy. Finally, we interrogated L-2TT vs. Topotecan-HCl tumors via RNAseq for chemoresistance pathways.
Results: IC50 values of L-2TT were lower than topotecan-HCl by almost 3-fold in 7/8 cell lines (empty liposomes at equal concentrations had no effect). DiD-tagged liposomes formed a punctate pattern and colocalized with lysotracker green, confirming liposomes are endocytosed by NB cells in vitro. L-2TT caused no changes adverse effects on mice. Drug circulation time remained stable over 48 hours and was still detectable at 72hrs after liposomal delivery. L-2TT resulted in 3-fold higher tumor apoptosis than Topotecan-hcl ($p<0.0001$), and itself 3-fold higher than controls ($p<0.001$, $n=5$). Mice receiving L-2TT+L-DiR resulted in 2-fold higher DiR signal than L-DiR only ($p<0.05$, $n=3$. Finally, RNAseq suggests L-2TT elicits less chemoresistance pathways than topotecan.
Conclusions: L-2TT is more potent than topotecan in vitro and in vivo. Mechanisms for these effects could be longer circulation times, different tumor cell uptake, as well as changes in tumor vascular permeability. These drug modifications could provide potent alternative for NB treatment as well as other solid tumor treatment.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Cell Cycle, Transcription Regulation, and Anticancer Drug Action
Poster Session

#0504 Anticancer effects of kaempferol through cell cycle arrest and the inhibition of proliferation in genetically distinct triple-negative breast cancer cells.

S. Kaur, P. Mendonca, K. F. Soliman;
Florida A&M University, Tallahassee, FL

Triple-negative breast cancer (TNBC) is one of the most known aggressive subtypes of breast cancer, affecting 1 in 3 newly diagnosed cancers in women. TNBC affects African-American women disproportionally in comparison to Caucasian women. Due to the lack of estrogen receptors (ER), progesterone receptors (PR), and human epidermal growth factor receptors (HER-2), it poses direct challenges to the efficacy of standard hormonal therapies. The current TNBC treatments present higher toxicity and multiple side effects. An alternative would be using natural compounds that have emerged as potential anticancer agents. Kaempferol is a major flavonoid aglycone found in many fruits, vegetables, and herbs, including grapes, tomatoes, broccoli, tea, and ginkgo biloba leaves. In this study, we investigated the differential effect of kaempferol on cell toxicity, cell growth, and underlying mechanisms in inducing cell cycle arrest in genetically different TNBC cells from Caucasian (MDA-MB-231) and African American (MDA-MB- 468) women. Kaempferol significantly inhibited cell growth in both the cell lines with a more profound effect against MDA-MB-231 (IC50: 43.86 µM) compared to MDA-MB-468 cells (IC50: 53.47 µM). Also, kaempferol treatment induced cell cycle arrest at S-phase in both cancer cell subtypes. The MDA-MB-231 cells showed a kaempferol effect at lower concentrations (6.25µM and 12.5µM), while MDA-MB-468 cells showed the same effect at higher concentrations (25µM and 50µM). Kaempferol also modulated CDK gene expression associated with cell cycle progression in breast cancer cells. The inhibition at S-phase is important in cancer treatment because it targets the highly proliferative nature of cancer cells characterized by uncontrolled cell division. This study indicates that, by inducing cell cycle arrest at the S-phase, kaempferol may interfere with cancer cell growth and proliferation by inhibiting DNA replication, offering potential therapeutic benefits. This approach could reduce side effects and increase treatment efficacy, providing hope for more effective interventions in the fight against TNBC.

#0506 TRIP13 is a promising therapeutic target for bladder cancer.

S. P. Singh, K. Goswami, A. S. Asch, C. V. Rao, V. Madka;
OU Health Stephenson Cancer Center, Oklahoma city, OK

Bladder cancer (BCa) is the second most common genitourinary cancer. High recurrence rate, progression to MIBC and poor prognosis in metastatic disease are major challenges for this disease management. Therapeutic options for advanced stage BCa are very limited, hence developing agents to treat this disease progression are highly needed. Thyroid receptor-interacting protein 13 (TRIP13), a member of the AAA-ATPase family, regulates various cellular processes such as DNA repair and spindle assembly. TCGA data analysis showed significant overexpression of TRIP13 that correlates with disease stage and mortality. Recent studies have shown that TRIP13 amplification occurs in several types of human cancers, including BCa, and it regulates cell proliferation, tumor growth, and drug resistance. However, the role of TRIP13 in BCa and its potential as a therapeutic target remain elusive. Therefore, in the present study we performed a preclinical investigation of the TRIP13 role in BCa progression, underlying molecular mechanisms, and develop promising therapeutics against BCa. Initially we profiled TRIP13 expression in 10 different bladder cancer cell lines from a panel of human and rodent origin and found elevated protein expression in multiple BCa cell lines. TRIP13 levels were also significantly elevated in the BBN induced rat- and SV40T driven mouse- bladder tumor tissues compared to normal bladder tissues. Pharmacological inhibition of TRIP13 with a potent drug DCZ0415 significantly suppressed cell proliferation (IC_{50} ~7μM) in J82, NBT-II and MB49 cell lines and induced cell death. DCZ0415 treatment led to cell cycle arrest at G1 phase ($P<0.001$) in BCa cells. In mechanistic investigations on its effect on cell cycle progression by DCZ0415 treatment decreased the expression of CDK4, CDK6, Cyclin D1, and PCNA protein expression. TRIP13 inhibition also suppressed the migration and invasion potential of BCa cells. Annexin V and γ-H2AX staining suggested that DCZ0415 induced apoptosis in BCa cells and increased DNA damage. These findings were also complemented by an increase in cleaved caspase-3 and PARP proteins. We also observed modulation of cGAS-STING signaling pathway in BCa cells with DCZ0415 treatment, indicating potential for its combination with cGAS-STING stimulators. Importantly, we found that TRIP13 inhibition with DCZ0415 significantly suppressed the growth of 3D BCa models as well BBN-induced rat BCa tumoroids and spheroids. Overall, these results suggest that TRIP13 could be a potential therapeutic target for prevention of bladder cancer and warrants further validation in *in vivo* models (Funding supported by P30CA225520 and ACS-IRG grant).

#0507 HLS-22001 induces G2/M cell cycle arrest and apoptotic cell death via tubulin depolymerization in colon cancer.

C.-h. Ahn, **G.-b. Jang**, C. Kim, J. Lee, T. Kim, Y. Yang, E. Cho, M. Kim, Y.-t. Kim, Y.-H. Han, H. Kang;
HLB Life Science R&D Co., Ltd., Gyeonggi-do, Korea, Republic of

Colorectal cancer (CRC) is one of the main malignant tumors and among the leading cause of death in cancer patients worldwide considering that recurrence and chemotherapeutic drug resistance are highly common in the advanced stage of CRC. Mutations in KRAS and BRAF occur frequently in colorectal cancers, and abnormal cell cycles caused by these mutations affect tumor progression and metastasis. Accordingly, inhibition of cell cycle has been a potential target for colorectal cancers and therefore, we have developed a new lead compound, HLS-22001.
Our studies confirmed that HLS-22001 inhibited the proliferation of several cancer cells and significantly induced G2/M arrest and apoptosis of colon cancer cells and chemotherapy resistant colon cancer cells. The docking model studies showed that HLS-22001 was expected to bind to the colchicine binding site of beta-tubulin, and in fact, as a tubulin inhibitor, it had the effect of inhibiting tubulin dimerization and polymerization in the microtubule dynamics. Consistently, in xenograft mouse model, oral administration of HLS-22001 significantly suppressed tumor weight and volume without acute toxicity in mice.
Collectively, these results suggest further development of HLS-22001 as a novel and promising oral drug for colorectal cancer.

#0508 Determining the nuclear and cytoplasmic function of BMI-1 in diffuse intrinsic pontine glioma during M phase.

H.-H. Pang, B. Umaru, S. Senthil Kumar, **R. Drissi**;
Nationwide Children's Hospital, Columbus, OH

Diffuse Intrinsic Pontine Glioma (DIPG) represents one of the most aggressive malignancies of the central nervous system, predominantly affecting children. DIPG is a particularly poor prognosis brain tumor with a median overall survival of less than 1 year. Hence, there is an urgent need to develop novel therapies that not only improve outcome but mitigate long-term complications in children with DIPG. The protein BMI-1, a critical component of the Polycomb Repressive Complex 1 (PRC1), is a proto-oncogene implicated in development, stemness of normal and malignant cells, and self-renewal. BMI-1 has emerged as a potential therapeutic target in DIPG; however, its role in DIPG tumorigenesis and progression remains elusive. We have previously shown that PTC596, a potent BMI-1 modulator, induces chromosome scattering, M phase cell-cycle arrest, BMI-1 phosphorylation and translocation to the cytoplasm leading to the inhibition of its PRC1 canonical function and cell death. These findings imply the induction of the spindle assembly checkpoint (SAC), thereby preventing mitotic exit followed by BMI-1 phosphorylation, probably at multiple sites, suggesting a survival role of BMI-1 in M phase in DIPG. The objective of the present study is to delineate the molecular pathways governing BMI-1 function during M phase and to establish the temporal sequence of these biochemical events related to BMI-1. Our data demonstrated that following PTC596 treatment, BMI-1 is actively transported from the nucleus to the cytoplasm. Furthermore, we observed colocalization of BMI-1 with COX4 in the mitochondria during M phase. Moreover, using Alphafold prediction model, BMI-1 could interact with CRM1 transporter. These findings suggest a potential PRC1-independent role of BMI-1 during early M phase required for DIPG proliferation. We are currently investigating potential pathways involved in BMI-1 nuclear-cytosol translocation through bioinformatic analyses, protein-protein interaction simulations, and pharmacological inhibitor assays. Collectively, these studies aim to elucidate the molecular mechanisms underlying BMI-1 functions in DIPG, thereby potentially paving the way for the development of targeted therapeutic strategies related to M phase progression.

#0509 The MPS1/TTK inhibitor, NMS-01940153, synergizes with tisotumab vedotin in colorectal cancer.

G. Texido[1], F. Gasparri[1], A. Ciavolella[1], L. Gianellini[1], A. E. Pedersen[1], A. Ocana[1], R. Colombo[1], D. Roberti[1], L. Mahnke[2], **C. Perrera**[1];
[1]Nerviano Medical Sciences S.r.l., Nerviano (MI), Italy, [2]Nerviano Medical Sciences Inc., Boston, MA

Background: MPS1 kinase plays a crucial role in maintaining genomic integrity by controlling the spindle assembly checkpoint (SAC). MPS1 is highly expressed in tumors of different origins and overexpression is associated with poor prognosis. By inhibiting MPS1, cancer cells are forced to enter anaphase before chromosomes are aligned, leading to mitotic catastrophe and apoptosis. NMS-01940153 (NMS-153) is a potent and selective MPS1 inhibitor, with antitumor activity *in vitro* and *in vivo*. NMS-153, under investigation in a clinical trial, shows early signs of clinical activity, an acceptable safety profile, with manageable and reversible neutropenia as the main adverse effect (EudraCT 2020-001002-26; Reig et al, Eur J Cancer 174S1, 2022).
Microtubule targeting agents (MTAs), such as taxanes and vinca alkaloids, cause mitotic arrest and activate the SAC. Concomitant SAC disruption by MPS1 inhibition synergizes with MTAs, but the combination is limited by neutropenia in the clinic.
Purpose and Methods: The goal is to show synergism between NMS-153 and MTA and to find a strategy to overcome the limiting neutropenia of this combination. For this, Tisotumab vedotin (TV), an anti-Tissue Factor (TF) with Monomethyl auristatine E (MMAE) payload, was used. TF is aberrantly expressed in a variety of tumors compared to normal tissue counterpart. In colorectal cancer (CRC), TF is overexpressed in patients with distinct molecular features including BRAF mutation, a colon cancer population that hardly responds to chemotherapy or BRAF inhibitors. At therapeutic doses, TV induces low rate of grade ≥3 neutropenia. The combination of NMS-153 and TV is expected to synergize and have an acceptable safety profile. LS411N CRC model expressing TF and harboring a BRAFV600E mutation was selected for testing NMS-153 and TV in combination. *In vivo*, NMS-153 was tested at 13 or 20 mpk every 4 days for 7 doses. TV was tested at 1 or 4 mpk weekly for 2 doses. The 2 therapeutic doses of both agents were tested in combination.
Results: *In vitro*, synergism of NMS-153 with TV in LS411N cells was observed. *In vivo*, NMS-153 and TV as single agents were efficacious in LS411N xenograft with TGIs up to 53% and 89%, respectively. The median survival time (MST) for the vehicle group was 35.5 days. NMS 153 and TV single agents prolonged survival with MSTs up to 53 and 73.3 days, respectively. When combined, a dose-dependent therapeutic benefit was observed, with an MST of >137 days, and 6 out of 10 mice profiting of long-term tumor regressions at the highest doses tested. The combination benefit was statistically significantly different from single agents and more than additive. Treatments were well tolerated.
Conclusions: The combination of NMS-153 with TV is synergistic in the LS411N CRC model. These data strongly suggest the potential for clinical efficacy of NMS-153 with TV and the combinability of NMS-153 with TV and other MMAE-based ADCs in different tumor contexts.

#0510 Flow cytometry evaluation of cell cycle arrest in A549 human non-small cell lung cancer cells and tumors following treatment with cell cycle inhibitors: A multifaceted approach to targeting cancer.

E. E. Trachet, E. Cluff, A. Lemos de Matos, D. Diaz, C. Holmquist, P. Gonzales;
Translational Drug Development (TD2), Scottsdale, AZ

The contemporary landscape of cancer treatment has witnessed significant progress with FDA-approved targeted drugs. The FDA's Project Optimus has underscored the growing need for innovative pharmacodynamic endpoints to determine the optimal biological dose in clinical development. Flow cytometry, a potent analytical tool in clinical and preclinical labs, now plays a leading role in cancer research, enabling the evaluation of new drug effects on cell cycle regulation and consideration of rational drug combinations with approved drugs. At TD2, we strive to enhance the translatability of in vitro induced cell cycle arrest studies to in vivo biomarker proof of concept and efficacy. We employ a comprehensive approach, utilizing flow cytometry to assess cell cycle dynamics in cultured cells and in vivo tumor models after treatment with approved and novel drugs. This abstract focuses on the translational relevance of combined in vitro and in vivo testing of well-known drugs that disrupt the cell cycle, laying the foundation for optimized treatment strategies and potentially personalized cancer therapies. Human A549 non-small cell lung carcinoma cells were treated with either thymidine (2.0mM) or the microtubule-depolymerizing drug nocodazole (100ng/ml) for 18 hours, then examined by flow cytometry. Thymidine induced a greater than 85% S-phase arrest, while nocodazole induced a greater than 88% G2/M-phase arrest. A549 cells ($5x10^6$ cells/mouse) were subcutaneously implanted in SCID mice, followed by treatment with an FDA-approved cell cycle inhibitor, Palbociclib, or cisplatin chemotherapy. Palbociclib, a CDK4/6 inhibitor, and low-dose cisplatin treatment resulted in an increased accumulation of cells in the G0/G1 phase, greater than 80% for each. Both treatments exhibited promising anti-cancer activity, with tumor growth inhibition (TGI) of 69% and 87%, respectively. Our findings highlight flow cytometry's multifaceted utility in assessing cell cycle arrest, providing a comprehensive view of agent effects on cancer cells in culture and within the complex in vivo tumor microenvironment. Determining the impact of any new drug on specific cell cycle checkpoints could allow for a more strategic plan for combination therapy. Integrating flow cytometry could enable early biomarker monitoring of tumor cell cycle changes, offering insights into the therapeutic potential of new agents alone or in combination. This multidimensional evaluation contributes to understanding cancer biology and has the potential to guide the development of novel therapeutic strategies, optimize treatment regimens to identify optimal biological doses, and improve patient outcomes in the era of precision medicine.

#0511 Cell cycle inhibitors exhibit anti-tumor immunomodulatory roles through the HIF-1-DDX41 cytosolic DNA sensing pathway in HCC.

C. Chan, P. Wong, H. Xue, C. Goh, J. Cheu, A. Tse, M. Zhang, C. Wong;
The University of Hong Kong, Hong Kong, Hong Kong

Cell cycle inhibitors have a long history as anti-cancer therapeutics in clinical applications. Uncontrolled and infinite cell cycles are hallmarks of cancer, which enable them to proliferate rapidly and survive. To target these key features of cancer cells, cell cycle inhibitors are used to arrest their active cell cycle and induce cell death. In this study, beyond the known primary effect on cell cycle control, we identified that an expected and a secondary effect in immune modulation by the cell cycle inhibitors. Anti-mitotic agents including Paclitaxel (microtubule stabilizer), Palbociclib (CDK4/6 inhibitor) and AZD1152 and GSK1070916 (Aurora Kinase B inhibitors) can also eliminate cancer cells via an alternative mechanism - the activation of STING signaling. Our results demonstrated that these anti-mitotic agents caused DNA damage and cytosolic DNA accumulation. The cytosolic DNA was captured by a cytosolic DNA sensor DDX41,which triggered STING-TBK1-IRF3/7 pathway to upregulate secretion of pro-inflammatory senescence-associated secretory phenotype (SASP) factors in cancer cells. In addition, we revealed that transcription of DDX41 was mediated by the transcription factor known ashypoxia-inducible factor (HIF). In HCC, hypoxia induced DDX41 expression through HIF-1,thus hypoxic HCC cells were more prone to STING activation and SASP production under mitotic stress induced by cell cycle inhibitors. In the tumor microenvironment, the SASP enhanced infiltration of immune cells into the tumor core to eliminate cancer cells. We also observed the additive effects of cell cycles inhibitors (Paclitaxel, Palbociclib, and AZD1152)with anti-PD-1 mAb to arrest growth of HCC in mouse models. In summary, this study exhibited the novel immune-mediated aspect of cell cycle inhibitors in suppressing tumor growth. Our data suggested the potential combination regimen of cell cycle inhibitors and currently available immunotherapy with promising result.

#0512 Cell-cycle inhibition may influence differences in 2D vs 3D tumor sensitivity profiles.

J. Kumar, C. Maestri, R. Nitiyanandan, I. Trus, R. J. Parker, B. Apfel, C. Apfel;
Sage Medic Corp., Redwood City, CA

Background: Traditional cell culture methods involve growing cells on flat surfaces, which do not fully replicate the human physiological conditions. In contrast, 3D cell cultures accurately reproduce aspects of the *in-vitro* malignant and non-malignant cell behavior. However, differences in tumor sensitivity platforms between 2D vs. 3D models might be relevant for some, but not for other drugs.
Methods: The colorectal cancer cell line HCT-116 was cultured and plated in flat bottom well plates for the 2D condition and in Ultra Low Attachment round-bottom plates for the 3D condition. After plating, cells were treated with chemotherapies and targeted therapies for four days; cellular sensitivity was assessed through a viability assay. Four-parameter logistic (4PL) dose response curves were generated and IC_{50}s were quantified to understand the differences in responses between 2D and 3D cellular environments.
Results: HCT-116 exhibited similar responses to platinum drugs, taxanes, and several other tested drugs in both platforms, with the exception of gemcitabine (2D IC_{50} 0.04 mcM; 3D IC_{50} 12.8 mcM), lapatinib (2D IC_{50} 23; 3D IC_{50} 418), tucatinib (2D IC_{50} 23.3; 3D IC_{50} 79.3), and palbociclib (2D IC_{50} 7.0; 3D IC_{50} 24.0). Interestingly, these drugs share a common mechanism of action, which is the inhibition of cell cycle progression from G1 to S phase. Hence, we hypothesize that this shared mechanism may account for the observed differences in drug efficacy between the two environments.
Conclusions: Similar dose responses have been observed with various drugs on both platforms, yet drugs that inhibit cell cycle progression from G1 to S phase, revealed higher sensitivity in 2D and more resistance in the 3D platform. Confirmatory cell-cycle results analyses are in progress. Further research is needed to understand if this applies to patient samples.

#0513 Intra-tubular damage is targeted by maytansinoids and rescued by NF1: Revisiting mechanism and biomarkers of an established ADC payload.

E. Messuti[1], B. Achutti Duso[1], A. Castiglioni[1], G. Tini[1], E. Bonetti[1], G. Ciossani[1], S. Monzani[1], D. Khuntsariya[2], Z. Lansky[2], M. Braun[2], L. Scietti[1], **L. Mazzarella**[1];

[1]IEO - European Institute of Oncology, Milan, Italy, [2]Institute of Biotechnology CAS - BIOCEV, Vestec, Czech Republic

There is great interest in the identification of biomarkers to guide development of antibody-drug conjugates (ADC). We previously showed that loss of Neurofibromatosis 1 (NF1), a gene frequently mutated across cancers, enhances the activity of DM1, the maytansinoid payload of T-DM1, through a novel function in regulating microtubule (MT) dynamics. Maytansinoids are puzzlingly more effective in cells (in the nanomolar range) vs in vitro (in the micromolar range). Since maytansinoids bind at the interface between tubulin dimers, they are thought to only bind soluble tubulin dimers or MT ends, which would suggest very few binding sites available for pharmacological interaction in vivo, at odds with data. Here we investigated the interaction of DM1 with NF1 and MTs, using cellular and reductionist in vitro systems. To measure in vivo MT dynamics, we transiently transfected the MT end-binding protein EB3-GFP and reconstructed MT trajectories by live-cell imaging. Upon DM1 treatment, KO cells showed a highly significant reduction in MT speed, demonstrating a direct role for NF1 on MT dynamics in cells. In turbidity-based tubulin polymerization assays, recombinant NF1 greatly accelerated polymerization, and completely rescued DM1-induced inhibition. Visual inspection of fluorescent MTs showed that NF1 induced significant MT bundling, a defining feature of many MT-associated proteins, which generates signal indistinguishable from true MT polymerization in turbidity assays. To follow the dynamics of individual microtubules, we applied Total Internal Reflection (TIRF) microscopy on glass-immobilized MTs. As expected, polymerization in the presence of NF1 led to a significant increase in MT dynamics (elongation speed, rescue and catastrophe rate). Expectedly, DM1 led to significant reduction in the fraction of elongating MTs and speed, but these defects were completely or partially rescued by NF1. Importantly, DM1 did not only lead to MT shortening (as proposed by the current model), but also to clear and frequent MT fracturing, indicating that the drug is not only engaging MT ends but also intra-tubular binding sites. This is consistent with recent models of MT formation which incorporate the frequent presence of areas of discontinuity or damage induced by mechanical stress, exposing intra-tubular DM1 binding sites. Interestingly, adding NF1 to DM1-treated MTs generated areas of de novo intra-tubular tubulin insertion, coincident with damaged sites, suggesting an entirely novel role for NF1 in MT repair.In conclusion, we provide evidence for a model in which maytansinoids bind not only to soluble tubulin dimers and MT ends, but also to intra-tubular damaged sites. Thus, the number of binding sites in cells would be proportional to MT damage, suggesting a mechanism for differential efficacy across tumor types and a potential avenue for combinatorial drug development.

#0514 Salt-inducible kinase inhibitor OMX-0407 drives cell-cycle arrest *in vitro* and *in vivo:* An in-depth MoA analysis by phospho-proteomics.

I.-P. Maser[1], M. Stebegg-Wagner[1], B. Bauer[1], F. Konstantinidis[1], A. Schirmer[1], M. Zulley[1], S. Lacher[1], B. Kracher[2], P. Kohvaei[2], M. Yule[1], H. Loferer[1], S. Bissinger[1];

[1]iOmx Therapeutics AG, Munich, Germany, [2]Evotec Munich GmbH, Munich, Germany

Based on iOmx' proprietary iOTarg™ genetic screening platform, salt-inducible kinase (SIK) 3 was identified as a novel cell signaling modulator in cancer biology. OMX-0407, an orally available, spectrum-selective kinase inhibitor targets several members of the SIK family and is known to prevent tumor-promoting function of the SIK-family through repolarization of the tumor microenvironment by enhancing caspase-mediated apoptosis upon death-receptor signaling. In addition, OMX-0407 inhibits individual key members of the tyrosine and tyrosine-like kinase family that are involved in cancer cell proliferation and cell cycle regulation. Via this dual mode of action, OMX-0407 has the potential to effectively fight solid tumors as exemplified by its striking single-agent efficacy in multiple pre-clinical tumor models.

A comprehensive anti-tumor viability screen of >200 human cancer cell lines revealed striking effects of OMX-0407 on cancer cell viability across various cancer indications, resulting in a distinct sensitivity profile across various tumor indications with particularly strong effects on renal cell carcinoma (RCC) and squamous non-small cell lung cancer (sqNSCLC). Phospho-proteomics screening demonstrated pharmacodynamic activity of OMX-0407 in sensitive tumor cell lines via inhibition of key cellular processes such as cell motility, proliferation, and cell cycle regulation across different indications. Orthogonal functional *in vitro* assays confirmed the association of the OMX-0407-mediated anti-tumor efficacy with the arrest of G1/S transition and corresponding downregulation of cell cycle associated proteins PAK1/2 and ARHGAP35.

The profound impact of OMX-0407 on fundamental regulatory mechanisms of cell division and cancer cell apoptosis translates into dose-dependent single-agent, anti-tumor efficacy in various pre-clinical tumor models of selected indications. Combination with Axitinib, a selective orally available inhibitor of vascular endothelial growth factor receptor 2, significantly enhanced anti-tumor efficacy and pharmacodynamic inhibition of cell growth as well as angiogenesis. These data further strengthen the potential of OMX-0407 in the treatment of RCC as well as other indications.

In summary, OMX-0407 is a novel spectrum selective kinase inhibitor, currently under evaluation in a clinical Phase I trial (NCT05826600). OMX-0407 demonstrates strong anti-tumor efficacy in monotherapy in selected sensitive indications through a dual-pronged MoA, by modulating the tumor microenvironment and exerting direct anti-tumor activity in solid tumor indications with high unmet medical need.

#0515 Endocycling cancer cells undergo multiple S phases while repressing myc activity.

M. A. Loycano, K. J. Pienta, S. R. Amend;
Johns Hopkins University School of Medicine, Baltimore, MD

Chemotherapy resistance remains a major challenge when treating patients with metastatic cancer. While intrinsic resistance to therapy has been well studied, phenotypic plasticity that drives entry and exit of resistant cell states is poorly understood. One of these plastic cell states used by cancer cells under chemotherapy treatment is characterized by the reprogramming of the mitotic cell cycle to enter a non-proliferative endocycle. Cells in this endocycling state decouple DNA synthesis from cell division by actively progressing through G1, S, and G2 phases of the cell cycle while repeatedly skipping mitosis. After a dormant period, cells can switch back to a mitotic cell cycle to repopulate a tumor. The underlying mechanisms that drive this cell cycle reprogramming remain unknown. C-myc is an oncogenic transcription factor that is dysregulated in ~70% of human cancers. C-myc is responsible for the activation of several cell cycle drivers, including cyclins and CDKs, and represses cell cycle inhibitors, such as CDK inhibitors. High levels of myc activity allow cells to move through the cell cycle quickly with a rapid doubling time. Documented endocycles in polyploid cells rely on high c-myc activity; however, our data shows that endocycling cancer cells have repressed levels of c-myc protein and transcriptional activity. Transcriptomic data shows that myc target genes are expressed at very low levels compared to the mitotic parental cells, and complementary data shows low protein levels. While myc downregulation is expected in non-proliferative cells, the compensatory mechanisms mediating the G1/S transition in the cancer endocycle remain unknown. Recent data has shown that myc suppression alone is not sufficient to induce a sustained endocycle at a population level, despite premature APC^{Cdh1} activation during G2 in a subset of cells. We hypothesize that restoring myc activity to the levels of mitotic parental cells will drive endocycling cells to resume a proliferative mitotic cell cycle and produce mitotic progeny cells. Understanding the mechanisms that govern this transition is crucial to generate next-generation cancer therapeutics to disrupt endocycling cells, blocking acquired resistance and disease recurrence.

#0516 The role of clathrin-mediated endocytosis of EGFR in glioblastoma cell viability and cell cycle progression.

A. Deter, A. J. Tsung, M. R. Guda, S. Asuthkar, K. Velpula;
University of Illinois College of Medicine (Peoria), Peoria, IL

Glioblastoma (GBM) is characterized by poor prognosis and overexpression of epidermal growth factor receptor (EGFR). EGFR signaling is regulated through endocytosis, including clathrin-mediated endocytosis. We hypothesized that clathrin-mediated EGFR endocytosis promotes GBM cell viability and proliferation. Analysis of patient data from the Gliovis database revealed decreased overall survival in GBM patients with above-median clathrin expression (n=262) compared to below-median expression (n=263, $p<0.05$). Immunocytochemistry and Western blot analysis confirmed increased clathrin levels in GBM patient samples compared to normal brain tissue (n=15, $p<0.01$). To determine the functional effect of inhibiting clathrin-mediated endocytosis, U87 and U251 GBM cells were treated with 15 μM Pitstop-2, a clathrin inhibitor, for 24 hours. Pitstop-2 significantly reduced clathrin levels and cell viability by 40% compared to control ($p<0.001$, n=3). Cell cycle analysis by flow cytometry revealed Pitstop-2 treatment led to G2/M arrest in both cell lines versus control ($p<0.01$, n=3). Together, these findings indicate clathrin-mediated endocytosis of EGFR may promote GBM cell viability and proliferation. Further studies on the effects of clathrin inhibition on EGFR signaling and tumor growth in vivo will elucidate the therapeutic potential of targeting this pathway.

#0517 2OHOA-mediated furin inhibition: Disrupting Notch via processing, transcription, and ADAM downregulation.

R. Rodriguez-Lorca[1], R. Beteta-Gobel[1], R. Roman[1], V. Llado[2], P. Escriba[1], P. Fernandez-Garcia[1];
[1]Laminar Pharma, Inc., Palma de Mallorca, Spain, [2]Laminar Pharma, Inc., Boston, MA

Purpose Glioblastomas (GBMs) are highly treatment-resistant and aggressive brain tumors. Herewe assessed the potential of melitherapy to treat GBM, a strategy based on regulating themembrane's structure and organization to modify aspects of intracellular signaling. In thiscontext, we have evaluated the effects of 2-hydroxyoleic acid (2OHOA) on GBM cells, acompound currently under study in a phase IIB/III clinical trial for newly diagnosed GBMpatients. The current study aims to determine whether 2OHOA modulates the Notch pathway aspart of its antitumoral mechanism, as seen its relevance driving the pathogenesis of GBM.
Methods The effect of 2OHOA was evaluated on different components of the pathway usingseveral methods: W-blot, Q-PCR, and confocal microscopy. The relevance of *HES1* in itsmechanism of action was evaluated by its overexpression and pathway activation assays byJagged1. To analyze Notch receptor processing, we performed subcellular fractionation andcolocalization studies. Furin activity was assessed by fluorescence assays measuring its substratecleavage and its binding affinity to 2OHOA was determined by surface plasmon resonance.
Results 2OHOA suppresses both the Notch3 and Notch2 signaling pathways in GBM cell linesusing a two-fold mechanism. Notch3 signaling is abolished by repressing its transcription.Instead, Notch2 pathway is hindered by blocking its first cleavage through the inactivation offurin activity by physical association. Consequently, the Notch2 receptor is retained in the Golgicomplex, preventing its trafficking to the plasma membrane to initiate the signaling cascade.Moreover, overexpression of its target gene, *HES1*, partially dampened the drug's antiproliferative effect showing the relevance of this pathway in the 2OHOA pharmacologicalefficacy. In addition, considering the levels of Notch intracellular domain (NICD) obtained inJagged1 assays in conjunction with 2OHOA, we evaluated the second cleavage of the Notchprocessing, being also downregulated, as ADAM10 constitutes a furin substrate.
Conclusions These findings elucidate that the antitumoral activity of 2OHOA involves theinhibition of Notch signaling, potentially driven by the direct inhibition of furin. This reveals anovel molecular target for this bioactive lipid in the therapeutic approach to treating GBM.

#0518 The CDK2/9 inhibitor fadraciclib is active in Richter transformation and lymphoma cell lines by targeting both cell survival and proliferation.

R. Chen, Y. Chen, P. Xiong, W. Plunkett;
UT MD Anderson Cancer Center, Houston, TX

Richter transformation (RT), characterized by the transformation of chronic lymphocytic leukemia (CLL) to an aggressive large-cell lymphoma, remains a challenge for the therapy. Genetic aberrations, such as Myc activation, TP53 abnormality, NOTCH1 gene mutation or loss of CDKN2A are associated with uncontrolled RT cell proliferation and escaping of apoptosis. Among those changes, gain of Myc activity, found in around 70% of RT, plays a nexus role in the pathogenesis of RT. As a transcription factor, Myc activation has a profound effect on cell survival, proliferation, adhesion and metabolism. Because of its essential role in lymphoma transformation and aggressiveness, Myc is a vital target for therapy toward RT. Fadraciclib (CYC065) is a second-generation CDK inhibitor with selective potency toward CDK2 and CDK9. We have shown previously that by inhibiting CDK9-mediated transcription, fadraciclib reduced expression of the short-lived anti-apoptotic protein Mcl-1 to initiate apoptosis in primary CLL cells. Like Mcl-1, Myc is a quintessential example of an oncogene with rapid turnover in both its mRNA and protein, therefore a promising target of CDK9 inhibition. Thus, we proposed that fadraciclib would target both the survival and proliferation pathways of RT pathogenesis through collaborative inhibition of Mcl-1, Myc and CDK2. First, our data showed that fadraciclib effectively induced apoptosis in the RT cell line HPRT1, as well as the lymphoma cell lines with Myc amplification, including Raji, Ramos and SU-DHL-2. The IC_{50} for apoptosis was 0.3 μM at 24h in the HPRT1 cells, which is less than the average IC_{50} for the primary CLL cells (0.8 μM). The IC_{50} for the lymphoma lines ranged from 0.8 μM to 1.3 μM. Immunoblots showed reduction of RNA Pol2 phosphorylation by fadraciclib, consistent with the inhibition of CDK9. As a result of loss of RNA Pol2 activity and pausing of transcription, there was a clear reduction of both Mcl-1 and Myc mRNA, measured by real-time RT-PCR, that was associated with the reduction of their protein levels. CDK2 was also inhibited by fadraciclib, shown by the reduction of the phosphorylation of both RB and NPM. Second, Fadraciclib inhibited cell proliferation of the HPRT1 cells at an IC_{50} of 0.25 μM measured by the CellTiter-Glo assay. The IC_{50} for growth inhibition in the lymphoma lines ranged from 0.5 to 0.7 μM. CFSE tracing demonstrated halting of cell division upon fadraciclib incubation. Cell cycle analysis by Click-iT EdU showed reduction of S-phase population and arresting of cells in both G1 and G2. We are currently working on dissecting the contributions of inhibiting Myc, Mcl-1 and CDK2 individually and together, in apoptosis induction and proliferation blockade. Taken together, these data suggest that fadraciclib is active in RT cells and Myc-dependent lymphoma cell lines and support expansion of its clinical testing in patients with RT.

#0519 Targeting MYC as a novel therapeutic strategy for an epigenetic-driven cancer: NUT Carcinoma.

C. Escudero-Iriarte[1], J. Castro[1], I. Beniavides-Puy[1], N. Tissera[1], J. Querol-Panos[1], I. Agusti[1], J. Whitfield[1], M. Vieito[2], L. Nonell[1], T. Macarulla[2], I. Brana[2], L. Soucek[3], T. Tian[1];

[1]VHIO Vall D'Hebron Institute of Oncology, Barcelona, Spain, [2]VHIO Vall D'Hebron Institute of Oncology, Universitary Hospital Vall d'Hebron, Barcelona, Spain, [3]VHIO Vall D'Hebron Institute of Oncology; Peptomyc S.L.; Department of Biochemistry and Molecular Biology, Universitat Autonoma de Barcelona; Institucio Catalana de Recerca I Estudis Avancats (ICREA)., Barcelona, Spain

Epigenetic dysregulation is widespread in cancer, playing a pivotal role in shaping cell function and contributing to the process of oncogenic transformation. NUT Carcinoma (NC) is an exceptionally rare and aggressive cancer lacking effective treatment, with a dismal prognosis - NC patients typically survive less than seven months after the initial diagnosis. NC is characterized by the presence of chromosomal rearrangements involving the gene encoding for the testis-specific NUT protein and a ubiquitous gene encoding an epigenetic regulator, BRD4 in most cases. Previous studies have demonstrated the role of the BRD4-NUT fusion protein in generating clusters of acetylated histones, namely “megadomains,” throughout NC cell chromatin. These NUT-containing fusion proteins are involved in NC oncogenesis by altering the epigenetic and transcriptional landscapes, promoting cell proliferation while impeding cell differentiation. Indeed, several downstream targets, including *P63*, *SOX2*, and *MYC*, have been identified to be modulated by NUT fusion proteins, independently of the fusion partners. This study focuses on a novel therapeutic approach targeting MYC for NC treatment. We conducted a comprehensive preclinical study of OMO-103, a MYC inhibitor currently undergoing clinical evaluation, using various NC patient-derived cell lines. Through cell viability assays, cell cytometry, western blotting, RNA-seq data analysis *in vitro,* as well as *in vivo* drug efficacy evaluation in NC xenografts, we delved into the effects of OMO-103 on NC cells. Our findings reveal that OMO-103 effectively inhibits NC cell growth both *in vitro* and *in vivo*. It induces cell apoptosis, differentiation, and cell cycle arrest *in vitro*, and when tested in xenografts *in vivo*, OMO-103 reduces tumor growth and enhances mouse survival, particularly when combined with a chemotherapy regimen. This study presents a promising therapeutic strategy for an incurable and aggressive cancer type.

#0520 circBRIP1 RNA as a non-invasive target engagement pharmacodynamic biomarker for DHX9 inhibition.

D. Brennan, J. Castro, M. H. Daniels, M. Laidlaw, C. Lu, S. J. Blakemore, S. J. Silver, P. Boriack-Sjodin, K. W. Duncan, J. A. Sager, R. A. Copeland; Accent Therapeutics, Lexington, MA

DHX9 is a multifunctional DEAH-box ATP-independent RNA helicase which has been reported to play important roles in replication, transcription, translation, RNA splicing and RNA processing which contribute to DHX9's role in maintenance of genomic stability. DHX9 can bind specifically to inverted repeat *Alu* elements, preventing back-splicing events that lead to circular RNA and exon skipping of the linear transcript. Upon DHX9 inhibition, a robust induction of *Alu*-mediated circular RNA is observed. For example, circBRIP1 is an *Alu*-mediated circular RNA that is robustly elevated upon DHX9 loss, with no observed change to levels of linear BRIP1. Here we describe data demonstrating circBRIP1 as a DHX9 specific target engagement pharmacodynamic (PD) biomarker and its potential utility as a non-invasive clinical PD biomarker. We have previously demonstrated that DHX9 inhibition by novel small molecule inhibitors is efficacious in microsatellite instable (MSI) colorectal cancer (CRC) with defective mismatch repair (dMMR), both *in vitro* and *in vivo.* DHX9 inhibition in the HCT116 dMMR CRC cell line results in a robust dose dependent induction of the *Alu*-mediated circular RNA, circBRIP1, as early as 6 hours after compound treatment. The development of lead series DHX9 inhibitors exhibited a positive correlation between circBRIP1 EC50 and DHX9 biochemical activity, as well as proliferation inhibition in a dMMR CRC cell line. However, dose dependent induction of circBRIP1 following DHX9 inhibition occurs with similar potencies across DHX9i sensitive and insensitive CRC cell lines. This suggests that elevation of circBRIP1 is a unique proximal target engagement PD biomarker of DHX9 inhibition, but not a predictor of DHX9 sensitivity. Importantly, induction of circBRIP1 is observed intratumorally in human xenograft *in vivo* efficacy studies in mice. Induction in each individual tumor correlates with observed tool compound exposure, providing evidence of a predictable PK/PD relationship. We also observe dose dependent circBRIP1 induction in mouse peripheral blood mononuclear cells (PBMC). We have extended these studies to primary human whole blood, where we see robust dose dependent induction of circBRIP1 after ex vivo treatment with DHX9 inhibitor for 24 hours. Altogether, these studies show evidence for the utility of circBRIP1 as a non-invasive target engagement biomarker for DHX9 inhibitors in the clinic.

#0521 Anticancer mechanisms of epigallocatechin gallate revealed via cellular and molecular profiling.

A. Panchal[1], J. H. Law[1], C. Lo[2], **K. W. Yip**[3];
[1]University of Toronto, Toronto, ON, Canada, [2]Anticancer.ca, Toronto, ON, Canada, [3]University of Toronto, Anticancer.ca, Toronto, ON, Canada

Introduction: Epigallocatechin gallate (EGCG) is a polyphenol present in green tea that is known for its anti-oxidant, anti-inflammatory, anti-angiogenic, pro-apoptotic, and anti-cancer properties. However, EGCG has not been systematically evaluated on a large panel of cancer cell lines. We hypothesized that EGCG exhibits varying effects on specific cancer cell genetic backgrounds and types. This study aimed to provide a comprehensive analysis of EGCG on both cell viability and gene expression profiles.

Methods: 750 cancer cell lines were cultured and seeded in 1536-well plates for cell viability studies (by the CTD^2 Center at the Broad Institute). After 24 h, cells were treated with 16 two-fold serial dilutions of EGCG. After 72 h, cell viability was assayed using CellTiter-Glo. For gene expression profiling (with the Broad Institute and NIH), 8 cell lines were treated with 10 µM EGCG for 6 and 24 h, and transcriptomes were assessed using Affymetrix GeneChip Human Genome U133 Plus 2.0 Arrays. The CMap large-scale transcriptome dataset was used for comparisons.

Results: EGCG had the highest potency in the non-Hodgkins B-cell lymphoma cell line DoHH2 (IC_{50}=0.42 µM), the myeloid leukemia cell line Ku812 (IC_{50}=3.76 µM), and the multiple myeloma cell line KMS-28BM (IC_{50}=4.57 µM). Tissue-of-origin analysis showed that EGCG was most potent against lymphoid cancers, and least potent against prostate cancers. Bioinformatics-based analyses found that EGCG-treated cells resembled cells overexpressing CHEK2, DDP4, CBLC, ZNF350, and TRAF6, and cells underexpressing TRIM16. EGCG-induced gene expression resembled lapatinib and sulfasalazine treatment.

Conclusions: This study provides a comprehensive examination of the differential impact of EGCG treatment on cancer cells. Subsequent research on the timing and duration of the changes, along with pathway enrichment analyses, will potentially guide the translational potential of EGCG and its chemical analogs in personalized cancer treatment approaches.

#0522 *TP53*mutations promote death of breast cancer cells following Kif11 inhibition.

A. L. Lanier, W. Tahaney, J. Qian, C. Moyer, Y. Ma, B. Arun, A. Mazumdar, P. H. Brown;
UT MD Anderson Cancer Center, Houston, TX

Background: Triple-Negative Breast Cancer (TNBC) comprises 15-20% of breast cancer diagnoses. These aggressive breast cancers are characterized by their lack of expression of the estrogen receptor (ER), human epidermal growth factor receptor 2 (HER2), and progesterone receptor (PR), resulting in few targeted therapy options for TNBC patients. While 85-90% of TNBCs contain mutations in *TP53,* mutant p53 is challenging to target directly. Instead, we aim to identify other survival pathways critical for the growth and survival of *TP53* mutant cells. Through a combined *in vitro* and *in silico* drug screen, we identified the Kif11 inhibitor SB-743921 as more effective in *TP53* mutant compared to wild-type breast cancer cells.
Hypothesis: We hypothesized that Kif11 inhibition causes *TP53* mutant cells to undergo cell death due to failure of activation of p53-mediated cell cycle checkpoints.
Methods: Clinical data from the TCGA and METABRIC cohorts was obtained from cBioPortal. Expression and survival analyses were performed using GraphPad Prism. Cell growth assays were conducted by seeding cells, treating under designated conditions, then staining with Hoechst 33342 for cell counting on the ImageXpress Pico. Cell death was determined by staining with Annexin V and PI or DAPI Staining followed by flow cytometry analysis. Cell cycle analysis was conducted following synchronization with Lovastatin and Mevalonate release followed by imaging analysis of cell lines expressing the Fast FUCCI reporter or PI staining and flow cytometry analysis. Immunofluorescence imaging was conducted by staining with anti-alpha-tubulin-AlexaFluor488 and DAPI and imaging on the Nikon TI2 or ImageXPress PICO. *In vitro* expression experiments were carried out through qPCR and western blotting.
Results: KIF11 is most highly expressed in *TP53* mutant and triple-negative tumors and high expression of KIF11 is associated with poorer overall survival. In breast cancer cell lines, Kif11 inhibition leads to a cell cycle block in both *TP53* mutant and wild-type cells, but *TP53* mutant cells then die following this cell cycle block. Furthermore, Kif11 inhibition causes mitotic dysfunction, including monopolar spindle formation and multinucleated cells in *TP53* mutants. Introduction of a *TP53* mutation into *TP53* wild-type cells also induces cell death following Kif11 inhibition.
Conclusions: KIF11 is highly expressed in aggressive breast cancers and is associated with poorer prognosis. Using the small molecule inhibitor SB-74321 that has been tested in phase I/II clinical trials with favorable tolerability, we found that Kif11 inhibition results in mitotic dysfunction and death of TP53 mutant breast cancer cells due to mitotic catastrophe. These results suggest that Kif11 is a promising target for the treatment of *TP53* mutant TNBCs.

#0523 Aronia berry and oligomeric proanthocyanidins synergistically exhibit anticancer effects in colorectal cancer by inhibiting LMNB1.

Y. Li[1], C. Xu[2], A. Goel[2];

[1]Beckman Research Institute of The City of Hope, Duarte, CA, [2]Beckman Research Institute of The City of Hope, Monrovia, CA

Background: Colorectal cancer (CRC) is one of the most common and recurrent diseases globally, ranking as the second leading cause of mortality. The high mortality rates associated with this disease are largely due to the ineffectiveness of current treatments and the development of chemotherapeutic resistance to conventional therapies. In recent years, several natural agents, such as Aronia berry extract (ABE) and oligomeric proanthocyanidins (OPCs), have shown promise in providing a safe, cost-effective, and synergistically multi-targeted treatment approach across various cancers. Herein, we hypothesized that the combined treatment with ABE and OPCs may synergistically regulate multiple oncogenic pathways, thereby presenting a more potent anti-cancer activity, particularly targeting CRC. Methods: We performed a series of cell culture experiments to evaluate the synergistic anticancer effect of the combination of ABE and OPCs in CRC cell lines. By performing genome-wide transcriptomic profiling, we identified specific growth-signaling pathways targeted by the combined treatment and subsequently validated these findings in cell lines and patient-derived 3D organoids. Results: The combined treatment with ABE and OPCs exhibited superior synergistic anti-tumor potential, affecting cell viability, proliferation, migration, and invasion in CRC cells. The transcriptomic analysis identified that LMNB1, associated with the cell apoptosis pathway Fold enrichment [FC]: 4.29, P =0.005), plays a crucial role in the anti-tumorigenic effects of these two natural products. Moreover, the combination of ABE and OPCs significantly altered the expression of key proteins involved in cell apoptosis and suppressed the expression level of LMNB1 in HCT116 (Combination vs. ABE, FC= 0.28; Combination vs. OPCs, FC= 0.24) and SW480 (Combination vs. ABE, FC= 0.65; Combination vs. OPCs, FC= 0.47), thereby inhibiting downstream Akt phosphorylation. Finally, we successfully demonstrated that the combined treatment displayed a superior anti-cancer activity in 3D organoids, significantly reducing both their number and size ($P < 0.05$). Conclusion: We present novel evidence for the synergistic anticancer effects of ABE and OPCs in CRC cells, which are in part achieved by regulating cellular apoptosis and the oncogene LMNB1 within the Akt signaling pathway.

#0524 Using acquired resistance to explore the mechanism of action of the integrated stress response/GCN2 activator NXP800 - A new developmental agent for platinum-resistant ARID1A mutant ovarian cancer.

M. V. Powers[1], R. Hodgson[2], S. Y. Sharp[1], T. Roe[1], K. E. Allen[2], S. Campbell[2], R. te Poele[1], M. Cheeseman[1], K. Jones[1], P. A. Clarke[1], P. Workman[1];
[1]The Institute of Cancer Research, London, United Kingdom, [2]Sheffield Hallam University, Sheffield, United Kingdom

Background: NXP800 is a potent, oral activator of the Integrated Stress response (ISR), inhibitor of heat shock factor 1 (HSF1) activation and tumor cell proliferation, which is in early clinical studies in ARID1A-mutated, platinum resistant, clear cell ovarian cancer (NCT05226507). We discovered NXP800 using multiparameter medicinal chemistry optimization of a hit identified from a cell-based phenotypic screen. Owing to the unbiased nature of phenotypic screening, target identification is crucial to understand the biological and therapeutic activity of hit compounds.
Methods and Results:: By RNAseq profiling human cancer cells treated with NXP800 we identified changes in expression of genes regulated by HSF1 or ATF4 - effects accompanied by eIF2alpha (eIF2a) phosphorylation and resulting activation of the ISR. To further understand this response, we explored whether NXP800 resistance models could inform on its mechanism of action (MoA). We used ARID1A mutant SK-OV-3 human ovarian carcinoma cells that are 1) highly sensitive to NXP800, 2) model the target patient population and 3) MSI-high so likely to have an elevated mutation rate contributing to acquisition of resistance. We generated two independent NXP800-resistant SK-OV-3 cell lines in which NXP800-mediated ATF4 induction and concomitant inhibition of global translation were abolished. By whole exome sequencing, we identified a heterozygous L99P mutation in the alpha subunit of eIF2B (eIF2Ba), the nucleotide exchange factor for eIF2a. Expression of eIF2Ba^{L99P}, but not wild-type, in parental SK-OV-3 cells reduced sensitivity to NXP800 to the same level as cells with NXP800-induced resistance. Using fluorescence recovery after photobleaching to monitor the dynamic association of the eIF2B:eIF2a complex, we elucidated that the eIF2Ba^{L99P} mutation reduces NXP800-mediated inhibition of eIF2a-GFP recycling through eIF2B bodies. Phosphorylation of eIF2a is regulated by four stress-controlled kinases GCN2, HRI, PKR and PERK. Using systematic siRNA knockdown or small-molecule inhibitors, we showed that GCN2 alone is required for ISR activation by NXP800 and that ISR induction inhibited HSF1 activation. Furthermore, inactivation of GCN2 reduced the antiproliferative activity of NXP800 to the same extent observed in NXP800-resistant SK-OV-3 cells. In contrast, exposure of resistant or parental SK-OV-3 cells expressing eIF2Ba^{L99P} to GCN2 inhibitors did not cause further reduction in NXP800 sensitivity - confirming the importance of the eIF2Ba^{L99P} mutation in the resistance mechanism.
Conclusions: We have used acquired resistance to understand the MoA of NXP800 as a potent activator of GCN2 and the ISR pathway. Further studies are underway to determine the exact proximal molecular target of NXP800 and the mechanism of GCN2/ISR activation.

#0525 A comprehensive approach: Copper chelation therapy modulates epigenetic, kinase signaling and metabolic pathways in diffuse midline gliomas (DMG).

F. Michniewicz[1], R. Cazzoli[2], J. Bell[2], F. Saletta[2], E. Poursani[2], J. R. C. Rouaen[2], T. Shai-Hee[2], V. Pham[2], T. Jue[2], M. Biery[3], L. Bramberger[4], T. Lim[4], A. Khan[2], F. M. Giorgi[5], D. Mercatelli[5], C. Mayoh[2], G. Cirillo[6], A. Macmillan[1], R. Whan[1], C. T. Barlow[4], M. Tsoli[2], N. Vitanza[3], S. Berry[1], P. Faridi[4], D. Ziegler[2], O. Vittorio[1];

[1]UNSW Sydney, Kensington, Australia, [2]Children's Cancer Institute, Kensington, Australia, [3]Seattle Children's Research Institute, Seattle, WA, [4]Monash University, Clayton, Australia, [5]University of Bologna, Bologna, Italy, [6]University of Calabria, Calabria, Italy

Diffuse Midline Gliomas (DMG) are incurable pediatric brain tumors driven by histone mutation H3K27M, globally reducing H3K27 trimethylation altering the epigenome and deregulating gene expression. These mutations often partner with and are strongly integrated into kinase signaling and metabolic alterations, driving aggressive tumor growth with many mechanisms which can compensate for one another and therefore evade traditional single agent therapies. Copper over-accumulation has been linked to epigenetic, kinase and metabolic dysregulation in various cancers and neurological disorders. Copper chelators are clinically approved for use in pediatric Wilson's Disease patients, improve neurological symptoms and are under clinical investigation for several cancers. We propose copper chelators may simultaneously target these mechanisms in DMG. We performed transcriptomic interrogation of patient datasets, *in vitro* investigations in a panel of DMG cell lines and an *in vivo* investigation using an orthotopic xenograft model of DIPG (SU-DIPGVI-*Luc*). Copper chelator tetraethylenepentamine-pentachloride (TEPA) was used to treat DMG cells. Transcriptomic (RNA-Seq), proteomic, phospho-proteomic and metabolomic (Mass Spectrometry) investigations, western blots and immunofluorescent microscopy determined efficacy and mechanism. *In vivo* investigation consisted of survival study with concurrent luminescence imaging, histology, and copper assay. We demonstrate copper chaperone transcript expression is increased in DMG patient samples compared to non-DMG samples. *In vitro*, apoptosis and growth assays demonstrated H3K27M DMG were more sensitive to TEPA than H3-WT DMG. In H3K27M DMG, TEPA downregulated ATP, GTP and SAM metabolism which corresponded with downregulated kinase signaling and altered H3K27 trimethylation and DNA methylation patterns around cell cycle genes. Affected genes included those regulating centrosome segregation and ATP synthesis. Further transcriptomic and proteomic investigations highlighted TEPA downregulated G2-M phase kinase pathways, with immunofluorescence demonstrating TEPA reduced expression of mitotic marker p-H3S10 and epigenetic methylators EZH2 and DNMT1. *In vivo,* TEPA reduced brain copper accumulation, eliminated tumors and increased survival in an orthotopic patient-derived xenograft DMG model. Collectively, our data indicates TEPA induced multi-modal targeting of M-phase cell cycle progression through epigenetic, kinase signaling and metabolic mechanisms. Efficacy was observed both *in vitro* and *in vivo*, providing a promising basis for future investigation of copper chelators in DMG. We propose copper-chelation is a viable therapeutic strategy for DMG patients warranting clinical investigation.

#0526 Identification of CDK6 binding proteins by proximity labeling reveals novel mechanisms for CDK4/6 inhibitor resistance in breast cancer.

Chung Wei Ting[1], Yong-Ji Zhuang[1], Chih-Yi Lin[2], Chung-Jen Yu[1], Ta-Chung Chao[2], Ling-Ming Tseng[2], Chun-Yu Liu[1], Yi-Fang Tsai[2], Chi-Cheng Huang[2], **Jiun-I Lai**[1]

[1]National Yang Ming Chiao Tung University, Taipei, Taiwan,[2]Taipei Veterans General Hospital, Taipei, Taiwan

Breast cancer is one of the most prevalent cancer type in human, and the majority (~70%) is the hormone positive (HR+) subtype. The current frontline treatment of choice in metastatic HR(+) breast cancer is CDK4/6 inhibitors (CDK4/6i) combined with endocrine therapy. Current guidelines recommend CDK4/6i treatment as 1st or 2nd line, as CDK4/6i provides survival benefit and good quality of life. However, resistance eventually emerges, leading to discontinuation of CDK4/6i and switching to subsequent treatment. Investigation of mechanisms to CDK4/6i resistance is an active area of intense research. CDK6 overexpression has been reported as an important mechanism for CDK4/6i resistance by several independent groups. We incidentally discovered a point mutation in the CDK6 protein that abolishes the CDK4/6i resistance conferred by CDK6 overexpression. When treated with CDK4/6i, overexpression of wild type CDK6 did not suppress G1/S, while both non-transfected and overexpression of mutant CDK6 both had similar suppression of G1/S. We hypothesized that a binding partner to CDK6 demonstrated differential binding activity to the mutant which abolished the resistance by CDK6 overexpression. To assess this hypothesis, we performed proximity labeling (PL) by APEX2. Both wild type and mutant CDK6 were cloned into APEX-Flag/V5 vectors with either cytoplasm (NES) or nuclear (NLS) signals. Mass spectrometry following treatment by H2O2 induced biotinylation produced candidate peptides that bound with overexpressed CDK6. We identified leading candidates of differentially binding partners that bound to mutant CDK6. Further experimental validation was performed to confirm physical proximity between CDK6 and the candidate protein. Our research uncovered novel insights to how CDK6 conferred resistance towards CDK4/6i and expands knowledge into further therapeutic development.

#0527 Cancer cells in the resistant, endocycling cell state exhibit centrosome amplification.

M. Purkerson, S. Amend, K. J. Pienta;
Johns Hopkins University School of Medicine, Baltimore, MD

Therapy resistance is one of the most common underlying causes of poor prognosis in cancer patients, ultimately driving fatal outcome. We have previous demonstrated that following chemotherapeutic stress, a subset of cancer cells undergo a mitotic skip and enter an endocycle, causing whole-genome duplication without division. This endocycling cell state is resistant to cytotoxic therapies and thus is an actuator of therapy resistance. Cells in the endocycling state eventually undergo depolyploidization and repopulate the tumor, observed clinically as a recurrence. We also demonstrated that the minus-end directed motor protein KIFC1, a mediator of centrosome clustering, has higher expression in cells following treatment. Centrosome amplification (CA) involves aberrations in centrosome number, where cells have 3 centrosomes. Cells with extra centrosomes create a multi-polar spindle during mitosis, which presents high risk for cell death and arrest, but cancer cells with CA avoid this by clustering extra centrosomes to create a pseudo-bipolar spindle. Based upon this data, we hypothesize that studying centrosome dynamics and abnormalities presents a window into better understanding endocycle biology and this novel mechanism of therapy resistance. Cancer cells were treated with LD50 dose of cisplatin and released from treatment for varying lengths of time. CA in endocycling cells increased from 59.2% to 100% during the treatment recovery period while maintaining identical levels of clustering. Endocycling cancer cells have a nearly 5-fold increase in declustered centrosomes compared to proliferative cells. Centrosomes in endocycling cells are displaced from the perinuclear region and toward the cell periphery. We hypothesize that centrosome number may indicate the number of times a cell has endocycled and provide insight into the timing and mechanism of mitotic bypass. Centrosomes play a major role in microtubule nucleation, affecting cell motility and polarity, and act as signaling platforms, enhancing signaling activation and specificity. Because of this, we hypothesize that CA may be a critical mechanism for endocycling cancer cells to survive and maintain this resistant cell state.

#0528 CDK9 inhibition activates innate immune response in prostate cancer cells.

S. Yalala[1], A. Gondane[1], N. Poulose[2], J. Liang[1], I. G. Mills[2], **H. M. Itkonen**[1];
[1]University of Helsinki, Helsinki, Finland, [2]University of Oxford, Oxford, United Kingdom

Hyper-activation of transcription is frequent in cancer, which often leads to increased sensitivity to compounds targeting the transcriptional kinases, in particular cyclin-dependent kinase 9 (CDK9). However, mechanistic details as to why CDK9 inhibition selectively kills cancer cells remain largely unknown. Here, we report that CDK9 inhibition activates innate immune response through viral mimicry. In MYC over-expressing prostate cancer cells, CDK9 inhibition leads to excessive accumulation of mis-spliced RNA. Double-stranded RNA (dsRNA)-activated kinase can recognize these mis-spliced RNAs, and we show that this kinase is required for the CDK9 inhibitor-induced anti-proliferative effects. Using time-resolved transcriptional profiling (SLAM-seq), targeted proteomics and ChIP-seq, we show that, similar to viral infection, CDK9 inhibition significantly suppresses transcription of most genes but allows selective transcription and translation of certain genes. In particular, CDK9 inhibition activates NFκB-driven cytokine-signaling at the transcriptional- and secretome-levels. Transcriptional signature induced by CDK9 inhibition identifies prostate cancers with high level of genome instability, and we propose that it is possible to induce similar effects using CDK9 inhibitors. In summary, here we show that inhibition of CDK9 activates innate immune response through viral mimicry. In the future, it is important to establish if CDK9 inhibitors can potentiate the effects of immunotherapy against the late-stage prostate cancer, a currently lethal disease.

#0529 Investigating the synergistic effect of milciclib and PD0325901 in colorectal cancer therapy.

X. Pei[1], A. Nguyen[2], H. Neiger[2], W. Wang[2], W. Bautista[2], L. Wang[3], A. Cai[2], V. A. Gerriets[2], J. K. Cusick[2], **Y. Shi**[4];
[1]City of Hope, Duarte, CA, [2]California Northstate University, Elk Grove, CA, [3]University of California, Berkeley, CA, [4]California Pacific Medical Center Research Institute, San Francisco, CA

Milciclib, characterized as a potent nanomolar inhibitor of multiple cyclin-dependent kinases, has recently emerged as a promising therapeutic agent in cancer treatment, particularly with its additional role as a spliceosome modulator. Our recent studies employing RNA sequencing technology revealed a comprehensive profile of Milciclib-induced transcriptional changes in colorectal cancer cells, identifying several key regulated pathways. In light of these findings, we explored a novel therapeutic strategy: combining Milciclib with specific inhibitors targeting pathways upregulated by Milciclib treatment. This hypothesis is based on the rationale that such a combination could exert a synergistic effect. We have assessed the efficacy of this combinational therapy and found that the combination of Milciclib and PD0325901 greatly potentiates the killing of colorectal cancer cells versus either treatment alone. PD0325901 has been extensively studied for its efficacy in targeting the MEK/ERK signaling pathway, a critical pathway in many cancers, including colorectal cancer. To further characterize the underlying molecular mechanisms contributing to the observed synergistic effect, we applied quantitative proteomic analysis of 8107 proteins in human colorectal cancer cells with the treatment of different doses of Milciclib and PD0325901 administered alone, or in combination. Our results demonstrate 49 proteins were significantly decreased in a dose-dependent manner, and that many of these proteins are key players regulating pathways associated with the cell cycle, apoptosis, gene expression, metabolism, WNT signaling, and the MEK/ERK signaling pathway. The discovery of the down-regulation of these proteins and pathways after treatment provides a molecular basis to elucidate the synergistic mechanism underlying Milciclib and PD0325901 combination therapy. In conclusion, our study establishes the combinatorial use of Milciclib and PD0325901 as a potential breakthrough in the treatment of colorectal cancer, offering a promising prospect for enhancing future patient outcomes.

#0530 The effect of cardamonin on PD-L1 expression in triple-negative breast cancer cells.

P. Mendonca, B. Kirpal, S. Kaur, K. F. Soliman;
Florida A&M University, Tallahassee, FL

Triple-negative breast cancer (TNBC) accounts for about 10% of all breast cancers and does not express estrogen, progesterone, or HER2 receptors. It has an aggressive nature, it is highly metastatic, and because of the lack of therapies, it continues to be a challenge. These cancer cells employ mechanisms to escape the immune system that induce the upregulation of PD-L1 expression, a ligand encoded by the CD274 gene. Because cancer cells tend to produce higher levels of PD-L1 compared to normal cells, therapies that inhibit PD-L1 may be helpful. Evidence also shows that high levels of oxidative stress and inflammation may participate in both the initiation and progression of cancer. Cardamonin, an aromatic enone flavonoid, has displayed an array of pharmacological activities, including modulation of different signaling molecules involved in the development and progression of cancer. This work investigated the cardamonin's ability to modulate PD-L1 expression and NF-KB in genetically distinct MDA-MB-231 (Caucasian) and MDA-MB-468 (African American) TNBC cell lines. The methodology included cytotoxic assays, ELISA, Real Time-Polymerase Chain Reaction (RT-PCR) assays, and Wes analysis. The results showed that cardamonin treatment caused a dose-dependent decrease in cell viability in both cell lines, ranging from 3.12 μM to 200 μM. The RT-PCR and ELISA data showed that even though IFN-γ stimulated MDA-MB-231 cells showed a higher expression of PD-L1, cardamonin reduced mRNA and protein expression of PD-L1 in both cell lines. As a possible molecular mechanism for PD-L1 inhibition, cardamonin modulated MUC-1, STAT3, and JAK, which are genes that activate the PD1/PD-L1 mechanism. Moreover, data also show that cardamonin modulated NF-KB1 and NF-KB2 genes involved in activating NF-KB signaling. NF-KB is a transcription factor of inflammation and immunity, emerging as a key positive regulator of PD-L1 expression in cancer. Therefore, cardamonin may have the potential utilization as a checkpoint inhibitor that acts by blocking PD-L1 protein, allowing the immune system to recognize and attack the TNBC cancer cells, providing a novel cancer therapy. (Supported by a grant from NIH-NIMHD U54 MD 007582)

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance 1: Models
Poster Session

#0533 Attenuating EZH2-mediated metastasis and tumor growth by pharmacological-based approaches using three-dimensional in vitro culture models.

x. Rima[1], G. Sarathy[1], C. Hu[2], D. S. Patel[2], D. Ramsey[3], L. Rizotto[1], D. Palmeri[4], G. Fewell[3], B. Ramaswamy[1], E. Reategu[2], **E. Shankar**[1];
[1]The Ohio State University Wexner Medical Ctr., Columbus, OH, [2]The Ohio State University, Columbus, OH, [3]SynVivo Inc, Huntsville, AL, [4]The Ohio State University school of Medicine, Columbus, OH

Triple Negative breast cancer (TNBC) accounts for 10-15% of all breast cancers where patients encounter poor clinical outcomes. Treatment modalities for TNBC are conventional cytotoxic chemotherapy and radiation leads to 35%-40% relapse within 5 years of diagnosis. There is a growing need for more effective targeted therapeutics to inhibit TNBC growth. The role of EZH2 in maintaining tumor growth and metastasis in TNBC is well documented. EZH2 promotes breast tumor-initiating cell expansion (BITC) and cancer progression by impairing the DNA damage repair process favoring activation of oncogenes. Despite the advancement in the discovery of inhibitors for EZH2 that attenuate its catalytic activity, resistance to these small molecules limits their use in solid tumors. The neurotransmitter dopamine via its D1 receptor activation in TNBC cell lines induces apoptosis and autophagy, as well as inhibits the invasion and regress in mammary tumors in vivo. Here we hypothesize that the presence of dopamine D1 receptor agonist (A77636) enhances the efficacy of EZH2 inhibitors (GSK126) to inhibit in vitro TNBC tumor growth and metastasis. To test the efficacy of the combination we employed a 3D culture system of MDA-MB-231 cells encapsulated in calcium-alginate microgels seeded from a microfluidic droplet generator. We also employed a 3D organ-on-chip-based microphysiological (MPS) platform (SynTumor) to study the effect of the drug combination on metastasis in vitro. The SynTumor MPS devices replicate the pathophysiological architecture of native vascularized breast tumors. The combination treatment enhanced a significant reduction of tumor spheroid diameter compared to the vehicle and indicated spheroid regression over treatment. Furthermore, the combination therapy induced necrosis and caused complete inhibition of EZH2 expression. The knockdown of EZH2 inhibited tumor spheroid formation and displayed cytoskeleton de-arrangement. In the microfluidic SynTumor model, circulating tumor cell numbers were reduced by half at 96 hrs after EZH2 combination treatment. Our data indicate that the combinatorial effect of DRD1 agonist and EZH2 inhibitor efficiently attenuates the EZH2-mediated in vitro tumor growth and metastasis (This work is supported by DOD: W81XWH2010065, for Eswar Shankar).

#0534 Novel marginal zone lymphoma models of resistance to the dual inhibition of PI3K and BCL2.

A. J. Arribas[1], L. Cascione[1], E. Cannas[1], H. Bellerjeau[1], F. Fuzio[1], A. Noguera[2], A. Rinaldi[1], M. Esteller[2], E. Zucca[3], A. Alimonti[1], D. Rossi[1], A. Stathis[3], F. Bertoni[1];

[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland, [2]Josep Carreras Leukaemia Research Institute (IJC), Barcelona, Spain, [3]Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background: Copanlisib is a PI3K inhibitor with selectivity against PI3Kδ and PI3Kα and is approved for treating patients with follicular lymphoma and marginal zone lymphoma (MZL). Preclinical studies have demonstrated strong synergism of copanlisib and BCL2 inhibitor venetoclax in different lymphoma models, and the combination is under clinical evaluation. Understanding the resistance mechanisms could help the design of improved therapies. Hence, we generated MZL cell lines resistant to the copanlisib/venetoclax combination.

Methods: All cells were tested for cell identity and Mycoplasma status. Resistance was confirmed stable after 3-weeks of drug-free culture. Multi-drug resistance phenotype was ruled out by confirming sensitivity to vincristine. Targeted agents already in the clinics were combined with copanlisib/venetoclax. Cells underwent transcriptome and methylation profiling, targeted DNA sequencing, and immunophenotypic and immunoblotting analyses.

Results: We developed SSK41-derived models with resistance to copanlisib (n.=1) or venetoclax (n.=1) as single agents and to copanlisib/venetoclax (n.=2) by long IC50 or by upfront IC90 exposure. The single-drug-resistant cells showed only partial resistance to copanlisib/venetoclax. In contrast, the cells that developed exposing cells to copanlisib/venetoclax IC90 exhibited a more substantial decrease in sensitivity to the combination. Copanlisib/venetoclax induced apoptosis and cell cycle arrest in PAR but not in resistant cells. Sensitivity to other PI3K, BCL2, and BTK inhibitors was decreased in all resistant lines. The response to MCL1-i, mTOR-i, and epigenetic agents (decitabine, HDAC, BET, and EZH2 inhibitors) was maintained. Triple combinations of copanlisib/venetoclax with the AURKA inhibitor alisertib, PLK inhibitor rigosertib, or the multikinase inhibitor amcasertib were active in both parental and resistant cells. No acquired mutations were observed via targeted DNA sequencing designed to cover various coding genomic regions known to be recurrently mutated in mature B-cell neoplasms, including BCL2, nor via RNA-Seq for PIK3CA/B/G/D genes. Integration of RNA and methylation profiles showed deregulation of genes involved in type-I IFN, chemokines (CCL25, CXCL13), apoptosis regulation, and JAK-STAT signaling. Resistant cells upregulated CD19 expression compared to parental cells. Immunoblotting showed the inability of copanlisib/venetoclax to block BCR signaling in resistant cells.

Conclusions: We created four novel MZL-derived models of secondary resistance to PI3K and BCL2 inhibitors, which will help clarify possible modalities to overcome resistance. Novel potential targets were already identified, such as AURKA or PLK, to be further exploited.

#0535 Resistant PDO models: Unraveling drug resistance mechanisms for discovering new drug targets.

Y. Abouleila, M. Doorn, R. Verkerk, J. Maas, C. Verissimo, S. Boj;
HUB Organoids, Utrecht, Netherlands

Resistance to cancer treatment remains a significant obstacle in curing patients with cancer. Despite recent advancements in novel drug targets for cancer therapeutics, patients often develop treatment resistance even after initial disease remission, leading to tumor relapse. To investigate the mechanisms responsible for developing resistance to standard-of-care therapies, it is essential to gain insights into the stepwise progression leading to complete resistance. Recent research has revealed that cancer cells can evade the effects of chemotherapy and targeted therapy by entering a reversible and slow proliferation state known as the drug-tolerant persister (DTP) state. This DTP state allows cancer cells to survive drug therapy long enough for additional mechanisms of acquired drug resistance to develop. HUB Organoids® or patient-derived organoid (PDO) models are derived from patient tissues, making them more physiologically relevant than traditional cell lines. Thus, studying drug persistence and resistance in PDO models is more likely to reflect in vivo conditions. This study demonstrates the successful development of persistent and resistant CRC PDO models to standard-of-care therapies. All models were characterized using whole exome sequencing and RNA sequencing to confirm their persistent or resistant state and to identify possible pathways involved in developing therapy resistance, as well as potential new drug targets. In conclusion, developing persistent and resistant PDO models is crucial for understanding drug resistance mechanisms, enabling the development of more effective and personalized cancer treatments, and advancing our overall knowledge of how resistance develops in cancer patients.

#0536 Breaking through ADCs resistance: Constructing preclinical enhertu-induced resistant model.

Y. Fang, H. Wang, J. Xing, L. Yang, J. Zhao, X. Gao, C. Ju;
Gempharmatech Co., Ltd., Nanjing, China

Antibody-drug conjugates (ADCs) are compounds that combine the specificity of monoclonal antibodies (mAbs) with the cytotoxic payload of toxic substances. In recent years, ADCs have rapidly developed in the field of cancer therapy, particularly in the treatment of HER2-positive breast cancer. One representative example is Trastuzumab deruxtecan (Enhertu), which has become a new benchmark for anti-HER2 ADCs due to its excellent performance in clinical trials. Despite the impressive clinical outcomes of ADCs, some tumors in patients may still develop resistance to these drugs. Therefore, it is crucial to understand the mechanisms of resistance and develop strategies to overcome ADCs resistance. To achieve these goals, it is essential to establish and utilize preclinical models to study these resistance mechanisms. Preclinical models of resistance to ADCs have mainly been generated using human cultured cell lines. JIMT-1 is a HER2-positive breast cancer cell line that exhibits primary resistance to the anti-HER2 antibody trastuzumab and also shows resistance to trastuzumab-derived ADC T-DM1. However, we found that Enhertu significantly inhibited tumor growth in JIMT-1 xenograft models. We subjected JIMT-1 tumor tissues to continuous passage in mice and administered long-term drug induction. The tumor growth rate gradually increased, and the drug sensitivity decreased, resulting in the acquisition of an Enhertu-resistant tumor model. The obtained resistant tumor tissues not only include tumor cells themselves but also comprise fibroblasts, extracellular matrix, and other cellular components, enabling a more comprehensive investigation into the interactions between different cells within the tumor microenvironment (TME). We believe that the establishment of preclinical Enhertu-resistant models helps predict resistance that has not yet emerged clinically and provides references for future drug development.

#0537 Preclinical PD-1 resistance models: Crucial tools for unveiling PD-1 resistance mechanisms and advancing novel treatment strategies.

Y. Zhu, Y. Fang, H. Wang, J. Xing, L. Yang, J. Zhao, X. Gao, C. Ju;
Gempharmatech Co., Ltd., Nanjing, China

In the cancer-immunity cycle, the immune checkpoint PD-1 and its ligand PD-L1 collaborate to facilitate tumor immune evasion and promote tumor progression by thwarting immunity-induced apoptosis. Immune checkpoint inhibitors disrupt this alliance by preventing PD-1 from binding to PD-L1, thereby reactivating the patient's immune system. While anti-PD-1/PD-L1 therapy has demonstrated remarkable efficacy in treating solid tumors, durable responses are observed in only a minority of patients. The majority of patients do not experience the full benefits of anti-PD-1/PD-L1 therapy, and a significant proportion of initial responders eventually develop acquired resistance. Thus, the establishment of reliable preclinical PD-1 resistance models is of paramount importance for uncovering resistance mechanisms and devising novel treatment strategies.

Common mechanisms contributing to PD-1/PD-L1 resistance include the absence of appropriate tumor antigens, inactivation of tumor surface MHC molecules, aberrant IFNγ signaling pathways, and the presence of an immunosuppressive tumor microenvironment. We have successfully generated multiple drug resistance models at both cellular and animal levels, offering valuable tools for the investigation of diverse drug resistance mechanisms. For instance, our animal model of drug resistance, induced by long-term treatment with the PD-1 antibody (Keytruda), simulates the clinical scenario of acquired resistance due to prolonged medication. Through gene editing techniques, we have created a drug-resistant cell line (CT26-B2M KO) by disrupting the B2M gene in the CT26 cell line, thereby mimicking a tumor model with B2M functional deficiency in mice. Additionally, we have compiled efficacy data from various naturally occurring resistant models, which serve as valuable resources for studying primary resistance or intricate resistance mechanisms.

In summary, preclinical PD-1 resistance models serve as crucial tools for researchers to dissect the intricacies of PD-1 resistance mechanisms and offer essential guidance for the development of innovative treatment strategies.

#0538 Establishment of PARP inhibitor-induced resistant patient-derived ovarian cancer xenograft models.

L. Hua, S. Li, C. Nie, X. Chen, G. Sheng, L. Bourre, **J. Wang**;
Crown Bioscience, Inc., San Diego, CA

Introduction: Poly (ADP-ribose) polymerases (PARPs) can recruit DNA repair effectors and cope with DNA single-strand breaks. For DNA double-strand breaks (DSB), there are two main repair mechanisms: non-homologous end joining repair (NHEJ) which is prone to error due to infidelity events, and BRCA1/2 mediated homologous recombination repair (HR) restoring the original sequence. Therefore, inhibition of PARPs may cause both single stranded break repair deficiency and HR deficiency in BRCA1/2 deficient patients, leading to cell death. The concept of “synthetic lethality” has led to the development of PARP inhibitors, including Olaparib, Niraparib and Rucaparib in clinical practice. Despite encouraging efficacy of these PARP inhibitors, acquired resistance, such as HR repair restoration, drug efflux pump upregulation and replication fork protection, has limited their clinical benefits. Therefore, to investigate novel therapeutic strategies which can overcome the acquired resistance, we established patient-derived xenograft (PDX) ovarian cancer models with PARP inhibitor-induced resistance.

Methods: OV9402, an ovarian cancer PDX model with BRCA 1 c.3155del, was implanted subcutaneously and treated with Niraparib at 35 mg/kg, daily, for 129 days. Relapse tumors (tumor #1 and tumor #2) were isolated and inoculated into naïve mice. Then the 2nd round of treatment (Niraparib, 35 mg/kg, daily) was given when the mean tumor volume reached 140 mm^3. The tumors showing no significant response to Niraparib were collected on either day 32 (#1 derived tumor model) and day 22 (#2 derived tumor model) after randomization and their gene changes were analyzed by RNA sequencing (RNA-seq).

Results: Niraparib significantly inhibited OV9402 tumor growth, with complete regression observed in nine out of ten mice on day 54 after the 1st round of treatment. However, tumor regrowth was observed in two out of the nine mice from day 68 onwards. The relapsed tumors (tumor #1 and tumor #2) from these two mice were collected and re-inoculated into 5 naïve mice to establish tumor models for the 2nd round of Niraparib treatment, separately. For #1 derived tumor model, all the tumors presented complete resistance to the Niraparib treatment. RNA-seq data showed that the gene expression of ABCB1, which encodes for efflux pumps, was upregulated. In parallel, complete resistance to Niraparib was observed in all the tumors derived from 2# tumor bearing mice. The RNA-seq data demonstrated that an acquired secondary genetic deletion on BRCA1 genes, which restored the functional protein expression loss in the parental line and restored HR repair, was found in the tumors.

Conclusion: Ovarian cancer PDX models that have effectively developed resistance to PARP inhibitors have the potential to serve as valuable preclinical tools to evaluate potential next-generation PARP inhibitors and innovative combination strategies.

#0539 LN18-MRTX1719R cell line, a useful cell model for the discovery of the new PRMT5 inhibitors..

Y. Tang, L. Wang, G. Wang, J. Ning, **F. Hao**;
Kyinno Biotechnology Co., Ltd, Beijing, China

In recent years, the PRMT5-MTA complex has emerged as a "synthetic lethal" novel target for the treatment of MTAP (methylthioadenosine phosphorylase)-deficient cancers. Kryukov et al. first reported the "synthetic lethal" effect of inhibiting PRMT5 in MTAP-deficient tumors, and they identified MTAP as the synthetic lethal partner of PRMT5 in 2016. MTAP is a tumor suppressor gene frequently lost in various cancers, including pancreatic cancer, non-small cell lung cancer, and mesothelioma. Furthermore, the loss of MTAP leads to the accumulation of MTA in cancer cells, which competes with PRMT5's co-factor SAM for binding and forms the PRMT5-MTA complex. Cancer cells lacking MTAP show enhanced sensitivity to PRMT5 loss. Therefore, this complex has emerged as a potential therapeutic target, particularly for the treatment of MTAP-deficient cancers. MRTX1719 is a highly effective selective inhibitor of the PRMT5-MTA complex, capable of selectively inhibiting PRMT5 activity in MTAP-deficient cells. As the most promising candidate drug, MRTX1719 is undergoing Phase I/II clinical evaluation for patients with MTAP-deficient cancers. Drug resistance is an inevitable problem with small molecule inhibitors. Currently, the mechanism of resistance to MRTX1719 is not clear, as MTAP/CDKN2A loss is an early driver event in most cancers. To further explore the resistance mechanism of MRTX1719, our group used the MTAP-deficient LN-18 cell line and induced mutagenesis using the mutagen ENU. We then used a drug low-concentration gradient method to establish the LN-18-MRTX1719R-resistant cell line. Specifically, LN-18 cells were treated with increasing doses of MRTX1719 for 6 months, and mixed clones that tolerated MRTX1719 were selected. Subsequently, single clones were selected, and a stable MRTX1719-resistant clone was obtained, named LN-18-MRTX1719R. Cell proliferation inhibition assay showed that the IC50 of LN-18-MRTX1719R was over 1000nM, which is 100-fold more resistant than the parental LN-18 cells (9.87 nM). We explored the resistance mechanisms using RNA-Seq and WES methods. The resistance to MRTX1719 of the LN-18-MRTX1719R cell line was highly stable after 20 cell passages. The LN-18-MRTX1719R cell line can be a useful cell line mode in the development of future PRMT5·MTA inhibitors.

#0540 Identification of therapy resistance mediating extracellular vesicles in single-cell level via a novel microfluidic co-culture device development.
C.-J. Kim, S. Amend, K. Pienta;
Johns Hopkins University School of Medicine, Baltimore, MD

Once cancer has metastasized, it is incurable because tumors evolve resistance to all systemically administered anti-cancer therapies. Resistance to therapy has classically been attributed to the presence of a cancer stem cell or genetic tumor cell heterogeneity. Extracellular vesicles (EVs) are nano-sized (40-1000 nm) vesicles that are released by all cells into the extracellular space. EVs carry diverse cargo dependent on the cell of origin and have been studied as a source of novel cancer-specific liquid biopsy biomarkers and contributors to tumor progression and metastasis. However, the paracrine function of EVs in promoting therapy resistance is under-studied, and the impact of EVs released from therapy-resistant cancer cells on surrounding therapy-sensitive cancer cells is unknown. In this study, we develop an innovative microfluidic device, TREVCo, to enable simultaneous single-cell trap, EV detection, and co-culture modules to evaluate EVs-mediated transfer of cellular information between therapy-resistant cancer cells and adjacent cells, and to characterize EVs released from resistant cells and determine their impact on the resistance phenotype of adjacent therapy-sensitive cancer cells. We utilize resistant cells from multiple prostate (PCa) cell lines that have been selected for therapy resistance by culture with increasing dosages of cancer drugs such as cisplatin, docetaxel. We use the matched untreated therapy-sensitive parental cell lines as the sensitive cells. We hypothesize a novel model of therapy resistance in lethal PCa: EVs released from resistant cells contain pro-resistance factors that are transferred to adjacent sensitive cells upon EV uptake, thus directly enabling therapeutic resistance. We will assess the impact of resistant cell-EVs at a single cell level via a novel device, TREVCo, that enables comprehensive downstream analysis. This single-cell approach enables dissection of critical EV-associated therapy-resistant factors within the large heterogeneity of resistant PCa. Co-culture of a single resistant cell and a hundred adjacent sensitive cells mimicking intra-tumoral interactions is also critical to demonstrate evidence of resistant cell secreting factors inducing a pro-resistance phenotype. These studies will be the first-in-field to assess the impact of resistant PCa cell-derived EVs at single-cell resolution. An understanding of resistant cell-derived EVs and the impact of that EV cargo on adjacent sensitive cells will provide critical insight into the acquisition of therapy resistance in lethal PCa. The novel approach to apply resistant cell-derived EVs in co-culture assay with sensitive cells will enable the screening of transmittable resistance-associated factors and provides critical opportunities for accelerating precision medicine for advanced PCa patients.

#0541 Establishment of Inotuzumab ozogamicin resistant leukemia cell lines; Focusing on p-gp and DNA damage repair for overcoming drug resistance.

N. Ida[1], M. Okura[2], N. Hosono[1], T. Yamauchi[1];
[1]University of Fukui Hospital, Fukui, Japan, [2]DMU Saitama Medical Center, Saitama, Japan

Introduction: Inotuzumab Ozogamicin (IO) is a humanized anti-CD22 monoclonal antibody conjugated with chalicheamicin, which causes single- and double-strand DNA breaks. Although IO shows a high CR/CRi rate in relapsed/refractory CD22-positive B-cell acute lymphoblastic leukemia (ALL), the duration of remission is short due to early acquisition of resistance. Therefore, the present study attempted to enhance the cytotoxicity of IO by focusing on polyadenosine diphosphate-ribose polymerase (PARP) inhibition. Furthermore, IO-resistant cell lines were newly established to investigate the mechanism of IO resistance.
Methods: Reh cell line derived from Ph-negative B-ALL cells was used. To establish IO-resistant cell lines, Reh cells were long-term exposed to IO, followed by limiting dilution. FACS analysis evaluated the CD22 positivity and the induction of apoptosis. WTS assay determined the cell growth inhibition effects. The Comet assay quantitatively assessed DNA damage. Gene expression profiles were determined by using DNA microarray.
Results: The 50%-inhibitory concentration (IC_{50}) of IO was 2.1 ng/mL in Reh cells. Reh cells were synergistically sensitized to IO by the addition of non-toxic concentrations of PARP inhibitors, olaparib or talazoparib, with the Combination Index of 0.19 and 0.42, respectively. Moreover, these combinations augmented the induction of apoptosis (23.5% in IO alone, 51.7% in IO + olaparib, 66.1% in IO + talazoparib). The Comet assay demonstrated that DNA strand breaks observed 1h after IO administration were repaired 6h later. In the combination of IO with olaparib or talazoparib, DNA damage remained even at 6h, suggesting the inhibition of DNA repair by PARP inhibitors. Next, six IO-resistant cell lines were established with IC_{50} more than 60-fold that of parental cells. All these cell lines kept CD22 expression. These cell lines were also resistant to apoptosis induced by IO. In addition of olaparib or talazoparib to IO, the IC_{50} of IO decreased by 40% to 70% in 6 IO-resistant cells. These combinations also augmented the induction of apoptosis (24.2% in IO alone, 45.3% in IO+olaparib, and 56.8% in IO+talazoparib). DNA microarray was performed to compare gene expression profiles between parental and IO-resistant cell lines. ABCB1 (p-gp), a drug efflux pump that causes multi-drug resistance, was overexpressed in resistant cell lines. Moreover, the addition of p-gp inhibitor, PSC-833, to IO enhanced the cell growth inhibition and induction of apoptosis due to more DNA strand break.
Conclusion: The present study demonstrated that the combination of IO with PARP inhibitors exerted synergistic cytotoxicity via the inhibition of DNA repair. In addition, it was suggested that overexpression of p-gp caused IO resistance, which was partially reversed with the combination of PARP inhibitors or a p-gp inhibitor.

#0542 Development of novel syngeneic tumor models with intrinsic or extrinsic resistance mechanisms to PD-1 blockade.

X. Wang[1], Z. Zhang[2], L. Liu[3], X. Zhang[3], D. Wang[1], N. Xu[2], X. Qiang[1], Q. Gu[1], J. Xiang[2], Z. Zhang[1];
[1]WuXi AppTec, Shanghai, China, [2]WuXi AppTec, Suzhou, China, [3]WuXi AppTec, Nantong, China

Programmed cell death-1 (PD-1) blockade has demonstrated remarkable clinical efficacy across various tumor types. However, the current PD-1 blockade monotherapy benefits only a small proportion of patients, and primary or acquired resistance can ultimately lead to cancer progression in clinical settings. Understanding the underlying mechanisms of resistance is both necessary and urgent to enhance clinical outcomes. Increasing evidence suggests that resistance to PD-1 therapy can arise from both tumor-cell-intrinsic and tumor-cell-extrinsic factors. Loss-of-function mutations in the antigen presentation pathway and downstream elements represent intrinsic mechanisms, while tumor-infiltrating immunosuppressive cells such as regulatory T cells (Tregs), myeloid-derived suppressor cells (MDSCs), and tumor-associated macrophages (TAMs) contribute to immune tolerance as extrinsic factors. Currently, the rational design of combination therapies based on these resistance mechanisms remains to be achieved.

In this study, we developed two types of anti-PD-1 antibody-resistant models based on the intrinsic anti-PD-1 treatment-sensitive MC38 models. These models include genetically engineered resistant models with B2M or STK11 knockout (KO) and induced resistant models through *in vivo* progressive drug selection. STK11 KO mutations resulted in reduced expression of PD-L1 on tumor cells and a lower infiltration of $CD8^+$ cytotoxic T lymphocytes in the tumor microenvironment, while B2M KO led to a lack of antigen presentation on the tumor cell surface, blocking the binding of the anti-PD-1 antibody. In terms of the induced anti-PD-1 resistant models, a higher proportion of immunosuppressive cells, including Tregs, MDSCs, and TAMs, were observed in the tumor microenvironment compared to the parental counterparts, contributing to immune escape from PD-1 blockade. These models simulate extrinsic and intrinsic mechanism-based anti-PD-1 resistance, allowing for the identification of combination therapies to overcome resistance to anti-PD-1.

Our study enhances our understanding of the biological basis of anti-PD-1 resistance and supports the discovery of mechanistically-designed combination therapies to overcome resistance to anti-PD-1 therapy, potentially broadening its clinical applicability.

#0543 Identifying drivers of chemoresistance in SQLC using forward and reverse genetic approaches.

M. Haarmann[1], D. Gadalla[2], J. Bragelmann[1];
[1]University Hospital of Cologne, Koln, Germany, [2]University of Cologne, Koln, Germany

Non-small cell lung cancer, mainly lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (SQLC), accounts for about 85 % of all lung cancers. While LUAD treatment options have greatly improved, SQLC remains challenging, as targetable mutations are rare. Immunotherapy provides benefits, nevertheless, chemotherapy remains a backbone of systemic treatment strategies for SQLC patients. Accordingly, a major challenge for SQLC treatment is the development of chemoresistant tumors, oftentimes leading to cross-resistance to multiple drugs and limiting patient survival. Currently, the causal pathways enabling tumor cells to survive therapeutic stress and drivers of chemotherapy resistance are insufficiently known, which impedes the development of novel therapeutic strategies. We therefore leverage forward and reverse genetic approaches including large-scale chemo-genetic perturbations to systematically map the landscape of molecular drivers involved in chemotherapy resistance in SQLC. By integrating the resulting data we derive specific knowledge of the underlying processes, in order to identify druggable targets in chemoresistant tumors and contribute to improved patient care.
To assess genes causally mediating chemotherapy resistance upon overexpression, we performed genome-wide CRISPR activation screens utilizing clinically used cisplatin and taxol. Additionally, we performed CRISPRa screens against four further drugs currently in clinical trials in order to distinguish genes causing cross-resistance to multiple drugs versus drug-specific mechanisms.
In parallel, we generated chemoresistant clones by prolonged low-dose treatment, to analyze transcriptomic adaptions to chemoresistance and validate the CRISPRa screening hits.
Initial findings show a large selection of unique and shared gene sets that were significantly enriched or reduced after treatment in the CRISPRa screen, indicating their involvement in the development of chemoresistance.
Of note, transcriptomic analysis of chemoresistant cells shows an overlap with the CRISPRa screen specifically for the unfolded protein response (UPR) that is transcriptionally enriched in chemoresistant cells and a positive hit in the CRISPRa screen. Chemoresistant clones show increased resistance to tunicamycine induced ER-stress, indicating an increased ability to overcome the accumulation of misfolded protein under cytotoxic treatment through the UPR. Specific inhibition of the UPR during cytotoxic treatment shows promising results in chemoresistant cells.
By combining our CRISPR activation screen and systematic analysis of chemoresistant cells we were able to identify the UPR as a driver and a druggable synthetically lethal dependency of chemoresistance in SQLC. This opens the possibility of studying the UPR as a potential target in the treatment of patients with chemoresistant tumors, improving patient outcome.

#0544 Reverse engineering strategy for new targets identification.

B. Xie[1], T. Zhang[1], L. Li[1], H. Chen[1], Y. Liu[1], L. Bi[2], **D. Wen**[1];
[1]Shanghai LIDE Biotech Co., Ltd., Shanghai, China, [2]China-Japan Union Hospital, Jilin University, Changchun, China

The issue of drug resistance in cancer is very similar to the field of infectious disease, either existing before treatment (intrinsic) or generated during therapy (acquired), highly affected by cell endogenous factors and/or the surrounding environment. Acquired resistance can be occurred several months after targeted therapy via alternations of drug targets due to the genomic mutations of the targets, epigenetic transcriptional or translational changes, for example the C797S mutation impairs AZ9291 binding to the EGFR kinase domain. To overcome this, novel well-designed chemical compounds targeting new mutations would be urgently needed, as well as the potential new oncogenes/susceptible genes driving the resistance. Considering about the heterogeneity of primary tumor tissues, LIDE has established one functional cost-effective *in vitro* and *in vivo* screening method, named reverse engineering strategy for targets identification by using patients-derived conditional reprogramed cancer cell lines (CRs) and IO-FIVE (Immuno-Oncology drugs Five In Vivo Efficacy test). Basically, pro-siRNA library or CRISPR/sgRNA library is carried out in CRs for candidates hunting, alternatively drug-response evaluation among multiple clinical biopsies in mice cancer trials, after filtered with bioinformatic scanning from large groups of patients, and finally it is validated *in vivo* by CRISPR, shRNA silence or targeted compounds. In addition to these known factors (EGFR C797S, Her2/Met amplification, Ras and MAPK activation), we have discovered that epigenetic factors for DNA modification, protein translation kinases, mitochondrial/ peroxisomal transporters and cell membrane lectins may contribute to AZ92921 resistance *in vivo*. And one previously unknown acyltransferase member has been identified as key driver gene for pan-cancer development by IO-FIVE, and patients with high expression level of this enzyme have had poor survival outcomes, accompany with uncontrolled tumor growth and immunotherapy resistance, which is becoming a promising therapeutic target.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Identification of Molecular Targets
Poster Session

#0548 Exploiting pronounced selection pressure from therapeutic bottlenecks to identify orthogonal immunotherapy targets.

J. Fisk[1], J. P. Townsend[2];
[1]University of Rhode Island, Kingston, RI, [2]Yale University, New Haven, CT

Evolutionary processes play a crucial role in the development of cancer, where tumor cells continuously adapt, leading to the dominance of cell populations over their non-tumor counterparts, evading treatment and ultimately resulting in death. Effective cancer therapies induce significant and targeted selection pressures. During and in response to the induced bottleneck by therapy, the heterogeneous cancer cell population either diminishes or evolves, causing a subsequent selective sweep and the emergence of cells with resistance traits. However, this bottleneck phase presents a unique opportunity to predictably reduce the diversity of tumor cells. In this context, we propose a framework to quantify the selection on variants before, during, and after the therapeutic bottleneck, enhancing our understanding of the mechanisms underlying the acquisition of therapeutic resistance. Furthermore, we combine measures of selection intensity with the prediction of neoantigens in a patient cohort to identify potential alternative targets for immunotherapy. The outcome is a strategy that exploits the predictability introduced by the primary therapeutic bottleneck to eliminate the remaining tumor cell population. Finally, we illustrate the efficacy of this strategy in the context of several cancer types and empirically identify potential cancer type specific and pan-cancer immunotherapy targets orthogonal to primary, first-line therapies.

#0549 PDZK1 sensitizes TNBC cells to erlotinib via promoting c-Cbl-mediated EGFR degradation and inhibiting EGFR phosphorylation.

J. Zheng, Y. Ma, Z. Fang, Y. Qi;
Capital Medical University, Beijing, China

Background: Triple-negative breast cancer (TNBC) is lack of effective targeted therapies. Epidermal growth factor receptor (EGFR) is a potential therapeutic target for TNBC. However, TNBC is resistant to EGFR-targeted drugs in clinical trials, and the tolerance mechanism remains unclear. This study aimed to elucidate the possible resistance mechanism for TNBC to EGFR-targeted therapy and how sensitize TNBC cells to erlotinib.
Methods: PDZ domain containing 1 (PDZK1) correlated with TNBC development was screened out by bioinformatics analysis and its correlation with resistance to erlotinib was identified by western blotting (WB). Its interaction with EGFR and structural basis were determined by GST-Pull down and coimmunoprecipitation. Its regulation on EGFR signaling activation and expression level were detected by WB in PDZK1 overexpression and knockdown TNBC cells, xenograft tissues and correlation analyses. Correlation was performed by gene set enrichment analysis (GSEA) and immunohistochemistry of tissue microarray followed by Pearson analysis. TNBC-suppressing effects of PDZK1 and its sensitizing effects on erlotinib were investigated using cell viability assay, colony-forming assay, wound healing assay, Matrigel invasion assay and xenograft model in combination with PDZK1 wild type/mutant transfection and rescue experiment.
Results: Here we found that PDZK1 was correlated with TNBC development and its level was downregulated in erlotinib-resistant TNBC cells, suggesting that PDZK1 downregulation was related to erlotinib resistance in TNBC. PDZK1 bound with EGFR. Through the interaction, PDZK1 promoted EGFR degradation by enhancing the binding of EGFR with c-Cbl and inhibited EGFR phosphorylation by hindering EGFR dimerization. PDZK1 was specifically downregulated in TNBC tissues and was correlated with poor prognosis of TNBC. Functional assays *in vitro* and *in vivo* showed that PDZK1 suppressed TNBC development. Restoring EGFR expression and kinase inhibitor treatment reversed the malignancy caused by PDZK1 overexpression and knockdown, respectively. PDZK1 wild type, but not mutant overexpression enhanced the inhibitory effect of erlotinib on EGFR signaling and TNBC malignancy *in vitro* and *in vivo*.
Conclusion: PDZK1 is a significant prognostic factor for TNBC and a potential molecular therapeutic target for TNBC to reverse the tolerance of TNBC cells to erlotinib.

#0550 Identification of isoform switching events linked with esophageal adenocarcinoma patient survival informs novel prognostic and therapeutic targets.

Y. Zhang[1], R. Israel[1], B. Vandenburg[1], S. Barnett[1], J.-J. Riethoven[2], J. L. Clarke[2], M. P. Lee[1], K. Lagisetty[1], J. Lin[1], R. Reddy[1], A. Chang[1], L. A. Kresty[1]; [1]University of Michigan, Ann Arbor, MI, [2]University of Nebraska, Lincoln, NE

Esophageal adenocarcinoma (EAC) represents a growing health problem characterized by rising incidence and poor prognosis. Although it is a cancer with a high mutational burden, it lacks highly prevalent oncogenic drivers that can be therapeutically targeted. Recently, our group characterized isoform switching events, defined by the changing of dominant gene isoforms between conditions, associated with EAC progression and identified 75 switching events comparing Barrett's low-grade dysplasia (BE.LGD) and Barrett's high-grade dysplasia (BE.HGD) patient samples. Herein, we further investigated whether isoform-switching events may offer prognostic or therapeutic value in EAC. Isoform switching analysis was performed using RNA-seq data derived from patient samples between BE.LGD and BE.HGD combined with EAC (BE.HGD + EAC) alone or in combination with *TP53* mutations. Patients were further stratified into tertiles based on isoform expression level followed by survival analysis. Thirty isoforms were significantly ($P \leq 0.05$) linked with all-cause mortality, comparing BE.LGD with BE.HGD + EAC, whereas 20 isoforms were identified when *TP53* mutation status was included. In terms of cancer-specific mortality, 10 isoforms were significantly linked with survival comparing BE.LGD with BE.HGD+EAC. With the inclusion of *TP53* mutation, 16 isoforms were also significantly linked with cancer-specific mortality. Isoform-specific genetic knockdown experiments were designed targeting the top isoforms identified in the analysis, including *TTLL12* and *HM13* isoforms. Knockdown of *TTLL12* and *HM13* isoforms led to significant inhibition of cell viability and migration in two EAC cell lines (OE19 and OE33). Chemotherapeutic agents (Paclitaxel + Carboplatin) further decreased cell viability with synergistic effects observed in both siRNA-treated cell lines suggesting a role for specific isoform switches in therapeutic sensitization. Protein-interaction prediction using STRING and immunoblot analysis suggest different mechanisms leading to the inhibition of cell viability and migration. *TTLL12* is linked with the activation of chaperon-medicated autophagy (LAMP2A and HSC70) and protein translation, whereas *HM13* is linked with unfolded protein response (IRE1α, PERK, and ATF6) and may be linked with immunotherapy outcome. An antigen-dependent cell-mediated cytotoxicity assay is currently underway to investigate whether the knockdown of *HM13* isoforms can sensitize EAC cells to PD-1/PD-L1 immunotherapy agents. Future direction includes using FDA-approved agents to target the two major pathways identified above. In conclusion, isoform switching may provide fresh insight for the identification of prognostic markers and inform new potential therapeutic targets for EAC treatment or prevention.

#0551 Investigation of the antipoliferative effect of the *Xylopia Aethiopica*extract in triple-negative breast cancer cells.

S. Soni, S. Modi, T. Andey;
Massachusetts Col. of Pharmacy & Health Sci., Worcester, MA

Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer and has very limited treatment options. *Xylopia Aethiopica* (XA) is a common spice that is widely used in the regions of central and western Africa. It is known to have various pharmacological properties, one of which is anti-inflammatory activity. The anti-inflammatory effect may portend antiproliferative activity. We hypothesized that the extract of XA will exert antiproliferative activity against TNBC cells. The study aimed to establish the molecular mechanism underlying the antiproliferative activity of XA extract (XAE) against TNBC. The dried fruits of XA were crushed in a mixer and macerated using diethyl ether for 72 h. The macerate was subjected to vacuum and rotary evaporation to remove the organic solvent, and a stock solution was prepared in dimethyl sulfoxide (DMSO). Assessment of the efficacy of XAE was performed using serial dilutions (100 µg/ml, 50 µg/ml, 10 µg/ml, 5 µg/ml, and 1µg/ml) of the XAE stock solution, followed by *in vitro* testing against two TNBC cell lines (MDA-MB-231, and MDA-MB-468 cells). The cytotoxic effect of the XAE was then measured using the resazurin dye assay. XAE resulted in a concentration-dependent cell death in both cell lines. At the highest concentration (100 µg/ml), XAE induced cytotoxic cell death of 89% and 91% in MDAMB231 and MDAMB468 cells, respectively. This was consistent with IC50 values of 32.95 ± 1.32 µg/ml (MDAMB231) and 20.83 ± 1.05 µg/ml (MDAMB468). At the molecular level, western blot analysis of mitogenic markers associated with MAPK oncogenic signaling pathway demonstrated the inhibition of EGFR and AKT protein levels after a 48-h treatment. Acridine orange-ethidium bromide (AO/EB) staining showed a concentration-dependent induction of apoptosis in both cell lines. Flow cytometric analysis was performed to quantify the apoptotic cells. A significant increase of apoptotic cells was observed in treatment groups as compared to control after 72 h. Apoptotic induction was associated with increased p53 protein levels after 48 h treatment compared to control. The study results underscore the anticancer effects of XAE in TNBC cells mediated through induction of apoptosis.

#0552 Non-canonical disulfide isomerases are strongly selective, understudied targets for cancer therapy.

M. E. Law[1], Z. M. Dulloo[1], E. Yaaghubi[2], G. M. Alexandrow[1], B. Forsyth[1], H. Su[3], R. K. Castellano[1], **B. K. Law**[1];
[1]University of Florida, Gainesville, FL, [2]Pacific University, Hillsboro, OR, [3]Smith College, Northampton, MA

A major challenge in cancer therapy is the identification of drug targets that are essential for cancer cells but not non-transformed cells. The Broad Institute's Dependency Map (DepMap) evaluates whether knocking down or knocking out expression of specific genes is "strongly selective" against subsets of cancer cells, in contrast with genes that are "common essential." Of the 22 human Protein Disulfide Isomerases (PDIs), only four, ERp44, TMX1, AGR2, and AGR3, were identified as strongly selective in the DepMap. Importantly, our team previously identified ERp44, AGR2, and AGR3 as targets of bicyclic thiosulfonate compounds termed Disulfide bond Disrupting Agents (DDAs). DDAs exhibit striking anti-cancer activity in xenograft tumor studies. DDA treatment of cancer cells blocks ERp44, AGR2, and AGR3 active site Cys residues, ablating their catalytic activity and binding to client proteins. Evaluation of cancer cell lines predicted to be sensitive to DDAs, based on their AGR2, AGR3, or ERp44 dependence, accurately predicts DDA sensitivity. Cell lines from a variety of tumor types exhibit AGR2, AGR3, or ERp44 dependencies. Our previous work identified HER-family members (i.e., EGFR, HER2, and HER3) and TRAIL receptors (Death Receptors 4 and 5) as important clients of DDA-sensitive PDIs in breast cancer cells, but it was unknown if these observations extend to other tumor types. Initial studies indicate that AGR2 DepMap dependencies are a strong predictor of sensitivity of cancer cells to DDAs, irrespective of their site of origin. It will be important in future studies to determine what the key client proteins for these DDA-sensitive PDIs are and whether they vary across tumor types.

#0553 Assessment of CNTN4 expression and its association with PD-L1 across 18 various cancers using an artificial intelligence-powered immunohistochemistry analyzer.

S. Shin[1], J. Moon[1], S. Cho[1], C.-Y. Ock[1], B.-N. Jeon[2], G. Kim[2], H. Yu[2], M. Cha[2];
[1]Lunit, Seoul, Korea, Republic of, [2]Genome & Company, Sungnam-si, Korea, Republic of

Background: Contactin-4 (CNTN4) has been identified as an inhibitory immune checkpoint protein and mainly expressed on tumor cells. It interacts with APP present in T cells, leading to a reduction in T cell proliferation, activation, and responsiveness to tumors. In this study, we applied artificial intelligence (AI)-powered analyzers to examine the expression of CNTN4 and its association with PD-L1 in various solid tumors.
Methods: The AI-powered immunohistochemistry (IHC) analyzers were developed using pan-cancer whole slide images (WSIs) stained with 18 different IHC types. Pathologists annotated cells and tissues on the WSIs. The universal model was trained by annotations from IHC WSI, which could detect tumor cells with four grade intensities (strong, moderate, weak, and negative) and segment invasive cancer area. Finally, the AI analyzer can count the tumor cells in an invasive cancer area and calculate the ratio based on intensity. The AI analyzer was applied to the pan-cancer tissue microarray dataset (n=795) consisting of 18 cancers to validate the analyzer. The dataset was stained with rabbit monoclonal antibody (clone EPR 8735) and PD-L1 22C3 antibody, respectively. The expression levels of CNTN4 and PD-L1 were calculated with H-score (range 0 to 300) or tumor proportion score (TPS).
Results: When positivity was defined as moderate-to-strong staining intensity in ≥ 30%, 50%, 75%, and 90%, 42.4% (337/795), 25.5% (203/795), 11.4% (91/795), and 5.2% (41/795) of samples were CNTN4 positive, respectively. In case of moderate-to-strong staining in ≥ 50% tumor cells, CNTN4 expression were most frequently observed in hepatocellular carcinoma (63.9%), endometrial carcinoma (50.0%), stomach cancer (43.9%), pancreatic cancer (40.0%), and prostate cancer (35.4%). Notably, 10% of cases with an H-score < 200 (75/757) showed a range of PD-L1 expression (PD-L1 TPS ≥ 1%), while all of the samples with an H-score ≥ 200 (n=38) were PD-L1 TPS <1%.
Conclusions: This study describes the CNTN4 expression levels in various tumors using an AI-powered IHC analyzer. CNTN4 tends to be expressed in opposition to PD-L1, making it a viable immune therapeutic target in cancers that do not conventionally express PD-L1.

#0554 Determining the role of *PROX1* in prostate cancer neuroendocrine trans-differentiation.

S. Raj[1], B. Capaldo[1], J. Bowman[1], M. White[1], X. Moore[1], B. Gryder[2], A. N. Alilin[1], D. Takeda[1], K. Kelly[1];
[1]National Cancer Institute, Bethesda, MD, [2]Case Western Reserve University, Cleveland, OH

Nonbiased mutational screening to identify essential genes and pathways in cancer is a powerful approach for understanding underlying biology as well as the identification of potential therapeutic targets. Epigenetic (EPI) and transcriptional factors (TF) play an important role in the change of phenotype and lineage plasticity from adenocarcinoma to castration resistant prostate cancer (CRPC), double negative (DN) or treatment-induced neuroendocrine prostate cancer (NEPC). When *RB1* loss occurs in combination with *TP53* alterations, stemness and lineage plasticity increase with one consequence being differentiation to a neuroendocrine (NE) lineage. Here, we are identifying and testing the functional role of epigenetic and transcription factors required for the viability of CRPC, DN and NEPC relative to a matrix of genotypic and phenotypic characteristics. We applied CRISPR-CAS9 dropout screens in prostate organoids and cell lines to identify gene/s associated with CRPC, DN and NEPC viability. We successfully CRISPR-engineered LNCaP clones of single (LNCaP-TP53-SKO, LNCaP-RB1-SKO) and double (LNCaP-TP53-RB1-DKO) gene knockouts, which were subsequently characterized for immuno-phenotype and transcriptome. Our dropout screens, targeting all TFs and EPIs, identified 117 TF and 40 EPI genes responsible for the viability of DN, NEPC and LNCaP models. We found known genes such as *FOXA1* and *ASCL1,* as well as novel genes including *PROX1* and *KLF3*, which were validated through guide RNA competition assays. Our results showed PROX1 is essential for cell viability in a DN organoid model, and its expression is associated with increased aggressiveness, indicating *PROX1* has role in stemness/lineage plasticity in treatment resistant adenocarcinoma. RNA-seq analysis following overexpression of *PROX1* in the LNCaP-TP53-RB1 null adenocarcinoma model, with and without enzalutamide, identified pathways enriched for cell proliferation, differentiation, neuronal development, and prostate gland development. In summary, our study has suggested an important role for *PROX1* in the growth and differentiation of poorly differentiated prostate cancer, which may lead to the identification of potential therapeutic targets.

#0555 Role of TRIM31 in the pathogenesis of esophageal adenocarcinoma.

M. Hassan[1], J. Mast[1], A. Ritter[2], S. Ponna[2], N. Awasthi[1], U. von Holzen[1];
[1]Indiana University School of Medicine-South Bend, South Bend, IN, [2]University of Notre Dame, South Bend, IN

Background: Esophageal adenocarcinoma (EAC) is one the deadliest cancers in United States (US) and the only major cancer in the US with increasing incidence. Gastroesophageal reflux disease (GERD) can cause Barrett's esophagus (BE), a columnar metaplasia of the esophagus strongly associated with the development of EAC. GERD leading to BE is a common pre-occurrence in EAC patients, but the mechanism remains obscure. To explore the mechanism and its components, we compared gene expression in BE and EAC cells with normal esophageal cells and found high expression of tripartite motif-containing protein 31 (TRIM31) in BE and EAC compared to normal esophagus (NE) by transcriptomic profiling of RNA extracted from human esophageal tissues. E3 ubiquitin ligase TRIM 31 is a new member of TRIM family and it has been reported to have oncogenic potentials in some cancers. However, its role in EAC pathogenesis is yet to be understood.
Methods: RNA sequencing and transcriptomic profiling were performed on human NE, BE, and EAC epithelial tissue samples. TRIM31 expression in NE cell line (Het-1A) and EAC cell lines (OE19, Flo-1, OE33, SK-GT-2, and OACM5.1C) were identified by Western blot analysis. The Het-1A cell line, after exposure to acidic pH and bile acids, was assessed for variable TRIM31 expression. Cell morphology and viability analyses of NE and EAC cell lines after exposure to acidic pH and bile acids either alone or in combinations were observed by microscopy and WST-1 assay respectively.
Results: Transcriptomic analysis showed that BE and EAC are similar in their differential gene expression with upregulation of the TRIM31 compared to that in NE. Concordant with their columnar phenotype, BE and EAC groups displayed a multitude of differentially expressed genes relative to NE samples; however, less differentially expressed genes were found comparing BE and EAC groups. Western blot demonstrated frequent overexpression of TRIM31 in EAC cell lines with very low expression of TRIM31 in NE epithelial cell line. When NE epithelial cell line Het-1A was exposed to acidic pH as well as bile acids in acidic pH, we saw a change in cell morphology that may correlate with the metaplasia of these cells to more resilient forms, as seen in human BE and EAC. Interestingly, bile acids in acidic pH increased TRIM31 expression in NE cell line Het-1A. Bile acids had a greater effect on decreasing cell viability at high concentrations and that effect is enhanced when bile acids were added in acidic pH. WST-1 cell viability assay revealed that EAC cells were more resistant to bile acids as well as bile acids in acidic pH induced decreased in cell viability compared to that in NE cell line Het-1A. The sustained cell viability of EAC cell lines under these harsh conditions correlates with the upregulation of TRIM31.
Conclusions: Thus, TRIM31 may be an important oncogenic factor in GERD-induced EAC development and may be an innovative therapeutic target and marker for EAC.

#0556 The Idylla™ IDH1-2 Mutation Assay Kit: A tool for mutation detection in *IDH1* and *IDH2* genes.

Bram De Craene[1], Katrien Trappeniers[1], **Ana Marcelino**[1], Lee Robertson[2], Phillippe Taniere[2], Jo Van Dorpe[3], Malaika Van der Linden[3], Maria Arcila[4], Khedoudja Nafa[4], Jochen K. Lennerz[5], Richard Craig Carson[6], Richard D. Ledding[6], Sofie Metsu[1]

[1]Development, Biocartis, Mechelen, Belgium,[2]Molecular pathology diagnostic service, University Hospitals Birmingham, Birmingham, United Kingdom,[3]Department of Pathology, Ghent University Hospital, Ghent, Belgium,[4]Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Department of Pathology, Center for Integrated Diagnostics, Massachusetts General Hospital/Harvard Medical School, Boston, MA,[6]Histology Laboratory, Benefis Health System, Great Falls, MT

Background: Mutations in the genes encoding isocitrate dehydrogenase *(IDH1* and *IDH2*) are frequently detected in various cancers, including acute myeloid leukemia (~20%) and glioma (up to ~80%). They commonly involve a single amino acid substitution at codon R132 in IDH1, and R140 or R172 in IDH2 and are important for diagnosis and prognosis as well as therapeutic decisions. With advancements in molecular diagnostics and precision therapy, IDH inhibitors such as ivosidenib, vorasidenib and enasidenib are now mainstay in management of patients with a susceptible mutation.
Methods: The Idylla™ IDH1-2 Mutation Assay Kit (RUO) is a fully automated qPCR assay for the qualitative detection of 15 common mutations in IDH1 (R132C/H/G/S/L) and IDH2 (R140Q/L/G/W, R172K/M/G/W/S) at codon level. The assay consists of a ready-for-use Idylla™ DNA Cartridge and an assay specific Idylla™ Vial. It runs on the Idylla™ Platform and covers the entire process from sample to result including specimen processing, real-time PCR amplification, detection, data analysis, and result reporting, within 100 minutes.Five clinical sites in US and Europe participated in an early access program to evaluate performance of the assay and establish a final classification algorithm by testing a total of 241 specimens, including FFPE, human whole blood and bone marrow samples, and extracted DNA from these sample types. Reference results were obtained using a range of established methods with different mutations in scope, such as Sanger sequencing, immunohistochemistry, NGS and qPCR.
Results: Of 241 Cartridges, one invalid result was obtained, while 13 results were flagged as having low DNA input. Compared to available reference methods, overall concordance was 98.3% (235/239), 100% (140/140) and 99.6% (230/231) for IDH1 R132, IDH2 R140 and R172, respectively (see table).
Conclusion: The Idylla™ IDH1-2 Mutation Assay Kit demonstrates a high concordance with established reference methods across a range of different specimen types.

#0557 Clofarabine inhibits U87MG glioblastoma cell line proliferation through CD99 signaling pathway.

C. C. W. de Souza[1], R. d. Soares[1], A. M. Lerario[2], S. K. N. Marie[1], **S. M. Oba-Shinjo**[1];
[1]University of Sao Paulo, School of Medicine, Sao Paulo, Brazil, [2]University of Michigan, Ann Arbor, MI

The present work aimed to test the efficacy of clofarabine in glioblastoma (GBM) cells that express high levels of CD99. GBMs are the most malignant with the poorest prognosis among tumors of the central nervous system. Patients have a median survival of 12 to 15 months despite surgical, radio, and chemotherapy. CD99 is a cell surface receptor overexpressed in several types of tumors, including GBMs, justifying the interest of studies in CD99 as a possible therapeutic target. Our group has previously demonstrated that knockout of CD99 in the U87MG GBM cell line promoted a decrease in cell adhesion, migration, and invasion. Clofarabine is a third-line drug used in the treatment of refractory/relapsed childhood acute lymphoblastic leukemia. It is a purine analog that is transported into intracellular space, phosphorylated, and incorporated into DNA chain, inhibiting DNA synthesis and ultimately inducing cell death by apoptosis. The clofarabine effect has also been demonstrated in cells from solid tumors, such as breast, gastric, and bladder. Clofarabine action on the proliferation of Ewing sarcoma cells *in vitro* and *in vivo* was proved to be by direct binding to CD99 and independent of the drug internalization. In addition, clofarabine also had an effect on cells from other tumor types that express CD99. The present work demonstrated the significant action of clofarabine on the high CD99-expressing U87MG cells by inhibiting cell proliferation, adhesion, and migration, and by inducing cell cycle arrest and apoptosis. U87MG cells knocked out for CD99 expression were more resistant to clofarabine action on proliferation. RNAseq analysis of U87MG cells treated with clofarabine and compared to control showed downregulated genes involved in cell cycle regulation and mitosis, while upregulated genes were enriched in extracellular proteins, cell adhesion, locomotion, p53 signaling pathway, and apoptosis. Our data indicates clofarabine as a potential CD99 inhibitor to treat GBM patients.

#0558 Stearoyl-CoA desaturase is a synthetic lethal target in SMAD4-deficient cancers.

A. Lu, S. Fenoglio, H.-J. Wu, M. Zhang, A. Tsai, M. L. D. Ferdinez, L. Grove, S. Liu, E. Wu, A. Choi, S. Throner, S. Meier, Y. Yu, W. Zhang, J. Maxwell, J. N. Andersen, T. Teng, B. B. Haines, Y. P. Chen;
Tango Therapeutics, Boston, MA

Mothers against decapentaplegic homolog 4, or SMAD4, is a member of the SMAD family of transcription factors that mediate TGF-β signal transduction. SMAD4 loss of function mutation or deletion is found in about 30% of PDAC and 15% of COAD and EAC patients, and it is associated with their poor prognosis. Over the past two decades, its tumor suppressor role has been elucidated, and the loss of SMAD4 is sufficient to promote tumorigenesis in multiple GEM models. To identify novel therapeutic vulnerabilities for SMAD4-deficient cancers, a CRISPR dropout screening approach was employed in SMAD4 isogenic PDAC models. We identified stearoyl-CoA desaturase, SCD, as a synthetic lethal target in SMAD4-deficient context. SCD is critical for de novo lipid biogenesis and catalyzes the rate-limiting step in the production of monounsaturated fatty acid. Genetic and pharmacologic studies in vitro confirmed this synthetic lethal relationship. Additionally, drug-anchored CRISPR dropout screening and RNA expression profiling demonstrated that accumulation of saturated fatty acid in response to SCD inhibition drives cytotoxicity in SMAD4-deficient cells. Mouse studies with CRISPR-based knockout of SCD and a well-characterized SCD inhibitor (A939572) demonstrated anti-tumor efficacy in SMAD4-mutant xenograft models. However, compared to genetic KO of SCD the pharmacological inhibitor was less effective at inhibiting tumor proliferation in vivo. Together, these data identify SCD as a selective vulnerability in SMAD4-mutant cancers.

#0559 Investigating DDX3X as a target to improve outcomes in Black and Native American endometrial cancer patients.

J. D. Lausen, D. M. Benbrook;
University of Oklahoma Health Sciences Center, Oklahoma City, OK

Introduction: The goal of this project was to identify and test a new molecular target that will help reduce the worse outcomes of endometrial cancer, especially in Black and Native American patients. Endometrial cancer is rapidly on the rise in the developed world. It has overtaken many other types of cancer in both incidence and mortality. Black populations are disproportionately impacted by endometrial cancer, both in Oklahoma and across the United States. In Oklahoma specifically, Native Americans are the most heavily impacted group.
Methods: Machine learning techniques were used to analyze comprehensive metabolic panel (CMP) data from electronic medical record of patients in the University of Oklahoma (OU) network of hospitals and clinics. This data was broken down by endometrial cancer status, race, and age. Plasma samples of endometrial cancer patients were collected from the OU Health Sciences Center Biobank. These samples were analyzed by mass spectrometry. Endometrial cancer cell lines Ishikawa (low-grade) and ARK-1 and ARK-4 (high grade) were cultured in EMEM. For treating the cells, we used RK-33, a small molecule inhibitor of DDX3X. MTT assays were performed in 96-well plates at increasing concentrations of RK-33 for 48 hours. Western blots were used to determine effect of the drug on cellular DDX3X and yH2AX protein levels.
Results: Machine learning analysis EMR data revealed a difference between races in albumin levels of women with endometrial cancer. Black and Native American patients had lower albumin, which is known to correlate to worse outcomes. IPA analysis of plasma proteomics revealed several proteins that were differentially expressed between races. Among these was DDX3X, the X-linked form of DDX3, a DEAD-box RNA helicase which is involved in DNA damage repair. Patient data indicated that patients with high DDX3X expression tended to have lower survival rates. MTT analysis determined that Ishikawa has a lower IC_{50} than the high-grade cell lines, but all responded. Western blotting confirmed that treatment with RK-33 reduced the amount of DDX3X in the cells and increased y-H2AX, indicating more DNA damage.
Conclusions: This study demonstrates that DDX3X is a valid molecular target in endometrial cancer. The differential expression across race groups indicates that Black and Native Americans may stand to benefit the most from a novel drug targeting this difference. Because DDX3X is involved in DNA damage repair, combining the treatment with a DNA-damaging drug may increase response to the drug as well.

#0560 IGF1 induces the expression of CYR61 in metastatic prostate cancer.

G. L. Ortiz Hernandez[1], M. Walker[1], L. Woods-Burnham[2], R. A. Kittles[2], C. A. Casiano[3], S. Neuhausen[1];
[1]City of Hope National Medical Center, Duarte, CA, [2]Morehouse School of Medicine, Atlanta, GA, [3]Loma Linda University School of Medicine, Loma Linda, CA

The cysteine-rich angiogenic inducer 61 (CYR61) is a member of the cellular communication network (CCN) protein family that can be induced by growth factors. CYR61-specific functions are dependent on cellular context. In prostate cancer (PCa), CYR61 contributes to cell growth and survival through its interactions with extracellular ligands, such as integrins avb3 and a6b4, in the extracellular matrix space. Interestingly, CYR61 contains an insulin-like growth factor-binding protein domain suggesting that it may interact with insulin-like growth factor-I (IGF1). High serum levels of IGF1 are directly linked to PCa development and recently have been studied as a predictor of metastatic disease. Given the important roles that IGF1 and CYR61 play in PCa and their potential interaction, it is critical to investigate their molecular interplay. The correlation between PCa aggressiveness and circulating levels of CYR61 and IGF1 is poorly studied. Our goal was to assess the contribution of CYR61-IGF1 interaction to PCa cell proliferation. Their combined role may explain a proportion of aggressive PCa. This study was designed to characterize the role of IGF1-induced expression of CYR61 in metastatic PCa cellular models and to determine if this interaction contributes to aggressive tumor properties (e.g., proliferation, migration, tumorsphere formation). Using immunoblotting, we demonstrated that CYR61 is upregulated in the metastatic cell line PC3. Furthermore, optimized knockdown of CYR61 using siRNA significantly reduced PC3 cell proliferation, viability, and prostasphere formation. To examine the underlying mechanisms associated with IGF1 signaling, we assessed the activation of either the PI3/Akt and MAPK pathways in PC3 cells with CYR61 silencing. CYR61 siRNA-mediated knockdown decreased activation of the PI3/Akt pathway but did not affect the MAPK pathway. In addition, we found that IGF1 induces protein expression of CYR61 in a time-dependent manner, validated by both immunoblotting and confocal microscopy. In conclusion, these data provided evidence that CYR61 expression is induced by IGF1, and its inhibition decreased the capacity of metastatic PCa cells to proliferate, indicating a potential utilization of CYR61 inhibition in the therapy of metastatic PCa.

#0561 Targeting Y box binding protein 1 (YBX1) in *MYC*-amplified medulloblastoma.

S. Carney[1], J. Hemenway[1], A. Rajendran[1], M. Hathaway[1], E. Nealy[1], C. Bonatto[1], D. Tailor[2], S. Malhotra[2], M. Evans II[1];
[1]Seattle Children's Research Institute, Seattle, WA, [2]Oregon Health & Science University, Portland, OR

Medulloblastoma is the most common malignant pediatric brain tumor. Patients diagnosed with *MYC*-amplified group 3 medulloblastoma (G3 MB) have a devastating prognosis with a 5-year survival rate of <50%. Standard of care (SOC) consists of maximal resection surgery followed by chemoradiotherapy, but these extensive treatments leave patients with neurocognitive and developmental deficits. Therefore, the identification of novel targets that can be used alone or in combination with SOC is of utmost importance. Using a batch-normalized bulk RNA-seq dataset (GSE124814) comprised of 1350 MB samples and 291 normal cerebella, we reveal upregulation of Y-box binding protein 1 (YBX1) in MB compared to normal cerebellum. Further analysis of this dataset and others demonstrates G3 tumors that display high MYC levels also have the highest YBX1 expression. Analysis of ChIP-seq data shows strong binding of MYC to the *YBX1* promoter in G3 MB, concurrent with H3K27ac and H3K4me3 histone modifications. Using a well-established ex vivo model, we demonstrate increased YBX1 expression as normal cerebellar progenitor cells transition to tumorigenic G3 MB stem-like cells. Recent work in leukemia reveals a reciprocal regulation of MYC by YBX1, however, this mechanism is not well established in G3 MB. We utilized an orthogonal pharmacogenetic approach to inhibit YBX1 function and determine its effects on G3 MB tumor biology. Suppression of YBX1 significantly reduced the proliferation and decreased MYC protein expression of G3 MB cells *in vitro*. These findings support a reciprocal MYC-YBX1 axis, which could influence tumor growth *in vivo.* Orthotopic implantation of YBX1 KO G3 MB cells leads to increased animal survival. We next evaluated the therapeutic potential of two recently characterized YBX1 inhibitors which display single agent efficacy *in vitro and in vivo.* YBX1 inhibitors synergized with SOC *in vitro* lowering the IC50 for both chemo and radiotherapy, which could reduce adverse effects experienced by patients. *In silico* molecular docking using PyMOL predicts YBX1 inhibitors interact with amino acids within the cold shock domain of YBX1, likely impairing its ability to bind RNA. We performed formaldehyde RNA immunoprecipitation (fRIP)-sequencing to identify changes in RNA transcript levels following YBX1 pharmacological inhibition. Disruption of YBX1-RNA binding impacts the stability of known oncogenic transcripts which may be required for tumorigenesis. Our findings impart an alluring prospect of targeting YBX1 in combination with standard-of-care, and possibly other compounds to improve patients' outcomes.

#0562 Frequent copy number gain of *MCL1* is a therapeutic target for osteosarcoma.

S. Takagi, R. Katayama;
Japanese Foundation for Cancer Research, Tokyo, Japan

Osteosarcoma (OS) is the most common primary malignant bone tumor that predominantly occurs in children, adolescents, and young adults. The treatment for OS that combines surgery with chemotherapy, which consists of a four-drug combination of adriamycin (DOX), cisplatin (CDDP), high-dose methotrexate (MTX), and ifosfamide, was established in 1970s, and it is still used as a standard therapy. Oncogenic driver mutations and fusion genes common to OS have not been identified, which is one of the reasons for the lack of success in drug development for OS. Herein, to explore the characteristic vulnerability in OS, molecular targeted drugs were screened against OS cell lines and patient-derived cells; obatoclax, a pan-BH3 mimetic, and a concomitant drug that enhances obatoclax-induced apoptosis, OSI906, a dual inhibitor of IGF1R and IR, were found. Fluorescence in situ hybridization (FISH) analysis revealed that copy number gains of *MCL1*, an antiapoptotic Bcl-2 family protein, were observed in 46.3% of formalin-fixed paraffin-embedded (FFPE) specimens from patients with OS (*N* = 41) and in 45.5% of OS cell lines (*N* = 11), thereby causing vulnerability to BH3 mimetics. IHC staining also revealed high expression of Mcl-1 protein in specimens with *MCL1*-amplification in FISH analysis. Pharmacological or genetic inhibition of Mcl-1 induced potent apoptosis in *MCL1*-amplified OS cells, which was enhanced by the co-inhibition with Bcl-xL. Moreover, chromosome 1q21.2-3, where *MCL1* is located, contains several IGF1R/PI3K pathway-related genes, including *PIP5K1A*, *TARS2, OUTD7B*, and *ENSA*, whose copy numbers were also increased in *MCL1*-amplified OS cells, suggesting that 1q21.2-3-amplified OS cells readily activate downstream pathways via IGF1R. IGF signaling activation in 1q21.2-3-amplified OS cells negated the obatoclax-induced apoptosis, which was overcome by OSI906 treatment. Combined obatoclax and OSI906 administration remarkably suppressed *MCL1*-amplified OS tumor growth in the xenograft mouse model and resulted in tumor regression; however, none of the treatments reduced tumor growth of OS without *MCL1* amplification. These results suggest that combining obatoclax with OSI906 could be a potential therapeutic intervention for 1q21.2-3-amplified OS, and that prior stratification of OS based on the 1q21.2-3 amplification status would be important for the success of this combination therapy. Thus, we elucidated the mechanism of action of drugs and their potential as a novel therapeutic strategy for approximately 50% of patients with OS. Moreover, a FISH analysis that can detect copy number gains of *MCL1* in FFPE specimens from patients with OS was established to stratify patients eligible for this therapy.

#0563 Targeting PDE4D reinstates toxic PARP trapping via cAMP-ROS-DNA damage axis and restores the efficacy of standard of care in treatment-refractory ER+ breast cancer.

O. Saatci[1], M. Cetin[1], M. Uner[2], U. M. Tokat[3], I. Chatzistamou[4], E. Montaudon[5], A. Akyol[2], S. Aksoy[6], A. Uner[2], E. Marangoni[5], M. Sajish[4], **O. Sahin**[1];
[1]The Medical University of South Carolina (MUSC), Charleston, SC, [2]Hacettepe University, Ankara, Turkey, [3]Bilkent University, Ankara, Turkey, [4]University of South Carolina, Columbia, SC, [5]Institut Curie, Paris, France, [6]Hacettepe University Cancer Institute, Ankara, Turkey

Endocrine therapies, modulating ER level and/or activity, and the CDK4/6 inhibitors are among the standard-of-care (SOC) therapies used in estrogen receptor-positive (ER+) breast cancer. However, most ER+ breast cancer patients eventually develop resistance to SOC, representing a major clinical challenge that reduces clinical outcome. Therefore, elucidating the common mechanisms of sensitivity and resistance to SOC therapies, and identifying novel actionable targets are urgently needed. Here, we demonstrated that cell death induced by endocrine therapies and CDK4/6 inhibitors involves toxic PARP1 trapping and generation of a functional BRCAness (i.e., *BRCA1/2* deficiency) phenotype, leading to transcriptional blockage. We showed that this is achieved by activation of the cAMP/reactive oxygen species (ROS)/DNA damage axis upon downregulation of phosphodiesterase 4D (PDE4D). Importantly, we identified PDE4D as a novel ER target gene that in turn stimulates ER activity in a feedforward loop in endocrine-responsive models. However, during SOC resistance, an ER-to-EGFR switch induces PDE4D overexpression via c-Jun. Inhibition of PDE4D using BPN14770, the first-in-class PDE4D allosteric inhibitor that has successfully completed Phase II trials in Fragile X syndrome, reinstates PARP1 trapping and BRCAness, leading to drug sensitization in vitro and in vivo. Furthermore, inhibition of EGFR or PARP1 recapitulates the effects of PDE4D targeting and overcomes SOC resistance irrespective of the BRCA1/2 status in cell line models, primary cultures and organoids of endocrine resistant ER+ PDXs. Notably, we demonstrated that high PDE4D mRNA and protein expression is associated with dramatically worse disease-free survival and overall survival in endocrine therapy-treated ER+ breast cancer. Given the availability of potent and non-toxic PDE4D inhibitors, and clinically approved EGFR and PARP1 inhibitors, our findings have great translational potential to improve the clinical outcome of refractory ER+ breast cancers.

#0564 Therapeutic targeting of JAK/STAT signaling and histone acetyltransferase activity in post-myeloproliferative neoplasm secondary AML.

K. Bertulfo[1], K. Debackere[1], H. Miller[1], C. Ma[1], R. Najac[1], A. Ferrando[2], T. Palomero[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Regeneron Pharmaceuticals Inc., Tarrytown, NY

Post-myeloproliferative neoplasm secondary Acute Myeloid Leukemia (Post-MPN sAML) is an aggressive and lethal hematologic malignancy arising from myeloproliferative neoplasms (MPN). Hyperactivation of JAK/STAT signaling was identified in 50-90% of MPNs - underscoring its role in driving MPN pathogenesis and transformation to post-MPN sAML. Ruxolitinib, a Type-I JAK2 inhibitor approved for the treatment of myelofibrosis, was tested in a Phase II clinical trial in post-MPN sAML. The trial revealed that ruxolitinib improved the quality of life in patients but was not disease-modifying. Thus, there is an urgent need to find synergistic drug combinations capable of complementing the therapeutic activity of JAK2 inhibitors in post-MPN sAML. Here, we demonstrate that combination treatment of ruxolitinib and CBP30, a bromodomain inhibitor of histone acetyltransferases (HAT) CBP and p300, enhances the therapeutic activity of ruxolitinib in post-MPN sAML. Genome-wide CRISPR loss-of-function screens in JAK2-mutated HEL cells determined that knockout of CBP sensitizes leukemic cells to JAK2 inhibitors. Consistently, functional validation through CRISPR/Cas9 demonstrated that genetic deletion of CBP but not of p300 renders HEL cells sensitive to ruxolitinib treatment. Pharmacologic inhibition of JAK/STAT signaling and HAT activity through ruxolitinib and CBP30 treatment in post-MPN sAML lines HEL and SET2 decreases proliferation and induces apoptosis and cell cycle arrest. Mechanistically, the synergism between ruxolitinib and CBP30 elicits a unique transcriptome profile in HEL with significant downregulation of E2F and MYC targets. In addition, epigenetic profiling revealed that the synergism induces global changes in H3K27ac signals with downregulation and upregulation of H3K27ac signals in predicted STAT5/BCL3 and GATA-bounded regions, respectively. Remarkably, combination treatment of ruxolitinib and CBP30 in HEL luciferase NSG mouse xenografts showed significant leukemia regression and decrease in spleen size compared to mice treated with vehicle or single agents. Overall, these results substantiate the potential of targeting JAK/STAT signaling and histone acetyltransferase activity in the treatment of post-MPN sAML.

#0565 PDE7 modulates EMT, cells morphology and mitochondrial cristae in high grade serous ovarian cancer.

L. B. Rangel[1], N. G. Tessarollo[1], I. d. Guimaraes[2], D. Z. dos Santos[1], T. B. Henriques[1], M. L. M. de Souza[1], L. F. Maciel[3], J. A. Almeida[3], T. M. Pimenta[1], J. C. de Souza[1], R. B. Wanzeler[1], B. S. Martins[1], S. S. Butzene[1], J. S. Padilha[1];

[1]Federal Univ. of Espirito Santo, Vitoria, Brazil, [2]National Cancer Institute, Rio de Janeiro, Brazil, [3]State University of the North Fluminense, Campos dos Goytacazes, Brazil

Background: Due to the acquisition of chemoresistant phenotype by epithelial ovarian cancer (EOC) cells and, consequently, disease relapse, the identification of novel therapeutic strategies is urgent. Herein, we targeted phosphodiesterase 7A (PDE7A) in EOC cells, based on data derived from RNA-sequencing assays comparing high-grade serous ovarian carcinoma (HGSOC) and fallopian tube samples.

Methods: To understand the role of PDE inhibition, we evaluated the effects of its inhibitor BRL50481 alone or in combination with paclitaxel (PTX) on untreated A2780 EOC cells and multi-resistant high grade serous ovarian cancer (HGSOC) OVCAR3 cells. To do so, we pursued with the: validation of data obtained by high throughput RNA sequencing assays using qRT-PCR; evaluation of PDE7 expression in normal and EOC cells, as well as in normal Fallopian tube cells by qRT-PCR; immunoblotting; metabolic cell viability (MCV) by MTT assays; cytokine dosage by qRT-PCR and ELISA; scanning electron microscopy; transmission electron microscopy; statistical analysis (GraphPad software).

Results: Drug-sensitive A2780 cells, but not OVCAR3 cells, exhibited lower MCV when treated with the PDE7 inhibitor; however, the combinatory therapy decreased MCV in both cell lines. Of clinical relevance, pre-treatment of A2780 and OVCAR3 with the PDE7 inhibitor BRL50481 followed by PTX lowered its IC_{50} by 10^3- and 625-fold, respectively. While the phosphatidylinositol 3-kinase (PI3K)/protein kinase B(AKT)/mammalian target of rapamycin (mTOR) pathway was inhibited in both cell lines, the pro-apoptotic protein Bcl-2 Associated X-protein (BAX) was overexpressed in A2780 cells only. Analysis of mRNA and protein expression in OVCAR3 pretreated with BRL50481 showed a 2-fold increase in IL-6 cytokine expression. Pre-treatment of OVCAR3 with BRL50481 followed by the combination of BRL50481 and PTX inhibited the expression of vimentin and Octamer-binding transcription factor 4 (OCT4) by 2-fold. BRL50481 promoted changes in EOC cells morphology and mitochondrial cristae.

Conclusions: Altogether, our data led us to postulate that inhibition of PDE7 in EOC cells, specifically in those presenting the chemoresistant phenotype, is a promising strategy to fight this yet highly lethal disease.

#0566 The anticancer effects of polyisoprenylated cysteinyl amide inhibitors involves interaction with the KRAS chaperone calmodulin.

K. Ofosu-Asante, J. M. Lazarte, A. Burra, N. S. Lamango;
Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL

Pancreatic cancer is the third leading cause of cancer-related deaths with a 5-year survival rate of less than 10%. Approximately 90% of reported cases are driven by *KRAS* mutations. The mutant *KRAS* acquires its functional localization through interactions with chaperone proteins via its polybasic polyisoprenylated tail. Polyisoprenylated cysteinyl amide inhibitors (PCAIs) mimic this region possibly disrupting the polyisoprenylation-dependent interactions with chaperone proteins. Here, we determine the effect of newly developed PCAIs that were designed to be more water-soluble on cell viability, 3D spheroid invasion, spheroid degeneration and F-actin filaments on MIA PaCa-2 and PANC-1 cells. Of the seven new PCAIs analogs tested, NSL-AB-51 and NSL-AB-45 were the most potent, with EC_{50} values of 2.5 and 5.6 µM against MIA PaCa-2, and 1.7 and 4.5 µM against PANC-1 cells, respectively. At 5 and 10 µM, NSL-AB-51 decreased the invasion area of 3D spheroids by 98 and 99%, respectively. MIA PaCa-2 spheroids degenerated by 61% after 72 h treatment with 10 µM NSL-AB-51. Treatment with 1.0 µM NSL-AB-51 caused cell rounding and reduction of mean cell areas by 69% and F-actin filaments by 96%. Moreover, to identify the pharmacological target of the PCAIs, NSL-AB-45 was coupled to an epoxy-activated Sepharose resin for affinity trapping of PCAIs-interacting proteins. Affinity-analysis of supernatants and detergent membrane extracts from MIA PaCa-2 and PANC-1 cells revealed single Coomassie band of about 17 kDa that was identified as calmodulin by western blotting analysis. The calmodulin-PCAIs affinity interaction was found to be strongest in the presence of calcium and weakest in the presence of EDTA. These findings reveal that calmodulin is the likely target of PCAIs. Since calmodulin is the chaperone protein responsible for KRAS trafficking and localization to the inner surface of the plasma membrane, this finding strongly suggests, at least in part, an anticancer role for the PCAIs that involve disruption of KRAS functions.

#0567 Fisetin sensitizes triple negative breast cancer cells to radiation.

S. Khozooei, S. Veerappan, **M. Toulany**;
University Hospital and Medical Faculty Tubingen, Tubingen, Germany

Triple negative breast cancer (TNBC) represents a highly aggressive subtype, constituting approximately 20% of all breast cancer cases. Y-box binding protein-1 (YB-1) is often overexpressed in various tumor types and has been implicated in conferring resistance to cell death induced by radiotherapy. Fisetin, a flavonoid compound with demonstrated anti-cancer properties, operates in part through inhibiting phosphorylation of YB-1 by p90 ribosomal S6 kinase (RSK). In this study, we investigated the potential synergistic effects of combining fisetin with radiotherapy in TNBC. The activation status of the RSK signaling pathway was assessed in both total cell lysate and subcellular fractions using Western blotting. A standard clonogenic assay was employed to evaluate post-irradiation cell survival. To investigate the frequency of double-strand breaks (DSBs) and chromosomal aberrations, γH2AX foci assay and 3-color fluorescence in situ hybridization analyses were conducted, respectively. The DSB repair pathways targeted by fisetin were examined in cells expressing genomically integrated reporter constructs by quantifying green fluorescence protein expression through flow cytometry. Apoptosis and autophagy were measured using flow cytometric quantification of sub-G1 cells and the assessment of LC3-II protein expression, respectively. Kinase array and phosphoproteomics analyses were carried out to study the potential impact of fisetin on the signaling involved in the DNA damage response (DDR) after irradiation. We demonstrated that fisetin mimics the effects of RSK pharmacological inhibitors in terms of effect on YB-1 phosphorylation. Treatment with fisetin increased frequency of DSB in non-irradiated cells and impaired repair of DSB after irradiation. Fisetin attenuated DSB repair by suppressing the classical non-homologous end-joining and homologous recombination repair pathways. The frequency of chromosomal aberration was enhanced by fisetin treatment. The effect of fisetin on inhibiting DSB repair was partially YB-1 dependent. Phosphoproteomic analysis revealed that fisetin inhibits DDR signaling, which leads to radiosensitization in TNBC cells, as shown in combination with single dose or fractionated doses irradiation. Fisetin neither inhibited DSB repair nor radiosensitized normal human fibroblast HSF7 cells. The radiosensitizing effect of fisetin was not attributed to enhancing apoptosis or modulating autophagy. In summary, combining fisetin with radiotherapy may enhance TNBC radiotherapy outcomes.

-This research was supported by a grant from the German Research Council (DFG,TO 685/2-3).

#0568 Modulation of HER4 isoforms expression in estrogen-stimulated *in vitro* models.

M. Valenti[1], G. F. Bischof[2], J. P. Crown[3], D. M. Collins[1];
[1]Dublin City University, Dublin, Ireland, [2]Puma Biotechnology, Inc.,10880 Wilshire Blvd., Suite 2150, Los Angeles, 90024, CA, [3]St. Vincent's University Hospital, Elm Park, Dublin, Ireland

Introduction HER4, a tyrosine kinase receptor belonging to the Human Epidermal Growth Factor/HER/ErbB-family, has a complex biology that includes four isoforms (JMa-CYT1/2, and JMb-CYT1/2) and tissue specific oncogenic or tumour suppressor roles. In estrogen receptor positive (ER+) breast cancer (BC), HER4 isoforms can either act as a co-regulator of ESR1-mediated gene expression by localising to the nucleus, or activate apoptosis by localising to mitochondria. There is very little known about HER4 function in cutaneous melanoma, despite cutaneous melanoma showing the highest HER4 genomic alteration frequency (17.34%) across different cancers (cBioPortal). Due to the interplay between estrogen signalling and HER4 isoforms in ER+BC, this study investigates the RNA expression of HER4 isoforms along with hormone and nuclear receptors associated with 17β-estradiol stimulation in ER+BC and cutaneous melanoma *in vitro* models.
Material and Methods CAMA1 (ER+BC) and SKMEL24 (cutaneous melanoma) cell lines were serum starved for 4h prior to stimulation with 17β-estradiol (0.5nM, 1nM, 5nM and 10nM). RNA was extracted from cells after 24h using TRIzol, followed by qRT-PCR to assess the expression of HER4 isoforms, the hormone receptors estrogen receptor 1 (ESR1/ER-alpha), estrogen receptor 2 (ESR2/ER-beta), progesterone receptor (PGR/PR), G protein-coupled estrogen receptor 1 (GPER1) and the nuclear receptors retinoic acid receptor alpha (RARA) and retinoid X receptor alpha (RXRA). Cell proliferation and caspase3/7 apoptosis analysis were performed at 24/48/72h in the 17β-estradiol stimulated cells by using the IncuCyte Live Cell Analysis Instrument (Sartorius). SN-38 (150nM) was used as positive control for apoptosis induction. Two-way ANOVA was used for the statistical analysis, $p<0.05$ was significant.
Results The qRT-PCR analysis showed that upon stimulation of CAMA1 with 1nM of 17β-estradiol there is a numerical shift in the CYT-1/CYT-2 ratio towards CYT-2 (not statistically significant, $p>0.05$) and a significant increase in PGR ($p= 0.0027$) and RAR-A ($p= 0.0248$) expression compared to control. CAMA1 stimulated with any concentration of 17β-estradiol showed an increase in proliferation compared to the control. The stimulation of SKMEL24 with 5nM of 17β-estradiol showed an increase in JM-a ($p=0.0075$) and CYT-1 ($p=0.0271$) HER4 isoforms, GPER1 ($p= 0.0286$), and a dose-dependent increase in RARA ($p=0.0011$) compared to control, even in the absence of ESR1, ESR2 and PGR. SKMEL24 stimulated with 17β-estradiol showed a decrease in proliferation compared to control, but no apoptosis induction was found.
Conclusion These findings suggest potential interplay between 17β-estradiol and HER4 isoforms leading to the activation of intracellular pathways that could influence tumour progression/suppression in melanoma. Further studies are needed to clarify the specific receptor interactions and pathways involved.

#0569 Targeting UHRF1's proteasomal destruction as a novel approach for small cell lung cancer treatment.

Yijun Gu, Claudia A. Benavente

University of California, Irvine, Irvine, CA

Small cell lung cancer (SCLC) is an aggressive lung cancer subtype with a five-year survival rate of less than 8% due to rapid tumor growth, early metastasis, and a "cold" immune environment. Genetic alteration at the RB transcriptional corepressor 1 (RB1) is nearly universally present in SCLC patients. However, the therapeutic development was impeded by a lack of druggable oncogenic mutations. Studies in our laboratory identified ubiquitin-like, containing PHD and RING Finger domains 1 (UHRF1) as a critical protein overexpressed in many cancers with RB-pathway inactivation, including SCLC. Despite UHRF1 overexpression correlates with poor survival in SCLC patients, the roles of UHRF1 in SCLC progression remain to be elucidated. We hypothesized that UHRF1 overexpression is essential for SCLC tumor progression and can be targeted through endogenous proteasomal degradation. To define the role of UHRF1 in SCLC, we generated UHRF1 knockout and knockdown human SCLC cell lines. Using these mutants, we assessed changes in proliferation, clonogenicity, migration, and invasion capabilities. We report that UHRF1 overexpression present in human SCLC cell lines contributes to a more aggressive tumor presentation, affecting both tumor growth and metastasis. Besides human cell line models, we also generated genetically engineered mouse models of SCLC to study the role of Uhrf1 in tumor development, especially in an immune environment. Our results indicate that Uhrf1 overexpression promotes SCLC proliferation, angiogenesis, and pro-tumoral macrophage polarization, overall conditioning a tumor microenvironment that supports a more aggressive phenotype. Loss of Uhrf1 in this system results in a robust increase in overall survival. These results strongly support a critical role of UHRF1 in SCLC tumor progression and provide guidance for future SCLC therapeutics targeting UHRF1 or its key downstream effectors. One approach we apply is to utilize UHRF1's endogenous degradative machinery by inhibiting its deubiquitinase USP7. In normal cells, UHRF1 abundance oscillates through cell cycle due to the regulation of ubiquitin machinery. USP7 cleaves ubiquitin marks on UHRF1, antagonizing UHRF1 degradation. We report that same as UHRF1, knocking out USP7 leads to decreased clonogenicity, migration, and invasion in human SCLC cell lines. Highly specific USP7 chemical inhibitors, XL-177A and FT671, were also tested and the same effects as USP7 knockout were observed. Collectively, our findings describe the oncogenic role of UHRF1 in SCLC proliferation, metastasis, and immune recognition and provide a therapeutic strategy of inhibiting USP7 for UHRF1 destruction.

#0570 The role of CD5L in chronic liver disease.

Handan Hong[1], Taojian Tu[1], Lina He[1], Meisam Razaviyayn[2], Sze-Chuan Suan[3], Liyun Yuan[4], Bangyan L. Stiles[1]

[1]Pharmacology and Pharmaceutical Sciences, USC - University of Southern California, Los Angeles, CA,[2]Electrical and Computer Engineering, USC - University of Southern California, Los Angeles, CA,[3]Industrial and Systems Engineering, USC - University of Southern California, Los Angeles, CA,[4]Medicine, USC - University of Southern California, Los Angeles, CA

Macrophage migration inhibitory factor (MIF) is a CD5 molecule like glycoprotein synthesized and secreted by macrophages, also termed CD5L. In liver cancer, serum levels of CD5L has been reported to be higher in steatohepatitis and hepatocellular carcinoma (HCC) patients and proposed to be a serum marker for these conditions. In the liver, steatosis and steatohepatitis is a major comorbid factor for HCC development and associated with poor response to therapy, particularly immune-checkpoint therapy. Here, we assessed the levels of CD5L in plasma samples from 50 advanced HCC patients obtained at baseline prior to initiation of systemic immunotherapy and compared them with that of healthy controls. The data demonstrated a 50% higher plasma CD5L levels in HCC patients vs. healthy donors. Furthermore, CD5L concentrations are higher in patients with higher Child Pugh score. In patients treated with immune checkpoint single or combination therapy, serum CD5L was found to correlate with clinical benefit. To address the role of CD5L and CD5L secreting macrophage in HCC development, we performed in-silico analysis of single cell RNA-seq data and identified Cd5l as a unique gene expressed on liver resident macrophages, the Kupffer cells (KCs). This finding was validated with additional datasets and using two steatosis mouse models representing ALD and NAFLD. Furthermore, our immunofluorescent staining and flow cytometry further confirmed the main source of Cd5l is KCs. In HFD fed mice, we showed that the expression and serum levels of CD5L became more significant with the severity of liver injury, particularly steatotic liver injury. We hypothesize that CD5L may be involved in establish the tumor microenvironment established by steatohepatitis, we performed a free fatty acid (FFA) uptake assay and found that CD5L increased the uptake of FFA in hepatic stellate cells. This ability of CD5L may have contributed to therapy resistance observed in the CD5L high patients who showed reduced clinical benefit.

#0571 CRISPR/Cas9 screening identifies the proteasome subunit PSMC6 as key for the survival of cisplatin-resistant ovarian carcinoma cells.

M. Costantino[1], P. D'arcy[2], L. Mirra[1], C. Corno[1], G. L. Beretta[1], J. Gubat[2], P. Pratesi[1], C. M. Ciniselli[1], P. Verderio[1], S. Linder[3], **P. Perego**[1];
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [2]University of Linkoping, Linkoping, Sweden, [3]Karolinska Institutet, Stockholm, Sweden

Ovarian carcinoma is a disease with poor prognosis, due to delays in diagnosis and the development of drug resistance. Since deregulation of the ubiquitin proteasome system may contribute to the development of drug resistance, the aim of this study was to investigate the interplay between expression of proteasome subunits and cisplatin resistance by utilizing a CRISPR/Cas9 dropout screen. Paired cisplatin-sensitive and -resistant cells (IGROV-1 and IGROV-1/Pt1) were transfected with Cas9 and transduced with gRNAs against proteasome components. Cells were collected at early (day 4) and late (day 21) time exposure and sequenced to identify genes necessary for survival. Various proteasome subunits were found to be essential for the survival of cisplatin-resistant ovarian carcinoma cells, including PSMA5, PSMC6, PSMD7, PSMD12 and PSMD14. Since PSMC6 knockout produced the greatest growth inhibitory effects, it was selected for functional studies utilizing conventional RNA interference. When IGROV-1 and IGROV-1/Pt1 cells were transfected with small interfering RNAs (siRNAs) targeting PSMC6, efficient down-regulation on the mRNA and protein level was observed. Phenotypic analyses of PSMC6 knockdown cells indicated reduced clonogenicity using both 2D and soft agar assays in parental and resistant cells associated with down-regulation of the canonical MAPK pathway. A slight but not significant increase in sensitivity to cisplatin was observed upon PSMC6 silencing in resistant cells using clonogenic assays. Finally, we carried out a pilot study using ovarian carcinoma specimens (n = 134) obtained through the institutional biobank. The samples were representative of the frequency occurrence of the various histological ovarian carcinoma subtypes. We found that PSMC6 expression, evaluated by qRT-PCR, was associated with tumor stage. These findings suggest that PSMC6 is linked to ovarian carcinoma aggressiveness and that PSMC6 targeting may be an interesting therapeutic strategy.

#0572 Identifying potential therapeutic targets through gene expression analysis of peritoneal cavity cells in gastric cancer with peritoneal dissemination.

Y. Hiroshima[1], W. Kawase[1], I. Hashimoto[2], S. Onuma[2], H. Watanabe[2], M. Furuta[2], T. Oshima[2], Y. Miyagi[1];
[1]Kanagawa Cancer Centre Research Institute, Yokohama City, Japan, [2]Kanagawa Cancer Centre, Yokohama City, Japan

Background: Peritoneal dissemination (PD) is the primary mode of metastasis in gastric cancer (GC) and is strongly associated with a poor prognosis. However, the mechanisms underlying PD formation in GC remain largely unknown.Methods and Results: In this study, we collected peritoneal washings from three cytology-positive (CY1) and five cytology-negative (CY0) gastric cancer patients undergoing laparotomy. We performed RNA sequencing on cell components in the peritoneal washings and identified 13 genes that were differentially expressed and upregulated in the CY1 group. Among these genes, we focused on thrombospondin 1 (THBS1) and 2 (THBS2). We evaluated their expression levels in 317 patients with gastric or gastroesophageal junction cancer who underwent primary curative resection at the Kanagawa Cancer Center between January 2002 and December 2012. Patients were stratified into two groups based on the median expression values of these genes, and Kaplan-Meier analysis was conducted. THBS2 expression was found to be inversely associated with disease-free survival (DFS) ($p = 0.041$), peritoneal dissemination-specific DFS ($p = 0.041$), and overall survival (OS) ($p = 0.041$) in the study cohort. In contrast, THBS1 expression did not exhibit a significant association with any of the aforementioned outcomes.Conclusion: Our results suggest that THBS2 expression in gastric cancer tissues may serve as a useful independent prognostic factor for patients, potentially playing a crucial role in the formation of PD.

#0573 SLC22A17 as a promising target for triple-negative breast cancer.

Ajaikumar B. Kunnumakkara, Krishan Kumar Thakur

Biosciences and Bioengineering, Indian Institute of Technology Guwahati, Guwahati, India

Introduction: Triple-negative breast cancer (TNBC) represents a highly aggressive subtype of breast cancer, accounting for approximately 15% of all cases of invasive breast cancer globally. The absence of a well-defined cell membrane receptor has significantly limited the therapeutic options available for treating this malignancy. Consequently, there is a compelling need to explore novel receptors that could potentially revolutionize the treatment strategies employed for TNBC. Recent scientific research has unveiled SLC22A17, a cell surface receptor known for its involvement in iron transport, as a substantial contributor to the development of various cancer types. Thus, the primary objective of this study is to comprehensively evaluate the significance of SLC22A17 and its potential as a therapeutic target in TNBC.
Experimental Procedures: In this study, we meticulously examined the expression patterns of SLC22A17 across distinct subtypes of breast cancer utilizing immunohistochemistry. Computational tools were employed to delve into the role of SLC22A17 within TNBC datasets. To assess the impact of SLC22A17 on TNBC, we employed various methods, including siRNA-mediated silencing, to investigate its role in cell proliferation, apoptosis, epithelial-mesenchymal transition (EMT), and migration. Additionally, we conducted western blot analyses to assess the expression levels of SLC22A17 and cellular signaling molecules, such as Akt/mTOR and JAK/STAT, within the context of TNBC cells.
Results: Our analysis revealed a significant upregulation of SLC22A17 in both TNBC tissues and cell lines, establishing a direct correlation with patient survival outcomes. Silencing the expression of SLC22A17 resulted in reduced cell proliferation, migration, EMT, increased apoptosis, and enhanced autophagy. These effects were accompanied by the inhibition of Akt/mTOR and STAT3 signaling pathways. Moreover, we observed the involvement of the inflammatory cytokine TNF-α, which induced the expression of SLC22A17 in TNBC cell lines and governed various hallmark features of TNBC. Notably, the suppression of SLC22A17 mitigated these processes.
Conclusion: In conclusion, this investigation suggests the pivotal role played by SLC22A17 in TNBC and posits its potential as a novel and promising therapeutic target for the management of this formidable disease.

#0574 Adipocyte-derived FABP4 promotes non-alcoholic fatty liver disease (NAFLD)-induced hepatocellular carcinoma by driving ITGB1-mediated β-catenin activation.

C. O. Leung, S. Gurung, K. Chung, S. Chan, T. Lee;
The Hong Kong Polytechnic University, Hong Kong, Hong Kong

Nonalcoholic fatty liver disease (NAFLD)-induced hepatocellular carcinoma (HCC) is an emerging malignancy in the developed countries. However, the mechanisms contributing to its formation remain largely unknown. Given the role of cancer stem cells (CSCs) in tumor initiation and therapeutic resistance, we hypothesize that adipocytes, one of the key cellular factors within the tumor microenvironment of NAFLD-induced HCC, may play a critical role in HCC development and drug resistance by regulating liver CSCs. Using a co-culture system in which differentiated adipocytes were grown with HCC cells, we found that adipocytes enhanced the self-renewal ability of HCC cells through indirect paracrine secretion. HCC cells pre-incubated with conditioned medium from adipocytes showed enhanced liver CSC properties including self-renewal, tumorgenicity, invasiveness and chemo-resistance to doxorubicin and sorafenib. Secretome profiles showed that FABP4 was preferentially secreted by adipocytes and its level was further augmented when co-cultured with HCC cells. Concurrently, recombinant FABP4 enhanced CSC properties of HCC cells. Drastic delay in the onset of tumor development in FABP4$^{-/-}$ mice upon DEN-injected and high fat diet-induced mouse models of NAFLD-HCC. Mass spectrometry analysis revealed ITGB1 as a direct binding partner of FABP4 for the first time. This data, together with the observation of significant downregulation of the Wnt/β-catenin pathway in tumors of FABP4$^{-/-}$ mice, revealed the role of adipocyte-derived FABP4 promotes liver CSC function by activating the PI3K/Akt/β-catenin signaling pathway via ITGB1. Overexpression of ITGB1 led to poorer survival of HCC patients with NAFLD as a risk factor. The development of a monoclonal neutralizing antibody against FABP4 successfully blocked FABP4-driven CSC functions, implicating the targetability of FABP4 for the treatment of NAFLD-induced HCC.

#0575 Identification of SORL1 as a key regulator of chemoresistance in ovarian cancer.

M. Mansolf, Z. Jian, F. Bi, T. M. P. Hartwich, Y. Yang-Hartwich;
Yale School of Medicine, New Haven, CT

This study aimed to understand the molecular mechanism of platinum chemoresistance in recurrent ovarian tumors with a focus on the SORL1-regulated pathways. SORL1 is an intracellular sorting receptor that binds to HER2 in breast cancer; this promotes HER2 recycling to the cell surface, which ultimately impacts the progression and treatment of breast cancer. The role of SORL1 in ovarian cancer has not been extensively studied.
Method: RNA was extracted from 15 pairs of matched primary and recurrent high grade serous ovarian tumors collected from patients. Human transcriptomic microarray was used to identify the differentially expressed genes. The identified genes were validated by RT-QPCR and western blot in five ovarian cancer cell lines that were treated or untreated with carboplatin. To study the effects of identified target gene SORL1, overexpression and knockdown in ovarian cancer cell lines were established using SORL1 plasmid and shRNA. Proliferation and response to carboplatin were analyzed using celltiter Glo and caspase-3/7 activity assays respectively. EGFR and FGFR4 were identified as the interacting proteins of SORL1 in ovarian cancer cells through FGF1 and EGF1 treatment and co-immunoprecipitation. A proximity ligation assay was performed to validate their interactions. Finally, a xenograft mouse model was used to compare the tumor forming abilities and the response to carboplatin of SORL1-knockdown ovarian cancer cells and the control cancer cells *in vivo*. Protein expression of SORL1, EGFR, and FGFR4 in the collected tumors was determined via western blot.
Result: Transcriptomic analysis of matched human primary and recurrent ovarian tumors identified SORL1 as an upregulated gene in recurrent tumors compared to primary samples. SORL1 expression was also upregulated in ovarian cancer cells surviving carboplatin treatment. Proliferation assays demonstrated that SORL1-overexpressing and knockdown cell lines had increased and inhibited proliferative capabilities respectively. Caspase-3 activity assays showed that SORL1-overexpressing and knockdown cell lines had reduced and increased sensitivity to carboplatin treatment respectively. SORL1 was found to bind to and promote the expression of EGFR and FGFR4. When injected subcutaneously into nude mice, SORL1-knockdown cells had reduced tumor forming capabilities and increased sensitivity to carboplatin. SORL1-knockdown caused the tumors to express lower levels of SORL1, EGFR, and FGFR4 proteins in comparison with the control tumors.
Conclusion: This study demonstrates that SORL1 regulates the EGFR and FGF4 pathways to promote the growth and carboplatin resistance of ovarian cancer cells. Targeting this pathway has potential to aid in the treatment of platinum-resistant ovarian cancer.

#0576 The pan-quadruplex drug QN-302 selectively down-regulates key pathway targets in pancreatic cancer cells that are up-regulated in human pancreatic cancer.

Stephen Neidle[1], Ahmed A. Ahmed[1], Tariq Arshad[2], Tariq Arshad[2]

[1]University College London (UCL), London, United Kingdom,[2]Qualigen Therapeutics Inc, Carlsbad, CA

We have previously disclosed (Ahmed et al, ACS Med Chem Lett, 2020) a novel small molecule G-quadruplex binding compound, QN-302, that is highly potent in pancreatic ductal adenocarcinoma (PDAC) cells and in several in vivo models for this disease. QN-302 was invented at University College London UK and has been subsequently developed by Qualigen Therapeutics Inc. It was cleared by the FDA in August 2023 for Phase 1a clinical trials in USA and is currently under clinical evaluation. RNA-seq whole-genome transcriptome analysis revealed that QN-302 selectively targets G-quadruplexes in cancer-related genes, notably by forming stable G-quadruplex complexes with appropriate promoter sequences. This results in the transcriptional down regulation of affected genes, which map to for example, the hedgehog, axon guidance, WNT/β-catenin and P38 signal transduction pathways. In many instances individual expression changes are modest, though statistically significant: cumulatively, they affect whole pathways. We have revisited the RNA-seq data for QN-302 in PDAC MIA-PACA2 cells (GSE151741 at https://www.ncbi.nlm.nih.gov/geo/) in detail and now identify a small group of eleven down-regulated genes, all with >3-fold expression changes. Interestingly all these genes and their genes products have been previously identified as playing a role in human PDAC (they also have varying roles in other cancer types). Some have been validated as anticancer targets. 10/11 of these genes (https://www.proteinatlas.org/) have been previously reported as being over-expressed in significant fractions of large (>150) groups of human cancer patients from The Cancer Genome Atlas (TCGA) project. Cellular transcriptome data on these eleven genes is presented here, which together with earlier reports on them, supports the designation of QN-302 as a pan-G-quadruplex agent targeting a group of major genes involved in PDAC maintenance and metastasis. Data from a xenograft model for pancreatic cancer is also available for four of these genes, which concurs with the cellular data. We suggest that the identification of these 11 genes may also provide a basis for biomarker selection and possible patient stratification based on transcriptome data.

#0577 Deciphering the mechanism of the menin-MLL complex dependency in HCC.

M. M. Dzama, P. C. Kuhlers, J. R. Raab;
UNC Chapel Hill, Chapel Hill, NC

Liver cancer is the third leading cause of cancer-related death worldwide, with hepatocellular carcinoma (HCC) being the most common primary liver cancer (~90%). The 5-year survival rate of patients with advanced HCC is ~18% due to the late prognosis and the moderate clinical benefit of available systemic therapy options. Mutations in chromatin regulators were detected in ~50% of liver cancer. Since many chromatin regulators have been shown a dependency in various cancer types and can modulate therapy response, we focused on identifying new therapeutic targets of HCC among epigenetic modifiers and evaluating them as potential targets for future drug development. We constructed a CRISPR library of 6000 gRNAs targeting 737 genes involved in chromatin-mediated gene regulation. Using the epigenome-focused CRISPR/Cas9 screening in two-dimensional and three-dimensional settings in multiple liver cancer cell lines (HepG2, HLF, PLC/PRF5), we identified a list of epigenetic regulators as potential new targets in HCC. Two of them, *MEN1* and *ASH2L*, are core subunits of the menin-MLL complex mediating H3K4 trimethylation (me3). We validated dependencies of HCC on *MEN1* and *ASH2L* by performing a negative selection CRISPR/Cas9 competitive growth assay in HLF and PLC/PRF5 cell lines. Moreover, treatment of HCC cell lines (HLF, PLC/PRF5, HepG2) with recently developed menin inhibitor SNDX-5613 (revumenib) revealed a dose-dependent reduction in cell proliferation. To determine transcriptional changes associated with disruption of the menin-MLL complex, we performed RNA sequencing of HLF and PLC/PRF5 cells following either inhibition with 5μM SNDX-5613 for 4 days or knockout of the *MEN1* or *ASH2L* gene. We observed the upregulation of KRAS and the oncogenic signature of TGFβ signaling pathways in all menin-MLL complex disrupting conditions. We did not detect global changes in H3K4me3 levels upon the menin inhibition or *MEN1* or *ASH2L* knockouts assessed by immunoblotting. To explore the mechanism of the antiproliferative effect of the menin inhibition on HCC further, we evaluated changes in the binding of menin to chromatin and H3K4me3 levels in HCC cells by performing CUT&RUN following treatment of HLF cells with 5μM SNDX-5613 for 4 days. Menin inhibition led to a drastic removal of menin from the chromatin, while H3K4me3 levels were only mildly decreased. We identified 8765 genes near promoter regions with menin binding and H3K4me3 mark, of which 1952 genes were near regions with simultaneous loss of menin and decreased H3K4me3 levels upon menin inhibition. Integration of our genomics data revealed a list of 30 genes, which are downregulated upon menin inhibition in both HLF and PLC/PRF5 cells (FC≥1.5) and the direct targets of the menin-MLL complex in HLF cells, suggesting their potential role in HCC cell survival. Altogether, we anticipate that menin and ASH2L serve as promising targets and represent an appealing therapeutic strategy for HCC treatment.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Immunotherapy
Poster Session

#0578 Prediction of PD-1 treatment outcome in mismatch repair deficient metastatic colorectal cancer using a multi-omic approach.

B. Saberzadeh-Ardestani[1], O. E. Emiloju[1], R. P. Graham[1], J. T. Lewis[1], C. W. Abbott[2], S. M. Boyle[2], F. A. Sinicrope[1];
[1]Mayo Clinic, Rochester, MN, [2]Personalis, Inc., Fremont, CA

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of patients with deficient DNA mismatch repair (d-MMR) cancers, yet less than half of patients with metastatic colorectal cancer (mCRC) receive clinical benefit. We analyzed heterogeneity within d-MMR tumors using a multi-omics approach inclusive of percent unstable microsatellite loci (MS).
Methods: We studied consecutive patients with d-MMR mCRC with available primary tumors (N=32) that were treated with an anti-PD-1 antibody at Mayo Clinic (2015-2022). Tumors were profiled using a whole exome and transcriptome platform (ImmunoID NeXT®). MSIsensor was used to calculate percent unstable microsatellite loci from whole exome sequencing data. CIBERSORT and ssGSEA were used to analyze immune gene expression in relationship to percent unstable microsatellite loci. An immune checkpoint gene expression signature was calculated as the mean expression of CD274, CTLA-4, HAVCR2, LAG-3, PDCD1, PDCD1LG2, TIGIT. Aforementioned variables were analyzed in relationship to objective tumor response (RECIST version 1.1). A Cox proportional hazards model was fit to predict progression-free survival (PFS).
Results: Among 32 patients with d-MMR mCRC treated with PD-1 blockade, 16 (50%) received first-line anti-PD-1 therapy; others had $\geq$ 1 prior chemotherapy regimen. Eighteen (56.3%) tumors harbored *BRAF*^{V600E}, 4 (12.5%) had mutant *KRAS*, and median PFS was 24.6 months (95% CI: 8.4, NR) with 18 events. Neither tumor mutation burden (TMB) nor PD-L1 mRNA expression predicted PFS. Median percent unstable MS loci was 14.38 (IQR: 2.6-23.2). Patients whose tumors had higher percent unstable MS loci had significantly better PFS (Q2-4 vs Q1; HR: 0.22, 95%CI: 0.06, 0.62; P=0.003), and were associated with increased objective response (P=0.049). Tumors with higher unstable loci also had higher neoantigen clonality (R= 0.64; P= 0.0003) and increased M0 (resting) macrophages (P=0.02). Nonresponders (vs responders) to PD-1 blockade had an increased immune checkpoint expression signature (P= 0.005).
Conclusion: A higher percentage of unstable microsatellite loci, associated with higher neoantigen clonality and resting macrophages, was predictive of anti-PD-1 efficacy. Furthermore, an immune checkpoint gene expression signature was associated with objective response.

#0579 Assessing the longitudinal efficacy of anti-PD-1 therapy in a murine non-small cell lung cancer model using single-cell and spatial transcriptomics.

N. F. Leon, O. A. Davalos, D. Baliu-Rodriguez, D. K. Murugesh, A. Sebastian, N. R. Hum;
Lawrence Livermore National Laboratory, Livermore, CA

Lung cancer has a high incidence rate and is the main cause of cancer-related deaths with 127,070 fatalities expected in the U.S. this year. Non-small cell lung cancer (NSCLC) accounts for an estimated 85% of all lung cancer cases and is typically diagnosed at an advanced disease stage, where outcomes are often poor and treatment options are limited. Targeted therapies are only available to a minority of NSCLC patients with identifiable tumor-driving mutations. Anti-programmed cell death protein 1 (anti-PD-1) immunotherapy has become a first-line treatment strategy for patients without tumor-driving gene mutations. However, only 15-20% of NSCLC patients exhibit a positive response to anti-PD-1 therapy. Moreover, patients who initially respond to anti-PD-1 therapy still face the risk of primary or acquired resistance, potentially leading to cancer progression. This study leverages a murine lung cancer cell line representative of NSCLC isolated from a genetically engineered mouse model expressing $Kras^{G12D}$ and $P53^{-/flox}$ oncogenic mutations in club cells, employing a cell type-specific promoter (Scgb1a1). After successfully establishing the oncogenic cell line, the cells were subcutaneously injected into immunocompetent C57BL/6 mice and subjected to anti-PD-1 therapy for 3 weeks post-injection. Tumor growth curves revealed a significant size reduction in anti-PD-1-treated tumors when compared to the IgG isotype control group, as confirmed by a paired t-test analysis ($p < 0.045$). To evaluate the longitudinal dynamics of the tumor microenvironment, single-cell sequencing, and spatial transcriptomics were performed throughout effective anti-PD-1 treatment and following tumor relapse. Samples were collected at 2 time points during anti-PD-1 treatment, specifically at 1 and 3 weeks, as well as 3 weeks after the completion of the anti-PD-1 treatment. Subsequently, these samples underwent single-cell RNA sequencing and spatial transcriptomics using the 10x Genomics platform. Single-cell sequencing revealed modulations in immune recruitment throughout the treatment while relapsed tumors display elevated levels of myeloid gene expression and a shift to a highly fibrotic tumor phenotype post-anti-PD-1 therapy. These findings suggest that the established oncogenic cell line exhibits initial responsiveness to anti-PD-1 therapy *in vivo* before undergoing major changes within the tumor microenvironment. This study highlights the relevance and translational potential of our oncogenic cell line in advancing our understanding of NSCLC and its response to anti-PD-1 therapy. *This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. LLNL-ABS-857319.

#0580 APP as a novel immune checkpoint: Expression in T cells and its clinical implications for immuno-oncology drug refractory.

M. Cha, **B.-N. Jeon**, G. Kim, A. Jeong, S.-M. Park, K. Park, H. Park;
Genome & Company, Sungnam-si, Gyeonggi-do, Korea, Republic of

Amyloid precursor protein (APP) is a type I transmembrane protein expressed in various cell types and tissues. We previously confirmed that APP expressed in T cells is a binding partner protein of a novel immune checkpoint contactin 4 (CNTN4), and APP is a central molecule for conveying the immunosuppressive signal of CNTN4 to T cells. We further profiled an expression of APP in tumor-infiltrating T cells from tumors of NSCLC patients who received anti-PD-1 as a neoadjuvant treatment combined with chemotherapy using single-cell RNA analysis. As a result, the proportion of APP-expressing $CD4^+$ T_{eff} or $CD8^+$ T_{eff} cells was higher in stable disease (SD) patients than in partial response (PR) patients. In contrast, we observed higher PDCD1-expressing $CD4^+$ $T_{naïve}$ and $CD4^+$ T_{eff} cell proportions in PR patients than in SD patients. When we performed a Differential Expression Gene analysis between the PR and SD patients within T_{eff} cells, we observed that the PR patients' $CD8^+$ T_{eff} cells manifested a higher *IFNG* and *PDCD1,* while the SD patients' $CD8^+$ T_{eff} cells predominantly exhibited elevated APP levels. Subsequent pathway analysis also suggested a negative relationship between immune-related pathways and APP expression in $CD8^+$ T_{eff} cells. Such findings imply that the predominant presence of APP in T cells is associated with I/O refractory. From a biological view, we demonstrated increased APP expression in T cells by stimulation with an anti-CD3 antibody or antigen-presenting cell. We also identified that upon stimulation with an anti-CD3 antibody, transcription factors for T-cell activation bind to the proximal promoter of *APP* and increase its expression. Furthermore, it was confirmed that APP in T cells not only increases its expression upon anti-CD3 antibody stimulation but also translocates from the cytoplasm to the membrane through the Golgi apparatus. When anti-CD3 antibody stimulation of T cells persists, the membrane expression of APP increases for 14 to 24 h, then gradually decreases when the stimulation disappears and becomes the same as before stimulation at 48 h. T cells differentiate into various subsets and play an essential role in adaptive immunological responses to foreign substances. In particular, $CD4^+$ (helper) T cells differentiate into different T-cell subsets, such as Th1, Th2, Th17, Th19, Th22, Tfh, and Treg, to govern the overall immune response by producing cytokines that can recruit other cells of the immune system. So, we investigated whether APP is expressed on T cell subsets including naïve, effector, memory, and exhausted T-cells. We identified that APP is expressed in various $CD4^+$ and $CD8^+$ T cell subsets upon stimulation with anti-CD3 antibody. Taken together, our results suggest that APP is expressed on multiple functional T cells and that increased expression of APP on T cells in TIL may increase resistance to immunotherapy.

#0581 Identification of potential biomarkers of response to RASMULTI(ON) plus anti-PD-1 combination in preclinical PDAC models.

L. Seu, M. Menard, J. Lee, C. Chow, C. Blaj, M. Moreno Ayala, N. Shifrin, A. Salmon, S. Ganesh, P. Wig, A. Kumamoto, P. Soto-Perez, T. Taavili, V. Morton, J. W. Evans, J. A. M. Smith, E. Quintana;
Revolution Medicines, Inc., Redwood City, CA

Mutant KRAS is present in more than 80% pancreatic cancer, promotes cancer cell survival, and protects cancer cells from immune recognition and attack. We have shown that inhibitors of the active state of RAS (RAS(ON)) promote cancer neoantigen recognition and synergize with immunotherapy in preclinical immunogenic models. [1] We evaluated the impact of RMC-6236, an investigational RAS^{MULTI}(ON) inhibitor on anti-tumor activity and tumor microenvironment (TME) remodeling in two congenic $KRAS^{G12D/+}$ GEMM-derived PDAC models resistant to anti-PD-1 therapy - KPCY clone 2 (6694c2) and clone 3 (2838c3), developed by Ben Stanger at UPenn. [2] Daily oral administration of RMC-6236 drove tumor regressions in KPCY clone 3, leading to 10% durable complete responses (CRs). In combination with anti-PD-1, 40% of durable CRs were achieved. However, RMC-6236 only drove tumor growth inhibition in KPCY clone 2, and no combination benefit with anti-PD-1. We conducted preclinical biomarker analyses in the TME and periphery to explore differences in response to RMC-6236 alone and in combination with anti-PD-1 in these models. Assessment of baseline predictive biomarkers in tumors elucidated that the KPCY clone 3 cells developed tumors with lower suppressive myeloid cells (gMDSCs) and higher CD8+ T cell infiltration compared to those derived from KPCY clone 2 cells. IHC analyses showed that T cells in clone 3 were in the tumor core, while CD8+ T cells in clone 2 were at the tumor border (the latter frequently observed in PDAC patients). RMC-6236 induced transformation of the TME in favor of anti-tumor immunity in only the KPCY clone 3 - with decreased immunosuppressive gMDSCs, and increased T cells. Limited modulation of the TME was observed in the KPCY clone 2 cells-derived tumors, and gMDSC levels significantly higher than those in baseline tumors of KPCY clone 3. Peripheral immunophenotyping analyses revealed that baseline peripheral suppressive myeloid cells (mMDSCs) were significantly higher in mice harboring tumors originated from KPCY clone 2 cells, suggestive of a more systemic immunosuppressive status. Studies are ongoing to assess additional peripheral immune signatures of preclinical activity of RMC-6236 in combination with anti-PD-1. Taken together, baseline tumor levels of suppressive myeloid cells (gMDSCs) were shown to be a negative predictive biomarker for treatment outcome to RMC-6236 +/- anti-PD-1 in KRAS mutant preclinical PDAC models. Peripheral mMDSCs were shown to be higher in the mice with tumors from the PDAC model not sensitive to the combination of RMC-6236 with anti-PD-1, suggesting that it could be predictive of poor outcome for this combination. These studies in immune-competent models of RAS mutant PDAC allow us to generate tumor and blood-based biomarkers that may predict outcomes to RAS(ON) inhibitor combinations in the clinic. 1 Menard et al. AACR 2023 2 Li et al. Immunity 2018

#0582 Oncogenic *PIK3CA* fortifies immune determinants in vascular cancers.

D. Lee[1], E. Kozurek[2], M. Abdullah[1], R. Li[1], E. B. Dickerson[2], **J. Kim**[1];
[1]University of Florida, Gainesville, FL, [2]University of Minnesota, St Paul, MN

Angiosarcomas are a group of vascular cancers that form malignant blood vessels. These malignancies are seemingly inflamed primarily due to their pathognomonic nature, which consists of irregular endothelium and tortuous blood channels. The malignant vascular spaces host a variety of blood and immune components, where a controlled scavenging system is necessary for tumor maintenance. Oncogenes may convey molecular signals to foster the tumor immune niche, and *PIK3CA* mutations that induce continuous activation of the PI3K pathway occur in a subset of angiosarcomas. Despite the undoubtedly oncogenic properties of *PIK3CA* mutations, the mechanistic role of these mutations - particularly the potential for controlling the hemato-endothelial system in angiosarcomas - remains undetermined. In this study, we demonstrate the functional consequences of oncogenic *PIK3CA* and its molecular properties in angiosarcoma cells. We created isogenic cell clones from two angiosarcoma cell lines engineered to harbor hotspot mutations in *PIK3CA* using CRISPR/Cas9: two homozygous *PIK3CA* H1047R cell clones (C8 and C35) and one wild-type (WT) clone were generated from DHSA-1426 angiosarcoma cells; and one homozygous mutant clone was created from COSB cells. We found that *PIK3CA* mutant cells constitutively activated the PI3K/AKT/mTOR pathway at a greater level than that of WT cells. Bulk- and single cell(sc)-RNA-seq data revealed that mutant cells enriched gene sets associated with PI3K signaling and other oncogenic pathways including KRAS, MAPK, and TGF-beta. Also, mutant cells significantly increased cytokines regulating immune cell migration and chemotaxis such as IL-8 and MCP-1. In addition to the common features, we identified functional and molecular divergence between mutant clones. Noticeable changes in cellular morphology, growth kinetics, and tube-forming capacity were observed between two mutant clones. C35 mutant cells were more sensitive to both pan-PI3K and PI3K-alpha specific inhibitor, and DNA damage was greater than in the C8 clone. C35 cells enhanced activation of IL-6/STAT3 signaling compared to C8, despite the increment of the aforementioned immune cytokines in both mutants. Moreover, our comprehensive analysis of bulk- and sc-RNA-seq, ATAC-seq, and metabolomics data identified molecular signatures associated with metabolic vulnerabilities of C35 cells. In summary, we demonstrate that oncogenic *PIK3CA* perpetuates PI3K signaling activation and reinforces a supply for immune signaling. Furthermore, our data suggest that *PIK3CA* mutations contribute to establishing cellular heterogeneity that reveals a spectrum of vascular, immunogenic, and metabolic activities. Our ongoing work involves developing an experimental model of angiosarcoma using induced pluripotent stem cells to examine if oncogenic *PIK3CA* controls immune determinants during malignant endothelial transformation.

#0583 Spatiotemporal analyses of longitudinal specimens reveal mechanisms of response and resistance to immune checkpoint blockade in metastatic melanoma.

G. Zhang[1], L. Coussens[2], M. Herlyn[3], K. T. Flaherty[4], G. Boland[4], G. Mills[2];
[1]The University of Hong Kong, Hong Kong, China, [2]Knight Cancer Institute, Portland, OR, [3]The Wistar Institute, Philadelphia, PA, [4]Massachusetts General Hospital, Boston, MA

Although durable responses to immune checkpoint blockade (ICB) therapies exhibit by a subgroup of patients with metastatic melanoma, most of patients have no response or develop to acquired resistance to ICB therapies within few years. Molecular mechanisms of primary and acquired resistance to ICB therapies are still elusive, which warrants further elucidation. Here, we used a holistic approach to profile 35 longitudinal tumor specimens at pre-, on-, and post-treatment time points which were derived from 7 patients (3 responders and 4 non-responders) with metastatic melanoma who progressed on sequential ICB therapies, including anti-PD-1 and anti-CTLA-4 therapies. We integrated analyses of RNA sequencing, Whole-exome Sequencing (WES), NanoString nCounter vantage 3D, Cyclic Immunofluorescence (Cyc-IF), NanoString Digital Spatial Profiling (DSP) and Multiplex Immunohistochemistry (mIHC) data of these longitudinal tumor specimens to elucidate evolutionary trajectories that occurred in both the tumor and the tumor immune microenvironment (TiME) that may have orchestrated response and resistance to ICB therapies. Simultaneous analyses of genomic, transcriptomic and proteomic data identified the re-activation of MAPK-RAS as well as PI3K pathway upon or after ICB therapies, which may elucidate the mechanism of resistance to ICB therapies. Spatially-resolved, image-based immune monitoring analysis at single cell resolution revealed that the activation status of T cell markers and T-cell checkpoint is conversely associated with potential mechanism of resistance to ICB therapies. In summary, integrated analyses of muti-oics and spatially image-based data from longitudinal tumor specimens allow us not only to reveal the dynamic co-revolution of both tumor and immune cells in TiME following sequential ICB therapies but also to provide a comprehensive perspective to molecular mechanisms of response and resistance to ICB therapies in patients with metastatic melanoma.

#0584 Synergistic action of ATF6 and EZH2 in sensing metabolic stress to boost anti-tumor immunity.

J. L. Edmondson, M. R. Reed, D. Fil, B. Heflin, B. Koss, A. J. Tackett;
University of Arkansas for Medical Sciences, Little Rock, AR

Although immune checkpoint blockade (ICB) marked a breakthrough in melanoma treatment, half of patients fail to respond, underscoring the crucial need for complementary adjuvant and neo-adjuvant therapies. Due to the low overall response rate and the stark contrast in outcomes between patients that respond and those that fail to respond, identifying the defining characteristics of immune checkpoint blockade (ICB) response is essential for enhancing the efficacy of melanoma treatments. To recapitulate and investigate the ICB-responsive phenotype *in vitro,* melanoma cells were metabolically adapted to an environment lacking glucose which successfully drove the dependence on oxidative metabolism and restored MHC-I expression, two established characteristics of ICB responsive tumors. Further, metabolic adaptations significantly enhance the tumor sensitivity to T-cell killing. Surprisingly even in JAK1 and IFNAR1 deficient cells, metabolic adaptation restored MHC I antigen presentation, indicating an interferon-independent mechanism of MHC-I regulation. Proteomic analysis of three metabolically conditioned melanoma cells lines (human and mouse) identified downregulation of the histone methyltransferase EZH2 and the activating transcription factor ATF6 as key corollaries of MHC-I expression. Interestingly, EZH2 and ATF6 activity were found to be inversely related in metabolically adapted cells and patient tumor samples. These studies mechanistically explore the epigenomic control of antigen presentation machinery and the transcriptional targets of ATF6 controlling sensitivity T cell killing. Here, through *in vitro* and *in vivo* studies, we demonstrate that constitutive activation of ATF6, and thereby activation of the adaptive unfolded protein response (UPR), sensitizes melanoma to immune control. These data suggest that EZH2 and ATF6 act synergistically to balance immune mediated killing during metabolic stress whereby loss of EZH2 increases MHC-I antigen presentation and activation of ATF6 sensitizes tumor cells to T cell-mediated control. Ongoing therapeutic studies combining EZH2 inhibition, ATF6 activation, and ICB in pre-clinical models further suggest targeting the synergy between EZH2 and ATF6 is a putative adjuvant or neo-adjuvant target to improve the clinical response of ICB.

#0585 Regorafenib antitumor immune response is enhanced by a novel drug combination in CRC syngeneic model.

P. Bajpai[1], F. Afaq[1], S. Al Diffalha[1], S. Agarwal[1], H. G. Kim[1], D. Otali[1], S. Varambally[1], A. Manne[2], R. Paluri[3], M. Khushman[4], U. Manne[5];
[1]Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, [2]Department of Internal Medicine, Division of Medical Oncology, the Ohio State University Comprehensive Cancer Center, Columbus, OH, [3]Department of Hematology and Oncology, Wake Forest School of Medicine, Winston-Salem, NC, [4]Department of Medicine, Division of Oncology, Washington University in St. Louis/Siteman Cancer Center, St. Louis, MO, [5]Department of Pathology, O'Neal Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, AL

Purpose: In the United States, colorectal cancer (CRC) is the second leading cause of cancer mortality. Metastatic CRC (mCRC) refractory to traditional chemotherapy is managed with regorafenib, a multiple-kinase inhibitor. However, patients show only a modest improvement in overall survival but experience high drug toxicity, adverse side effects, and poor tolerability. Thus, to reduce regorafenib-induced toxicity and to enhance antitumor activity, we combined it with a hybrid/dual JAK/HDAC small-molecule inhibitor (JAK/HDACi) to leverage the advantages of both JAK and HDAC inhibition in a single agent. With syngeneic mice, the efficacy and impact on immunomodulation of this drug combination was assessed.
Methods: To assess effects of the agents, C57BL/6 immunocompetent mice were injected with MC38 murine CRC cells and treated with regorafenib (6mg/kg body wt) or JAK/HDACi (30mg/kg body wt), and their combination every third day for 21 days. Upon completion of the experiment, the tumors were harvested and processed for RNA and protein expression profiles. The effect of drug treatment on immune response was analyzed by nCounter Gene Expression assays (NanoString Technologies). Cytokines were measured in serum using the MesoScale Discovery mouse V-Plex Proinflammatory Panel kit. For pharmacokinetic studies, plasma samples were assayed from C57BL/6 treated with drugs after 1, 7, 21, and 48 hrs of treatment.
Results: The combination treatment significantly reduced tumor growth (volume and weight),relative to the vehicle control or single treatments. Gene expression showed higher CD45 abundance score in the combination treatment. This is an exciting observation, as CD45 has phosphatase activity and dephosphorylates key targets of the drugs used in the study. Additionally, after treatment with the combination, there was higher expression of Gzmb and Gzme and lower expression of Cx3cr1, indicating enhanced immuno modulation relative to regorafenib alone. We confirmed these findings by immunoprofiling of tumors. Higher CD45 staining, noted in tumors of mice treated with the combination, corroborated the gene expression results. Pronounced CD8 T lymphocytes infiltration was observed in combination, compared to regorafenib alone. Reduction of proinflammatory cytokine, TNF-α was noted in the combination group. This is an interesting observation as CD45 negatively regulates TNF, and combination treated mice had highest number of CD45 positive cells. Pharmacokinetic studies showed that the bioavailability of regorafenib was elevated after combination treatment relative to single-agent treatment.
Conclusions: Relative to the single agents, the combination of regorafenib with JAK/HDACi was more effective, with an elevated antitumor immune response and with sustained inhibition of tumor growth. A clinical trial to evaluate this combination for the treatment of mCRCs is warranted.

#0586 Tumor cell-intrinsic PD-1 activation drives therapeutic resistance in colorectal cancer cells.

H. Mok[1], D. Yapp[2], I. Tai[1];
[1]University of British Columbia, Vancouver, BC, Canada, [2]Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada

Background/Aim: Despite advancements in diagnosis and treatment, advanced CRC remains a formidable treatment challenge with limited therapeutic options because these tumors are resistant to chemo-, radio- and targeted-therapies. Emerging research shows that the presence of tumor cell-intrinsic PD-1 (ciPD-1) in various tumor types is involved in tumorigenicity and therapy-refractory disease. For example, ciPD-1 promotes tumor growth in melanoma and liver cancer, but in lung cancer, ciPD-1 exhibits tumor-suppressive behavior. These findings highlight the intriguing possibility that ciPD-1 may exert context specific functions within the tumor, beyond its well-known role in immune response suppression. Consequently, the present study addressed the pressing need to explore the effects of immune checkpoint inhibitors within broader tumor context and tumor microenvironment. We have established drug-resistant CRC cells and found that ciPD-1 was upregulated in these cells. This, together with an observation that ciPD-1-mediated survival signaling pathways was activated in CRC patient populations, prompted us to investigate the role of ciPD-1 in regulation of therapeutic resistance in CRC in the absence of immune cells.
Methods: We evaluated the clinicopathological relevance of ciPD-1 and its correlation with disease progression in CRC samples from clinical cohorts. Monoclonal antibody inhibition and siRNA interference methods were used to characterize the functional roles of ciPD-1 in regulating therapeutic resistance in CRC. The gene expression profiles of PD-1-High and PD-1-Low patient groups retrieved from clinical cohorts were compared to identify ciPD-1-medatied survival pathways in CRC patients.
Results: We found that ciPD-1 had a critical role in regulating CRC tumorigenicity and survival outcomes. Tumors with high expression levels of ciPD-1 also showed higher mutation rate and levels of microsatellite instability. Exposing CRC cells to chemotherapy, radiation, and nutrient deprivation increased ciPD-1 levels. In line with these observations, drug-resistant CRC cells also expressed higher levels of ciPD-1. The inhibition of ciPD-1 in CRC cells by monoclonal antibody or siRNA interference decreased cell proliferation and self-renewal rates, while enhancing treatment efficacy.
Conclusion: Our studies reveal that CRC cells increase ciPD-1 expressions in response to drug treatment and targeting ciPD-1-mediated survival pathways can delay the onset of drug resistance and promote therapeutic sensitiveness in CRC cells.

#0587 Tumor treating fields induce the integrated stress response, alter the transcriptional signatures of cellular metabolism, and modulate immune-related cytokines dependent and independent of p53.

P. R. Srinivasan[1], A. George[1], C. Chou[2], M. Pinho-Schwermann[1], M. Ghandali[1], V. Tajiknia[1], Y. Porat[3], M. Giladi[3], A. Armstead[3], A. Uzun[1], E. T. Wong[4], W. S. El-Deiry[1];

[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]Rhode Island Hospital, Providence, RI, [3]Novocure, Haifa, Israel, [4]Lifespan Cancer Institute, Providence, RI

Tumor treating fields (TTFields) are an FDA-approved therapy for the treatment of glioblastoma and pleural mesothelioma. TTFields employ alternating electric fields delivered by cutaneous transducer arrays to induce cytostatic and cytotoxic effects on solid tumors. Additionally, recent studies suggest that TTFields may enhance anti-tumor immunity. We performed RNA-seq and multiplexed cytokine profiling in HCT116 wild-type and HCT116 p53-/- human colorectal cancer cells to elucidate TTFields' effects on the transcriptome and secretome. TTFields lead to profound changes in the transcriptome related to metabolism, including downregulation of transcripts coding for multiple enzymes involved in the Krebs cycle, fatty acid synthesis, and glycolysis. Furthermore, though only HCT116 p53-wild type cells strongly induced the p53 pathway, both cell types' transcriptomes showed strong downregulation of cell cycle progression. Our cytokine data showed that key tumor-promoting cytokine IL-8 was downregulated independently of p53. We identified upregulation of immunomodulatory cytokines MIF and MICB independently of p53. While MICB promotes NK cell activation, MIF drives tumor progression. Therefore, MICB may be one way in which TTFields enhance anti-tumor immunity; targeting MIF during TTFields treatment may lead to synergy by abolishing its pro-tumor effects. We also identified a p53-dependent decrease in the TRAIL decoy receptor DcR3, which normally protects tumor cells from TRAIL-induced apoptosis. Further mechanistic work showed that TTFields induce EIF2-alpha phosphorylation, the central protein involved in activating the integrated stress response (ISR), across multiple cancer types, leading to suppression of global protein translation. TTFields treatment also resulted in increased expression of surface calreticulin, an endoplasmic reticulum stress marker, which activates the ISR. Future mechanistic work will explore the impact of identified cytokines and the ISR on anti-tumor immunity both *in vitro* and *in vivo*, as well as metabolic alterations induced by TTFields. This work identifies potential biomarkers and rationales for therapeutic combinations exploiting TTFields-induced molecular alterations.

#0588 Preclinical evaluation of novel chimeric vesiculovirus mediated expression of proteolytic enzymes targeting two major stromal components of pancreatic ductal adenocarcinoma.

Khandoker Usran Ferdous, Mulu Z. Tesfay, Camila C. Simoes, Aleksandra Cios, Bolni Marius Nagalo

Department of Pathology, University of Arkansas for Medical Sciences, Little Rock, AR

The vesiculovirus genus has recently garnered interest as an oncolytic virotherapy for pancreatic ductal adenocarcinoma (PDAC). A new synthetic chimeric vesiculovirus, VMG, demonstrated efficacy and safety against PDAC both *in vitro* and *in vivo*. The therapeutic effectiveness of virotherapies against PDAC is often hindered by immunosuppressive factors in the tumor environment, as well as the presence of hyaluronic acid (HA) and collagen (CN), which increase tumor stiffness and interstitial fluid pressure, leading to reduced drug/oncolytic virus and immune cell penetration into tumor. To address this, we engineered VMG viruses incorporating enzymes PH20, collagenase (CNase), and novel proteolytic enzyme SMC, the latter exhibits both PH20 and CNase-like activity. We characterized these modified viruses for their cytotoxicity and performance *in vitro*. Various PDAC cell lines displayed varied sensitivity to VMG vectors, yet they showed consistent oncolytic effects relative to the parent VMG-GFP virus. Our results revealed no compromise in viral replication or apoptosis-inducing ability after transgene insertion, which is evident as infectious viral progenies were produced to approximately similar level of magnitude of around 10^8 $TCID_{50}$/ml in all the cell line tested. Additionally, the VMG-SMC and VMG-hPH20-CNase variants demonstrated notable enzyme activity. To enhance clinical relevance, we utilized an *ex vivo* live tumor platform, which indicated around 20% tumor cell death using VMG vectors compared to that of the control, signifying tumor viability and virus replicability 72 hours post-infection. Fluorescent imagery highlighted the viruses' ability to spread and express functional enzymes within tumors. In summary, VMG vectors expressing stroma-degrading proteolytic enzymes can effectively express PH20, CNase and SMC enzymes that degrade stromal barrier of HA and CN without interrupting the replicability, performance, and oncolytic characteristics of the VMG vectors. Future research should prioritize the safety of these vectors and their potential to augment neoantigen expression and immune cell infiltration *in vivo*, which are the hallmarks of antitumor efficacy.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Kinase and Phosphatase Inhibitors 1
Poster Session

#0591 Discovery of ZM-2322, a highly selective, potent inhibitor of membrane-associated tyrosine- and threonine-specific cdc2-inhibitory kinase (PKMYT1).

F. Zhou[1], L. Liu[2], L. Jiang[2], B. Cheng[2], Z. Li[1], D. Zhu[2], J. Xue[2], L. Xue[1], R. Tang[1];
[1]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China, [2]Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

The genome DNA is consistently threatened by a variety of intrinsic and exogenous DNA damage factors. Cell cycle checkpoint is one important mechanism in response to DNA damage and maintaining genome stability. In tumor cells, gene alterations, such as *CCNE1* amplification (encoding for Cyclin E1), result in G1/S checkpoint loss and replication stress, leading to high dependency on the G2/M checkpoint. PKMYT1 inhibits crucial checkpoint protein CDK1 activity by phosphorylating CDK1 at the residues of Thr-14 and Tyr-15 in the G2/M phase. In *CCNE1* amplification cells, the inhibition of PKMYT1 leads to the reduction of pCDK1 and loss of G2/M checkpoint, consequently results in premature mitosis and the accumulation of DNA damage, then finally induces cell death. Here we identify a novel small molecular ZM-2322, which displays robust intracellular binding to PKMYT1 and inhibits the specific downstream phosphorylation of CDK1 Thr-14 with IC_{50} values of 14 nM and 29 nM, respectively. ZM-2322 strongly inhibits the proliferation of the HCC1569 cell line with *CCNE1* high-level amplification and shows a >400× selectivity folds over a *CCNE1* wildtype cell line SKOV3. ZM-2322 also shows significant inhibition of tumor growth in a dose-dependent manner in the HCC1569 xenograft model, and the efficacy correlates well with PK and target inhibition. There is evidence showing that loss-of-function mutations of FBXW7, a cyclin E E3 ligase, lead to cyclin E accumulation and are synthetic-lethal with PKMYT1 inhibition. Consistently, a potent anti-proliferation of ZM-2322 is observed in DLD-1 FBXW7 -/- cells, but not DLD-1 parental cells. These data suggest a high potency of ZM-2322 on PKMYT1 inhibition and a potential good kinase selectivity which is further confirmed by using a kinase panel biochemical assay. As expected, when compared head-to-head with another clinical PKMYT1 inhibitor RP-6306 which shows inhibitory effect on 27 of 217 human kinases with inhibition rates >90% at 1 μM, ZM-2322 is found to be a much more PKMYT1-selective inhibitor and hits only several individual kinases under the same assay condition, suggesting a potentiality in better safety profile and higher dose tolerance. Furthermore, our data illustrates that in combination with gemcitabine, ZM-2322 elicits strong synergetic anti-proliferation activities on HCC1569 cells *in vitro* and results in tumor regression with a minor effect on body weight *in vivo*. Besides, a strong synergy effect is also observed in the combo of ZM-2322 and ATR inhibitor in HCC1569 *in vitro*. These data indicate that ZM-2322 has the potential of application expansion and good tolerance under continuous administration. Taken together, our data suggest that ZM-2322 is a potent and highly selective PKMYT1 inhibitor.

#0592 A novel pMEK inhibitor ABM-4095 for the treatment of pancreatic cancer.

M. Xu, Y. Hu, L. Zhao, X. Chen, Y. Chen, C. Yang, J. Li, C. Chen, X. Lv;
ABM Therapeutics, San Diego, CA

The MEK-ERK pathway is often activated in tumors by mutations of upstream BRAF- or RAS-proteins. The RAS is frequently mutated in several cancers, especially in pancreatic cancer with an about 95% rate. Pancreatic cancer has the highest mortality rate with a 5-year survival rate of 8% and a median survival of 6 months. Targeted therapies have been extensively evaluated in pancreatic cancer, however, survival improvement of this aggressive disease using a targeted strategy has been minimal. The only currently approved targeted therapy is erlotinib in combination with the chemotherapy drug gemcitabine. To date, four MEK inhibitors that block RAF-activation have been approved by the FDA, but their ability to inhibit ERK signal activated by RAS-mutations is limited due to the induction of MEK phosphorylation by relief of ERK-dependent feedback inhibition of RAF. Here, we report a novel small molecule, ATP-uncompetitive, pMEK inhibitor ABM-4095 that potently prevents phosphorylation of MEK by RAF with moderate inhibition of MEK kinase activity. Most of MEK inhibitors approved by FDA or in clinical trials increase pMEK levels instead. ABM-4095 has a good cell permeability. Its anti-cancer efficacy has been demonstrated both in the in vitro cancer cell line proliferation assay and in vivo xenograft models. ABM-4095 showed a synergy effect with erlotinib in pancreatic cancer cells. In a Miapaca-2 xenograft model, ABM-4095 showed good dose-dependent tumor inhibition as a single agent or combining with the KRAS G12C inhibitor AMG-510, and tumor regressions were observed. In summary, ABM-4095 is a potent pMEK inhibitor with a high activity against the RAS-mutant pancreatic cancer in vitro and in vivo. Detailed preclinical results will be presented.

#0593 DCC-3084, a brain penetrant RAF dimer inhibitor, broadly inhibits BRAF class I, II, and III alterations leading to growth inhibition of intracranially implanted tumors in preclinical models.

G. Al-Ani, S. L. Bulfer, J. D. Zwicker, C. K. Crawley, K. M. Elliot, S. Javed, Q. Groer, M. M. Hood, J. W. Large, K. Luther, Y. K. Romero, F. A. Stanley, D. C. Tanner, H. Telikepalli, B. Le Bourdonnec, B. D. Smith, D. L. Flynn;
Deciphera Pharmaceuticals, LLC, Lawrence, KS

Background: Mutations in the RAS/MAPK pathway are a frequent driver of cancer, with oncogenic RAS or RAF mutations occurring in >30% of all cancers. First generation BRAF inhibitors are approved for use for tumors with Class I BRAF mutations (V600X). However, these drugs are not efficacious in RAF dimer mutant and RAS mutant cancers due to paradoxical activation of RAF dimers. Herein, we describe DCC-3084, a brain penetrant, potent and selective investigational switch-control inhibitor of BRAF and CRAF kinases, shown preclinically to target all relevant aberrant signaling mechanisms (monomers, heterodimers and homodimers) and inhibits growth of subcutaneously and intracranially implanted tumors in preclinical models.
Methods: Inhibition of RAF kinases was measured using recombinant enzymes. Cellular proliferation was measured using resazurin to monitor cell viability. Inhibition of ERK or RSK phosphorylation was measured by AlphaLISA or ELISA. Pharmacokinetics (PK) in the plasma, brain and CSF compartments were measured following oral dosing in Wistar rats. Subcutaneous or intracranial BRAF mutant mouse xenograft models were used to assess PK, pharmacodynamics (PD), and efficacy.
Results: DCC-3084 treatment resulted in potent single-agent inhibition of MAPK pathway signaling, and cellular proliferation in a wide range of Class I, II, III BRAF and BRAF fusion altered cell lines. DCC-3084 was demonstrated to be CNS penetrable and exhibited dose dependent oral exposure with robust inhibition of the MAPK pathway in PK/PD models. Oral treatment of DCC-3084 as a single agent resulted in tumor regression in subcutaneously implanted BRAF Class I and BRAF fusion xenograft models. Additionally, DCC-3084 resulted in tumor regression or growth inhibition in intracranially implanted BRAF Class I and BRAF fusion tumor models.
Conclusions: The switch-control inhibitor DCC-3084 broadly inhibits Class I, II and III BRAF mutations, BRAF fusions, and BRAF/CRAF heterodimers leading to tumor regression in preclinical models. DCC-3084 CNS penetration enables potential for further research in brain metastases or primary brain cancer.

#0594 ORIC-613, a potential first- and best-in-class, orally bioavailable, potent and selective PLK4 inhibitor with synthetic lethality in TRIM37 high cancer models.

K. A. Edgar, S. McRee, G. Andretta, C. Chen, C. Colas, W. Fang, W. Kong, J. Long, F. Liu, J. Moore, A. Pankov, D. Shore, J. Tan, R. Warne, L. Ulicna, R. Vekariya, A. Daemen, F. A. Romero, M. R. Junttila, L. S. Friedman;
ORIC Pharmaceuticals, South San Francisco, CA

A synthetic lethal interaction between polo-like kinase 4 (PLK4) and elevated TRIM37 was discovered in breast cancer and neuroblastoma (Meitinger et al. 2020; Yeow et al. 2020). High TRIM37 renders cells dependent on PLK4, a kinase that controls centriole duplication. Amplification and copy number gains of the 17q23 amplicon, where TRIM37 resides, are common in breast cancer and neuroblastoma and associated with early relapse and poor prognosis, making PLK4 a promising new synthetic lethal target for these patients. The development candidate ORIC-613 is an orally bioavailable, potent and exquisitely selective small molecule inhibitor of PLK4, which is synthetic lethal in TRIM37 high cells. ORIC-613 is highly selective against the kinome, including against the closely related aurora and PLK families. ORIC-613 ADME/PK profile includes high cell permeability and low potential for drug-drug interactions based on CYP profiling. ORIC-613 blocked PLK4 trans-autophosphorylation of phosphodegrons, leading to stabilization of PLK4, thus directly demonstrating target engagement in cells. PLK4 protein stabilization correlated with cell viability for ORIC-613, providing a quantifiable pharmacodynamic (PD) association with antitumor activity. Cell viability assessment in cancer cell lines revealed that ORIC-613 showed greater potency in TRIM37 high versus TRIM37 low cell lines. Importantly, ORIC-613 induced significantly greater apoptosis in TRIM37 high versus low cancer cell lines as measured by caspase 3/7 assay. We confirmed that ORIC-613 activity is on-target using an engineered cell line system of PLK4 G95L, in which the leucine mutation maintains enzymatic function but blocks compound binding. In cell viability assays, ORIC-613 was potent in the parental cells and lost activity in G95L cells. Analysis of genomic data from tumors indicates that TRIM37 copy number amplification and gain is prevalent across numerous cancers. Oral dosing of ORIC-613 resulted in tumor growth inhibition and regressions in TRIM37 high xenograft breast tumors with no body weight loss. In summary, ORIC-613 is a potential first- and best-in-class development candidate, with exquisite selectivity for PLK4, which demonstrates synthetic lethality in TRIM37 high tumors and has the potential to benefit these patients.

#0595 Preclinical development of the CDK4 selective inhibitor PF-07220060: Increased CDK4 versus CDK6 inhibition leads to improved anti-tumor efficacy at therapeutic concentrations.

L. Anders, B. Pascual, B. Boras, J. Cianfrogna, S. Garza, N. Li, J. Yuan, M. Moen, N. Huser, G. Gallego, M. Jalaie, S. Ninkovic, S. Cho-Schultz, H. Shen, J. Kath, K. Dress, W. Diehl, S. Nair, R. Jones, J. Lafontaine, A. Murtaza, A. Sacaan, S. Chintharlapalli, T. VanArsdale;
Pfizer Oncology, San Diego, CA

PF-07220060 is a selective inhibitor of CDK4, displaying ~20-fold and ~4-fold increased selectivity for CDK4 versus CDK6 when compared to palbociclib and abemaciclib/ribociclib, respectively. This translates to less PF-07220060 associated neutropenia in beagle dogs and humans when compared to dual CDK4/6 inhibitors. Because neutropenia is the primary culprit necessitating limited and often interrupted clinical dosing of dual CDK4/6 inhibitors, the advantage of PF-07220060 lies in the flexibility to escalate the drug's exposure in patients and thus realize near-complete target coverage of the CDK4 oncogene in tumors that are dependent on this kinase. Here we select tumor types/indications that show dependency on CDK4 but not CDK6 and includes cells derived from luminal breast cancer and androgen-receptor positive metastatic prostate cancer. Additionally, we investigate certain drugs with which PF-07220060 may be combined to maximize its efficacy in these tumor indications. PF-07220060 sensitizes HR+ HER2- breast cancer to the estrogen inhibitor, fulvestrant and the degrader, ARV-471 (vepdegestrant). PF-07220060 + vepdegestrant showed significantly longer tumor regrowth delay vs monotherapy groups and vs Palbo + vepdegestrant and vs PF-07220060 + fulvestrant*. Similarly, PF-07220060 sensitizes prostate cancer to the androgen receptor antagonist, enzalutamide. In HR+ HER2- breast cancer cells, the senescent cell fraction was markedly increased by co-treatment with PF-07220060 and fulvestrant versus either drug alone, albeit the combination did not trigger tumor cell death. Further addition of the PI3K inhibitor alpelisib was sufficient to enforce tumor shrinkage in vivo. Alternatively, inhibition of CDK4 plus CDK2 also led to tumor shrinkage in xenograft models of HR+, HER2- breast cancer. Finally, our preclinical data indicate that the propensity of CDK6 to compensate for CDK4 inhibition in these tumor types is limited. Compensation by CDK6 was seen in only a fraction of the evaluated in vitro and in vivo models. Even so, in these instances, PF-07220060's efficacy remained comparable to palbociclib's when both drugs were used at their therapeutic doses. We conclude that PF-07220060's anti-tumor efficacy is broadly superior to currently approved dual CDK4/6 inhibitors.

#0597 Vebreltinib: A novel brain-penetrating MET kinase inhibitor demonstrates the mechanism of action and pharmacological anti-tumor activity in diverse patient-derived MET-dysregulated tumor models at clinically relevant drug levels.

X. Zhang[1], E. Liu[2], Y. Song[1], P. Yu[1], S. Redkar[1], G.-L. Yu[1];
[1]Apollomics, Inc., Foster City, CA, [2]Zhejiang Apollomics Biotech Co., Ltd., Hangzhou, China

Background: Dysregulation of the MET signaling pathway drives oncogenesis in many human cancers, the majority of which have not been addressed by a MET targeted therapy albeit the emerging therapies for *MET* exon 14 skipping (*MET* ex14) NSCLC. We have developed a novel highly selective MET kinase inhibitor vebreltinib (APL-101, PLB1001, bozitinib) to address unmet medical need. Vebreltinib is being jointly investigated in ongoing pivotal Phase 2 and 2/3 studies in *MET*-dysregulated NSCLC, primary CNS cancers and basket solid tumors in China (as PLB-1001) and globally ex-China (as APL-101). The Phase 1 portion of both studies have been concluded with the same RP2D (200 mg BID by oral administration). Vebreltinib demonstrated blood-brain barrier permeability in PLB-1001 Phase 1 glioblastoma study as previously reported.
Methods: MET enzyme kinetics and vebreltinib intrinsic potency were studied by a radiometric MET kinase assay. Selectivity was profiled by *in vitro* KINOME. Vebreltinib cellular activity on MET signaling and *in vivo* anti-tumor activity were assessed in tumor cell lines and patient-derived tumors (PDX) carrying *MET* alterations.
Results: Vebreltinib is an ATP-competitive inhibitor with Ki of approximately 2.2 nM for recombinant MET kinase and inhibited the native form of activated MET with 0.52 nM IC50. Vebreltinib demonstrated exquisite selectivity in KINOMEscan selectivity panel. Vebreltinib inhibited HGF-dependent and -independent MET signaling in KP4 tumor cell lines with nanomolar concentrations. Vebreltinib inhibited IL-3 independent Ba/F3 cell lines carrying exogenous *MET* ex14 or with secondary mutations induced by other MET TKIs. Vebreltinib inhibited MKN45 gastric tumor xenograft *in vivo* with ED90 of 6 mg/kg PO/QD. Furthermore, Vebreltinib demonstrated strong anti-tumor activity in a variety of PDX tumor types carrying *MET* ex14, *MET* fusions, and *MET* amplification. In these preclinical studies, the total and unbound vebreltinib plasma concentration observed at steady state trough of RP2D was used as a clinically relevant drug level to interpret Vebreltinib efficacy in blocking oncogenic MET signaling, proliferation of Ba/F3 cell lines with a broad spectrum of *MET* mutations and *in vivo* tumor growth in PDXs carrying diverse *MET* alterations. We demonstrated the rationale for Vebreltinib to be an efficacious single-agent MET inhibitor in treating tumors carrying *MET* driver alterations beyond *MET* ex14 NSCLC.
Conclusion: Vebreltinib is a novel potent MET kinase inhibitor showing promising preclinical activity against PDXs from diverse organs sites and genomic alterations such as *MET* ex14, *MET* fusion, *MET* amplification, or *HGF* over-expression at clinically relevant drug levels, providing proof-of-concepts for continued clinical development.

#0598 HSK42360: A potent, brain permeable, BRAF paradox breaker for the treatment of BRAF-driven cancers.

S. Gao[1], Y. Li[2], **J. Wang**[2], P. Tang[1], Z. Shi[1], Y. Li[1], P. Yan[1];
[1]Haisco Pharmaceutical Group Co., Ltd., Chengdu, China, [2]Haisco Pharmaceutical Group Co., Ltd., Shanghai, China

Mutations in the BRAF gene are among the most common identified in human cancers approximately 7% of all cancers evaluated, including 70% of melanomas, 50% of thyroid-like cancers, 10% to 20% of colorectal cancers, 13% of serous ovarian cancers, 3-7% of non-small-cell lung cancers, and most recently, hairy cell leukemia. Approved BRAF inhibitors (or +MEKi) against BRAFV600E/K improved initial clinical efficacy. However intrinsic and acquired resistance often arise through BRAF paradoxical activation, limiting durable responses to current BRAF inhibitors. In addition, Approved BRAFi responds poorly to patients with BRAF mutant gliomas or brain metastases, mainly due to limited brain permeability. More effective therapeutic options are therefore needed. To address this clinical challenge, we developed a potent, brain-penetrating paradox breaker HSK42360, as a promising therapy for patients with BRAFV600E mutation, progression or brain metastases following treatment with approved BRAFi or BRAFi/MEKi therapies. HSK42360 is a potent BRAFV600E inhibitor with IC_{50} value of 5 nM at enzymatic level. Further characterization showed that HSK42360 did not induce homodimer or heterodimer of CRAF with CRAF or BRAF and thereby blocked reactivation of the MAPK pathway in HCT116 cells, whereas Dabrafenib significantly induced RAF dimerization and MAPK reactivation. HSK42360 exhibited significant anti-proliferation activity against multiple tumor cell lines with BRAFV600E, including A375 (melanoma), DU4475 (breast cancer), and COLO205 (colon cancer), but was highly selective for BRAF wild-type cells. HSK42360 was administered orally once daily and showed broad-spectrum antitumor activity in the COLO205 and A375 CDX models. Immunohistochemistry showed a close correlation between the inhibition of tumor growth and ERK1/2 phosphorylation in A375 CDX tumor tissues. To explored the impact of HSK42360 in a brain micro-metastasis model aimed at mimicking early CNS metastatic spread, tumor progression was monitored through BLI (full name) imaging, which revealed that HSK42360 was highly brain penetrant with Kp,uu greater than 1 and triggered potent antitumor activity and prolonged survival in brain metastatic models of melanoma. We next tested the hypothesis that HSK42360 could retain activity in models presenting RAF dimer-driven resistance. Surprisingly, HSK42360 demonstrated promising antitumor effects in the first gen-resistant NRASmA375($NRAS_{Q61K}$, $BRAF_{V600E}$) CDX model, supporting its use as a follow-on therapy for current BRAFi resistance. Collectively, these preclinical studies validated that HSK42360 is a novel brain-permeable BRAF paradox breaker that exhibits outstanding antitumor activity in brain metastasis and RAF dimer-driven resistance.

#0599 Combination of CDK4/6 inhibitors with biguanides for treatment of triple negative breast cancer.

M. Morales Martinez, E. Mauricio Gonzalez, G. Deng, G. Ma, H. Kim, L. Stiles, N. Hamilton, M. E. Jung, R. J. Pietras, D. C. Marquez-Garban;
UCLA David Geffen School of Medicine, Los Angeles, CA

Triple negative breast cancer (TNBC) is the most aggressive subtype of breast cancer (BC) and is associated with early relapse and high frequency of metastasis. This has been attributed in part to the lack of targeted therapies. TNBC occurs more frequently in younger women of African and Hispanic ancestry and with a higher risk of mortality than women of European ancestry. Emerging data shows activation of the AKT/mTOR pathway by insulin may occur in aggressive TNBC and inhibition of mTOR signaling by rapamycin, a potent mTOR inhibitor, induces cell cycle arrest and downregulation of cyclin D1 in TNBC cells. CDK4/6 inhibitors have demonstrated to be an effective therapeutic for estrogen receptor positive BC and although their use in TNBC patients remains uncertain their use in combination with other targeted therapies may be promising. We have developed a set of newly designed biguanides with potent anticancer action and safety doses in vivo that in combination with CDK4/6 inhibitors block TNBC cell growth in vitro and in vivo. Using TNBC cell proliferation in vitro assays, new biguanides show dose-dependent inhibition of cell proliferation ($P<0.01$). Further, combination of biguanides with ribocliclib, an orally bioavailable CDK4/6 inhibitor, produced additive and synergistic effects in TNBC cell lines in vitro ($P<0.01$). Biguanides are known to activate de LKB1-AMPK pathway. Western immunoblots showed our biguanide analogues also induce AMPK phosphorylation and significantly reduce phosphorylation of downstream mTOR signaling pathway components including S6 ribosomal protein and 4E-BP1, an effect that is potentiated by combination treatment with ribociblib. Further, cyclin D1 is known to be overexpressed in about 50% of BCs and binding to CDK 4/6 induces phosphorylation of Rb and cell cycle progression. Treatment with biguanides downregulated cyclin D1 expression in TNBC cells and combination treatment of ribociclib with biguanide JD006 was more effective at decreasing Rb phosphorylation than each drug alone. In addition, seahorse analysis evaluated mitochondrial respiratory function. Treatment with biguanides inhibited oxidative phosphorylation in a dose dependent manner, an important metabolic pathway that can drive drug resistance to therapy in cancer cells. In vivo, combination treatment of ribociclib with biguanide JD006 was more effective than each agent alone in stopping human TNBC xenograft progression in nude mouse models ($P<0.05$). Our preliminary data offer evidence that human TNBC are highly vulnerable to metabolic reprogramming by new biguanides. This work can yield insight on unanticipated mechanisms of biguanide action and rationale for new combination therapies with CDK 4/6 inhibitors as a new option for treatment of TNBC. #0602 Targeting CDK9 with a novel potent and selective inhibitor, YX0798, in CAR-T-relapsed mantle cell lymphoma models.

V. Jiang[1], Y. Xue[2], H. Kim[1], J. McIntosh[1], H. Chen[3], T. Zhang[1], Y. Liu[1], J. Zhou[3], M. Wang[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Texas Medical Branc, Galveston, TX, [3]University of Texas Medical Branch, Galveston, TX

Introduction

Cyclin-dependent kinase (CDK) family members play critical roles in multiple cellular processes. CDK9 is a central regulator at several stages of PolII transcription, including initiation, elongation, and termination. CDK9 dysfunction resulted in transcriptomic reprogramming and promotion of the development of cancers, including lymphoma and leukemia. We and others reported that transcriptomic reprogramming is associated with disease progression and therapeutic resistance in mantle cell lymphoma (MCL). Targeting CDK9 with its inhibitors AZD4573 and enitociclib is safe and effective for treatment in preclinical MCL models, and they are currently under clinical investigation to assess their efficacy and safety. The data demonstrated that CDK9 is a promising therapeutic target. In this study, we developed a novel CDK9 inhibitor, YX0798, and assessed its potency and safety in preclinical MCL models.

Method

Cell viability assays were conducted in a time- and dose-dependent manner to assess the *in vitro* efficacy of YX0798 as well as AZD4573. Apoptosis assays and western blots were used to determine the mechanism of action in MCL cells. Patient-derived xenograft models from primary MCL patient samples were established in immunodeficient mice and used to determine the therapeutic potential YX0798.

Results Next generation sequencing showed that CDK9 was upregulated and cancer hallmarks MYC-TARGETS-v1 and -v2 were highly enriched in CAR-T-relapsed MCL patients compared to CAR-T-naïve patients. We hypothesized that CDK9 overexpression and activity may greatly contribute to the enrichment of MYC-TARGETS-v1 and -v2 in patients with CAR-T resistance, so targeting CDK9 may overcome that resistance. YX0798 was developed to be a potent and selective CDK9 inhibitor. It markedly inhibited cell viability and induced robust apoptosis in MCL cell lines. As expected, it inhibited CDK9 kinase activity and suppressed the expression of short-lived proteins like c-MYC and MCL-1 that are critical for MCL cell survival and growth. YX0798 at 2 mg/kg for continuous 7 days via pump or at 5 mg/kg daily by oral administration potently inhibited the tumor growth of xenografts derived from a patient with therapeutic relapse to the CAR-T therapy *in vivo* ($P<0.0001$). This treatment efficacy was found to be similar at that of AZD4573 but at a higher dosage (15+15 mg/kg, 2 hours split, QW, IP). No adverse effects in mice were observed for any of treatments.

Conclusion

These data show that our novel CDK9 inhibitor YX0798 is potent and efficacious in treating aggressive MCL models and overcame CAR-T resistance at a lower dosage than AZD4573.

#0603 BB5523, a multiple kinase inhibitor with HPK1, VEGFR2 and TNIK inhibition, enhanced antitumor immunity in tumor models.

Gongping Duan, Min Li, Puyong Zhang, Wei Hua, Enlun Hao, Shipeng Wang, Xiaoyi Ma, Junheng Wang, Lijie Wei, **Xingmin Zhang**

BroadenBio Co., Ltd, Beijing, China

Introduction: Immuno-suppressive micro-environment and abnormal signaling pathways are crucial for the proliferation of tumor cells. Hematopoietic progenitor kinase 1 (HPK1) inhibitor plays important roles in activation of exhausted T cells and enhancement of anti-tumor immune responses. VEGF/VEGFR2 pathway is the central therapeutic target in anti-angiogenic treatment in multiple cancers. Traf2- and Nck-interacting kinase (TNIK) is a member of the germinal center kinase family, and is reported to be essential for Wnt signaling and colorectal cancer (CRC) proliferation and progression. Blockade of critical kinases in multiple signaling pathways inhibits the proliferation, invasion and metastasis of cancer cells. Therefore, intergradation of these functions in a small molecule serves as the next generation of immune-oncology small molecules for cancer therapy. Methods: BB5523 was developed through structure-based drug design, and optimized by SAR analysis and medicinal chemistry iteration. Biochemical assays and cell-base functional assays were applied in compound evaluation. Pharmacokinetic (PK) and preliminary toxicity studies were performed with mice. CDX and syngeneic tumor models in mice were conducted to evaluate the *in vivo* efficacy of BB5523 as a single agent. Results: BB5523 shows high inhibition potency on HPK1 with good selectivity against other TCR signaling-related kinases, such as FYN and ZAP70. Inhibition of HPK1 kinase activity (IC50 = 3.3 nM) by BB5523 strongly suppresses the phosphorylation of the downstream biomarker protein SLP-76 (IC50 = 30 nM); and boosts the IL-2 secretion in purified human T cells and human peripheral blood mononuclear cells. BB5523 also shows good activities on VEGFR2 (IC50 = 1.6 nM) and TNIK (IC50 = 0.7 nM) which are crucial for the proliferation of cancer cells. In *in vitro* experiments, BB5523 significantly inhibits the proliferation of various tumor cell lines at sub-micromolar concentrations. PK profile of BB5523 shows good oral bioavailability (F > 80%). In preliminary safety evaluation, no abnormal symptoms were observed in mice dosed up to 100 mpk for 14 days. BB5523 showed significant tumor-growth inhibition efficacy in TE-8, JIMT-1, B16-F10 and MC38 tumor models. Conclusion: As a potent and oral available small molecule kinase inhibitor, BB5523 boosts anti-tumor immunity through HPK1 inhibition, while also blocking crucial signaling pathways in tumor micro-environment. BB5523 shows promising *in vitro* and *in vivo* efficacy with a well-tolerated safety profile. The preclinical study of BB5523 is in progress.

#0604 Targeting casein kinase 1 alpha (CK1 alpha) and transcriptional CDKs (CDK7/9) in human liposarcomas.

R. Liu[1], N. L. Solimini[1], P. Bhola[1], T. B. Branigan[1], J. Hao[1], X. Wang[1], R. Alharthi[1], M. Yorsz[1], S. Soni[1], C.-s. Hu[1], I. Snir-Alkalay[2], P. Gokhale[1], A. Letai[1], Y. Yinon Ben-Neriah[2], G. D. Demetri[1], G. I. Shapiro[1];

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Hebrew University-Hadassah Medical School, Jerusalem, Israel

Introduction: Liposarcomas (LPS) are rare mesenchymal cell malignancies of adipocytic origin that are diagnosed in more than 3500 patients in the US each year. The two most common subtypes, well-differentiated LPS (WDLPS) and dedifferentiated LPS (DDLPS), are characterized by extrachromosomal DNA amplifications harboring the *MDM2* (100%) and *CDK4* (90+%) genes, generally with wild type *TP53*. Management of metastatic or surgically unresectable LPS remains purely palliative. Recent clinical trials targeting MDM2 or CDK4/6 with small-molecule inhibitors have shown promise but have been hampered by dose-limiting toxicities. The development of new therapeutics is greatly needed to improve outcomes for patients with LPS.

Results: To identify unique liposarcoma-specific vulnerabilities, we screened multiple human LPS cell lines for transcriptional CDK expression and found high levels of CDK7 and CDK9. We demonstrate that CDK9 inhibitors suppress LPS cell growth and induce apoptosis by decreasing MDM2 levels while inducing expression of p53. To enhance p53 activation in these cells, we screened for expression of known regulators of p53, including CK1α, whose inhibition has previously been shown to activate p53. We demonstrate that LPS cells express CK1α and that the cytotoxic effects of CDK9 inhibitors are enhanced upon CK1α depletion. These data led us to examine combined targeting of CK1α and CDK9 in LPS with the novel agent BTX-A51, which has previously been shown to inhibit CK1α, CDK9, as well as CDK7 with nanomolar efficacy in AML models. BTX-A51 potently reduces expression of MDM2 with marked induction of p53, resulting in profound apoptosis of LPS cells. Through CRISPR/Cas9-mediated p53 knockout, we establish that BTX-A51-mediated apoptosis is primarily p53-dependent. However, BTX-A51 also reduces expression of MCL1 and primes LPS cell lines and primary LPS cells for BIM-induced apoptosis, as demonstrated by BH3 profiling. Importantly, preliminary *in vivo* data in an LPS patient-derived xenograft model reveal that BTX-A51 is well-tolerated with tumor growth inhibition.

Conclusions: Our results suggest that BTX-A51 has potent preclinical efficacy in treating LPS, primarily through inhibition of CK1α and CDK9. Future mechanistic studies will further clarify mechanisms of BTX-A51-mediated apoptosis, as well as the contribution of CDK7 inhibition to anti-tumor activity. Our data justify a planned clinical trial that will evaluate the efficacy of BTX-A51 in patients with advanced WDLPS or DDLPS.

#0605 ABBV-101, a highly potent and selective clinical stage Bruton tyrosine kinase degrader, overcomes BTK mutation-induced resistance to BTK inhibitors.

C. Pan, J. Riehm, T. L. Gururaja, H. Li, H. Nguyen, Y. Zhai, X. Xie, R.-X. Ding, R. Matthew, H. Y. Hoh, Z. J. Jia, B. Liu, C. P. Shu, C. A. Stevenson, C. Will, F. Innocenti, W. Assaily, **L. T. Lam**, A. Rivkin;
AbbVie Inc., North Chicago, IL

Bruton tyrosine kinase (BTK), a clinically validated target for various B-cell malignancies, plays a critical role in regulating cell growth, adhesion, and homing to lymphoid tissues that provide a microenvironment favorable to cancer cells. Despite the success of approved covalent BTK inhibitors in diseases such as CLL, most patients do not achieve complete response with monotherapy and eventually relapse, often via the emergence of the BTK-C481S mutation. Although second-generation reversible BTK inhibitors may temporarily overcome the C481S mutation, novel BTK mutations associated with resistance emerged in the clinic recently. Additionally, covalent BTK inhibitors have not shown sufficient differentiation from standard-of-care (SoC) in B-cell malignancies, such as diffuse large B cell lymphoma (DLBCL) to warrant approval to date. To address these unmet needs, a next-generation orally bioavailable BTK degrader ABBV-101 has been developed. Unlike BTK inhibitors that solely bind to and impede the catalytic domain of BTK, ABBV-101 eliminates the protein in a highly selective fashion. This degradation mechanism targets both the catalytic and scaffolding functions of BTK, and thus may enable deeper and more durable responses in patients with B-cell malignancies. Cellular activity of ABBV-101 was determined in a panel of DLBCL cell lines. We show that most non-germinal center B cell DLBCL (non-GCB-DLBCL) cell lines are sensitive to ABBV-101. To determine whether ABBV-101 could overcome BTK mutations-induced resistance, we engineered human DLBCL cell line TMD8 using CRISPR technology to express these BTK mutations and tested for sensitivity to ABBV-101 and BTK inhibitors. We show that ABBV-101 demonstrates similar potent activity against all BTK mutations associated with resistance to both covalent and reversible BTK inhibitors. The modulation of downstream pathway by ABBV-101 and how it differentiates from other BTK inhibitors will be presented. Further, ABBV-101 induces complete tumor regression in the BTK-C481S TMD8 DLBCL xenograft model. A spontaneous mouse CLL model carrying BTK-C481S mutation was developed through crossing BTK-C481S knock-in mice with the Emu-TCL1 transgenic mice in the C57BL/6 background. ABBV-101 completely inhibits BTK-C481S Emu-TCL1 CLL burden increase in the blood compartment and reduces CLL burden in the spleen and lymph nodes, whereas covalent BTK inhibitors show no activity. Finally, combination with a BCL-2 inhibitor enhances the efficacy of ABBV-101 in CLL and DLBCL models. Taken together, our results suggest that ABBV-101 has potent *in vitro* and *in vivo* efficacy. ABBV-101 is currently in phase 1 clinical trial for a variety of B-cell malignancies. ClinicalTrials.gov identifier: NCT05753501

#0606 The PLK1 inhibitor, onvansertib, synergizes with paclitaxel in small cell lung cancer.

J. C. Schmitz[1], G. Zhang[1], A. Pannucci[1], T. Smeal[2], C.-C. Wu[2], M. Ridinger[2], T. K. Owonikoko[1];
[1]University of Pittsburgh, Pittsburgh, PA, [2]Cardiff Oncology, San Diego, CA

Background: Small cell lung cancer (SCLC) is an aggressive neuroendocrine tumor with rapid disease progression and poor patient survival. Therapeutic options for SCLC remain a challenge due to limited understanding of both the biology of the disease and the major determinants of treatment response. Key transcription factors associated with unique biological phenotypes of SCLC include ASCL1, NEUROD1, YAP1, and POU2F3. Previously, we demonstrated that onvansertib, a highly specific inhibitor of the PLK1 Ser/Thr kinase, was effective in SCLC preclinical models, leading to its ongoing clinical development for relapsed/refractory SCLC patients (NCT05450965). Here we further explored potential strategies to enhance onvansertib activity by assessing its *in vitro* and *in vivo* activity in combination treatments.
Methods: Human SCLC cell lines were treated for 72 hr with onvansertib in combination with paclitaxel, lurbinectedin or the ATR inhibitors BAY1895344 and AZD6738. Effect on cell proliferation was analyzed by WST1 and CellTiterGlo assays. In vivo activity of onvansertib in combination with paclitaxel was tested in 3 SCLC patient-derived xenograft (PDX) models either cisplatin-sensitive (TKO5- ASCL1 subtype) or cisplatin-resistant (TKO2-ASCL1 subtype, TKO8-NEUROD1 subtype). Tumor-bearing nude mice were treated with vehicle, onvansertib (50 mg/kg, oral, 4 times/week), paclitaxel (15 mg/kg, IP, once a week) or the combination for 5 weeks. Mice were followed for tumor growth and survival (defined as time to reach tumor volume greater than 2000 mm^3).
Results: The combination of onvansertib and paclitaxel inhibited cell proliferation synergistically in cell lines from 3 SCLC subtypes (ASCL1, NEUROD1, and YAP1), while the combinations with lurbinectedin or ATR inhibitors were not synergistic. We further examined the combination of onvansertib and paclitaxel in SCLC PDXs. The combination exhibited potent anti-tumor activity, resulting in significantly greater tumor growth inhibition and increase in survival compared to the monotherapies in all 3 PDXs. The combination was well tolerated with no observed body weight loss. While onvansertib and paclitaxel had negligible single agent activity in cisplatin-resistant TK02 PDX and TKO8 PDX models, the combination induced durable complete responses in 25% and 100% of treated mice respectively.
Conclusion: The PLK1 inhibitor onvansertib in combination with paclitaxel showed synergy in multiple SCLC cell lines *in vitro* and potent anti-tumor activity in cisplatin-sensitive and -resistant SCLC PDX models *in vivo*. Tumor tissue analysis is underway to detail the mechanisms of this interaction.

#0607 Development of a novel, selective, and potent inhibitor of RON kinase.

M. Kaadige[1], T. Thode[1], J. Fornetti[2], A. Weston[1], S. Ng[1], T. Ghosh-Halder[1], T. Bargenquast[1], B. Durbin[1], S. Kasibhatla[1], R. Soldi[1], A. Welm[2], S. Sharma[1]; [1]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [2]Huntsman Cancer Institute, SLC, UT

Purpose: Receptor d'origine nantais (RON) is a highly conserved transmembrane protein expressed at low levels in healthy adult tissues of epithelial origin and at various levels in immune cells such as macrophages. Aberrant activation of RON has been described in many solid tumors, and it contributes to tumorigenesis by modulating the immune tumor microenvironment, activating numerous oncogenic signaling pathways, and protecting tumor cells under stress. The overexpression of RON protein and the subsequent generation of oncogenic variants are mainly responsible for the persistent activation of downstream signaling pathways. In breast cancer, more than 80% of primary cancer samples are positive for RON expression, with overexpression reported in approximately 50% of cases. Importantly, tumoral RON expression correlates with increased breast cancer progression, metastasis, and poor prognosis independent of molecular subtype. We hypothesize that a small molecule inhibitor of RON that can target both full-length and truncated isoforms will promote anti-tumor immunity within the tumor microenvironment and block pro-metastatic signaling pathways. Herein, we report the development of a novel, orally bioavailable, selective, and potent inhibitor of RON kinase.

Methods: With structure-guided and iterative medicinal chemistry approaches, we identified a novel chemical entity that potently inhibited RON kinase activity. Further optimization resulted in the identification of ZB-60 with improved potency, selectivity, and desirable drug-like properties. *In vitro* kinase assays were performed using ADP-Glo RON kinase assay kit (Promega). Changes in phosphorylation of RON was demonstrated by Western blotting. Plasma pharmacokinetics (PK) was conducted in mice to measure exposures and to determine the oral bioavailability of ZB-60. *In vivo* efficacy of ZB-60 was evaluated in syngeneic mouse models of breast (EMT6) and colorectal (CT26) cancer.

Results: ZB-60 inhibited RON kinase activity with an IC_{50} of 56 nM and showed greater than 40-fold selectivity against MET and other closest members of the tyrosine kinase family. In ZB-60 treated breast cancer cells, there was a dose dependent reduction of RON phosphorylation and downstream signaling. PK analysis showed a high oral bioavailability with low clearance. *In vivo* evaluation of ZB-60 showed inhibition of tumor growth in EMT6 and CT26 models. Ongoing studies are focused on testing ZB-60 in combination with checkpoint inhibitors. The results from these studies along with ADME-TOX and pharmacokinetics will be presented.

Conclusion: ZB-60 has target specific activity and exhibits favorable drug-like properties.

#0608 NEOS-223 is a small molecule kinase inhibitor which induces apoptosis in selected cancer models.

H. Potu, S. A. Little, S. Fedorchak, S. Chittamuru, T. Murphy, R. Wexler, S. Croce, M. George, L. S. Desai;
NeoSome Life Sciences, Billerica, MA

Due to their critical role in cancer signaling pathways, members of the kinase family have emerged as one of the most comprehensively pursued targets in pharmacological cancer research. Deregulation of kinase activities leads to a variety of upstream and downstream signaling pathway changes in cancer cell. The Ras/Raf/MEK/ERK and PI3K/Akt/mTOR cascades are activated by genetic alterations in selected upstream signaling molecules such as receptor tyrosine kinases. Recently developed therapies which target such kinases (EGFR, BRAF, MEK) with kinase inhibitors have notably improved the prognosis within various cancer patient groups. However, patients with different mutations of EGFR, RAS, and BRAF do not respond completely. In this study the potential of NEOS-223 as a new kinase-targeted therapy in selected cancer models was investigated. Multiple cancer cell lines were assessed for cell growth as well as the direct inhibitory effects of NEOS-223 alone and in combination with other clinically approved kinase inhibitors. NEOS-223 treatment caused cell growth inhibition, blocked colony growth, and induced apoptosis in lung, pancreatic, melanoma, and colon cancer cell lines in vitro and demonstrated potent antitumor activity in *in vivo* xenograft models of colon and lung cancer. We were particularly interested in examining different components of the ERK and PI3K signaling pathways in selected sensitive cell lines, it was identified that NEOS-223 treatment led to downregulation of the expression of pERK and pAKT signaling. Blockage of the PI3K/mTOR pathways showed inhibitory synergy with NEOS-223 in lung cancer in vitro. Most importantly, *in vivo* data showed that while administration of NEOS-223 alone decreased tumor growth, the addition of PI3K/Akt/mTOR inhibitor onatasertib significantly enhanced anticancer effect in a lung cancer model. In lung and pancreatic cancer models, inhibition of EGFR by the small molecule drug gefitinib strongly showed synergistic effect with NEOS-223 both in vitro and *in vivo.* This may be because EGFR potentially activates both the mitogen activated protein kinase (MAPK/ERK) and the PI3K/mTOR signaling cascades in different mutant cancer models. These studies reveal that NEOS-223 inhibits cell proliferation and induces apoptosis via suppressing the PI3K/Akt/mTOR pathway and further suggest that the combination of PI3K/Akt/mTOR and EGFR inhibitors and that NEOS-223 would be a strong potential chemotherapeutic strategy against lung and pancreatic cancers.

#0610 ClpP-dependent and -independent activation of HRI kinase by small molecules.

X. Tian, P. Srinivasan, W. S. El-Deiry;
Brown University, Providence, RI

HRI was initially identified as a kinase essential for maintaining heme-globin balance within red blood cells as well as for controlling the ISR in response to oxidative stress. HRI also responds to a broad range of stresses such as osmotic stress, heat shock, proteasome inhibition. The recently discovered unexpected functions of HRI include innate immunity, translational control of immune evasion in cancer by upregulating PD-L1, proteostasis, mitochondrial stress, inhibition of histone H3 lysine 27 (H3K27) demethylase (KDM6A) and iron deficiency. Importantly, recent evaluation of patient data uncovered high expression of HRI mRNA in a subset of epithelial tumors versus normal tissues. Elevated expression of HRI protein in these tumor cells lead to cell death when BIRC6 ubiquitin complex is inhibited, which mediates degradation of HRI and is required for the survival of the tumors. These further broaden the importance of this member of the eIF2α kinase family as a cancer therapeutic strategy. Dordaviprone (ONC201), an imipridone small molecule, binds to and activates mitochondrial protease ClpP leading to integrated stress response (ISR) and ATF4 transcription factor activation. PG3, a prodigiosin analog, induces ATF4 and pro-apoptotic PUMA. Our data indicate that PG3 activates ATF4 through ISR via eIF2α kinase HRI. ALAS1 (5'-aminolevulinate synthase 1) catalyzes the first rate-limiting step in heme (Iron-protoporphyrin) biosynthesis. ONC201 treatment leads to potent downregulation and inhibition of ALAS1, indicating that ONC201 inhibits heme biosynthesis. It is well known that reduced heme results in activation of the HRI kinase. We show that an inhibitor of heme biosynthesis or knockdown of ALAS1 results in HRI activation, while silencing of HRI or knockout of *HRI* gene potently inhibit the eIF2α phosphorylation and upregulation of ATF4, CHOP and PUMA by PG3 and imipridones. Knockdown of ClpP rescues ONC201-induced downregulation of ALAS1 which blocks ONC201-induced upregulation of CHOP. Also, silencing of ClpP significantly reduced PARP cleavage in HCT116 $p53^{-/-}$ and MDA-MB-468 cancer cells. Our studies identify a novel link between ClpP activation induced by ONC201 treatment and ATF4 upregulation, via the ClpP/ALAS1/HRI/ATF4 pathway. However, PG3 treatment did not lead to degradation of ALAS1, indicating that PG3 does not activate ClpP. PG3 potently induced cell apoptosis through ISR via HRI/ATF4/PUMA pathway independent of ClpP. We are further investigating the targets of PG3 and the signaling pathway that leads to PG3-induced activation of HRI. Our results suggest that different small molecule inducers of the ISR such as ONC201 and PG3 can achieve an anti-tumor effect through different pathways converging on kinase HRI ultimately leading to ATF4 activation and tumor cell death.

#0611 Discovery of LNX231, a multi-kinase inhibitor mainly target FLT3 with robust *in vivo* efficacy in FLT3 mutant AML models.

L. Zhao[1], G. Hao[1], R. Deng[1], N. Zhang[2], J. Yao[1], A. Zhu[2], G. Li[2], E. Wang[2], Z. Li[1], Z. Liu[1], G. Zhang[1];
[1]Lunan Pharmaceutical Group Co. Ltd., Linyi City, China, [2]Shandong New Time Pharmaceutical Co., LTD, Linyi City, China

LNX231 is a multi-kinase inhibitor mainly target FLT3, which could both directly kill cancer cells and promote tumor immunity. LNX231 potently inhibits FLT3 activity in biochemical assay, with a 50% inhibitory concentration (IC_{50}) of 3.5 nM, significantly inhibits FLT3-D835Y and FLT3 ITD, the values of IC_{50} are 20 nM and 4.4 nM. LNX231 inhibits the proliferation of FLT3 mutant AML cell lines via RAS-MARK and JAK-STAT pathway. LNX231 significantly decreases the phosphorylation of STAT5 and ERK in MV-4-11 cells at the high concentration, but has no effect on the phosphorylation of FLT3 and AKT. LNX231 significantly decreases the phosphorylation of FLT3, STAT5 and ERK in MOLM-13 cells at the high concentration, but has no effect on the phosphorylation of AKT. In FLT3 mutated AML models, LNX231 induced sustained tumor shrinkage as a single agent and was well tolerated. At the same dose, LNX231 was more potent than the FDA-approved drug Gilteritinib. In the MC38 tumor-bearing model, the efficacy of LNX231 was better than Sunitinib and Lenvatinib. LNX231 has good oral bioavailability in different species, such as mouse, rat, dog and monkey. DMPK data predicted oral QD dosing in human. It also showed excellent ADMET profile as a pre-clinical candidate. Safety tolerability studies were conducted in mice and dogs. LNX231 has low cardiotoxicity (IC_{50} of hERG is 25.84 μM) and 5-6 times safety window. In conclusion, we discovered LNX231 as a multi-kinase inhibitor for FLT3 mutated AML.

#0613 Oral CHK1 inhibitor BBI-355 allows flexibility of dose and schedule with demonstration of monotherapy and combinational antitumor activity in extrachromosomal DNA (ecDNA) driven preclinical models.

R. J. Hansen, A. Steffy, J. Plum, A. Ardeshiri, E. Tse, S. Garcia, B. Norman, J. Moininazeri, A. Pferdekamper, E. Holmes, D. Liao, R. Elsdon, J. Lange, A. Pinkerton, J. Apuy, S. Chowdhry, C. Hassig, S. Kasibhatla;
Boundless Bio, San Diego, CA

Focal, high copy number amplifications of prevalent oncogenes (e.g., *MYC, EGFR*) frequently occur on extrachromosomal DNA (ecDNA), highly transcribed units of circular, non-chromosomal DNA. While use of targeted therapies is associated with improved survival in patients with cancers that have activating oncogene mutations or fusions, they have demonstrated limited activity for patients whose tumors harbor oncogene amplifications, including those mediated by ecDNA. We have previously identified Checkpoint Kinase 1 (CHK1) as a target essential for ecDNA function in cancer, as tumor cells with oncogene amplification on ecDNA exhibit increased DNA replication stress (RS) and are hypersensitive to inactivation of CHK1, cells' master regulator of RS. Thus, we have developed BBI-355, a novel, orally bioavailable, and selective small molecule inhibitor of CHK1, which is currently being studied in the first-in-human Phase 1/2 POTENTIATE clinical trial for patients with cancer harboring oncogene amplifications, including on ecDNA (NCT05827614).

In vitro antiproliferation activity of BBI-355 was observed in a panel of ecDNA+ oncogene amplified tumor lines and non-amplified lines, with heightened sensitivity and induction of RS observed in ecDNA+ cells. Oral administration of BBI-355 resulted in dose dependent on-target activity, with induced p-CHK1-S345 protein expression, in agreement with measured plasma and tumor concentrations. Subsequent pharmacokinetic/pharmacodynamic (PK/PD) modeling guided continuous and intermittent dose/schedules of single agent BBI-355 that demonstrated durable antitumor activity, including tumor regressions, in multiple ecDNA+ tumor models. Single agent targeted therapy treatment of cancers with oncogene amplification on ecDNA can result in acquired resistance via ecDNA-based mechanisms, further increasing reliance on CHK1. Enhanced antitumor activity of BBI-355 in combination with agents targeting the protein products of amplified oncogenes was demonstrated in multiple in vivo tumor models; these included combination with a pan-FGFR inhibitor in *FGFR2* ecDNA+ amplified gastric cancer and combination with CDK4/6 inhibitors in *CDK4* ecDNA+ amplified sarcoma models.

The first ecDNA-directed therapy (ecDTx) in development, BBI-355 demonstrated significant antitumor activity as a single agent and in combination with targeted therapies in multiple ecDNA+ oncogene amplified tumor models. Oral dosing of BBI-355 provides dose/schedule flexibility to attempt to optimize antitumor activity with a tolerable safety profile in patients with highly aggressive cancers and significant unmet need. The POTENTIATE clinical trial is open and currently enrolling.

#0614 Src family kinase inhibition demonstrates antitumor activity in vitro and in patient-derived xenograft models of human cholangiocarcinoma.

H. Kuipers, J. L. Tomlinson, D. M. Carlson, A. M. Abdelrahman, E. Jessen, J. W. Sample, N. W. Werneburg, H. E. Stumpf, M. J. Truty, S. I. Ilyas, G. J. Gores, R. L. Smoot;
Mayo Clinic, Rochester, MN

Background: Cholangiocarcinoma (CCA) is a lethal and heterogenous malignancy of the biliary tree characterized by perineural invasion. About 85% of CCA show activation of YAP signaling, which promotes proliferation, anti-apoptosis, and therapeutic resistance. YAP signaling is mediated by Src family kinases (SFK) by phosphorylation of YAP ($pYAP^{y357}$). NXP900 is a first-in-class, highly selective, SFK inhibitor with a novel mechanism of action which locks SFK in its closed and inhibited conformation, in contrast to other Src inhibitors such as dasatinib. A phase 1a study of NXP900 in patients with advanced solid tumors was recently initiated. Here, we examined treatment responses of CCA to NXP900 *in vitro* and *in vivo*.
Methods: Cell viability was determined in seven CCA cell lines by CellTiter-Glo. Cell death and apoptosis were assayed by PI/Hoechst and Caspase-Glo 3/7 assay. CalcuSyn software was used to determine synergistic drug effects. Immunoblot analysis, RT-PCR, and IF staining of YAP localization were used to evaluate YAP knockdown. Clones of human CCA cell lines resistant to NXP900 were generated through escalating exposure to NXP900 over 6 months. Five patient-derived xenograft (PDX) tumors were expanded into flanks of NOD/SCID mice. Tumor bearing mice were randomized 1:1 with 5 mice per arm and treated with vehicle or NXP900 (40 mg/kg) once daily for up to 4 weeks. To determine drivers of sensitivity and resistance, predicted sensitivity scores based on tumor growth were linked to multi-omics (RNA seq and [phospho-]proteomics) of our PDX models.
Results: All cell lines were sensitive to NXP900 with IC_{50} values between 7nM-15μM; IC_{50}'s of resistant clones were 1000 times higher. NXP900 induced more cell death compared to vehicle, which appeared to be through apoptosis. NXP900 inhibited pSrc, decreased $pYAP^{y357}$, and upregulated inactive $pYAP^{s127}$. Correspondingly, decreased YAP target gene (Cyr61, NUAK, and CTGF) levels and a nuclear-to-cytoplasmic translocation were observed. NXP900/GemCis combination therapy increased cell death demonstrated a synergistic effect (Combination Indices <1) at all concentrations. In our PDX models, treatment was associated with a significant decrease in tumor growth in 3 models (mean fold change 3.1 vs. 14.2; 1.0 vs. 7.6; 1.4 vs. 2.6). The major resistant signature was the TRK signaling network, involved in nerve growth factor binding activity, while drivers of sensitivity included the SRC network.
Conclusion: NXP900 demonstrated therapeutic activity in vitro and in human PDX models. We are currently performing multi-omic approaches in NXP900 sensitive and resistant cell lines to unravel determinants of activity and resistance. Additional *in vivo* studies will be performed to determine effects of NXP900/GemCis and NXP900/anti-PDL-1 combination therapy.

#0615 NXP900, a novel YES1/SRC kinase inhibitor in phase 1, demonstrates potent inhibition of proliferation in cell lines resistant to ALK and EGFR inhibitors.

N. O. Carragher[1], E. Poradosu[2], B. King[1], A. F. Munro[1], J. C. Dawson[1], A. Unciti-Broceta[1];
[1]University of Edinburgh, Edinburgh, United Kingdom, [2]Nuvectis Pharma Inc., Fort Lee, NJ

Background: NXP900 (eCF506) is a novel potent and selective SRC family kinase (SFK) inhibitor, (IC50 of 0.47 nM against YES1). NXP900 locks its target into its native “closed” conformation (type 1.5), thereby inhibiting both kinase activity and complex formation with protein partners (Temps et al. Cancer Res. 2021, 81, 5438). In contrast, multi-kinase inhibitors, including dasatinib and bosutinib, block SRC in the active “open” conformation (type 1) promoting the association of SFK and signaling partners via allosteric facilitation (Higuchi et al. Cell Rep. 2021, 34, 108876). Activation of SFK suggests that NXP900 may have therapeutic potential in cancers with acquired resistance to EGFR and ALK inhibitors.
Methods: Cell lines: Alectinib sensitive (NCI-H2228, ATCC) and osimertinib sensitive (PC9, RIKEN). Alectinib resistant (H2228-ALR1, H2228-ALR2, H2228-ALR3, H2228-ALR4) and osimertinib resistant (PC9-OR1, PC9-OR3) cell lines were generated by treatment of NCI-H2228 or PC9 with increasing concentrations of, respectively, alectinib or osimertinib. Cell proliferation assay: Intracellular ATP (Oncolines B.V.); cells were treated with inhibitors for 120 hours. Reverse Phase Protein Array (RPPA): Protein extracts were prepared from cell lines at sequential timepoints following treatment with NXP900 or a combination of NXP900 and osimertinib. Extracts were printed as a concentration series onto nitrocellulose coated slides across multiple sub-arrays using an Aushon2470 arrayer, each sub-array was addressed with individual mono-specific antibodies to quantify the abundance of SRC, EGFR and other canonical cancer signaling pathway phosphorylation events.
Results: NXP900 single agent potently inhibited cell proliferation of ALK sensitive (GI50=83nM) and all ALK resistant cell lines (GI50=5.8-16nM). GI50 for EGFR sensitive and EGFR resistant cells were 605 nM and 826-4665 nM, respectively. In combination with a fixed concentration of osimertinib (160nM), NXP900 potently reversed osimertinib resistance in both EGFR resistant cell lines (GI50= 43-121 nM).
Conclusions: Despite high response rates to osimertinib and alectinib, acquired resistance almost universally arises. Here we demonstrate that NXP900 can potently inhibit cell proliferation of ALK resistant cell lines as a single agent and EGFR resistant cell lines in combination with osimertinib. Activation of SFK and YAP1 has been shown to be important in the development of resistance to ALK and EGFR treatment. We have previously demonstrated that NXP900 potently inhibits YAP1 nuclear localization and induces tumor regressions in squamous models in vivo providing additional proof of concept for targeting solid tumors with YES1/SRC and Hippo pathway alterations. A FIH, Phase1 dose escalation study for NXP900 has been initiated.

#0616 Integrating organotypic tissue slices and polypharmacology-based screening to map the toxicity landscape of kinase inhibitors.

Y. Kang, M. Chan, S. Zhu, T. S. Gujral;
Fred Hutchinson Cancer Center, Seattle, WA

Protein kinases play important role in the regulation of various biological processes, and their malfunction and dysregulation are intricately linked to the initiation and progression of cancer. The effectiveness of small-molecule kinase inhibitors (KIs) has been well-established in the therapeutic landscape, with the FDA approving over 70 KIs for the treatment of cancer and other diseases. However, the widespread utilization of KIs has been accompanied by reported adverse events, prominently featuring cardiac complications, alongside hepatic and renal function. While many studies have indicated on-target and off-target kinase specificity associated with organ damage, there is an urgent need for building predictive models that can pinpoint which specific kinases might be involved in different types of organ injuries. Such a model would not only facilitate mechanistic elucidation but also serve as a valuable tool for preemptively identifying potential adverse events associated with KI treatment. In this study, we performed polypharmacology-based screening of kinase inhibitors in organotypic tissue slices prepared from the normal heart, liver, and kidney of three distinct species—human, canine, and rodents. These tissue samples were treated individually using a curated selection of 32 KIs that are representative of a larger set of KIs and collectively target most of the 'kinome.' Subsequently, we developed Elastic Net Regularization models by utilizing the kinase inhibition profiles of ~300 kinases. These models were used to predict changes in tissue viability, measured as a percentage change, following the treatment with the respective kinase inhibitors. Using these models, we predicted the toxicity of 428 kinase inhibitors, both as single agents and in pairwise combinations, against three organs—heart, liver, and kidney—in humans, rodents, or canines. Our data show that the models accurately predicted the renal and cardiac toxicity of many FDA-approved KIs that were previously known. For example, the inhibition of RET kinase was identified to be linked with renal toxicity. Further, we compared the toxicity landscape of kinase KIs among different species and identified distinct sets of kinases that were recognized as essential indicators of toxicity within the same organ across species. These disparities underscore the potential distinctions in organ metabolism. In summary, our data provide a comprehensive landscape of kinase inhibitor toxicity. Our models could serve as a valuable resource for predicting kinase inhibitor toxicity across species by leveraging inhibitor profile data.

#0617 BH-30236, a novel macrocyclic CLK inhibitor modulating RNA splicing, demonstrates potent inhibition of cancer cell growth in a broad panel of cancer cell lines.

P. Jiang, D. Li, N. Ling, D. Zhai, W. Deng, E. Rui, J. Cui;
BlossomHill Therapeutics, Inc., San Diego, CA

Alternative splicing (AS) is a primary mechanism for mRNA transcript diversification and protein expression regulation. In cancer, altered mRNA splicing promotes oncogenic transformation, induces metastasis, and confers resistance to cancer treatment. Mutations or imbalanced expression/activity of splicing factors (SF), such as serine-arginine-rich SFs (SRSFs), often result in deregulation of RNA splicing and tumor progression. CDC2-like kinases (CLK) and dual-specificity tyrosine-regulated kinase (DYRK) are key regulators of AS *via* phosphorylation of SRSFs. BH-30236 is a novel macrocyclic ATP-competitive inhibitor of CLK1/2/4. It also inhibits DYRK1/2, provirus integration site for moloney leukemia virus 3 (PIM3) and FMS-like tyrosine kinase 3 (FLT3) at clinically relevant concentrations. The inhibitory activity of BH-30236 against CLK, DYRK, PIM3 and FLT3 in cancer cells was investigated *via* the phosphorylation inhibition of SRSFs, Tau, 4EBP1 and FLT3, respectively. A panel of 119 hematological and solid tumor cell lines were used to investigate the spectrum of BH-30236 against cancer cell growth. To understand the mechanism of anti-cancer cell growth, the effect of BH-30236 on AS and protein expression of key tumor related biomarkers were examined. In conclusion, BH-30236 effectively inhibited pSRSF (IC_{50} 40-60 nM in IMR-32 cells), pTau (IC_{50} ~50 nM in SH-SY5Y cells), p4EBP1 (IC_{50} ~80 nM in MM1S cells) and pFLT3-ITD (IC_{50} 0.16 nM in MV-4-11 cells). BH-30236 demonstrated broad inhibition of cancer cell growth with a median IC_{50} of 85.2 nM (range 0.55-393 nM) across 12 tumor types. BH-30236 showed great efficacy against cell lines derived from hematological malignancy (median IC_{50} 23.34 nM), neuroblastoma (median IC_{50} 25.73 nM), breast cancer (median IC_{50} 83.80 nM), colon cancer (median IC_{50} 85.17 nM), and lung cancer (median IC_{50} 102.65 nM). Furthermore, BH-30236 demonstrated synergy with KRAS inhibitors in KRAS mutant cell lines, with EGFR inhibitors in RBM10 mutant H1975 cells, and with BCL2 inhibitor Venetoclax in MOLM-13 cells. Mechanistically, BH-30236 modulated AS by increasing pro-apoptotic and anti-proliferative splicing variants of key factors, such as BCL2L1, S6K, and BCLAF1. Meanwhile, BH-30236 downregulated RNA expression of SRSFs and modulated BCL2 family to increase apoptosis. These results strongly support the clinical applications of the novel multikinase CLK inhibitor BH-30236 in hematological malignancies and solid tumors as a single agent or in combination with other therapies.

#0618 Preclinical assessment of APL-030, a selective and orally bioavailable inhibitor of the integrated stress response regulator GCN2 with activity against acute myeloid leukemia.

M. Roman-Trufero[1], G. Whitlock[2], M. Fuchter[3], M. Jeyakumar[3], P. Chaida[4], S. Herzog[4], A. Zebisch[4], R. Butt[5], H. W. Auner[1], N. Clemo[5];
[1]CHUV Lausanne University Hospital, Lausanne, Switzerland, [2]Sandexis Medicine Chemistry Ltd, Sandwich, United Kingdom, [3]Imperial College London, London, United Kingdom, [4]Medical University of Graz, Graz, Austria, [5]Apollo Therapeutics, Cambridge, United Kingdom

GCN2 (EIF2AK4) is an evolutionarily conserved kinase and a pivotal regulator of the Integrated Stress Response (ISR), an adaptive cellular program triggered primarily by amino acid scarcity. Active GCN2 phosphorylates the translation initiation factor eIF2α, resulting in the attenuation of global protein synthesis and a largely ATF4-driven program of resource enhancement. GCN2 promotes cancer cell survival under conditions of microenvironmental or drug-induced intracellular nutrient scarcity. Here, we describe the preclinical development of APL-030, a novel and selective ATP-competitive inhibitor of GCN2. APL-030 was confirmed as a potent inhibitor of GCN2 in an on-target biochemical kinase assay with a Ki of 4.4nM. In a cell-based assay APL-030 decreased eIF2α phosphorylation in a dose-dependent manner via direct GCN2 inhibition with an IC_{50} of 50.8nM. In acute myeloid leukemia (AML) cell lines GCN2 inhibition resulted in a decrease in gene expression of effector genes CHAC1 and DDIT3. Moreover, treatment with APL-030 dose-dependently decreased cell viability in multiple AML cell lines, which was accompanied by an increase in caspase 3/7 activity. Bulk mRNA sequencing of MOLM-13 AML cells showed that APL-030 inhibited the extensive transcriptome changes triggered by glutamine depletion, in line with a high degree of selectivity of APL-030 for GCN2-mediated ISR signaling. In cells grown in rich medium, APL-030 triggered a largely ISR-independent transcriptome response that was dominated by the enrichment of pathways related to cell cycle as well as RNA and protein metabolism. In vivo, APL-030 treatment of an AML xenograft animal model completely inhibited tumor growth and prolonged survival time. Inhibition of AML tumor growth was shown to be a consequence of decreased cell viability and induction of caspase-dependent apoptosis. APL-030 was also tested on primary diagnostic AML cells, which were assessed for cell death by flow cytometry following staining for Annexin-V, 7-AAD, CD45, CD34, and CD38. Treatment with APL-030 caused a statistically significant increase in AML cell death in all six samples studied. Three samples exhibited a measurable CD34+/CD38- compartment, enabling evaluation of this leukemic stem cell-enriched population. APL-030 caused a statistically significant increase in cell death in the leukemic stem cell-enriched population in all three samples studied. APL-030 is a novel GCN2 inhibitor that that has shown encouraging efficacy in preclinical studies using both AML cell lines and patient-derived AML samples. Based on these preclinical results, a phase 1/2 study is planned in hematological tumors.

#0619 Comprehensive cell line profiling of monomer- and dimer-selective small molecule RAF inhibitors uncovers determinants of cellular responses.

J. J. Kooijman, A. Al Koerdi, S. B. van der Leeuw, D. J. F. Kluitmans, E. van den Bossche, J. Dylus, J. A. D. de Roos, J. J. T. Melis, N. Willemsen-Seegers, G. J. R. Zaman;
Oncolines B.V., Oss, Netherlands

Dysregulation of the Mitogen-Activated Protein Kinase (MAPK) pathway is a frequent event in many cancers. The RAF family of kinases, which includes ARAF, BRAF, and CRAF (*RAF1*), plays a key role in MAPK signaling. Of the three isoforms, only BRAF is currently targeted by approved RAF inhibitors. These inhibitors were designed to target BRAF-mutant variants that act as oncogenic monomers. However, BRAF-monomer inhibitors can induce activation of wild-type RAF by the formation of dimers, resulting in hyperproliferative lesions of *BRAF* wild-type cells. Additionally, BRAF-monomer inhibitors do not target RAF-dimers, although this is a potential vulnerability of many MAPK-driven cancers. Novel inhibitors are in development to circumvent these limitations. Further insights into the precise targeting and mechanism of action of RAF inhibitors can help in determining the most promising avenues for drug development. We performed extensive cellular profiling experiments with three approved and five clinical stage inhibitors of RAF to gain more insight into the differences and cellular targeting of these agents. The inhibitors were tested in cell viability assays on a panel of 130 human cancer cell lines from diverse tissue origins. Cell lines were exposed to dose ranges of each inhibitor spanning four logarithmic orders, and viability was determined by measurement of intracellular ATP. Effects of compound on cell viability were related to genomic, transcriptomic, and proteomic status using bioinformatics, with the aim to identify predictive biomarkers for drug response, and to determine selective targeting of MAPK-driven cell lines. Additionally, the primary mechanism of cellular inhibitor activity was determined by relating cell line responses to gene dependency data from large CRISPR knockout screens.
Our results showed striking similarity in the overall inhibitory profile of BRAF-monomer inhibitors and the vemurafenib-derivative and paradox breaker plixorafenib, which all selectively targeted *BRAF*-mutant cell lines. However, whereas vemurafenib increased cell viability in *RAS*-mutant cell lines at high drug concentrations, this effect was greatly reduced for plixorafenib. Western blot analysis of phosphorylated MEK and ERK levels in *RAS*-mutant cell lines treated with BRAF-monomer inhibitors confirmed MAPK pathway activation as cause of the increased cell viability. In addition, RAF-dimer inhibitors potently targeted *BRAF*-mutant cell lines, as well as several *KRAS*- and *NRAS*-mutant cell lines. Lastly, correlation analyses of cell line profiling data with CRISPR knockout data revealed the preferential targeting of *RAF1*-dependent cell lines by the dual RAF/MEK inhibitor avutometinib. The results of our analyses shed light on the intricacies of cellular targeting by RAF inhibitors and provide insights to guide the development of new RAF inhibitors.

#0620 Screening of small-molecule MAPK pathway inhibitors on a panel of 130 human cancer cell lines identifies determinants of response in *RAS*-mutant subgroups.

J. J. Kooijman, A. Al Koerdi, D. J. F. Kluitmans, E. van den Bossche, J. Dylus, J. A. D. de Roos, J. J. T. Melis, G. J. R. Zaman;
Oncolines B.V., Oss, Netherlands

Oncogenic mutations in members of the RAS family, HRAS, NRAS, and KRAS, are frequently identified in various cancers and often lead to increased signaling of the mitogen-activated protein kinase (MAPK) pathway. KRAS is the most frequently mutated RAS isoform, with a mutation incidence of >10% across all cancers, and up to 70% and 20% in pancreatic and non-small cell lung cancer (NSCLC), respectively. RAS has long been considered to be undruggable, and direct inhibition of RAS with small molecule inhibitors has only recently been achieved, with the approval of the KRAS G12C-mutant selective inhibitors sotorasib and adagrasib for treatment of NSCLC. Indirect targeting of *RAS*-mutated cancers by inhibitors of downstream components such as MEK and ERK has shown variable responses. Novel insights into MAPK signaling have renewed interest into targeting the MAPK pathway in *RAS*-mutant cancer, with pan-RAF dimer inhibitors and dual RAF/MEK inhibitors reaching clinical trials. To improve the chances of success, it is important to determine which patient populations are most likely to respond to these inhibitors. To gain more insight into the cellular targeting of MAPK pathway inhibitors, eighteen inhibitors of the MAPK components KRAS, RAF, MEK, and ERK were profiled on a panel of 130 cell lines in cell viability assays (the Oncolines® panel). The cell lines represented a diverse range of tumor tissues and had different genomic backgrounds. Many of the cell lines had mutations in *KRAS*, *NRAS,* or *BRAF*. Drug responses were determined by exposing the cell lines to nine-point duplicate dose ranges of the inhibitors. Using bioinformatics, cell line responses to the inhibitors were related to genomic and transcriptomic features, to identify determinants of drug response in both tissue-agnostic and tissue-specific contexts.
The results of our analyses revealed variable responses of *KRAS*-mutant cell lines to the inhibitors, reflecting clinical responses. Tissue-focused analyses showed that the different responses could be traced back to the different KRAS amino acid substitutions. For instance, in pancreatic cancer cell lines, the KRAS Q61H mutation predicted increased sensitivity to MAPK pathway inhibitors compared to other KRAS amino acid substitutions. Additionally, in tissue groups with a more heterogenous mutation profile, co-mutations explained the decreased effectivity of MAPK pathway inhibitors in *KRAS*-mutant cell lines, such as *PIK3CA* mutations in colorectal cancer cell lines. Lastly, a gene expression-based signature of MAPK activity predicted response to MAPK pathway inhibitors, independent of mutation status. Our findings have uncovered determinants of response to MAPK pathway inhibitors in *RAS*-mutant cell lines. These determinants can serve as markers to select patients who are most likely to benefit from MAPK inhibitors.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanisms of Drug Action
Poster Session

#0624 Ptpn1 deficiency collaborates with a NUP98::HOXD13 fusion gene to generate B cell precursor acute lymphoblastic leukemia.

N. Nigam[1], T. Matsukawa[1], R. Bertoli[1], M. L. Tremblay[2], M. Yin[1], P. D. Aplan[1];
[1]NIH-NCI, Bethesda, MD, [2]McGill University, Montreal, QC, Canada

Background: Acute lymphoid leukemia is characterized by inherited or acquired mutations that effect critical differentiation and proliferation pathways. We have shown that Mcm2 deficient mice developed T cell acute lymphoblastic leukemia, due to copy number variations, most commonly interstitial deletions throughout the genome. When crossed with mice that expressed a NUP98::HOXD13 (NHD13) fusion gene, $Mcm2^{-/-}$NHD13 mice developed B cell precursor ALL (BCP-ALL). A majority of these BCP-ALL had acquired homozygous deletions of Ptpn1, a protein tyrosine phosphatase, leading to the hypothesis that Ptpn1 deficiency combined with NHD13 expression leads to BCP ALL.
Objective: To investigate the role of Ptpn1 deletion in BCP-ALL development using mouse models.
Methods: Mice expressing an NHD13 fusion gene were crossed with Ptpn1 knockout mice, generating 6 possible genotypes. Mice were followed for 18 months. Mice with signs of leukemia were characterized by clinical evaluation, CBC, flow cytometry, and IHC. Primary BCP-ALL and derived BCP-ALL cell lines were also evaluated with RNA-seq and molecular pathway analysis.
Results: NHD13+Ptpn1-/- mice developed BCP-ALL with 65% penetrance, characterized by hyperleukocytosis, anemia, thrombocytopenia, and invasion of non-hematopoietic tissues. Similar to human BCP-ALL, NHD13+Ptpn1-/- BCP-ALL had clonal IGH as well as clonal Tcrd gene rearrangements. Flow cytometry revealed CD19 and/or B220 expression. NHD13+Ptpn1+/- mice with BCP-ALL frequently lost the wild-type (WT) Ptpn1 allele in leukemic cells, reinforcing the hypothesis that Ptpn1 can function as a classic tumor suppressor gene in this context. Whole exome sequencing revealed acquired mutations in B-cell differentiation genes (Pax5 or Bcor) and activating mutations in tyrosine kinase genes (Jak1/3 and Flt3). Transcription signature analysis showed significant upregulation of Hoxa/b gene clusters, RNase12 and LncRNAs subsets.
Conclusion: This study demonstrates that Ptpn1 loss combined with expression of NHD13 fusion gene leads to highly penetrant BCP-ALL in mice, suggesting a role for Ptpn1 in preventing malignant transformation. These findings present a collaborative model for BCP-ALL in which the NHD13 transgene leads to increased stem cell self-renewal, somatic Bcor or Pax5 mutations block normal B cell differentiation, and somatic signaling mutations (Jak1/3,Flt3) lead to hyperproliferation, which is potentiated by Ptpn1 deficiency.

#0625 Remodeling of the tumor microenvironment in esophageal squamous cell carcinoma by neoadjuvant immunochemotherapy and its impact on therapeutic efficacy.

R. Aizemaiti[1], H. Zhang[2], C. Zhu[3], K. Zhou[1], T. Hu[3], S. Lin[1], X. Teng[1], J. Wang[3], X. Li[3], P. Ye[1];
[1]Department of Thoracic Surgery, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Department of Pathology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Department of Translational Medicine, Amoy Diagnostics Co., Ltd., Xiamen, China

Background: Patients with local advanced esophageal squamous cell carcinoma (ESCC) benefited from neoadjuvant immunochemotherapy (NAI) with 22%-55% of complete pathological responses (pCR). While unpredicted therapeutic resistance hampered prognosis of these patients. Thus, this study aimed to investigate tumor microenvironment (TME) remodeling pre- and post-NAI identifying predictive biomarkers and potential targets for patients with resistance to NAI.
Methods: 65 patients with locally advanced ESCC, who were treated with neoadjuvant anti-PD-1 antibody and platinum-based chemotherapy at the First Affiliated Hospital of Zhejiang University School of Medicine between November 2019 and June 2020, were included in this study. Genomic DNA and RNA from paired pre-and post-treatment FFPE samples were harvested and subjected to targeted DNA and RNA sequencing. Pre- and post- therapeutic microenvironment and immune cell infiltration were dynamically assessed based on RNA sequencing data.
Results: 37 of 65 patients responded to NAI(TRG0-1), while 28 of 65 patients displayed unfavored response (TRG2-3). Comparative analysis of TME characteristics before and after NAI revealed that, in the TRG2-3 group, LRRC15+ CAFs, and fibroblasts were significantly upregulated, while CD4 T cells and endothelium cells exhibited downregulation. Especially, TIGIT tended to be upregulated after NAI in the TRG 2-3 group. In the TRG0-1 group, significant upregulation of activated B cells, T-cells, myeloid dendritic cells, together with notable downregulations of immune suppressive features like Type 2 T helper cells, Tregs and LRRC15+ CAFs were observed in post-treatment samples.
Conclusions: Our study indicates the dynamic remodeling of TME during-NAI treatment might influence therapeutic efficacy and disclose potentially targetable resistant mechanisms. These preliminary findings pave the way for further validation through prospective clinical studies.

#0626 EGFL6 induced HER2-HER3 signaling controls accurate centrosome deposition of activated ERK and mitotic spindle formation in ovarian cancer cells.

S. Bai, N. Gupta, **Q. Jiang**, R. J. Buckanovich;
Magee-Womens Research Inst. & Foundation, Pittsburgh, PA

Epidermal growth factor EGF-like domain multiple-6 (EGFL6) is highly expressed in high grade serous ovarian cancer (HGSOC) cells and ovarian tumor vasculature. EGFL6 acts on tumor cells to drive tumor cell proliferation and migration. To better understand EGFL6 signaling and develop therapeutic strategies to target EGFL6 signaling in HGSOC, we evaluated phosphorylation of putative EGFL6 receptors and their downstream signaling. We demonstrated that EGFL6 induced phosphorylation and activation of ERBB/HER family of receptors; EGFL6 treatment of ovarian cancer cells led to rapid and transient phosphorylation of EGFR while inducing prolonged activation of both HER2 and HER3, with subsequent phosphorylation of ERK. Interestingly, we found that in EGFL6 stimulated ovarian cancer cells undergoing mitosis, pERK localized to the centrosome and the contractile ring. EGFL6 neutralizing antibodies reduce ERK phosphorylation and resulted in pERK being aberrantly localized. This resulted in altered mitotic spindle alignment and an increased number of cells undergoing mitotic catastrophe. Furthermore, combination anti-EGFL6 therapy with the pan-EGFR receptor inhibitor neratinib, compared to either therapy alone, led to an increase in aberrant pERK localization and cancer cell death in vitro. Consistent with these findings, dual anti-EGFL6 and neratinib therapy significantly restricted tumor growth in vivo, resulting in increased tumor cell death and a reduction in angiogenesis. Combined our data identify an unexplored role for pERK at the centrosome and suggest that dual targeting of the EGFL6/HER signaling axis maybe an effective therapeutic strategy in ovarian cancer.

#0627 IL-6 signaling via JAK/STAT axis influences PIM1 expression in renal cell carcinoma.

K. S. Meza, K. Seymour, S. L. Holder;
Brown University, Providence, RI

Renal cell carcinoma (RCC) is a top ten malignancy in the U.S. Overexpression of the proviral integration site for moloney murine leukemia virus 1 (PIM1) kinase is associated with poor clinical outcomes in RCC patients. PIM1 is a constitutively active serine/threonine kinase promoting cell proliferation, apoptosis resistance, invasion, and migration. The mechanisms underlying PIM1 expression and its function in RCC are not fully delineated. IL-6 is a pleiotropic cytokine that activates the JAK/STAT signaling cascade. High serum IL-6 levels are associated with the poor prognosis of RCC patients and may contribute to RCC invasion and metastasis. STAT3/5 binds directly to the PIM1 promoter inducing PIM1 expression. An IL-6/STAT3/PIM1 axis exists in pancreatic and breast cancer. We previously reported that PIM1 is overexpressed in a panel of human RCC cell lines relative to normal and immortalized renal proximal tubule epithelial cells. We also identified that RCC cells secrete IL-6. Our prior studies suggest that differential expression of PIM1 may be linked to autocrine IL-6 signaling. We thus hypothesize that an IL-6/JAK/STAT pathway regulates the expression of PIM1 in RCC. To understand how IL-6 signaling through the JAK/STAT pathway may regulate PIM1 expression in RCC cells, we examined whether IL-6 blockade using anti-IL-6 antibody or tocilizumab, would modulate PIM1 expression. Similarly, we assessed whether ruxolitinib, and LLL12, a STAT3 inhibitor could regulate PIM1 expression. We then evaluated the effect of ruxolitinib treatment on cell viability. In RCC cell lines, IL-6 blockade through either anti-IL-6 antibody or tocilizumab was sufficient to decrease PIM1 protein levels. Treatment with ruxolitinib leads to a dose and time-dependent decrease in PIM1 levels. Incubation with a STAT3 inhibitor also resulted in decreased PIM1 levels in RCC cells. Treatment with ruxolitinib also appears to decrease cell viability in a dose-dependent manner. These results suggest that differential expression of PIM1 in RCC may be linked to autocrine IL-6 signaling via a JAK/STAT/PIM1 axis. Multiple FDA-approved agents are available that target this pathway. Further investigation is required to determine the efficacy of these agents in pre-clinical models and even clinical trials.

#0628 RNA binding protein Matrin3 acts as a tumor suppressor by inhibiting microtubule nucleation.

P. Subbarayalu[1], S. Rajamanickam[1], S. Timilsina[1], S. Nirzhor[1], D. Medina[1], S. Abdulsahib[1], P. Prabhakar[1], D. Singh[1], F.-Y. Li[1], P. Yadav[1], E. Reddy[2], K. Evani[3], V. Eedunuri[1], T. Do[1], B. C. Onyeagucha[4], T. A. Mohammad[1], J.-H. Ji[1], Y. Chen[1], N. Abdelfattah[5], N. Dybdal-Hargreaves[6], L.-J. Wang[7], Y.-C. Chiu[7], S. Viswanadhapalli[6], R. K. Vadlamudi[6], M. K. Rao[1];

[1]UT Health San Antonio Greehey Children's Cancer Res. Inst., San Antonio, TX, [2]Southern Methodist University, Dallas, TX, [3]UT San Antonio, San Antonio, TX, [4]Mississippi University for Women, Columbus, MS, [5]Houston Methodist Research Institute, Houston, TX, [6]UT Health San Antonio, San Antonio, TX, [7]University of Pittsburgh School of Medicine, Pittsburgh, PA

Introduction: Microtubule-associated proteins (MAPs) regulate microtubule dynamics, which is critical for controlling cell division, proliferation, migration, and intracellular transport. Due to their critical role in maintaining cellular integrity, microtubules have served as potent therapeutic targets for cancer treatment. Here, we report “Matrin 3 (MATR3)” as a novel MAP that interacts with β- tubulin and γ-tubulin, which constitutes microtubule organizing center (MTOC) essential for proper spindle formation and chromosomal segregation.

Methods: Breast cancer cell lines (MDA-MB-231, MDA-MB-468, SKBR3, MCF7, BT549, HMEC, and MCF10A) were purchased from the American Type Culture Collection and cultured in standard medium. Breast cancer cells were transfected either with MATR3 overexpression plasmid or siRNA specific to MATR3. These overexpression/knockdown breast cancer cells were analyzed for cell viability, migration, invasion, colony formation, cell cycle, apoptosis assays, RNA sequencing, RT-qPCR, western blotting, RNA immunoprecipitation, and *in vivo* tumor xenograft study.

Results: Our findings show that MATR3 binds to RNA encoding MAPs including β-tubulin and γ-tubulin, and regulate their stabilization. MATR3 also interacted with β-tubulin protein. Our data demonstrate that MATR3 functions as a tumor suppressor, as its overexpression inhibits cancer growth, while its depletion increased tumor growth *in vivo*. Mechanistic studies confirmed that MATR3 mediates its tumor suppressor role by regulating the expression of the MTOC-associated protein-encoding gene MZT2B (Mitotic Spindle Organizing Protein 2B), which is overexpressed in cancers and promotes cancer growth. Further, loss of MATR3 expression or function results in dysregulated microtubule dynamics and uncontrolled expression of the oncogenic proteins including MZT2B.

Conclusions: In conclusion, our data strongly suggests that MATR3 serves as a novel RNA-binding protein with tumor suppressor properties. This discovery holds significant importance as MATR3 becomes the second protein, following Adenomatous Polyposis Coli (APC), to be identified for its binding to both MAP RNA and protein.

#0629 Activity of VIP943 on AML patient-derived leukemic blasts and healthy donor-derived bone marrow hematopoietic stem cells.

B. Stelte-Ludwig[1], T. Schomber[1], M. M. Frigault[2], J. Birkett[1], A. J. Johnson[2], A.-S. Rebstock[1], S. Ludwig[1], R. Izumi[2], A. Hamdy[2];
[1]Vincerx Pharma, Monheim, Germany, [2]Vincerx Pharma, Palo Alto, CA

Introduction: In patients with acute myeloid leukemia (AML), CD123 has been shown to have high expression on blast cells and leukemic stem cells (LSC) compared with normal hematopoietic stem cells (HSCs) and other more mature CD34+ subsets (Zhou J, World J Stem Cells 2014). LSCs are inherently resistant to standard of care chemotherapeutics and LSC persistence after chemotherapy is associated with disease relapse. VIP943 is an ADC consisting of an anti-CD123 antibody, a unique linker cleaved intracellularly by legumain which is required for release, and activation of a novel kinesin spindle protein inhibitor (KSPi) payload that accumulates inside the cell. Herein, we evaluated the potential of VIP943 to target LSC and progenitor cells.
Methods: Cytotoxicity assay: Bone marrow aspirates (BMA) and peripheral blood from previously untreated patients with primary or transformed from myelodysplastic syndrome AML were used in this experiment. Cells were treated with VIP943 (66 nM or 330 nM). After the end of the 48 h or 72 h incubation, the CD123+ cells and the CD34+CD38- LSC were detected by flow cytometry. Characterization of progenitor cell population: Fresh BM samples from healthy volunteers (HVBM) were stained with specific monoclonal antibodies to identify progenitor cell populations. Depletion assay: The effect of VIP943 on HVBM was evaluated by measuring the depletion of CD34+ progenitor cell populations in comparison to the anti-CD33-ADC, gemtuzumab ozogamicin (gem-oz). At the end of the incubation time, red blood cells were lysed; the remaining cells were stained with a cocktail of antibodies to discriminate between progenitor cells and analyzed by flow cytometry.
Results: Treatment of patient-derived CD123+ leukemic blasts with VIP943 resulted in a 50% reduction after 48 h and up to 80% at 72 h. A reduction of >70% of CD123+CD34+CD38- LSCs derived from BM aspirates of untreated patients with AML was achieved after incubation with VIP943 up to 72h. In addition, HVBM samples derived from five healthy volunteers were treated with VIP943 or gem-oz in a depletion assay, where gem-oz was toxic to CD34+ cells with an EC50 of 0.16 µM in contrast to VIP943 with an EC50 value of 8.83 µM.
Conclusions: In this in vitro analysis of primary samples from patients with AML, activity of VIP943 is observed in AML patient-derived CD123+ blasts as well as chemoresistant LSCs. At anticipated pharmacologic levels, VIP943 shows no adverse effects on HSCs unlike gem-oz suggesting an improved therapeutic index. In the ongoing first-in-human dose-escalation study in subjects with advanced CD123+ hematologic malignancies, VIP943 demonstrates a promising safety profile (NCT06034275).

#0630 The role of AKT pathway in β-catenin mutated hepatocellular carcinoma.

X. Wang, X. Chen;
University of Hawai'i Cancer Center, Honolulu, HI

The Wnt/β-catenin and PI3K/AKT pathways are pivotal contributors to the development of the malignant phenotype in cancer. The activated Wnt/β-catenin pathway synergizes with various signaling cascades to propel HCC formation, operating through its downstream effectors. It has been well-established that the mammalian target of rapamycin complex 2 (mTORC2) serves as an upstream regulator of AKT, orchestrating the phosphorylation and activation of AKT. Once activated, AKT phosphorylates and inhibits canonical downstream targets like forkhead box O protein (FOXO) and tuberous sclerosis complex 2 (TSC2). Studies indicated that AKT-mediated phosphorylation of TSC2 activates mTORC1, subsequently suppressing autophagy. However, there are limited data exist on the interplay between Wnt/β-catenin and AKT pathways in HCC. In this study, we sought to explore the role of the AKT pathway in β-catenin activated HCC tumors. Sleeping beauty-mediated hydrodynamic transfection was used to overexpress constitutively active forms of β-catenin (N90-β-catenin) and c-MET in the livers of mice to establish the HCC model (c-Met/β-catenin model). Notably, the knockout of Rictor, a component of the mTORC2 complex, significantly impeded tumor growth, underscoring the pivotal role of AKT in c-Met/β-catenin tumor development. AKT1 and AKT2 are the two main isoforms expressed in the liver. We determined that both AKT1 and AKT2 isoforms are critical for c-Met/β-catenin tumor growth. Intriguingly, simultaneous knockout of Rictor and activation of mTORC1 in the c-Met/β-catenin model resulted in delayed tumor growth, indicating that mTORC1 is not the sole downstream determinant of AKT signaling during c-Met/β-Catenin tumor development. Furthermore, overexpression of the activated FOXO1 (FOXO1AAA) significantly delayed the tumor growth, which highlighted the importance of FOXO1. Given the limited understanding of FOXO1 in HCC, we extended our investigation on FOXO1 to human HCC cell lines. Overexpression of FOXO1AAA notably delayed tumor growth *in vitro*. RNAseq analysis of FOXO1AAA-overexpressed human HCC cell lines revealed a significant upregulation of "metabolic pathways", suggesting metabolic reprogramming post FOXO1 activation. This study, for the first time, unveils the role of the AKT pathway in β-catenin-mutated HCC growth and highlights the potential therapeutic value of targeting the AKT pathway in patients with β-catenin-mutated HCC.

#0631 Functional genetics of APR-246 rescuable TP53 mutants.

Anais Saunders[1], Caili Tong[1], Anthony N. Karnezis[2], Gary S. Leiserowitz[3], Jeremy R. Chein[1]

[1]Biochemistry and Molecular Medicine, UC Davis School of Medicine, Sacramento, CA,[2]Pathology, UC Davis School of Medicine, Sacramento, CA,[3]Obstetrics and Gynecology, UC Davis School of Medicine, Sacramento, CA

TP53, often referred to as the guardian of the genome, encodes for the p53 tumor suppressor protein, and is one of the most frequently mutated genes in human cancers. Some cancer sub-types, such as non-small cell lung carcinoma (NSCLC) and high grade serous carcinoma (HGSC), have high *TP53* mutation rates reaching up to 56% and 96%, respectively. Given its multi-faceted role in human cancers, there have been several emerging therapeutic approaches targeting mutant p53. APR-246 is a small molecule drug currently in clinical trials for the functional rescue of p53 missense mutants, the most common type of p53 mutant protein, across various cancer types. APR-246 is proposed to bind mutant p53 and promote thermodynamic stabilization of the protein allowing it to regain wild-type-like conformation and consequentially regain WT-like functionality. However, there has yet to be a functional genomic screening of p53 mutants to systematically catalog which mutants are rescuable by APR-246. To address this critical gap, we have performed functional genetic screenings using a *TP53* mutagenesis library. This pooled lentiviral library contains ~8,000 amino acid variants, spanning the entirety of the *TP53* gene. Following stable transduction of this library into p53-null NSCLC and HGSOC cell lines, we performed functional screenings against sublethal doses of APR-246. Next-generation sequencing of the untreated and treated cell population allows for comparison of variant representation and determination of APR-246-sensitivity of p53 mutants. Preliminary statistical analysis of our screens has identified a pool of 117 “hit” mutants which are significantly depleted following treatment, indicative of APR-246-sensitivity. Two of these mutants, C242F and G266V, are non-functional, damaging mutations which occur in patients. Identifying p53 mutants that can be rescued by APR-246 will help identify which patients may benefit most from treatment with the drug.

#0632 AKT supports cancer cell survival through modulation of cholesterol homeostasis.

I. Vivanco[1], K. N. Myint[1], S. Wallace[1], G. Lazaro[2], E. Kostaras[2], N. Palaskas[3];

[1]King's College London, London, United Kingdom, [2]Institute of Cancer Research, London, United Kingdom, [3]University of California, Los Angeles, CA

AKT is a critical effector kinase downstream of PI3K activation. It has been shown to regulate a variety of cellular processes important for homeostasis, many of which are altered during oncogenesis. Not surprisingly, AKT is constitutively activated in a large number of human cancers, and has consequently been pursued as a therapeutic target for many years. Some of these functions are directly involved in establishing one or more hallmarks of cancer including sustained proliferative signaling, resisting cell death, and reprogrammed cellular metabolism. Although AKT inhibitors have demonstrated clinical benefit (most recently in a phase III trial) in combination with other therapies, single agent activity has been limited to a few cases with relatively infrequent activating AKT1 mutations. We have previously proposed that the clear disconnect between the high frequency of AKT activation in cancer and the lack of broad clinical activity of AKT inhibitors is due, at least in part, to the inability of existing compounds to block non-catalytic functions. We have found that while allosteric AKT inhibitors are partial suppressors of these functions, ATP-competitive inhibitors fail to suppress these functions to any significant extent. We now provide evidence that one important non-catalytic function of AKT that impinges on its oncogenic function is the regulation of cholesterol metabolism. We show that AKT represses the activation of LXRβ, thereby maintaining a level of intracellular cholesterol that is compatible with cancer cell viability, and that this repression does not require catalytic activity. Consistently, we find that allosteric AKT inhibitors induce LXRβ activation, and that genetic or pharmacological suppression of LXRβ function limit the growth inhibiting effects of these drugs. Our findings suggest that through a kinase-independent activity, AKT may play a significant role in the regulation of cholesterol homeostasis, and that the therapeutic potential of AKT inhibitors could be broaden by optimizing their ability to interfere with these functions.

#0633 Integrin αVβ3 activation by thyroid hormones triggers JAK/STAT oncogenic pathways that promote T cell lymphoma dissemination.

M. M. Debernardi[1], M. V. Revuelta[2], H. Sterle[1], G. Gonzalez[1], I. L. Souza[3], A. Correa[3], L. Cerchietti[2], G. Cremaschi[1], F. Cayrol[1];
[1]Instituto de Investigaciones Biomedicas (BIOMED-UCA-CONICET), Buenos Aires, Argentina, [2]Weill Cornell Medicine, New York, NY, [3]Instituto Carlos Chagas, Curitiba, Brazil

T cell lymphomas (TCL) are a heterogeneous group of lymphoproliferative disorders with poor prognosis. Aberrant activation of JAK/STAT pathway is associated with lymphoma dissemination in TCL patients. Although the FDA approved the use of inhibitors to target this pathway (Ruxolitinib), significant toxic effects have been reported and their use is limited. Thus making an excellent opportunity to study biological factors that regulate the activation of these pathways. In this sense, we recently showed that thyroid hormones (THs) acting through integrin αVβ3 induced TCL proliferation, which is reduced *in vitro* and *in vivo* in the presence of integrin αVβ3 pharmacological inhibitor. Our aim is to evaluate the impact of THs on JAK/STAT pathway activation and their implications on anti-lymphoma therapy. For the *in vitro* assays we used human and murine TCL cell lines. We used EL4 cells and c57bl/6 syngeneic mice for *in vivo* analysis. Proteomic profiles were evaluated by LC-MS-MS analysis. The GSE58445 database was used for *in silico* analysis. We found that THs induced STAT1, 3 and 5 phosphorylation in TCL cells and that the integrin αVβ3 inhibitor, Cilengitide (Cile) blunted these effects ($p<0.05$). Interestingly, we found that high mRNA expression levels of integrin β3 significantly correlate with worse overall survival in a cohort of TCL patients ($p<0.05$). Additionally, Ruxolitinib (Ruxo) diminished THs-induced STATs phosphorylation ($p<0.05$). As Ruxo reported toxic effects we aim to study alternative therapies such as Bexarotene (Bex), a synthetic retinoid used for cutaneous LCT treatment. We found that Bex significantly reduced cell viability *in vitro* of all TCL subtypes analyzed and combination with Cile resulted in improved anti-lymphoma activity ($p<0.01$). Also, Ruxo significantly decreased TCL cell viability but to a lesser extent than Bex+Cile ($p<0.05$). We previously found that BexT4+Cile (T4+, thyroxine supplementation) significantly decreases the *in vivo* growth of TCL tumors. To understand the mechanisms under this effects we analyzed tumor proteomics profiles and metalloprotease activity after 12 days of treatment. We found that BexT4+Cile regulates proteomic profiles related not only to lymphoma progression (JAK/STAT and PI3K-Akt signaling) but also pathways that impact the tumor microenvironment (TNF and angiogenic factors secretion and Th1/Th2 T cell differentiation). Regarding metalloprotease activity, we found that BexT+Cile inhibited MMP2 and MMP9 activity ($p<0.05$). Finally, we evaluated the dissemination of TCL in an *in vivo* model (by vain tail) and found that BexT4+Cile reduced EL4 cell implantation into the liver and kidneys ($p<0.05$). These results described the mechanisms by which THs induce the activation of JAK/STAT oncogenic pathway and showed how the inhibition of integrin αvβ3 in combination with bexarotene has therapeutic potential for TCL.

#0634 Tuba-seq and CRISPR/Cas9 analysis of TBX2 subfamily genes: Exploring contextual tumor suppression in lung adenocarcinoma.

A. Khalil, J. Maltas, M. Rahm, Z. Faber, M. Bedrock, X. Wei, B. Patel, C. McFarland;
Case Western Reserve University School of Medicine, Cleveland Heights, OH

Lung adenocarcinoma (LUAD) is a multifaceted and genetically diverse cancer, shaped by a myriad of oncogenic and tumor suppressive events. Through recent clinical and *in vitro* investigations, we have discovered that the TBX2 subfamily of genes, encompassing TBX2, TBX3, TBX4, and TBX5, are linked to LUAD progression. Specifically, we have observed marked downregulation of their expression in clinical LUAD specimens, and reduced growth in LUAD cell lines when the subfamily is re-activated- hinting at a potential tumor suppressive function. Paradoxically, the role of TBX2 subfamily genes in other cancer types remains enigmatic, with varying reports of both oncogenic and tumor suppressive effects. In this study, we harnessed the power of Tumor Barcoding with Ultradeep Barcode Sequencing technology (Tuba-seq) and CRISPR/Cas9-mediated genome editing to systematically investigate the effects of knocking-out Tbx genes and associated partners EGR1, CHD2, A20 and ATF3 in LUAD preclinical models. We investigated their effects in both normal lung epithelium and Ras-driven lung tumors via *in situ* gene editing and assessed tumor burden via histology and targeted DNA sequencing of tumor barcodes. TBX2 subfamily gene losses appear to have a profound effect on tumor initiation and early growth, which somewhat attenuates with progression. In Ras-driven tumors, we found that these genes are moderately tumor suppressive when measuring mean growth rate, although these effects (sans Egr1 loss) are more pronounced at 6 weeks of growth than at 20 weeks. Strikingly, however, we observed an unprecedented increase in total tumor burden when deleting these genes in genomically-normal (Kras w.t.) cells, including 4-20+ fold increase in Tbx2, Tbx3, Tbx4, and Tnfaip3-deficient cell lineages 20-week following transduction. Increases in total lineage burden of this magnitude are typically only seen for frequently-deleted hallmark tumor suppressor genes such as Tp53, Stk11, or Pten. This increased burden, however, seems to primarily affect early-stage progression, as no appreciable increases in mean lineage size relative to w.t. lineages are observed after 40 weeks of growth. Our study reveals the context-specific functions of the TBX2 subfamily while introducing the first *in vivo* model for TBX2-driven LUADs. This model facilitates the development of targeted therapeutic strategies and encourages accurate tumor modeling across various progression stages and diverse genetic backgrounds.

#0635 Osteoclasts mediate chemotherapy resistance in a fully humanized microphysiologic system of prostate cancer bone metastases.

A. B. Ding[1], E. Heninger[1], S. R. Reese[1], C. Sanchez-de-Diego[1], R. C. Yada[1], N. Sethakorn[2], S. C. Kerr[1], X. T. Hazelberg[1], M. N. Sharifi[1], D. J. Beebe[1], J. M. Lang[1];

[1]University of Wisconsin - Madison, Madison, WI, [2]Loyola University Chicago, Chicago, IL

Bone metastases (BM) are the most common sites of metastases in prostate cancer, occurring in ~85% of patients. Overall survival of men with castrate resistant prostate cancer with BM is less than 24 months. Docetaxel is the most commonly used therapy for patients with prostate cancer, but the response rate is only 30-40% and median duration of response is less than 9 months. Non-tumor components of the Tumor Microenvironment (TME) have been proposed to mediate treatment resistance, but few pre-clinical models capture the complex physiology of the human bone TME. We report the development of a bone TME using a humanized microphysiologic system to address this need. The LumeNEXT platform is a microphysiologic system that allows the 3-dimensional (3D) reconstitution and integrated analysis of a bone-specific TME microenvironment with functional microvasculature that traverses the chip and can be used to mimic drug delivery in patients. Primary human osteoclasts (OC) were differentiated from patient peripheral blood monocytes. LNCaP prostate cancer spheroids were grown in hanging droplets. We performed co-culture of OCs with 3D LNCaP spheroids and evaluated the efficacy of docetaxel-induced tumor cell killing in the presence of bone cells. OCs and PC spheroids were seeded into LumeNEXT devices in a collagen-based matrix and treated with 20 nM Docetaxel or DMSO vehicle for 48 hours. Docetaxel response was assessed using confocal microscopy for single spheroid diameter and cytotoxicity was measured using fluorescent cell death markers. Docetaxel-mediated killing of tumor spheroids was found to be significantly attenuated in the presence of OCs. In LNCaP only conditions, average Docetaxel-mediated cell death was 68.82%, compared to 53.86% in the LNCaP and OC co-culture condition ($p<0.0001$). Furthermore, Docetaxel treatment resulted in reduced tumor spheroid diameter compared to DMSO control when prostate cancer spheroids were cultured alone ($p=0.0118$). Additionally, the presence of OCs attenuated Docetaxel-induced morphological changes. Our data suggest that osteoclasts play a significant role in mediating chemotherapy response in prostate cancer. Future studies will examine transcriptional changes in prostate cancer cells that may be associated with Docetaxel resistance in the bone microenvironment and identify mechanisms of BM microenvironment-mediated drug resistance. Bioinformatic analysis of patient sequencing datasets is ongoing to identify osteoclast-associated signatures of treatment resistance.

#0636 Coculture model for investigating cellular interactions between colorectal tumor organoids and cancer-associated fibroblasts.

Y. Zhou[1], Y.-K. Huang[1], E. J. Fong[1], E. Elton[1], E. McManus[2], B. Choi[2], S. Kim[1], S. M. Mumenthaler[2];
[1]Ellison Institute, LLC, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA

The tumor microenvironment (TME) is well recognized for its role in tumor progression, chemoresistance, and recurrence. The TME consists of various components, such as extracellular matrix (ECM), chemical and mechanical cues, as well as stromal cells and their interactions. As the most abundant cells in tumor stroma, cancer-associated fibroblasts (CAFs) have drawn a lot of attention. It has been reported that CAFs not only directly interact with cancer cells via surface proteins and cytokines, but also influence their behaviors by remodeling the ECM. However, due to their heterogenous characteristics and diverse functions, the influence of tumor-CAF interactions on drug response is not fully understood. Here, we present a coculture model for investigating CAF effects on patient-derived colorectal tumor organoids (CTOs) growth, differentiation, and drug response. It consists of normal colon fibroblasts, CCD18-Co, or patient-derived CAFs seeded with CTOs in a mixed hydrogel containing 90% basement membrane extract (BME) and 10% collagen type I. Media conditions were optimized (1:1 mix of CTO culture media plus reduced media excluding growth factors and inhibitors) to achieve similar organoid sizes in the monoculture and coculture conditions at the onset of drug testing. To support higher throughput investigations, our workflow incorporates a liquid handler for automated CTO seeding, media and drug exchange, and an automated microscope with a robotic arm for multi-plate imaging. Briefly, single cell CTOs and fibroblasts were seeded at a 1:1 ratio (3000 total cells/well) in 96-well plates. After 4 days in culture, anti-cancer drugs were administrated in reduced media to the samples. Brightfield images were acquired on days 0, 3, and 5 after drug administration. The collected images were analyzed with a neural network (NN) to dynamically monitor the growth and viability of individual organoids. The CellTiter-Glo assay was performed on day 5 to quantify the total CTO cell viability. The normalized drug response (NDR) was calculated from the NN processed images to determine the drug response. An immunostaining panel, which includes protein markers such as CK20, Ki67, α-SMA, Vimentin, and FAP, was used to evaluate the fibroblast phenotypes and CTO differentiation. Additionally, the cultures were subjected to fluorescent lifetime imaging microscopy (FLIM), a label-free imaging technique, to measure the metabolic adaptations of each cell population. Preliminary studies revealed a CAF-dependent increase in CTO growth and glycolytic signatures in the co-culture setting; however, minimal effects on drug response to common chemotherapy agents such as 5-fluorouracil and irinotecan were observed. In the future, we will use this integrated pipeline as a screening method to identify new treatment strategies aimed at targeting the stromal microenvironment in colorectal cancer.

#0638 FGFR4 mediates nuclear accumulation of NRF2 by binding to P62 in gastric cancer.

N. S. Bhat[1], M. Soutto[1], X. Zhang[2], Z. Chen[1], S. Zhu[1], S. Maacha[1], M. Genoula[1], D. Peng[1], H. Lu[1], O. McDonald[1], X. Chen[1], L. Cao[1], Z. Xu[1], W. El-Rifai[1]; [1]University of Miami, Miami, FL, [2]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Helicobacter pylori (H. pylori) is the major cause of gastric cancer. Fibroblast growth factor receptor 4 (FGFR4) is a member of the highly conserved tyrosine kinase family known to be activated in cancer. Nuclear Factor Erythroid 2-Related Factor 2 (NRF2), a transcription factor, is essential for the antioxidant response and exhibits cytoprotective properties against cellular stress and oxidative damage. This study investigates the novel functions of FGFR4 and its role in regulating the antioxidant response in gastric tumorigenesis.

Methods: We used public datasets, gastric tissues from mice and human, and gastric cancer cell lines. In vitro and in vivo H. pylori infections were performed. Western blot, RT-qPCR, Immunofluorescence, flow cytometry, Immunohistochemistry, Immunoprecipitation, Proximity ligation assay and Luciferase reporter assays were performed.

Results: The analysis of a public dataset revealed that overexpression of FGFR4 is associated with an oxidative stress signature and poor survival. Gene set enrichment analysis (GSEA) showed that tissue samples with high FGFR4 levels had an enrichment of NRF2 signature genes. In vitro cell models infected with H. pylori showed an increase in reactive oxygen species (ROS). Knockdown of FGFR4 resulted in significant reductions in NRF2 protein and transcriptional activity, leading to increased ROS levels and DNA damage. Immunofluorescence analysis using various models confirmed that FGFR4 knockdown reversed the accumulation of NRF2 in the nucleus. Dysplastic and neoplastic gastric lesions in the TFF1-KO mouse model exhibited high levels of both FGFR4 and NRF2. Pharmacologic inhibition or knockdown of FGFR4 significantly decreased NRF2 levels, as well as the size and number of gastric cancer spheroids. Mechanistically, elevated levels of P62 protein were associated with FGFR4 expression. Binding between FGFR4 and P62 proteins, which competes with NRF2-KEAP1 interaction, was detected using immunoprecipitation and proximity ligation assay. Immunohistochemistry analysis on a tissue microarray showed increased FGFR4 immunostaining in HGD/Cancer samples compared to adjacent normal samples, and this increase correlated with an increase in NRF2 and P62 levels.

Conclusion: These findings revealed that FGFR4 has a distinct functional role in promoting gastric carcinogenesis. FGFR4 binds to P62 to inhibit the interaction between NRF2 and KEAP1, allowing NRF2 to avoid degradation facilitating its translocation and accumulation in the nucleus. The use of FGFR4 inhibitors is a viable treatment option that warrants further research in patients with gastric cancer.

#0639 Evaluation of individual drug response in tumor microenvironment to cisplatin treatment in precision-cut tumor slices of ovarian cancer.

J. Thiel[1], A. Kneer[2], W. Yu[3], B. Winkler[2], G. Sauer[2], G. Ott[2], W. Aulitzky[2], T. Murdter[1], M. Schwab[1], C. Liang[3], M. Dong[1];
[1]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, Germany, [2]Robert Bosch Hospital, Stuttgart, Germany, [3]University of Wurzburg, Wurzburg, Germany

Ovarian cancer is a complex and heterogeneous disease and the major cause of death among women with gynecological cancers. While patients usually respond well to the platinum-based first-line chemotherapy, the disease often becomes increasingly resistant to the treatment. The tumor microenvironment (TME) plays an important role in tumor development and drug resistance. Characterizing the TME of ovarian cancer after drug treatment is essential to identify molecular mechanisms that allow residual tumor cells to survive chemotherapy in ovarian cancer. We have established a preclinical model using precision-cut tumor slices (PCTS) with 250 µm thickness which preserves the TME of solid tumors with their heterogeneous cell composition during cultivation. The tumor morphology, viability and heterogeneity in terms of tumor and stromal cells as well as the immune compartment are preserved within the system. Based on the PCTS model, we also established a method to perform single-cell RNA sequencing (scRNA-seq) of the PCTS after cultivation and drug treatment to characterize the cellular features and dynamic relationships of different cell populations in the TME after drug treatment. Over 20 cell subtypes including different clusters of epithelial cells, immune cells and fibroblasts can be identified in PCTS after cisplatin treatment through the scRNA-seq analysis. This enables further deeper analysis of each cell subgroup in the TME after drug treatment. In response to cisplatin treatment, patients PCTS showed an individual induction of PD-L1 in different cell types. Additionally, multiplex immunofluorescence (mIF) stainings of the PCTS were performed to spatially trace the response of the TME to drug treatment. The mIF staining allows the simultaneous detection of up to 6 different markers on one FFPE tissue section. Images were analyzed using a machine-learning based workflow, which allows the comparison of biomarker expression and immune cell spatial distribution in the PCTS stromal and tumor areas before and after treatment. Combining the PCTS as a preclinical model with scRNA-seq and mIF staining analysis allows us to bridge the cellular characteristics and cellular spatial distribution with treatment response in the TME of solid tumors. It enables the systematic analysis of residual cancer populations after cisplatin treatment within the complex TME and further identification of predictive markers and targets for an individualized combination of chemotherapy with compounds targeting these mechanisms. The individual drug response of patients can be deeply evaluated and efficacious therapies can be further developed.

#0640 *In vivo* rescue of p53 tumor suppressor function with ADGN-531 across Pan-p53 alterations.

G. Divita[1], A. Grunenberger[2], E. Czuba[2], V. Josserand[3], M. Guidetti[3], N. Desai[1];
[1]AADIGEN, Pacific Palisades, CA, [2]DIVINCELL, Nimes, France, [3]IAB, Grenoble, France

p53 tumor suppressor mutations result in loss of function of p53 in approximately 50% of all human cancers.TP53 missense, nonsense mutations and p53 deletion are present in about 50%, 12% and 5% of all p53 driven cancers, respectively. To date there is no effective treatment for rescuing p53 function in cancers using a pan-p53 approach. The use of ADGN-531 is a new potent strategy combining mRNA with a tumor selective peptide nanocarrier to rescue of p53 tumor suppressor function.

ADGN-531 contains proprietary p53-mRNA complexed with proprietary short amphipathic peptides in the form of nanoparticles. ADGN-531 was evaluated on 20 different cancer cell lines harboring various p53 mutations. In-vivo efficacy of IV-administered ADGN-531 nanoparticles was evaluated on colorectal SW403 (p53 nonsense/KRAS^{G12V}), osteosarcoma SaOs2 (p53 null) and NSCLC NCI-H358 (p53 null/KRAS^{G12C}) mouse xenografts at a dose of 0.25-1.0 mg/kg weekly. ADGN-531/sotorasib synergy was evaluated *in vitro* on NCI-H358 (p53 null/KRAS^{G12C}) and Mia-PACA (p53^{R48W}/KRAS^{G12C}) cells and in vivo on NCI-H358 mouse xenograft. ADGN-531 markedly inhibits the growth of a large panel of cancer cells harboring p53-missense or nonsense mutations or p53-deletion, by rescuing p53 transcriptional activity and subsequent expression of its target proteins.

ADGN-531 induces cell cycle arrest in G1 due to p21 upregulation and apoptosis following BAX and PUMA activation. IV-administration of ADGN-531 resulted in dose responsive tumor growth inhibition in SaOs2, SW403 and H358 xenografts independent of KRAS status. We demonstrated a strong synergy in a NSCLC H358 xenograft (tumor regression 80%) when restoring P53 function with ADGN-531 (0.5mg/kg, weekly) along with inhibition of KRAS^{G12C} mutant using sotorasib (10mg/kg, daily). ADGN-531 potentiated the effect of sotorasib on sotorasib resistant cells harboring high level of KRAS^{G12C} in permanent active state. ADGN-531 treatments are well tolerated, no sign of clinical toxicity was detected after single or repeated administrations.

ADGN-531 is effective in rescuing p53 function both in vitro and in vivo across a wide range of p53 alterations. Our study provides a proof-of-concept that restoration of tumor suppressor function by ADGN-531 could be used as a single agent therapy in P53 altered tumors independent of other driver mutations e.g., KRAS, or with other therapies for potent combinatorial cancer treatment.

#0641 *SCD1* upregulation due to *STK11/KEAP1* loss upregulates *SLC7A11* and causes deregulation of fatty acid metabolism leading to ferroptosis evasion.

U. Sen, C. Coleman, D. Hasson, T. Sen;
Icahn School of Medicine at Mount Sinai, New York, NY

Introduction: Non-small cell lung cancer (NSCLC) with co-occurring loss-of-function (LOF) mutations in serine/threonine kinase 11 (*STK11*) and Kelch-like ECH-associated protein1 (*KEAP1*) (*SK*) are notably aggressive and unresponsive to chemo and immunotherapy, in current care standards. Novel therapeutic strategies are in demand to improve the outcomes for *SK* co-mutant NSCLC patients. We reported earlier that *SK* LOF mutations enhance cell proliferation and tumor growth in xenograft lung cancer models. We also found the ferroptosis evasion genes are enriched, and targeting ferroptosis regulators is a therapeutic opportunity in *SK* co-mutant NSCLC.

Methods: We used CRISPR/Cas9 gene editing to create stable knockouts of *STK11* (S^{KO}), *KEAP1* (K^{KO}) or both (DKO), non-targeting control (NTC) in two NSCLC lines. We performed an *in vitro* druggable genome library CRISPR screening in the same NSCLC lines. We performed kinase profiling and RNA-seq in the cell lines to depict the transcriptomic and proteomic landscape, followed by western blotting and qRT-PCR validation. We also performed BODIPY/C11 assay and lipidomics to explore the ferroptosis and metabolic landscape of *SK* co-mutant NSCLC models.

Results: Stearoyl CoA desaturase-1 (*SCD1*) was the top CRISPR screen hit, a critical modulator of fatty acid metabolism and ferroptosis evasion. *SCD1* expression is significantly higher in NSCLC tissue than adjacent normal tissue ($p<0.0001$), and high *SCD1* expression correlates with poorer prognosis in patients with NSCLC ($p=0.027$). GSEA from the bulk RNA sequencing in *SK* co-mutant cells pre-and post-*SCD1* inhibitor treatment showed *SCD1* inhibition leads to upregulation of the glutathione and glutamic acid pathways compared to NTC cells. Moreover, *SK* co-mutant cells have a significantly higher expression of *SLC7A11, enabling* cystine uptake and subsequent conversion to cysteine, essential for maintaining redox balance and cell survival. Hence, *SK* co-mutant cells are more resistant to cysteine depletion than NTC cells. *SCD1* inhibition causes a decrease in *SLC7A11* expression exclusively in DKO cells. Eventually, *SCD1* inhibition leads to global metabolomic changes in *SK* co-mutant cells, including key pathways involved in lipid and glucose metabolism. Finally, genetic and pharmacological inhibition of *SCD1* prevents tumor growth and sensitizes DKO cells to ferroptosis inducers like erastin.

Conclusions: Our findings highlight the importance of the *SCD1-SLC7A11* axis in regulating ferroptosis in *SK* co-mutant models. Current data impact our understanding of ferroptosis in NSCLC and its ability to target *SCD1* or ferroptosis in cancer treatment. Compounds such as inhibitors of *SLC7A11* (Erastin/IKE) are safe to use with acceptable toxicity and established doses. Hence, our study will facilitate the translation of ferroptosis inducers or *SCD1* inhibitors in clinical trials.

#0642 Flavopiridol inhibits cell proliferation, migration, and invasion via downregulation of FOXM1 in triple negative breast cancer.

S. Dilmac[1], N. Kahraman[1], F. Onder[2], Z. Hamurcu[3], B. Ozpolat[1];

[1]Houston Methodist Research Institute, Houston, TX, [2]Canakkale Onsekiz Mart University, Faculty of Medicine, Canakkale, Turkey, [3]Erciyes University, Faculty of Medicine, Kayseri, Turkey

Triple-negative breast cancer (TNBC) represent 15-20% of all breast cancers and is the subtype of breast cancer that is not responsive to targeted breast cancer treatments such as anti-estrogens (tamoxifen) or HER2 targeted antibodies due to the lack of ER, PR, and HER2 receptors. TNBC is associated with poor prognosis, early relapse, and distant metastasis and drug resistance. With the use of standard chemotherapeutics in the neoadjuvant setting, unfortunately the majority of patients (~60%) with TNBC do not achieve complete remission and 40% of the patients with regional (Stage II) and 90% of the patients with distant metastasis (Stage IV) die within 5-years. Currently, there is no effective targeted therapy for TNBC patients for targeting oncogenic pathways. Although recently the FDA approved sacituzumab (govitecan), a Trop-2-receptor directed antibody conjugated with chemotherapeutic agent topoisomerase inhibitor in metastatic TNBC, and response rate was 30% and the median duration of response is 7.7 months, and the majority of patients did not maintain response longer than 12 months. Therefore, identifying novel molecular targets and developing alternative therapeutic strategies are urgently needed. FOXM1 is a protooncogenic transcription factor suppressed by p53 and drives expression of genes, which play a crucial role in promoting cancer cell proliferation, metastasis, progression, tumorigenesis of TNBC. We previously demonstrated for the first time that *in vivo* targeting of FOXM1 suppresses TNBC tumor growth in mice. Here, analyzing TCGA patient database we found that FOXM1 expression correlates with shorter patient survival and prognosis in TNBC patients. Overall data suggest that FOXM1 is a potential molecular target. However, currently, there is no FDA approved inhibitor of FOXM1. To identify potential inhibitors, utilizing silico docking and molecular dynamics studies we screened the FDA-approved compounds found that flavopiridol interacts with FOXM1. Flavopiridol is a small molecule inhibitor for CDKs and is approved by the FDA for the treatment of Acute Myeloid Leukemia. We demonstrated that flavodilol inhibits FOXM1 expression at nanomolar concentration and cell proliferation, migration, invasion, and induces apoptosis in TNBC cells. We are currently testing favopridol in MDA-MB-231 (human) and 4T1 mouse mammary) TNBC tumor models. In conclusion, our studies suggest that flavopiridol is a highly potent FOXM1 inhibitor and is a promising agent for repurposing to target FOXM1 and for the treatment of TNBC.

#0643 Analysis of the effect of FGFR inhibitor and cannabidiol in colorectal cancer.

Y. Ju[1], W. Kim[1], B. Kim[2], J. Kim[1], J. Bong[1], C. Cheong[1], S. Kang[1], B. Min[1], S. Oh[2], S. Lee[1];

[1]Division Of Colon And Rectal Surgery, Department of Surgery, Korea University Guro Hospital, Korea University College of Medicine, Seoul, Korea, Republic of, [2]Division of Oncology, Department of Internal Medicine, Korea University Guro Hospital, Korea University College of Medicinel, Seoul, Korea, Republic of

Introduction: Colorectal cancer (CRC) remains a serious health problem worldwide. In particular, in the case of stage 4 metastatic cancer, a cure can be expected as multidisciplinary treatment is possible by combining surgery, chemotherapy, and the development of targeted anticancer drugs, but there is still no type of treatment available. It is limited. FGFR (Fibroblast Growth Factor Receptor) has emerged as an important anticancer target in various malignant tumors, and small molecule-based targeted treatments have been developed and clinical trials are underway, and some colon cancer patients are known to have FGFR genetic alterations. Cannabidiol (CBD), a non-psychoactive cannabinoid, has recently been reported to be associated with the ability to induce cell death through various signaling systems in colon cancer, and has anticancer effects and mechanisms related to overcoming anticancer drug resistance. has been identified. Therefore, we sought to analyze the effect of FGFR inhibitors on colon cancer, explore the possibility of developing them as new target substances, and find ways to increase anticancer effects by confirming the effects of combination with cannabidiol (CBD) and related mechanisms.
Method: Cell survival was confirmed through the WST-1 assay, an assay for measuring cell viability. The signaling pathway was identified through western blot. Data were compared using two-tailed Student's t-test or one-way analysis of variance and Tukey's post hoc test.
Result: The FGFR expression pattern was confirmed in various cancer cell lines, and NCI-H716 was confirmed to have high FGFR2 expression in the colorectal cancer cell line. (Figure 1) As a result of treating CBD 4uM and AZD 10nM (Cell proliferation, apoptosis, western blot), cell death occurred more clearly when treated together than when treated alone, confirming the effectiveness of the combination. (Figure 2) An increase in apoptosis of NCI-H716 cells was confirmed when CBD and AZD 4547 were combined. (Figure 3)
Through a heatmap of differentially expressed genes in RNA sequencing, it was estimated that ER stress may be related to the combination effect. (Figure 4)
The relationship between ER stress and the combination of CBD and AZD 4547 on apoptosis of NCI-H716 cells was confirmed. (Figure 5)
Conclusion: It was confirmed that the combined effect of FGFR inhibitor and cannabidiol was effective in colorectal cancer cells, and it was assumed to be related to the ER stress pathway.

#0644 PKC-iota specific inhibitor ICA-1S causes the degradation of mutant p53 in ovarian cancer cell lines.

M. Marzan, N. Oishee, **A. Olatunji**, M. Acevedo-Duncan;
University of South Florida, Tampa, FL

Ovarian cancer is the most lethal malignant disease of female. Treatment options for ovarian cancer are mostly the use of chemotherapeutics, surgery, or radiotherapy. However, due to resistance to drugs, relapse occurs and thus 5 years survival rate is only 47%. The tumor suppressor protein p53 works as a transcription factor to transcribe several proteins such as p21, p16 and PUMA that lead to halt cell cycle and also induce apoptosis when there is a damage in DNA. Mutation in several regions of p53 (mutp53) is quite common in cancers and can lead to the accumulation of p53 with loss of functions or sometimes gain of oncogenic functions. Thus there is a search for drugs that can degrade the mut53 and can restore the functions of normal p53. In this research, it was observed that the treatment of ovarian cancer cell lines (ES-2, HEY and OVCAR3) with atypical protein kinase C-iota (aPKCι) specific inhibitors ICA-1S can cause the degradation of mutp53 (53.6%, N=6 trials). Treatment with ICA-1S also lowered the level of phosphorylated p53 (ser15, 87%, N=3 trials). However, the level of MDM2 protein (murine double minute 2), a known p53 E3 ligase was not significantly (98%, N=2 trials) affected by ICA-1S in ES-2 cell line with mut p53 as well as p21 was also not affected. However level of PUMA was decreased both in ES-2 and HEY cell lines. Immunoprecipitation (IP) with aPKCι specific beads showed the aPKCι is associated with p53, though reverse IP with p53 beads was not able to show the association. Application of proteasome inhibitor MG-132 at a single dose of 0.5μM could not completely inhibit the degradation of mut53 and WTp53 in ICA-1S treated ES-2 cell line and HEY cell line, respectively, indicating the drug may be affecting the transcription of p53 as well. It is therefore postulated that aPKCι can phosphorylate p53, stabilizing it and may be affecting the transcription of p53 as well in those cell lines. Further research (kinase activity assay, immunoprecipitation, immunofluorescence) is going on to reveal the mode of this degradation.

#0645 A systems biology approach uncovers the anticancer mechanisms of curcumin.

A. Aggarwal[1], J. H. Law[2], C. Lo[3], **K. W. Yip**[1];
[1]University of Toronto, Anticancer.ca, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Anticancer.ca, Toronto, ON, Canada

Introduction: Curcumin, the active ingredient of turmeric, generates reactive oxygen species, increases p53 expression, inhibits NF□B signaling, and can induce apoptosis. Despite these potential anticancer effects, there has not yet been a systematic analysis of the effects of curcumin on a large panel of cancer cell lines. We hypothesized that curcumin has differential effects based on the specific cell line and its tissue of origin. This study assessed curcumin's anticancer properties via cell survival assays and gene expression analyses.

Methods: Cell survival assays were performed by the CTD[2] Centre at the Broad Institute. 860 human cancer cell lines were seeded into 1536-well plates, and 24 hours after plating, either DMSO control or curcumin was added to the wells at 16 different concentrations by serial dilution. 72 hours later, cellular ATP levels were measured with CellTiter-Glo as an indication of cell survival. For gene expression analysis, the L1000 assay from the Broad Institute was used. 9 core cell lines were treated with 10 μM of curcumin in 384-well plates. After 6 and 24 hours of incubation, a gene expression signature was identified with the Affymetrix GeneChip HG-U133 Plus 2.0 Array. This signature was compared against signatures from other small molecule and genetic perturbations contained in the CMap database. Afterwards, connectivity scores (incorporating an enrichment score, nominal p-value, and false discovery rate) were used to rank the L1000 signatures by similarity to the signature induced by curcumin.

Results: Curcumin was most potent against SEM (IC_{50} = 1.00 μM; B-acute lymphoblastic leukemia), RPMI-8226 (IC_{50}= 1.62 μM; myeloma), and SCC-4 (IC_{50} = 1.81 μM; squamous cell carcinoma) cell lines. Lymphoid and peripheral nervous system cancers were generally the most sensitive to curcumin, whereas prostate cancers were the least sensitive. Curcumin-induced gene expression changes resembled GPR87 and PRKRA knockdowns, which are associated with reductions in cancer cell survival, chemoresistance, and proliferation in various cancer cell lines. However, these transcriptomic changes also resembled CERS2 downregulation, which is associated with increased cell migration. *In vitro*, curcumin treatment mimicked 2',5'-dideoxyadenosine, BMS-299897, and eudesmic acid administration.

Conclusion: Curcumin induces changes in cell survival and gene expression that support its anticancer properties in a variety of cancer cell lines. However, separating these effects from CERS2 downregulation may be an important component of future translational research for curcumin and its analogs.

#0646 Proteome wide target deconvolution of pharmacologically active natural products by CETSA® coupled to mass spectrometry.

Tomas Friman, Tuomas Tolvanen, Erin Gilson, Alexey Chernobrovkin, Stina Lundgren, Victoria Brehmer, Daniel Martinez Molina

Pelago Bioscience AB, Solna, Sweden

Nature has provided a large plethora of different molecules that in the hands of man has been ascribed to a vast range of pharmacological actions. In some cases, pharmacology is clearly connected to a phenotype e.g., Golgi apparatus dissolution by Brefeldin A, whereas in other cases the proposed phenotypes are many and disparate e.g., Quercetin. Many claims are made around natural compounds as having various positive therapeutic effects on cancer e.g., curcumin and quercetin. Intriguingly, claims about therapeutic effects of various natural compounds keep on surfacing, and we wanted to address this issue by performing target deconvolution of a selection of natural compounds in Hepatic cancer cells: HepG2. We took advantage of the CETSA® (CEllular Thermal Shift Assay) method coupled to Mass spectrometry detection in order to deconvolute the mode of action of seven highly cited natural compounds that comprised both well annotated compounds with an established mode of action: Brefeldin A and Wortmannin; and compounds with a less well established mode of action: Carnosol, Curcumin, Resveratrol, Rhoifolin, and Quercetin. CETSA is a method that allows detection of compound-induced thermal shifts of proteins in intact living cells as well as in cell lysates. Subsequently, a thermal shift of a protein in the presence of a compound then implicates a direct or in the case of intact cells, also an indirect interaction between the protein in question and compound. As CETSA can be performed in intact living cells we could detect proteins that were potential direct binders as well as proteins that were part of the downstream signaling events or part of the phenotypic response. The Natural compounds were assessed in a screening format in which three bio-replicates were analyzed at a single concentration, 30 µM. Good proteome coverage was obtained in the HepG2 cells and all compounds tested induced thermal shifts of proteins at 30 µM. Most of the compounds displayed many protein shifts of both suggested direct targets and proteins presumed to be part of a phenotypic response, as well as novel targets/off-targets. Curcumin and Rhoifolin were the exceptions, which only had a few shifted proteins. Brefeldin A, Quercetin, and Wortmannin engaged proteins associated to their annotated mode of action pathways, whereas Carnosol, Curcumin, and Resveratrol was less specific in their responses with regards to shifted proteins i.e., no clear signaling pathway was determined. In this study we use CETSA coupled to MS detection to delineate mode of action of natural compounds, which shed light on why they could be implicated to have a role in tumor biology. We also found that compounds with a well-established mode of action give a clearer target engagement profile compared to less annotated compounds.

#0647 FDA approved library screen revealed Ewing and clear cell sarcomas have increased sensitivity to filanesib over other cancer types.

H. L. Walker-Mimms, N. Londono, Y. Liao, N. Chaudhary, D. Pena Gomez, Y. Zhang, M. Teng, U. Rix, D. R. Duckett;
Moffitt Cancer Center, Tampa, FL

There is a compelling need for the development of more effective and less toxic therapies for patients with Ewing Sarcoma (ES) and Clear Cell Sarcoma (CCS). ES and CCS are characterized by chromosomal translocations which result in two distinct fusion proteins: EWS-ATF1 (t(12;22)(q13;q12)) in CCS and EWS-FLI1 (t(11;22)(q24;q12)) in ES. There is a strong premise that targeting the fusion proteins or their key downstream signaling pathways will be disease modifying and improve outcomes for patients. Preliminary high throughput screening studies using an FDA approved small molecule compound library identified filanesib, a kinesin spindle protein (KIF11) inhibitor, as having potent anti-proliferative activity in ES and CCS cells over other cancer subtypes. The mechanism linking the fusion proteins with KIF11 and the tumorigenic role of KIF11 in ES and CCS has yet to be described. Previous studies have shown that the EWS-ATF1 fusion protein forms a heterodimer with transcription factors to target the promoters of its downstream genes. In breast cancer, the knockdown of KIF11 has been shown to significantly reduce the phosphorylation of these transcription factors. Additionally, KIF11 has been shown to directly interact with p300/CBP-associated factor (PCAF), a histone acetyltransferase (HAT). HATs are necessary for EWS-FLI1-induced chromatin remodeling. We hypothesize that the fusion proteins, EWS-FLI1 and EWS-ATF1, form a complex with KIF11 that regulates the activity of co-transcription factors during chromatin remodeling. The target of filanesib, KIF11, has essential roles in maintaining cell cycle progression through mitosis and its inhibition results in mitotic arrest and subsequent cell death. We used ImageStream to assess the effects of filanesib on the cell cycle. ImageStream allows both a quantitative and qualitative analysis of the cell cycle by measuring the population of cells that are positive for a given marker as well as imaging each cell by microscopy. Results demonstrate that filanesib promotes an increase in cells arrested in prophase with dramatically altered spindle formation. We are currently addressing the role of KIF11 in regulating the expression levels of the fusion proteins' associated transcriptional coactivators and downstream target genes. By completing these studies, we aim to, i) outline the mechanism underpinning the relationship between KIF11 and the oncogenic fusion proteins in ES and CCS cells, and ii) gain an understanding of why ES and CCS cells are particularly vulnerable to KIF11 inhibition.

This work has been supported in part by the Flow Cytometry and the Molecular Genomics Cores at the H. Lee Moffitt Cancer Center & Research Institute, a comprehensive cancer center designated by the National Cancer Institute and funded in part by Moffitt's Cancer Center Support Grant (P30-CA076292)

#0648 Relevance of substrate selection for the results of biochemical WEE1 in-vitro kinase activity inhibition assays.

D. G. Mueller, **A. Gericke**, F. Totzke, C. Heidemann-Dinger, C. Ketterer, D. Kraemer, T. Weber, M. H. G. Kubbutat;
Reaction Biology Europe GmbH, Freiburg im Breisgau, Germany

Essential biological signaling pathways affecting e.g., proliferation, differentiation, migration, and apoptosis are regulated by protein kinases. Deregulation of protein kinases is observed in many tumor cells and frequently the development and progression of human cancers and other diseases is found to be causally connected to altered activity of specific protein kinases.
Therefore, protein kinases have become a prime molecular target for therapeutic intervention. Multiple small molecule inhibitors targeting different kinases are currently in clinical use for treatment of various types of cancer and other diseases.
A first step in preclinical development of new compounds is testing candidate substances in biochemical in-vitro assays, either based on binding of the compounds to their target or based on alterations of the in-vitro activity of the target kinase monitored in biochemical activity assays.
Depending on the actual mode of action of a compound, the relevance of the results of such in-vitro assays may depend on the actual setup of the assay.
Mainly for reasons of cost and technical feasibility, the use of generic substrates for in-vitro kinase activity assays is well established. While many of those substrates are highly artificial and can only be considered as generic phosphate-group acceptors, they have been successfully used in the past in the development of many approved small molecule kinase inhibitors currently in clinical use.
However, even while many kinases may show activity with generic substrates, for some physiological substrates are required. Members of e.g. the RAF family and other members of the MAPK pathway are highly substrate specific and will not show kinase activity with generic substrates.
Such kinases which have been established with generic substrates are rarely switched to more physiological substrates as most often this will result in increased complexity and associated cost of preclinical compound development.
We have compared the in-vitro activity of WEE1 using different in-vitro activity assay readouts like autophosphorylation, phosphorylation of generic substrates and phosphorylation of its physiological substrate CDK1. In addition, we examined the substrate specificity of WEE1 towards CDK1 alone and in complex with Cyclin B1.
We compared the potency of a selection of WEE1 inhibitors when different substrates were used.
While in early preclinical development the use of rather artificial biochemical assays has been successfully been applied in the past, it should be taken into consideration that at least for the kinase target in focus, the identification, establishment and use of a more physiologically relevant substrate may increase the value of early-stage compound screening results significantly.

#0649 SOX11 regulates BCR signaling via the PAX5/CD19 axis in MCL.

R. Dutta[1], H.-H. Lee[2], V. Leshchenko[1], R. Shukla[1], Y. Liu[2], J. Jin[3], M. Wang[2], S. Parekh[1];

[1]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, The Precision Immunology Institute at Mount Sinai, New York, NY, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Mantle cell lymphoma (MCL) is an incurable lymphoid neoplasm, comprising about 6% of all non-Hodgkin lymphoma (NHL). The transcription factor SOX11 is overexpressed in the majority of MCL patients and linked to a more aggressive disease course and poorer clinical outcomes. In MCL, naïve B cells experience continuous proliferation because of the dysregulation of the B-cell receptor (BCR) pathway. Our previously published data (Kuo et. al., Blood 2018) identified that SOX11 aberrantly upregulated BCR signaling in transgenic mouse models. The current study describes the exact mechanism by which SOX11 regulates the BCR pathway using a combination of functional and pharmacological approaches.

Methods: To investigate the alterations in signaling pathways regulated by SOX11, we utilized a small molecule SOX11 inhibitor (Jatiani et. al., CCR 2021), performed CRISPR/CAS9 knockout of SOX11, 3X FLAG TAG overexpression, as well as conducted western blot and flow-cytometry experiments.

Results: Our prior published results (Kuo et. al., Oncogene 2015), as well as others (Vegliante et. al., Blood 2013), have shown that PAX5 is a direct target of SOX11. We confirmed PAX5 downregulation after SOX11 depletion in three human MCL cell lines (JEKO, MINO, Z138) using CRISPR-CAS9. Decrease of PAX5 expression was associated with reduction in CD19 expression and a concurrent reduction in phospho-BTK (Bruton tyrosine kinase). Conversely, overexpression of SOX11 could rescue PAX5/CD19 expression and restore p-BTK levels. Furthermore, the treatment of SOX11 expressing cells with small molecule SOX11-specific inhibitors resulted in a reduction in PAX5, CD19 and BCR activation (p-BTK).

Conclusion: Taken together, these findings delineate PAX5 as the direct target and PAX5/CD19 axis as the downstream pathway by which SOX11 regulates B-cell receptor (BCR) signaling in MCL. Notably, our treatment using a SOX11 inhibitor successfully replicated the effects observed with genetic knockdown. In conclusion, our findings provide valuable insights into the molecular mechanisms by which SOX11 contributes to MCL pathogenesis. The further development of pharmacological inhibitors targeting SOX11 holds promise as a beneficial therapeutic strategy for MCL patients, as these will block signaling upstream of current resistance mechanisms.

#0650 Pim3 kinase is a poor prognostic marker and novel molecular target for triple negative breast cancer.

P. Atalay, G. Kara, R. Ozyurt, N. Kahraman, B. Ozpolat;
Houston Methodist Research Institute, Houston, TX

Triple-negative Breast cancer (TNBC) is characterized by the absence of ER, PR, and HER-2 receptors and is associated with poor prognosis, early relapse, and distant metastasis. In neoadjuvant setting, most patients (~50-70%) with TNBC do not achieve complete remission. Currently, there is no effective targeted therapy for TNBC patients. Therefore, identifying novel molecular targets and developing alternative therapeutic strategies are urgently needed. PIM3 is a serine/ threonine kinase and is upregulated in leukemia and various solid cancers. Although PIM1 has been shown to play a critical role in cell proliferation in cMyc-enriched TNBC tumors, the role of PIM3 in TNBC is not known. To determine the clinical significance of PIM3 in TNBC patient prognosis and progression, we performed a Kaplan-Meier analysis in the TCGA TNBC patient database. We found that PIM3 expression is significantly associated with shorter patient survival in TNBC patients (n=77, p=0.0088). PIM3 protein is highly expressed in TNBC cells compared to normal breast epithelium and other ER+ and HER2+ breast cancer subtypes. Inhibition of PIM3 by siRNA significantly suppressed TNBC cell proliferation, migration, and invasion of TNBC cells including MDA-MB-231, MDA-MB-436, and BT20 cells. Lenti-based PIM3 overexpression induced TNBC cell proliferation, invasion, and migration. Non-biased reverse phase protein array (RPPA) assay and Western blot analysis showed that PIM3 inhibition markedly reduced the expression of EF2 Kinase protein, and we found it to be associated with shorter patient survival and poor prognosis. Immunoprecipitation of PIM3 indicated that it forms a heterodimer with EF2K whose inhibition by siRNA also suppressed TNBC cell proliferation, migration, invasion, and tumor growth. Furthermore, PIM3 inhibition by siRNA significantly enhanced the antiproliferative effect of Doxorubicin, which is one of the first-line chemotherapeutics used in patients. Moreover, *in vivo* therapeutic delivery of PIM3 siRNA loaded albumin nanoparticles (ALNPs-PIM3 siRNA) markedly delayed tumor growth of two different TNBC tumor xenograft models (MDA-MB-231 and MDA-MB-436) in mice. Analysis of tumors by IHC after 4 weeks of treatment demonstrated that ALNP-PIM3 siRNA treatment led to inhibition of intra-tumoral proliferation and induction of apoptosis. Currently, we are conducting an in vivo study in TNBC tumor models by combining ALNP-PIM3 siRNA therapy with doxorubicin. Overall, our studies suggest that PIM3 is a marker for poor patient survival that drives TNBC tumor growth and progression and a novel potential molecular target in TNBC.

#0651 3D-bioprinted cancer models for target discovery, drug development, and personalized therapy.

R. Satchi-Fainaro[1], A. Krinsky[1], A. Katyal[1], O. Avramoff[1], E. Yeini[1], L. Neufeld[1], S. Halparin[2], R. Frommer-Shapira[2];
[1]Tel Aviv University, Tel Aviv, Israel, [2]Sheba Medical Center, Ramat Gan, Israel

Many drugs show promising results in laboratory research, but eventually fail in clinical trials. We hypothesize that one main reason for this translational gap is that the cancer models used are inadequate. Most models lack the complex tumor-stromal cell interactions with their microenvironment which are required for tumor progression. Conventional 2D cultures, where cells grow on rigid plastic plates mainly as mono-cultures of a single type of cells, are not able to recapitulate the complex settings of such interactions. Therefore, there is a need to develop a 3D model that better mimics the tumor microenvironment. Hence, we developed a vascularized, hydrogel-based 3D-bioprinted tumor model consisting of patient-derived tumor and microenvironmental cells. Our 3D-bioprinted models are based on a library of hydrogels that we developed as scaffolds for different tumor types, designed according to the mechanical properties of the tissue/organ of origin. The patient-derived models consist of cells from a biopsy, constructed based on CT/MRI scans, and include functional vessels that allow serum and peripheral blood mononuclear cells (PBMC) to flow when connected to a pump. Using this unique model platform, we identified P-selectin as a novel immune checkpoint in the brain regulating cancer-microglia-tumor-associated macrophages (TAMs) interactions. Moreover, we are currently validating our 3D platform for its ability to mimic patient-specific tumors and their microenvironment in order to predict patient response to different treatments (such as chemotherapy, immunotherapy, and targeted therapies). Hence, we are currently conducting an 80-patient “basket” clinical trial testing different treatments on patient samples to validate the ability of our model to predict patient outcomes covering 7 different cancer types. These unique 3D-bioprinted models have the potential to facilitate target discovery and drug development, as well as to serve as a reliable system for precision medicine.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 2
Poster Session

#0655 Fungal extract screening reveals malformin C to preferentially kill glioblastoma stem-like cells via concerted induction of proteotoxic stress and autophagic flux blockade.

E. L. Phillips[1], S. van Enk[1], S. Kildgaard[2], S. Schlue[1], M. Gottmann[1], V. Jennings[1], F. Bethke[1], G. Muller[1], C. Herold-Mende[3], D. Pastor-Flores[1], M. Schneider[1], D. Helm[1], T. Ostenfeld Larsen[2], V. Goidts[1];

[1]German Cancer Research Center, Heidelberg, Germany, [2]Technical University of Denmark, Copenhagen, Denmark, [3]University Hospital Heidelberg, Heidelberg, Germany

Glioblastoma is a highly aggressive brain tumor for which there is no cure. The dire prognosis of this disease is largely attributable to a high level of heterogeneity, including the presence of a sub-population of tumor initiating glioblastoma stem-like cells (GSCs), which are refractory to chemo- and radiotherapy. Here, in an unbiased marine-derived fungal extract screen, together with bioguided dereplication based on high resolution mass spectrometry, we identified malformin C to preferentially induce cell death in patient-derived GSCs, and explore the potential of this cyclic peptide as a therapeutic agent for glioblastoma. Malformin C significantly reduced tumor growth in an *in vivo* xenograft model of glioblastoma. Using transcriptomics and chemoproteomics, we found that malformin C binds to many proteins leading to aggregation, and rapidly induces unfolded protein response, including autophagy, in GSCs. Malformin C also appears to accumulate in lysosomes, disrupting autophagic flux and driving cells to death. Supporting this, malformin C synergizes with chloroquine, an inhibitor of autophagy. Strikingly, we observed that autophagic flux is differentially regulated in GSCs compared with normal astrocytes. The sensitivity of GSCs to malformin C highlights the relevance of proteostasis and autophagy as a therapeutic vulnerability in glioblastoma.

#0656 A novel dual-targeting peptide HS1002 enhances anti-tumor activity via GnRH/human telomerase reverse transcriptase (hTERT) interaction in human prostate cancer cells.

J. Park, J. Kim, H. Cha, H. Kim;
Sungkyunkwan University College of Pharmacy, Suwon, Korea, Republic of

Human telomerase reverse transcriptase (hTERT) is overexpressed in most human cancers. hTERT is considered as an important target for cancer therapy. In the present study, a new peptide HS1002 were synthesized with sequence of pGlu-His-Trp-Ser-Tyr-Arg-Leu-Arg-Phe-Ile-Pro-NHEt based on the GnRH agonist and hTERT. The aim of this study was to evaluate HS1002 for its anticancer activity by dual-targeting to GnRH/hTERT in prostate cancer cells. Upon comparison with different prostate cancer cell lines, HS1002 exhibited highest cytotoxicity against LNCaP cells. The hTERT expression correlated with telomerase activity in LNCaP cells, was significantly inhibited by HS1002, resulting in reduction of proliferation, metastasis and increase in apoptosis. Additionally, HS1002 suppressed c-Myc and AKT/ERK pathway in LNCaP cells. In the tumor-bearing nude mice model, HS1002 significantly inhibited tumor growth and downregulated the expression of hTERT and Ki-67 in tumor tissue as evidenced by western blot and immunohistochemistry analysis, respectively. Moreover, repeated subcutaneous injection of HS1002 resulted in the reduction of both serum testosterone levels and seminal vesicle weight. HS1002 also increased cytosolic calcium influx and CRE-luciferase activity in GnRHR-overexpressing HEK293 cells compared to mock-transfected transfected cells. Furthermore, a potent cytotoxicity in LNCaP cells was exhibited by HS1002-activated peripheral blood mononuclear cell (PBMC) with interleukin (IL)-2 using LDH release assay. In addition, a flow-cytometric analysis confirmed an elevation in the production of granzyme B and IFN-γ in $CD8^+$ T cells in the MC38 syngeneic mouse model by HS1002. These data indicate that the inhibition of hTERT expression by HS1002 suppresses prostate cancer cell growth and induced anti-cancer immunity. Therefore, HS1002 might be used as a novel therapeutic drug for prostate cancer.

#0657 Discovery of a novel brain penetrant SHP2 allosteric inhibitor with anti-tumor effects.

M. Kim[1], D. Kim[1], Y. Jeon[1], K. Yoon[1], A. Jang[1], M. Lee[2], D. Jeon[2], S. Jang[2], J. Kim[2], E. Kim[2], J. Park[3], V. Hong[3], H. Jung[1], S. Choi[1];
[1]KANAPH Therapeutics, Seoul, Korea, Republic of, [2]Yungjin Pharm, Suwon, Korea, Republic of, [3]Keimyung University, Daegu, Korea, Republic of

KRAS is the most frequently dysregulated oncogene with high prevalence in non-small cell lung cancer (NSCLC), colorectal cancer (CRC), and pancreatic ductal adenocarcinoma (PDAC). Currently, FDA-approved sotorasib and adagrasib provide ground breaking through therapies for cancer patients harboring KRAS G12C mutation. However, there is still high unmet medical needs for inhibitors targeting broader KRAS-driven tumor, especially a substantial unmet medical need for agents that can penetrate BBB to control the brain metastases. SHP2, a key activator of KRAS located in the upstream of RAS pathway, facilitates the conversion of GDP-bound KRAS (off) state to GTP-bound KRAS (on) state serving as a key mechanism of KRAS activation. Therefore, SHP2 could be a promising therapeutic target to shut down the oncogenic RAS pathway as a broad combination partner with RAS/RAF/MEK/ERK pathway inhibitors. Here we report a highly potent and selective brain penetrant SHP2 inhibitor that is designed to target solid tumors metastazied to brain. KT-01766 showed excellent potency against SHP2 protein in various biochemical and cellular assays and showed the robust synergistic effect with RAS pathway inhibitors. KT-01766 as a mono therapy and in combination with KRAS G12C inhibitors demonstrated great anti-tumor efficacy with no apparent toxicity in mouse xenograft models harboring KRAS mutations. Furthermore, robust anti-tumor acitivty was confirmed in intracranial brain tumor model, supporting its potential to control brain-metastasized tumors. The present data suggest that KT-01766 is a potential candidate for combination therapy with agents targeting RAS pathway, as it is able to effectively suppress tumor growth both systemically and within the brain in KRAS mutated cancers.

#0658 Small molecule allosteric regulators of eIF4E activity target proteomic dysregulation and demonstrate potent antiproliferative activity in multiple myeloma models whilst sparing normal immune cells.

L.-M. Sturla, X. Zhang, Y. Kan, R. Gedrich, K. Bowdish, C. VanDeusen;
PIC Therapeutics, Natick, MA

Multiple myeloma is characterized by significant dysregulation of protein translation. The eukaryotic translation initiation factor 4E (eIF4E), a rate determining element of oncogene translation, is highly expressed in multiple myeloma cells compared to normal plasma cells and is associated with enhanced levels of key oncogenic drivers such as MYC. We have developed potent small molecule allosteric regulators of eIF4E activity by aligning medicinal chemistry tools with patient directed pharmacology to optimize and identify orally bioavailable, potent compounds with *in vivo* activity. To identify sensitive cancer models and markers associated with response to PIC eIF4E regulators, we screened the 302-cell line Eurofins OncoPanel™, followed by gene expression profiling comparing the most and least sensitive cell lines and QIAGEN Ingenuity Pathway Analysis. Consistent with the role of eIF4E, we identified proteomic dysregulation as a marker of sensitivity to PIC eIF4E regulators. In addition, the multiple myeloma cell line MM.1R was amongst the most sensitive cell lines. Proteomic analysis of PIC eIF4E regulator treated MM.1R cells identified significant changes, both increases and decreases, in approximately 8% of the 7800 proteins detected by label free mass spectrometry. QIAGEN Ingenuity Pathway Analysis of significantly altered proteins identified enrichment of proteins involved in the G2/M checkpoint, cell cycle control of chromosomal replication, and DNA repair as well as protein translation, EIF4E regulation and mTOR signaling. PIC eIF4E regulators significantly decreased cell viability of both the steroid sensitive MM.1S and steroid resistant MM.1R multiple myeloma cell lines, which was associated with significantly reduced MYC protein levels. Consistent with earlier reported findings and the mechanistic impacts of PIC eIF4E regulators, reduced MYC expression was associated with a significant decrease in hyper-phosphorylated 4EBP1. In contrast to cancer cells, PIC eIF4E regulator treatment did not affect viability of B, T, NK and plasma cell populations in freshly isolated peripheral blood mononuclear cells (PBMCs) at exposures that cause significant cell death in multiple myeloma cells. Furthermore, CD4+ T-cells isolated from fresh PBMCs demonstrated proliferative responses following stimulation (ImmunoCult™) in the presence of PIC eIF4E regulators. The impact on key oncogenic drivers and potent antiproliferative activity in multiple myeloma models with minimal effects on normal immune cell populations suggests that targeting eIF4E activity with PIC allosteric eIF4E regulators could offer an attractive therapeutic strategy in multiple myeloma.

#0659 TR-107 and erastin produce synergistic inhibition of colorectal cancer cell viability *in vitro*.

M. Giarrizzo[1], J. F. LaComb[1], H. R. Patel[1], A. B. Bialkowska[1], R. Reddy[1], L. M. Graves[2], E. J. Iwanowicz[3];
[1]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY, [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Madera Therapeutics LLC, Cary, NC

Introduction: Ferroptosis is an emerging potential target for the treatment of colorectal cancer (CRC) and has been shown to sensitize cancer cells to combinatory chemotherapy. Our studies show that the TR-107 compound, an agonist of ClpP - the proteolytic subunit of mitochondrial maintenance complex - can synergize with Erastin, an inducer of ferroptosis cell death. TR-107 potently disrupts mitochondrial proteostasis and attenuates oxidative phosphorylation, resulting in excessive oxidative stress. Here, we show that Erastin synergizes with TR-107 activity by downregulating the cofactor of GPX4, a major intracellular antioxidant defense resulting in CRC cell apoptosis.
Methods: We first evaluated the efficacy of TR-107 against eight CRC cell lines belonging to four established consensus molecular subtypes. Cells were treated with control (DMSO) or TR-107 (10 nM, 50 nM, 1 μM) for 24, 48, and 72 hours. We determined IC_{50} values with Cell Titer-Glo, cell proliferation with the Beckman Coulter cell counter, cell cycle with flow cytometry, OXPHOS activity with Seahorse Real-Time ATP Rate assay, mitochondrial protein levels with western blot and proteomics, and differential gene expression using RNA sequencing and RT-PCR. Subsequently, we assessed the efficacy of TR-107 and Erastin co-treatment. Cells were treated with DMSO, TR-107 (10, 50 nM), Erastin (1, 10 μM), or combinations of the abovementioned concentrations. Cell viability was measured 72 hours post-treatment with Cell Titer-Glo. Synergy scores (HSA) were calculated with Synergyfinder on RStudio. Ferroptosis-related protein expression 24 hours after co-treatment was assessed with western blot and densitometry.
Results: TR-107 IC_{50} values ranged from 2-70 nM, producing a dose- and time-dependent inhibitory effect in cell proliferation. Western blot showed that 50 nM TR-107 abolished the expression of critical mitochondrial proteins ClpX, TFAM, and TUFM. Seahorse data showed a significant reduction in OXPHOS activity. Multi-omics revealed downregulation of respiratory chain complex subunits, mtDNA transcription/translation factors, and upregulation of mitophagy and ferroptosis-related pathways in treated cells. Co-treatment with Erastin produced synergistic HSA scores in 63% (5/8) of assessed CRC cell lines. RKO and NCI-H508 were highly sensitive to Erastin treatment, suggesting that lower Erastin concentrations may synergize with TR-107 and thus reduce dose toxicity. Western blot analysis 24 hours post-treatment showed a loss of GPX4 protein levels in co-treated cells compared to 50 nM TR-107 treatment. This suggests a rapid downregulation of intracellular antioxidant defense that may induce ferroptosis sooner and more effectively than single-agent treatment.
Conclusion: *In vitro* results suggest that co-treating with TR-107 and Erastin produces a significant, synergistic reduction in CRC cell viability.

#0660 OPN-6602, a potent dual EP300/CBP bromodomain inhibitor, targets multiple myeloma through concomitant suppression of IRF4 and c-MYC.

B. Matusow[1], W. Spevak[2], C. Zhang[2], Y. Ma[2], R. Shellooe[1], J. Tsai[2], P. Li[2], P. Chen[1], G. Habets[1], C. Nichols[1], P. Singh[1], K. Inokuchi[1], J. Walling[1], J. Halladay[2], G. Bollag[1];

[1]Opna Bio LLC, South San Francisco, CA, [2]Plexxikon Inc., South San Francisco, CA

Multiple myeloma (MM) is an aggressive hematological cancer derived from malignant plasma cells in the bone marrow. E1A-binding protein (EP300) and CREB-binding protein (CBP) are transcription coactivators that contain both epigenetic writer histone acetyltransferase (HAT) and reader bromo- (BRD) domains that regulate transcription of genes via chromatin remodeling. EP300/CBP inhibition causes cell cycle arrest and apoptosis in MM through suppression of interferon regulatory factor (IRF4) and concomitant repression of c-MYC, rendering EP300/CBP as a novel target for MM. OPN-6602 is a potent, selective, and orally active small molecule dual EP300/CBP inhibitor discovered through structure guided drug design. Its binding interaction exhibits low nM activity on EP300 (Kd= 1.5 nM) and CREBBP (Kd= 1 nM), with > 200-fold less activity against BRD4. OPN-6602 binding to EP300 is particularly potent by Surface Plasmon Resonance analysis, displaying a Kd of 0.87 nM, with a fast association rate (1.5 E+06/Ms) and a slow dissociation rate (1.3 E-03/s) with a residence time of 13 min. It potently inhibits cell growth in MM cell lines OPM-2 (IC50 ~ 4 nM) and MM.1S (IC50 ~ 47 nM) as well as histone acetylation (IC50 ~ 2 nM) via BRD intramolecular modulation of HAT activity. OPN-6602 demonstrated potent inhibition of H3K27Ac in both LK2 (CBP-deficient lung cancer cells, IC50 = 11 nM) and in OPM-2 (IC50 = 1.6 nM). OPN-6602 also potently inhibited H3K27ac expression in PBMCs with IC50s of 0.75 and 1.4 nM, respectively. The effects of OPN-6602 with dexamethasone (dex) or lenalidomide (len) on the growth of OPM-2 and MM1.S cells were evaluated in a matrix combination study. As single agents, maximal growth inhibition reached 60-75% following dex treatment and only 30-40% following len treatment. *In vitro* combination studies utilizing a systematic assessment of a broad range of OPN-6602 concentrations in combination with dex or len demonstrated strong synergy. Synergy was observed between OPN-6602 at 3.7 nM and len through a concentration range from 0.027 to 20 µM. Synergy was observed with 1.2 or 3.7 nM of OPN-6602 in combo with dex concentrations from 0.055 to 40 µM. In the OPM-2 xenograft model, OPN-6602 inhibits tumor growth by 30-111% at doses from 2.5-60 mg/kg QD. This growth inhibition correlated with downregulation of IRF4 and cMYC in tumor samples analyzed by QPCR analysis. The pharmacokinetic profile is favorable for oral QD dose administration due to a high Cmax (19 µg/mL at 24 mg/kg) and short half-life ($T_{1/2}$ = 1.5 hr). A first-in-human study of OPN-6602 in patients with MM is planned for 2024.

#0661 An oral Cbl-b inhibitor with sustained T cell activation demonstrated robust anti-tumor efficacy along with enhanced infiltration and activation of functional T cells.

F. Zhou[1], G. Yang[1], Y. Liu[2], L. Xue[1], W. Chen[2], Z. Li[1], X. Liu[2], J. Li[2], R. Tang[1];

[1]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China, [2]Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

The E3 ubiquitin ligase Casitas B-lineage lymphoma b (Cbl-b) is a member of the highly conserved family of Cbl (casitas b-lineage lymphoma) proteins, which associates with multi-immune response regulations including Teff and NK activation, Treg differentiation. *Cbl-b* KO mice showed enhanced immune responses and resistance to tumor transplantation. Previously, we reported a novel Cbl-b inhibitor, ZM-8026, which robustly activated T cells and efficiently inhibited tumor growth as monotherapy or in combination with anti-PD-1. Here, we further demonstrated that Cbl-b inhibition restores the Teff cells' function in immune suppression conditions, such as in the presence of PGE2, A2AR agonist, and TGF-β. $CD8^+$T proliferation and cytokines induction were maintained in the presence of MDSC. Furthermore, $CD8^+$T function was reversed from an exhausting status induced by a continuous anti-CD3/CD28 activation for a long period. To investigate whether continuous target occupancy was necessary for sustained TCR activation, the dynamic impacts of Cbl-b inhibition on $CD8^+$T cell activation were explored using a washout assay. The results showed that the high-level activated T cells lasted for 48 h after more than 4hs preincubation with 1 μM Cbl-b inhibitor followed by a washout, however, short and weak activation states were found with less than 4hs preincubation or low inhibitor concentration treatment (< 0.1 uM). This finding revealed sufficient inhibitor concentration and treatment time ensure high T-cell activation. Further, *in vivo* efficacy studies demonstrated less anti-tumor growth efficacy for intermittent dosing (Q2D, Q3D) compared with QD dosing. *In vitro* and *in vivo* pharmacokinetics studies exhibited favorable ADME profiles and bioavailability of our Cbl-b inhibitor for oral administration in mice, rats, and dogs. At least in two syngeneic models, our Cbl-b inhibitor exhibited efficient anti-tumor growth with more than 70% TGI (tumor growth inhibition). In a CT26 syngeneic model, complete tumor growth inhibition in 6 of 8 mice was found in the Cbl-b inhibitor combined with an anti-PD1 antibody. The complete regression mice were re-challenged with the same tumor cells, and no measurable tumors were found for up to 30 days, suggesting the treatment-induced immune memory. Tumor samples in mice were collected, RNAseq showed that activated functions of tumor-infiltrated T, NK, DC, and macrophage were dramatically increased in the Cbl-b inhibitor treatment group, and the T and NK activation signature genes such as Gzmb, Ifng were significantly upregulated by RT-PCR. In conclusion, our Cbl-b inhibitor exhibited a favorable PK profile in multi-preclinical animals. The sustained T cell activation *in vitro* was identified and robust anti-tumor growth *in vivo* was demonstrated with optimized dosing frequency.

#0662 Vitamin B1 derivative, fursultiamine, prevents lung cancer cells growth.

N. Boekweg, R. Powers, K. Ramana;
Noorda College of Osteopathic Medicine, LLC, Provo, UT

Lung cancer is the leading cause of cancer death in men and the second leading cause of cancer death in women worldwide. Cigarette smoke-induced oxidative and inflammatory responses are the major risk factors for the development of lung cancer. Several compounds have been tested for their efficacy in preventing lung cancer. However, very few compounds have gone through clinical studies. We hypothesize that with its potent anti-oxidative and anti-inflammatory actions, fursultiamine, a disulfide lipid-soluble derivative of vitamin B1 (thiamine), could prevent lung cancer growth and spread. Our results indicate that treatment of non-small cell lung cancer cells (A549 cells) with fursultiamine prevents A549 cells death in a dose-dependent manner. Similarly, live and dead cell staining assay also confirms that fursultiamine prevents proliferation of A549 cells. Further, fursultiamine prevents A549 cell proliferation by inducing the apoptotic cell death. It also promoted the activation of caspase-3 and cleavage of PARP protein. Fursultiamine also prevented reactive oxygen species in A549 cells. Further, fursultiamine regulated the expression of various anti-apoptotic (Bcl-2, Bcl-x) and pro-apoptotic (Cleaved Caspase-3), survival (Survivin) and anti-survival factors (Clusterin, p-Rad17) in A549 cells. We next planned to examine the effect of fursultiamine on lung cancer growth in vivo using athymic nude mice injected with A549 cells subcutaneously without or with a diet containing fursultiamine. In conclusion, our in vitro results suggest that vitamin B1 derivative, fursultiamine, by promoting the apoptotic pathways prevents lung cancer growth and has potential for further development as a chemoprevention drug.

#0663 Irreversible covalent azetidine-based small molecule inhibitors of Stat3 activity block growth of human pancreatic tumors.

Y. Chen[1], N. Zhai[1], P. Yue[1], C. Brotherton-Pleiss[2], W. Fu[2], K. Nakamura[2], W. Chen[2], M. Tius[2], F. Lopez-Tapia[1], **J. Turkson**[1];
[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]University of Hawaii, Manoa, Honolulu, HI

The incidence and death rates for pancreatic adenocarcinoma in the US have been increasing by about 1% per year and the death rate has increased by approximately 0.2% yearly. The five-year survival rate has remained below 10% for many years. With surgery, radiation, and chemotherapy being the main treatment options to extend survival or for symptom relief, there is an urgent unmet need for effective new treatment options. Signal Transducer and Activator of Transcription (Stat) 3, one of the Stat family members, is aberrantly activated in human pancreatic and many other cancers. Aberrantly-active Stat3 promotes abnormal tumor-cell intrinsic and extrinsic mechanisms, including dysregulation of gene expression and mitochondria energy metabolism in the tumor cells, and suppression of immune cell functions in the tumor microenvironment. Stat3 is therefore an important target for therapeutic development. Herein we present two small molecules, H182 and H333, which are covalent inhibitors of Stat3 and that potently block Stat3 DNA-binding activity *in vitro*, with IC_{50} 0.66-0.98 μM. H182 and its structural analog, H333 bind Stat3 via irreversible covalent interactions with key cysteine residues in the Stat3 DNA-binding domain to induce a time-dependent inhibition of Stat3 activity. Both compounds inhibit intracellular constitutive Stat3 tyrosine phosphorylation and induce loss of viable cells and apoptosis *in vitro* of human pancreatic Panc-1 and Mia-Paca2 cells. H333 is 13-fold more specific and H182 is 4-fold more specific against tumor cells over normal cells. Furthermore, MiaPaca-2 cells treated with H182 and analyzed by Seahorse showed dramatically decreased mitochondria respiration. Notably, xenograft models of MiaPaca2 treated with H182 or H333 via i.p. every other day for 27 days showed dramatic growth inhibition. Collectively, our results identify H182 and H333 as therapeutically-viable small molecules with unique irreversible mechanism of Stat3 inhibition which accounts for their strong antitumor effects against human pancreatic tumor xenografts.

#0664 GSC000190, a highly potent inhibitor of KIF18A, for tumors with chromosome instability.

P. Tu, C. Zhang, B. Lu, **Y. Xia**, F. Yang;
Changchun Genescience Pharmaceuticals Co., Ltd., Shanghai, China

Chromosome instability (CIN) and Genetic instability is a common feature of malignant tumor cells, which may contribute to tumor progression and lead to drug resistance and tumor metastasis. KIF18A, a member of the kinesin-8 family, is an ATP dependent plus end microtubule motor protein. Studies have found that genetic depletion of KIF18A greatly impacts the chromosome alignment, elongation of mitotic spindles, activation spindle assembly checkpoint of CIN+ tumor cell and leads to cell death, while have little impact towards the survival of normal cells, making KIF18A an attractive therapeutic target for targeting the vulnerability of CIN related tumors. Here we report the pharmacology characterization of a “best in class” potential KIF18A inhibitor for CIN+ tumors. *In vitro*, GSC000190 inhibited KIF18A ATPase activity with a single nM potency and has great potency inhibiting growth of a wide range of TP53 mutant/CIN+ tumor cells. *In vivo*, GSC000190, at approximately one tenth of systematic exposure comparing to that of AMG650, the leading clinical KIF18A inhibitor, causes tumor shrinkage in multiple CDX models including ovarian, colon and lung cancers. In an HGSOC PDX model which is resistant to platinum and olaparib, GSC000190 induced strong tumor regression both as single agent and through combination without significant body weight reduction. PD study confirms a more elevated mitotic phosphorylated histone 3 (PH3) staining in GSC000190 treated tumor tissues, correlating with a better *in vivo* efficacy than that of AMG650. GSC000190 has a favorable ADME profile in rodents, dogs and NHPs, as well as a much better safety profile. GSC000190 is now under IND-enabling study and P1 study is planned in the second quarter of 2024.

#0665 MEN1703/SEL24 exhibits promising antitumoral activity in preclinical models of myelofibrosis both as single agent and combined with ruxolitinib.

M. Iannitto, D. Bisignano, S. Zicari, F. Belli, A. Fiascarelli, S. Talucci, G. Merlino, V. Nicolis di Robilant, C. Irrissuto, M. Bigioni, A. Bressan, D. Bellarosa, M. Binaschi;
Menarini Group, Pomezia, Italy

Myelofibrosis (MF) is a pathological chronic bone marrow (BM) condition characterized by abnormal growth of erythroid and megakaryocytic precursors and deposition of fibrotic tissue. The JAK/STAT pathway plays an important role in MF (Cardoso 2015), and multiple JAK1/2 inhibitors (JAKis) are approved for MF treatment. Despite initially limiting disease symptoms, JAKis often fail due to persistent JAK2 activation and survival of MF-driving cells, hence new treatment strategies are highly needed. PIM kinases also contribute to MF pathogenesis. PIM1 is highly overexpressed in granulocytes, peripheral blood mononuclear cells (PBMCs), and BM of patients with MF. PIM1/2 expression is dependent upon JAK2 signaling in myeloproliferative neoplasms (MPNs). Hence, PIM inhibitors represent potential therapeutic targets for MPNs and have been evaluated in several preclinical and clinical studies (Rampal 2021). MEN1703/SEL24 (MEN) is an oral, first-in-class, dual PIM/FLT3 kinase inhibitor in development for hematologic malignancies.

This study aims to investigate the efficacy of MEN alone and in combination with the JAKi ruxolitinib (RUX) in preclinical MF models and to elucidate the underlying signaling pathways.

MF cell lines ($JAK2^{V617F}$ and JAK2 wild type) were used in MTS assays to assess the *in vitro* cytotoxicity of MEN alone and in combination with RUX, compared with the PIM inhibitor TP-3654 (Dutta 2022). Cell cycle distribution and signaling pathways were analyzed via propidium iodide/FACS analysis and immunocapillary electrophoresis, respectively, upon treatment with the single agents and MEN + RUX. *In vivo* efficacy was assessed in a murine xenograft model treated with MEN +/- RUX.

In vitro studies showed single agent MEN activity with an IC_{50} ranging from 0.3 to 2.3 µM. Moreover, a synergistic drug interaction was found with MEN + RUX in all tested cell lines (Combination Index [CI] range 0.41-0.80). MEN presented cytotoxic and cytostatic capacity, inducing apoptosis and arresting a proportion of cells in G2/M phase. This effect was maintained in combination with RUX. Signaling pathway analysis showed that MEN inhibits phosphorylation of STAT proteins and decreases Mcl1 protein expression. These effects were enhanced with MEN + RUX. Compared with TP-3654, MEN was more effective both as a single agent (IC_{50} 2-3 fold lower than TP-3654) and in combination with RUX (mean CI of 0.77-0.80 compared to 0.79-0.98 with TP-3654).

MEN showed anti-tumoral efficacy in MF preclinical models, moderately higher than TP-3654, exhibiting *in vitro* activity at clinically relevant concentrations. Importantly, MEN combined with the standard of care RUX was synergistic, and molecular analyses confirmed the role of PIM downstream target inhibition. Our results support the therapeutic potential and relevance of MEN in MF treatment strategies.

#0666 ASTX295 engages p53-mediated apoptosis and an inflammatory response in patient derived mesothelioma explants.

D. A. Fennell[1], J. Dzialo[1], J. Rogel[1], D. Faulkner[1], N. Nusrat[1], A. Bzura[1], K. Kutywayo[1], P. Wells-Jordan[1], C. Poile[1], A. Biondo[2], M. Sims[2], A. Nakas[3], J.-L. Luo[1], M. Zhang[4], M. Ahn[2];

[1]University of Leicester, Leicester, United Kingdom, [2]Astex Pharmaceuticals, Cambridge, United Kingdom, [3]Glenfield Hospital, Leicester, United Kingdom, [4]Novogene, Beijing, China

Mesothelioma is a universally lethal, rare cancer caused by asbestos that is lacking effective targeted treatments, particularly in the relapsed setting. P53 is predominantly wildtype (WT 83%) but is likely restrained by MDM2 particularly in the context of 9p21 deletion, a common, clonal somatic event affecting around half of all mesotheliomas that results in deletion of the MDM2 suppressor ARF. 9p21 deletion is also associated with a cold, immunosuppressed microenvironment. Unleashing $p53^{WT}$ by inhibiting its interaction with MDM2 has therapeutic potential in mesothelioma. To test this hypothesis, we employed live *patient derived explants* (PDEs) as a model that reflects the genomic inter-patient heterogeneity of mesotheliomas, and harbours an intact tumour microenvironment. Between August 2017 and April 2021 a total of 71 patients were consented prior to extended pleurectomy decortication, and PDEs were harvested at the time of surgery. PDEs were then cultured and treated with ASTX295, an inhibitor of p53-MDM2 interaction, using two concentrations (0.5 and 1 micromolar) and two timepoints (48 and 72 hours). PDEs passing quality control were subjected to spatial profiling using multiplex immunofluorescence microscopy. PDEs harbouring $p53^{WT}$ showed ASTX295-induced p21 (CDK1A) upregulation, which correlated with induction of apoptosis ($p=0.04$). PDE rank-order sensitivity was conserved across different doses and exposure-times. Transcriptome analysis confirmed ASTX295 induced p53 pathway activation in conjunction with a pro-inflammatory phenotype; both of which were absent in one PDE harbouring an inactivating p53 single nucleotide variant. Constitutive epithelial mesenchymal transition (EMT) was enriched in responding PDEs, as well as MDM2 inhibitor sensitive mesothelioma cell lines. 9p21 deletion (revealed by exome sequencing) was detected in both responding and non-responding PDEs. In summary, inhibition of MDM2-P53 interaction triggers robust p53 activation and a pro-inflammatory phenotype, which is potentiated in EMT enriched mesothelioma PDEs. ASTX295 is currently under clinical investigation (NCT03975387).

#0667 Identification of biomarkers of response to MDM2 inhibition in solid tumours using computational, multi-omics approaches.

H. K. Saini, M. Ahn, G. Ward, J. Kucia-Tran, C. Gewinner, N. Ferrari, J. Brothwood, L. Bevan, **M. Davis**, L. Fazal, M. Sims, M. O'Reilly, G. Chessari, R. Ferraldeschi, J. Lyons, N. Wallis, N. Thompson;
Astex Pharmaceuticals, Inc., Cambridge, United Kingdom

Background High-throughput drug screening and computational methods to associate genomic features of cell lines to drug sensitivity are valuable tools for predicting biomarkers of sensitivity. In addition, integrating genomic features to expression-based patterns could improve biomarker prediction and patient stratification. Particularly weighted gene co-expression networks represent an effective approach to identify key modules and possible biological mechanisms of sensitivity. Using a combination of cell panel screening and gene co-expression networks, we predicted markers of sensitivity to ASTX295 (MDM2i) in cancer cell lines and confirmed expression-based signatures in publicly available clinical datasets.
Method ASTX295 was screened in a panel of 210 p53 wild-type cancer cell lines derived from a range of tumor tissues. ANOVA was used to identify significant associations of genomics features of cell lines to drug response. Transcriptomics profiling of apoptotic and non-apoptotic patient-derived cell lines was performed and significant differentially expressed genes were identified. Further, pathway enrichment and expression-based signatures identified in cell lines were further confirmed in TCGA patient data using weighted gene co-expression network analysis (WGCNA). Expression modules identified by WGCNA were correlated to genomic features and clinical parameters to identify potentially clinically relevant biomarkers.
Results Analysis of the cell panel data identified CDKN2A loss as a statistically significant biomarker predictive of sensitivity to ASTX295. As mesothelioma is one of the indications with high prevalence of loss of CDKN2A, the anti-proliferative activity of ASTX295 was further confirmed in an independent panel of p53 wild-type, patient-derived mesothelioma cell lines. Further, pathway and transcriptional regulator analysis identified the Interferon signalling as significantly enriched in apoptotic cell lines and was confirmed in a TCGA mesothelioma patient data set and the module was found to be significantly correlated with a subgroup of P53 wild-type patients with CDKN2A loss. In conclusion, combining cell panel drug screening with co-expression networks helped to identify biomarkers associated with ASTX295 sensitivity, and provided new insights into the underlying mechanism of ASTX295 response.

#0668 Enhancing chemosensitivity of lung adenocarcinoma via Y-box binding protein 1 (YB-1) inhibition.

J. Lee[1], D. Tailor[1], F. J. Garcia-Marques[2], A. Bermudez[2], S. Pitteri[2], S. V. Malhotra[1];
[1]Oregon Health & Science University, Portland, OR, [2]Stanford University School of Medicine, Palo Alto, CA

Background: Y-box binding protein 1 (YB-1, *YBX1*) is a multifunctional nucleic acid binding protein that regulates the expression of various genes by binding to their mRNA and stabilizing them. In over 20 cancer types, including lung adenocarcinoma (LUAD), *YBX1* expression is significantly elevated in tumor samples compared to normal tissue. Within cancer cells, YB-1 promotes the expression of genes involved in tumorigenesis and chemoresistance. Consequently, elevated *YBX1* expression in tumor is associated with poor clinical outcomes and significantly reduced overall survival in LUAD patients. Therefore, YB-1 emerges as a promising therapeutic target for LUAD treatment. Utilizing a small molecule YB-1 inhibitor, CET056, we performed a series of *in vitro* and *in vivo* analyses to assess the therapeutic efficacy of YB-1 inhibition and unravel YB-1's role in tumorigenesis and disease progression in LUAD.
Methods: Four human and one mouse LUAD cell lines were treated with CET056 and/or chemotherapeutic drugs and analyzed for the *in vitro* therapeutic activity of CET056. Using xenograft and syngeneic LUAD mouse models, the preclinical therapeutic efficacy of CET056 on disease progression of LUAD was also tested.
Results: CET056 was shown to effectively decrease YB-1 expression in both human and mouse LUAD cell lines and exert inhibitory effects on LUAD *in vitro* and *in vivo*. This treatment delayed tumor progression and metastasis in CMT-64 syngeneic mouse model. Proteomics analysis revealed that translational machinery-associated pathways were down-regulated in LUAD cells after CET056 treatment whereas apoptosis and cell death-associated pathways were up-regulated. In alignment with this finding, CET056 treatment in combination with cisplatin showed chemo-sensitizing effect on LUAD *in vitro* and *in vivo*.
Conclusion: Our studies suggest that YB-1 could be a promising target for combating chemoresistance in LUAD. Inhibition of YB-1 with a small molecule drug as a monotherapy or combination therapy could an effective strategy to treat LUAD.

#0669 Interrogating circadian clock compounds as an adjuvant to chemoradiation against GBM.

P. Chan[1], Q. Wu[2], A. Hovsepyan[3], S. Mkhitaryan[3], G. Karapetyan[3], K. Shah[4], H. Wakimoto[5], T. Kamenecka[6], L. A. Solt[6], J. Cope[7], T. Hirota[8], R. A. Moats[3], J. N. Rich[2], S. A. Kay[1];

[1]University of Southern California, Los Angeles, CA, [2]School of Medicine UPMC, University of Pittsburgh, Pittsburgh, PA, [3]Children's Hospital of Los Angeles, Los Angeles, CA, [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [6]UF Scripps, University of Florida, Jupiter, FL, [7]Synchronicity Pharma, San Jose, CA, [8]Nagoya University, Nagoya, Japan

Despite the extensive efforts of researchers and physicians over the past two decades, glioblastoma (GBM) remains the most prevalent brain tumor type with a grim average survival time of 8 months following diagnosis irrespective of treatment. Additionally, the current standard-of-care has not changed from maximal surgical resection followed by concurrent chemoradiation from its establishment in 2005. One of the major challenges that limits progress in treating GBM is the presence of GBM stem cells (GSCs) that are highly invasive, reaching far past the tumor margins, are resistant to both chemotherapy and radiation, and can recapitulate the primary tumor following resection. Recent studies have found that GSCs, however, are highly sensitive to targeting of core circadian clock components, particularly positive regulators of the clock Brain and Muscle ARNTL-Like 1 (BMAL1) and Circadian Locomoter Output Cycles Protein Kaput (CLOCK). Here we employ the use of small molecule compounds that upregulate the activity of the negative regulators of the clock in order to suppress BMAL1::CLOCK transcriptional activity or repress *BMAL1* transcription. We find that these compounds not only have a much more potent effect against GSCs compared to temozolomide (TMZ) chemotherapy but also, they display combination effect against both GSCs and differentiated GSCs (DGCs) when combined with TMZ. These results suggest that the blood brain barrier (BBB) penetrant circadian clock compounds can be utilized as an adjuvant to current GBM therapies as they can effectively target both the primary tumor cells and GSCs.

#0670 Preclinical candidate LAE120, a novel selective USP1 inhibitor shows effective anticancer and combination activity with PARP inhibitor.

J. Wang, Y. Chen, J. Chen, L. Jiang, X. Lin, C. Cai, M. Zhang, M. Li, J. Gu;
Laekna Therapeutics Shanghai Co., Ltd., Shanghai, China

The Fanconi anemia (FA) and translesion synthesis (TLS) are DNA damage tolerance and repair pathways that have been found to be regulated by reversible ubiquitination in which ubiquitin-specific protease 1 (USP1) plays a key role. Numerous studies have indicated that USP1 inhibitors have therapeutic effects on tumors with homologous recombination deficiency (HRD), including mutations in BRCA1/2. Due to the emergence of resistance to PARP inhibitors in clinical applications, new strategies are needed to address this issue. Here we present LAE120, a novel, allosteric and highly potent USP1 inhibitor, displayed monotherapy potency and combination activity with PARP inhibitor in HRD cancers. LAE120 has a unique tail group distinct from all the published USP1 inhibitors and is predicted to induce a different conformational change at the USP1 allosteric site. In the biochemical assay, LAE120 strongly inhibited USP1 enzymatic activity with IC_{50} of 5.6 nM. LAE120 potently inhibited proliferation of BRCA-mutated MDA-MB-436 breast cancer cell (IC_{50}:19 nM) and exhibited anti-proliferative activity in NCI-H1792 (IC_{50}: 69 nM) and K562 (IC_{50}: 38 nM) cell lines. In the xenograft model of MDA-MB-436 cells with BRCA mutations, LAE120 demonstrated robust single-agent tumor inhibitory activity (TGI: 88%, 10 mg/kg BID) and a favorable dose-dependent response (TGI: 106%, 25 mg/kg BID). We also observed strong tumor-inhibition efficacy of LAE120 as a single agent in the K562 xenograft model with Bcr-Abl expression (TGI: 86%, 10 mg/kg BID). Current research indicates that USP1 inhibitors exhibit synergistic activity in combination with PARP inhibitors and re-sensitizes PARP refractory tumors. Similar results have been confirmed in the xenograft model of BRCA-mutated MDA-MB-436 cells. The combination of LAE120 and Olaparib (PARP inhibitor) yielded a more robust and durable anti-tumor efficacy at low dose (TGI: 110%, LAE120, 5 mg/kg BID + Olaparib, 50 mg/kg QD). LAE120 also displayed favorable ADME properties and PK profiles. Preclinical-tox studies indicated the molecule was well tolerated without significant toxicities and hematological observations. Both in vitro and in vivo data strongly support further investigation of LAE120, whether as a single agent or in combination therapy.

#0671 G-protein coupled receptor (GPCR) screening library identifies sertindole, an antipsychotic, as potential therapeutic option to target GNAQ mutation Q209L in uveal melanoma.

S. Rheinschmidt[1], **T. Bargenquast**[2], S. Adamson[1], T. Thode[1], A. Weston[1], T. Ghosh Halder[1], S. Ng[1], H. Tulasi[1], B. Durbin[1], J. Moser[2], M. Kaadige[1], R. Soldi[1], S. Sharma[1];

[1]TGen (Translational Genomics Research Institute), Phoenix, AZ, [2]HonorHealth Research Institute, Scottsdale, AZ

Background: Uveal melanoma is a rare but aggressive intraocular malignancy with limited therapeutic options. A hallmark genetic alteration associated with uveal melanoma is the mutation of the GNAQ gene, particularly the Q209L substitution in the Gαq protein, which contributes to oncogenic signaling and tumor progression. The GNAQ gene encodes for a Gαq protein that plays a critical role in signal transduction pathways involving G protein-coupled receptors (GPCRs). The Q209L substitution results in a gain-of-function mutation, leading to the chronic activation of downstream signaling pathways. This persistent signaling activity contributes to the uncontrolled growth of uveal melanoma cells. As G protein-coupled receptors (GPCRs) play a crucial role in this process, screening libraries of GPCR inhibitors has been explored as a potential therapeutic avenue. These libraries comprise a vast array of compounds with the potential to block or modulate GPCR activity. Identifying specific inhibitors that can effectively interfere with the oncogenic signaling cascades triggered by the mutated Gαq protein is a critical step in developing targeted therapies for uveal melanoma.
Methods: GPCR library high throughput screening employed isogenic cell lines expressing wild type or mutant (Q209L) GNAQ. This process utilized IP-One assays to identify compounds affecting Gq-coupled receptors by detecting inositol monophosphate accumulation. Subsequently, promising hits were evaluated for their impact on inhibiting the growth and proliferation of uveal melanoma cells. Further analysis involved Western blotting to assess their potential in promoting autophagy and apoptosis, inhibiting downstream signaling pathways, and a migration assay. Finally, ROS generation was assessed using flow cytometry.
Results: Using isogenic cell lines expressing GNAQ gene wild type and the Q209L mutant, a high-throughput screening of GPCR libraries identified sertindole among 5 hits. Sertindole showed a dose-dependent inhibition of Q209L-mutated uveal melanoma cells, significantly reducing cell viability, proliferation, and migration. It also suppressed key signaling pathways, including the critical MAPK pathway, and activated autophagy and apoptosis, likely via ROS generation. These findings suggest sertindole's multifaceted approach in suppressing cancer in uveal melanoma.
Conclusion: Our study highlights the potential therapeutic value of sertindole in GNAQ Q209L-mutated uveal melanoma. Further research is needed to evaluate the efficacy of sertindole in preclinical mouse models of uveal melanoma.

#0672 Small molecule NSC59984 stimulates mitochondria-dependent ferroptosis and overcomes integrated stress response pro-survival signaling in pre-clinical pancreatic and colorectal cancer models.

P. R. Srinivasan, A. J. De La Cruz, M. Pinho-Schwermann, A. George, W. J. MacDonald, S. Zhang, W. S. El-Deiry;
Legorreta Cancer Center at Brown University, Providence, RI

Pancreatic and colorectal cancer are leading causes of cancer deaths worldwide. Resistance to current therapeutics is a significant challenge in treating these cancers. Ferroptosis, a non-apoptotic iron-dependent form of cell death characterized by overwhelming lipid peroxidation, has emerged as a potential strategy to overcome drug resistance. Our lab previously identified the small-molecule NSC59984 as a p53 pathway restoring compound that induces reactive oxygen species, requires p73, and targets mutant p53 for ubiquitin-mediated proteolysis involving MDM2 and HSP90. In pre-clinical models of pancreatic and colorectal cancer, we now show that the small-molecule NSC59984 induces lipid peroxidation and causes reactive oxygen species-dependent apoptosis as monotherapy. However, when combined with ferroptosis inducers or cystine deprivation, NSC59984 potently induces ferroptosis in a mitochondrial complex III-dependent manner. Using CRISPR/Cas9 in pancreatic cancer cells, we further show that HRI, an EIF2-alpha kinase responsible for the cellular response to mitochondrial stress, induces the integrated stress response (ISR) upon treatment with NSC59984 or ferroptosis inducers. The ISR serves as a mechanism for resistance to cell death induced by NSC59984 or ferroptosis inducers, causing upregulation of key anti-oxidative stress and anti-ferroptosis proteins, including the cystine importer SLC7A11 and the GPX4-stabilizing protein HSPA5/BIP/GRP78. The combination therapy overcomes the ISR to induce potent cell death. Our work demonstrates the importance of the interplay between mitochondria and the ISR during ferroptosis induction in pancreatic and colorectal cancer cells.

#0673 Mechanisms of drugs in ovarian cancer and prevention of invasion and metastasis.

L. F. Mortan, D. Benbrook;
University of Oklahoma Health Sciences Center, Oklahoma City, OK

Introduction: Ovarian cancer patients are typically diagnosed late stage after the cancer has left the primary site, this is the major factor contributing to the 70% 5-year mortality rate. Standard of care is Platinum therapies or debulking surgery followed by maintenance therapies to keep cancer from coming back. The limitation to these therapies is overall toxicity to the patient forcing them to stop treatments or eventual resistance to the therapy. The objective of this study is to evaluate the mechanisms in which the novel drug, SHetA2, alone compares to the competitor, Olaparib. Additionally, discover the genetic differences between attached tumor and floating tumor in ascites.Objective: Our objective was to evaluate the mechanisms in which the novel drug, SHetA2, alone compares to the front-line competitor, Olaparib, in affecting Filamin A and cyclin d1 levels in ovarian cancer. Methods: Individual and combination drug treatments were preformed on two ovarian cancer cell lines and patient samples for cell viability assays. Immunocytochemistry was performed to visualize colocalization of proteins. RNA isolation was performed for Nanostring analysis.
Results: Ovarian cancer cells treated with SHetA2 or olaparib demonstrate a decrease of cyclin D1 on the membrane colocalized with filamin A, a structural protein that facilitates movement by acting as a signaling molecule for downstream effects. Nanostring analysis of attached tumor and spheroids form ascites shows significant differential gene expression in tumor versus ascites.
Conclusions: These results suggest the decrease of cyclin D1 with filamin A upon treatment with SHetA2 or olaparib could be one of the primary factors leading to each drug’s efficacy and additivity with each other. The differential gene expression of tumor versus ascites begins to elucidate the fundamental differences between attached and floating tumors and spheroids.

#0674 Novel anti-cancer small molecule targeting the protein regulator of cytokinesis pathway.

A. Peled[1], M. Abraham[2], H. Wald[2], R. Rosenfeld[2], O. Eizenberg[2], A. Aharon[2];
[1]Hadassah Hebrew University Hospital, Jerusalem, Israel, [2]Alonbio ltd, Ness Ziona, Israel

Aberrant migration and proliferation of cancer cells are the hallmark of metastatic tumors. Protein Regulator of Cytokinesis 1 (PRC1) is a scaffold protein that regulates metabolic pathways of cancer cell proliferation, survival, and metastasis. BKT300 is a small molecule (MW 399.33, C22H25NO6), that selectively inhibits the migration and survival of hematological and solid cancer cells. BKT300 inhibits, at high affinity, both actin and microtubule formation and organization leading to G2/M cell cycle arrest, mitotic catastrophe, and apoptosis through the caspase 3 pathway. These effects are selective to cancer cells and were not observed on normal cells. BKT300 was found to arrest PRC1 in a phosphorylated form at position T481, down regulates the expression of CDC25C and up regulate p21. Suppression of PRC1 using SiRNA ablation inhibited BKT300 induced apoptosis on several tumor cell lines and inhibited the effect of BKT300 on G2M cell cycle arrest. Furthermore, using Biacore SPR, microscale thermophoresis (MST), and ELISA assays we were able to demonstrate the direct binding of BKT300 to PRC1. Beyond its single agent activity, BKT300 was shown to synergize with standard of care (SoC) treatments, including anti PD-1 immunotherapy, BCL-2 inhibitor (Ventoclax), topoisomerase I inhibitor (Irinotecan) topoisomerase II inhibitor (Doxorubicin), anti-metabolite Fluorouracil (5-FU) and alkylating agent (Temozolomide). BKT300 has a remarkable safety profile when administered at high doses to mice rats, minipigs and non-human primates. Treatment with BKT300 showed almost no effects on hematopoiesis and biochemistry in doses far higher than the affective ones. The in-vivo activity of BKT300 was demonstrated in multiple Xenograft, Syngeneic and PDX models in mice. In-vivo treatment with BKT300 resulted in preventive (small tumors) as well as therapeutic (large tumors) activity in triple negative breast cancer (TNBC) xenograft, MDA-MB-453 and MDA-MB-468 models leading to over then 70%-90% reduction in tumor size following one to two treatments cycles. Similar results were obtained using PDX models derived from patients with Colon, Ovarian and Pancreatic cancer. BKT300 is a novel, first in class, targeted anti-cancer treatment that inhibits the activity of the scaffold protein PRC1. BKT300 is expected to provide a new treatment option to, the high unmet medical need of, advanced difficult to treat cancers, specifically ones that overexpress PRC1 and CDC25C.

#0675 Targeting Bcl-2/Bcl-xl for small cell lung cancer treatment with LP-118.

L.-L. Lee[1], H. Chen[2], C. Zhu[3], Y. Chen[4], B. Feldmeier[5], Y. Shen[3], Y. Chen[1], S. P. Anthony[1], F. Tan[6], Y. Chen[1], **B. Dai**[1];
[1]Newave Pharmaceutical Inc., Pleasanton, CA, [2]University of Toronto Scarborough, internship at Newave Pharmaceutical Inc., Toronto, ON, Canada, [3]Guangzhou Lupeng Pharmaceutical Co. Ltd., Guangzhou, China, [4]The Quarry Lane School, internship at Newave Pharmaceutical Inc, Pleasanton, CA, [5]Amador Valley High School, internship at Newave Pharmaceutical Inc, Pleasanton, CA, [6]Guangzhou Lupeng Pharmaceutical Co. Ltd., Guanghzou, China

Small cell lung cancer (SCLC) is an aggressive form neuroendocrine carcinoma with limited treatment options and poor prognosis, and novel approaches are urgently needed for the treatment of this disease. Bcl-2 and Bcl-xl are aberrantly expressed in 60-70% SCLC and have been considered as promising therapeutic targets for SCLC. However, navitoclax (ABT-263), a Bcl-2/Bcl-xl dual inhibitor, demonstrated limited efficacy in SCLC while induced sever adverse events, such as thrombocytopenia due to the platelet toxicity mediated by Bcl-xl inhibition. Therefore, agents with novel mechanisms of action and safety profile are to be developed for the treatment of SCLC with Bcl-2/Bcl-xl dependency. LP-118 is a new generation and super potent Bcl-2 inhibitor with moderate Bcl-xl activity, and it is being evaluated in Phase1 clinical trials in solid tumors and hematological cancers (NCT05025358, NCT04771572). In this preclinical study, we aimed to evaluate the single agent activity of LP-118 in a panel of 9 SCLC cell lines and to further determine if LP-118 can enhance the efficacies of Standard of Cares (SOC) *in vitro* and *in vivo*. The results show that LP-118 has high *in vitro* activity in a subset of SCLC cell lines, and it is particularly potent in Bcl-2-depended cell lines, such as NCI-H889, with the IC_{50} of 0.15 nM. LP-118 is also very potent in NCI-H1963, a Bcl-xl dependent cell line (IC50: 5nM), and NCI-H526, a Bcl-2/Bcl-xl co-dependent cell line (IC50: 4-5.1 nM). Overall, LP-118 is more potent than ABT-263 in Bcl-2 or Bcl-2/Bcl-xl co-dependent cell lines, and it is relatively less active in Bcl-2/Bcl-xl/Mcl-1 co-dependent cell lines, such as NCI-H69 (IC50: 169.7 nM). In addition, combinations of LP-118 and SN-38 (the active metabolite of irinotecan), topotecan, or etoposide, induced strong synergist effects in both NCI-H69 and NCI-H146 cell lines, suggesting that LP-118 could enhance the cytotoxicity of these drugs. Consistent with the *in vitro* data, treatment with LP-118 alone induced complete tumor remissions in NCI-H889-derived xenograft models (10/10), whereas no complete tumor remission was observed in the ABT-263-treated group. Moreover, LP-118 plus carboplatin or topotecan dramatically inhibited tumor growth of NCI-H526 xenograft models and has significantly better efficacy than either carboplatin or topotecan alone. Importantly, no significant body weight loss was observed in mice treated with LP-118 single agent or the combinations, indicating such regimens were well tolerated. In summary, LP-118, a new generation Bcl-2/Bcl-xl dual inhibitor, is highly active, as single agent or in combination with SOCs, in a large subset of SCLC cell lines. Clinical trials are ongoing to further evaluate the safety and efficacy of LP-118 in hematological cancers and solid tumors, including SCLC. Additional studies are also underway to develop predictive biomarkers for facilitating patient stratification in the clinic.

#0676 The integrated stress activator BTM-3566 overcomes therapeutic resistance in mantle cell lymphoma.

Y. Liu[1], H.-H. Lee[1], J. McIntosh[1], Y. Li[1], T. Zhang[1], W. Wang[1], M. J. Kostura[2], M. Wang[1];
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Bantam Pharmaceutical, 8 Davis Dr. Suite 220, Research Triangle Park, NC

Successive generations of BTK inhibitors and CAR T-cell therapy have transformed the treatment of mantle cell lymphoma (MCL). However, treatment resistance has inevitably emerged, creating significant medical need. Recently a novel, clinical stage small molecule, BTM-3566, has been described that targets a mitochondrial process essential for Diffuse Large B-cell lymphoma (DLBCL) survival. BTM-3566 activates the mitochondrial protease OMA1, triggering the ATF4 integrated stress response (ISR). BTM-3566 has robust *in vitro* efficacy in DLBCL cell lines irrespective of genomic background and elicits complete tumor regression in multiple CDX and PDX mouse models of DLBCL. Based on the activity observed in DLBCL, we further explored the effectiveness of BTM-3566 in MCL models *in vitro* and in xenograft mouse models *in vivo*. BTM-3566 inhibited cell proliferation across a panel of MCL cell lines, irrespective of resistance status to ibrutinib and venetoclax (IC_{50}s of 142.5-687.6 nM). Following a 24-hour treatment with BTM-3566, a dose-dependent increase in apoptosis was observed in four tested MCL cell lines—JeKo-1, JeKo-IBN-R, Mino, and Mino-VEN-R, as determined by increased caspase-3 activation and PARP cleavage. Similarly, western blot analysis revealed dose-dependent reductions in MCL-1 and c-MYC, accompanied by an increase in the transcription factor ATF4, indicative of activation of the stress response. We evaluated the *in vivo* efficacy of BTM-3566 in the JeKo-CDX mouse model. Daily oral administration of BTM-3566 at 10, 20 and 30 mg/kg ($n = 5$ for each group) in a 5-day on and 2-day off schedule resulted in tumor regression at all three doses (Treatment vs. Vehicle, $p < 0.01$). We expanded our investigation to PDX mouse models, including those derived from patients resistant to multiple therapies. Four PDX models encompassing naive, rituximab-resistant, BTKi-CAR T dual-resistant and BTKi-VEN-CAR T triple-resistant models were evaluated. BTM-3566 treatment results in nearly complete tumor growth inhibition associated with robust reductions in tumor burden in treated mice across all four PDX models (reduction in tumor weight at the study endpoint, $p < 0.001$). Notably, no toxicity was observed during the treatment period. In summary, BTM-3566 is effective in treating MCL *in vitro* and *in vivo* in preclinical studies.

#0677 Discovery of a first-in-class allosteric inhibitor of the small GTPase Rac1.

Robert Silverman[1], Alan Cooper[1], Ronodip Kar[2], Mayuri V. Raman[2], Ramu Ravirala[2], Mubarak Hasan Shah[2], Sandeep Mahankali[2], **Erik T. Goka**[1]

[1]Revere Pharmaceuticals, Arlington, MA,[2]Aurigene Pharmaceutical Services Limited, Telangana, India

The Rac1 signaling pathway is known to be hyperactivated in numerous solid tumors. We developed a Rac1 AlphaLISA assay that is amenable to high-throughput screening (HTS) to screen large libraries of small molecules. Based on molecular modeling of a putative allosteric binding site for several of the hits, we optimized a series of compounds that lead to RP-102124. RP-102124 engages with Rac1 in both biochemical and cellular target engagement assays. RP-102124 has greater potency than previously reported Rac1 inhibitors in biochemical assays, with potent inhibition of phenotypic characteristics of Rac signaling such as cell migration and cytoskeletal rearrangements. RP-102124 is a Rac^{multi} inhibitor with activity against oncogenic Rac1b. RP-102124 is orally bioavailable and shows dose dependent inhibition of tumor growth in xenograft models at doses that are well-tolerated. RP-102124 is a first-in-class allosteric Rac^{multi} inhibitor that shows promising therapeutic potential.

#0678 Experimental therapy of triple negative breast cancer with next-generation of MDM2 inhibitors.

W. Wang[1], H. Chen[2], Y. Xie[2], S. Datta[1], W. Li[2], R. Zhang[1];
[1]University of Houston, College of Pharmacy, Houston, TX, [2]University of Tennessee Health Science Center, Memphis, TN

Patients with triple-negative breast cancer (TNBC) typically experience minimal benefits from the existing hormonal or trastuzumab-based therapies, necessitating reliance on chemotherapy as the predominant treatment approach, which, unfortunately, is limited by insufficient efficacy, significant side effects, and the development of drug resistance. These issues highlight an urgent demand for the discovery and development of more effective and safer therapeutics for TNBC. Overexpression and amplification of the MDM2 oncogene frequently occur in TNBC, which is associated with invasive and high-grade/late-stage tumors, metastasis, and recurrence, and is an independent negative prognostic factor for TNBC patients. Extensive studies have indicated that MDM2 represents a novel molecular target for TNBC. Thus far, multiple strategies aiming at MDM2 inhibition have not succeeded in Phase II-III clinical trials, largely due to factors like inadequate efficacy, significant drug toxicity, and emergence of resistance. In addition, TNBC tumors commonly harbor mutant p53, and the existing MDM2 inhibitors that block p53-MDM2 binding and depend on wild-type p53 expression in the tumor to exert anticancer effects would have little or no clinical responses or even induce resistant clones by increasing MDM2 expression and its oncogenic activity. Therefore, there is a need for developing new-generation MDM2 inhibitors that are p53-independent. We recently discovered a novel class of MDM2 degraders, representing a paradigm shift in the strategy of targeting MDM2. One of these analogs, WW68, was identified as a potent and selective MDM2 inhibitor. Its *in vitro* and *in vivo* anti-breast cancer activities and underlying mechanisms of action were evaluated in breast cancer cell lines with various p53 backgrounds. Our results demonstrate that WW68 effectively induces MDM2 protein degradation. It selectively inhibits breast cancer cell growth, decreases cell proliferation, and induces G2/M phase arrest and apoptosis in breast cancer cells, regardless of p53 status. Notably, in clinically relevant TNBC PDX models, WW68 inhibited MDM2 and suppressed tumor growth without causing host toxicity. In conclusion, WW68 represents a new class of MDM2 inhibitor that exerts its anticancer activity through directly down-regulating MDM2, and may be developed as a novel anti-TNBC therapeutic agent. (Supported by NIH R01CA214019 and R01CA240447; and DoD W81XWH2010011)

#0679 TXB-001 is an upgraded conjugated anthracycline that targets tumors with reduced risk of cardiotoxicity, hand-foot syndrome and alopecia.

K. Oshida[1], M. Hirakata[1], E. Tomikawa[1], C. Sakai[1], M. Uchida[1], R. Shimozono[1], A. Izawa[1], Y. Koga[1], T. Okano[1], H. Narumi[1], L. Munakata[2], R. Suzuki[2], M. Nonaka[3], Y. Uezono[3];

[1]Toray Industries, Inc., Kamakura, Japan, [2]Teikyo University, Tokyo, Japan, [3]The Jikei University School of Medicine, Tokyo, Japan

TXB-001 is a well-optimized N-(2-hydroxypropyl)methacrylamide copolymer-based conjugated pirarubicin (THP) and a novel candidate for developing anticancer drugs. It exhibits tumor-specific accumulation due to the enhanced permeability and retention effects and prolonged circulation time compared with free THP. Its hydrazone bond is dissociated under lower pH conditions, providing selective and rapid release of THP in acidic tumor environments. Therefore, TXB-001 is expected to have high efficacy and low toxicity. Anthracycline anticancer drugs have been widely used for the treatment of several cancers, but their use is limited by several adverse effects (AEs), including cardiotoxicity, which is a life-threatening AE. Furthermore, the maximum lifetime cumulative dose is decided for each anthracycline in clinical use, which leads to discontinuation of the medication. Hand-foot syndrome (HFS) is a dose-limiting AE of DOXIL®, a liposomal formulation of doxorubicin (DOX), and although it is not a life-threatening condition, it significantly deteriorates quality of life (QOL). Alopecia is another common AE, which is relatively noninvasive but adversely affects mental health and reduces QOL. In this study, we confirmed the efficacy of TXB-001 in a mice triple-negative breast cancer (TNBC) model and evaluated the cardiotoxicity-, HFS- and alopecia-inducing effects of TXB-001 in mice and rats to compare the severity with existing anthracycline anticancer drugs, including DOXIL®. The pharmacokinetic (PK) analysis in several tissues, including plasma, tumor, heart, skin of the chest, and palmar and plantar areas, was also performed after a single intravenous administration in rodents. As a result, TXB-001 showed an equivalent or greater antitumor effects than other anthracyclines in the TNBC model, and the AEs were scarcely observed. TXB-001 did not decrease left ventricular ejection fraction, with no or little HFS-like changes compared with DOXIL®, which showed significant histopathological changes. TXB-001 also showed weaker alopecia-inducing effects than DOX, DOXIL®, and THP. In the PK analysis, TXB-001 was distributed in the tumor at a higher concentration than in other tissues, except for plasma. Hence, most of the THP, the active ingredient, was released in the tumor. The exposure of the heart in the TXB-001-treated group was one-tenth of that in the DOXIL®-treated group. Moreover, accumulation in the skin, especially in palmar and plantar areas, was observed for DOXIL®, but no accumulation in the skin was observed for TXB-001. This PK profile consistently demonstrated the antitumor activity of TXB-001, without AEs. TXB-001 reduces the chance of dose-limiting and QOL-threatening AEs, and thus, cancer patients can continue treatment, making it a more convenient anticancer drug in clinical use with a wide safety margin.

#0680 Leveraging an RNA-targeting platform for the discovery of cell-active c-MYC mRNA-binding small molecules.

M. J. Smola, K. Marran, S. E. G. Thompson, B. Patterson, R. K. Pavana, C. Sutherland, J. A. Sorrentino, **K. D. Warner**;
Ribometrix, Durham, NC

The MYC gene, with its oncogenic potential, has long been a formidable challenge in conventional drug discovery efforts, and its critical role in cancer progression and resistance has underscored the need for innovative therapeutic strategies. Here we demonstrate the capabilities of the Ribometrix RNA-targeting platform to modulate the c-MYC mRNA with small molecules with the aim of reducing c-MYC protein levels.

Using our comprehensive platform of RNA-targeting drug discovery tools and analyses including chemical probing, structure modeling, high-purity RNA production, high-throughput screening, and biophysical characterization, we evaluated the potential to directly target c-MYC mRNA using small molecules. Our analysis revealed six high-confidence structured elements throughout the c-MYC mRNA expected to harbor tertiary structures amenable to drug-like ligand binding. Leveraging the multifaceted chemical probing and structure modeling components of our platform, we confirmed that our *in vitro*-transcribed RNA screening constructs adopt the same structures found in endogenous cellular c-MYC transcripts. After large-scale *in vitro* RNA preparation, we subjected four of these RNA elements to high-throughput screens of chemically diverse drug-like libraries using mass spectrometry affinity-selection that identified multiple chemical series with sub-micromolar affinity. We validated binding affinity using orthogonal methods including isothermal titration calorimetry and NMR. To eliminate pan-binding ligands, we evaluated of selectivity against a panel of non-target mRNA structures. Importantly, these compounds lead to rapid (4 hr) reduction of MYC protein levels in a small cell lung cancer cell line, DMS-273, with no cellular toxicity at 72 hr suggesting an on-target effect. Employing our suite of chemical probing tools, we confirmed that compounds from multiple series engage the c-MYC mRNA in cells. Medicinal chemistry efforts are ongoing to increase potency and define the precise mechanism of action in clinically relevant models.

The discovery of these c-MYC mRNA-binding small molecules not only validates the utility of the Ribometrix RNA-targeted small molecule discovery platform but also showcases its potential in tackling traditionally 'undruggable' targets and provides a promising avenue for developing novel anti-cancer therapies. As we learn more about the intricacies of c-MYC mRNA biology and further refine effective small molecules, our results provide practical insights into previously-unknown vulnerabilities of MYC and present tangible opportunities for advancing targeted cancer therapies.

#0681 Rewiring collagen architecture using a highly potent bi-thiazole inhibitor of LOX mediates chemosensitization in triple-negative breast cancer.

Metin Cetin[1], Ozge Saatci[1], Abdol-Hossein Rezaeian[2], Chintada N. Rao[2], Chad Beneker[2], Harrison Taylor[1], Breanna Pederson[2], Ioulia Chatzistamou[2], Brian Buckley[3], Susan Lessner[2], Peggi Angel[1], Campbell McInnes[2], **Ozgur Sahin**[1]

[1]The Medical University of South Carolina (MUSC), Charleston, SC,[2]University of South Carolina, Columbia, SC,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Lysyl oxidase (LOX) is the founding member of the LOX family proteins and mediates the conversion of lysine residues in collagen I and elastin precursors into highly reactive aldehydes, leading to crosslinking of extracellular matrix (ECM). LOX is upregulated in aggressive tumors with high stiffness, and its higher expression correlates with metastasis, therapy resistance, and worse clinical outcome; however, relatively LOX-specific, orally bioavailable inhibitors are still lacking. Here we discovered bi-thiazole derivatives as potent LOX inhibitors by combining a robust screening platform for drug-like molecules, cell- and recombinant protein-based assays. Structure-activity relationship analysis further identified a potent and relatively LOX-specific lead compound (LXG6403) that reduces collagen content and crosslinking, and fibronectin assembly, leading to increased chemoresponse in triple-negative breast cancer (TNBC) cell lines and PDX organoids in 3D collagen. LXG6403 shows favorable pharmacokinetic properties, reduces collagen content and crosslinking, as demonstrated by the state-of-the-art MALDI-MSI and MP-SHG analyses, respectively. This leads to better drug penetration, inhibition of FAK signaling, and induction of ROS generation/DNA damage, leading to G1 arrest and apoptosis in chemoresistant TNBC PDXs. Overall, our novel, potent, tolerable bi-thiazole LOX inhibitor enhances chemoresponse in TNBC, the deadliest breast cancer subtype.

#0682 Development of novel eIF4E inhibitors to potently and selectively suppress tumor growth across multiple indications.

M. B. Friedersdorf, D. R. Blake, S. E. G. Thompson, R. Pavana, R. V. S. Changalvala, A. S. Truong, K. Marran, A. Bias, J. A. Sorrentino;
Ribometrix, Durham, NC

Despite considerable progress in treating cancer, drug resistance remains the primary hurdle to achieving cures in patients. Tumors often develop resistance through reactivation of the drug-targeted pathway, or activation of alternative parallel pathways, thereby maintaining the original downstream signaling effects. One of the furthest downstream effectors and critical nodes for many oncogenic signaling pathways is eukaryotic translation initiation factor 4E (eIF4E); the main regulator and rate limiting factor for protein synthesis. eIF4E is reactivated by many resistance mechanisms to promote translation of multiple pro-oncogenic factors including Cyclin D1/3, making it an attractive target to potentiate the anti-cancer activity of targeted therapies and to overcome drug resistance. Here, we present the development of novel, potent, and selective eIF4E inhibitors for use in both treatment-naïve and resistance settings across multiple tumor indications.

To capitalize on the potential of targeting eIF4E, we developed a series of compounds with unique properties that maintain anti-tumor efficacy while minimizing toxicity. Our novel, selective, and potent oral eIF4E inhibitors (RBX-eIF4Ei) elicit a reversible, dose-dependent cell cycle arrest. Unlike targeting eIF4A, eIF4E inhibition selectively regulates translation of cancer-dependent pathway proteins instead of global protein synthesis, thus reducing on-target toxicity and increasing tolerability. Cellular profiling demonstrates RBX-eIF4Ei are highly selective, nanomolar inhibitors across many tumor types including, NSCLC, CRC, breast, and melanoma. Additionally, RBX-eIF4Ei demonstrate consistent efficacy across both sensitive and resistant cell lines, including intrinsic and acquired resistance models. Combining RBX-eIF4Ei with standard of care targeted therapies produces additive responses in both settings, suggesting its potential anti-neoplastic benefits post progression.

In vivo, daily oral monotherapy treatment with RBX-EIF4Ei causes significant tumor growth inhibition across a variety of indications including BRAFmut CRC, BRAFmut melanoma and ER+ breast cancer, with minimal signs of toxicity. Intratumoral concentration of RBX-eIF4Ei correlate with significant tumor cell growth inhibition, as well as reductions in eIF4E target proteins, ODC1 and Cyclin D1. Combination studies with standard of care in both the treatment naïve and resistant settings are ongoing.

Collectively, these data support the addition of RBX-eIF4Ei to standard of care in both the naïve and treatment resistance settings across a variety of indications including NSCLC, breast, CRC, and melanoma. IND enabling studies are planned, marking a significant step toward advancing these promising eIF4E inhibitors into clinical development.

#0684 DT-9045, a novel PAR2 inhibitor with best-in-class properties that reduces resistance to both EGFR-targeting therapies and immunotherapy in oncology models.

T. Brugat[1], M. Kadiri[2], S. Aouad[2], A.-L. Blayo[1], B. Rugeri[1], A. Mousson[1], A. Janvier[1], E. Steinberg[1], L. Baron[1], M. Recolet[1], X. Wirth[1], M. Garcia-Leon[1], Q. Ruet[1], M. Semache[3], L. Sabbagh[3], O. Blanchard[1], C. Franchet[1], S. Mayer[1], J. Stagg[2], N. Lenne[1], S. Schann[1];

[1]Domain Therapeutics, Illkirch, France, [2]Universite de Montreal, Montreal, QC, Canada, [3]Domain Therapeutics NA, St-Laurent, QC, Canada

Protease-activated receptor 2 (PAR2) is a promising therapeutic target in oncology and immuno-oncology. It is upregulated and associated with poor prognosis in several cancer types. A pan-cancer meta-analysis showed that PAR2 is one of the genes most significantly associated with resistance to immune checkpoint blockade (ICB) and T cells dysfunction in cancer patients. Mechanistically, being expressed by various cells of the tumor microenvironment, PAR2 promotes both survival and proliferation of cancer cells and dampens the anti-cancer immune response. Domain Therapeutics has developed a novel PAR2 inhibitor, DT-9045, with best-in-class properties. Indeed, compared to its most advanced competitors, DT-9045 is a small molecule, orally bioavailable, insurmountable, biased, and active in tumor-like conditions (i.e. acidic pH and high level of activating proteases). This compound is also highly potent and selective on PAR2. Pharmacokinetic properties are suitable with a once-a-day oral administration. In vitro, DT-9045 completely prevented PAR2-mediated resistance to EGFR-targeting drugs. In vivo, its combination with anti-PD1 therapy showed a significant increase in efficacy over monotherapies in preclinical syngeneic mouse cancer models. This result was similar to the one observed in PAR2 knockout mice, indicating that oral administration of DT-9045 induces a complete inhibition of the receptor. We have further demonstrated that treatment with a PAR2 inhibitor enhances dendritic cell-mediated T cell activation and intratumoral infiltration of CD4+ and CD8+ T cells as well as a decrease in M2 macrophage infiltration. In conclusion, Domain Therapeutic has identified a novel PAR2 inhibitor, DT-9045, with clear competitive advantages. This preclinical candidate has shown strong potency in alleviating the resistance to both EGFR-targeting therapies and immunotherapy in preclinical cancer models. IND-enabling studies are currently ongoing to bring this new hope for cancer patients to the clinic.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Radiotherapeutic Combinations, Modifiers, Protectors, Sensitizers, and Molecular Targets Poster Session

#0688 Radium-223 in combination with darolutamide exhibits synergistic antitumor efficacy in LNCaP prostate cancer models.

C. A. Schatz[1], M. I. Suominen[2], A. Schlicker[1], M. Knuuttila[3], E. Alhoniemi[4], S.-M. Kakonen[3], B. Haendler[1], U. B. Hagemann[1], **A. Scholz**[1];
[1]Bayer AG, Berlin, Germany, [2]Pharmatest Services Ltd., Turku, Finland, [3]Aurexel Life Sciences Ltd., Askainen, Finland, [4]Inoi Oy, Turku, Finland

Radium-223 dichloride (radium-223) is a targeted alpha therapy that binds to newly formed abnormal bone in bone metastases and induces DNA double-strand breaks (DSBs) in cancer cells, osteoblasts and osteoclasts. Radium-223 is used for the treatment of patients with metastatic castration-resistant prostate cancer (mCRPC). Darolutamide is an androgen receptor inhibitor indicated for patients with metastatic hormone-sensitive prostate cancer or non-metastatic CRPC. We studied the antitumor effects of radium-223 in combination with darolutamide using LNCaP human prostate cancer cells *in vitro* and an intratibial LNCaP model mimicking prostate cancer metastasized to bone.
The *in vitro* antiproliferative effects of radium-223 and darolutamide were determined using LNCaP cells. Gene set enrichment analysis (GSEA) was conducted on RNA sequencing data from LNCaP cells treated with the synthetic androgen R1881 alone or in combination with darolutamide. LNCaP cells were inoculated into the right tibia of male NOD.scid mice. The mice (n=7-9/group) were randomized based on serum prostate-specific antigen (PSA) and treated with vehicle, radium-223 (330 kBq/kg, Q4Wx2, i.v.), darolutamide (100 mg/kg, BID, p.o.), or with a combination of radium-223 and darolutamide, for 41 days. PSA and the bone turnover markers PINP and CTX-I were measured every second week in serum. Tumor-induced abnormal bone area, bone formation rate and radium-223 uptake in tumor-bearing tibiae were determined by X-ray, histomorphometry and gamma counter, respectively.
The combination of radium-223 and darolutamide showed synergistic antiproliferative effects with combination indexes between 0.69-0.75 *in vitro*. GSEA demonstrated a prominent darolutamide-induced downregulation of DNA damage response (DDR) signaling pathways. *In vivo,* the combination treatment showed synergistic antitumor efficacy (p=0.04) as demonstrated by lower PSA concentrations when compared with the vehicle, radium-223 or darolutamide monotherapies (p=0.004, p=0.011 and p=0.002, respectively). In the vehicle and combination treatment groups, the mean serum PSA was 541% and 95.9% of the pre-treatment level, respectively. Furthermore, radium-223 alone or in combination with darolutamide inhibited increased bone turnover, tumor-induced abnormal bone growth and trabecular bone formation when compared to vehicle. Concurrent administration of darolutamide did not affect radium-223 uptake in tibiae.
Radium-223 in combination with darolutamide exhibited synergistic antitumor efficacy both *in vitro* and *in vivo*. The synergistic effects could be due to the radiosensitization of cancer cells by darolutamide-induced downregulation of DDR pathways. Our results suggest that the combination of targeted alpha therapy with an androgen receptor inhibitor is a promising treatment strategy for mCRPC.

#0689 BUB1 interferes with the repair of radiation-induced DNA damage to radiosensitize triple-negative breast cancer.

S. Sriramulu[1], S. Thoidingjam[1], P. Li[1], S. L. Brown[1], F. Siddiqui[1], B. Movsas[1], M. Green[2], C. Speers[3], S. Nyati[1];
[1]Henry Ford Health, Detroit, MI, [2]University of Michigan, Ann Arbor, MI, [3]UH Seidman Cancer Center, University Hospitals Case Medical Center, Case Western Reserve University, Cleveland, OH

Triple-negative breast cancer (TNBC) is associated with locoregional recurrence and low survival rates. Novel molecular targets are expected to improve the efficacy of radiation therapy (RT) in TNBC. BUB1, a mitotic checkpoint Serine/Threonine-protein kinase is known to impact chromosomal segregation during mitosis. However, its precise role in DNA damage repair in response to RT remains largely unknown. We demonstrated that BUB1 is overexpressed in BC (vs. normal breast) and considerably raised in TNBC with poor survival outcomes using differential gene expression analysis. In multiple TNBC cell lines, cell proliferation assays revealed that pharmacological (BAY1816032) or genomic (CRISPR) ablation of BUB1 was cytotoxic. Using clonogenic survival assays, we observed that BUB1 ablation radiosensitized TNBC cell lines (SUM159, MDA-MB-231, MDA-MB-468, BT-549) while its ablation did not radiosensitized breast epithelial cells (MCF10A). Furthermore, by depleting endogenous BUB1 (siRNAs and CRISPR) and reintroducing wild-type (WT) or kinase-dead (KD) BUB1, we demonstrated that inhibition of BUB1 kinase function is responsible for the radiosensitization phenotype. BUB1 ablation increased tumor doubling time in SUM159 xenografts when combined with radiation. Ki67 levels were also reduced in these tumors, confirming the efficacy of the combined treatment. BUB1 ablation led to persistent radiation-induced DNA DSB (gH2AX foci) indicating decreased DNA-DSB repair. BLRR assays confirmed that BUB1 impacts the non-homologous end joining (NHEJ) pathway. Biochemical analyses showed that BUB1 ablation stabilized total- and phospho- DNAPKcs (S2056) following RT such that half-lives could not be estimated. In contrast, RT alone caused BUB1 stabilization, but pre-treatment with BUB1i and DNAPKi prevented stabilization. To evaluate the recruitment of DDR proteins to the chromatin following RT, soluble nuclear and chromatin-enriched fractionations were performed which illustrated an increase in recruitment of phospho- and total-DNAPK, KAP1, and ATM to chromatin indicating that BUB1 is important in the activation and recruitment of critical NHEJ proteins to DSBs. In addition, BUB1 staining of TNBC TMAs demonstrated significant correlation between BUB1 protein expression with tumor grade and stage in TNBC patients. Our findings demonstrate that ablation of BUB1 sensitizes TNBC cell lines and xenograft to RT and BUB1 mediated radiosensitization may occur through NHEJ. Our results suggest that BUB1 may serve as a novel molecular target for radiosensitization in women with TNBC.

#0690 Investigation of BH-3 mimetics as radiosensitizing agents in glioblastoma.

L. R. Dutton[1], C. Mullen[2], A. L. Koessinger[1], M. Jackson[1], K. Stevenson[1], A. J. Chalmers[1], S. Tait[1], K. J. Campbell[2], J. L. Birch[1];
[1]University of Glasgow - Institute of Cancer Sciences, Glasgow, United Kingdom, [2]CRUK Scotland Institute, Glasgow, United Kingdom

Glioblastoma (GBM) is a highly aggressive primary brain tumor. Treatment consists of maximal safe tumor resection, chemotherapy (temozolomide) and radiotherapy; however, this aggressive treatment offers only a modest improvement in outcomes, with average life expectancy of approximately 12 months. Consequently, novel, effective and easily translatable therapies are urgently required. While radiotherapy is an effective treatment for many solid tumors, GBM displays an innate radio-resistance that contributes to treatment failure. Therefore, there is a need to identify chemotherapeutics that can be used as radiosensitizers to increase efficacy. Notably, a key pathway involved in therapeutic resistance is apoptotic evasion, which is driven by upregulation of pro-survival BCL-2 proteins that inhibit the pro-apoptotic proteins necessary for the apoptotic response. Recent advances in drug development have produced a range of BH3 mimetics - novel chemotherapeutics with potential to reinstate apoptosis by targeting specific pro-survival molecules. We hypothesized that the radiation sensitivity of GBM cells would be enhanced by using BH3 mimetics to inhibit pro-survival molecules and release the apoptotic block. A panel of BH3 mimetics was tested in combination with radiotherapy across three patient-derived GBM cell lines (G7, E2 and R15), using a 3D clonogenic culture system that recapitulates *in vivo* growth patterns and responses. We found that the BCL-XL inhibitor, A1331852, significantly radiosensitized all 3 GBM lines. In addition, Western blot analysis revealed A1331852 to induce PARP1 cleavage in G7 cells when used as a single agent. Subsequent *in vivo* studies were conducted in our well characterized orthotopic G7 xenograft murine model of GBM. Immunohistochemical studies showed that the pro-survival proteins MCL-1 and BCL-XL were upregulated in irradiated tumors. Furthermore, a pharmacokinetic study in the same orthotopic murine model, allowing for drug delivery evaluation, and optimized treatment scheduling. Importantly, A1331852 was found to be blood brain barrier penetrant at 25 mg/kg, with increased drug detected in tumor vs normal brain tissue. From these data, a survival study investigating A1331852 as a radiosensitizing agent was carried out in the same G7 GBM orthotopic xenograft model. Kaplan-Meier analysis showed an increase in survival of mice treated with A133852 plus radiotherapy compared with the radiotherapy only group (p = 0.0309). Overall, we have demonstrated that dependence on BCL-2 family proteins is a vulnerability that can be targeted to improve radiotherapy response in GBM. Furthermore, we have identified a promising BH3 mimetic, A1331852, to use in combination with RT and have completed a proof-of-concept *in vivo* study that confirms the potential of BH3 mimetics to improve outcomes for patients with GBM.

#0691 Preclinical evaluation of valproic acid in combination with radiation in orthotopic models of glioblastoma.

M. Stavnichuk, Z. Opachich, D. Huttenlocher, J. McNamara, J. Molloy, X. He, S. Patel, N. Sanai, A.-C. Tien, S. Mehta;
Barrow Neurological Institute, Phoenix, AZ

Background: Valproic acid (VPA) is an FDA-approved anti-seizure medication that has been demonstrated to have an anti-tumor and radiosensitization effect on multiple cancer cells including aggressive brain cancer, glioblastoma (GBM). VPA is thought to exert its anti-tumor effects in part through inhibition of histone deacetylases (HDACs), upregulation of apoptosis and autophagy, and disruption of DNA repair mechanisms. Overall survival of patients treated with VPA in combination with TMZ and radiation therapy (RT) was significantly improved compared to historical controls (mOS 29.6 months). Hence, to establish a preclinical benchmark, we investigated the effectiveness of VPA alone and in combination with the radiotherapy in patient-derived xenograft (PDX) models of GBM *in vitro* and *in vivo*.
Methods: Anti-proliferative effect of VPA in combination with radiation was assessed across multiple GBM cells lines (long-term cultures and PDX lines). Athymic mice were implanted with PDX GBM cells orthotopically and were randomized into four cohorts: vehicle, VPA, IR (6 gy), VPA + IR (6 gy). Animals were treated with 300mg/kg/day of VPA alone or in combination with 6Gy of radiation. Treatments were performed either via intraperitoneal route for 3 consecutive days or via a gastric gavage 5 days on/2 days off for the duration of the study. For pharmacodynamics (PD), animals were sacrificed after 3 days of drug treatment at 2hr, 24hr and 4 days post last dose and processed for immunohistochemical (IHC) analysis for acetylated H3K9/14, KI67, pH2AX, and cleaved caspase 3.
Results: VPA treatment demonstrated a dose-dependent decrease in GBM cell viability and enhancement of radiation sensitivity. Pharmacodynamic analysis of tumor-bearing mice demonstrated a significant increase in acetylated H3K9/14 levels upon treatment with combination of VPA and irradiation. Elevation of acetylated H3K9/14 levels was present 2 hours after the administration of the last dose of VPA and it persisted for 4 days. Treatment of mice with irradiation upregulated levels of the apoptosis marker, cleaved caspase 3, which was further enhanced upon VPA and irradiation combination treatment. No reduction in tumor volume or survival benefit was seen in VPA alone or combination cohorts.
Conclusion: Consistent with previous reports, treatment of PDX GBM line with VPA reduced cell viability *in vitro*, increased histone acetylation, and cell death. However, these changes were not sufficient to provide survival benefit in the intracranial model and warrants further investigation into the genetic requirements for radiation sensitization by VPA.

#0692 Uncoupling protein 2 (Ucp2) loss of function enhances mitochondrial ROS and sensitizes PDAC to radiation therapy.

E. G. Caggiano, M. Yu, A. Acevedo-Diaz, C. M. Taniguchi;
UT MD Anderson Cancer Center, Houston, TX

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a lethal cancer with a dependence on highly active mitochondria to grow and metastasize. Normally mitochondria exist in long networks due to mitochondrial fusion but in PDAC mitochondria are fragmented due to excessive fission. We previously found that forcing PDAC cells to increase mitochondrial fusion suppressed tumor growth and metastasis, leading to improved survival in multiple preclinical models. The tumor suppressive mechanisms of mitochondrial fusion remain unclear, and thus we explored the role of redox homeostasis through uncoupling protein 2 (UCP2), a metabolic protein normally upregulated in PDAC that was downregulated upon forced mitochondrial fusion. We hypothesize that UCP2 mediates the oncogenic effects of mitochondrial fragmentation in PDAC.

Methods: We explored if Ucp2 is necessary and sufficient for inducing tumor suppression upon mitochondrial fusion. The effects of Ucp2 loss or overexpression were characterized by metabolic flux assays, proliferation, mitochondrial ROS (mROS), membrane potential, and morphology measurements. We also examined if Ucp2 recapitulates mitochondrial fusion-induced tumor suppression via pharmacological inhibition and genetic ablation and assessed the impact on mitochondrial health and cell growth. We utilized the *LSL-KRAS*^{G12D}; *Trp53*$^{R172H/+}$; *Ptf1α Cre* (KPC) cell line as our parental line for all genetic manipulations, with a nontargeting (sgGFP) KPC cell line as a control.

Results: Murine PDAC cells with enhanced mitochondrial fusion reduced Ucp2 transcript levels by 70% and was correlated with 3.5-fold increase in mROS, 50% reduction in OXPHOS via oxygen consumption rate assay, and a 4-fold increase in membrane potential compared to controls. Ucp2 re-expression did not rescue these phenotypes, suggesting that Ucp2 alone may not be sufficient for tumor suppression. However, inhibition of Ucp2 in PDAC cells reduced proliferation by 70%, while inducing a 3-fold increase in mROS levels, which was recapitulated with Ucp2 abrogation, thus Ucp2 may be necessary for tumor suppression. Enhanced mROS via Ucp2 inhibition significantly increased radiosensitivity (p-value < 0.0001), suggesting that although it does not recapitulate the mitochondrial fusion phenotype, UCP2 may be a novel target for radiosensitization in PDAC.

Conclusions: Mitochondrial fusion may not suppress tumor growth by altering redox homeostasis via UCP2, but forcing mitochondria to fuse elucidated the impacts of UCP2 downregulation on cell metabolism. Thus, we uncovered that UCP2 may be a novel target for radiosensitization. Further insight into UCP2's role in redox balance, and how it is disrupted with UCP2 modulation enables development of novel therapeutic combinations with UCP2 inhibition that complement and potentially synergize with existing therapeutic strategies such as radiation.

#0693 The effect of butyrophilin 1A1 blockade in combination with radiation treatment in tumor models.

N. Li[1], C. Braun[1], Y.-S. Kim[2], A. Park[2], S. Yoo[2], S. Lin[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]STCube Pharmaceuticals, Inc., Gaithersburg, MD

Expression of radiation-induced immune escape molecules, including PD-L1, contributes to the efficacy of cancer immunotherapy. We used an unbiased in vivo gene knockdown screen in naïve T-cells and introduced them into irradiated host tumors to identify novel immunosuppressive genes activated during radiation. From the screen, we found that butyrophilin 1A1 (BTN1A1) knockdown causes T-cell expansion in irradiated tumors. This points to the potential immune checkpoint role of BTN1A1. We validated that BTN1A1 expression is inducible in activated T-cells and that blocking BTN1A1 contributes to T-cell activation. We tested an anti-mouse BTN1A1 antibody (STC109) in mouse colon tumor models (CT26 tumors), we observed partial anti-tumor efficacy using single agent STC109, which was enhanced by the combination of STC109 with radiation. We also got similar result in in mouse lung tumor models (LLC tumors) using anti-mouse BTN1A1 antibody, and the combination treatment showed an improved suppression of tumor growth and lung metastasis compared to single agent. Moreover, our data shown that knockout of BTN1A1 in 4T1 tumor models shown dramatic defect of tumor growth, and the BTN1A1 ko tumors are more sensitive to radiotherapy. These findings indicate the role of BTN1A1 in tumor immune response from radiation stress, and that anti-BTN1A1 has strong potential to enhance efficacy of radiotherapy for cancer treatment.

#0694 Evaluation of a synergistic drug combination with ^{177}Lu-rhPSMA-10.1 for prostate cancer: Results of an *in vitro* screen and *in vivo* proof of concept study.

C. Foxton[1], B. Cornelissen[2], E. O'Neill[2], B. Waldron[3], F. Pretzmann[4], R. Veggerby Gronlund[4], M. Wikke Hallund[4], D. J. Stevens[3];
[1]Blue Earth Diagnostics, Oxford, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]Blue Earth Therapeutics, Oxford, United Kingdom, [4]Minerva Imaging, Olstykke, Denmark

Purpose: Prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (RLT) has been shown to extend survival in men with advanced prostate cancer (PCa). Novel radiohybrid (rh) PSMA-targeted ^{177}Lu-rhPSMA-10.1 has shown promising preclinical efficacy and advantageous radiation dosimetry in humans. We conducted an *in vitro* screen to identify known anticancer drugs with potential for synergistic interaction with ^{177}Lu-rhPSMA-10.1. Here we present key screening data and a subsequent *in vivo* efficacy analysis of the lead novel drug combination in PSMA-expressing 22Rv1 PCa xenografts.
Methods: Over 150 FDA-approved anticancer drugs were screened in a clonogenic survival assay of 22Rv1 cells using the test drug alone, at a range of concentrations <20 μM to determine the IC_{50}, and results compared to incubations of the drug + 15 MBq/mL ^{177}Lu-rhPSMA-10.1 after 10 d. A focused screen of 5 lead candidates was then conducted to determine the impact of ^{177}Lu-rhPSMA-10.1 (0-25 MBq/mL) on the drug IC_{50}. A synergy score was determined using the zero interaction potency (ZIP) reference model and the multi-dimensional synergy of combinations (MuSyc) platform.
Subsequently, to evaluate the efficacy of the lead combination, ^{177}Lu-rhPSMA-10.1 (single 30 MBq iv dose) and Cobimetinib (0.25 mg orally per day for 21 d) alone and in combination were administered to 22Rv1 tumor-bearing NMRI nude mice (n = 8 per group plus untreated controls). Tumor volume was measured 2x week for 69 d. Two-way ANOVA and Tukey's multiple comparisons test (data analyzed until n = 3 remained per group) and Kaplan-Meier Log-rank survival analyses were performed.
Results: The *in vitro* screen identified MEK inhibitor Cobimetinib as a lead candidate for synergistic combination with ^{177}Lu-rhPSMA-10.1 across a wide concentration range, with a ZIP synergy score of 13.25% (95% CI ± 2.17) and promising results on MuSyc analysis. The ^{177}Lu-rhPSMA-10.1 + Cobimetinib combination significantly suppressed tumor growth *in vivo* vs untreated controls (from day 13-30; $p<0.01$) and ^{177}Lu-rhPSMA-10.1 alone (from day 17-30; $p<0.001$). The median survival in the combination group (49 d) was significantly longer vs the untreated group (23 d; $p=0.001$) and the group treated with ^{177}Lu-rhPSMA-10.1 alone (36 d; $p=0.002$).
Conclusions: Through an extensive *in vitro* screen, we identified Cobimetinib to have potential for a synergistic anti-tumor effect in combination with ^{177}Lu-rhPSMA-10.1. This may be due to inhibition of the MEK-MAPK pathway by Cobimetinib during DNA damage response, resulting in radiosensitization of cancer cells to ^{177}Lu-labeled RLT agents such as ^{177}Lu-rhPSMA-10.1. This novel combination showed an enhanced therapeutic efficacy vs the single agents in 22Rv1 xenografts and the lack of overlapping monotherapy toxicity reported in the clinic supports clinical investigation in men with PCa.

#0695 Enhancing radiotherapy with lenvatinib by targeting the CXCL13/CXCR5/NF-KB axis.

T.-L. Liao[1], I.-T. Chiang[2], B.-H. Huang[1], F.-T. Hsu[3], M.-H. Chan[1];
[1]National Yang Ming Chiao Tung University, Taipei, Taiwan, [2]Show Chwan Memorial Hospital, Taipei, Taiwan, [3]China Medical University, Taipei, Taiwan

Lung cancer is the leading cause of cancer death worldwide, with non-small cell lung cancer (NSCLC) accounting for approximately 85% of all lung cancers. At the time of diagnosis, it is often already advanced or metastatic, resulting in poor treatment outcomes. Treatment of NSCLC mainly relies on surgery, radiation and chemotherapy, but the survival rate has not increased significantly in the past decade. Therefore, finding appropriate treatment methods is necessary and crucial. Radiotherapy (RT) is a frequently employed approach for tumor treatment and serves as the primary local treatment for NSCLC. However, it often results in a poor prognosis and severe side effects when administered at high-dose irradiation. Existing literature suggests that RT may trigger the expression of nuclear factor kappa B (NF-KB), potentially compromising its therapeutic efficacy. Consequently, the question remains: Can targeting NF-KB signaling enhance the sensitivity of RT in NSCLC Furthermore, studies have indicated that elevated levels of CXCR5 in NSCLC contribute to tumor growth. CXCR5 is situated upstream of the NF-KB pathway. As a result, it becomes imperative and indispensable to develop strategies targeting the CXCL13/CXCR5/NF-KB signaling axis to counteract NSCLC growth. Lenvatinib is a multi-kinase inhibitor targeted drug. It has been proven to inhibit VEGFR1-3, FGFR1-4 and PDGFR, inhibiting tumor growth. Lenvatinib has received clinical approval from the US FDA for the treatment of advanced hepatocellular carcinoma (HCC) and has been shown to inhibit NF-KB expression in HCC. However, the potential radiation-sensitizing mechanism of Lenvatinib in lung cancer remains unexplored. This study is dedicated to investigating the effects and molecular mechanisms of combining Lenvatinib with radiotherapy in NSCLC. Our results suggest that lenvatinib may enhance the sensitivity of NSCLC to RT. Furthermore, evidence from both the intrinsic and extrinsic apoptosis pathways (Caspase-3/Caspase-8/Caspase-9) and TUNEL experiments supports the idea that the combined treatment of lenvatinib with RT induces a more pronounced apoptotic response compared to individual treatments. Additionally, silencing CXCR5 in NSCLC also appears to enhance its responsiveness to RT. In our western blot (p-ATM, p-CHK2), flow cytometry (p-ATM), we showed that the combination of lenvatinib and RT may effective induce DNA damage. Our *in vivo* data demonstrates that the combination of Lenvatinib and RT exhibits superior tumor growth inhibition. Immunohistochemistry (IHC) staining of tumor tissue also revealed an upregulation of apoptosis-related proteins and the downregulation of CXCL13/CXCR5/NF-KB related proteins. In conclusion, our findings suggest that Lenvatinib can serve as a radiosensitizer, enhancing the sensitivity of NSCLC patients to radiotherapy by targeting the CXCL13/CXCR5/NF-KB signaling pathway.

#0696 Proton radiation and Seco-Duocarmycin SA: A synergistic strategy unveiling new frontiers in glioblastoma multiforme therapy.

A. Morcos, A. Bertucci, R. N. Fuller, N. R. Wall, M. E. Vazquez;
Loma Linda University, Loma Linda, CA

Glioblastoma multiforme (GBM) is one of the most aggressive brain cancers with a 6.9% five-year survival rate. More effective therapies are needed as standard treatments, which include surgery, radiation, and chemotherapy are inefficient due to radio-chemo-resistance and relapse. The goal of this project is to investigate the efficacy of seco-duocarmycin SA (sDSA) as an anticancer drug, alone and the potential synergy of combining proton radiation and sDSA in human GBM cell lines. Proton therapy offers numerous advantages in treating cancers because of its superior dose distribution and biological effects. sDSA is an exceptionally potent agent that selectively alkylates DNA at the N3 position of adenine, making it of great interest as a therapeutic drug. We hypothesize that by pairing sDSA with proton radiation, a more dynamic effect will result, which will amplify their collective power, unleashing an enhanced cytotoxicity against human GBM cells. GBM cell lines (T98G and LN18) were exposed to graded doses and concentrations of protons and sDSA respectively in order to evaluate cellular changes in proliferation, survival, cell cycle, apoptosis/necrosis induction, and DNA damage. Results show that proton radiation and sDSA when used alone induce a dose-dependent decrease of cell proliferation, an increase in foci formation, and an increase in G2/M phase arrest in LN18 and T98G cells. The data also illustrates that the combination of proton radiation and sDSA synergistically enhances these effects. The utilization of proton radiation in conjunction with sDSA against GBM represents an innovative and previously unexplored approach. Currently, the cellular mechanisms of sDSA cytotoxicity are not well understood or studied, and even less is known regarding the effects when combined with proton radiation. This study serves as a vital cornerstone in unraveling the biological response of GBM cells when confronted with proton radiation and sDSA, paving the way for the future development of a more precise and potent combination therapy.
.

#0697 Enhanced tumor control and survival in solid tumor models following combined low dose radiotherapy and T cell therapy.

N. Puebla[1], G. Srivastava[2], S. Nizzero[3], N. W. Fowlkes[1], H. Barsoumian[1], Y. Hu[1], C. Leuschner[1], T. Riad[1], M. Loparic[2], M. Plodinec[2], J. Welsh[1];
[1]MD Anderson Cancer Center, Houston, TX, [2]ARTIDIS AG, Basel, Switzerland, [3]ARTIDIS AG, Houston, TX

Background: Solid tumors remain a significant challenge in cancer therapy due to their resistance to conventional treatments. Chimeric antigen receptor (CAR)-T cell therapy has emerged as a promising approach for treating solid tumors, but its effectiveness is often limited by the poor infiltration of CAR-T cells into the tumor microenvironment. Thus, enhancing a robust infiltration of chimeric antigen receptor T cells into solid tumors is essential for an effective antitumor response and therapeutic success.
Methods: In this study, we investigated the combined effects of multiple doses of low-dose radiotherapy (LD-RT) and CAR T-cell therapy on tumor growth and survival using two models of NSG mice implanted with gastric carcinoma (GSU) or pancreatic adenocarcinoma (CAPAN-2) cells. The engineered CAR-T cells were designed to target guanyl cyclase-C (GCC) or mesothelin, respectively. Furthermore, our study employed atomic force microscopy (AFM) in a small cohort to investigate the impact of LD-RT and CAR-T cell therapy on tumor stiffness and plasticity.
Results: The synergistic effect of combining low-dose radiotherapy (LD-RT) with T-cell therapy resulted in enhanced tumor control and prolonged survival in mice with tumors, surpassing the outcomes observed with either monotherapy alone. This combined treatment holds promise for improving responses in patients with solid tumors by leveraging LD-RT to enhance the intratumoral infiltration of effector T cells. Our findings suggest that the nanomechanical signature may be a potential biomarker for LD-RT combined CAR T cell therapy in solid tumors.
Conclusions: Our findings substantially contribute to treating solid tumors using cell therapies, highlighting the potential for improved infiltration of adoptively transferred T cells following radiotherapy (RT), which can transform existing therapeutic strategies for solid tumors while minimizing toxicity.

#0699 Targeting radiation-driven invasion and metastasis in pancreatic cancer.

K. Mclay[1], M. Tesson[2], D. Gilmour[1], J. P. Morton[2], J. L. Birch[1];
[1]University of Glasgow - Institute of Cancer Sciences, Glasgow, United Kingdom, [2]Cancer Research UK Scotland Institute, Glasgow, United Kingdom

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive cancer with a dismal prognosis. Standard of care includes chemotherapy and radiotherapy (RT) for locally advanced, unresectable disease. Despite radiotherapy being an effective and sometimes curative option for many cancer types, radio-resistance is common, and pre-clinical research in recent years has found that RT can initiate a more aggressive, pro-invasive phenotype in the remaining cells post treatment (1,2). Little is known about the molecular mechanisms responsible for this phenomenon.There is accumulating evidence highlighting a role for the RhoGTPase family in mediating radioresistance and enhanced invasion (2, 3). Understanding their role in PDAC progression may aid the identification of novel chemotherapeutics that could be used alongside RT in the future. We present *in vitro* data that confirms the pro-migratory effect of RT and importantly indicates a significant increase in metastases formed in a clinically relevant model of PDAC (KPC Pdx1-Cre; $Kras^{G12D/+}$; $Trp53^{R172H/+}$) after treatment using a small animal radiation research platform (*n=31, p<0.0001*). In concurrence with previous literature, we found that PDAC cell motility was dependent on the RhoGTPase pathway, RhoA/ROCK1 (p=0.004). However, post-RT, this dependency was switched to an alternative pathway, CDC42/Rac1/MRCK, indicating a clear change in the balance of RhoGTPase signaling (p=0.002). This switch was confirmed via high-throughput immunofluorescence analysis. To widen this investigation further, we performed an siRNA screen targeting all members of the RhoGTPase family. Preliminary results indicate signaling dependency on Rac2, Rac3 and CDC42 post-RT. Additionally, we have performed RNAseq to investigate pro-invasive gene signatures arising from the acute irradiation of pancreatic cancer cells. This was done at sufficient depth to identify splice variants, with differential transcript expression (DTE) analysis identifying 236 differentially expressed transcripts and the differential transcript usage (DTU) analysis identifying 28 transcripts and 23 genes. Initial functional enrichment analysis found gene signatures relating to cell migration and adhesion, which may be indicative of an invasive phenotype. In conclusion, we present in vitro and in vivo data suggesting RT may promote a more invasive phenotype in PDAC at least in part due to a switch in RhoGTPase signaling.

#0700 Impact of heterogeneity for mismatch repair activity on colon tumor development and therapeutic response.

S. M. Snow, D. Albrecht, P. A. Clark, C. P. Kerr, J. J. Grudzinski, J. J. Jeffery, H. Comas Rojas, R. Hernandez, K. A. Matkowskyj, J. P. Weichert, Z. S. Morris, R. B. Halberg;
University of Wisconsin-Madison, Madison, WI

Background: Colorectal cancers (CRC) that are deficient for DNA mismatch repair (dMMR) proteins have high levels of genetic instability and consequently high mutational burden, creating numerous neoantigens that can elicit an immune response. Therefore, dMMR CRC are the best candidates for immune checkpoint inhibition (ICI) compared to proficient DNA mismatch repair (pMMR) CRC. Early clinical trials revealed that only 30-55% metastatic dMMR CRC responded to ICI. Recent studies utilizing allograft models have demonstrated that tumor immune landscape can be primed with radiopharmaceutical therapy (RPT). Although early results have been quite promising, allograft models often fail to accurately predict efficacy for many reasons, but most often are due to a lack of heterogeneity.
Methods: To better understand how heterogenous MMR expression impacts tumor development and response to ICI alone or in combination with RPT, we developed a new mouse model that develops three tumor types: (1) homotypic dMMR tumors that express green fluorescent protein, (2) homotypic pMMR tumors that express red fluorescent protein, and (3) heterotypic tumors with a mixture of dMMR and pMMR cells. Surveillance bright field and fluorescent colonoscopies allow us to assess treatment response by measuring tumor size and proportion of dMMR and pMMR tumor cells in real-time. These outcomes are verified through *ex vivo* imaging and histological analysis.
Results: Tumor response to anti-PD-L1 ICI was dependent on MMR status. Homotypic dMMR tumors exhibited the strongest response: significantly smaller in treated mice than controls, exhibited areas of vascular congestion and increased CD8+ cytotoxic T-cells infiltration. Response of heterotypic MMR tumors varied depending on percentage of dMMR cells; tumors with a high percentage of dMMR cells remained small, whereas tumors with a low percentage of dMMR had an outgrowth of pMMR cells. Treated and untreated homotypic pMMR tumors were indistinguishable. To enhance the response of all three tumor types, mice were treated with dual ICI treatment, anti-PD-L1 and anti-CTLA-4, or RPT. Animals administered the tri-therapy (dual ICI + RPT) survived significantly longer with fewer tumors than animals treated with either dual ICI or RPT alone.
Conclusions: Our innovative mouse model allows for the highly detailed characterization of tumor response to therapies. Simplistic allograft models may not adequately account for the dynamic effects that neighboring cell death may have on radio-resistant cells, on tumor vascular perfusion and oxygenation, or on tumor immune infiltration and adaptive immune recognition of remaining cells. We begin to fill these critical gaps in knowledge and therefore the results from our studies will help guide the translation and integrated use of ICIs and RPTs in clinic.

#0701 Preclinical data of a novel DNA-PK inhibitor in combination with radiation therapy shows promise in the treatment of established GBM and lung carcinoma cell lines.

A. C. Mladek[1], D. L. Burgenske[1], W. F. Elmquist[2], W. Zhong[3], J. N. Sarkaria[1];
[1]Mayo Clinic, Rochester, MN, [2]University of Minnesota, Minneapolis, MN, [3]Waynola Biopharm, Inc, Corona, CA

Radiation therapy (RT) is a cornerstone of oncologic therapy for the majority of solid malignancies, and unrepaired DNA double-strand breaks are responsible for radiation-induced cytotoxicity. RT-induced DNA lesions can be repaired by multiple mechanisms including homologous recombination (HR) and non-homologous end joining (NHEJ), and disruption of either of these pathways can enhance cytotoxicity. A key component of the NHEJ pathway is the catalytic subunit of DNA-dependent protein kinase (DNA-PKcs), and loss of kinase activity can significantly increase radiosensitivity. Herein we describe the results of our medicinal chemistry campaign to develop a potent and selective DNA-PKcs inhibitor, WNC0901. WNC0901 inhibits DNA-PKcs kinase activity in a cell free system with an IC_{50} of 0.071 nM and demonstrated at least 30-fold higher sensitivity than other family members (ATM, ATR, mTOR, PI3K). WNC0901 has limited aldehyde oxidase (AO) liability with a $T_{1/2}$ >2000 min in liver cytosol and is stable for over 120 minutes in the presence and absence of an AO inhibitor. A preliminary pharmacokinetic analysis in wista han rat (IV=2mg/kg, PO=20mg/kg) demonstrated 116% apparent absolute oral bioavailability, 2.6 hour terminal half-life, 33.0 mL/min/kg clearance, and a 2.6% unbound brain-to-plasma partition coefficient (Kpuu). WNC0901 also had favorable pharmacokinetic properties in beagle dog (IV=2mg/kg, PO=20mg/kg) with moderate clearance (8.5 mL/min/kg), high apparent absolute oral bioavailability (131%) with good exposure (AUC=36092 h*ng/mL), moderate half-life (4.28 h), and low protein binding (74.3% fraction unbound). The volume of distribution was moderate in both species (Vss = 1.32 L/kg in wistar han rat and 1.87 L/kg in beagle dog). In cell culture, WNC0901 inhibited autophosphorylation of DNA-PKcs in HT29 cells irradiated with 10 Gy with an IC_{50} of 32.7 nM and robustly inhibited autophosphorylation in both U251 glioma and A549 lung cancer cell lines at 300 nM in combination with 5Gy. In a clonogenic assay, 5Gy irradiation (10% survival) combined with 100nM WNC0901 demonstrated modestly enhanced cell killing (1.5% survival), and maximal effects were seen at 300nM (0.04% survival, $p<0.01$). Similar radiosensitizing effects with 300 nM WNC0901 were seen in the A549 cell line (0.2% survival with combination compared to 19% with 5Gy alone, $p<0.01$).
In summary, WNC0901 inhibits DNA-PK kinase activity and provides potent radiosensitization in a GBM and lung cancer cell line. Future studies will assess the combination of WNC0901 and RT in GBM patient-derived xenograft models *in vivo*.

#0702 Development of a radioresistant PDX prostate cancer model to evaluate potential radiosensitizing compounds.

M. Z. Alfsen[1], M. Thaysen[2], N. Nielsen[1], M. Wick[3], L. Piggott[4], S. Gnosa[1], C. H. Nielsen[1];
[1]Minerva Imaging, Oelstykke, Denmark, [2]University of Copenhagen, Copenhagen, Denmark, [3]XenoSTART, San Antonio, TX, [4]Debiopharm International SA, Lausanne, Switzerland

Prostate cancer is the second most common cancer diagnosis worldwide and the fifth leading cause of cancer related death among men. Several treatment strategies are used including the FDA approved ^{177}Lu-vipivotide tetraxetan (^{177}Lu-PSMA-617) for the treatment of prostate-specific membrane antigen (PSMA)-positive metastatic castration-resistant prostate cancer. However, not all patients respond to treatment due to tumor intrinsic resistance mechanisms. Therefore, the combination of targeted radionuclide therapy with inhibitors against e.g. DNA damage response, cell cycle progression or cell survival pathways are investigated to enhance the radiosensitivity of the tumor. Current models to study radioresistance in prostate cancer are based on cancer cell lines or cell-line derived xenograft models, but these models do not account for the heterogenous and complex biology of the disease. To overcome this issue, we have developed a radioresistant patient-derived xenograft (PDX) prostate cancer model (ST1273, XenoSTART), that is positive for PSMA. Resistance to radiation was initially established by sequential irradiation of the tumors with external beam radiation. Moreover, the model has proven to be resistant towards treatment with 30 MBq ^{177}Lu-PSMA-617. Utilizing this radioresistant model we are now able to investigate the treatment response of ^{177}Lu-PSMA-617 in combination with different drug inhibitor classes to evaluate their potential radiosensitizing effect. The PARP inhibitor, Olaparib, was administered at 50 mg/kg QDx48 alone or in combination with a single dose of ^{177}Lu-PSMA-617 in radioresistant ST1273 tumor bearing NMRI nude mice. First results showed a prolonging treatment effect of Olaparib given in combination with ^{177}Lu-PSMA-617 compared to ^{177}Lu-PSMA-617 alone. Tumor relapse was observed 29 days after treatment with ^{177}Lu-PSMA-617 alone, whereas it was observed 49 days after combination treatment. Olaparib given alone did not influence tumor growth. To further investigate the mechanism of resistance we are currently investigating the radiosensitizing potential of additional compounds and evaluating the tumors by RNA- and whole-exome- sequencing. Altogether, we successfully established a PSMA positive prostate cancer model resistant to PSMA targeted radionuclide therapy. With this model we are able to investigate the radiosensitizing effect of different drug classes.

#0703 GABA(A) receptor activation drives GABARAP-Nix mediated autophagy to radiosensitize primary and metastatic lung adenocarcinoma tumors.

D. Bhattacharya[1], R. Barrile[2], D. Kamdem Toukam[1], V. S. Gawali[1], L. Kallay[1], T. Ahmed[3], H. Brown[4], S. Rezvanian[3], A. Karve[5], P. B. Desai[5], M. Medvedovic[2], K. Wang[1], D. Ionascu[1], N. Harun[6], C. Wang[1], A. M. Baschnagel[7], J. A. Kritzer[4], J. Cook[3], D. A. Pomeranz Krummel[8], S. Sengupta[9]; [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]University of Cincinnati, Cincinnati, OH, [3]University of Wisconsin-Milwaukee, Milwaukee, WI, [4]Tufts University, Medford, MA, [5]University of Cincinnati College of Pharmacy, Cincinnati, OH, [6]Cincinnati Children's Hospital, Cincinnati, OH, [7]University of Wisconsin School of Medicine and Public Health, Madison, WI, [8]University of North Carolina at Chapel Hill, Chapel Hill, NC, [9]University of North Carolina at Chapel Hill, Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC

In non-small cell lung cancer (NSCLC) treatment, targeted therapies help a subset of patients, and radiotherapy responses are not durable and toxicity limits therapy. Most advanced-stage NSCLC patients have brain metastases that render an abysmal prognosis. Standard-of-care radiation therapy for NSCLC brain metastasis includes stereotactic radiosurgery (SRS) if the number of lesions is less than ten, otherwise whole brain radiation therapy (WBRT) is administered. Challenges in applying radiotherapy include overcoming radiation resistance and reducing significant associated co-morbidities. Cancer neuroscience is an evolving area, and the purpose of this study is to determine if activation of GABA(A) receptors intrinsic to NSCLC cells can improve radiation efficacy in primary NSCLC and its brain metastasis. We find that a GABA(A) receptor activator, AM-101, impairs the viability and clonogenicity of NSCLC primary and brain metastatic cells. Employing a human-relevant *ex vivo* ‘chip’, AM-101 is as efficacious as docetaxel, a chemotherapeutic used with radiotherapy for advanced-stage NSCLC. *In vivo*, AM-101 potentiates radiation, including conferring a significant survival benefit to mice bearing NSCLC intracranial tumors generated using a patient-derived metastatic line. GABA(A) receptor activation stimulates a selective-autophagic response via multimerization of GABA(A) Receptor-Associated Protein (GABARAP), stabilization of mitochondrial receptor Nix, utilization of ubiquitin-binding protein p62, and upregulation of Beclin-1. A high-affinity peptide disrupting Nix binding to GABARAP inhibits the cytotoxicity of AM-101. This supports a model of GABA(A) receptor activation driving a GABARAP-Nix multimerization axis that triggers autophagy. In NSCLC brain metastases patients, GABA(A) receptor activation may improve radiation efficacy and tumor control while allowing radiation dose de-intensification to reduce toxicity.

#0704 Targeting hypoxic survival pathways to overcome radiotherapy-related treatment resistance.

C. Beckers, L. Vasilikos, A. Sanchez-Fernandez, L. Moor, M. Pruschy;
University of Zurich, Zurich, Switzerland

Tumor cells undergo biological adaptations in order to survive stress conditions, such as hypoxia and nutrient deprivation. These biological adaptations include the activation of hypoxic survival pathways that play an important role in acquiring radioresistance which becomes most challenging with treatment regimens using high doses of radiation/fraction (e.g., hypofractionated radiotherapy). Therefore, inhibiting key regulators within these pathways and thereby exploiting these survival mechanisms, gives rise to new potential drug targets for combined treatment modalities. This novel strategy investigated in our laboratory relies on the concept of biological cooperation: while ionizing radiation kills primarily well-oxygenated cells, such inhibitors of survival kinases will drive quiescent tumor cells under hypoxia and/or nutrient deprivation either directly into cell death or into re-entry into a proliferative and thereby more ionizing radiation-sensitive state. One of the survival kinases we are investigating in combination with ionizing radiation (IR) is DYRK1B (dual-specificity tyrosine regulated kinase 1B). We demonstrated that the expression of DYRK1B was upregulated under serum-starvation and hypoxia, but not in response to IR. The small molecule DYRK1B inhibitor AZ191 and shRNA-mediated DYRK1B knockdown significantly reduced proliferative activity and clonogenicity of SW620 tumor cells alone and in combination with IR under serum-starved conditions, which correlated with increased ROS levels and DNA damage. Furthermore, AZ191 successfully targeted the hypoxic core of tumor spheroids while IR preferentially targeted normoxic cells in the rim of the spheroids. A combined treatment effect was also observed in patient-derived colorectal carcinoma organoids but not in healthy tissue organoids. This data shows that inhibition of DYRK1B in quiescent tumor cells could drive tumor cells on their own into crisis or into a more radiosensitive cell cycle phase and thus supports our strategy of biological cooperation. In the continuation of this project, we have performed a drug-screen with approx. 3’000 clinically relevant compounds in colorectal tumor cells lines under normoxic and hypoxic conditions in order to explore additional hypoxia-mediated survival pathways contributing to radioresistance. Thereby we aim to identify novel combined treatment modalities to overcome radiotherapy-induced hypoxia and hypoxia-related resistance mechanisms.

#0705 *miR-21-5p* induces radioresistance through reinforced DNA damage response in oral squamous cell carcinoma.

Q. Liu, W. Hu, X. Li, Y. Deng, L. Ma;
Shenzhen University, Shenzhen, China

Cancers arising from oral cavity and oropharynx are commonly treated with radiotherapy, whereas tumor radioresistance results in poor outcome. The prerequisite for developing more effective interventions for these patients is that the molecular mechanisms leading to a radioresistant phenotype in these tumors are clear to researchers. Unfortunately, the radioresistant mechanisms remain elusive to date. We recently identified that a highly conserved and cancer-related microRNA, i.e. *miR-21-5p*, plays an important role in radioresistance of oral squamous cell carcinoma (OSCC). We analyzed the RNA-sequencing data of 290 tissue samples from TCGA database, and found the expression of *miR-21-5p* was significantly upregulated in many OSCC samples (N=271) when comparing to adjacent normal tissues (N=19). The difference was further confirmed on our freshly collected OSCC tissues from patients in operation room. We performed RNA-sequencing analysis in 11 OSCC samples and their adjacent normal tissues. Among the 2106 differentially expressed genes between OSCC and normal control groups, we found that several important DNA repair genes (RAD50 double strand break repair protein gene, *RAD50*; DNA Polymerase Theta, *POLQ*; Ataxia Telangiectasia and Rad3-related, *ATR*) were significantly overexpressed in OSCC samples ($P<0.05$), while positive correlations between *miR-21-5p* expression and DNA repair genes *RAD51* and *XRCC4* were identified in the OSCC cohort. Notably, *ATR* is an important DNA damage response gene, while *XRCC4*, *RAD51*, and *POLQ* are involved in DNA double strand break (DSB) repair through non-homologous end joining, homologous recombination, and microhomology-mediated end joining, respectively. OSCC cell lines were further recruited to study the relations of *miR-21-5p* with radiation-induced DSB repair. By analyzing kinetics of 53BP1 foci, a biomarker for detecting DSBs, we found that anti-*miR-21-5p* transfected cells showed more residual foci, indicating of unfinished repair of DSBs, at 5 hours and 18 hours post irradiation. The deficient DSB repair resulted from anti-*miR-21-5p* transfection were further confirmed by single cell gel electrophoresis with comet assay. Consistently, the same treatment resulted in fewer clonogenic survivors in colony formation assay, demonstrating increased radiosensitivity of OSCC cells when *miR-21-5p* was antagonized. This work provided novel insights about the mechanism of *miR-21-5p*-induced radioresistance in OSCC, which may give rise to novel therapeutic strategy for improved treatment of OSCC patients.

#0706 Advancing radiotherapy strategies for high-risk rhabdomyosarcoma: Unveiling BCL-xL inhibition as a potent sensitizer to radiotherapy.

S. Park[1], N. Struyf[1], T. Erkers[1], S. Lehmann[2], M. T. Meister[3], J. Drost[3], F. C. P. Holstege[3], N. Herold[1], P. Ostling[1], J. Stenman[1], O. Kallioniemi[1], J.-I. Henter[1], B. Seashore-Ludlow[1], K. Karlsson[1];

[1]Karolinska Institute, Stockholm, Sweden, [2]Uppsala University, Uppsala, Sweden, [3]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands

Pediatric soft-tissue sarcomas are a group of solid tumors that account for about 7% of childhood cancer cases. Rhabdomyosarcoma (RMS), the most common subtype, further stratifies into PAX3 or PAX7 and FOXO1 fusion-negative (FN) or fusion-positive (FP) RMS. FP RMS is the higher risk subtype and is more aggressive, metastatic, and less responsive to treatment. Front-line treatments for RMS FP patients have had limited progress in the recent years and existing treatments such as radiotherapy lacks tumor cell selectivity, resulting in toxic side effects.

To address this, we conducted a high-throughput drug screen to identify radiosensitizers to enhance efficacy of RMS radiotherapy. Using three patient-derived FP RMS tumoroids, we screened a comprehensive drug library with and without radiation, comprising 528 drugs at varying stages of pre-clinical and clinical trials. A validation screen of the top 29 drugs was conducted on a larger cohort of samples including eight patient-derived FP RMS tumoroids and three non-cancer models. The screening revealed that drugs targeting the anti-apoptotic protein B-cell lymphoma-extra-large (BCL-xL) exhibited both potent radiosensitization and cytotoxicity selectively for FP RMS. Notably, the sensitivity to BCL-xL inhibitors correlated with elevated *BCL2L1* expression and PAX3 fusion status. Additionally, drugs targeting polo-like kinase 1 (PLK1) and other cell cycle-related genes exhibited robust radioprotective effects across both RMS and non-cancer models.

Our findings propose the therapeutic potential of BCL-xL inhibition, either as a standalone treatment or in combination with radiotherapy. In parallel, we show the protective potential of PLK1 inhibition to mitigate radiation toxicity. In the long term, we aspire to integrate the identified radiosensitizing and radioprotecting compounds with existing treatment regiments for RMS, maximizing precision and efficacy in RMS radiotherapy.

#0707 Calorie restriction to augment radiation response in models of Black women with breast cancer.

N. B. Francois[1], A. A. Shastri[1], S. Harding[2], T. DeAngelis[1], A. Adekeye[1], N. Simone[1];
[1]Thomas Jefferson University, Philadelphia, PA, [2]Sidney Kimmel Medical College, Philadelphia, PA

Introduction: Black women have higher mortality from breast cancer (BrCa) than other populations. While several factors contribute to this disparity, insulin-like growth factor 1 receptor (IGF-1R), is notably overexpressed in tumors originating in Black women compared to White women, which is associated with tumor progression and resistance to radiation therapy (RT). Caloric restriction (CR) is noted to reduce the expression of members of the IGF-1R pathway. We hypothesize that CR increases the efficacy of RT, in Black women, by downregulating the IGF-1R pathway to decrease tumor growth.
Methods: To understand the feasibility of implementing CR in Black women with BrCa, patients received a CR diet during adjuvant breast RT on an IRB approved investigator-initiated clinical trial and pre- and post- measures were evaluated. BrCa cell lines originating from Black (MD-MBA-468 and MD-MBA-157) or White patients (MDA-MB-231 and MDA-MB-436) were exposed to RT in the presence and absence of CR medium, IGF-1 to upregulate the pathway, and PPP, an IGF-1R inhibitor to evaluate the role of dietary interventions and IGF-1R pathway modulation in altering the RT response. Finally, human BrCa tissue was collected and ex vivo explants were used to evaluate the role of diet to augment the RT response.
Results: In the pilot clinical trial, 32 patients were enrolled, 50% of whom were Black (16B/16W). Black patients had more adverse baseline physiologic parameters and corresponding higher insulin and systemic inflammation as measured by ESR, IFNγ, Il-1β, and TNFα at baseline. Adherence to CR was 87.3% for the Black patients who had an average weight loss of 7.33 lbs, and decreased insulin and cholesterol levels after CR+RT. In intro, in Black originating cells, cell viability experiments showed that CR+RT decreased cell viability by 53% & 46% while RT alone reduced viability by 32 & 41%. In White originating cells, CR+RT decreased cell viability by 52% and 53% while RT alone reduced viability by 42% and 26%. IGF-1R inhibition with PPP caused a more significant decrease in viability when given with RT than CR+RT did. The opposite effect was noted when IGF-1 was added to the cell lines and that increase was prevented by treatment with IGF-1+RT+CR. This was confirmed in vivo. Explants revealed CR helped decrease proliferation and increase apoptosis for all cancer patients.
Conclusion: Taken together, these data demonstrate that Black patients can adhere to dietary interventions during RT therapy for breast cancer which may help achieve better tumor control via downregulation of the IGF-1R pathway which is often notably upregulated in this population. This benefit is widely applicable with equivalent efficacy between patients of both races and all breast cancer subtypes. Future studies should investigate the role of downregulating IGF-1R via dietary interventions to narrow disparities in breast cancer outcomes in our black patient population.

#0708 Targeting aurora kinase B (AURKB) as a radiosensitizing strategy in syngeneic models of triple negative breast cancer (TNBC).

K. M. Jungles[1], Z. Wang[1], C. Bishop[1], C. Wilson[1], M. Liu[1], J. James[1], M. Green[1], J. M. Rae[1], C. W. Speers[2], L. J. Pierce[1];
[1]University of Michigan, Ann Arbor, MI, [2]Case Western Reserve, Cleveland, OH

Purpose: Triple negative breast cancer (TNBC) is an aggressive breast cancer (BC) subtype with few treatment options. Radiation therapy (RT) is a mainstay therapy for the treatment of BC, but local recurrence following RT therapy is common. Consequently, decreasing local recurrence in patients with TNBC is a critical clinical need. Prior work demonstrated that AURKB is overexpressed in TNBC, and over-expression correlates with poor prognosis. Here, we examined the effects of AURKB inhibition as a novel radiosensitizing strategy in syngeneic TNBC models.
Methods: Cell viability assays were used to determine the half-maximal inhibitory concentrations (IC50) of the AURKB inhibitors Barasertib-HQPA and SP-96 72 hours post treatment. Clonogenic survival assays were used to assess the radiosensitivity of TNBC murine cell lines to AURKB inhibition. In these assays, AURKB inhibitors were delivered at sub-IC50 concentrations 24 hours prior to RT, and radiation enhancement ratios (rERs) were calculated. Immunofluorescent microscopy using DAPI stain assessed micronuclei. Propidium iodide staining to assess aneuploidy was completed via flow cytometry. To assess the radiosensitizing effects of AURKB inhibition *in vivo*, the 4T1 syngeneic TNBC cell line was injected bilaterally into Balb/c mice and treated with Barasertib and RT. Tumor volume was recorded twice weekly throughout the study.
Results: Aurora kinase B inhibitors (500-750 nM Barasertib-HQPA, 100-200 nM SP-96) delivered 24 hours prior to radiation therapy induced radiosensitization in the murine TNBC cells 4T1 (rER: 1.24-1.56) and Py8119 (rER: 1.51-1.72). Mechanistically, combined AURKB inhibition and RT significantly increased micronuclei formation in 4T1 cells 24 hours after RT compared to vehicle control ($p<0.0001$). Furthermore, combined AURKB inhibition and RT induced aneuploidy in murine TNBC cell lines 24 hours after radiation therapy compared to vehicle control. Combined AURKB inhibition (Barasertib 25 mg/kg, IP) and RT (8 Gy RT in 1 fraction) significantly decreased tumor volume compared to mice that had received vehicle control (777 ± 61 mm^3 vs 1623 ± 126 mm^3; $p < 0.0001$).
Conclusion: AURKB inhibition induces radiosensitization in syngeneic models of TNBC and leads to increased micronuclei and aneuploidy, suggesting a mechanism of sensitization. These results suggest that AURKB is a potential radiosensitizing strategy for the treatment of triple negative disease. Ongoing studies are further refining the underlying mechanisms of AURKB inhibition and RT on the antitumoral immune response.

#0709 Enhancing prostate cancer treatment: Synergistic effects of mechano-thermal focused ultrasound and radiation therapy.

S. Chatterjee[1], S. Singh[1], S. Barry[2], C. Guha[2];
[1]Albert Einstein College of Medicine, The Bronx, NY, [2]Montefiore Medical Center, The Bronx, NY

Current treatments for prostate cancer primarily rely on radiation and hormone deprivation therapy, yet they often lack effective immunotherapeutic effects. Furthermore, long-term hormone ablation has side effects, such as, impotency and osteoporosis. Addressing this gap, we introduce an innovative dual-frequency focused ultrasound (FUS) platform for non-ablative focal therapy, which induces protein unfolding, ER stress, and increases heat-shock protein expression along with translocation of endoplasmic reticular chaperone proteins (e.g., calreticulin) on the tumor cell surface, thereby sensitizing them for phagocytosis by dendritic cells for efficient antigen presentation and cross priming. We hypothesized that FUS-mediated acoustic immune priming can be combined with ablative therapies, such as, hormone ablation and/or radiation therapy (RT) for induction of tumor-specific adaptive immune response and better tumor control than monotherapy in murine prostate cancer models. Utilizing murine prostate cancer cell lines, MyC-CaP and RM1, we explored the cellular responses to androgen deprivation, observing distinct sensitivities. Twenty-four hours after FUS treatment tumor cells experienced mechano-thermal stress response with 15-fold increase in Hspa1a expression. Transmission Electron Microscopy studies showed formation of myelin figures, nuclear membrane deformation, and lipid droplet formation. In vivo, the combination of FUS (220w/cm^2 intensity for 3 sec at focal point) and RT (8-10 Gy daily x two fractions) markedly delayed tumor growth and achieved complete cure in 14-17% of animals. Through multicolor flow cytometry, we detected significant alterations in the immune microenvironment, including increased CD8+ T cell infiltration and reduced tumor-associated macrophages in the tumor bed. However, we also observed a compensatory rise in pro-tumor immune cells such as PMN-MDSCs and Tregs with significant suppression of eosinophils ($p<0.05$). Interestingly, there was suppression of splenic PMN-MDSCs, Mo-MDSCs, and tumor draining lymph node macrophages, suggesting systemic immune modulation in peripheral lymphoid organs of FUS+RT-treated tumor-bearing animals. Our findings reveal that the combination therapy of FUS and RT improves tumor control in murine prostate cancer and significantly modulates the systemic and tumor immune microenvironment. This approach offers new avenues for immunotherapy, potentially transforming the treatment landscape for prostate cancer, typically resistant to conventional immunotherapeutic strategies.

#0710 Post-exposure suppression of radiation pneumonitis suggests non-redundant independent effects of TGF-beta and TRAIL/DR5.

J. Strandberg[1], A. Louie[1], W. MacDonald[1], P. Srinivasan[1], L. Zhang[1], L. Zhou[1], S. Lee[2], W. El-Deiry[1];
[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]D&D Pharmatech, Gaithersburg, MD

Radiation pneumonitis is one of the most common but challenging toxicities seen in patients that are receiving ionizing radiotherapy for thoracic malignancies. While radiation effectively eliminates cancer cells, the damage it causes to surrounding healthy lung tissue leads to an immune response that can impact treatment regimen and lead to long term fibrotic tissue formation. The mechanism of radiation pneumonitis and the inflammatory response in the lungs is poorly understood. However, it is known that the TRAIL pathway plays an important role in inflammatory and fibrotic response. Through our previous work, it was discovered that modulating the TRAIL pathway via pegylated recombinant long-acting TRAIL (TLY012) in both WT and TRAIL-/- C57Bl/6 could suppress radiation pneumonitis in mice that were exposed to 20 Gy of thoracic radiation with shielding of other organs as early two weeks post exposure. In addition to the TRAIL pathway, transforming growth factor-beta (TGF-β) is a cytokine that is known to play a key role in fibrosis. Broad spectrum integrin inhibitor GLPG0187 is known to inhibit the activation of TGF-β via binding to specific integrin receptors. In order to determine if the inhibition of TGF-β could suppress radiation pneumonitis without stimulation of the TRAIL pathway, DR5 null mice were utilized for the experiment. Male DR5-/- C57Bl/6 mice received a single 20 Gy thoracic radiation dose with shielding of other organs and were treated with 100 mg/kg of GLPG-0187 or control twice a week via IP injection with the first dose being administered 1 hour before radiation (n = 4/treatment/group). 13 days post-irradiation, lungs, sternal bone marrow, and peripheral serum were collected. Upon histological analysis, it was observed that there were thinner alveolar borders and lessened inflammation compared to the control mice. Mice were weighed every three days, and it was discovered that mice treated with GLPG-0187 maintained steady weight compared to the control group. Additional analysis including immunohistochemistry, cytokine profiling, and quantification needs to be conducted. As the TRAIL pathway could not be modulated in the DR5 null mice, these findings suggest that GLPG-0187 was able to suppress radiation pneumonitis via inhibition of TGF-β. While some rescue from radiation pneumonitis was observed via GLPG0187, it was to a lesser extent compared to treatment of WT and TRAIL-/- C57Bl/6 mice with TLY012. Future directions include investigating the synergistic effects between TLY012 and GLPG0187 in suppressing radiation pneumonitis and decreasing fibrotic response to radiation.

#0711 HDAC3 sustains resistance to hypofractionated radiotherapy in fusion positve rhabdomyosarcoma cells.

M. Cassandri[1], A. Porrazzo[2], **S. Pomella**[1], S. Camero[2], F. A. Aiello[1], L. D'Archivio[1], C. Zwergel[2], B. Noce[2], M. Tomaciello[2], F. Vulcano[3], L. Milazzo[3], F. Pedini[3], M. Signore[3], A. Fanzani[4], C. Marchese[2], G. Minniti[2], S. Valente[2], A. Mai[2], F. Megiorni[2], R. Rota[1], F. Marampon[2];
[1]Bambino Gesu Children's Hospital, Rome, Italy, [2]Sapienza University of Rome, Rome, Italy, [3]Istituto Superiore di Sanita, Rome, Italy, Rome, Italy, [4]University of Brescia, Brescia, Italy

Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma of childhood. The fusion-positive (FP)-RMS variant expressing chimeric oncoproteins such as PAX3-FOXO1 and PAX7-FOXO1 shows a dismal prognosis with 5-year survival of less than 30% compared to non-metastatic fusion-negative (FN)-RMS variant. In the last years, a lot of interest has focused on new targets identification to improve the radiotherapy (RT) efficacy. HDAC inhibitors (HDACi) radio-sensitize different cancer cell types including RMS. Recently, we reported that MS-275, a Class I and IV HDACi, in combination with RT affected cell survival, reduced colony formation ability, increased DNA damage repair inhibition and reactive oxygen species formation in FP-RMS cells. However, despite promising preclinical studies , HDAC inhibitors (HDACi) achieved only modest success in human clinical trials for solid tumors, frequently showing several toxicities, probably because of the limited specificity of many HDACi. Thus, a major effort is being directed toward identification of HDACi which are selective for HDAC isoforms often uniquely implicated in the radioresistance of specific cancers. In order to identify the class I HDAC responsible of radioresistance in RMS we knocked-down HDAC1, HDAC2, HDAC3, and HDAC8 expression in combination with RT. Interestingly, we observed an increased radiosensitivity only in HDAC3-depleted FP-RMS cells. Thus, we focused on HDAC3 to understand the mechanisms by which it promotes radioresistance in RMS. We observed that HDAC3 is overexpressed in RMS patients and cell lines compared to the normal counterpart. Furthermore, RMS cells are strongly dependent by HDAC3 expression while slight dependency has been observed with other class I HDACs in DepMap portal. We demonstrated that HDAC3 depletion by CRISPR in combination with RT in FP-RMS cells increases apoptosis, reduces colony formation ability, cancer stem cells population and anchorage independent growth and reduces cell growth *in vivo* and *in vitro*. Accordingly, HDAC3 depleted cells in combination with RT reduces levels and activation of key player of FP-RMS biology such as MYCN, ERK and AKT. Moreover, HDAC3 KD increases radiotherapy-induced DNA double strand break and impairs DNA repair mechanisms reducing levels and activation of both homologous recombination (HR) and non-homologous end joining (NHEJ) factors such as ATM, RAD51 and DNA-PKcs. Thus, we developed a new potent and highly specific HDAC3 inhibitor (HDAC3i). The new HDAC3i is highly specific in targeting FP-RMS cell growth *in vitro* while no effects have been observed in normal cells such as myoblasts and lung fibroblast. Moreover, the drug treatment in combination with radiotherapy phenotypically and molecularly recapitulated what observed in HDAC3 depleted cells.The study has been founded by Italian Association for Cancer Research (AIRC) to FM.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Tumor Microenvironment
Poster Session

#0715 Nanomedicines loaded with TLR agonists and inhibitors of immunosuppression to reprogram the tumor microenvironment.

F. Torres Andon, Sr.[1], A. Pensado-Lopez[1], C. Anfray[2], A. Ummarino[2], I. Fernandez-Marino[3], L. Sanjurjo[3], J. Crecente-Campo[3], E. Fernandez-Megia[4], F. Castro[5], M. Oliveira[5], A. Calvo[6], R. Garcia Campelo[1], A. Mantovani[2], M. Alonso[3], P. Allavena[2];
[1]Oncology Unit, Complexo Hospitalario Universitario de A Coruna (CHUAC) Instituto de Investigacion Biomedica de A Coruna (INIBIC), A Coruna, Spain, [2]Clinical and Research Hospital Humanitas, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS), Milan, Italy, [3]Centre for Research in Molecular Medicine and Chronic Diseases (CIMUS), Universidade de Santiago de Compostela, Santiago de Compostela, Spain, [4]Centre for Research in Biological Chemistry and Molecular Materials (CIQUS), Department of Organic Chemistry, Universidade de Santiago de Compostela, Santiago de Compostela, Spain, [5]i3S-Instituto de Investigacao e Inovacao em Saude, Universidade do Porto, Rua Alfredo Allen, Porto, Portugal, [6]School of Medicine, IDISNA and Program in Solid Tumors and Biomarkers, Center for Applied Medical Research (CIMA), CIBERONC, ISC-III, University of Navarra, Pamplona, Spain

The stroma of solid tumors is populated by myeloid cells, which mostly represent macrophages. Tumor-associated macrophages (TAMs), strongly influenced by cancer cell-derived factors, are key drivers of immunosuppression and support tumor growth and spread to distant sites. Increasing evidence demonstrates their ability to hamper cancer patients' response to most treatments currently applied in the clinic, including immunotherapy. Therefore, strategies to counteract negative effects of TAMs are nowadays gaining momentum at preclinical, translational, and clinical levels.
Here, we present the development and evaluation of nanoparticles (NPs) loaded with TLR agonists and/or inhibitors of immunosuppressive pathways to reprogram TAMs and the tumor microenvironment (TME) to unleash an effective immune response to fight against the tumor. Firstly, we have evaluated *in vitro* the ability of poly(I:C) and/or R848, agonists of TLR3 and TLR7/8 respectively, to reprogram TAMs into antitumor effector cells, and also the efficacy of Stattic and/or Galunisertib, inhibitors of STAT3 and TGF-β pathways respectively, to inhibit immunosuppression by cancer cells and/or TAMs. The best combinations of these drugs were encapsulated in nanoemulsions or polymeric nanocapsules for improved TAM-targeting and pharmacokinetics *in vivo*. These NPs were characterized for their physicochemical properties and also tested *in vitro* using primary human macrophages. For *in vivo* evaluation, subcutaneous and orthotopic murine models of lung cancer (CMT167) were used, showing antitumoral efficacy and TME reprogramming as evaluated by FACS, RNA analysis and multiplex immunofluorescence. Protamine-NCs-loaded with poly(I:C)+R848 and coated with an additional layer of hyaluronic acid functionalized with mannose were used to target the CD206 receptors, showing antitumoral efficacy mediated by TAM reprogramming, evaluated as higher CD86 while lower CD206 and Arg1 expression. Nanoemulsions with a PEGylated surfactant, encapsulating Stattic+Galunisertib+R848 showed faster antitumoral activity *versus* the free drugs. Experiments performed in IFN-γ KO mice and immune deficient mice (NSG and Balb/c nude) revealed that a fully functional immune system is crucial for the response to the treatment.
In conclusion, our work demonstrates the antitumoral efficacy and reprogramming of the tumor microenvironment by combinations of TLR agonists and/or inhibitors of immunosuppression, which can be improved by nanotechnological approaches. Further investigations are ongoing to assess their antitumoral efficacy in other tumor models (i.e. breast and pancreatic cancer), with the final aim of clinical translation.

#0716 Depletion of stromal cells remodels tumor microenvironment and potentiates immune checkpoint blockade in pancreatic cancer.

J. Rupert[1], A. Daquinag[1], L. Cai[2], Y. Dai[1], Z. Zhao[1], D. Anastassiou[2], M. Kolonin[1];
[1]University of Texas at Houston, Houston, TX, [2]Columbia University, New York, NY

During carcinoma progression, mesenchymal stromal cells (MSCs) become recruited to tumors and contribute to the pool of cancer-associated fibroblasts (CAFs). Sub-populations of CAFs, have diverse and incompletely understood effects on disease progression and resistance to therapy. Adipose stromal cells (ASCs), the MSCs from fat tissue increasingly recruited by carcinomas in the context of obesity, have been shown to support cancer progression. Here, the roles of perivascular CAFs expressing platelet-derived growth factor receptor beta (*Pdgfrb)* and of CAFs expressing non-glycanated decorin (ngDCN), a marker of ASCs, were analyzed. We used mice orthotopically grafted with pancreatic ductal adenocarcinoma (KPC) cells. Ablation of cells expressing thymidine kinase under the control of *Pdgfrb* promoter with ganciclovir resulted in suppression of primary pancreatic tumor growth. However, ablation *Pdgfrb*+ cells induced spontaneous metastases to the liver. For depletion of ngDCN+ cells, we used a hunter-killer peptide D-CAN, which has been previously reported to induce apoptosis of ASCs and CAFs in mouse models. Here, D-CAN also had a negative effect on pancreatic tumor growth, however, there was no significant effect on metastatic dissemination. Single cell RNA sequencing of tumors demonstrated that targeting of *Pdgfrb*+ and ngDCN+ stromal cells had distinct effects on sub-populations of CAFs. Endothelial cell and cancer cell survival was decreased by depletion of either *Pdgfrb*+ or ngDCN+ stroma. However, pathway analysis revealed that depletion of *Pdgfrb*+ and ngDCN+ stromal cells has different effects on the markers of cancer cell aggressiveness. D-CAN treatment, and to a less extent *Pdgfrb*+ cell ablation, suppressed macrophage M2 polarization and increased infiltration of cytotoxic T-lymphocytes. This observation, confirmed in the MyCap graft model of prostate cancer, suggested that ablation of ngDCN+ stroma should synergize with immune checkpoint inhibitors. We tested the effect of D-CAN on the efficacy of anti-PDL1 antibody in the orthotopic KPC model. Compared to D-CAN and anti-PDL1 antibody alone, combination treatment had a synergistic effect on tumor growth. Importantly, liver metastases were suppressed by the D-CAN / anti-PDL1 antibody combination, but not by individual agents. We conclude that improved approaches to target mesenchymal stroma in tumors may be effective in combination with immunotherapy.

#0718 CCR8 antibody drug conjugates: Targeting regulatory T cells for tumor sensitization.

L. J. Stafford[1], H. Roth[1], S. Campbell[1], S. Brady[1], V. Fiers[1], F. Yu[2], A. Tsourkas[2], R. Payne[1], M. Pitts[1], K. Guldner[1], T. Phillips[1], B. Tyrell[1], C. Ulke[1], A. Snyder[1], M. Assogba[1], H. Ohl[1], I. Sanchez[1], B. Doranz[1], J. Rucker[1], R. Chambers[1];
[1]Integral Molecular, Philadelphia, PA, [2]AlphaThera, Philadelphia, PA

Background: Regulatory T (Treg) cells in the tumor microenvironment have an immune suppressive function, and their presence is associated with poor prognosis. Depletion of Treg cells may be a mechanism to sensitize tumors and represents a novel strategy for cancer immunotherapy. High expression of chemokine receptor CCR8 has been found in Treg cells in microenvironments of numerous tumors but not on Treg cells in systemic lymphoid tissues. The ability to selectively kill Treg cells in tumor environments may provide an opportunity for therapy that leaves Treg function intact elsewhere in the body where they normally mediate tolerance to self-antigen.
Methods: We sought to identify CCR8 antibodies for therapeutics and designed an antibody discovery strategy to address the challenges of this target. CCR8 is a member of the G protein-coupled receptor (GPCR) family. Like many GPCRs, CCR8 is a valuable therapeutic antibody target but challenging to access due to its poor expression, membrane-dependent structure, and poor immunogenicity due to sequence conservation. We developed an antibody discovery platform (MPS) that specifically addresses each of these challenges through use of advanced immunization techniques and evolutionarily divergent host species (chickens) for robust immune responses against conserved targets. We extensively engineered CCR8 antigen to enable high expression for immunization. When sufficient antibody diversity was not obtained using our standard immunization techniques, we developed mRNA immunization techniques for this program. Antibody binding was measured using flow cytometry on transfected cells and human Treg cells. The ability of antibodies to inhibit CCR8 function was measured using intracellular calcium influx assays. Antibody internalization was measured using dye uptake assays and flow cytometry. Antibodies were conjugated with cytotoxic payloads and tested for the ability to mediate killing.
Results: Using these approaches, we identified a panel of high-affinity antibodies that bound in the nanomolar or subnanomolar range with high specificity, and we selected a lead molecule to progress. We will present data from our antibody discovery campaign including mRNA immunization, binding profiles, GPCR functional data, receptor-mediated internalization, and the ability of antibody-drug conjugates (ADC) to kill CCR8+ cells, including human Treg cells, *in vitro*.
Conclusion: Treg cells are a primary driver of the immunosuppressive microenvironment in many solid tumors. Targeting immune-suppressive CCR8+ Treg cells using ADC has potential to expand the treatment of solid tumors

#0719 A tumor-activated PD1/IL2 bispecific molecule, designed to overcome IL-2 receptor-mediated clearance, improve tolerability and stimulate antigen-experienced $CD8^+$ T cells in the tumor microenvironment of murine models.

E. Eryilmaz, W. Guzman, S. Hsiao, P. Johnson, L. Quinn, J. Lakhani, B. Whalen, R. Quiroz, K. Jenkins, B. Lanter, O. Yerov, W. Scott, J. Greene, Z. Liu, J. Hedges, M. McLaughlin, S. Vu, C. Turcotte, J. Taylor, C. O'Toole, M. Pederzoli-Ribeil, H. Duprey, N. Malkova, D. Fantini, D. Crowe, K. Smith, J. Card, J. Lee, K. Smith, B. Nicholson, J. O'Neil, C. U. Bialucha;
Xilio Therapeutics, Waltham, MA

PD-1/PD-L1 therapies have shown significant activity across a range of tumor types, however, 70-90% of patients do not derive durable benefit. In preclinical settings, delivery of PD-1 blockade and IL-2 agonism in cis via a bispecific molecule, comprising a PD-1 antibody fused to IL-2, has demonstrated superior activity compared to delivery of individual components or their combination. Targeting of IL-2 to $PD\text{-}1^+$ cells in cis has been shown to drive a unique differentiation path endowing $CD8^+$ T cells with enhanced functionality. However, we show that the IL-2 component in an unmasked PD1/IL2 bispecific molecule dominates its pharmacology, driving marked peripheral activation of immune cells, rapid IL-2 receptor-mediated clearance and systemic toxicity. To address these challenges and enable tumor-specific activity, we designed a PD1/IL2 bispecific molecule that incorporates a single domain antibody-based mask to bind to the IL-2 component and maintain it in a quiescent state until activated by prevalent and dysregulated proteases in the tumor microenvironment (TME). In preclinical models, the affinity-optimized mask prevented peripheral IL-2 receptor binding, associated toxicity and receptor-mediated clearance. Improved pharmacokinetics of our tumor-activated PD1/IL2 enabled PD1 antibody-like exposures and is projected to achieve complete blockade of PD1 signaling. Tumor-activated PD1/IL2 significantly inhibited tumor growth compared to anti-PD-1 alone or vehicle and demonstrated improved tolerability compared to an unmasked PD1/IL2 bispecific in mouse models. In addition, pharmacodynamic activity of tumor-activated PD1/IL2 was restricted to the TME. Consistent with the masked design, we observed no significant change in $CD8^+$ T cells in the periphery and significant increases in antigen specific $CD8^+$ T cells, memory $CD8^+$ T cells and $TCF1^+$ stem-like $CD8^+$ T cells in the TME. Ex vivo protease cleavage assays performed in human samples demonstrated efficient activation of tumor-activated PD1/IL2 by multiple tumor types and minimal activation in human plasma. In non-human primates, tumor-activated PD1/IL2 achieved tolerable exposures that were comparable to those of existing PD-1 blocking immunotherapies. Taken together, these preclinical data suggest that tumor-activated PD1/IL2 has the potential to improve upon existing PD-1/PD-L1 immunotherapies by inhibiting PD-1/PD-L1 axis and simultaneously directing immunostimulatory IL-2 to antigen-experienced effector cell populations in the TME.

#0720 Combining zelasudil, a small molecule ROCK2 inhibitor, with chemotherapy or immunotherapy improves response in preclinical models of pancreatic cancer.

M. Pajic[1], B. McLean[1], D. Chacon Fajardo[1], S. Porazinski[1], D. H. Upton[1], D. Schuhmacher[1], A. Istadi[1], T. Cox[1], P. Timpson[1], D. J. Wilcock[2], K. J. Anderson[2], H. Mason[2], N. E. S. Guisot[2], C. D. Jones[2], C. Phillips[2], R. Armer[2];

[1]Garvan Institute of Medical Research, Sydney, Australia, [2]Redx Pharma Plc, Greater Manchester, United Kingdom

Zelasudil (RXC007) is an orally available, highly selective small molecule inhibitor of Rho-associated coiled-coil containing protein kinase 2 (ROCK2), which has demonstrated pre-clinical anti-fibrotic efficacy and is currently being tested in a Phase 2a clinical trial for the treatment of idiopathic pulmonary fibrosis (IPF) (NCT05570058). Pancreatic ductal adenocarcinoma (PDAC) is an aggressive and therapeutically challenging disease with a dense and highly fibrotic tumor microenvironment which may limit efficacy of conventional therapies. Here, we investigate the benefit of combining an anti-fibrotic, RXC007, with either standard of care chemotherapy or immunotherapy in mouse models of PDAC.In a fibrotic patient-derived metastatic PDAC orthotopic model, RXC007 (10mg/kg, 50mg/kg and 100mg/kg BID 5d on/2d off PO) in combination with SoC chemotherapy Gemcitabine (100mg/kg IP QW)/Abraxane (30 mg/kg IP QW) improved survival in a dose-dependent manner (all P<0.0001) compared to Gemcitabine/Abraxane alone.In the immunocompetent orthotopic LSL-KrasG12D/+; LSL-Trp53R172H/+; Pdx1-Cre (KPC) model of metastatic PDAC, survival was significantly increased (P<0.0001) upon treatment with a combination of RXC007 (50 mg/kg BID 5d on/2d off PO) and anti-PD1 (200 ug BIW) compared to anti-PD1 alone. ROCK2 inhibition elicited positive immunomodulatory effects in KPC pancreatic tumors, with increase of CD8+ (P=0.0031) and CD4+ (P=0.008) T cell infiltrate into the tumor cortex and reduction in immunosuppressive FOXP3+ regulatory T cells at the tumor border. Furthermore, RXC007 monotherapy exhibited anti-fibrotic effects, via a decrease in collagen content and organization, effects associated with CAF reprogramming and reduced intra-tumoral aSMA+ PDPN+ myofibroblast-like CAFs (myCAFs; P=0.0406).This data highlights the potential for treating highly fibrotic tumours with RXC007 in combination with SoC chemotherapy or immunotherapy in order to improve patient outcomes in this aggressive and treatment-refractory cancer.

#0721 Novel and distinctive anti-HLA-G antibody, IMB-201, inhibits tumor progression by breaking immune escape mechanism and enhancing cytotoxicity.

H. Kang, S. Baek, I. Lee, M. Ju, S. Han, E. Han, S. Kang, J. Koo, Y. Kim, S. Park, E. Cho, C. Lee, G. Ha;
IMBiologics Corp., Suwon, Korea, Republic of

Human leukocyte antigen-G (HLA-G), a type of MHC class I, is known to be expressed only in the placenta and acts as an immune suppressor to protect the fetus from maternal immunity. Recent studies have revealed that HLA-G suppresses various tumor-infiltrated immune cells, such as T cells, NK cells, and macrophages, through interaction with inhibitory receptors Ig-like transcript 2 (ILT2). HLA-G has recently emerged as an attractive anticancer target because HLA-G is a highly specific tumor antigen and has a role in immune evasion of cancer cells. Additionally, the expression pattern of ILT2 differs from that of PD-1 in tumor-infiltrated CD8+ T cells. Therefore, an HLA-G targeting strategy is expected to be an alternative to address unmet medical needs for those not responding to anti-PD(L)1 therapies. In this study, we screened the novel anti-HLA-G antibody, IMB-201, using phage display technique and confirmed that IMB-201 selectively bound to the membrane HLA-G of cancer cells. It exhibited superior activities in ILT2 blockade, NK cell activation, and antibody-dependent cellular cytotoxicity (ADCC) compared to the reference antibody. Furthermore, IMB-201 demonstrated more efficient suppression of tumor growth compared to the reference antibody in subcutaneous gastric cancer xenograft model. Notably, the group administered IMB-201 with NK92MI cells (CD16-negative NK cells) in the ovarian cancer xenograft model showed stronger tumor growth inhibition compared to the group treated only IMB-201, indicating that NK92MI cells were activated by IMB-201. This result indicates that one of the mechanisms of action (MoA) of IMB-201 worked effectively *in vivo*. In addition, to maximize the efficacy of IMB-201 and differentiate it from competitors, various efficacy enhancing modality could be applicable. We aim to develop biopharmaceuticals by selecting the optimized modality. Based on these results, IMB-201 could overcome the limitations of existing cancer immunotherapy, potentially becoming highly influential in cancer treatment as a novel immune checkpoint inhibitor. It is also expected to exhibit higher anticancer efficacy in combination therapy with immune checkpoint inhibitors.

#0722 A cancer-associated fibroblast model to discover mechanisms of growth, survival, and treatment sensitivity in PAX3/7-FKHR fusion-positive alveolar rhabdomyosarcoma.

Patrick Sipila[1], Son Tran[1], Chunfen Zhang[1], Anne-Marie Langevin[2], Aru Narendran[1]

[1]Department of Oncology, University of Calgary, Calgary, AB, Canada,[2]Pediatric Hematology/Oncology, UT Health San Antonio, San Antonio, TX

Introduction: Rhabdomyosarcoma (RMS) is the most common pediatric soft tissue sarcoma. Among various subtypes, alveolar RMS (ARMS) is generally more aggressive and usually carries the fusion transcription factor, PAX3/7-FKHR. High-risk ARMS has an extremely poor prognosis, with ~25% five-year survival. Hence, novel therapeutic approaches are urgently needed. However, potential therapies are often hindered by the immunosuppressive tumor microenvironment (TME) associated with sarcomas. The TME is highly dynamic and includes fibroblasts, immune cells, and extracellular matrix. Cancer-associated fibroblasts (CAFs) may promote tumor growth and survival by secreting distinct factors to regulate proliferation, metastasis, and resistance to therapy. In this study, we investigated mechanisms involved in this phenomenon and identified a novel therapeutic strategy targeting the TME of ARMS.

Methods: Cells were isolated from a PAX3-FKHR fusion-positive ARMS tumor specimen, following ethics approval and informed consent. The PAX3-FKHR fusion status and mesenchymal biomarkers were analyzed by immunoblotting. The patient's CAFs (designated KCCF14), RMS lines (RD, RH30, RH41), and control fibroblasts (BJ, HS68, WI-38) were cultured in vitro and their respective supernatant media was harvested for subsequent experiments. Cell proliferation and viability were determined by hemocytometer and alamar blue assay, respectively. The scratch wound healing assay was used to assess cell migration. Cytokine analysis was performed with a 96-plex array. For drug screening, cells were treated with a panel of CXCR4 antagonists to generate dose-response curves.

Results: KCCF14 CAFs isolated from an ARMS tumor exhibit elongated spindle morphology and are positive for mesenchymal biomarkers, including PDGFR-β and smooth muscle α-actin. As expected, these cells lack characteristics of the patient's tumor, notably the expression of PAX3-FKHR fusion and N-myc. KCCF14-conditioned media significantly enhances ARMS cell proliferation and migration in a concentration-dependent manner. Analysis of the conditioned media revealed upregulation of key growth factors and cytokines, including PDGF-AA, VEGF-A, MCP-1, and IL-11, that promote tumor aggressiveness through proliferative signaling, angiogenesis, activation of migration, and immune evasion. Because SDF-1 (CXCR4 ligand) was also increased, we tested targeted inhibition of CXCR4, which induced cytotoxicity with increased sensitivity (IC_{50} = 0.5 μM) in KCCF14 cells compared to control fibroblasts.

Conclusions: This study provides, for the first time, findings from a continuously growing CAF model system for RMS. Our data describes key tumor growth and survival mechanisms supported by the TME and establishes a method to identify treatments with novel therapeutic strategies.

#0723 Reduction of immunosuppressive function of regulatory T cells enhances antigen-specific T cell mediated cytotoxicity against tumor cells.

A. A. Khan[1], J. Park[1], N. LaVoy[1], C. Tompkins[1], J. Bellinder[2], T. San Miguel[2], N. Lawrence[2], B. Schoen[2];
[1]Charles River Laboratories, Inc., Bothell, WA, [2]Charles River Laboratories, Inc., Northridge, CA

Regulatory T cells (Tregs) maintain immune homeostasis by suppressing abnormal immune response to self and non-self-antigens. Tregs are also involved in tumor development and progression by inhibiting anti-tumor immunity. Infiltration of Tregs in the tumor microenvironment (TME) inhibit anti-tumor immunity by suppressing tumor antigen-specific T cell responses. This results in tumor progression and poor prognosis in patients with various types of cancers. Therefore, depletion of Tregs could be a promising immunotherapy target to augment the anti-tumor immune response. Molecules highly expressed by Tregs such as CD25, immune checkpoint molecules, and chemokine receptors have been targeted by antibodies or small molecules to deplete Tregs and its immunosuppressive function has been tested in the clinic. However, a thin line exists between augmenting effective immunity and inducing autoimmunity, posing difficulties in harnessing Tregs modulation in cancer treatment. Thus, additional strategies to selectively control Tregs are urgently needed for the effective treatment of cancer. In this study we evaluated the role of Tregs in suppressing the effector function of antigen-specific T cells and targeted killing of cancer cells *in vitro*. We observed Tregs mediated suppression of antigen-specific cytotoxicity against cancer cells. When Tregs were treated with cyclophosphamide, CD25 depleting antibody and anti-CTLA4 antibody alone or in combination, we observed enhanced killing of cancer cells *in vitro* as a result of potentiated effector function of antigen-specific T cells. This study provides a path forward to fine-tune and optimize strategies to target various molecules that are highly expressed on Tregs and augment anti-tumor immunity by antigen-specific T cells to achieve therapeutic outcome.

#0724 MPSA-AB5000: A high-throughput membrane proteins screening array for therapeutic biologics specificity profiling.

L. Li, J. Xiong, J. Ning, **F. Hao**;
Kyinno Biotechnology Co., Ltd, Beijing, China

The development of novel antibody drugs is a lengthy journey. Many factors can lead to failures during clinical development. According to reports, off-target binding of antibodies could also be a significant cause. It has been stated that about 25% of preclinical candidates might have off-target issues. With the emergence of new modalities like CD3 bispecific antibodies, ADCs, and CAR-T therapies, early-stage off-target screening of antibodies has become even more crucial. Although techniques such as immunohistochemistry, ELISA, and flow cytometry (FACS) have been used for off-target testing of antibodies, these methods still lack sensitivity and specificity, and their throughput is limited. To address the need for antibody target deconvolution and receptor identification, we developed a novel membrane protein screening array-AB5000 (MPSA-AB5000). MPSA-AB5000 is a high-throughput cell-based platform for identifying the targets of antibodies and other ligands that bind to membrane proteins. MPSA-AB5000 is an excellent solution for antibody specificity screening, which enables early off-target screening and can de-risk the antibody drug development program. The MPSA-AB5000 makes use of the full coverage of unique human membrane proteins, including receptors, transporters, enzymes, miscellaneous, and others. Each membrane protein is expressed in live cells to ensure native conformation. In addition, the same membrane protein clones with a C-terminal epitope tag were constructed, allowing confirmation of protein expression and cellular location. To provide the highest level of sensitivity, MPSA-AB5000 uses luciferase reporter cell line detection. The wash-free strategy reduces false negatives, and signal amplification makes remarkable discrimination. Compared to similar technologies, we possess significant advantages in the following aspects: a. High sensitivity and sigh throughput: our technology platform offers not only high sensitivity, capable of detecting subtle interactions but also supports high-throughput screening, allowing for the evaluation of a large number of samples in a short timeframe. b. Avoidance of false negative signals: by eliminating washing steps, our method reduces the risk of false negative signals, ensuring reliable detection of non-specific binding. c. Comprehensive validation approaches: We employ various validation methods such as FACS and ELISA to eliminate false positive signals and enhance the accuracy and credibility of our results. All the advantages ensure that MPSA-AB5000 is more rapid, simple, and highly sensitive than traditional assays.

#0725 Listeria-inspired phagosome escape drives STING responses to CD47 blockade.

B. R. Schrank, Y. Wang, A. Antony, W. Jiang;
UT MD Anderson Cancer Center, Houston, TX

Purpose: Through phagocytosis, antigen-presenting cells (APCs) engulf and neutralize malignant cells. However, engulfed tumor cells are destroyed in phagolysosomes leaving few peptides to enter cytosol, where cross-presentation of antigens and immune activation occurs. *Listeria (L.) monocytogenes* escape phagolysosomes by secreting a pore-forming protein Listeriolysin O (LLO). Our breakthrough centers on harnessing LLO to create LLO-CD47, a novel protein-antibody conjugate that fuses the myeloid checkpoint anti-CD47 to LLO. By promoting tumor cell-phagocytosis and the release of tumor peptides and DNA from phagolysosomes, we hypothesize that LLO-CD47 enhances the immune functionalities of APCs.
Procedures: Anti-CD47 was conjugated to LLO using a water-soluble SPDP crosslinker and purified by affinity chromatography. Transmission electron microscopy (TEM) was used to visualize the integrity of macrophage phagolysosomes following treatment. C57BL/6 mouse bone marrow-derived macrophages (BMDMs) were used to study M2-to-Ml polarization, tumor cell phagocytosis, STING activation, and antigen presentation. Mice bearing orthotopically implanted spontaneously metastatic murine triple-negative 4T1 tumors and E0771 tumors received intratumoral (IT) or intraperitoneal (IP) injection. CD8+ T cells or tumor-associated macrophages (TAMs) were depleted from tumor-bearing mice using an anti-CD8 antibody or anti-CSF-1R antibody prior to treatment.
Results: 1. LLO-CD47 skews BMDMs from M2-to-M1 inflammatory phenotypes and enhances the phagocytosis of E0771 tumor cells. 2. BMDMs visualized by TEM show breaches in phagosome membranes following LLO-CD47, but not anti-CD47, treatment. 3. LLO-CD47 increases levels of phosphorylated STING, IFN, and TNFa in BMDMs in vitro and TAMs in vivo, relative to anti-CD47. 4. IT delivery of LLO-CD47 inhibits the growth and metastasis of orthotopically implanted murine breast tumors relative to anti-CD47. Harvested tumors show increased M1 polarized macrophages and CD8+ T cells, which express high levels of PD-1. 5. Co-administration of IP anti-PD-1 and LLO-CD47 delays the progression of breast tumor metastasis and prolongs animal survival relative to animals treated with anti-PD-1 and anti-CD47. 6. The elimination of CD8+ T cells or TAMs abrogates the antitumor effect of LLO-CD47. 7. IP administration of LLO-CD47 showed acceptable toxicity with stable body weight gain and no long-term hematological, renal, or hepatic toxicities.
Conclusion: Conjugation of LLO to anti-CD47 enhances macrophage STING activation, antigen presentation, and tumor cell phagocytosis. Our work represents the first antibody-drug conjugate specifically designed to enhance immune activation against cancer.

#0726 The retinoid X receptor agonist MSU42011 enhances efficacy of anti-PD1 therapy in a HER2+ breast cancer model through a CD4-IL12 axis.
A. S. Leal, K. T. Liby;
Indiana University School of Medicine, Indianopolis, IN

Immunotherapy is rarely effective in breast cancer and most current therapeutic options fail to target the stromal compartment. We have developed a new small molecule, MSU42011, that induces tumor regression in experimental models of Kras-driven lung cancer and HER2+ breast cancer. This tumor regression is dependent on a functional immune system. Here, we dissected the tumor stroma, revealing a CD4 and IL12a dependency for the anti-tumor activity of MSU42011. Cancer immunotherapy responses are mostly driven by CD8 T cells. Using a murine HER2+ tumor model, anti-CD8 antibodies (200ug/mouse) were injected 24 hours before treatment with MSU42011 (100MG/KG in power diet) was started. Mice were maintained on diet for 10 days. Anti-CD8 antibodies were also administered on days 3, 7 and 10. The combination did not affect the inhibition of tumor growth by MSU42011, suggesting that its anti-tumor efficacy is not dependent on CD8 T cells. In contrast, tumors treated with MSU42011 and anti-CD4 antibodies grew ($p=0.0016$ versus MSU42011 alone) at the same rate as tumors treated with control diet ($p=0.0139$ versus MS42011). Furthermore, anti-CD4 reversed inhibition of tumor growth by MSU42011 in a carcinogen-induced lung tumor model. Interestingly, MSU42011 increased the levels of IL12 by 4x ($p=0.01$) and IFN by 8x ($p=0.03$) compared to the controls. These data suggest that MSU42011 increased Th1 CD4 T cell polarization; the increase in IL12 was lost following CD4 T cell depletion. Following depletion of IL12a with antibodies (loading dose of 1 mg, followed by 0.5mg per mouse IP), tumors treated with the combination of MSU42011 and anti-IL12a antibodies grew at the same rate as the controls. T cell engagement with MSU42011 suggests that this small molecule is a good candidate for combination with immunotherapy. HER2+ MMTV-Neu mice with established tumors were treated with the combination of MSU42011 and anti-PD1 antibodies. Treatment with MSU42011 at 100mg/Kg of diet for 10 days, followed by anti-PD1 antibodies (200ug) twice weekly failed to increase survival. In contrast, 2 doses of anti-PD1 antibodies (300ug), followed by treatment with MSU42011 increased survival by 10 days compared to controls. The tumors in the MSU42011+anti-PD1 group initially grew rapidly, with increased redness and heat, suggesting an enhanced inflammatory response. When anti-PD1 antibodies were given at a lower loading dose (200ug and then 100ug twice weekly) followed by a higher dose of MSU42011 (300 mg/Kg of diet), survival markedly increased ($p=0.052$). These findings demonstrate that activation of RXR in the stroma can be used to increase the effectiveness of immunotherapy.

#0727 FGFR4 promotes colon cancer progression through CAF activation via the CXCL10-CXCR3 axis.

S.-H. Cho, H. Bang, E.-G. Sun, J.-N. Choi, M.-R. Park, H.-J. Shim, J.-E. Hwang, W.-K. Bae, I. Chung;
Chonnam National Univ. Hwasun Hospital, Hwasun-Gun, Korea, Republic of

Cancer-associated fibroblasts (CAFs) contribute to cancer progression via crosstalk with cancer and immune cells in the tumor microenvironment (TME). Despite the significant role of CAF, the understanding of the trigger mechanisms of cancer-mediated CAF activation remains unclear. We previously reported the mechanism by which FGFR4 in colon cancer secretes amphiregulin (AREG), resulting in anti-EGFR chemoresistance. It motivated us to investigate whether FGFR4 overexpressing tumors may change the TME, so we explored the mechanism of CAF activation under the FGFR4 signaling pathway. CAF was isolated from BALB/C mice after injecting 1×10^6 CT-26/EV or FGFR4 cells using microbeads and conditioned media (CM) was prepared by filtering after 48h cancer cell culture with serum-free medium In mice model, CT-26/FGFR4 showed more significant tumor progression and CAF abundance (α-SMA, FAP, PDGFR, and vimentin) than CT-26/EV. Additionally, CT26/FGFR4-derived CAFs showed significantly increased invasiveness and contractility, indicating the highly activated status of CAFs. In order to verify the effect of cancer secretome from FGFR4 in cancer cells , normal fibroblast (NIH/3T3) were co-cultured with either stable cancer cells or CM. As a result, CT-26/FGFR4 cells robustly induced the expression of CAF markers in NIH/3T3 cells, indicating the promotion of CAF differentiation from resting fibroblasts. Also, CT-26/FGFR4-derived CM significantly promoted further activation of CAFs compared to CT-26/EV-derived CM. Taken together, FGFR4 contributes not only to CAF differentiation but also to CAF activation via secretome. Next, we performed RNA seq of CT-26/EV and CT-26/FGFR4 cells and identified the upregulated genes related with the interferon (IFN) signaling. Among these genes, we identified IFNβ and CXCL10 as targetable molecules via the activation of TLR3-TBK-IRF and IFN-STAT-CXCL10 signaling pathways. These results were confirmed by RT-PCR and western blot assay. Secreted CXCL10 induced gene expression of CAF markers in fibroblast and increased CAF functions such as migration, invasion and contractibility, reflecting CAF activation. Blocking antibodies and knocking down of CXCL10 inhibited the cancer secretome-mediated CAF markers. The blockade of CXCR3, which is the CXCL10 cognate receptor, also showed an inhibitory effect on the FGFR4-overexpressing cancer-educated CAF. In human colon cancer specimens, the expression of FGFR4, CXCL10, and CAF markers showed a positive correlation with each other. Finally, dual inhibition of FGFR4 and CXCR3 in tumor mouse model suppressed the tumor growth, accompanied by CAF suppression. Our findings reveal the novel mechanism of FGFR4 leading CAF differentiation/activation in TME via the CXCL10-CXCR3 axis. This suggests that FGFR4/CXCR3 inhibitor could be used as a potential therapeutic strategy to attenuate CAF in stromal dominant tumors.

#0728 Oral TGF-beta receptor1 inhibitor vactosertib promotes osteosarcoma regression by targeting tumor proliferation and enhancing anti-tumor immunity.

S. Choi[1], J. Myers[1], S. Tomchuck[1], M. Bonner[1], S. Eid[1], D. Kingsley[1], K. VanHeyst[1], S.-J. Kim[2], B.-G. Kim[1], A. Huang[1];
[1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]MedPacto Inc, Seoul, Korea, Republic of

Osteosarcoma (OS) is an aggressive malignant bone cancer, with the lung as the most frequent site of metastasis. Unresectable pulmonary metastasis remains a significant challenge with a survival rate of less than 20%. Identification of novel therapeutic strategies are desperately needed. Transforming growth factor-β1 (TGF-β) is a potent immune suppressive cytokine in OS tumor microenvironment (TME). TGF-β1 expression is increased in the sera and tumor tissues of OS patients and this increase is associated with high-grade OS and lung metastases. Therefore, blocking TGF-β1 signaling may be a novel therapy for OS treatment. In this study, we show that blocking TGF-β1 signaling using the orally bioavailable small molecule TGF-βR1 inhibitor, Vactosertib, significantly inhibited OS proliferation *in vitro and in vivo*. Notably, Vactosertib inhibits c-Myc expression in the OS cells and oral administration of Vactosertib significantly reduces OS growth *in vivo*. Vactosertib increased immune effectors (e.g., $IFN\gamma^{+}CD8^{+}$ cells and NK cells) and inhibited immune suppressors (e.g., M2-like TAM, MDSC) in the OS TME. Our results suggest that inhibition of TGF-β1 signaling is an effective therapeutic strategy against OS through a multi-pronged approach that targets tumor intrinsic and extrinsic factors to achieve optimal immune-effector functions and maximal clinical response.

#0729 IDO1 inhibition enables IFNγ-elicited responsiveness of pulmonary breast cancer metastases to hypoxia-directed tumoricidal agents.

S.-C. Shen[1], S. Dey[2], J. B. DuHadaway[3], E. Sutanto-Ward[3], G. C. Prendergast[3], A. J. Muller[3];
[1]Drexel University College of Medicine, Philadelphia, PA, [2]Wuxi Advanced Therapeutics, Inc., Philadelphia, PA, [3]Lankenau Institute of Medical Research, Wynnewood, PA

In mouse models of lung carcinoma and pulmonary breast cancer metastasis, genetic ablation of the tryptophan catabolizing enzyme IDO1 (indoleamine 2,3-dioxygenase 1) resulted in restricted tumor outgrowth associated with attenuated induction of the inflammatory cytokine IL6 (interleukin 6). Utilizing the 4T1 breast cancer metastasis model to further elucidate the mechanistic basis underlying IDO1's pro-tumor activity in the lungs established that IDO1 acts as an integral determinant of a tumor-promoting inflammatory state that supports neovascular retention. *Ido1*$^{-/-}$ (nullizygous) mice exhibited impaired pulmonary metastases neovascularization and outgrowth that was driven by IFNγ (interferon gamma) in the absence of IDO1-dependent IL6 production. Hypoxia was likewise elevated, and these stress conditions increased the susceptibility of the metastatic tumor cells to cytotoxicity associated with administration of GSK2656157, an inhibitor of PERK (protein kinase RNA-like ER kinase), which acts as a primary sensor for activating the UPR (unfolded protein response) survival pathway. In WT (wild type) mice with established 4T1 lung metastases, administration of the IDO1 inhibitors epacadostat, navoximod or indoximod each similarly resulted in rapid collapse of the metastatic tumor neovasculature and concomitantly increased intratumoral hypoxia and sensitivity to PERK inhibition. Therefore, while IDO1 inhibition does not directly promote effective tumor cell killing in this context, the disruption of blood supply due to IFNγ-mediated neovascular regression subjects the tumor cells to hypoxic environmental stress, raising the possibility for therapeutic intervention with selectively targeted agents. Combining chemotherapy with immune checkpoint blockade (ICB) is recognized as an effective strategy for treating lung cancer, with first-line therapy for some patients including the alkylating agent carboplatin in conjunction with pembrolizumab. The challenge remains, however, that chemotherapy causes systemic side effects that can negatively impact quality of life and limit efficacy. Evofosfamide is an alkylating prodrug that was designed to be selectively activated in regions of hypoxia, thereby limiting systemic exposure. We report that enhanced metastatic tumor cell killing with evofosfamide can be achieved by co-administration of an IDO1 inhibitor. Elevated intratumoral hypoxia has also previously been linked to increased expression levels of PDL1, a favorable indicator of ICB responsiveness, and we have confirmed the upregulation of PDL1 in 4T1 lung metastases following IDO1 inhibitor administration. Our data in the lung metastasis model support future studies to evaluate whether IDO1 inhibition can be effectively combined with evofosfamide and anti-PD1 treatment to improve therapeutic outcomes.

#0730 Leveraging microdissection for proteogenomic analysis of histological sections to advance drug development.

I. Shin[1], M. Tangrea[2], M. R. Emmert-Buck[3], **D. J. Johann, Jr.**[1];
[1]UAMS Winthrop P. Rockefeller Cancer Institute, Little Rock, AR, [2]Loyola University Maryland, Baltimore, MD, [3]Avoneaux Medical Institute, Baltimore, MD

Background: Combining proteogenomics with laser capture microdissection (LCM) in cancer research offers a targeted way to explore the intricate interactions between tumor cells and the tumor microenvironment. This is especially important for immuno-oncology (IO) research where improvements in the predictability of patient response to IO-based drugs is sorely needed. An improved understanding of the spatial relationships involving tumor cells proper, stromal cells, blood supply and immune cell interactions may help to inform drug development and improve the indicators of success for IO-based drug regimens.
Methods: LCM is used to isolate and obtain distinct histological cell types from fresh frozen tissue. Once cells have been captured, nucleic acids and proteins are extracted for in-depth multi-modality molecular profiling assays involving multiple genomic modalities and a customized solution-based mass spectrometry proteomics approach for samples or specimens with a limited amount of tissue.
Results: Optimizing analysis of minute tissue quantities from LCM captured cells is challenging. Following the isolation of nucleic acids, RNA-seq may be performed for gene expression and DNA sequencing performed for the discovery and analysis of actionable mutations, copy number variation, and methylation profiles. Regarding genomic-based studies, commercial kits are often utilized for these steps due to their general availability, rapid innovation, and the robust performance of these products. However, this kit-based adaptive approach is not true for proteomics. There remains a need for highly sensitive proteomic methods targeting small-sized samples. A significant part of our proteogenomics approach is focused around an enhanced liquid chromatography mass spectrometry (LC-MS) analysis of micro-scale and/or nano-scale tissue sections. This is achieved with a silver-stained one-dimensional sodium dodecyl sulfate polyacrylamide gel electrophoresis (1D-SDS-PAGE) approach developed for LC-MS analysis of fresh-frozen tissue specimens obtained via LCM. This includes an in-gel digestion method adjusted and specifically designed to maximize the proteome coverage from amount-limited LCM samples to better facilitate in-depth molecular profiling.
Conclusions: Reported here is a proteogenomic approach that is leveraging from microdissected fresh frozen tissue. The methodology may also be applicable to other types of specimens having limited nucleic acids, protein quantity, and/or sample volume.

#0731 pHLIP targeted intracellular delivery of calicheamicin.

M. DuPont[1], C. Klumpp[1], M. Iraca[1], D. Allababidi[1], H. Visca[1], D. Engelman[2], O. Andreev[1], A. Moshnikova[1], Y. Reshetnyak[1];
[1]University of Rhode Island, Kingston, RI, [2]Yale, New Haven, CT

Calicheamicin is a potent, cell-cycle independent enediyne antibiotic that binds and cleaves DNA. Toxicity has led to its approved use in a targeted form as antibody-drug conjugates (ADC) for the treatment of liquid tumors. Mylotarg, one of the first such ADCs, was voluntarily withdrawn from the market due to safety concerns. However, Mylotarg was recently reapproved for acute myeloid leukemia based on new data that demonstrated efficacy with an acceptable safety profile. Besponsa, a related ADC, was approved for acute lymphocytic leukemia in 2017. In both agents, Mylotag and Besponsa, calicheamicin is conjugated to antibodies via an acid-labile hydrazone linker. We used a reduced calicheamicin to conjugate it to a single cysteine residue at the membrane-inserting end of a pH Low Insertion Peptide (pHLIP) via a disulfide bond to generate a linkerless cytoplasmic release. The cytoplasmic reduction of the disulfide releases the calicheamicin, which leads to its activation, DNA binding, and strand scission. pHLIP is a tumor-targeting agent now in clinical trials with imaging and therapeutic payloads. We studied the interaction of pHLIP-calicheamicin with liposomal and cellular membranes and demonstrated that the agent exhibits cytotoxic activity both in highly proliferative cancer cells and in non-proliferative immune cells, such as polarized M2 macrophages. In mice, treatment led to the growth inhibition of immuno-suppressive CT26 tumors with no signs of toxicity. Biodistribution studies confirmed tumor targeting with no accumulation of the agent in organs and tissues. The fluorescent version of the agent was observed within the tumor mass and tumor-stroma interface, where CD206+ M2 tumor-associated macrophages (M2-TAMs) reside. Treatment of tumors led to the depletion of M2-TAMs within the tumor core. Thus, pHLIP-calicheamicin could be developed into an effective therapeutic for the treatment of solid tumors with abundant immuno-suppressive M2-TAMs.

#0732 Toward optimizing CXCR4 inhibition with beta adrenergic blockade to enhance chemotherapy response in acute myeloid leukemia.

B. Loera[1], C. Zhang[2], P. M. Cardarelli[3], N. G. Caculitan[3], S. Chien[4], J. Dai[4], V. G. Oehler[5], J. Zhang[1], G. Marcucci[1], **P. S. Becker**[1];
[1]City of Hope National Medical Center, Duarte, CA, [2]Amgen, Thousand Oaks, CA, [3]GPCR Therapeutics, Redwood City, CA, [4]University of Washington, Seattle, WA, [5]Fred Hutchinson Cancer Center, Seattle, WA

Introduction: CXCR4 is a chemokine receptor for CXCL12 that plays a critical role in homing of hematopoietic stem cells (HSCs) to the bone marrow microenvironment. The CXCR4 inhibitor plerixafor is used to increase mobilization of peripheral blood stem cells in combination with filgrastim. This pathway has also been investigated for applications in hematologic malignancies such as acute myeloid leukemia (AML), including clinical trials, with the goal of disrupting AML from the protective marrow environment. These have included use of plerixafor with 7+3 or MEC, BL-8040 with cytarabine, and ulocuplumab with MEC. For the ulocuplumab trial, at the study site of the authors, CR/CRi correlated with >10% CXCR4 expression (Becker et al. ASH 2014). The objective of this preclinical study is to identify the AML patient population most likely to respond to CXCR4 inhibition, and the role of combined beta-adrenergic blockade, as the latter has been shown pre-clinically to augment mobilization of HSCs when combined with a CXCR4 inhibitor, GPC-100 (Sukhtankar et al. PLoS One, 2023).
Procedures: AML patient samples (N=124 including 90 blood and 34 bone marrow samples, and 21 with both) were obtained with informed consent on an IRB approved protocol. Multicolor flow cytometry was performed with sequential gating on blasts (by FSC/SSC, CD45/SSC, CD34 or phenotype), and leukemia stem cells (LSCs:$CD34^{+}CD38^{-}$,$CD123^{+}$), then analysis for CXCR4 and beta-2 adrenergic receptor (ADRB2) surface expression. Correlations between CXCR4 expression and clinical characteristics including age, gender, new diagnosis vs. relapse, ELN2022 risk, cytogenetics, FLT3/NPM1 mutation status, CR1 duration, and overall survival were performed. GraphPad Prism9 was used for statistical analysis, and Mann Whitney test (two groups) and ordinary one-way ANOVA (>2 groups) were used for comparisons.
Results: The range of CXCR4 expression by AML blasts is 0.05 to 99.7% (median 13.1%; mean 16.2%), and by AML LSCs 0 to 99% (median 2%, mean 15.7%). The expression by blasts and LSCs for each patient exhibited tight correlation, R^2=0.88 p=1.23 X10e-25). There was higher % expression of CXCR4 by both blasts and LSCs for new diagnosis, as compared to relapsed, patient samples (p=0.002). There was no correlation between level of CXCR4 expression and the other clinical features. For a subset of 20 patient samples analyzed for both CXCR4 and ADBR2 expression by AML blasts, ADBR2 expression ranged from 0.4 to 20.1%. For the samples that express ADBR2, there was high level expression of CXCR4, range 35.9 to 98.7% (median 78.4%, mean 76%).
Conclusion: These studies support further investigation of whether simultaneous blockade of CXCR4 and ADBR2 may potentiate chemotherapy response in AML by limiting microenvironment mediated chemotherapy protection and reveal that patients with new diagnosis may be more susceptible to this approach.

#0734 Inhibition of equilibrative nucleoside transporter 1 relieves intracellular adenosine-mediated immune suppression.

T. J. Sanders[1], C. S. Nabel[2], M. Brouwer[1], A. L. Hermant[1], L. Chaible[1], J.-P. Deglasse[1], A. Pabois[1], W. Cathou[1], A. Smets[1], M. Deligny[1], J. Marchante[1], Q. Dubray[1], M.-C. Lettelier[1], C. Martinoli[1], R. Marillier[1], O. De Henau[1], Y. McGrath[1], M. G. Vander Heiden[2], **E. Houthuys**[1];
[1]iTeos Therapeutics, Gosselies, Belgium, [2]Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA

The profound benefit of immune checkpoint blockade for cancer therapy is restricted to limited subsets of patients with specific cancers. Many factors contribute to primary and acquired resistance to immune checkpoint blockade, including local accumulation of immunosuppressive metabolites such as the nucleoside adenosine and downstream adenosine receptor signaling. Pharmacological inhibition of adenosine generation and signaling are active areas of clinical investigation. Here we report a novel mechanism whereby adenosine suppresses anti-cancer immune responses by intracellular accumulation. We show that human T cells readily take up adenosine via equilibrative nucleoside transporter 1 (ENT1), suppressing proliferation and effector function by inhibition of *de novo* pyrimidine nucleotide synthesis in T cells. ENT1 expression increases upon T cell activation, suggesting uptake of extracellular adenosine is a mechanism to limit T cell responses in high adenosine environments. Quantitative mass spectrometry imaging reveals adenosine concentrations in human tumors up to the range of 100 µM - levels significantly greater than previously demonstrated and consistent with suppression of T cell responses. Deletion of ENT1 leads to potent control of tumor growth in syngeneic mouse models including KPC, a poorly immunogenic model of pancreatic ductal adenocarcinoma, and is associated with increased CD8+ T cell frequency, proliferation and cytokine production within tumors. Furthermore, ENT1 expression was observed by flow cytometry on human tumor-infiltrating $CD8^+$ T cells. We have discovered and characterized EOS301984, a potent ENT1 antagonist that is currently being evaluated in patients with advanced solid tumors. EOS301984 blocks intracellular adenosine transport and restores pyrimidine levels in T cells activated in the presence of adenosine, resulting in enhanced tumor cell killing by memory T cells and increased *ex vivo* expansion of functional human tumor-infiltrating lymphocytes in adenosine-rich environments. Finally, in a humanized mouse model of triple negative breast cancer resistant to anti-PD-1 blockade (MDA-MB-231), combination of EOS301984 with nivolumab synergistically led to control of tumor growth. Thus, ENT1 inhibition represents a novel approach to augment anti-cancer immune responses through restoring pyrimidine nucleotide synthesis in T cells suppressed by adenosine.

#0735 Mitigation of liver toxicity effects of bispecific T cell engagers in immune-competent liver-tumor co-culturing high-throughput platform.

M. Rudnik[1], L. Holting[1], T. Hafeli[1], O. Yavaş Grining[1], F. Greve[1], D. Ortiz Franyuti[2], R. Matheis[2], **L.-A. Ligeon**[1], E. Breous-Nystrom[3], O. Frey[1];
[1]InSphero AG, Schlieren, Switzerland, [2]Roche Pharma Research & Early Development, Roche Innovation Center, Basel, Switzerland, [3]Roche Pharma Research & Early Development Roche Innovation Center, Basel, Switzerland

The remarkable clinical therapeutic effects and wide-ranging applications of bispecific T cell engagers (BiTEs) have revolutionized the treatment approaches in the field of oncology. While the advantages of these innovative immunotherapies are undeniable, it is imperative to thoroughly investigate their safety aspects. With increasing use of biologics for treatment of various cancers, the incidence of immune-related adverse events (irAEs) will undoubtedly increase. Therefore, there is a compelling need to develop measures to effectively prevent or manage irARs already on the stage of the development of new clinical candidates. To address this need, we have created a high-throughput, automation friendly, 384-well-format platform in which 3D spheroid models are co-cultured in units interconnected by microfluidic channel. The tissue-tissue interaction was facilitated by a gravity-driven, tubeless flow system. The design allows for the simultaneous evaluation of the anti-tumor efficacy and liver safety of immunotherapeutics. In our system, we employed 3D spheroids comprised of primary human hepatocytes and Kupffer cells to model the liver, ensuring the preservation of their metabolic and inflammatory functions. Additionally, we established a solid tumor model using human cancer cell lines (HCT116-GFP) and primary cancer-associated fibroblasts, effectively mimicking the complex tumor microenvironment We treated 3D spheroid models with runimotamab (HER2xCD3 BiTE), catumaxomab (EPCAMxCD3), nivatrotamab (GD2xCD3) and control bispecific antibodies in the presence of peripheral blood mononuclear cells (PBMCs). Tumor viability and growth was assessed by fluorescence measurements, while liver toxicity and function were monitored by release of liver aminotransferases ALT and microscopy. To mitigate potential liver toxicity, we co-treated spheroid co-cultures with adalimumab (anti-TNF), tocilizumab (anti-IL-6R), raleukin (IL-1R antagonist) (each 100ug/ml), desatanib, dexamethasone or ruxolitinib (each 100nM). The treatment with all bispecific antibodies resulted in a significant decrease of fluorescence and size of tumor spheroids in comparison to control antibody. At the same time increased ALT concentrations were observed after the treatment with BiTEs. The application of small molecular drugs protected against liver damage, but also severely disrupted tumor killing. Interestingly, adalimumab revealed liver protective actions without affecting tumor killing, suggesting TNF-mediated mechanism of toxicity. In summary, we have developed a relevant, high-throughput platform for the evaluation of novel immunotherapies closely reflecting clinical scenarios. High throughput of the assay represents a powerful screening tool for clinical candidate development.

#0736 ACTM-838 safely and comprehensively re-activates the immunosuppressive TME by exploiting myeloid biology intrinsic in many cancers.

W. Lu, K. Cron, J. Janes, L. Berryman, G. Singh, C. Thanos, A. Udyavar;
Actym Therapeutics, Berkeley, CA

ACTM-838 is a genetically modified bacterial vehicle encoding a DNA plasmid with two engineered payloads, IL-15plex and constitutively active eSTING. The bacterial vehicle is a highly attenuated S. typhimurium, engineered to facilitate safe IV administration. ACTM-838 is designed to specifically enrich in the TME via auxotrophic dependency on extracellular adenosine and purine metabolites. ACTM-838 is then selectively internalized by tumor-resident myeloid cells achieving tumor-specific payload delivery.

Previously, we showed ACTM-838 exhibited significant and durable anti-tumor efficacy across syngeneic tumor mouse models (EMT6 breast, MC38 colon) and MMTV-PyMT GEMM.

To elucidate TME changes induced by ACTM-838, EMT6 tumors were analyzed post-treatment by scRNA-seq, which demonstrated that ACTM-838 induced significant transcriptional changes in several cell populations in the TME. Cytolytic pathways were upregulated in T and NK cells, while type I IFN and PDL1 were upregulated in myeloid populations consistent with previous bulk RNAseq analyses.

To understand the tolerability and safety of ACTM-838, a GLP toxicology study was performed on naïve cynomolgus monkeys (NHP). No ACTM-838-related clinical or veterinary observations were reported at any dose level. Acute dose-dependent increases in serum cytokines were observed at 4 hours which reverted to baseline by 24 hours. ACTM-838 was cleared from blood by 24 hours post-dose with no significant shedding in urine or feces. ACTM-838 was only detected in the spleen in 2 and 1 animals at 22- and 49-days post treatment, respectively. Pre-existing ADA was observed in some animals with subsequent increases in ADA upon dosing in most animals. However, no correlation of serum ADA and blood PK levels suggested that the presence of ADA does not impact drug stability.

The ACTM-838 mechanism of action requires high levels of adenosine or purine metabolites to enrich and colonize the TME as well as phagocytic internalization by tumor-intrinsic myeloid cells to achieve tumor-specific payload delivery. Myeloid cells comprise roughly half of all cells in the TME in human tumors. Bioinformatics analyses of the public patient datasets identified key tumor indications enriched in both adenosine and myeloid pathways. To further understand the spatial heterogeneity in the TME across tumors, we performed multiplex immunofluorescence on patient tumor microarrays to validate tumor types with a high prevalence of myeloid populations coupled with an active adenosine pathway, which will help guide future clinical study design.

In summary, we demonstrate that ACTM-838 modulates the TME and is stable and safe in animal models. Additionally, our studies recommend the prioritization of certain tumor indications for treatment with ACTM-838 in the clinic.

#0737 Arrays of 3D ECM-embedded fibroblast clusters for characterization of ECM remodeling by primary cancer associated fibroblasts and for evaluation of drugs attenuating fibrotic ECM remodeling.

E. H. Danen;
Leiden Univ., Leiden, Netherlands

Chronic fibrosis can lead to organ failure and is also associated with cancer, where the tumor is interpreted as a chronic wound, and the fibrotic tumor environment drives disease progression. Fibrosis occurs in an inflammatory environment where macrophages are activated, and fibroblasts transdifferentiate into myofibroblasts. Activated macrophages stimulate the myofibroblasts to produce excessive amounts of collagen-rich ECM. Changes in proteolytic activity and high contractile forces that myofibroblasts apply onto their tissue environment, further lead to extensive remodeling of the healthy tissue matrix into a scar matrix. Similar activity is displayed by cancer-associated fibroblasts (CAFs) in tumors. Intervening with the excessive ECM remodeling by activated fibroblasts represents a candidate therapeutic strategy to normalize the architecture of fibrotic and malignant tissues. We developed a screening platform using an assay based on automated image guided injection of clusters of fibroblasts in wells of multi-well plates preloaded with a collagen-rich ECM network. The identical x-y-z position, spacing, and size of the ECM-embedded fibroblast clusters in each well facilitates automated real time confocal microscopy and quantitative image analysis algorithms. We use this setup for automated quantitative analysis of ECM remodeling activity of CAFs obtained from early-stage colorectal cancer patients. We find that CAFs from these early-stage lesions display increased ECM remodeling capacity as compared to patient matched normal fibroblasts. We then use the same setup to screen a series of compounds for their ability to attenuate ECM remodeling triggered by TGFb-activated primary human fibroblasts. We detect known and novel pathways, and we identify small molecule inhibitors with a promising efficacy versus toxicity profile. Lastly, we detect a previously unknown concentration-dependent side effect of ALK5 inhibitors that leads to the identification of a novel profibrotic pathway and indicates that caution is warranted for the clinical application of ALK5 inhibitors.

#0738 MBRC-101: a novel antibody-drug conjugate (ADC) targeting the tyrosine kinase receptor EphA5.

F. I. Staquicini[1], F. H. F. Tang[2], V. de Oliveira[1], D. I. Staquicini[2], Y. Wu[1], K. F. Barnhart[1], J. Parsons[1], W. Arap[3], I. Chen[1], R. Pasqualini[3];
[1]MBrace Therapeutics, San Diego, CA, [2]Rutgers University, Newark, NJ, [3]Rutgers University and Cancer Institute of New Jersey, Newark, NJ

Introduction: The receptor tyrosine kinase EphA5 has the classical receptor kinase topology with an extracellular-binding domain, a single-pass transmembrane domain, and a cytoplasmic kinase domain. Previously, EphA5 has been shown to contribute to DNA-damage repair and radiation therapy resistance in lung cancer. We investigated EphA5 expression in lung cancer as well as breast, pancreatic, gastric, and colorectal cancer and assessed its potential as a therapeutic target using a novel ADC, MBRC-101.
Methods: MBRC-101 is composed of a humanized anti-EphA5 IgG1 monoclonal antibody conjugated to monomethyl auristatin E (MMAE) via a cleavable valine-citrulline linker using site-specific ThioBridge™ technology. The specificity profile of the anti-EphA5 antibody was characterized using a membrane proteome array. Receptor-mediated antibody internalization was determined by real-time live-cell analysis, and cell killing assays were performed using analysis of cell confluence and luminescent-based viability. Expression of EphA5 in archival human tissue sections was evaluated by immunohistochemistry (IHC) using a commercial antibody. Efficacy studies used patient-derived xenograft (PDX) models of lung adenocarcinoma, squamous cell carcinoma of both lung and head and neck, and breast cancer.
Results: IHC demonstrated selective EphA5 membrane expression in 78% (18/23) of triple negative and 88% (23/26) of hormone receptor-positive breast cancer tumors tested. EphA5 membrane expression was also detected in 85% (29/34), 73% (16/22), 70% (7/10), 70% (15/22), and 50% (6/12) of lung squamous cell carcinoma, lung adenocarcinoma, gastric, colorectal, and pancreatic patient tumors tested, respectively. EphA5 expression was not detected in adjacent, non-malignant tissue in any of the tumors examined. The anti-EphA5 antibody bound exclusively to EphA5 and did not cross-react with other members of the Eph receptor/ephrin ligand family. Binding of the anti-EphA5 antibody on the cell surface triggered rapid internalization and processing through the endosomal-lysosomal system. MBRC-101 was cytotoxic to EphA5-expressing cells and its activity was concentration-dependent and commensurate to levels of EphA5 on the cell surface. In PDX models, once weekly administrations of intravenous MBRC-101 showed dose-dependent, robust, and reproducible anti-tumor activity. Partial tumor responses were observed at doses of 2.5 mg/Kg and complete tumor responses starting at 5 mg/Kg. Toxicologic findings in Sprague-Dawley rats and cynomolgus monkeys were attributed to the MMAE payload and not target-related. Based on an HNSTD of 10 mg/kg in monkeys, the starting human dose was 0.5 mg/kg with ~15-fold safety margin.
Conclusions: EphA5 is a new and promising molecular target for the development of ADC-based therapies against many human cancers. A Phase 1/1b study of MBRC-101 is currently recruiting (NCT06014658).

#0739 AMT-253, a first-in-class MUC18-targeting antibody-drug conjugate, for the treatment of MUC18-positive solid tumors.

Jing Shi[1], Jiaqing Yan[1], Yaling Huang[1], Jun Guo[2], Yan Kong[2], Xun Meng[1], **Shu-Hui Liu**[3]

[1]Multitude Therapeutics, Shanghai, China,[2]Peking University Cancer Hospital and Institute, Beijing, China,[3]Multitude Therapeutics, Redwood City, CA

MUC18, also known as MCAM (melanoma cell adhesion molecule) or CD146, is a type I transmembrane glycoprotein originally identified as a cell adhesion molecule of melanoma that plays important roles in tumor growth and progression including tumor angiogenesis, epithelial-mesenchymal transition (EMT), and metastasis. MUC18 is overexpressed in a variety of solid tumors including (but not limited to) melanoma, osteosarcoma, head and neck, lung, esophagus, breast, ovarian, and cervical cancer and hepatocellular carcinoma, with restricted presence on normal healthy tissues, mainly on blood vessels and a minor subset of T helper cells. Limited expression in normal tissues and high expression in tumors makes MUC18 a promising target for the development of antibody drug conjugate (ADC). AMT-253 is a novel ADC targeting MUC18. It is composed of a humanized MUC18-targeting IgG1 antibody conjugated with Exatecan, a topoisomerase I inhibitor, attached to a proprietary self immolative T moiety linker through reduced interchain disulfide bonds with a drug-to-antibody ratio (DAR) of 8. AMT-253 was stable *in vitro* with less than 0.5% of payload releasing when incubated with human, monkey, mouse or rat plasma for 21 days at 37℃. AMT-253 selectively bound to cell surface MUC18 and was efficiently internalized into MUC18-positive cancer cells. AMT-253 exhibited antiproliferative activity against several MUC18-positive cancer cell lines and demonstrated potent bystander killing effect *in vitro*. Treatment with AMT-253 resulted in tumor growth inhibition or regression in a panel of MUC18 positive cell line derived xenograft (CDX) or patient derived xenograft (PDX) models. In addition, AMT-253 was well tolerated in a GLP compliant toxicity study in cynomolgus monkeys at dose levels ≤45 mg/kg. Taken together, our preclinical *in vivo* efficacy and toxicity studies demonstrated that AMT-253 has a wide therapeutic window and could potentially provide benefits for cancer patients with highly unmet medical needs. AMT-253 is currently being evaluated in a Phase I first-in-human clinical trial (NCT05906862).

#0740 CNTN4 as a novel target for solid cancer with antibody-drug conjugate.

M. Cha, **H. Kim**, S. Byun, Y. Ha, K. Park, H. Yu, B.-N. Jeon, M. Kim, S. Moon, K. Park, H. Park;
Genome & Company, Sungnam-si, Gyeonggi-do, Korea, Republic of

As a novel immune checkpoint, we previously confirmed that contactin 4 (CNTN4) regulates T cell activity negatively by binding to amyloid precursor protein (APP) on T cells. CNTN4 is highly expressed in various types of tumors, including gallbladder, pancreas, stomach, endometrium, liver, prostate, bladder cancer, melanoma, and other tumors, with positive rates over 70% through immunohistochemistry analysis in contrast to low-level expression in normal tissues. Based on the tumor-specific expression profile of CNTN4, we evaluated the potential of CNTN4 as a novel target for antibody-drug conjugate (ADC). First, the internalization of the anti-CNTN4 antibody in the IND submission stage, GENA-104A16, into CNTN4-positive cancer cells was confirmed. For investigation of the potential of targeting CNTN4 using ADC, clinically validated various linker-payloads (MMAE, MMAF, SN-38, and exatecan derivate) were conjugated to GENA-104A16 using thiol maleimide conjugation with average drug-to-antibody ratio (DAR) in the range of 4.0 to 4.8. After preparing ADCs, we confirmed the binding affinity for CNTN4 was maintained as high even after the payload conjugation through an ELISA. *In vitro* studies have demonstrated the highly cytotoxic effect of MMAF conjugate among the conjugates of GENA-104A16 on CNTN4-positive cancer cells compared to negative cancer cells. And there was no cytotoxic effect on normal cells. Furthermore, treating MMAF conjugate of GENA-104A16 showed promising efficacy in the Pan02 pancreatic orthotopic mouse model and the patient-derived xenograft model. These results suggest that CNTN4 could be a highly potential ADC target that could expand the options for cancer treatment strategies.

#0741 Distinct functional effects of ILT family members in mediating the activity of an ILT2/ILT4/ILT5 cross-reactive monoclonal antibody in releasing the suppression on innate and adaptive anti-tumor immunity.

S. Ye[1], D. Zhang[1], B. Singh[1], J. Bankoti[1], D. Cohen[1], S. Tan[1], D. Choi[1], J. Hickson[2], M.-Z. Wu[1], U. Kolhatkar[1], M. Binnewies[1], W. Jin[1], J. Hall[1], J. Engelhardt[1], A. Shoemaker[2];

[1]AbbVie Bay Area, South San Francisco, CA, [2]AbbVie Inc., North Chicago, IL

The expression of ILT (LILRB) family members and their major ligand HLA-G within solid tumors are associated with immune suppression and poor patient survival. Blocking multiple ILT family members might be more potent than targeting individual members by overcoming compensatory resistances within tumor microenvironment. Based on this hypothesis, we developed a monoclonal antibody (mAb) LITCHI 7 which reacts to three major ILT family members, ILT2, ILT4 and ILT5, and blocks ligand binding to these receptors. LITCHI 7 exhibits a broad binding capability to a wide range of human myeloid and T cell subsets that express ILT2, ILT4, and/or ILT5. Binding to monocyte-derived dendritic cells (moDC), LITCHI 7 released the inhibition on activating Fcγ receptor. On LPS-treated macrophages, LITCHI 7 enhanced inflammatory macrophage differentiation. The effect is primarily mediated by blocking ILT4 since ILT4 mono-specific mAb is as potent as cross-reactive LITHI 7 in modulating myeloid differentiation although both ILT2 and ILT5 are highly expressed by different myeloid subsets. The result was further confirmed by CRISPR Cas9 knock down of ILT2 or ILT5. In the absence of either ILT2 or ILT5, the accumulation of $CD14^+$ monocytes and inflammatory macrophages were not changed during differentiation. While different ILT family members are generally enriched on myeloid cells, ILT2 is also expressed on NK cells and effector memory $CD45RA^+$ T cells (Temra). Blocking ILT2 by LITCHI 7 enhanced TCR signaling when co-culturing the MART-1 specific T cell reporter line with MART-1/HLA-G positive melanoma cells. The effect of LITCHI 7 is mediated by ILT2 blockade since knocking out ILT2, but not ILT4 and ILT5, reduced accumulation of Temra in activated PBMC. To assess whether immune modulation of LITCHI 7 can be translated into anti-tumor activity by blocking different ILT family members, tumor killing assays were performed using innate and adaptive immune effector cells. LITCHI7 enhanced NK cell-mediated cytotoxicity on HLA-G^+ tumor cells by blocking ILT2. Both ILT2 and ILT4 blockade play a role in macrophage phagocytosis on lymphoma cells since LITCHI 7 as well as individual anti-ILT2 or ILT-4 mAbs increased macrophage phagocytosis to a similar level. Finally, LITCHI 7 could boost *in vitro* T cell-mediated killing of $CD19^+$ lymphoma by CD19 specific CAR-T cells in the presence of $CD33^+$ myeloid cells. In summary, LITCHI 7 can enhance both innate and adaptive anti-tumor immunity through ILT2 or ILT4 blockade directly on effector cells or indirectly through myeloid cell reprogramming. As clinical trials are ongoing by targeting ILT2 and ILT4, blocking multiple ILT family members through a single cross-reactive mAb may provide broad anti-tumor effects and advantages when combining with additional oncology treatments.

#0742 PYX-201, a stroma-targeting ADC composed of an anti-EDB+FN antibody conjugated to Auristatin0101, demonstrates strong anti-tumor efficacy across multiple human cancer indications in pre-clinical PDX tumor models.

N. Severe, A. Facklam, L. McMichael, B. Das, S. Lewandowski, J. Trickett, L. Diao, C. Merriman, C. Shen, J. Feng, S. Harriman, M. Crochiere, P. Steiner, J. Pinkas;
Pyxis Oncology, Boston, MA

Stroma is crucial to support solid tumor growth, metastasis and resistance to treatment. While most antibody-drug conjugates (ADCs) directly bind to cancer cells, PYX-201, an investigational drug, is designed to target tumor stroma by binding to the extra-domain B splice variant of fibronectin (EDB+FN), a matrix protein abundantly expressed in the tumor microenvironment of many solid tumors with absent or low expression in normal adult tissues. *In vitro* studies demonstrated PYX-201 was strongly cytotoxic to EDB+FN positive Caki2 cells, but not to EDB+FN negative HT29 cells. In addition, PYX-201 was 30-times more potent than a non-targeted ADC control, demonstrating PYX-201 cytotoxic effects were EDB+FN dependent. Furthermore, when Caki2 and HT29-luciferase cancer cells were co-cultured, the luciferase activity was used to quantify the amount of EDB+FN negative HT29 cells only. Interestingly, PYX-201 was able to kill EDB+FN negative cancer cells in a co-culture assay as shown by a decrease in luciferase activity, demonstrating PYX-201 bystander activity. Pre-clinical mouse model studies were conducted to evaluate PYX-201 anti-tumor efficacy and pharmacokinetic (PK) properties. First, a comprehensive patient-derived xenograft (PDX) mouse model trial was designed to evaluate the anti-tumor efficacy of PYX-201. To fully represent the diversity and characteristics of human tumors, PDX models were pre-selected from ten solid tumor indications based on different levels of EDB+FN protein expression and stromal density. PYX-201 (Q4D×4 at 3mg/kg) was well tolerated, and strong anti-tumor responses (% Tumor Growth Inhibition [TGI] >90%) were observed in PDX models across various cancer indications. Potential correlations between EDB+FN protein expression with anti-tumor activity will be evaluated. Remarkably, long-term anti-tumor efficacy of PYX-201 was observed as tumors did not relapse even after >100 days in a breast cancer PDX model. Additionally, plasma samples were analyzed from a cell line derived xenograft mouse model after a single dose of PYX-201 to determine its PK profile. At 3 mg/kg, the maximum concentration (Cmax) was 28.1 µg/mL, area under the curve (AUC) was 1,732.7 h*µg/mL, with a low clearance of 1.5 mL/h/kg, and the half-life of the mAb from PYX-201 was calculated at 81.2 h. These PK parameters were associated with strong PYX-201 anti-tumor efficacy (% TGI >90%) in the H1975 xenograft model. Altogether, PYX-201 was well tolerated and demonstrated strong anti-tumor efficacy in a variety of pre-clinical human PDX models. PYX-201 is a promising and innovative ADC which is currently under investigation in a Phase I clinical trial (NCT05720117).

#0743 Using a novel NextGen linker system to generate a conditionally active biologic (CAB) anti-nectin4-ADC demonstrates improved efficacy in pancreatic PDX cancer models and improved tolerability and toxicity profile in non-human primates.

J. Wang, J. Chen, G. Frey, H. Liu, C. Xing, K. Woodard, H. Chang, W. J. Boyle, **J. M. Short**;
BioAtla, San Diego, CA

Antibody-drug conjugates (ADCs) are a promising treatment for various forms of cancer. The treatment efficacy is often limited by on-target/off-tumor toxicity caused by the antigen expression in healthy tissue and by unwanted payload release outside the tumor caused by cleavage of the linker via circulating proteases. Our conditionally active biologics (CAB) technology addresses the on-target/off-tumor toxicity and assists in reducing the off-target/off-tumor toxicity by reducing binding to the target under normal physiological conditions (1). To eliminate the remaining off-target/off-tumor toxicity, we developed a novel linker with superior serum stability, solubility, and tumor-specific payload release. Conjugation can be accomplished using regular IgG backbones without the need for sequence modification. Here we report the *in vitro* and *in vivo* characterization of a NextGen linker system to generate a CAB anti-Nectin4-ADC that combines the advantages of CAB antibody pH selectivity with the new linker technology. *In vivo* efficacy data demonstrated complete tumor regression in several cell line derived xenograft models as well as superior efficacy to an enfortumab vedotin analogue in a patient derived pancreatic cancer model. PK and tox data from a toxicology study in non-human primates will be presented. In addition, data demonstrating the influence of linker technology on specific cancer models will also be presented. In conclusion, the NextGen Nectin4 CAB ADC represents a potentially more effective treatment with increased safety in the clinic.

#0744 Novel conditionally active biologic (CAB) tetravalent T-cell engagers targeting solid tumors.

A. Cugnetti, H. Liu, P. McNeeley, C. Xing, K. Woodard, H. Chang, G. Frey, W. J. Boyle, **J. M. Short**;
BioAtla, San Diego, CA

The use of T-cell engagers (TCEs) has great therapeutic potential in oncology. This potential, however, is diminished due to severe toxicity (cytokine release effects, as well as on-target off-tumor toxicities). We leveraged BioAtla's Conditionally Active Biologic (CAB) technology (1) to develop bispecific antibodies which have no or very little binding to CD3 and to the tumor target antigen (TAA) in healthy tissue (normal physiological conditions), yet have strong binding in diseased tissues (*i.e.* tumor microenvironment, TME) derived from glycolytic tumor metabolism, which supports tumor growth (Warburg effect). The conditional activity in the TME is achieved by optimizing the sequences of the binding domains and does not require masking and subsequent activation of the binding domain as used in pro-drugs. We have developed dual-CAB T-cell engagers targeting serval well-established tumor associated antigens. Data demonstrating superior potency with reduced off-target binding through *in vitro* and *in vivo* characterization of three new DualCAB TCEs, targeting PSMA, Trop2, and Tissue Factor (TF) will be presented.(1) Chang HW, Frey G, Liu H, Xing C, Steinman L, Boyle WJ and Short, JM Generating tumor-selective conditionally active biologic anti-CTLA4 antibodies via protein-associated chemical switches. Proc Natl Acad Sci U S A 2021;118.

PREVENTION / EARLY DETECTION / INTERCEPTION: Cancer Prevention
Poster Session

#0748 Impact of oral supplementation of sulforaphane for 12 months on lung cancer-related gene expression in former smokers at high risk for lung cancer: Results from a randomized placebo-controlled phase II clinical trial.

K. Demanelis[1], A. Spira[2], Y. Kefella[2], R. Wang[3], J. Adams-Haduch[3], T. W. Kensler[4], J. E. Beane[2], D. O. Wilson[1], J.-M. Yuan[1];
[1]University of Pittsburgh, Pittsburgh, PA, [2]Boston University, Boston, MA, [3]UPMC Hillman Cancer Center, Pittsburgh, PA, [4]Fred Hutchinson Cancer Center, Seattle, WA

Introduction: Higher consumption of dietary sulforaphane (SFN), a phytochemical found in many cruciferous vegetables, has been shown to be associated with lower risk of lung cancer (LC). SF activates the NRF2-pathway, which initiates cellular detoxification, antioxidant, and anti-inflammatory responses. To date, no chemoprevention trial for LC has examined the impact of SFN on LC-related gene expression (GE) as an endpoint in nasal and bronchial tissue. The objective of our study was to examine whether oral intake of SF for 12 months impacts the GE of previously identified LC- and premalignant lesions (PML)-related genes in bronchial and nasal brushing samples.
Methods: A randomized, placebo-controlled clinical trial (NCT03232138) was conducted in former smokers with ≥ 30 pack-years and quitting smoking for 1-10 years in Western Pennsylvania, USA. Forty-three subjects were randomly assigned to the SFN treatment (n = 21) or placebo group (n = 22) in 2018-2022. Each participant was instructed to take 4 Avmacol® or identical placebo capsules BID for 12 months. Each Avmacol® capsule contained 15 mg of glucoraphanin, which yielded a daily internal dose of 120 µmol SFN. Nasal swabs and bronchial brushings were obtained at baseline and after 12 months. Among the 37 participants who completed the study, RNA was extracted from their nasal swabs and bronchial brushings. We constructed single sample gene signature scores (GSS) using the GSVA algorithm for the following: 1) the NRF2-pathway, 2) genes associated with LC risk in bronchial biopsies, and 3) genes associated with PML. The genes in these sets were stratified by their up- or down-regulation in LC or PML. We evaluated the association between the interaction of SFN supplementation over time (pre-/post-treatment) on GSS using linear mixed models, adjusted for the fixed effects of age at baseline, RNA integrity number (RIN), packyears of smoking, and random effect of participant.
Results: GE data was available for 31 participant pairs with bronchial and/or nasal samples. Within nasal tissue, SFN treatment increased both the GSSs of the NRF2-pathway (p=0.0089) and the downregulated LC-risk genes (p=0.0047), and decreased the upregulated LC-risk genes (p=0.012) over time, whereas SFN had no significant impact on GSSs of the NRF2-pathway and LC-risk genes in the bronchial tissue. No association between SFN treatment over time and the PML-related GSS was observed in nasal or bronchial tissue.
Conclusion: Our initial analysis indicates that SFN treatment over 12 months impacted LC-associated GE in nasal tissue but not in bronchial tissue from former smokers. The discrepancy results may be due to small sample size and additional studies are warranted to confirm if SFN has direct impact on LC-risk related genes in bronchial tissue (NIH grant No. R01CA213123).

#0749 Randomized placebo-controlled phase II clinical trial on oral supplementation of sulforaphane for 12 months that reduced bronchial Ki-67 index in former smokers at high risk for lung cancer.

J.-M. Yuan[1], T. W. Kensler[1], S. Dacic[1], D. J. Harman[1], R. Wang[1], P. Balogh[1], L. Seigh[1], Y. T. Pham[1], J. Adams-Haduch[1], S. Singh[1], J. G. Herman[1], A. Spira[2], D. O. Wilson[1];

[1]University of Pittsburgh, Pittsburgh, PA, [2]Boston University, Boston, MA

Background: Epidemiological studies showed higher intake of cruciferous vegetables or their active compounds, isothiocyanates (ITCs), with lower risk of lung cancer. ITCs inhibited tobacco-carcinogen induced lung adenocarcinoma in animal models, along with reduced cellular proliferative marker Ki-67 and increased apoptotic markers Caspase-3 and TUNEL. However, human data lack. The aim of our study was to assess if oral intake of sulforaphane (SFN) for 12 months would stop/reverse the progression of bronchial histopathology, reduce Ki-67 index and/or increase Caspase-3 and TUNEL indices.

Methods: A randomized clinical trial (NCT03232138) was conducted in former smokers with ≥ 30 pack-years and quitting smoking for 1-10 years in USA. Forty-three subjects were randomly assigned to the SFN (n = 21) or placebo group (n = 22) in 2018-2022. Each participant was instructed to take 4 Avmacol® or identical placebo capsules BID for 12 months. Each Avmacol® capsule contained 15 mg of glucoraphanin, which yielded a daily internal dose of 120 µmol SFN. Biopsies were collected from 6 predetermined bronchial sites at baseline and the end of treatment, respectively. The primary outcomes were the average changes of histopathology scores, Ki-67, Caspase-3 and TUNEL indices in post- *vs*. pre-treatment biopsies.

Results: Thirty-seven participants completed the study. In the SFN group (n = 17) at baseline, 13 were men, all white, mean age 64.1 (SD 5.3) years, body mass index (BMI) 30.6 (6.1) kg/m^2, years of smoking 39.5 (8.2), cigarettes per day (CPD) 23.8 (10.7), and years of quitting smoking 4.3 (2.9). The corresponding figures in the placebo group (n=20) were 9 men, 19 white, age 68.0 (3.2), BMI 28.6 (4.2), years of smoking 42.2 (4.5), CPD 25.5 (8.4), and years of quitting smoking 6.8 (3.2). The baseline medians of total Ki-67 positive nuclei were 22.3 nuclei/mm^2 in the SFN group and 22.9/mm^2 in the placebo group (p = 0.96). After treatment, the number of positive Ki-67 nuclei decreased by 5.3/mm^2 (-24%) in the SFN group and increased by 18.0/mm^2 (+79%) in the placebo group (p = 0.014) with adjustment for baseline Ki-67 and other covariates. The post- and pre-treatment difference was even greater in high-density (3+) positive Ki-67, with -46% decrease in the SFN group *vs.* +99% increase in the placebo group (p = 0.004). There was a dose-response effect of higher compliance with SFN intake on reducing Ki-67 index (p_{trend} = 0.01). SFN treatment had no impact on Caspase-3, TUNEL, or bronchial histopathology. No severe adverse event was observed in the SFN group.

***Conclusion*:** Daily intake of 120 µmol SFN for 12 months significantly reduced Ki-67 index in bronchial tissue. The findings support the potential chemopreventive effect of SFN against lung cancer development in high-risk former smokers (Grant # R01CA213123).

#0750 Specific oral bacterial profile associated with oral HPV status in Puerto Rican People with HIV.

Y. N. Ortiz-Maldonado[1], G. Borges-Velez[1], J. Torres-Reyes[1], A. A. Peralta-Betanncourt[1], J. L. Salgado-Montilla[1], J. Viera-Vera[1], M. M. Sanchez-Vazquez[1], M. Martinez-Ferrer[2], A. P. Ortiz-Martinez[1], R. F. Gonzalez-Garcia[3], **J. Perez-Santiago**[1];

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR, [2]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [3]University of Puerto Rico Medical Science Campus, San Juan, PR

Human papillomavirus (HPV) accounts for more than 70% of oropharyngeal cancers and people with HIV (PWH) are disproportionately affected by HPV infection even with successful antiretroviral therapy. Puerto Rico (PR) is in the top ten in terms of HIV prevalence in the US, and also has disparities in HPV-related malignancies. The oral microbiome can increase the risk of HPV infection and persistence; however, it has not been investigated in the context of HIV in PR. Therefore, we evaluated diversity and composition of the oral bacteriome of 48 virologically suppressed PWH (men and women ≥21 and <64 years old) living in PR in relation to HPV status (HPV+: n=18 vs. HPV-: n=30). We collected saliva (16S rDNA sequencing), oral rinse (HPV genotyping) as well as sociodemographic, lifestyle and behavioral characteristics. Short chain fatty acids (SCFA, acetate, butyrate and propionate) were quantified using gas chromatography and mass spectrometry. Periodontal disease was assessed by a clinical full-mouth periodontal assessment using the CDC/AAP guidelines. All analyses were performed using QIIME2 and R-statistical software. There were no significant differences in alpha diversity (Shannon, observed OTUs, and Faith) between HPV+ and HPV- groups. Absolute CD4 count was not significantly different between HPV+ and HPV- participants (794 cells/µL vs. 735 cells/µL), and did not correlate with either microbial richness or diversity. Higher microbial richness was associated with lower levels of acetate ($r=-0.35$, $p<0.05$) and propionate ($r=-0.31$, $p<0.05$,). Additionally, higher phylogenetic diversity was also associated with lower levels of acetate ($r=-0.38$, $p<0.05$) and propionate ($r=-0.35$, $p<0.05$) irrespective of the HPV status. On the other hand, higher levels of butyrate was significantly associated with higher microbial diversity (Shannon index; $r=0.33$, $p< 0.05$). Taxonomic analyses showed significantly higher abundance of *Dialister* and *Nanosynbacter* genera in HPV+ participants and higher abundance of *Rothia* genus and *Capnocytophaga sputigena* in HPV- participants. Overall, we found specific prokaryotic profile and associated metabolites associated with HPV infection, which may suggest that the oral microbiome could influence the natural history of HPV infection via SCFA signaling. Members of the *Dialister* genus have been found to be prevalent in Hispanic and Black women cervicovaginal microbiota, and as well as in HPV infection and oral cancer. Understanding the underpinning mechanisms of how the oral microbiome can facilitate HPV infection and persistence in PWH is essential to establish targets for early identification and personalized treatment approaches for oral HPV-related malignancies.

#0751 Gut microbiome and breast cancer: Report from a case-control study in Vietnam.

Sang Minh Nguyen[1], Huong T. T. Tran[2], Jirong Long[1], Martha J. Shrubsole[1], Hui Cai[1], Yaohua Yang[3], Thuan V. Tran[4], Wei Zheng[1], Xiao-Ou Shu[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]Vietnam National Cancer Institute, National Cancer Hospital, Hanoi, Viet Nam,[3]Department of Public Health Sciences, School of Medicine, Center for Public Health Genomics, UVA Comprehensive Cancer Center, University of Virginia, Charlottesville, VA,[4]Hanoi Medical University, Ministry of Health, Hanoi, Viet Nam

The importance of gut microbiome on human health is being increasingly recognized. The gut microbiota may play a critical role in breast cancer etiology, likely through the roles of the gut microbiota in estrogen and nutrient metabolism as well as in immune regulation. However, evidence on associations between breast cancer and gut microbiota is limited and inconsistent. Using resources from the Vietnamese Breast Cancer Case-Control Study (VBCS), we evaluated differences in gut microbiome profiles between women with breast cancer and healthy women. Pre-treatment tool samples of 162 incident breast cancer cases (age: 50.0±9.5) and stool samples of 370 age-matched controls (age: 49.7±9.0) were included in the study. The gut microbiome was measured using shotgun metagenomic sequencing. Differences in gut microbiome α-diversity and β-diversity between breast cancer patients and healthy controls were evaluated via linear regression models and PERMANOVA testing, respectively. Case-control differences in gut microbial taxa abundance were assessed through the differential abundance analysis with adjustment for potential confounders, including age, income levels, residence, menopausal status, reproductive factors, body mass index, comorbidity, dietary intake, and physical activity. An association with a false discovery rate (FDR) <0.1 was considered statistically significant. No significant difference between breast cancer patients and healthy controls was observed for α- and β-diversities. A total of 2,905 gut microbial taxa were evaluated. Among them, significant case-control differences were found in the abundance of one phylum, two classes, four orders, three families, four gena, and 67 species (all p<0.05 and FDR <0.1). Compared to healthy controls, breast cancer patients had a decreased abundance of species *Pauljensenia keddieii*, *Bifidobacterium bifidum* (phylum *Actinobacteriota*), *Clostridium Q symbiosum, Faecalicatena fissicatena, Massilioclostridium methylpentosum, Parvimonas micra* (phylum *Firmicutes A*), *Leptotrichia wadei* (phylum *Fusobacteriota*)*, Enterococcus D gallinarum, Lactobacillus H fermentum, Gemella haemolysans B,* genus *Streptococcus* and its 24 species such as *S. anginosus C, S. constellatus, S. equinus, S. infantis I, S. mitis, S. oralis, S. pseudopneumoniae O* (phylum *Firmicutes*) (all p<0.05 and FDR <0.1). The species *Clostridium Q symbiosum* showed the strongest association, with a log2 fold-change (SE) of -2.02 (0.45), $p=7.35x10^{-6}$; FDR=0.006. Additionally, breast cancer patients had an increased abundance of three species belonging to the phylum *Firmicutes A* including MGYG-HGUT-03165, MGYG-HGUT-04111, and MGYG-HGUT-00903, compared to healthy controls (p<0.05 and FDR <0.1). These results suggest that the gut microbiome of breast cancer differs from that of control women. Additional analyses are ongoing to reveal the biological underpinning of the observed associations.

#0752 Association of gut bacterial toxins with colorectal neoplasia in Lynch syndrome patients in Puerto Rico.

I. Montes-Rodriguez[1], D. Rodriguez-Santiago[2], N. Marquez-Andino[2], G. Montalvo-Noguera[3], S. Colon-Serrano[4], L. R. Llanos[1], O. Diaz-Miranda[1], H. Centeno-Girona[1], M. Gonzalez-Pons[1], M. Cruz-Correa[1];

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR, [2]University of Medicine and Health Sciences, KN, Saint Kitts and Nevis, [3]University of Puerto Rico-Medical Sciences Campus, San Juan, PR, [4]University of Puerto Rico- Rio Piedras Campus, San Juan, PR

Lynch syndrome (LS) is an autosomal dominant condition caused by germline mutations in DNA mismatch repair pathway genes that predispose individuals to develop colorectal cancer (CRC) and other malignancies. Not all LS patients develop CRC, and age at diagnosis varies significantly, even among individuals with identical mutations. Although several prospective genetic modifiers have been reported, the contribution of environmental exposures to colorectal carcinogenesis and age of onset is unknown. The gut microbiota composition, influenced by environmental factors, may have a role in CRC development. Dysbiosis, or abnormalities in host-bacteria interactions, can lead to inflammatory bowel disorders and CRC. Certain strains of bacteria, like *Escherichia coli* and *Enterococcus sp.*, harbor pro-inflammatory/genotoxic genes that promote sustained inflammation in the host- *pks, tcpc, gelE, cnf-1, usp,* and *murB*. The association between inflammation and carcinogenesis is well established, yet the contribution of bacteria-induced inflammation and genotoxicity to CRN is not fully understood. This study aims to investigate if changes in the prevalence of the genotoxic/pro-inflammatory bacterial genes are associated with CRN in LS patients. Stool samples were collected from 32 LS subjects and 94 age/gender-matched control subjects without a history of CRC. Qualitative data regarding the six genes in these samples were assessed using RT-PCR with SYBR green. Among LS subjects, 68.8% had two or more of the six genes in their stool samples, whereas controls only had 27.7%. Furthermore, LS subjects had 4.06 times the odds of having ≥2 gut bacterial toxin genes in their stool (95% CI: 1.48-11.12) when compared to controls after adjusting by age. The most prevalent gene in LS patients was *murB*, detected in 62.5% of the individuals. The presence of *gelE* and *murB* genes was significantly higher among LS patients (p-value <0.001 and 0.02, respectively). Interestingly, the *usp* gene was absent in any LS patients. Additionally, LS subjects had 4.52 times the odds of having the *gel-E* gene (95% CI: 1.69-12.14) compared to controls after age adjustment. Given the documented evidence about the impact of CRC on the composition of gut microbiota, we performed analysis to assess the prevalence of these genes in LS subjects without a history of CRC, as well as in control subjects. After adjusting by age, LS subjects had higher odds of having ≥2 gut bacterial toxin genes in their stool (OR= 2.94, 95%: CI 0.52-16.50) than controls. This study shows that LS patients have a higher prevalence of the genotoxic/pro-inflammatory bacterial genes. However, further studies are necessary to validate these associations and provide a more comprehensive understanding of the role of gut bacterial genes in colorectal neoplasia among LS patients.

#0753 CEACAM1 induces microbiome and metabolite driven diversion of TGF-β signaling to promote colon cancer.

K. Bhowmick[1], K. Ohshiro[1], X. Xiang[1], S. John[1], X. Yang[1], K. Idicula[1], N. Beauchemin[2], R. Mazumder[3], K. A. Crandall[4], M. I. Hassan[5], T. Mohammad[5], **L. Mishra**[1];

[1]Feinstein Institutes for Medical Research, & Cold Spring Harbor Laboratory, New York, NY, [2]The Rosalind and Morris Goodman Cancer Institute, Montreal, QC, Canada, [3]The George Washington University, Washington, DC, [4]Milken Institute School of Public Health, Washington, DC, [5]Jamia Millia Islamia, New Delhi, India

Background: Colon cancer is rising in younger individuals in the United States. Potential causal factors are altered diets and gut microbiomes. Yet key signaling pathways, host-microbe interactions, and metabolites such as ammonia in cancer remain unclear. CEACAM1 responds to pathogenic microbes, interacts with the TGF-β/SPTBN1 and levels are raised in invasive colon cancer. Alterations in the TGF-β pathway occur ~40% of human GI cancers, and mouse models with disrupted TGF-β signaling (*Tgfbr2*$^{-/-}$, *Smad4*$^{+/-}$*Sptbn1*$^{+/-}$, *and Tgfb1*$^{-/-}$) develop colorectal cancer (CRC) that is dependent upon an altered gut microbiome. Our previous studies indicate the lipid metabolites (reactive aldehydes) form toxic adducts with cleaved SPTBN1 and divert TGF-β signaling to pro-oncogenic process. Poor prognosis CRC is associated with raised levels of microbial metabolites, such as ammonia. Thus, we hypothesized that "*the intricate relationships among pathogen-binding CEACAM1, the gut microbiome, metabolites such as ammonia, and βII-Spectrin drive colon cancer development".*

Methods: We examined gut microbiota composition, immune cell population, inflammation, and cancers in *Smad4*$^{+/-}$*Sptbn1*$^{+/-}$ and *Sptbn1*^{LSKO} mice fed a normal chow diet or a high-fat diet (HFD). We evaluated CEACAM1 and TGF-β member alterations in in CRCs using TCGA datasets. Alphafold-based molecular modeling predicted interaction sites between βII-Spectrin and CEACAM1 was followed by functional studies.

Results: Increased CEACAM1 levels with alterations in TGF-β members were associated with lower survival (TCGA). Mice with disrupted TGF-β signaling (*Smad4*$^{+/-}$*Sptbn1*$^{+/-}$) develop CRC, have high CEACAM1 levels, and an altered gut microbiome signature. CEACAM1 interacts with βII-Spectrin, and levels are restored to normal in βII-Spectrin LSKO which restores the gut microbiome and blocks inflammation and cancer. Ammonia induces CASPASE-3 mediated cleavage of βII-Spectrin, forms toxic adducts and divert TGF-β signaling to pathological pro-oncogenic signaling, triggering CRC.

Conclusion: We have found a critical role for CEACAMs in CRC cancer development, through diverting the TGF-β signaling pathway to a pro-oncogenic phenotype. CEACAM1 and βII-Spectrin are attractive therapeutic targets for CRC.

#0754 Exploring the association among pain, gut microbiota, and dietary intake of macronutrients.

E. Samami[1], F. Yi[2], M. Weaver[1], A. Starkweather[1], D. Lyon[1], D. L. Kelly[1];
[1]University of Florida, Gainesville, FL, [2]University of Idaho, Moscow, ID

Hematopoietic cell transplantation (HCT) is a potentially curative treatment for individuals diagnosed with hematological malignancies. As survival gains increase, symptom management is also being considered as an endpoint for treatment success yet there is paucity in the literature regarding biological correlates of symptoms. Pain is a major concern for patients undergoing HCT. Underlying inflammation has been suspected in the pathogenesis of symptoms including pain. Emerging evidence supports the gut microbiota (GM) as a potential pathway for the initiation of inflammation. Diet is a potentially modifiable factor demonstrating a significant impact on GM diversity and amenable to intervention. Understanding the interplay among pain, GM, and diet, particularly macronutrients, may inform the development of a targeted, dietary self-management intervention to mitigate pain symptoms in HCT patients. This investigation uses baseline data from a longitudinal descriptive study to explore associations among pain, GM composition (richness and evenness) using Shannon and Chao beta diversity indices, and macronutrients (protein, carbohydrates and fat), in 47 adults (> 18 years of age) receiving HCT for hematologic cancer. Pain was measured using the Brief Pain Inventory, GM was assessed using 16S ribosomal gene (V4 region) amplicons using Illumina MiSeq, and dietary information was collected using the Automated Self-Assessment 24-hour Dietary Assessment Tool (ASA-24). Data analysis was performed with the R ‘correlation’ package using Bayesian estimation of robust correlations and production of 95% Credibility Intervals (CI) and Bayes Factors (BF).The mean age of participants was 56.21 years + 14.67 years. Participants were diagnosed with myeloma (40%), lymphoma (29%) and leukemia (13%). The majority received autologous HCT (n=30). Macronutrient fat {r=-0.25, BF=1.72} had an inverse association with pain interference. Results provided at least anecdotal (BF > 1) support for a positive correlation between Healthy Eating Index (HEI) {r=0.21, BF=1.08}, total fat {r=0.32, BF=4.50}, carbohydrate {r=0.28, BF=2.47} and fat {r=0.32, BF=4.50}, and GM composition. Also, there was a positive association between the amount of protein {r=0.21, BF=1.03}, carbohydrate {r=0.27, BF=2.22}, and Chao Index. There was an inverse association between total HEI {r=-0.27, BF=1.87} and CRP levels. Taxonomic units {r=-0.41, BF=21.44}, Chao Index {r=-0.41, BF=20.28} and Shannon Index {r=-0.25, BF=1.47} had an inverse association with CRP level. This study associate pain, GM, and dietary macronutrients, suggesting potential GM targeted interventions. More research with larger sample size is needed to understand underlying dietary macronutrients' role in pain through GM diversity after HCT, aiming to ease symptoms and enhance survivorship.

#0755 Fecal microbial dysbiosis is associated with colorectal cancer risk.

J. Kim[1], **M. Gunathilake**[1], H. Yeo[1], J. Oh[1], B. Kim[1], N. Han[1], B. Kim[1], H. Pyun[1], M. Lim[2], Y.-D. Nam[2], H. Chang[1];
[1]National Cancer Center - Korea, Seoul, Korea, Republic of, [2]Korea Food Research Institute - Korea, Jeollabuk-do, Korea, Republic of

Although there is evidence of an association between the fecal microbiota and colorectal cancer (CRC) risk in epidemiologic studies, there is a lack of data from large-scale population-based studies. To address this gap, we assessed the dysbiosis of the fecal microbiome in a large-scale study in Korea. We recruited 287 CRC patients from the Center for Colorectal Cancer, National Cancer Center Hospital, Korea to perform 16S rRNA gene sequencing of fecal samples. A total of 287 age- and sex-matched healthy participants were selected from 890 cohort of healthy Koreans that are publicly available (PRJEB33905). The microbial dysbiosis index (MDI) was calculated based on the differentially abundant species. The association between MDI and CRC risk was observed using conditional logistic regression. Alpha-diversity indices were not significantly different between CRC cases and controls. The first three principal coordinates derived by a principal coordinate analysis (PCoA) based on weighted UniFrac distance explained 41.24% of the overall microbial diversity, with a significant divergence of the microbial composition between CRC patients and controls (PERMANOVA p=0.001). Three enterotypes were found based on CRC patients' microbial composition. Those who were in the third tertile of the MDI showed a significantly increased risk of CRC in the total population (OR: 6.59, 95% CI: 3.83-11.33, p-trend<0.001) compared to those in the lowest tertile. Similar results were found for men (OR: 6.58, 95% CI: 3.17-13.63, p-trend<0.001) and women (OR: 6.69, 95% CI: 2.91-15.37, p-trend<0.001). Dysbiosis in the fecal microbiota may be associated with an increased risk of CRC. Due to the potentially modifiable nature of the gut microbiota, our findings may have implications for CRC prevention among Koreans.
Key words: Fecal microbiome, 16S rRNA gene sequencing, Microbial dysbiosis, Colorectal cancer

#0756 Differences in composition, diversity, and function of the fecal microbiota of post-menopausal breast cancer patients compared to healthy, age-matched controls.

N. Kabbej, F. Ashby, E. Atencio, E. Rosenkrantz, D. Day, K. Dang, J. Gauthier, R. Newsome, J. Sommerville, T. Naas, R. Gharaibeh, C. Jobin, A. Quevedo, C. D. Heldermon;
University of Florida College of Medicine, Gainesville, FL

Gut microbiota are a community of organisms that colonize the intestinal tract with essential roles in immune function, gut epithelial integrity, and metabolite production. Dysbiosis occurs when the gut microbiota environment is negatively altered causing detrimental changes to these functions, which may predispose an individual to breast cancer development. To understand the relationship between dysbiosis and breast cancer development, fecal microbiota samples were collected from 27 post-menopausal breast cancer patients of varying hormone receptor statuses (ER+HER2-, ER+Her2+, ER-HER2+, or ER-Her2-) prior to starting chemotherapeutic treatment. Samples were compared to 25 healthy controls, and all samples underwent 16srRNA sequencing. Samples from breast cancer patients and control groups were compared for significant differences ($P<.05$) in alpha (within sample) and beta (between sample) diversity. Using the Shannon Index and Generalized Least Squares Model, significant differences in alpha diversity were identified between all breast cancer types vs. controls ($P=.0104$), and between ER+HER2- breast cancer vs. controls ($P=.00153$). Healthy controls exhibited a higher mean Shannon Index than breast cancer patients, thus higher within sample diversity. Using principal coordinate analyses, significant differences in beta diversity were identified between all breast cancer types vs. controls ($P = .01199$), and ER+HER2- breast cancer vs. control ($P = .008991$). Further analyses identified significant taxa of microbiota with functions related to breast cancer development and progression. Of note, *Lachnoclostridium*, a genus of bacteria that can produce β-glucuronidase, which can deconjugate estrogen, was increased in all breast cancer types and ER+HER2- breast cancer when compared to controls. Deconjugation of estrogen can cause elevated blood estrogen levels, potentially increasing Estrogen Receptor binding in hormone-receptor-positive breast cancer. Additionally, *Akkermansia*, a genus implicated in gut barrier dysfunction, was decreased in ER+HER2- patients, while *Parvimonas*, a tumorigenic cell-cycle regulator, was increased. Elucidating if these effects are causative or reactionary may have important implications for understanding breast cancer etiology. Samples are currently undergoing additional metagenomic analyses using long-read sequencing to identify specific bacteria, viruses, fungi, parasites, and phages that may be contributing to dysbiosis. Overall, this study is the first, to our knowledge, to employ short and long-read sequencing to the fecal samples of untreated postmenopausal breast cancer patients. We provide mechanistic insight into the relationship between microbiota and breast cancer development, with the intent of informing future patient screening and prevention.

#0757 Integrating microbiome analysis and multi-modal data to identify high-risk population for esophageal adenocarcinoma.

D. Altinok Dindar[1], M. Krieger[1], A. Palma[1], J. Cheney[1], F. Otaki[2], J. Yu[2], S. Wood[3], T. J. Sharpton[4], J. McGann[1], L. Karstens[2], G. G. Yardimci[1], Z. Zhang[1]; [1]OHSU Knight Cancer Institute, Portland, OR, [2]OHSU, Portland, OR, [3]OHSU School of Medicine, Portland, OR, [4]Oregon State University, Portland, OR

INTRODUCTION: Esophageal Adenocarcinoma (EAC) represents a pressing public health concern with a rising incidence and a staggering 5-year survival rate of less than 20%, emphasizing the critical need for early detection. Barrett's Esophagus (BE) serves as a well-established precursor to EAC, presenting an opportunity for proactive screening. The salivary microbiome provides a novel opportunity to identify a high-risk population with early-stage esophageal diseases. Here, we assessed whether the oral microbiome, in combination with lifestyle and clinical data, is associated with esophageal disease progression.
METHODS: The study included n=23 esophageal adenocarcinoma patients, n=51 with Barrett's Esophagus, and n=32 healthy controls. Saliva samples were collected along with comprehensive lifestyle, dietary intake, and clinical data. Shotgun Metagenomics Sequencing was employed to investigate the microbiome composition of participants. Comprehensive microbiome analyses were performed to evaluate taxonomic profiles, including microbial abundance, microbiome diversity, and functional/metabolic insights. A multi-modal data integration strategy was used to incorporate data from the Diet Health Questionnaire (DHQ) and lifestyle and health records, aiming to utilize these multimodal features to predict esophageal disease formation and progression.
RESULTS: A significant difference was observed in the salivary microbiome beta diversity between healthy controls and esophagus disease groups (p= 0.03). Clustering by microbiome taxonomic composition using the Dirichlet Multinomial Mixtures (DMM) framework indicates that some microbial signatures are associated with esophageal diseases (p=0.03). Healthy Eating Index Scores, total score (p=0.01); vegetables (p=0.003); greens, and beans score (p=0.009) were significantly different between study groups. Microbial pathways associated with diet, microbial taxa linked to lifestyle and medications, and supervised classification results reveal group characteristics and diversity variations based on key covariates such as B12 and sugar uptakes.
CONCLUSION: The study presents an innovative analytic approach to identify high-risk populations for esophageal diseases by integrating microbiome analysis and multi-modal data, providing insights into early detection and prevention. The potential of this research lies in its ability to revolutionize screening strategies, offering a non-invasive and cost-effective means to identify individuals at risk of EAC at earlier, more treatable stages.

#0758 Comparative Microbiome Analysis of Paired Mucosal and Fecal Samples in Korean Colorectal Cancer Patients.

S. Lee;
Dankook Univ., Yongin-Si, Korea, Republic of

Background Beyond the known risk factors such as age over 50, unhealthy diet, ethnicity, and smoking, emerging evidence suggests that gut microbial dysbiosis plays a crucial role in the early stages of colorectal cancer (CRC) by contributing to chronic inflammation and various intestinal dysfunctions. Even though various bacterial species have been studied, the gut microbiome profile as a representative biomarker in CRC patients remains largely unreported. This study presents a comparative analysis of the microbiome profiles of fecal and mucosal samples from CRC patients, followed by metagenomic profiling investigation to validate dominant bacteria in each sample type of CRC patients.
Methods The study involved 12 patients receiving CRC resection at Myongji Hospital in South Korea, recruited from May 2020 to June 2021. Fecal samples were collected pre-surgery, and mucosal samples during surgery. Paired-end sequencing was performed using Illumina MiSeq (Illumina, San Diego, USA) platform. 16s rRNA gene-based microbiome profiling was analyzed using QIIME2 (V.2020.11), a plugin-based platform for microbiome analysis. Sequencing reads were filtered, denoised, and clustered into amplicon sequence variants (ASVs) using DADA2 included in QIIME2. Taxonomic classification was assigned in the QIIME2 pipeline using a pre-trained classifier based on the Silva 138.1 reference sequence. Linear discriminant analysis (LDA) effect size (LEfSe) analysis was performed with LDA score ≥3.0 and *p*-value of 0.05.
Results The study subjects included 12 Korean patients, with an average age of 71 ± 10 years. The gender distribution included 3 men and 9 women whose body mass index was 24.6 ± 2.4 (mean ± SD). There was significant difference observed in UniFrac beta-diversity between the two groups (p=0.001). The relative taxonomic patterns of the microbiota between CRC stool and tissue showed that *Bacteroides* and *Fusobacterium* were more dominant in tissue than stool at both phylum and genus levels. Further taxonomic differences between the samples revealed that *Firmicutes*, *Bacilli*, and *Lactobacillacease* were over-represented in CRC patient stool, while *Pseudomonadales* (p<0.001) and *Pseudomonas* (p<0.001) were identified in the mucosal tissue.
Conclusion Our findings revealed that notable distinction was observed in the beta-diversity, indicating a unique microbial composition in tissue. Specifically, higher prevalence of *Bacteroides* and *Fusobacterium* at the genus level were identified in tissue. Additionally, our analysis highlighted *Pseudomonadales* and *Pseudomonas* emerged in CRC mucosal tissues. Furthermore, by comparing with a healthy control group, we aim to further elucidate potential markers unique to CRC patients.

#0759 Soy protein diet changes metabolic profile in liver of 7,12-dimethylbenz(*α*)anthracene (DMBA)-induced mammary tumors in obese zucker rats.

R. Hakkak[1], S. Melnyk[2];

[1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]Arkansas Children Research Institue, Little Rock, AR

Obesity is associated with the risk of certain types of cancers development including breast cancer. Previously, we reported that obesity increased mammary tumor development using obese Zucker rat model. Several studies have shown the health benefit of soy protein consumption. However, the effects of soy protein diet on liver of mammary tumor for oxidative stress and DNA reaction is less known. We used DMBA induced-mammary tumor model to investigate the effects of soy protein diet on pro-oxidative environment and oxidative DNA modification in liver of obese DMBA mammary tumors rats. Female obese zucker rats (n=45) were either fed casein as control (OC; n=20) or soy protein isolate (OS; n=25), received DMBA (65mg/kg BW) at the age 50 days and sacrificed 20 weeks later. We used HPLC-ECD, HPLC-UV and LC-MS techniques for liver metabolic analysis. Comparing liver of OS vs. OC, soy protein 1) decreased the level of Methionine ($P<0.02$), increased 2) free reduced Homocysteine ($P<0.02$), 3) S-Adenosylmethionine (SAM, $P<0.03$), 4) S-Adenosyhomocysteine (SAH, $P<0.001$) and 5) 5methyl-Cytosine (5mC, $P<0.03$). Also, soy protein decreased ($P<0.003$) level of free oxidized Glutathione (GSSG), increased ($P<0.02$) GSH/GSSG oxidative stress ratio, without any changes a level of free reduced Glutathione (GSH), followed decrease ($P<0.04$) in liver DNA level of 8-OH-Guanosine (8-OH-G) and level ($P<0.02$) of 5hmethyl-Cytosine (5hmC). Our results shows soy protein diet capable change liver metabolism: a. Modify a methylation status by increasing levels of SAM (universal methyl group donor) following global liver DNA hypermethylation (5mC), and SAH (methylases inhibitor); b. Alleviate level of oxidative stress in liver by decreasing level of GSSG (not active glutathione), increasing GSH/GSSG ratio (antioxidative capacities), following lower ROS liver DNA damages by decrease levels of 8-OH-G and 5hmC. In conclusion, using obese DMBA-induced mammary tumor Zucker rat model, soy diet making a complex and significantly modification of metabolic conditions in liver affecting both methionine cycle and transsulfuration metabolic pathways.

#0760 Alteration to transcriptional rhythmicity in mammary glands from pubertal MMTV-PyMT mice fed a high-fat diet.

L. Yan, D. G. Palmer, H. Zeng;
USDA-ARS (Agricultural Research Service), Grand Forks, ND

Biological clocks, existing in all human organ systems, cycle every 24 hours in a diurnal pattern and control the daily rhythms of human life (e.g., eating vs. fasting, sleep vs. wakefulness), which is essential for health and wellbeing. Disruption of the biological clocks, either by genetic or environmental alteration, disturbs circadian rhythms, which may lead to chronic diseases. Childhood obesity is a risk factor for breast cancer in adult women. Lifestyle changes in the modern world (e.g., energy-dense diets) serve as environmental factors that contribute to alterations in biological clocks and obesity. The present study examined transcriptional rhythmic changes in mammary glands from pubertal MMTV-PyMT mice fed a high-fat diet (HFD). Three-week-old female mice (FVB background) were randomly assigned into three groups - wild-type (WT) mice fed the AIN93G diet and MMTV-PyMT mice fed the AIN93G diet or an HFD for three weeks. At the end of the study, mammary glands were collected every 4 hours over a period of 24 hours (Zeitgeber time 0-24 hours) for RNA-sequencing analysis. The mammary weight was 0.45±0.02, 0.59±0.02, and 0.67±0.02 g for WT mice fed the AIN93G diet and MMTV-PyMT mice fed the AIN93G and HFD, respectively (means ± SEM, all *p*<0.05 when three groups were compared each other). The rhythmicity analysis using R showed that greater than 1,000 transcripts were classified as “loss of rhythm” when MMTV-PyMT mice (both AIN93G-fed and HFD-fed groups) were compared to WT mice fed the AIN93G diet. Eighteen transcripts were classified as “loss of rhythm” in MMTV-PyMT mice when the HFD was compared to AIN93G diet. Hierarchical clustering analysis showed differentially expressed genes that were significantly altered and KEGG enrichment analysis showed the most upregulated and downregulated metabolic pathways in treatment groups than in the control group at each time point over the 24-hour period. These findings indicates that genetic alterations may have a greater effect than dietary effects on transcriptional rhythmicity in mammary glands from pubertal mice.

#0761 The relationship between ANGPTL4 and epidermal malignant transformation.

N. A. Yawson[1], J. D. Diedrich[1], K. T. Liby[2], J. Veenstra[3], J. J. Bernard[1];

[1]Michigan State University, East Lansing, MI, [2]Indiana University School of Medicine, Indianapolis, IN, [3]Henry Ford Health, Detroit, MI

High body mass index (BMI) is a risk factor for several types of cancers. Although epidemiology suggests obesity is negatively associated with non-melanoma skin cancer (NMSC), bariatric surgery has been shown to reduce the risk, suggesting a possible role of adipose tissue in the initiation and promotion of skin cancer. To gain mechanistic insight into how adipose tissue drives cutaneous carcinogenesis, we cultured non-tumorigenic mouse keratinocytes (JB6 P^+ cells) with or without factors released from murine visceral adipose tissue (mFTF) and performed RNA-Sequencing. Published work demonstrated mFTF induces anchorage-independent cell growth, a surrogate marker for malignant transformation. Transcriptomic analysis demonstrated a significant induction of *Angptl4* mRNA in JB6 P^+ cells cultured with mFTF for 3 and 8 hours compared to the vehicle-treated cells. ANGPTL4 is an endogenous inhibitor of lipoprotein lipase that modulates free fatty acid delivery to adipose tissue and oxidative tissues such as muscle and liver. The C-terminal protein demonstrates tumor-associated activities such as angiogenesis, metastasis, protection against anoikis, and enhancement of cell survival. Therefore, we hypothesized that the induction of this gene promotes malignant transformation. RNA-seq data was validated in multiple cell models, including primary keratinocytes with human adipose tissue. Immunohistochemistry was used to assess ANGPTL4 expression in 37 actinic keratosis (pre-malignant) and cutaneous squamous cell carcinoma (cSCC) from patients with different BMIs (18.6 - 49.5). Notably, ANGPTL4 was only observed in the suprabasal epidermal layers in normal skin. For samples containing both lesional and perilesional skin, there was an increase in ANGPTL4 expression in the lesional epidermis relative to the normal perilesional skin. Furthermore, ANGPTL4 expression increased from transition to actinic keratosis to cSCC *in situ*, suggesting that ANGTL4 is induced during malignant transformation as observed in our pre-clinical models. Interestingly, once cSCC developed an invasive component, ANGTPL4 expression was lost in the invasive keratinocytes but persisted in the *in situ* component. There was no association between ANGPTL4 expression and BMI in lesional tissue. These data suggest that targeting ANTPLT4 may be a novel therapy for the prevention of skin cancer and that ANGPTL4-high patients or cancer patients with obesity may be a critical demographic for potential risk assessment or therapeutic intervention. Future studies will determine the impact of knocking out ANGTPL4 in our models of malignant transformation.

#0762 The combination of EPA and naproxen suppresses colon tumorigenesis via altering the TME, and promoting epithelial maturation in cancerous crypts.

R. Beach[1], M. Martinez[1], V. Gunasekharan[2], D. W. Rosenberg[1];
[1]UConn Health, Farmington, CT, [2]NIH/NCI, Bethesda, MD

Introduction: Colorectal cancer (CRC) is a leading cause of cancer-associated mortality. Our recent study in Pirc rats revealed that the combination of eicosapentaenoic acid and sodium naproxen exhibited additive tumor protection. While the results from this preclinical study were impressive, showing tumor suppression in excess of 95%, potential mechanisms underlying this tumor protection remain unclear. The purpose of this study was to determine the transcriptomic changes resulting in the tumor suppression afforded by the combination of EPA and naproxen supplementation in the diet.
Methods: Six week-old Pirc rats were fed either a control AIN-93G diet, or AIN-93G diet supplemented with 2% EPA combined with 200 ppm naproxen, for a total of 20 weeks. Global transcriptomic analysis was performed using RNA sequencing (RNA-Seq) of colon tumors and tumor-adjacent normal tissue from 26-week-old Pirc rats. 100-bp paired-end sequencing was performed on an Illumina NovaSeq to a depth of 25 million reads per sample. Reads were trimmed with Trimmomatic-v0.39, and reads were mapped to the mRatBN7.2.105 rat reference genome using HISAT2. Differentially expressed genes were calculated using DESeq2, and gene set enrichment analysis (GSEA) were performed using Rstudio.
Results: DESeq2 identified 809 differentially expressed genes (DEGs, 2-fold change > 1, FDR < 0.05) between large tumors from AIN-93G fed rats versus suppressed tumors from rats fed the combination of EPA and naproxen (490 up-regulated, 319 down-regulated). GSEA analysis revealed activation of inflammatory pathways including IL-17 signaling, JAK-STAT signaling, complement activation, cytokine signaling, ribosome biogenesis, and cell cycle were enriched in untreated control. In contrast, suppressed tumors from animals supplemented with EPA and naproxen were enriched in pathways including negative regulation of *Wnt* signaling, cell fate specification, ion channel complexes, and nutrient absorption. Furthermore, suppressed tumors shared significant GSEA pathway overlap with normal tissue, leading us to believe the combination of EPA and naproxen may be preventing tumorigenesis in part by maintaining cells in a differentiated state.
Conclusion and Future directions: Inflammation plays a key role in tumorigenesis and promoting cancer stem cell niches in tumors. According to our analysis, the combination of EPA and naproxen attenuated cancer-associated inflammation and reduced proliferation in part by augmenting tumor differentiation. Future studies will utilize single-nuclei RNA-Seq (snRNA-Seq) to determine at a single cell resolution the transcriptomic changes of epithelial and stromal populations within the TME. This work was supported by National Cancer Institute task order 75N91019F00132.

#0765 Tobacco smoke exposure, hormonal history, and estrogen metabolism in women with EGFR-mutant non-small cell lung cancer (NSCLC).

A. Raza[1], J. Treat[2], D. D. Krzizike[2], L. Vanderveer[2], M. Cheung[2], C. Zawislak[2], L. Etkins[2], E. Ross[2], D. B. Flieder[2], M. J. Edelman[2], M. L. Clapper[2], J. N. Bodor[2];

[1]Temple Univ. Lewis Katz School of Medicine, Philadelphia, PA, [2]Fox Chase Cancer Center, Philadelphia, PA

Introduction: The factors responsible for NSCLC development in never-smokers remain unclear, thus hindering prevention efforts. Our group is one of the first in the U.S. to build a registry of never-smokers with NSCLC to facilitate research to address this global problem. Given the high prevalence of women among cases, we are investigating the contribution of estrogen metabolism to this disease. CYP1B1 converts parent estrogens to the putative carcinogen 4-hydroxyestrogen (4-OHE), a process further accelerated by tobacco smoke exposure. In contrast, CYP1A1 generates 2-hydroxyestrogen (2-OHE), which may be converted to anti-proliferative derivatives. We determined previously that women with EGFR-mutant NSCLC enrolled in the registry have a 2-fold higher ratio of 4-OHEs to 2-OHEs, as compared to cancer-free controls. While EGFR-mutant NSCLCs are typically thought to be diagnosed in never-smokers, prior data indicate that a fraction of patients report some smoking history. The goal of this current study is to determine the smoking prevalence among women with EGFR-mutant NSCLC in our registry and explore the impact of smoking and hormonal history on estrogen metabolism.
Methods: The Lung Cancer in Never-Smokers Risk Registry (LCNS-RR) is recruiting patients with NSCLC who are never-smokers (<100 cigarettes/lifetime) and/or have tumors with oncogenes characteristically present in never-smokers (e.g., EGFR, ALK). In addition to donating biospecimens (e.g., blood, urine), participants complete a survey on tobacco and environmental exposures, hormonal history, and other factors. Using UPLC-MS/MS, profiles of urinary estrogens (E_1, E_2, E_3, 4-OHE_1, 4-OHE_2, 2-OHE_1, 2-OHE_2) were determined for 32 women with EGFR-mutant NSCLC in the LCNS-RR. The proportion of each estrogen species over total estrogen and the ratio of 4-OHEs to 2-OHEs were calculated. Medians were compared using the Wilcoxon rank-sum test.
Results: Among women in this EGFR-mutant cohort, none were current smokers, 16 were former smokers, and 16 were never-smokers. Among the former smokers, median pack-years was 11.6. The ratio of 4-OHEs to 2-OHEs was comparable in former- vs. never-smokers (0.51 vs. 0.49, p-value = 0.956). Twenty-three women (71.8%) had a history of oral contraception use, and 5 (15.6%) reported early menarche (<12 years of age). However, neither of these factors correlated with 4-OHE production. Among 28 post-menopausal women, 7 (25%) reported estrogen use since menopause, an exposure that was not associated with 4-OHE levels.
Conclusion: This preliminary analysis suggests that smoking history, use of hormones, or early menarche do not enhance the production of 4-OHEs in women with EGFR-mutant NSCLC. Recruitment to the LCNS-RR is ongoing and will facilitate future analyses in a larger cohort. (Supported by a Ride Hard Breathe Easy Innovation Award)

#0766 Effects of supplemental calcium and vitamin D on circulating biomarkers of gut barrier function in colorectal adenoma patients: A randomized controlled trial.

Sangji Lee[1], Veronika Fedirko[2], Roberd M. Bostick[3], Bradley Pearce[3], Elizabeth L. Barry[4], Robin E. Rutherford[3], March E. Seabrook[5]

[1]Texas A&M University, College Station, TX,[2]MD Anderson Cancer Center, Houston, TX,[3]Emory University, Atlanta, GA,[4]Dartmouth College, Hanover, NH,[5]Consultants in Gastroenterology, West Columbia, SC

Introduction: Recent experimental evidence shows that intestinal barrier disruption initiates colon inflammation, which may promote colorectal carcinogenesis. In experimental models, vitamin D and calcium improved gut barrier function; however, this has not been assessed in humans.
Method: To test the effects of supplemental calcium and vitamin D_3 on circulating biomarkers of intestinal mucosal damage (intestinal fatty-acid binding protein, IFABP) and exposure to bacterial products due to impaired gut barrier (lipopolysaccharide-binding protein, LBP), we conducted an “adjunct biomarker study” to a larger 11-center, randomized, placebo-controlled, partial 2x2 factorial chemoprevention clinical trial, the Vitamin D/Calcium Polyp Prevention Study. Participants were randomized into four different treatment groups: placebo, 1,200 mg/day calcium, 1,000 IU/day vitamin D_3, and 1,200 mg/day calcium plus 1,000 IU/day vitamin D_3. Circulating concentrations of LBP and IFABP were measured at baseline and 1-year follow-up using the Meso Scale Discovery electrochemiluminescence assays in a subset of 118 participants included in the adjunct biomarker study.
Result: Following one year of vitamin D_3 treatment, in the vitamin D_3 plus calcium and vitamin D_3 groups *versus* placebo and calcium groups, LBP decreased 10% (316 ng/ml; *P=0.23*) and IFABP 18% (77 ng/ml; *P=0.06*). A similar decrease of 20% (*P=0.10*) was observed for IFABP, but not LBP, in the vitamin D_3 plus calcium *versus* the calcium group. There were no appreciable biomarker changes with calcium treatment. In stratified analyses, we found possible effect modifications by baseline serum 25-OH-vitamin D, total calcium intake, body mass index, and interleukin 6 (IL-6) concentration on estimated vitamin D_3 treatment effects on LBP and/or IFABP.
Conclusion: These preliminary results are consistent with vitamin D’s potential protective effects on intestinal mucosal barrier and support further research of vitamin D against gut barrier disruption and colorectal neoplasms.

#0767 The role of abdominal obesity in the association between obesity and prostate cancer: A U.S. population-based cross-sectional study NHANES 2001-2020.

A. E. Ahmed[1], C. B. . Martin[1], B. Dahman[2], S. Q. Kern[1], G. T. Chesnut[1];
[1]Uniformed Services University of the Health Sciences, Bethesda, MD, [2]Virginia Commonwealth University, Richmond, VA

Background: Research suggests inconsistent evidence regarding the association between general obesity and prostate cancer among men in the United States. This study aimed to examine whether the association between general obesity and prostate cancer is influenced by abdominal obesity.
Methods: This study utilized data from the National Health and Nutrition Examination Survey (NHANES), 2001-2020, a nationally representative survey. The analysis was restricted to 16,703 non-Hispanic men (10,683 White and 6,020 Black). General obesity was defined by a body mass index of 30 kg/m^2 or greater and abdominal obesity was defined by a waist circumference of 102 cm or greater. Respondents were classified into four mutually exclusive groups according to the body fat indicators: 1) presence of both general and abdominal obesity, 2) abdominal obesity without general obesity, 3) general obesity without abdominal obesity, and 4) none of the two (the reference group).
Results: The overall prevalence of prostate cancer was 2.25% (95% CI: 2.0-2.5%). Men with abdominal obesity without general obesity have significantly higher prevalence of prostate cancer (4.28%) compared to men with both abdominal obesity and general obesity (2.23%), men with neither abdominal obesity or general obesity (1.70%), and men with general obesity without abdominal obesity (0.18%), P <.0001. Black men with abdominal obesity without general obesity have the highest prevalence of prostate cancer (7.21%), followed by White men with abdominal obesity without general obesity (4.10%). With and without adjusting for age and education, men with abdominal obesity without general obesity had significantly higher odds of prostate cancer, regardless of ethnicity. Black men with both abdominal obesity and general obesity had significantly higher odds of prostate cancer. General obesity without abdominal obesity was inversely associated with prostate cancer in White men but not in Black men.
Conclusions: This study illustrates that waist circumference is a potential classifier of prostate cancer as it shows variation in prevalence of prostate cancer by general obesity within the same and different racial and ethnic groups.

#0768 Awareness and use of genetic testing among cancer survivors in the United States: A HINTS-SEER study.

K. Ramalingam[1], A. Scheffler[1], E. Van Blarigan[1], S. Li[1], R. C. Vanderpool[2], S. H. Nash[3], S. Shariff-Marco[1], S. Gomez[1], M. Hebert-DeRouen[1];
[1]University of California San Francisco, San Francisco, CA, [2]National Cancer Institute, Rockville, MD, [3]University of Iowa, Iowa City, IA

Background: Germline genetic testing is a valuable tool for cancer treatment and family cancer risk assessment, but its uptake among cancer survivors remains low. Understanding the factors that influence awareness and use of genetic testing among survivors is crucial for improving access to this important tool.
Methods: We analyzed HINTS-SEER data, a pilot project conducted by the National Cancer Institute (NCI) in 2021, that oversampled cancer survivors diagnosed prior to 2018 using three registries from the Surveillance, Epidemiology, and End Results (SEER) Program (Iowa, New Mexico, Greater Bay Area). We examined sociodemographic factors in relation to awareness and use of genetic testing using survey-weighted multivariable logistic regression models. We also examined associations among breast and prostate cancer survivors, separately, as these cancer types have guidelines for genetic testing and had sufficient observations (>100) for stratified analyses.
Results: Of 1232 survivors included in the analysis, 277 (23%) had a history of breast cancer, 285 (23%) had prostate cancer, 82 (6.7%) had colorectal cancer, 25 (2%) had ovarian cancer, and 563 (45.7%) had other cancers. Overall, 76.5% of survivors were aware of genetic testing and 23.5% had used it. Among breast and prostate cancer survivors: 40.0% of breast and 20.6% of prostate cancer survivors were aware of genetic testing, and 21.0% and 2.4% had used it, respectively.
In multivariable models, female gender (vs. male; OR=3.1, 95% CI: 2.3, 4.2), higher education (high school or less education vs. greater than high school; OR=2.4, 95% CI: 1.4, 3.9), higher income ($100,000 or more vs. <$20,000; OR=3.2, 95% CI: 1.8,5.7), and family history (OR=2.0, 95% CI: 1.4,3.0) were significantly associated with higher odds of awareness of genetic testing. Older age (≥65 vs. <40 years; OR=0.4, 95% CI: 0.2,0.6), Asian American race (vs. non-Hispanic white; OR= 0.3, 95% CI: 0.3-0.9), and Hispanic ethnicity (vs. non-Hispanic white ; OR= 0.5, 95% CI: 0.3-0.9) were associated with lower odds of awareness of genetic testing.
Female gender (vs. male; OR=5.3, 95% CI: 3.3,8.5) was significantly associated with higher odds of use of genetic testing. Older age (>65 years vs. <40 years; OR=0.4, 95% CI: 0.2,0.7) and unemployed status (OR=0.4, 95% CI: 0.3-0.6) were significantly associated with lower odds of use of genetic testing. In stratified analyses, only older age among breast cancer survivors (≥65 vs. <40 years; OR=0.2, 95% CI: 0.0,0.9) was associated with lower odds of use of genetic testing.
Conclusion: Our study provides valuable insights into genetic testing awareness and utilization among a large sample of cancer survivors in the United States. The identified factors associated with awareness and utilization can be used by healthcare providers to target interventions aimed at improving genetic testing awareness and utilization among cancer survivors.

#0769 Incorporating a cross-ancestry polygenic risk score into a clinical model improved breast cancer risk prediction in women with pathogenic variants.

P. Tshiaba[1], M. Sun[1], D. Ratman[1], J. N. Weitzel[2], P. Shah[1], M. Rabinowitz[1], A. Kumar[1], K. Im[1];
[1]MyOme, Menlo Park, CA, [2]Precision Prevention, The University of Kansas Comprehensive Cancer Center, Kansas City, KS

Introduction. We previously developed and validated a cross-ancestry polygenic risk score (caPRS) to predict risk of developing breast cancer (BC) in women who do not carry pathogenic variants (PVs) in BC susceptibility genes. Here we aimed to expand upon that study by integrating the caPRS with the Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA) model to combine the effects of genetic and clinical factors in carriers of PVs in BRCA1, BRCA2, PALB2, CHEK2 and ATM.

Methods. We explored the association of caPRS among 12,525 women from the UK Biobank and the Consortium of Investigators of Modifiers of BRCA1/2. The effect size of the caPRS was evaluated separately for individuals carrying PVs in BRCA1, BRCA2, CHEK2, ATM and PALB2. We used a logistic regression model adjusted for age, first-degree BC family history (FHx) and cohort for BRCA1 and BRCA2 to examine the association of the caPRS with BC. The effect sizes were expressed as standardized odds ratios (ORs) with 95% confidence intervals (CIs). The estimated absolute risks to age 80 of developing BC were calculated for unaffected women by combining the caPRS-based risk with gene-specific clinical risk estimates from the BOADICEA model based on U.S. incidences.

Results. The caPRS was significantly associated with BC risk across all PV carrier groups. Using BOADICEA alone, the estimated absolute BC risk by age 80 for an average unaffected 20-year-old female in the U.S. with an unknown FHx ranged from 23.8% for CHEK2 carriers to 79.4% for BRCA2 carriers. Integration of caPRS into BOADICEA, yielded the distribution of risk for each gene. (Table)

Gene	N	OR per SD (95% CI)	Absolute risk by BOADICEA	Median absolute risk by BOADICEA + caPRS (Range)
ATM	2,037	1.46 (1.25 - 1.71)	24.9%	27.1% (0.1 - 70.5)
BRCA1	5,794	1.24 (1.18 - 1.31)	76.1%	75.6% (55.6 - 87.7)
BRCA2	4,018	1.40 (1.31 - 1.49)	79.4%	78.7% (45.2 - 92.1)
CHEK2	372	1.88 (1.41 - 2.55)	23.8%	28.2% (0.0 - 78.4)
PALB2	304	1.81 (1.37 - 2.43)	53.9%	56.3% (2.9 - 90.9)

Conclusions. The caPRS significantly modified BC risk for carriers of PVs and could help tailor guidelines for women with PVs, particularly in moderate penetrance genes. More data is needed to increase the precision and reach of risk assessment in diverse populations.

#0770 The innate immune system response to malignancy- under the radar?.

M. Tobi[1], H. Talwar[1], B. McVicker[2];
[1]Saginaw VA Medical Center, Southfield, MI, [2]Omaha VA Medical Center, Omaha, NE

It has become clear that many cancers evade detection by, for example, silencing of immune checkpoints. Re-activation of the immune armamentarium by checkpoint inhibitors has improved survival in many types of cancer. However, we still are unable to gauge the response of the innate immune system (InImS) to incipient malignancy. The InImS is likely both a sentient early warning system and an immediately deployed cancer combatant. We describe a potential marker that quantifies the innate immune system response to multiple deadly tumors. Methods: We obtained a database of patients at high risk of colorectal neoplasia and prospectively noted those who contracted cancer on follow up. We contrasted the historic, premorbid biomarker response from the time of enrolment, primarily using the FERAD ratio. This was obtained by dividing the ferritin blood concentration by the denominator of fecal shedding of a Paneth cell marker, p87. We also compared the FERAD response to the absolute neutrophil:lymphocyte ratio (NLR), a known prognostic biomarker, and also the available, known PDL-1 response for each group of cancers. Results: We found that certain groups of cancers historically had very low FERAD ratios while others were high. Using FERAD ratios for lung, gastric, non-Hodgkin's lymphoma, melanoma, thyroid, renal, and head and neck cancers, there is a significant inverse correlation between survival and FERAD ($r=-0.8;p<0.025$) which is similar to that of NLR ($r=-0.7;p<0.035$). For prostate cancer, breast, colorectal cancer (CRC), leukemia/MDS, there is a direct correlation between survival and FERAD ($r=0.99;p<0.002$). There is also an inverse relationship between NLR and PDL-1 response rates ($r=-0.8;p<0.04$). An observed mild positive trend for FERAD PDL-1 response rates may bode well for melanoma, lung, head and neck and renal cancers. Conclusions: Since p87 could be manipulated by dietary means to affect the FERAD ratio favorably, this could be incorporated into more effective chemotherapy regimens and result in better cancer treatment outcomes. Hepatocellular cancer (HCC) and CRC-liver metastasis appear to be immunological outliers. This will need an additional unique approach such as TIGIT intervention therapy (Zheng et al.. Immune checkpoint targeting TIGIT in HCC. Am J Transl Res. 2020). This may allow modulation of the immune response based on FERAD, NLR ratios, and other considerations of mutational burden and genetic mutations, in patients with selected cancers.

#0771 A TGF-β superfamily member, myostatin contributes to MASH and HCC via muscle atrophy by disrupting TGF-β signaling, and is a potential marker with PKM2 for human HCC.

K. Ohshiro[1], K. Bhowmick[1], X. Xiang[1], S. Kapoor[1], R. Amdur[1], S. Dasarathy[2], A. R. Krainer[3], **L. Mishra**[1];
[1]Feinstein Institutes for Medical Research & Cold Spring Harbor Laboratory, New York, NY, [2]Cleveland Clinic, Cleveland, OH, [3]Cold Spring Harbor Laboratory, New York, NY

Background: In patients with cirrhosis and hepatocellular carcinoma (HCC), sarcopenia or skeletal muscle loss, as well as metabolic alterations are frequent and progressive comorbidities. Myostatin, a TGF-β superfamily member is expressed primarily in skeletal muscle, inhibits muscle growth, and causes sarcopenia in cirrhosis. Previously, we had observed liver-specific knockout of the SMAD3 adaptor, βII-spectrin -*Sptbn1* (βS-LSKO) or siRNA targeting βII-spectrin blocks sarcopenia, fatty liver disease-MASH and HCC (Sci TM 2021), suggesting that βII-spectrin may be a viable strategy to identify mechanisms, as well as new biomarkers of MASH and HCC.
Methods: 1. SPTBN1^{Flox} (control) and liver-specific βII-spectrin knockout (SPTBN1^{LSKO}) mice were fed Western diet (WD) and treated with Diethylnitrosamine (DEN) for obesity-associated HCC. Muscle mass, body weight and multiple enzymes involved in glycolysis as well as sarcopenia were measured in mutant mice. 2. In tumors, a rate-limiting enzyme in glycolysis, pyruvate kinase isozyme M2 (PKM2) that mediates inflammation and aerobic glycolysis in Warburg effect. Therefore, we further examined TGF-β pathway-enriched biomarkers such as Myostatin and PKM2 for markers of HCC and whether these could stratify risk in patients with cirrhosis for HCC, in a four-institution cohort, (n=157) compared to cirrhosis patients (n=380).
Results: 1. Like human fatty liver disease, obese mutant mice show marked sarcopenia with increased PKM2 and Myostatin levels with decreased p-RPS6/total-RPS6 ratio (indicating mTOR signaling inhibition) in striated muscle tissue. In contrast, levels are restored to normal in the liver specific knockout of SPTBN1. 2. Using the 108 markers as well as PKM2 and myostatin (MSTN), we found 31 markers with false discovery rate (FDR) p values < 0.10 from univariable Kruskal-Wallis tests for the associations of markers with HCC vs. cirrhosis.
Conclusions: Our results reveal that SMAD3 adaptor, βII-spectrin liver-specific knockout decreases Myostatin and PKM2 expression, providing new insight into molecular mechanisms in MASH and HCC. These studies reflect that these are biologically functional circuits that could provide new serum markers, such as Myostatin and PKM2 for risk stratification of HCC.

#0772 Investigation of gender disparity in liver tumor formation using a hydrodynamic tail vein injection mouse model.

A. Bernal, M. McLaughlin, A. Tiwari, F. Cigarroa, L. Sun;
The University of Texas Health Science Center At San Antonio, San Antonio, TX

The incidence of hepatocellular carcinoma (HCC), the major form of liver cancer, is 4 times higher in men than in women. This gender disparity is difficult to study since it is believed to be multifactorial, due in part to differences in risk factors, behaviors, and hormones. The liver is a sexually dimorphic organ that is extremely susceptible to interactions with estrogens and androgens. Estrogen has been proven to have a protective effect against HCC with a demonstrable gender-related hormonal effect on the growth of HCC, though the underlying mechanisms are not fully understood. The hydrodynamic tail vein injection (HTVI) mouse model allows for the induction of liver tumors in the host. Eliminating the social and behavioral aspects of the gender disparity will allow us to determine what role estrogen plays in tumor development. In our study, a gender disparity in tumor development was observed between 6-week-old male and female FVB/NJ mice injected via HTVI of plasmids expressing c-MET, a mutated beta-catenin (b-Cat) and Sleeping Beauty transposon. HTVI of a Luciferase and Sleeping Beauty transposon expressing plasmid showed no significant difference in photon flux by bioluminescence imaging between male and female mice 24 hours after injection. When imaging was repeated one week after injection, the photon flux reduced by an order of magnitude in both male and female mice with the female mice showing more uniform reduction than the male mice. Similar luciferase gene copy number was detected in the liver tissue of male and female mice. These data suggest that there appears to be no gender difference in the transient expression and stable integration of the transfected plasmid. Plasma alpha-fetoprotein (AFP) was used to monitor tumor formation in the mice that were injected with c-MET and b-Cat without luciferase as luciferase is immunogenic. The male mice had significantly higher AFP levels at 3.5 weeks, 8 weeks, and 12 weeks post-injection than the female mice. At termination, the liver weight confirmed that female mice had much lower tumor burden than the males. We are currently using quantitative PCR to confirm similar copy number of exogenous c-MET and b-Cat inserted in the tumor cell genome and using RT-qPCR and Western blotting to determine whether the transgene expression is different in tumors from male and female mice. To determine whether estrogen played a role in preventing tumor development and progression in female mice, six-week-old male and ovariectomized female mice have been injected with the same oncogene plasmid combination plus the sleeping beauty. Interestingly, AFP levels between male and ovariectomized female mice were comparable when measured at 3 weeks. We will present our findings at the meeting.

#0773 Overexpression of phosphoserine phosphatase (PSPH) in prostate cancer and in tumor microenvironment promotes tumor cell proliferation.

Liankun Song[1], Noriko Yokoyama[1], Jun Xie[1], Yunjie Hu[1], Zhenyu (Arthur) Jia[2], Beverly Wang[1], Dan Mercola[1], Edward Uchio[1], Thomas Ahlering[1], Michael Lilly[3], Xiaolin Zi[1]

[1]University of California, Irvine, Orange, CA,[2]University of California, Riverside, Riverside, CA,[3]Medical university of south Carolina, Charleston, SC

Reprogrammed cellular metabolism is one of the key features of cancer and tumor microenvironment. L-3-phosphoserine phosphatase (PSPH) is one of the five rate-limiting enzymes in the biosynthesis of serine from glucose that supports cell proliferation. Here, we aim to study the role of PSPH in prostate cancer (PCa) and its tumor microenvironment. We find that PSPH not only is overexpressed in prostate cancer cell lines compared to normal prostate epithelial cells (PrEC) and benign prostate epithelial cells (BPH-1), but also exhibits a higher level in patient-derived carcinoma-associated fibroblasts (CAFs) compared to the matched benign associated fibroblasts (BAFs), which are derived from fresh radical prostatectomy specimens of African American (AA) and European American (EA) men. Notably, MDAPCa2b cells derived from an AA prostate cancer patient and AA CAFs have even higher expression of PSPH protein. The mRNA levels of PSPH are also significantly elevated in prostate cancer tissues in AA men compared to EA men and predict poor survival in PCa patients. Knock-down of PSPH expression significantly inhibits the proliferation and colony formation of prostate cancer cells. Growth of xenograft tumors derived from PSPH knockdown MDAPCa2b cells has also been suppressed markedly. Gene expression profiling revealed that suppression of PSPH expression by shRNAs in LNCaP and MDAPCa2b cells is associated with the regulation of gene expression related to metabolism, immunity, extracellular matrix remodeling, and Ion channels. Similarly, analysis of publicly available PCa RNA seq databases also demonstrates that PSPH amplification or over-expression is associated with alterations of gene expression related to metabolism and immunity. Our results suggest that PSPH is upregulated in prostate cancer cells and their surrounding fibroblasts to support tumor growth via reprogramming metabolic pathways and transcriptomes.

#0774 Genetic architecture, evolutionary genomics, and genomic risk of prostate cancer in sub-Saharan Africa.

T. R. Rebbeck[1], R. Janivara[2], W. C. Chen[3], U. Hazra[2], M. Network[1], J. Lachance[4];

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Georgia Institute of Technology, Atlanta, GA, [3]Wits Health Consortium, Johannesburg, South Africa, [4]Georgia Institute of Technology, Atlanta, GA

Men of African descent have the highest prostate cancer (CaP) incidence and mortality rates, yet the genetic basis of CaP in African men has been understudied. We performed the first large-scale genomic analysis of CaP across sub-Saharan Africa (SSA). We evaluated the evolutionary history of CaP-associated loci, generated a novel genomic risk score, inferred ancestry-specific genetic architectures, and fine-mapped disease associations using in 3,963 CaP cases and 3,509 controls recruited in Ghana, Nigeria, Senegal, South Africa, and Uganda through the Men of African Descent and Carcinoma of the Prostate (MADCaP) Network. Fifteen independent associations at 8q24.21, 6q22.1, and 11q13.3 reached genome-wide significance, including four novel associations. Multiple lead SNPs were private alleles in SSA, a pattern arising from recent mutations and the out-of-Africa bottleneck. These SSA-specific alleles contribute to haplotypes with odds ratios for CaP above 2.4. The genetic architecture of CaP differs across SSA, with effect size differences contributing more to this heterogeneity than allele frequency differences. Population genetic analyses reveal that SSA CaP associations are largely governed by neutral evolution, as opposed to natural selection. This finding is consistent with the late onset of this disease. Focusing on 2,502 age-matched cases and 2,222 non-cancer controls, we generated a novel genomic predictor of CaP. We then assessed the extent to which this polygenic risk score was correlated with age of onset, PSA levels, genetic ancestry, and family history of study participants. The performance of this novel polygenic risk score was tested on other populations of African descent, as well as populations with non-African ancestry. Our findings emphasize the utility of conducting genetic studies in diverse populations.

#0775 Underlying germline genetic architecture of pediatric sarcomas: Evaluating the role of common and rare variants in 4,160 patients.

Some evidence suggests that pediatric sarcomas have both shared and distinct genetic profiles; however, large-scale efforts to characterize germline genetic susceptibility across these malignancies are limited by their rarity. We evaluated the role of common and rare variants in the genetic etiology of the more frequent pediatric sarcomas: osteosarcoma (OS); Ewing sarcoma (ES); and rhabdomyosarcoma (RMS), subcategorized into embryonal (ERMS) and alveolar (ARMS).

METHODS: We evaluated 4,161 European-ancestry cases with genotype data (1,843 OS, 733 ES, 1,585 RMS, and ~61,000 cancer-free adult controls) and 2,474 cases with exome or genome sequencing (1,002 OS, 579 ES, 893 RMS, and 1,057 controls; jointly called with the same QC). Analyses included: 1) estimating disease heritability for both common SNPs (MAF>3%; genome-wide) and rare loss-of-function variants (MAF<1%; exome-wide); and 2) determining the frequency of rare predicted pathogenic (P) or likely pathogenic (LP; ACMG-AMP) variants in cancer susceptibility genes (CSG).

RESULTS: For OS, we conducted a new GWAS and determined that common variants explained 2.7% (SE 1.1%) of disease heritability, while rare LOF variants explained 12.7% (SE 1.5%; compared to 0.4% for synonymous variants). A similar pattern was observed for ERMS, where rare LOF variants explained a greater proportion of disease heritability (RMS 8.6%, SE 1.2%; ERMS 12.6%, SE 1.7%; ARMS n/a due to small sample size) compared to common variants from our new GWAS (0.9%, SE 1.6%). Conversely, common variants explained a greater proportion of ES heritability (5.4%, SE 0.5%) and of ARMS heritability (15.5%, SE 6.4%). For 113 established CSGs, and for the 60 moderate-to-high penetrant autosomal dominant (AD) genes, OS and ERMS had significantly (P_{exact}<0.01) more rare P/LP variants overall compared to controls; whereas ARMS and ES had significantly fewer P/LP variants than ERMS and OS, similar to the controls. We confirmed previously reported AD genes, and identified new genes, with an enrichment of P/LP variants in ERMS and OS compared to controls. For both ARMS and ES, the only AD gene significantly enriched for P/LP variants was *CHEK2*. For all cases, patients with a P/LP variant were significantly younger and had significantly more poor outcomes (ie, metastasis, stage 4 disease, and/or death) than those without. For 49 autosomal recessive CSGs, heterozygous P/LP carrier frequencies were similar among all sarcomas (8-11%), and several specific genes had similar P/LP variant enrichment across sarcomas, and for ES and ARMS only, compared to controls.

CONCLUSION: In the largest set of pediatric sarcoma cases assembled to date, genetic susceptibility was largely driven by rare P/LP AD gene variants in tumor types not characterized by canonical somatic fusions (OS and ERMS). In contrast, fusion-driven tumor types (ES and ARMS) were driven more by common variants.

#0776 Change in background contrast enhancement category on abbreviated breast MRI with administration of 6 months of bazedoxifene and conjugated estrogen vs wait list control.

C. J. Fabian, O. Winblad, A. L. Kreutzjans, K. Pittman, C. Altman, K. R. Powers, M. McCarthy, L. Nye, **B. F. Kimler**;
University of Kansas Medical Center, Kansas City, KS

Background MRI background contrast enhancement (BPE) has found to be a marker of breast cancer risk providing information beyond that provided by assessment of breast density. BPE is qualitatively classified into categories that correspond to BPE estimates as minimal, <25% BPE; mild, 25-50% BPE; moderate, 50-75% BPE; and marked, >75% BPE. We divided minimal into minimal and almost none (≤5%). We conducted a feasibility study of change in BPE after 6 months of the selective estrogen receptor modulator bazedoxifene (BZA) 20 mg + conjugated estrogen (CE) 0.45 mg marketed commercially as Duavee™ for relief of hot flashes and prevention of osteoporosis in postmenopausal women.
Methods STUDY00145121 started 5-27-2020 with randomization to 6 months of Duavee™ vs waitlist control but was stopped after 11 entrants because participants were unable to receive follow-up breast MRIs due to COVID and Duavee™ became unavailable. STUDY0014761 was opened in early 2022 when a source of BZA was found. Doses of BZA and CE were the same as Duavee™ but given as two pills instead of one. 16 women have been randomized to 6 months of BZA/CE vs a wait list control between 2-14-2022 and 9-19-2023. Inclusion criteria are postmenopausal women ages 45-65 at increased risk for breast cancer, BMI < 36 kg/m^2 and having current vasomotor symptoms. Participants had a blood draw, 3D mammogram, and abbreviated breast MRI at baseline and the studies were repeated at 6 months. Volumetric density was assessed by Volpara™ fully automated software. Research evaluation of abbreviated MRI background parenchymal contrast enhancement (BPE) was assessed by 5 categories as almost none, minimal, mild, moderate, and marked. BPE was evaluated by a single radiologist blinded to treatment assignment and compared to the 4-category clinical assessment.
Results A total of 27 women have been entered in these studies. Six were not evaluable from STUDY00145121 because of the inability to perform 6-month MRI. Two women on STUDY0014761 are not endpoint evaluable due to early drop out and 3 have not yet completed study. A total of 16 women have completed the 6-month portion of the study and abbreviated MRI, with median age 55 (range 47-62) and median BMI 26 kg/m^2 (20-33 kg/m^2). At baseline, BPE were 3 almost none, 4 minimal, 8 mild, 1 moderate, and 0 marked. There was little correlation between absolute baseline mammographic fibroglandular volume and baseline BPE. A shift in BPE category using the 5-category assessment was noted in 6/11 women (all but one decreased) randomized to BZA +CE and 2/5 women (both decreased) on waitlist. The one increase and four categorical decreases would not have been detected without expansion of BPE to a 5-category system.
Conclusion Using the 5-category classification, abbreviated MRI BPE may have promise as a response biomarker in prevention trials for postmenopausal high-risk women.

#0777 Notch signaling dependent chemoresistance in racial disparity in ER$^+$ breast cancer.

S. Singh, M. Das, R. Chakrabarti;
University of Miami Miller School of Medicine, Miami, FL

Breast cancer (BCa) is the leading cause of cancer related death in women worldwide. The most common BCa subtype is the Estrogen/Progesterone receptor (ER$^+$/PR$^+$) luminal subtype, comprising up to 75% of all newly diagnosed BCa. Although these patients show initial benefit with chemotherapy and endocrine therapy, however, 40-50% of them eventually don't respond to treatment due to resistance. Thus, the need for additional targeted therapies for this large subset of ER$^+$ BCa patients is critical. Based on recent studies, it is observed that Afro-American (AA) patients experience substantially higher BCa mortality (40% more) than White American (WA) women in ER$^+$ breast cancer. Unfortunately, the cause behind this difference in mortality in AA patients is not well understood. Notch signaling is a highly conserved intercellular communication mechanism critical for many cellular processes and is composed of several receptors and ligands. Recent data show that Notch receptors are overexpressed in hormone treatment refractory ER$^-$ patients of (Afro-American) AA origin, hinting connection of Notch signaling to racial disparity in breast cancer. Notch signaling is also identified in several metabolic disorders involving fatty acids and other lipids. However, function of Notch signaling in context of chemoresistance in AA ER$^+$ breast cancer is still unknown. Using single cell sequencing, we found that chemo-resistant AA ER$^+$ breast cancer patient samples have a distinct Notch signature enriched subpopulations in tumor cells, which was missing in WA patients. Notch signaling happens through juxtacrine signaling of ligand/receptor signaling. Further analysis in tumor microenvironment shows lipid enriched tumor associated macrophages, which are Notch dependent, suggesting potential crosstalk between lipid heavy tumor-macrophages and tumor cells, which may drive the chemoresistance in AA patients. Further analysis using patient derived explants, an attractive new tool for drug efficacy testing in ex vivo, we found that chemotherapy itself increases Notch signaling in the tumors. Ongoing studies involving scRNAseq, untargeted lipidomics and chemo-resistant PDE will delineate the precise mechanism of action between tumor cells and tumor associated lipid heavy macrophages in context of Notch signaling in chemo-resistant AA ER$^+$ breast cancer.

#0778 Atorvastatin modulates serum biomarkers in women at increased risk for breast cancer.

A. L. Lanier, J. Fahrmann, F. N. A. Mustafayev, A. Gutierrez Barrera, P. H. Brown, B. Arun;
UT MD Anderson Cancer Center, Houston, TX

Background Tamoxifen and Aromatase inhibitors have been shown to be highly effective at reducing the incidence of ER-positive breast cancers in women at increased risk, but there are no approved agents for the risk reduction of ER-negative cancers. Evidence from observational and preclinical studies supports the study of statins for breast cancer risk reduction.
Objective This study aimed to investigate the effects of Atorvastatin treatment on serum and tissue biomarkers in women at increased risk for breast cancer.
Methods Women at increased risk for breast cancer were accrued prospectively at UTMDACC, Breast Medical Oncology High-Risk Clinic. The study was approved by the IRB and all participants signed informed consent. High risk was defined as having a previous history of DCIS, LCIS, or atypical hyperplasia, 5-year projected Gail risk >1.67 %, or lifetime risk >20 % calculated by clinical models. Patients were randomized to no treatment (n=15) or daily 10mg (n=15), 20mg (n=14), or 40mg (n=16) Atorvastatin for 3 months. Fasting blood and breast tissue samples via fine needle aspiration (FNA) were collected at baseline and at study completion. Serum biomarkers were analyzed with ELISA (R&D Systems). The IGF1/IGFBP3 molar ratio was calculated using [IGF1 (ng/mL) x 0.13] / [IGFBP-3 (ng/mL) x 0.035]. The Wilcoxon matched-pairs signed rank test was used to determine significance.
Results Tissue biomarker evaluation was previously reported. Serum biomarker levels of IGF1 and its main binding proteins IGFBP1 and IGFBP3 were compared in baseline and post-intervention samples by ELISA analysis. The average change in serum IGF1 (ng/mL) levels between pre- and post-treatment samples (represented as average difference with interquartile range) was +3.5 (-16.8 to 8.7) p=0.98, -0.6 (-23.6 to 15.4) p=0.64, -1.76 (-27.7 to 28.6) p=0.81, and +2.6 (-14.5 to 32.2) p=0.67 in the 0, 10, 20, and 40mg groups respectively. The average change in serum IGFBP1 (pg/mL) was -23.2 (-2372 to 4487) p=0.33, -480 (-4567 to 3008) p=0.72, 429 (-1259 to 3039) p=0.54, and -250 (-3581 to 2492) p=0.94 in the 0, 10, 20, and 40mg groups. The average change in serum IGFBP3 (ng/mL) was -24 (-193 to 98) p=0.72, -119 (-353 to 111) p=0.17, -190 (-433 to 14) p=0.07, and -234 (-369 to -79) p=0.002 in the 0, 10, 20, and 40mg groups. Serum IGF1/IGFBP3 molar ratio was +0.012 (-0.018 to 0.026) p=,0.76, +0.0065 (-0.013, to 0.047) p=0.53, +.0073 (-0.036 to 0.045) p=0.86, and +.027 (-.011 to .062) p=0.058 in the 0, 10, 20, and 40mg groups.
Conclusions Serum IGFBP3, which has been associated with breast cancer risk, was decreased in a dose-dependent manner in patients treated with Atorvastatin. The IGF1/IGFBP3 molar ratio was increased in the 40mg group, although not statistically significant (p=.0577). This shows that treatment with Atorvastatin induced changes in circulating biomarkers and that Atorvastatin could be further studied in larger prospective breast cancer prevention trials.

#0779 Functional role of TGF-beta receptor type-2 in breast cancer progression and survival.

M. Srivastava[1], A. Bera[1], H. B. Pollard[1], H. Hu[2], C. D. Shriver[3];
[1]Uniformed Services University, Potomac, MD, [2]Chan Soon-Shiong Institute of Molecular Medicine, Windber, PA, [3]Murtha Cancer Center Walter Reed National Military Medical Center,, Bethesda, MD

Background and Rational: Transforming growth factor β (TGFβ) signaling is pivotal in cellular proliferation and can exhibit either tumor-suppressive or promoting effects depending on cellular context and genetic alterations. TGFβ receptor type-2 (TGFβR2), the ligand-binding receptor, is implicated in various cancers. This study explores the functional role of TGFβR2 in breast cancer (BrCa) progression. Materials and
Method: Genomic alterations in TGFβR2 were assessed in TCGA samples. TGFβR2 mRNA and protein expression were examined in a panel of BrCa cell lines, including MCF7, MCF12A, MDA-MB-231, and MDA-MB-468. Additionally, serum samples from BrCa patients, meticulously categorized into subtypes such as triple-negative (TN), human epidermal growth factor receptor 2-positive (Her2+), Luminal A (LA), Luminal B1 (LB1), and Luminal B2 (LB2), were analyzed. BrCa cell lines were treated with TGFβ ligand to investigate receptor expression modulation.
Results: Analysis of genomic alterations in TGFβR2 from The Cancer Genome Atlas (TCGA, n=1084, BrCa samples) revealed TGFβ copy number amplification in 25% of samples, while less than 1% showed TGFβR2 amplification. Elevated TGFβR2 levels were identified in aggressive triple-negative MDA-MB-231 cells compared to other tested cell lines. Serum samples from BrCa patients (n=240) demonstrated higher TGFβR2 levels, particularly in Luminal B1 subtype and African American patients. Treatment of BrCa cell lines with TGFβ ligand induced TGFβR2 expression, suggesting ligand-induced receptor upregulation.
Discussion: The findings suggest TGFβR2 as a potential biomarker for BrCa, with higher levels associated with aggressiveness and racial disparities. Ligand-induced receptor upregulation implies a potential oncogenic role. These results contribute to understanding TGFβR2's functional significance and its implications in breast cancer progression, offering insights into potential biomarkers and therapeutic targets.

#0780 Normal breast tissues harbor rare populations of aneuploid epithelial cells.

Y. Lin*[1], J. Wang*[1], K. Wang[1], S. Bai[1], A. Thennavan[1], R. Wei[1], Y. Yan[1], J. Li[1], H. Elgamal[1], E. Sei[1], A. Casasent[1], M. Rao[1], C. Tang[1], J. Montalvan[2], C. Nagi[2], S. Winocour[2], B. Lim[2], A. Thompson[2], N. Navin[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor Medical College, Houston, TX

Although aneuploidy is a hallmark of invasive breast cancers, the presence of aneuploid cells in breast tissues of disease-free women is poorly understood. Furthermore, the expansion of aneuploid cells and the specific copy number events that they harbor, as well as their relationship to invasive breast cancers has not been characterized in large cohorts of women. In this study, we obtained viable cell suspensions from 31 disease-free women that underwent reduction mammoplasty surgeries and fresh tissue collection in the HBCA project along with the collection of clinical metadata. The viable cell suspensions from 31 women were enriched for epithelial cells and used to perform high-thoughput nanowell scDNA-seq. In total, 55,321 cells were analyzed. The normal breast tissue samples were also embedded into OCT and frozen to perform Spatial Transcriptomics (Visium 10X Genomics) profiling and embedded into FFPE to perform histopathological analysis. Our data shows that all women harbored rare populations of aneuploid epithelial cells (mean 4.3%) that increased in frequency and their number of copy number aberrations with age. Many aneuploid epithelial cells (mean 79%) in normal breast tissues underwent clonal expansions of their genomes and harbored chromosomal aberrations detected in invasive breast cancers (gain of 1q and loss of 7q, 10q, 16q). Spatial mapping showed that aneuploid cells are localized in focal regions of ductal and lobular epithelial structures with normal histopathological features. Collectively, these data show that aneuploid epithelial cells exist in the normal breast tissues of disease-free women and increase with age. In many women, the aneuploid cells expand and harbor CNA events associated with invasive breast cancer.

#0781 Impact of vitamin D and pyruvate carboxylase on hypoxia inducible lipid droplet associated (HILPDA) protein in metastatic breast cancer cells.
Y. Song, C. Andolino, D. Teegarden;
Purdue University, West Lafayette, IN

Metastatic breast cancer, a critical health issue for women globally, is closely linked to aberrant lipid metabolism. One feature of this dysregulated metabolism is the increase in lipid storage in the form of cytoplasmic lipid droplets (CLDs), although what drives their accumulation or their role in metastasis is not clear. In prior studies, we demonstrated that the active form of vitamin D (1,25-dihydroxyvitamin D, $1,25(OH)_2D$) downregulates pyruvate carboxylase (PC), a key metabolic enzyme, thereby reducing lipid accumulation in metastatic breast cancer cells (MCF10CA1a). Additionally, we have demonstrated that both $1,25(OH)_2D$ treatment and PC-inhibition reduce breast cancer cell migration. Therefore, the goal of the current research is to identify the proteins associated with CLDs in metastatic MCF10CA1a breast cancer cells following $1,25(OH)_2D$ treatment or reduction in PC expression (shPC). Proteins from CLDs and whole cell lysates (WCL) were processed for untargeted proteomic analysis. In the CLD fractions, 1562 identified enriched proteins were common to both MCF10CA1a and $1,25(OH)_2D$ treated cells, while 160 proteins were higher in the MCF10CA1a cells, and 550 proteins were higher in the $1,25(OH)_2D$-treated cells compared to MCF10CA1a CLD fraction. In the CLD fractions, MCF10CA1a and shPC cells had a similar level of 380 enriched proteins, although 65 were higher in the shPC compared with MCF10CA1a, whereas 1268 were more enriched in the MCF10CA1a CLD fraction. Hypoxia Inducible Lipid Droplet Associated (HILPDA, known to inhibit triacylglycerol lipolysis) was only enriched in the CLD fraction of the metastatic MCF10CA1a cells. HILPDA was not identified in the CLDs of the $1,25(OH)_2D$ treated or the shPC cells, nor in any WCL fraction. Further investigation of HILPDA is important to determine if HILPDA plays a role in dysregulated cellular metabolism, including CLD accumulation, or migration, and may potentially be a target for future therapies to prevent breast cancer progression.

#0782 Correlation between collagen peptides and physical features of fibrosis in breast tissue from women at increased risk of cancer.

D. Rujchanarong[1], A. T. Stopeck[2], C. Preece[1], R. Sun[1], P. Chalasani[3], S. Brown[4], J. D. K. Bai[5], H. Jensen Smith[6], S. You[1], P. M. Angel[4], P. Thompson[1]; [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Stony Brook Cancer Center, New York, NY, [3]George Washington University, Foggy Bottom, DC, [4]Medical University of South Carolina, Charleston, SC, [5]Stony Brook University, Stony Brook, NY, [6]University of Nebraska Medical Center, Omaha, NE

Breast cancer risk increases significantly in women who maintain higher radiologically dense breast tissue as they age. However, the mechanisms that underlie this association remain poorly understood, especially in postmenopausal women. A predominant contributor to dense breasts and differences between women is the relative amount of fibrillar collagens. Experimental models suggest that changes in collagen properties such as fiber alignment and stiffness promote local stromal fibrosis, which we hypothesize may contribute to the relationship between breast density, aging, and tumorigenesis. Normal breast biopsy samples from the contralateral, healthy breast of 32 postmenopausal breast cancer patients participating in a clinical trial for drug effect on breast density were examined and scored for areas of fibrosis and analyzed using second harmonic generation microscopy (SHG) and mass spectrometry proteomics. Our aim was to identify areas of fibrosis and relate the severity of focal fibrosis to the physical properties and peptide composition of collagen fibers. Using GraphPad Prism, we conducted one-way ANOVA and Kruskal-Wallis tests and post-hoc multiple comparison tests. H&E-stained breast tissue samples were scored according to percent fibrosis. The minimum and maximum percent fibrosis were 5% and 100%, respectively, with a median of 60% (95% CI: 97.06%). Out of 31 people, 16 had a higher fibrosis score than the median. Consistent with pathologic scoring of the presence and extent of fibrosis, fiber counts were significantly lower in tissue with lower fibrosis scores than samples with more highly scored fibrosis (p-value <0.001). Distance to the nearest fiber was greater in samples with < 20% fibrosis, whereas greater alignment to the nearest fiber was observed in higher fibrosis percentages. At the molecular level, 22 peptides demonstrated a strong correlation with percent fibrosis (spearman r ≥ 60), of which 13 peptides were statistically significant (p-value <0.0001). The putatively identified peptides belong to type I, III, IV and VI collagens. Fiber length and straightness, but not fiber width, were higher in tissues with greater percent fibrosis. Significant correlations were identified between collagen physical features and peptides: two distinct peptides correlated with collagen fiber length and straightness while 20 peptides correlated with fiber width. These putative peptides belong to types I, III, IV and V collagens with ~70% of the peptides containing at least one hydroxyproline modification. This study is the first to explore the link between focal fibrosis and collagen-associated peptides in healthy breast tissue of high-risk postmenopausal women. These findings provide novel insights on stromal collagens associated with fibrotic changes in normal at-risk breast tissue that may act in tissue susceptibility to tumor formation.

#0783 Early impact assessment of in-house EGFR testing for NSCLC in Kenya.

A. Njau, S. Nguku, J. Abuodha;
Aga Khan University Hospital, Nairobi, Kenya

Introduction: Quality of life and survival among non-small cell lung cancer (NSCLC) patients have improved in the last two decades owing mainly to use of tyrosine kinase inhibitors (TKIs) and other targeted therapies. Low and middle-income countries (LMICs) especially in Africa, are lagging in realizing these benefits largely due to hurdles in molecular testing. In addition, quality histology and molecular data from LMICs is deficient. The aim of this study is to assess the immediate impact of improved access to epidermal growth factor receptor (EGFR) testing in Kenya, and to establish a long term-lung cancer data base.
Methods: Staring mid-June 2023, an in-house PCR-based method was adopted for EGFR testing of NSCLC in order to side step the challenges of out-of-country send outs which was until then, the only option for EGFR testing. Further, a sponsored access program was created. From prospectively accrued samples, we performed a before-and-after assessment of the number of NSCLC cases intercepted, cost and turnaround times (TAT) as measures of impact. Demographic, histopathology, and EGFR mutation profiles were analyzed in comparison to Asia, USA and European data. Whole slide histology scanned images are made to compliment the database.
Results: Over the four-month period, 62 NSCLC cases were accrued, median age at diagnosis was 63 with a range of 24 - 93. The male to female ratio was 1: 1.5. Adenocarcinomas comprised 89%, squamous cell carcinoma 5% and 3% were not classifiable. Metastatic disease was reported in 14 (22%) with the brain being the commonest site. EGFR mutations were identified in 16 (25%) with exon 19 deletions and L858R mutations constituting 94% of them. Monthly requisitions for EGFR have increased 3-fold, and the average TAT has been halved to 7 days.
Conclusion: Similarities between our data and global patterns are noted; median age is in the seventh decade, NSCLC is more common in women, and so are the rates of EGFR mutations, adenocarcinomas are the predominant type, and there are high rates of brain metastasis at diagnosis. EGFR mutation rates appear to be higher than USA and European data but lower than Asian data. In-house and sponsored testing has had an immediate impact in reduction of costs and TAT and increased requisitions. Assessment of access to targeted therapy, clinical outcome, survival, expansion of molecular profiling beyond EGFR, and build-up of the database including virtual histology images for exploring artificial intelligence algorithms are our next steps.

#0784 Proteome-wide mendelian randomization identifies causal association between plasma proteins and lung cancer.

G. Si, W. Li, Y. Zhang, Z. Lyu, F. Song, **K. Chen**;
Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Lung cancer is one of the world's main health issues, and the exploration of novel protein markers can help to understand the mechanisms of lung cancer development and the discovery of therapeutic targets. Based on this, we used proteome-wide Mendelian Randomization to determine causal associations between plasma protein levels and the risk of developing lung cancer and subtypes. Methods: We performed a two-sample Mendelian Randomization analysis using genome-wide association data for 4907 proteins from the deCODE genetics study and five lung cancer and its subtypes from the FinnGen database. Causal effects were estimated using the Wald-ratio method or the inverse variance weighted (IVW) method, with additional analyses using the other four common methods when the number of SNPs was more than one. The Steiger filter method was used to test the correct direction of the causal effect. Multiple corrections were utilized by the Benjamini-Hochberg method. Results: After filtering, we finally analyzed 4645 proteins for the causal association with lung cancer, and the F-statistic of the instrumental variable for each protein was more than 10. After multiple tests, the levels of four genetically predictive proteins were found to be associated with the risk of lung cancer, and one protein was associated with the risk of small-cell lung cancer. In detail, elevated levels of three genetically predicted proteins were significantly associated with increased risk of lung cancer, namely, SYSC (OR:4.75, 95%CI: 2.47-9.16, FDR=0.007), TM11D (OR: 1.34, 95%CI: 1.17-1.53, FDR=0.02), and PDC6I (OR: 2.35, 95%CI: 1.58-3.49, FDR=0.03). Elevated levels of FASLG (OR: 0.87, 95%CI: 0.82-0.92, FDR=0.007) were associated with a reduced risk of lung cancer. In addition, genetically predicted elevated levels of GRP (OR: 0.05, 95%CI: 0.01-0.17, FDR=0.02) were associated with an increased risk of small-cell lung cancer. The Steiger filter test showed that all directions were from proteins to lung cancer. Conclusion: In this study, we found that five proteins may have effects on the risk of lung cancer, in which genetically predicted SYSC, TM11D, and PDC6I were significantly associated with an increased risk of lung cancer, whereas FASLG and GRP were associated with a decreased risk of lung cancer and small-cell lung cancer, respectively. The above may help to explore the pathogenesis of lung cancer, but further comprehensive studies are still needed.

#0786 Genomic distinctions of HIV- and EBV-associated DLBCL in a diverse African cohort.

K. Antel[1], A. Nesmelov[2], M.-X. Wu[1], C. Slome[3], D. Chetty[3], R. Kriel[3], E. Postovalova[2], R. Redd[1], M. Aryee[1], D. Armand[1], L. McGrath[1], N. Xiong[1], J. Oosthuizen[3], K. Brown[3], A. Tyshevich[2], S. Podsvirova[2], F. Frenkel[2], N. Kuzkina[2], J. Scher[2], C. Tazearslan[2], K. Zornikova[2], N. Kotlov[2], A. Bagaev[2], N. Fowler[2], A. Freedman[1], S. Rodig[4], E. Verburgh[3], M. A. Murakami[1];

[1]Dana-Farber Cancer Institute, Boston, MA, [2]BostonGene, Waltham, MA, [3]University of Cape Town, Cape Town, South Africa, [4]Brigham & Women's Hospital, Boston, MA

Lymphoma, a leading cancer cause of death among people living with HIV (PLHIV) globally, poses a pressing public health challenge in Sub-Saharan Africa (SSA), the epicentre of the HIV epidemic. Despite its prevalence, the genetic underpinnings of lymphoma in Black Africans and PLHIV remain poorly defined, contributing to regional disparities. This study aims to elucidate the impact of HIV status and EBV on the genetic landscape, molecular subtypes and survival outcomes of diffuse large B-cell lymphoma (DLBCL) in ethnically diverse SSA patients.

We established a cohort of 117 newly diagnosed DBLCL cases (55 HIV+, 21 EBV+, 62 Black Africans), with histopathologic and clinical annotation from a public teaching hospital in Cape Town, South Africa (2010-22). Tumor specimens underwent histologic review, whole exome sequencing (WES) and bulk whole transcriptome sequencing. Germline variants were filtered by paired normal WES (when available) and normal references augmented by supervised machine learning in tumor-only specimens. Aberrant somatic hypermutation (ASHM) was assessed in curated genes within paired samples. Microsatellite instability (MSI) was assessed via MSI-sensor.

Canonical genetic aberrations reproduced in this cohort included recurrent SNVs in *TP53*, *CARD11*, *TET2*, *SOCS1*, *MYD88*, and *KMT2D* with differences in relative proportion compared to the NCI consortium cohort being more attributable to HIV or EBV status than ethnicity. HIV+ cases harbored frequent mutations in *TET2*, *BRAF*, and *KRAS*, with fewer in NFKB pathway genes including *CARD11*, *IKBK*, and *BTK*. ABC-type HIV+ cases manifested higher expression of genes in the JAK-STAT pathway. EBV+ cases exhibited distinct genomic features including amplifications in *NOTCH1*, *CARD11*, *NFKBIE*, *MYC*, *CD274*, and *JAK2*, as well as frequent gain-of-function (GOF) mutations in the *NOTCH1* PEST domain (40% vs 3.8% q=0.04). Tumor mutation burden was consistent across ethnic and virological strata (median mutations 139-167, p>0.05). Notably, ASHM was not identified as a predominant mutational signature in either HIV-positive or negative cases, and 4 HIV+ DLBCL cases exhibited MSI, corroborated by protein-affecting mutations in mismatch repair genes. The 2-year overall survival (OS) was less than 40%, markedly inferior to published Western cohorts, even when controlled for clinical prognostic factors and treatment regimen.

This study highlights genetic and biological distinctions in DLBCL due to HIV and EBV. Key findings include the absence of ASHM correlates of pathogenic driver mutations, challenging a prevailing hypothesis of HIV-associated lymphomagenesis, and the identification of MSI in HIV+DLBCL. The dismal survival of this cohort and distinct genomic features, especially in EBV+DLBCL, highlight the urgency of further biological interrogation and inclusive clinical trials for these demonstrably underserved populations.

#0787 SARS-COV-2 P.1 strain infection in lung, breast and colon tumoral patient-derived organoids.

T. F. Sassaro[1], A. Viana[1], M. Zalis[2], C. Ferreira[2], J. Canedo[2], D. Ferreira[3], A. S. Moreira[1], E. Mello[1], F. Rondao[2], B. I. S. Ferreira[1], O. C. Moreira[1], D. A. Moreira[1], B. B. Souza[4], M. C. Waghabi[1], **T. M. Tilli**[1];

[1]Oswaldo Cruz Foundation, Rio de Janeiro, Brazil, [2]Oncoclinicas, Rio de Janeiro, Brazil, [3]Invitrocue Brazil, Rio de Janeiro, Brazil, [4]Oncoclinicas, Sao Paulo, Brazil

Coronavirus 2019 disease (COVID-19), caused by the newly identified strain of the coronavirus family capable of inducing acute respiratory syndrome, rapidly escalated into a pandemic, triggering a public health emergency. Throughout this period, it became evident that increased attention should be addressed towards at-risk groups, particularly individuals with chronic illnesses, including cancer. World widely, lung, breast, and colon cancer stand as the most prevalent types of cancer exhibiting high mortality rates in both men and women. Epidemiological data demonstrate that cancer patients, particularly those with lung, breast, and colon cancer, face elevated risk and severity when infected by SARS-CoV-2, resulting in even higher mortality rates. However, there is a knowledge gap concerning the interaction between COVID-19 and cancer patients, and thus, the current proposal evaluated SARS-CoV-2 infection in biopsy cells extracted from lung, breast, and colon cancer patients, cultivated as a patient-derived organoid (PDOs). Additionally, we also evaluated SARS-CoV-2 infection in a 3D model of spheroids in LC319, CALU-3, A549, H460, MRC-5, MDA-MB-231, MCF-10A and CACO-2 cell lines. Both PDOs and spheroids were infected with the SARS-Cov-2 P.1 strain with a multiplicity of infection (MOI) of 0.01 for 24 hours. We observed that PDOs and tumoral and non-tumoral spheroids were equally permissive to SARS-CoV-2 infection showing similar viral load levels. However, we observed a cytopathic effect after SARS-CoV-2 P.1 strain infection only in tumoral cells in comparison to non-tumoral cells from the same tissue. Furthermore, we explored the cytopathic effects caused by SARS-CoV-2 infection in PDOs and in tumoral and non-tumoral spheroids by scanning electron microscopy (SEM). Interestingly, we observed morphological alterations on the surface of SARS-CoV-2 P.1 strain -tumoral infected cells, with the occurrence of surface projections after 1 hour infection. Finally, we performed an exome sequencing analysis of PDOs and
tumoral and non-tumoral cells which preliminarily indicated an intriguing and informative crosstalk between cancer-related genes and SARS-CoV-2 infection pathways. Here we have identified missense and nonsense mutations in genes involved in PI3K pathway, immune function, and cell cycle regulation. In summary, our study showed that SARS-CoV-2 P.1 strain can infect and directly induce cytopathic effects in lung, breast, and colon tumors.

#0788 Leveraging multi omics approach to examine the potential role of causative viruses in glioblastoma..

Bavani Gunasegaran[1], Aziz Abdullah A Alnakli[1], Gilles J. Guillemin4[2], Seong Beom Ahn[1], Benjamin Heng[1]

[1]Macquarie University, Sydney, Australia,[2]ICTRYM Pty Ltd, Sydney, Australia

Glioblastoma (GB), a grade IV brain cancer, has the lowest survival rate. Despite aggressive and targeted therapies, patients remain to have the worst prognosis. More than 16% of cancer incidence worldwide has been attributed to infectious agents, raising uncertainties about the role of infections in the development of brain cancer. While numerous studies have suggested potential viral involvement in GB pathogenesis, a common limitation is the reliance on a singular technology, such as DNA/RNA sequencing or immunohistochemistry, within each study. This approach may restrict the comprehensive exploration of viral contributions, as different technologies offer distinct insights into the complex mechanisms underlying GB development. Utilizing a combination of techniques could provide a more holistic understanding, enhancing the robustness of findings and potentially uncovering nuanced aspects of viral influence that a single technology might overlook. To clarify the role of viruses in GB pathology, our study employs a comprehensive approach integrating three distinct research methods. We screened 178 publicly accessible raw mass spectrometry (MS) data of GB tumors from three independent publications (PMID: 31331834, 31154438, 36720864) by employing our internally developed data identification pipeline. The pipeline transforms raw MS data for downstream analysis, conducts database searches against the latest viral protein databases and undergoes peptide validation for enhanced robustness. Subsequent analysis filters duplicate hits and consolidates nested peptides. The final protein list includes only those identified with two or more peptides of over eight amino acids. The pipeline concludes by inferring and listing the corresponding viruses, ensuring a comprehensive and refined approach to the identification and analysis of viral proteins in the context of MS data. To enhance this dataset, we incorporated whole-genome metagenomics and MS-based proteomics, examining a preliminary cohort of15 GB tumor tissues. This approach explored a wide range of viral encoded proteins. Our comprehensive analysis, integrating bioinformatics, genomics, and proteomics, identified multiple herpesvirus species across our cohorts. This potential identification of viruses within GB has the capacity to redefine the stratification of tumor types in GB patients, signaling a significant development in our understanding of the disease.

#0789 GrafGen: Distance-Based Inference of Population Ancestry for *Helicobacter pylori* Genomes.

W. Wheeler[1], D. Wang[2], I. Zhao[3], Y. Jin[4], **C. S. Rabkin**[2];
[1]Information Management Services, Rockville, MD, [2]National Cancer Institute, Bethesda, MD, [3]Axle Informatics, Rockville, MD, [4]National Center for Biotechnology Information, Bethesda, MD

BACKGROUND: The 1.67 megabase *H. pylori* genome contains ~143,000 biallelic single-nucleotide polymorphisms (SNP) with minor allele frequency > 1%. Confounding by population stratification is a major source of bias requiring adjustment in genome-wide association studies (GWAS). Previous model- and distance-based methods for bacterial genomes yield varying results depending upon which strains are included for comparison in analyses. We therefore developed a robust classification of *H. pylori* ancestry to facilitate generalizable inferences about disease associations. **METHODS:** GrafGen is an R software package adapted from the GrafPop tool for human ancestry (Jin et al., 2017; Jin et al., 2019). The underlying classification algorithm compares SNPs of an individual genome with frequencies in reference populations to estimate subject ancestry and ancestral proportions based on calculated genetic distances. Outputs incorporate visualization tools that provide natural geometric interpretation of population structure. **RESULTS:** Training data were obtained from the *H. pylori* Genome Project (*Hp*GP), a global survey of 1011 *H. pylori* genomes collected across 51 countries (Thorell et al., 2023). Based on genetic distances, *Hp*GP sequences clustered into nine mutually exclusive populations designated by their predominant geographic source. Previously published population assignments for a test set of 255 sequences obtained from GenBank mapped to specific GrafGen classifications (Table). GrafGen assignments based on randomly selected sets of 14,300 and 1430 SNPs were >97% and >90% identical, respectively, to those based on all 143,000 SNPs. **CONCLUSIONS:** GrafGen's universal categorization of *H. pylori* ancestry has utility for bacterial GWAS. The software code is publicly available for research on this important pathogen. Theoretically, the same algorithm can be implemented to infer ancestry of any single chromosome haploid species that has sufficient sequence data for references.

#0790 Sex and race-dependent variations in the mutational landscape of clonal hematopoiesis.

Kanaka Dhuri, Houda Alachkar

USC - University of Southern California, Los Angeles, CA

Introduction: Clonal hematopoiesis of indeterminate potential (CHIP) has emerged as a significant precursor to hematological malignancies and is associated with several age-related diseases. Recent studies in relatively small disease specific cohorts have suggested that CHIP may exhibit variations among different races and between males and females raising intriguing questions about potential genetic and environmental influences. Understanding the differences in CHIP across races and between males and females may have implications for personalized cancer risk assessment and targeted therapeutic strategies.
Methods: Patient's data were obtained from the Cancer Therapy and Clonal hematopoiesis via cBioportal. The original study was designed to examine clonal hematopoiesis mutations that were found in blood samples obtained from 24,146 patients with non-hematological cancers and their tumor-blood pairs were analyzed using targeting sequencing data MSK-IMPACT (Memorial Sloan Kettering-IMPACT). The cohort consisted of 45.7% males and 54.3% females; including 6.8% Asians, 6.2% Blacks, and 76.3% Whites. We examined mutation frequencies among these racial groups and between genders, employing the two-sided Fisher's exact test and adjusting p-values for multiple comparisons. Differences were considered significant when both P value and Q values are less than 0.05.
Results: *DNMT3A* mutations were substantially more prevalent in females than in males (38.94% vs 31.37%, p-value: $<10^{-10}$, q-value: $6.19e^{-09}$), While *ASXL1* mutations were more frequent in males than females (5.82% vs 2.69%, p-value: $<10^{-10}$, q-value: $6.19e^{-09}$). In the racial cohorts with sufficient sample sizes, *STAT5B* and *CSF1R* mutations were most frequent in Asian (1.40% and 0.84%), followed by Black (0.98% and 0.24%) and White populations (0.29% and 0.09%), (p-value: $8.099e^{-04}$ and $7.490e^{-04}$, q-value: 0.0234 and 0.0232). Several other CHIP mutations were enriched in Black: *RARA*, *SMAD2*, *CDKN1B*, *CENPA*, *CTLA4*, *EIF1AX*, *ELF3*, *MSI1*, *MYC*, *SOX17*, *AURKA*. On the other hand, *H3C1*, *H3C4*, *MYCL* were enriched in the Asian cohort.
Conclusion: Our analysis provides insights into the complex interplay of sex and racial factors in shaping CHIP mutation frequencies. As CHIP continues to gain recognition as a critical precursor to malignancies, understanding these variations contributes to refining our understanding of its underlying mechanisms and clinical implications.

#0791 Evaluation of BCR spike-in controls using DriverMap adaptive immune receptor (AIR) profiling technology.

A. Chenchik, T. Liu, M. Makhanov, D. Hu, K. Ghias, P. Diehl;
Cellecta, Inc., Mountain View, CA

The DriverMap™ Adaptive Immune Receptor (AIR) repertoire profiling assay employs multiplex RT-PCR for comprehensive profiling of CDR3 or full-length receptor profiling of all variable heavy and light chains of T-cell receptors (TCR) and B-cell receptors (BCR) from either RNA or DNA. In this study, initiated by a U.S. Food and Drug Administration (FDA) consortium to compare performance of different BCR repertoire profiling technologies, we tested spike-ins in peripheral blood mononuclear cell (PBMC) RNA and DNA control mixtures prepared from nine different B-cell lines. We measured the sensitivity, linearity and accuracy of AIR RNA and DNA BCR profiling for the IGH, IGK and IGL chains of the spike-in controls. Our comprehensive analysis, encompassing CDR3 profiling and full-length receptor profiling (CDR1, CDR2, and CDR3) sequencing, revealed a 100X increase in sensitivity of detection of spike-in controls in RNA compared to the DNA assay. The high sensitivity of the full-length DriverMap AIR RNA assay allowed the detection of controls from all nine cell lines, with 8 out of 9 cell lines detected in the DNA assay, which demonstrates the robustness of the DriverMap AIR profiling technology.
This study highlights the remarkable sensitivity of the AIR RNA assay in quantifying transcripts. This approach enables the detection of low-frequency BCR clonotypes, which is particularly advantageous when working with samples containing low numbers of B cells. Furthermore, our AIR DNA assay in combination with spike-in controls offers a quantitative tool for minimal residual disease (MRD) applications, providing accurate insight into cell numbers, which then facilitates tracking clonal expansion of immune cells.

#0792 Continuous, probabilistic variant interpretation with Bayesian graphical models.

W. M. Korn, Y. Kobayashi, F. M. Facio, A. Nampally, K. Nykamp, R. Nussbaum, A. Colavin, B. Johnson, T. Manders;
Invitae, San Francisco, CA

Introduction: Current variant classification (VC) frameworks rely on rules-based approaches that use heuristic weighting of various types of evidence, resulting in > 50% of variants being classified as variants of uncertain significance (VUS), and leaving many patients with uncertainty about their disease risk or diagnosis. We propose a probabilistic and scalable Bayesian approach to model the causal relationships between various types of evidence. A fully quantitative system maximizes the utility and integration of various evidence types, empowering clinicians to make more nuanced management decisions.
Methods: Probabilistic graphical models (PGMs) are uniquely suited to the needs of clinical VC. Two different component PGMs were developed to model two of the evidence categories that will ultimately be used in a comprehensive VC system: population allele frequency (Population PGM) and reported phenotype observations (Reported Phenotype PGM).
Results: The Population PGM treats population allele frequency observations as a binomial process. By conditioning the model on partial observations, the probabilistic relationships between pathogenicity and allele frequencies can be estimated while stochastic variational inference allows uncertainty to be efficiently propagated. The resulting model performs well across a large number of genes at inferring pathogenicity of a variant from its allele frequency, with an average precision of >99% for benign variants.
In the Reported Phenotype PGM, phenotypic features characteristic of a disorder are learned from patients expected to be affected based on genotype. Patient-level predictions are in turn combined at the variant level to derive variant pathogenicity likelihoods. To date, models representing at least 102 inherited conditions and 259 genes have demonstrated high predictive performance (>0.8 AUROC) for both patient-level and variant-level predictions.
Finally, as a proof-of-concept, we demonstrate how each component PGM can be combined into a probabilistic Bayesian VC framework that also includes protein structure and stability, evolutionary conservation, and sequence context. This framework has high concordance with known, well-accepted pathogenic and benign variants classified with rules-based systems, and could make high-confidence predictions for many variants currently classified as VUS.
Conclusion: We present a Bayesian approach that can integrate diverse types of evidence to achieve high VC accuracy while quantifying uncertainty. Future expansion of this Bayesian framework to all evidence types relevant to VC may allow for more accurate risk management guidelines and further inform medical and genetic counseling recommendations.

POPULATION SCIENCES: Cancer Disparities 1: Emerging Trends in Cancer Disparities Research
Poster Session

#0796 Exploring the impact of masculine beliefs on colorectal cancer screening participation among Hispanic/Latino men in Florida, New York, and Texas.

A. E. Sedani[1], J. Y. Islam[2], D. M. Griffith[3], K. K. Rifelj[1], C. L. McCall[1], O. Garcia-Rodriguez[2], M. Camacho-Rivera[4], C. R. Rogers[1];
[1]Medical College of Wisconsin, Milwaukee, WI, [2]H. Lee Moffitt Cancer and Research Institute, Tampa, FL, [3]Georgetown University, Washington, DC, [4]SUNY Downstate Health Sciences University, Brooklyn, NY

Introduction: The existing literature on colorectal cancer-related inequities among Hispanic/Latino men may be poorly descried as most outcome data to date for this ethnic group are reported in aggregate. This study explored how masculine beliefs may influence colorectal cancer screening participation among ethnic subgroups of Hispanic/Latino men aged 45-75 years.
Methods: Utilizing a consumer panel, self-identified Hispanic/Latino men that were age-eligible for colorectal cancer screening and fluent in either English or Spanish were recruited from Florida, New York, and Texas (February-March 2022). The Masculinity Barriers to Medical Care (MBMC) scale, comprising six theoretically derived subscales, was assessed masculinity. Multivariable logistic regression was employed to estimate the association between MBMC and colorectal cancer screening participation, adjusting for Hispanic/Latino subgroup, marital status, survey language, age, and health insurance status. Next, to explore differences by Hispanic/Latino subgroups (Mexican/Mexican American/Chicano; Puerto Rican; Cuban; Other Hispanic/Latino), results were stratified by subgroup and adjusted for confounding.
Results: There were 611 male participants, with roughly 31% identifying as Puerto Rican, 30% a different Hispanic ethnic background ("Other Hispanic/Latino"), 26% Mexican, and 14% Cuban. More than half (63%) of whom had ever been screened for colorectal cancer. No variations in screening rates were observed across Hispanic/Latino subgroups. Stool-based tests were more commonly used for screening compared to exam-based tests (60% vs. 49%). After adjusting for confounding, masculinity barriers reduced the odds of the screening participation. Differences were observed by Hispanic/Latino subgroup for a few MBMC scale items. Specifically, Cuban men were most likely to report trust in healthcare professionals, but least likely to report receiving quality medical care. Latino men of other Hispanic ethnicity were more likely to report taking risks with their own health if it benefits their family. Among Puerto Rican men, higher scores on the restrictive emotionality subscale were associated with a lower likelihood of screening participation. Conversely, higher scores on the health-related self-reliance subscale were associated with a greater likelihood of screening participation among men of other Hispanic/Latino ethnicity.
Conclusion: Differences in colorectal cancer screening participation by Hispanic/Latino ethnicity were not observed, suggesting barriers to screening may be similar among subgroups. Masculinity barriers to colorectal cancer screening may exist among Latino men, particularly among Puerto Rican men. Intervening on these masculinity-related barriers masculinity may improve colorectal cancer screening uptake among Latino men.

#0797 Area deprivation, rurality, healthcare utilization, quality of life, and health status among cancer patients.

H. Lee[1], D. Lee[1], D. Ng[2], D. Wiese[1], A. Jemal[1], F. Islami[1];

[1]American Cancer Society, Atlanta, GA, [2]University of California Irvine, Irvine, CA

Background: Living in deprived or rural neighborhoods can negatively influence individual health through various mechanisms, including limited access to care due to scarce resources, medical facilities, or health professionals. Prior ecological studies have shown an association between living in rural or disadvantaged areas and higher cancer morbidity or mortality, but research on the association between neighborhood of residence and cancer patients' healthcare utilization, health status, or quality of life has been limited.

Method: We used survey and electronic health records data on cancer patients aged ≥18 years (N=16,606) from All of US Controlled Tier Dataset v7 (summer 2017-July 1, 2022). Area deprivation index (ADI) was based on six items, including 3-digit zip code-level median household income, proportions of high school graduation, vacant housing, recipients of public assistance income, and individual without health insurance or with incomes below the poverty level. Rural-urban status was defined at the 3-digit zip code-level as urban (100% urban), mostly urban (≥50%-<100% urban), and rural (>50% rural). Logistic regression models were used to estimate the association between ADI or rurality and health care utilization (general doctor, specialist, mental health, or nurse practitioner/physical assistant [NP/PA] visits) or health outcome (fair/poor physical and mental health status, quality of life), controlling for various covariates.

Results: Cancer patients living in the most deprived areas (ADI 5th quintile) were less likely to have general doctor visits (OR=0.73; 95% CI=0.54-0.85), NA/PA visits (OR=0.87; 95% CI=0.77-0.99), or mental health professional visits (OR=0.85; 95% CI=0.74-0.98), and more likely to have fair or poor quality of life (OR=1.31; 95% CI=1.06-1.62), compared to those living in the least deprived areas (ADI 1st quintile), controlling for all covariates. Similarly, rural cancer patients were less likely to have general doctor visits (OR=0.58; 95% CI=0.42-0.79) or mental health professional visits (OR=0.53; 95% CI=0.41-0.67), and more likely to have fair/poor physical health (OR=1.27; 95% CI=1.03-1.57), compared with urban cancer patients. However, rural cancer patients were more likely to have NA/PA visits (OR=1.29; 95% CI=1.04-1.58) and less likely to have fair/poor mental health (OR=0.66; 95% CI=0.48-0.92). Cancer patients in mostly urban areas showed similar patterns to those in rural areas but the magnitudes of associations were smaller.

Conclusions: In this study, cancer patients living in deprived or rural areas were less likely to have general doctor or mental health professional visits and more likely to have poor physical health compared to patients in the least deprived or urban area. Community-level interventions in deprived or rural areas are required to mitigate disparities in healthcare and health among cancer patients.

#0798 Increasing breast cancer incidence across generation status in Mexican American women: The Multiethnic Cohort.

X. Zhang[1], I. Cheng[2], A. Paik[1], B. Huang[1], **V. W. Setiawan**[1];
[1]University of Southern California, Los Angeles, CA, [2]UCSF, San Francisco, CA

Background: Breast cancer (BC) is the most commonly diagnosed cancer among Latino women in the US. Compared to foreign-born Latino women, US-born Latino women have a higher incidence of BC. While prior studies have suggested this difference in incidence may be explained by risk factors such as unhealthy lifestyle behaviors, reproductive history, and neighborhood socioeconomic status, it is unclear how the risk of BC has changed over generations among Latinos women. In this study, we investigated the association between generational status and BC incidence among Mexican American women within the Multiethnic Cohort (MEC).

Methods: The study population included 15,303 self-reported Mexican Americans from the MEC. Generational status was categorized as: 1st generation (Mexico-born, n = 6,347), 2nd generation (US-born with one or two parents born in Mexico, n = 6,390), or 3rd generation (US-born with both parents born in the US, n = 2,566). Multivariable Cox models were used to calculate the hazard ratios (HR) and 95% confidence intervals (CI) of BC incidence by generational status. All models were adjusted for relevant risk factors including age, physical activity, smoking, alcohol intake, education, body mass index, diet, family history of BC, menopausal status, age at menarche, parity, mammography history, hormone use, neighborhood socioeconomic status, and Hispanic ethnic enclave.

Results: During an average 21.5-year follow-up, 815 incident BC cases were identified. The age-adjusted incidence rate (per 100,000) of BC increased by generation (1st: 191.9; 2nd: 265.3; 3rd: 284.0). Third (70.4%) and 2nd (66.5%) generations had a larger proportion of localized disease at diagnosis compared to 1st generation women (59.7%). Compared to 1st generation Mexican Americans, 2nd (HR = 1.24; 95% CI: 1.03-1.49) and 3rd generation (HR = 1.28; 95% CI: 1.02-1.60) had elevated risks of BC (p-trend: 0.02) The positive association with generational status remained significant when restricting to women who reported mammogram use (HR 2nd vs. 1st = 1.27, 95% CI: 1.04-1.55; HR 3rd vs. 1st = 1.34, 95% CI: 1.06-1.70) (p-trend: 0.01).

Conclusions: Our findings suggest that generational status among Mexican American women is associated with risk of BC, after adjusting for sociodemographic, lifestyle, neighborhood, and reproductive risk factors. Further studies are warranted to discover the potential factors that contribute to this increased risk and elucidate the underlying etiology.

#0799 Area-level socioeconomic deprivation is associated with inadequate access to quality preoperative care and increased readmission after surgery for early-stage lung cancer.

S. Tohmasi[1], D. B. Eaton, Jr.[2], B. T. Heiden[1], N. E. Rossetti[1], M. W. Schoen[3], S.-H. Chang[1], Y. Yan[1], M. R. Patel[2], B. F. Meyers[1], B. D. Kozower[1], V. Puri[1]; [1]Washington University in St. Louis School of Medicine, St. Louis, MO, [2]Veterans Affairs St. Louis Health Care System, St. Louis, MO, [3]Saint Louis University School of Medicine, St. Louis, MO

Objective: Socioeconomic deprivation (SED) has been associated with higher lung cancer risk and mortality. However, the effects of SED on lung cancer outcomes in an integrated, single-payer healthcare system, such as the Veterans Health Administration (VHA), remains unknown. We sought to examine the impact of area-level SED on access to care and outcomes in veterans with early-stage non-small cell lung cancer (NSCLC).
Methods: We conducted a retrospective cohort study of patients with clinical stage I NSCLC receiving definitive surgical treatment in the VHA from 2006-2016. Patients were assigned an area deprivation index (ADI) score, a ZIP code-level measure of SED incorporating multiple poverty, education, housing, and employment indicators from the United States Census. Using multivariable analysis, we evaluated the relationship between ADI and guideline-concordant quality metrics (QMs) that stage I NSCLC patients should routinely meet in the preoperative (positron emission tomography [PET] imaging, smoking cessation support [SCS], pulmonary function testing [PFT], and timely surgery) and postoperative (cancer surveillance imaging, SCS, and appropriate oncology referral) periods. We also assessed the association between ADI and various cancer-specific outcomes including overall survival (OS).
Results: The study included 9,704 patients. High ADI was associated with lower likelihood of receiving PET imaging (ADI ≥76 vs. ≤50: adjusted odds ratio [aOR] 0.592, 95% CI 0.502-0.698) and PFT (ADI ≥76 vs. ≤50: aOR 0.816, 95% CI 0.694-0.959) before surgery. High ADI was also associated with delayed surgery (>12 weeks after diagnosis; ADI ≥76 vs. ≤50: aOR 1.202, 95% CI 1.058-1.366). ADI was associated with 30-day readmission after surgery (ADI ≥76 vs. ≤50: aOR 1.380, 95% CI 1.103-1.726) but not with 30-day mortality (ADI ≥76 vs. ≤50: aOR 1.221, 95% CI 0.816-1.826), major complications (ADI ≥76 vs. ≤50: aOR 0.927, 95% CI 0.780-1.101), prolonged hospital length of stay (≥14 days; ADI ≥76 vs. ≤50: aOR 0.893, 95% CI 0.755-1.056), or 90-day mortality (ADI ≥76 vs. ≤50: aOR 0.876, 95% CI 0.645-1.190). ADI was not associated with adherence to postoperative QMs (ADI ≥76 vs. ≤50: aOR 0.888, 95% CI 0.764-1.032), OS (ADI ≥76 vs. ≤50: aHR 0.984, 95% CI 0.911-1.062), or cumulative incidence of cancer recurrence (ADI ≥76 vs. ≤50: aHR 1.047, 95% CI 0.930-1.179).
Conclusions: Area-level SED is associated with inadequate adherence to preoperative QMs and increased readmission after surgery for stage I NSCLC. Our data suggests that veterans with high SED experience inadequate access to quality preoperative care for early-stage NSCLC but do not have inferior long-term outcomes after resection. Future VHA policies should focus on providing more equitable guideline-concordant preoperative care and preventing postoperative readmission for stage I NSCLC.

#0800 Spatial accessibility of gynecologic oncologists and time to surgery in a diverse cohort of women with ovarian cancer in Northern California.

E. Chirikova[1], P. P. Inamdar[1], V. McGuire[1], S. Shariff-Marco[1], V. S. Lee[2], L. J. Collin[3], C. T. Sanchez-Diaz[4], J. Kavecansky[5], C. B. Powell[1], J. A. Doherty[3], L. H. Kushi[2], E. V. Bandera[4], S. L. Gomez[1];

[1]UCSF - University of California San Francisco, San Francisco, CA, [2]Kaiser Permanente Northern California, Oakland, CA, [3]University of Utah, Salt Lake City, UT, [4]Rutgers Cancer Institute, New Brunswick, NJ, [5]Kaiser Permanente Northern California, Antioch, CA

Introduction: To expand our understanding of factors contributing to racial and ethnic disparities in ovarian cancer outcomes, we examined the association between spatial accessibility of gynecologic oncologists and time from cancer diagnosis to surgery in the KPROCS Study, a diverse cohort of women diagnosed with ovarian cancer between 2000-2018 at Kaiser Permanente Northern California (KPNC). Spatial medical accessibility is a component of healthcare access that captures the proximity and availability of healthcare resources in the area.

Methods: Ovarian cancer cases were identified through the KPNC Cancer Registry. Demographic and clinical information was extracted from KPNC databases. Neighborhood characteristics from the California Neighborhoods Data System were linked to the residential addresses of cases at the time of diagnosis. Spatial medical accessibility was measured using the 2-step floating catchment area method based on the location of the infusion centers where KPNC gynecologic oncologists practice and the residence location of cohort members. We used generalized estimating equations with independent correlation structure and robust standard errors to examine the association between spatial accessibility of gynecologic oncologists and time to ovarian cancer surgery, adjusting for year and age at diagnosis, stage, histotype, race, ethnicity, neighborhood socioeconomic status (nSES), and receipt of neoadjuvant chemotherapy.

Results: The cohort comprised 4,910 women with ovarian cancer, of whom 3,304 had surgery at KPNC. Of this group, 13% were Hispanic, 14% were non-Hispanic (NH) Asian American women, 5% NH Black women, and 67% NH White women. The proportion of women residing in areas of the lowest spatial accessibility of gynecologic oncologists was highest among NH White women (26%) and women residing in the highest quintile of nSES (29%). The median time from diagnosis to surgery was 4 days (interquartile range 22 days). In adjusted analyses, not including the information on spatial accessibility, the time from diagnosis to surgery was 5.1 days longer (95% CI 1.5, 8.7) for NH Black women than NH White women. After adding information on spatial accessibility, this time did not considerably change, resulting in a 5.3-day (95% CI 1.7, 8.9) difference. In this model, the lowest quintile of spatial accessibility of gynecologic oncologists was associated with a longer time from diagnosis to surgery, but this association was not statistically significant (0.4 days difference, 95% CI -1.3, 2.0).

Summary: In our preliminary analyses, spatial accessibility of gynecologic oncologists was not found to be a contributing factor to the disparity in time from diagnosis to surgery between NH Black and NH White women. Further analyses will examine time from diagnosis to chemotherapy overall and stratified by racial and ethnic groups.

#0801 Severe housing cost burden and premature cancer mortality by state Medicaid expansion status.

W. R. Lawrence[1], N. D. Freedman[1], J. K. McGee-Avila[1], L. Mason[1], Y. Chen[1], A. P. Ewing[2], M. S. Shiels[1];
[1]National Cancer Institute, Bethesda, MD, [2]The Ohio State University, Columbus, MS

Introduction: The fraction of people living in unaffordable housing in the U.S. has grown, and prior studies have documented a relationship between housing cost burden and worsening health. Medicaid expansion has been suggested to improve housing financial stability by reducing health care costs and improving access to preventative care. However, the role of expanded access to Medicaid on the relationship between housing cost burden and cancer mortality remains poorly understood. We investigated the relationship between county-level severe housing cost burden and premature cancer mortality by state Medicaid expansion status for all cancers and leading sites.
Methods: This ecological study used county-level data from 2016-2020 American Community Survey linked with county-level mortality data. Severe housing cost burden measured by percentage of households within a county that spend ≥50% of their income on housing categorized into quintiles (1=lowest, 5=highest) and state Medicaid expansion status (expanded and non-expanded). Age-adjusted cancer mortality rates and adjusted-mortality rate ratio (aRR) were estimated by sex.
Results: Across quintiles of county-level severe housing cost burden, age-adjusted cancer mortality rates were largely greater in non-Medicaid expanded states than Medicaid expanded states among women and men. Among counties in the lowest quintile of severe housing cost burden, rates for overall cancer mortality in women were 9% (aRR=1.09; 95%CI 1.05-1.14) higher in non-Medicaid expanded states compared with expanded states. Additionally, among the third quintile of severe housing cost burden, colorectal cancer mortality rate was 8% higher (aRR=1.08; 95%CI 1.02-1.14) in non-Medicaid expanded states. Among men in the lowest quintile of severe housing cost burden, overall cancer mortality rates were 5% (aRR=1.05; 95%CI 1.02-1.09) higher in non-Medicaid expanded states than Medicaid expanded states. Further, among men in counties in the highest quintile of severe housing cost burden, colorectal cancer mortality rate was 8% higher (aRR=1.08; 95%CI 1.05-1.12) and lung cancer mortality was 13% higher (aRR=1.13; 95%CI 1.10-1.15) in non-Medicaid expanded states compared with expanded states.
Conclusions: Counties with a lower fraction of households experiencing severe housing cost burden had greater premature cancer death rates within non-Medicaid expanded states than Medicaid expanded states. However, among men rates were also elevated in non-Medicaid expanded states in counties with the greatest severe housing cost burden.

#0802 Molecular profile of gastric cancer in Hispanics living in Puerto Rico.

I. Montes-Rodriguez, H. Centeno-Girona, N. Rivera, M. Cruz-Correa;
University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Gastric cancer (GC) is the 4th leading cause of cancer death globally. The incidence and mortality rates of GC differ dramatically between racial/ethnic groupings. In the United States (U.S.), Hispanics, non-Hispanic Blacks, and Asian or Pacific Islanders are more likely to be diagnosed with GC and have a higher mortality rate than non-Hispanic Whites. Among the Hispanic population living in Puerto Rico (PRH), GC ranks among the top ten leading causes of cancer death, whereas this malignancy is not a major cause of cancer mortality in the mainland U.S. Tumor profiling approaches have resulted in the discovery of actionable gene alterations, which serve as a guide for treatment strategies and ultimately enhance the overall survival rates of individuals diagnosed with cancer. However, descriptive information regarding the genetic mutational landscape of GC tumors from PRH is limited. This study aims to describe the genomic profile of GC tumors in PRH and to identify the most prevalent genetic mutations. We retrospectively examined GC tumor mutational profiles from 106 PRH that underwent NGS testing from 2015 to 2022 (provided by CARIS Life Sciences and the Precision Oncology Alliance). We compared PRH GC tumor somatic mutation prevalence to TCGA and the AACR Project Genomics Evidence Neoplasia Information Exchange (GENIE), both available through the cBioPortal for Cancer Genomics. Descriptive statistics were performed to characterize the database. Among the top mutated genes for GC tumors in PRH were *TP53* (54.1%, n=85), *ARID1A* (34.2%, n=73), *KMT2D* (30.5%, n=82), *CDH1* (29.4%, n=85) and *ZFHX3* (27.3%, n=55). The most frequent gene amplifications were *ERBB2* (7.1%, n=84), *KRAS* (6.0%, n=84), and *CCNE1* (4.9%, n=81). Compared to other datasets, PRH had significantly different mutational frequencies of GC driver genes like *TP53, ARID1A, CDH1*, and *KMT2D*. This study is the first to report PRH GC tumor mutational profiles and compare the mutational frequencies to other non-Hispanic and U.S. mainland Hispanic populations using TCGA and GENIE data sets. Furthermore, our study provides data on the specific mutational landscape for Hispanics with GC and the implications on therapeutic options and clinical outcomes. Developing new treatments for genomically diverse populations requires understanding the most common carcinogenic molecular pathways that affect Hispanics with GC.

#0803 Disparities unveiled: A comprehensive analysis of evolving trends in lung cancer risk factors in the ten most populous countries.

C. T. Jani[1], S. A. Kareff[1], H. Singh[2], A. Salazar Zetina[1], G. Lopes[1];
[1]University of Miami Miller School of Medicine, Miami, FL, [2]Medical College of Wisconsin, Milwaukee, WA

Introduction: Evolving Lung cancer (LC) trends necessitate a continual reassessment of associated risk factors.
Methods: We utilized the Global Burden of Disease database to extract Age-Standardized Mortality Rates (ASMR) and risk factor-associated ASMR for Tracheal, Bronchial, and Lung cancer (TBLC) from 1990-2019. The aim was to analyze overall trends along with two pivotal LC risk factors associated trends—tobacco use and air pollution—across ten most populous nations as of 2023 population census. Joinpoint analysis was employed to analyze trends.
Results: Globally, TBLC mortality has decreased by 8%, with reductions observed in both tobacco and air pollution-associated mortality. Despite a decrease in male mortality (-17%) and increase in female mortality (+15%), males have exhibited higher mortality for past three decades with M:F ratio of 2.5 in 2019. Similarly, male mortality was higher across all countries. Globally, although tobacco and air pollution-associated mortality has decreased for males and increased for females, both risk factors are linked to significantly higher mortality in males, with M:F ratios of 4.4 and 2.6 for tobacco and air pollution, respectively, in 2019. For tobacco-associated ASMR, China and Indonesia have shown an increase, while China, India, Pakistan, and Nigeria have shown an increase for Air pollution-associated ASMR. On evaluating proportional ASMR, tobacco and air pollution have overall shown a reduction, indicating an increase in other or non-risk factor-related mortality.
Conclusion: The fluctuating trends in tobacco-associated and the concerning rise in air pollution-associated in specific countries underscore the complex interplay of societal and environmental factors in LC mortality. The decline in ASMR associated with established risk factors emphasizes the necessity for focused interventions to tackle the changing molecular characteristics of lung cancer and its associated risk factors.

Comparison of risk factor-associated Lung Cancer ASMR (1990 vs 2019)

Country(ASMR per 100,000 population)	1990 overall ASMR (N)	1990 Tobacco associated ASMR N (%)	1990 Air Pollution Associated N (%)	2019 overall ASMR(N)	2019 Tobacco associated ASMR N (%)	2019 Air Pollution Associated ASMR N (%)
Global	27.3	19.8 (72)	5.6 (20)	25.2	16.7 (66)	4.8 (19)
India	7.0	4.2 (60)	2.5 (35)	8.1	4.0 (50)	2.6 (33)
China	31.2	20.2 (65)	10.3 (33)	38.7	26.3 (68)	10.7 (28)
US	49.4	40 (81)	4.5 (9)	36.1	26.1 (72)	1.5 (4)
Indonesia	18.0	10.6 (59)	5.4 (30)	24.4	14.7 (60)	4.6 (19)

Mexico	15.1	9.6 (63)	3.4 (22)	9.7	4.4 (45)	1.5 (16)

#0804 Temporal trends and disparities by race and ethnicity in treatment of women diagnosed with advanced hormone receptor-positive breast cancer: A SEER-Medicare analysis.

K. Zhu[1], E. Bandera[2], F. Khosrow-Khavar[1];
[1]Rutgers Institute for Health, Healthcare Policy and Aging Research, New Brunswick, NJ, [2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Background: The clinical guidelines for management of advanced hormone receptor-positive (HR+) breast cancer (BC) have changed in the past decade with the addition of novel drug classes. We assessed temporal patterns of treatment initiation among women diagnosed with advanced HR+ BC and examined disparities in treatment initiation by race and ethnicity.
Methods: Women aged ≥65 years diagnosed with stage IV or metastatic HR+ BC between 2010-2019 were identified in SEER-Medicare. Poisson models were used to estimate age-adjusted annual incidence rates (IR) and 95% confidence intervals (CIs) for treatment initiation within 12 months of BC diagnosis independently by human epidermal growth factor receptor 2 (HER2) status. Age-adjusted incidence rate ratios (IRR) and 95% CIs were estimated to compare rates of initiation among non-Hispanic Black (NHB) and Hispanic patients with non-Hispanic White (NHW) patients.
Results: Among 3,476 eligible patients with a mean age of 76.7 (SD: 7.5) years at diagnosis, 79.6% were NHW, 9.5% were NHB, and 6.0% were Hispanic. Among 2,668 women with HR+/HER2- BC, most initiated on aromatase inhibitors (AIs) alone (56.7%), followed by AIs with palbociclib (12.6%). There was a temporal increase in rates of initiation of AIs with palbociclib (IR [95% CI] per 1000 person-years: 252.8 [240.8, 265.4] in 2015 and 343.9 [330.8, 357.7] in 2019. We did not observe significant differences in rates of initiation of AIs alone or with palbociclib by race and ethnicity. Among 537 HR+/HER2+ patients, 25.0% initiated on AIs alone, 24.6% on pertuzumab and trastuzumab with chemotherapy, 14.3% on trastuzumab with chemotherapy, and 9.1% on AIs and trastuzumab with chemotherapy. IRs (95% CI) for initiation of pertuzumab and trastuzumab with chemotherapy increased from 175.6 (146.3, 210.9) in 2013 to 756.5 (698.3, 819.5) in 2019, while rates for trastuzumab with chemotherapy declined from 963.1 (809.4, 1146.0) in 2010 to 88.4 (72.6, 107.5) in 2019. Rates of initiation of AIs and trastuzumab with chemotherapy remained constant over time. Compared to NHW, NHB and Hispanic women were less likely to initiate pertuzumab and trastuzumab with chemotherapy (IRR [95% CI]: 0.52 [0.27, 1.00] and 0.54 [0.24, 1.23] respectively) and more likely to initiate AIs alone (IRR [95% CI]: 2.23 [1.39, 3.55] and 2.98 [1.69, 5.24] respectively).
Conclusions: We observed a temporal increase in the initiation of AIs with palbociclib among patients with advanced HR+/HER2- BC. Among patients with HR+/HER2+ BC, rates of initiating pertuzumab and trastuzumab with chemotherapy increased while rates of trastuzumab with chemotherapy declined. The observed differential management of NHB and Hispanic compared with NHW patients with HR+/HER2+ BC using pertuzumab and trastuzumab with chemotherapy and AIs alone requires further investigation.

#0805 Employment characteristics and work ability differences by race and income before undergoing curative treatment for prostate cancer (PCW WF-1802).

Joanne C. Sandberg[1], Emily V. Dressler[1], Louis S. Krane[2], Karen M. Winkfield[3], Lingyi Lu[1], Andrew M. Mayfield[1], Drew C. Monitto[4], J. Daniel Pennington[5], Deimante M. Tamkus[6], Glenn J. Lesser[1]

[1]Wake Forest University School of Medicine, Winston-Salem, NC,[2]Southeastern Louisiana Veterans Care Health System, New Orleans, LA,[3]Meharry-Vanderbilt Alliance, Nashville, TN,[4]Spartanburg Regional Healthcare System, Spartanburg, SC,[5]Virginia Urology, Richmond, VA,[6]John H. Stroger, Jr. Hospital of Cook County, Chicago, IL

Background: African American (AA) men are, on average, diagnosed with prostate cancer at younger ages and more advanced stages than white men and therefore may be at greater risk of having cancer treatment negatively impact their work ability and job opportunities. This longitudinal, observational study aims to better identify whether race, household income (< or ≥ 300% the U.S. poverty line), or work-related factors may place some men with prostate cancer at greater risk for experiencing negative employment impacts from cancer treatment and its side effects. Here we report on individual and employment-related factors by race and income prior to treatment initiation.

Methods: AA and white men who were expected to undergo primary curative treatment (prostatectomy or radiation therapy) in the near future for prostate cancer were recruited through the Wake Forest NCORP Research Base (UG1CA189824, NCT03963739) between 2019 and 2023. Participants were AA or white, recently employed, expecting to be working in 6 months, and willing to disclose income status. Participants answered questions prior to treatment initiation related to employment and working conditions, work ability, and demographic characteristics. Differences in outcomes by race and income were analyzed with Fisher's exact test or t-test.

Results: The baseline questionnaire was completed by 244 men; 48% AA/52% white and 64% higher/36% lower Income. Most planned treatments included radiation therapy (60%) and/or prostatectomy (41%), with no statistical differences by income or race. Higher income men were significantly more likely than lower income men to be married, have attained higher education, have a management or professional job, work full-time, be a permanent employee, salaried, eligible to retain their job under FMLA, work in an office/home, have a psychologically demanding job, and less likely to hold a physically demanding job. AA men were significantly less likely than white men to be married, have attained higher education, have a management or professional job, or work in an office/home. AA men were more continuously hopeful about the future (69%) compared to white men (52%; p=0.0079). There were no significant differences across categories in age, perceived current work ability in relation to physical (69% very good) or mental (71% very good) demands, or number of jobs held. Prior to treatment, participants reported almost optimal current work ability (mean 9.0, SD 1.2) with a range of 0 to 10 with 10 as best possible work ability.

Conclusion: In this study, income category is a greater predictor than race of job characteristics that may impact employment following definitive prostate cancer treatment.

#0806 Rural residence as a protective factor in melanoma mortality: Insights from a comprehensive analysis of 3,979 New Mexico cases (2010-2017).

Y. Park[1], A. Segura[2], L. Midani[1], B. Gutierrez[2], L. I. Rodriguez[3], C. Wiggins[2], V. S. Pankratz[2], J. R. Durkin[1];

[1]University of New Mexico School of Medicine, Albuquerque, NM, [2]University of New Mexico Hospital, Albuquerque, NM, [3]University of Miami Miller School of Medicine at Holy Cross Hospital, Miami, FL

Purpose

Cutaneous melanoma is a significant public health concern with increasing incidence rates over the past three decades. While survival rates have improved, disparities exist among racial/ethnic groups and socioeconomic factors. Our objective was to explore the connection between survival rates of cutaneous melanoma and demographic/socioeconomic factors in New Mexico's varied population, particularly in rural vs. urban settings.

Methods

This retrospective study utilized data from the New Mexico Tumor Registry (NMTR) within the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) Program. A total of 3,979 cases of cutaneous melanoma diagnosed between 2010 and 2017 among New Mexico residents were analyzed based on specific ICDO-3 criteria. The impact of demographic characteristics, socioeconomic factors, and stage at diagnosis on melanoma-specific mortality was investigated. Cases with incomplete data or where melanoma was not the primary cancer were excluded. Survival differences were assessed using Kaplan-Meier methods and the Cox Proportional Hazards Model, with analyses conducted with a significance threshold set at P=0.05. Only histologically confirmed melanoma cases were included in the study.

Results

In our analysis of 3,979 melanoma cases spanning 2010 to 2017, non-Hispanic whites (NHW) displayed the highest incidence (n = 3,617, $P < 0.001$). Conversely, Hispanic Whites (HW) and American Indians (AI) exhibited a higher likelihood of later-stage diagnoses, with 19.2% of American Indians diagnosed at stage 3, in contrast to 3.9% of NHW and 10.3% of Hispanic Whites ($P < 0.001$). Rural areas showed a propensity for advanced-stage diagnoses ($P < 0.001$), and diagnosis stage exhibited an inverse relationship with per capita income ($P < 0.001$). Increased mortality was observed among males, individuals over 50, and American Indians (all $P <0.05$). Rural American Indian or Hispanic patients had a hazard ratio of mortality at 0.37 (95% CI, 0.15-0.89). An overall decline in melanoma mortality post-2012, with a notable reduction after mid-2015 ($P < 0.001$), despite a slight increase in diagnoses from 529 in 2010 to 569 in 2017 ($P = 0.034$) was observed. Sensitivity analyses revealed that rural residence among AI/Hispanic individuals was associated with a lower risk of melanoma-specific mortality (HR 0.37, $p = 0.026$ in the inclusive analysis; HR 0.36, $p = 0.025$ in the exclusion of in-situ cases).

Conclusions

Our study indicates rural residency is associated with more advanced melanoma diagnoses and lower income correlates with later-stage diagnoses. However, rural living may offer a protective effect against mortality for American Indian/Hispanic populations. Overall mortality has declined since 2012, contrasting with a slight rise in diagnoses.

#0807 An ethno-phenomenology based approach to study breast cancer disparity in rural India.

D. Dutta[1], R. Das[2], C. Das[3], T. Sarma[3], S. Das[4], A. Dutta[1], T. Baishya[3], L. Pathak[1], **B. Das**[3];
[1]KaviKrishna Laboratory, Research park, Indian Institute of Technology, Guwahati, India, [2]KaviKrishna center of Indian Knowledge System, Sualkuchi, India, [3]KaviKrishna Telemedicine Care, Sualkuchi, India, [4]Thoreau Laboratory for Global Health, Lowell, MA

There are fundamental lack of right methodologies to study the breast cancer disparity in rural India. Here, we have used an ethnographic-phenomenology approach to study the disparity in breast cancer care in Assam by using retrospective database of a rural cancer care non-profit clinic, the KaviKrishna Telemedicine Care (KTC), set up 1994 to develop a CBPR based cancer care (Abstract 3342, AACR 2019). Methodology: For one and half years, the doctors, researchers, nurses, caregivers, and physician assistants of KaviKrishna Laboratory and KaviKrishna Telemedicine Care were interviewed (total number: 15), and plus literature of the lab and the clinic were studied. Then, the breast cancer patients (n=10) and the families were subjected to ethnographies-phenomenology study to find their experiences of treatment and suffering. Next, thematic analysis and grounded theory were applied to come up with novel approaches to reduce breast cancer disparity. For comparison, 5 patients from rich urban families were interviewed. Results: We found that 10/10 patients found it extremely difficult to navigate the complexity of care in urban hospitals, but found the KTC approachable and comfortable. Importantly, these 10 breast cancer patients were positively responding to our KTC based care services/focussed group discussion (https://zenodo.org/records/8062404). They revealed positive experiences in emotionally and psychologically dealing with diagnostic, surgery, and chemotherapy processes. Next, our analysis of the last 25 years of the care data at KTC showed that in rural population, the loweconomic status, inadequate access to breast cancer detection clinics, lack of awareness,indecisive treatment protocols and social stigma are the main reasons for breast cancer disparity. Grounded theory-based analysis indicates that cancer biomarker study in rural populations can be a suitable method for early detection. Whole genome sequencing of cancer tissue frombiopsy samples shall provide landscape of mutation in the entire coding as well as noncodingregions. Mutation profiling along with correlation studies from patients can lead to discoveryof novel marker(s). Primary health care clinics in rural areas can be trained to collect patientsamples, isolate genomic DNA and perform PCR for the markers (a similar model asfollowed during Covid-19). The PCR samples can be sent to non-profit advanced diagnostic center such as KaviKrishna Lab to perform sequencing to study mutation markers. The method is also cost effective to both thecare givers and the patients as compared to setting up advanced diagnostic lab in every part ofrural area. Conclusion: The community based participatory research based model developed by KTC can be an effective strategy to reduce breast cancer disparity in the rural population since the primary health clinics shall act as a bridge between geologically isolated areas and modern technology.

#0808 iCCaRE engagement of faith-based organizations to co-create and co-disseminate infographics addressing disparities in prostate cancer literacy and clinical and biospecimen studies.

J. C. Morrison[1], K. T. Ashing[1], G. Song[1], T. J. Bonner[2], C. Ngufor[2], G. Dagne[3], A. Merriweather[4], J. McCall[5], E. Cobran[6], C. N. Moore,[7], F. Bedell[8], R. Oladapo[9], F. B. Willis[10], R. Chidebe[9], N. A. Stephenson,[11], J. S. Oliver[12], V. Gordon[10], F. Odedina[11];

[1]City of Hope National Medical Center, Duarte, CA, [2]Mayo Clinic, Rochester, MN, [3]University of South Florida, Tampa, FL, [4]American Legion Post 197, Jacksonville, FL, [5]iCCaRE Consortium Community PI, Bethel Baptist Church, CA, Duarte, CA, [6]Mayo Clinic, Phoenix, AZ, CA, [7]Mayo Clinic, Phoenix, AZ, [8]City of Hope National Medical Center, Lancaster, CA, [9]Covenant University, Nigeria, Nigeria, [10]Mayo Clinic, Jacksonville, CA, [11]Mayo Clinic, Jacksonville, FL, [12]University of Alabama, Tuscaloosa, AL

Black men hold the highest prostate cancer burden among all ethnicities; thus, there is an urgent need for research to inform the development and implementation of a culturally tailored intervention to reduce disparities and improve outcomes. In response, the Inclusive Cancer Care Research Equity (iCCaRE) Consortium was created to advance health equity and reduce disparities in prostate cancer. Addressing the unique needs of Black men require a genuine bidirectional relationship between scientist and the community. In the Black community, faith-based organizations are respected institutions advocating for health equity and justice. Given their vital role as community health gatekeepers, the iCCaRE Consortium partners with faith-based organizations. Rooted in community engaged research (CER), we conducted an environmental scan through stakeholder meetings to discuss the prevailing challenges and opportunities to meet the needs of the Black community along the prostate cancer care continuum. iCCaRE investigators including Partnership Engagement Services (PES) core partnered with faith-based organizations to ensure and advance community responsive cancer prevention. Together, with our faith-based leaders (N=18), we identified gaps including issues associated with the care continuum from screening to diagnosis and from treatment to survivorship; disparities according to health coverage and social determinants of health, and best practices to assist patients including care coordination, patient navigation, digital innovations, and programs offered by patient advocacy organizations. In response to the needs of the community and the strengths of faith-based organization, we prioritized our initial focus on increasing community prostate cancer literacy and activation using co-design educational infographics for both traditional and technology-based communication platforms. The infographics provided evidence-based facts about prostate cancer burden in the Black community; and using a call to action approach, we emphasized the importance of taking action for life saving screening, prevention and healthy lifestyle. Taking action in prostate cancer symptom recognition, survivorship care, and quality care. Also, co-designed infographics were created for clinical studies and biospecimen awareness and participation and the importance of advocacy and equitable care. Another component incorporated face to face trainings and presentations to enhance their knowledge of cancer screening tools, epidemiology of prostate cancer, and pathways to care. This presentation highlighted the first step towards community based intervention development, implementation and dissemination towards equity and justice for prostate cancer prevention and patient/survivor improvements for Black men.

#0809 Neighborhood disadvantage and prostate tumor aggressiveness among African American and European American men.

J. Boyle[1], J. Yau[2], J. L. Slade[3], D. A. Butts[4], J. Wimbush[5], J. Y. Park[6], A. Hussain[2], E. Onukwugha[7], C. L. Knott[8], D. C. Wheeler[1], K. H. Barry[2]; [1]Virginia Commonwealth University, Richmond, VA, [2]University of Maryland School of Medicine, Baltimore, MD, [3]Maryland Community Health Engagement Partnership, Upper Marlboro, MD, [4]Prostate Cancer Awareness Alliance of DC, MD, and VA, New York, NY, [5]University of Maryland Greenebaum Comprehensive Cancer Center Tumor Registry, Baltimore, MD, [6]H. Lee Moffitt Cancer Center, Tampa, FL, [7]University of Maryland School of Pharmacy, Baltimore, MD, [8]University of Maryland, College Park, College Park, MD

Introduction: African American (AA) men experience greater prostate cancer (PC) incidence and mortality compared to European American (EA) men, but the reasons are not fully understood. Some literature has identified connections between neighborhood disadvantage and aggressive PC, and AA men may be more likely to experience these factors than EA men. However, it is unclear if these associations may vary by race. We tested associations of two neighborhood disadvantage measures (neighborhood socioeconomic deprivation and racial segregation) with prostate tumor aggressiveness, overall and separately by race. We hypothesized that they would be positively associated and that associations would be stronger among AA men.
Methods: We leveraged data from the University of Maryland Greenebaum Comprehensive Cancer Center Tumor Registry for AA and EA men who were diagnosed with PC from 2004-2021. We geocoded participants' addresses at diagnosis to determine census tract-based Area Deprivation Index (ADI) and Racial Isolation Index (RI) values. ADI analyses included men diagnosed in 2005 or later (778 AA men and 687 EA men), and RI analyses included men diagnosed in 2009 or later (606 AA men and 454 EA men) based on data availability. We used logistic regression to model the odds of aggressive PC, defined as a Gleason pattern of 4+3 or a total Gleason score >=8, overall and by race. We fit models with scaled ADI or RI as the exposure variable, adjusting for race, age at diagnosis, and year of diagnosis. We also assessed an interaction between each neighborhood measure and race.
Results: Median (interquartile range) ADI scores were 118 (101-137) for AA men and 92 (83-102) for EA men, and RI scores were 0.68 (0.35-0.87) for AA men and 0.11 (0.06-0.20) for EA men, indicating greater neighborhood deprivation and AA residential segregation among AA participants. The greatest values for these scores were concentrated in central and west Baltimore. A one-standard deviation (SD) increase in ADI was associated with significantly greater odds of aggressive tumors for AA men (OR=1.28, 95% CI: 1.10, 1.49; p<0.01), but not for EA men (OR=0.85, 95% CI: 0.67, 1.08; p=0.19), and the p-value for interaction (p<0.01) was statistically significant. Similarly, a one-SD increase in RI was significantly associated with aggressive tumors for AA men (OR=1.24, 95% CI: 1.03, 1.49; p=0.03), but not for EA men (OR=1.23, 95% CI: 0.84, 1.80; p=0.29), although the p-value for interaction was not statistically significant.
Conclusions: Neighborhood disadvantage was significantly associated with higher odds of aggressive PC. The association of neighborhood deprivation and tumor aggressiveness was stronger among AA men. Additional analyses will consider other measures, including historical redlining, to further evaluate the relationship of neighborhood disadvantage with prostate tumor aggressiveness.

#0810 Assessing human papillomavirus (HPV) awareness and intentions to participate in HPV vaccination and clinical trials (CT) among Latinos/as in Los Angeles (LA) County: A multicomponent intervention.

Alejandra Ramos, Carolina Aristizabal, **Lourdes A. Baezconde-Garbanati**

Keck School of Medicine of USC, Los Angeles, CA

Background: The incidence of HPV-related cancers continues to disproportionately affect women and men of Latino origin. In LA, a total of 20,868 individuals have been diagnosed with HPV-related cancers from 2009 to 2019. HPV infection knowledge and interpersonal barriers contribute to HPV vaccine delay and refusal. Similarly, Latinos/as continue to also have low participation in clinical trials research. To address the low knowledge, attitudes, and intentions towards HPV vaccination and participation in clinical trials (CT), we have adopted the NCI National Outreach Network framework and have used community health educators to deliver bilingual-culturally appropriate workshops on HPV and CT.
Methods: Individuals, 18 and over and parents with eligible age children (in respect to the HPV initiative) were recruited through community outreach and local community partnerships to participate in the bilingual (English and Spanish) health education workshops. A baseline assessment was administered before each educational workshop and a follow-up assessment was administered after to evaluate change in HPV and CT knowledge, intentions to vaccinate, and likelihood to participate in CT. Descriptive statistics were calculated to assess distribution of demographic variables of interest and a paired T-test was used to explore matched pre-post differences in knowledge scores and intentions.
Results: 290 (HPV) 272 (CT) individuals participated in the workshops. The mean age of participants was 41.13yrs with a (SD=11.63). More than half of participants were women 453 (81.7%), men 94 (16.9%) and other 7 (1.26%). Comparing HPV knowledge scores of matched pre-and post-surveys, showed that for baseline (n=182) (M=72.9%, SD=13.3) was statistically different from post-scores (n=182) (M=81%, SD=9.85) where $p<0.05$. Intentions were measured using a Likert scale, baseline (M=4.1), agree to get HPV vaccine, post (M=4.5) strongly agree to get HPV vaccine. In respect to CT baseline knowledge (n=174) (M=75.3%, SD=0.15), following a Likert scale response of (M=3.4), unsure to join a clinic trial. In assessing post-CT scores (N=174) (M=78%, SD:0.14), mean scores were significant where $p<0.05$ and an increase to (M=3.7) agree to join a clinical trial. After workshops attendance, not only was knowledge increased, but intentions to vaccinate against HPV and to participate in a clinical trial was strengthen.
Conclusions: Strengthening community-based education and providing the necessary tools, can help reframe misconceptions about HPV and HPV vaccination and promote willingness to vaccinate and participate in clinical trials.

#0811 Impact of Medicaid eligibility expansion to adults regardless of immigration status on health insurance access among Latina patients.

N. Huguet[1], J. Kaufmann[1], H. Holderness[1], M. Vieira[1], G. Mertes[2], J. Shannon[1], J. Heintzman[1];
[1]OHSU, Portland, OR, [2]OCHIN, Portland, OR

Background: Disparities in the receipt of cancer screening and preventive services are strongly associated with health insurance status. Even after federal- and state-wide initiatives to boost access to health insurance such as the Patient Protection and Affordable Care Act (ACA) Medicaid Expansion to all individuals earning ≤138% of the federal poverty level (FPL) and nationwide individual health insurance marketplaces, Latino populations continue to have the highest uninsured rate of any racial or ethnic group in the US, with 17% of Latinos remaining uninsured compared to 5% of non-Hispanic white peers. In 2021, California and Oregon states amended their respective Medicaid program to expand eligibility to adults regardless of immigration status; which could reduce access disparities for patients from Latino communities. This study shows preliminary results of changes in health insurance status among Latina patients (who have multiple cancer prevention services recommended in middle age) receiving care in community health centers.
Methods: A retrospective cohort study of Latina, non-Hispanic Black, and non-Hispanic white women ages 50-64 years receiving primary care from 382 community health clinics in California and Oregon. Using 2018, 2019, 2021, and 2022 electronic health record data, we estimated monthly rates of insured-type visits per 100 visits. We compared rates pre- and post-Medicaid eligibility expansion, both within and between race and ethnicity groups. Reported estimates were derived from generalized estimating equations Poisson regression, clustered on clinic, and adjusted for clinic-level demographics.
Results: Of 41,960 patients, over half (53%) were Latina, most of whom (83%) preferred Spanish language communication. Latina patients had more uninsured visits pre-Medicaid eligibility expansion than did non-Hispanic Black and white patients (Rate: 27% versus 5% and 4%, respectively). All racial and ethnic groups experienced a decrease in uninsured visit rates, and this change was similar for all groups [Difference-in-difference Latina versus Black patients: 0.77 (95% CI 0.55, 10.7) and versus white patients: 1.02 (95% CI 0.89, 1.17)]. Overall rates of Medicaid-insured visits increased only for Latina patients [pre-to-post Relative Rate=1.06 (95% CI: 1.03-1.10)]. Both non-Hispanic Black and white patients experienced a drop in Medicaid-insured visits. Only Black patients experienced a significant decline in private-insured visits [pre-to-post RR=0.79 (95% CI: 0.70-0.89)].
Conclusion: These early results suggest an uptake of Medicaid-paid visits among Latina patients. This increase in healthcare coverage for Latina patients could significantly reduce disparities in access to primary care and especially in cancer preventive care.

#0812 Association of obesity with the early onset and diagnosis of triple negative breast cancer in black women.

S. Sudan[1], A. Sharma[1], K. Vikramdeo[1], W. Davis[2], C. Nelson[1], K. Singh[3], A. Singh[1], S. Singh[1];
[1]USA Health Mitchell Cancer Institute, Mobile, AL, [2]University of South Alabama, Mobile, AL, [3]University of Texas Tyler, Mobile, AL

Breast cancer (BC) continues to be the most common cancer and the second leading cause of cancer-related death in American women. Furthermore, it affects Black women more adversely than their White counterparts, who experience an early disease onset, diagnosed more often with aggressive triple-negative breast cancer (TNBC) molecular subtype, and face greater mortality. The reasons for these disparities; however, are largely unknown. Here, using a retrospective dataset, we examined the association of body mass index (BMI) with BC early onset and diagnosis with specific molecular subtype in race-based distributions. Study cohort included 1085 BC patients, who visited University of South Alabama Health clinics between October, 2017 and March, 2022. Patients were divided into three BMI [(normal weight, NW (<24.9), overweight, OW (25-29.9), and obese, Ob (>30.0)], three age (<45 years, 45-65 years, >65 years), and four molecular subtypes [Luminal A (HR+, HER2-), Luminal B (HR+, HER2+), HER2 enriched (HR-, HER2+), and TNBC (HR-, HER2-) categories. The data show a higher prevalence of BC in Ob women (46%) than OW (27%) and NW (27%) women of all age groups and its incidence was much greater in Ob Black women (61%) than Ob White women (39%). Further, Black women had nearly twice higher diagnosis at an early age than White women. Moreover, Ob Black women had over 7- and 1.5-folds higher incidence of early onset BC than NW and OW Black women, respectively, whereas, early onset BC did not exhibit a correlative pattern in White women. Luminal A and TNBC subtypes were the most common in women with early onset BC and Black women exhibited more than twice incidence of TNBC (32%) compared to the White women (14%) of all ages. In contrast, incidence of luminal A subtype was less prevalent in Black (57.4%) than in White (72.6%) women. Interestingly, both luminal A and TNBC subtypes were also more prevalent in Ob women; however, the risk of being diagnosed with TNBC increased dramatically in Ob Black women compared to Ob White women. Together, these findings establish obesity as a major underlying cause of early onset BC and TNBC diagnosis in Black women, which could be targeted to diminish the BC disparity gaps.

#0813 Primary cutaneous gamma-delta T-Cell lymphoma in the United States: A nationwide analysis of demographics and survival outcomes among the Hispanic population.

K. Thiel, R. White, Q. Liu, J. Michalek, A. Diaz Duque;
UT Health Science Center at San Antonio, San Antonio, TX

BACKGROUND: Primary Cutaneous Gamma-Delta T-Cell Lymphoma (PCGDTCL) is a rare subtype of cutaneous T-cell lymphoma (CTCL) that, despite comprising <1% of cutaneous lymphomas, has gained recognition in recent years as an entity separate from other rare CTCLs. (*LeukemiaPMID 35732829)* A 5 year survival of 11% demonstrates a low response to current available therapies. (*BloodPMID 30635287*, *Clin Hematol Int.PMID 35950208)* Due to lack of consistency in behavior between CTCLs, there exists a need for studies of demographic, clinical, and survival disparities, including between Hispanics (HI) vs. non-Hispanics (NH).
METHODS: Data were analyzed on PCGDTCL patients in the United States reported to the National Cancer Database (NCDB) between 2004-2019. Demographic and treatment characteristics were compared between ethnic groups. Kaplan-Meier and Cox regression analyses were used to compare OS between populations. Multivariate analysis and propensity score matching was performed with adjustment for age, stage, co-morbidity score, and insurance status, type of facility and great circle distance.
RESULTS: Among 132 PCGDTCL patients studied (5% HI, 92% NH), the HI group was younger at diagnosis than NH (49.5y vs. 60y) (p=0.384); The majority of HI (50%) was diagnosed between 2010-2012 vs 2017-2019 for NH (45%) (p=0.673). Most of HI and NH were white (67% vs 79%).
Private insurance was the most prevalent type in HI (67%) vs government sponsored for NH (49%). The most non-Insured group was NH (3%) vs HI (0%).
The most prevalent bracket for Census Median Income (2008-2012) was $63,000+ for both HI (50%) and NH (31%). 17% HI vs 13%. NH had median income <$38,000.
For Charlson-Deyo Score (comorbidities score), HI had 0% =/> 2 score, vs NH 6%. NCI-designated comprehensive cancer centers were the most prevalent type of facility providing care for HI (100%) and NH (56%)
Survival probability (OS) at 2, 5 and 10y (HI vs NH) were (80% vs 48%), (80% vs 44%), and (80% vs 26%), respectively. Median survival time (MS) was not reached for HI vs 1.9 years for NH. Overall survival (OS) difference favored HI (p=0.13)
On multivariate analysis, there was no independent variable associated with better or worse OS. Interestingly, the propensity matched analysis demonstrated significant MS difference between HI vs NH (median not reached vs. 1.35 years).
CONCLUSION: There was no significant difference in OS between groups; however, the weighed MS favored the HI cohort, likely in part due to the difference in numbers between cohorts. The drastically low survival in all demographics is consistent with prior studies. These results demonstrate an unmet need for more comprehensive studies with the potential inclusion of correlatives looking at intrinsic biologic characteristics that may offer insight into druggable targets, aiming for improvement in survival outcomes for this rare lymphoma.

#0814 Bridging the gap: Informal caregivers' access to information on genetic testing for cancer risk.

E. Adjei Boakye[1], P. G. Patel[2], C. S. Dagli[2], S. Wagoner[3], M. Nair[1], N. Osazuwa-Peters[4], V. Bernacchi[5], S. H. Tam[1];
[1]Henry Ford Health System, Detroit, MI, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Kansas Medical Center, Kansas City, KS, [4]Duke University School of Medicine, Durham, NC, [5]Michigan State University, East Lansing, MI

Introduction: Cancer risk genetic testing (referred to as genetic testing thereafter) benefits patients by allowing them to make informed behavioral and medical decisions to reduce cancer risk and by facilitating surveillance and earlier detection. Informal caregivers, who often serve as primary advocates for those at risk, play a pivotal role in supporting behavioral and medical decisions based on genetic testing information. Assessing caregivers' knowledge of genetic testing can guide future interventions supporting informed decision-making to ensure that all groups benefit equally from advances in genetic testing. We examined the association between caregiving and knowledge of genetic testing as well as other individual and socioeconomic factors.
Methods: Secondary data analysis was conducted using the 2020 Health Information National Trends Survey (HINTS 5 Cycle 4). HINTS is a nationally representative survey of adults in the civilian non-institutionalized US population. Exposure variable was caregiving (yes/no) assessed with the question "Are you currently caring for or making health care decisions for someone with a medical, behavioral, disability, or other condition?". The outcome variable was genetic testing knowledge (yes/no) assessed with the question "have you heard of high-risk cancer genetic testing - e.g., BRCA 1/2". Weighted, multivariable logistic regression was used to estimate the association between caregiving and genetic testing knowledge adjusting for age, gender, race/ethnicity, marital status, education level, having a regular provider, rural-urban residence, and self-reported general health status.
Results: A total of 3,136 participants aged ≥18 were included in the study, of whom 16.4% were caregivers and 35.9% had heard of genetic testing. In the adjusted analysis, there was no statistically significant difference between caregivers and non-caregivers in relation to genetic testing knowledge (P=0.7881). However, respondents who were ≥65 years old (aOR=0.54, 95% CI: 0.40-0.72) were less likely to have heard about genetic testing compared to those aged 18-49, as were respondents who had no regular provider (aOR=0.71, 95% CI: 0.53-0.95) compared to those with a regular provider. Compared to non-Hispanic White respondents, non-Hispanic Black (aOR=0.45, 95% CI: 0.31-0.66) or Hispanic respondents (aOR=0.44, 95% CI: 0.29-0.68) were less likely to have heard about genetic testing. Female respondents (aOR=2.02, 95% CI: 1.55-2.61) were twice as likely to have heard about genetic testing than their male counterparts.
Conclusions: We found that about a third of Americans had heard about genetic testing; patients who were younger, female, White, and those who had access to a regular provider were more likely to be aware of testing. Interventions targeting under-resourced caregivers are urgently needed to promote equity in genetic testing and its benefits.

#0815 Leveraging clinical workflow for rapid integration of social needs assessment in a urologic oncology clinical practice.

Samuel L. Washington[1], Kim F. Rhoads[2], Peter R. Carroll[2], Salma Shariff-Marco[2], June M. Chan[2]

[1]UCSF - University of California San Francisco, Daly City, CA,[2]UCSF - University of California San Francisco, San Francisco, CA

Introduction: Social determinants of health and resulting social needs are known to impact cancer care, yet characterization of social needs within a specific clinic's population remains in its infancy. We aim to characterize early findings from social needs screening in patients seen in a tertiary urologic oncology clinic.
Methods: Screening was conducted using survey questions about specific domains of social needs (e.g., financial strain, unmet transportation needs, and food insecurity) that were integrated into new patient and annual follow-up questionnaires for all patients seen within a urologic oncology faculty clinic, starting in January 2023. Screening items were rapidly implemented into workflow by taking advantage of existing processes. Clinical and demographic data and screening responses were abstracted from the electronic medical record. Summary statistics were calculated. P value<0.05 was deemed statistically significant.
Results: A total of 2305 patients were included (4% Non-Hispanic Black, 11% Asian American, 8% Latinx, and 63% Non-Hispanic White). Responses increased from 30 in January to 399 in October. Respondent mean age was 67 years [standard deviation (SD) 12.3] with 87.8% identifying as male. Roughly 13% screened positive for at least one social need (one positive 8.1%, two positive 3.4%, three positive 1.2%) with variations by domain [transportation 3.6%, food insecurity 5.4%, 10.2%] and race and ethnicity (Figure 1, p<0.001 for all).
Conclusions: By leveraging the existing clinical workflow, rapid uptake of social needs screening demonstrates variations by social needs domains and race and ethnicity within a urologic oncology patient population. These efforts represent institutional action towards characterizing the burdens faced by our patient population and inform the design of interventions to address social needs within the catchment area, to improve clinical care and clinical trial participation.

#0816 Implementation of a community-based multi-component cancer screening intervention supported by a cross-sector community coalition.

R. Rechis, M. Aquino, H. Gardiner, B. Puga, M. T. Walsh, Jr.;
The University of Texas MD Anderson Cancer Center, Houston, TX

It is widely agreed that screening and early detection of cancer saves lives. However, disparities exist in those who received routine screenings and variability in clinic screening protocol. Working with community-based clinics on quality improvement as well as systematically screening all eligible patients can result in increased equity in screening and thus early detection. Be Well Communities™ is MD Anderson's place-based approach for cancer prevention and control, working with communities to promote wellness and address modifiable risk factors for cancer. The first several years of the initiative in Baytown focused on healthy eating and active living interventions for cancer prevention, over time the community's trust and appetite increased which allowed for additional and more traditional cancer prevention interventions (e.g., human papilloma virus vaccination, screening). In this project, three evidence-based interventions for cancer screening were implemented in collaboration with Chambers Health, a local FQHC in Baytown, Texas, to work toward addressing the disparities in screening outcomes experienced by community residents. Chambers Health compliance rates have increased since the beginning of the Cancer Screening Navigation program, supported by Be Well Communities. Two full-time patient navigators are supported to facilitate increased screening through patient education, increased clinic compliance and development of standard operating procedures for navigation related operations. In addition, one full-time Outreach Coordinator is supported to engage with patients and provide education on cancer screenings. Compared to 2022, there was a 39% increase in colon cancer screening compliance rates, a 25% increase in cervical cancer screening compliance rates, and a 47% increase in breast cancer screening compliance rates. Compliance refers to any patient who is up-to-date in their cancer screenings. The Be Well Communities team supported Chambers Health through funding, technical assistance, and capacity building. They were then able to provide culturally relevant and high-quality care to enhance community capacity to address low rates of cancer screening in Baytown. Furthermore, Chambers Health has since integrated the patient navigators and Outreach Coordinator into their operational budget, a notable systems change for the organization and demonstration of commitment to the project and continued clinic quality improvement and more so dedication to the patients served.

#0817 Establishing a niche to improve Africa's contribution to cancer research.

U. A. Malami[1], S. A. Malami[1], U. E. Nwokwu[1], U. W. Mohammed[2], F. Mohammed[2];
[1]National Institute for Cancer Research and Treatment (NICRAT), Abuja, Nigeria, [2]Ahmadu Bello University, Zaria, Nigeria

Africa has been a key source of scientific discoveries to the global community, especially in areas of scientific experiments and implementation. However, Africans are underrepresented in their contribution to global science and within the African countries, access to adequate funding and infrastructure to do high quality science is limited. These inequities contribute to the 10/90 gap in which only an estimated 10% of global health research funding is used to address health problems in Africa. Thus, it is not surprising that today, Africa contributes just about 2 percent of world research output, 1.3 percent of research spending, and 0.1 percent of all patents. To bridge the aforementioned gaps, mitigate the effect of brain drain and structural constraints and improve support for the next generation scientists, the Nigerian Government recently established the National Institute for Cancer Research and Treatment (NICRAT). It is worthy to note that cancer incidence and mortality rates in Africa are increasing 1.1 million new cases, with 711,000 deaths reported in 2020. This indicate a mortality-to-incidence ratio (MIR) of 0.64. These cancer challenges in Africa necessitates a concerted approach towards effective cancer control and management. Here, we show in detail how the NICRAT support improving science while integrating with Nigerian national development plans and strategies. We also show how the NICRAT is establishing a mechanism for domestic funding, while fostering national and international collaborations for African scientists and encouraging women into careers in cancer research. Currently, the NICRAT's key task also includes centralizing cancer control efforts, mobilizing funding from different sources for cancer research, and coordinating cancer treatment activities across Nigeria. In addition, the institute facilitates collaboration between researchers, healthcare providers, and patients, and provides guidance for cancer policy formulation and implementation. The establishment of NICRAT by Nigeria's government as well as similar centers elsewhere in Africa may improve active participation of African scientists in scientific practice, discourse, and decision making and spotlight their intellectual contributions towards solving science-associated global problems.

#0818 Fighting prostate cancer with a multimedia approach.

Introduction: Black men have the highest prostate cancer (CaP) mortality rates. The reason for this disparity is multifaceted, including the barriers that they face at the individual, provider, and health system levels. To address these challenges the iCCaRE for Black Men Consortium uses a multi-level approach to disseminating CaP information. This approach is rooted in research which shows that Black men prefer to receive information through multi-media channels tailored to their needs. In addition, studies have reported that CaP survivors were viewed as credible sources of information. This presentation reports on how iCCaRE Consortium is bridging the digital divide in minoritized communities to disseminate CaP information in a way that is meaningful to the community.
Methodology: iCCaRE uses a multimedia method to reach Black men. This includes twitter post, Facebook, YouTube, ecancer and community lunch and learns. In addition to social media, we have partnered with LitTV Network, a locally owned digital TV platform, on which we have iCCaRE TV. On Lit TV network we have the ability to reach 11,000 homes in our catchment area. Furthermore, the consortium has produced informational flyers that are disseminated at outreach events and at the American Legion Post 197. On the twitter page the consortium post: (1) 2 scientific publications per day authored by members of the consortium, (2) 2 weekly “Did You Know” facts about prostate cancer with sources attached, (3) 2 weekly url post sharing a link to a video from the iCCaRE consortium YouTube page and (4) clips of CaP survivors sharing their experiences. On the YouTube page we currently have: videos series of a CaP survivor who is also a physician scientist, interview series with MPIs and members of the consortium, CaP survivor series including a barbershop interview with a survivor.
Results: The iCCaRE Consortium multimedia efforts have a global reach, in less than a year we have gained 102 twitter followers. On average the twitter page receives 8,700 impressions during the CaP awareness month in September the twitter page garnered over 14,000 impressions. Our videos on the ecancer platform have a combined global view of 341 representing countries such as the United States, Nigeria, Cameroon, United Kingdom, Macedonia, and Mexico. The American Legion Post 197 in North Jacksonville has served a cumulative of 229 people through outreach and educational event called lunch and learns. Our YouTube channel has had almost 100 views in its first month of being active.
Conclusion: Using a multi-level approach to reduce the burden of CaP for Black men is vitally important; without such efforts the disparate thread in mortality will continue to persist. Meeting Black men through the mediums they use for gathering health information removes barriers, increases access and will aid in the fight against CaP for Black Men.

#0819 Feasibility of patient-centered home care (PCHC) to reduce disparities in high-risk black men with advanced prostate cancer.

R. S. Dronca[1], F. Odedina[1], C. Ngufor[1], K. Ashing[2], E. Kaninjing[3], S. Rotimi[4];
[1]Mayo Clinic College of Medicine and Science, Jacksonville, FL, [2]City of Hope Medical Center, Duarte, CA, [3]Georgia College & State University, Tallahassee, FL, [4]Covenant University, Ota, Nigeria

The objective of our study is to evaluate the feasibility, acceptance, and impact of patient-centered home care (PCHC) on patient reported outcomes (PROs) and health-related quality of life (HQoL) of black men with advanced prostate cancer (CaP). Meeting patients where they are and offering treatment in or closer to their homes reduce psychological distress and increase treatment compliance, especially for disadvantaged patients in rural areas, those on low incomes, with poor access to transport, elderly and people with disabilities. In 2023, Mayo Clinic has developed the Cancer Care Beyond Walls (CCBW) program, a cancer care delivery model that integrates virtual with in facility treatment and provides a package of care to support administration of cancer-directed therapy (chemotherapy, immunotherapy, hormonal therapy) and/or supportive care in the patients' homes. Our study will assess if patients and families are comfortable with cancer therapy at home, what factors influences their decision, and use this data to inform our understanding of the proportion of the black men with advanced CaP who would be willing to receive and would benefit from this level of care at home. Patients with advanced CaP from our practice requiring active anti-cancer therapy are administered a brief questionnaire regarding preference for location of therapy at the infusion center or in the home, with perceived difficulties and advantages of each approach. A focus group session with prostate cancer survivor advocates is also conducted to capture patients' thoughts, feelings, attitudes, and questions towards cancer treatments being administered at home versus a hospital setting. In addition, we are conducting an observational study of 20 patients with advanced prostate cancer receiving supportive care/symptom management and/or anti-cancer therapy in the home as part of the Mayo Clinic CCBW Program to assess the safety of cancer directed therapy when administered at home by a home health provider with remote patient monitoring and command center support, and establish the impact of home cancer treatment administration on patient-reported function and global health/quality of life, patient-reported symptoms, clinical outcomes, and cost of care. Successful completion of the project will deliver data on patient understanding and acceptability of cancer care at home, strategies for overcoming barriers to care for underserved communities, and the foundation from which we discover, translate and apply new knowledge in administering personalized care to vulnerable populations.

#0820 Decolonizing data: Diversifying cancer registries to include SWANA.
